The equation above, known as Langevin's equation of diamagnetism, is applicable to every substance, whether it be diamagnetic or paramagnetic. If an atom has a permanent moment and the material is consequently paramagnetic or ferromagnetic, it is still true that its susceptibility has the diamagnetic component given by this equation.

Knowing the number of electrons in the atom. one may calculate from the diamagnetic susceptibility the average (root mean square) radius of an atom and compare this with the radius determined by other means. Values so obtained are consistent with our other knowledge of atomic structure.

In quantum mechanics (*q.v.*) the Langevin formula still holds when the field of the nucleus is spherically symmetrical, as it is in atoms or ions. The meaning of the orbital radius, r, however, is somewhat different. since the electrons are assumed to be distributed in less localized orbits. Calculation of diamagnetic susceptibilities by wave mechanics has been attempted for a number of the

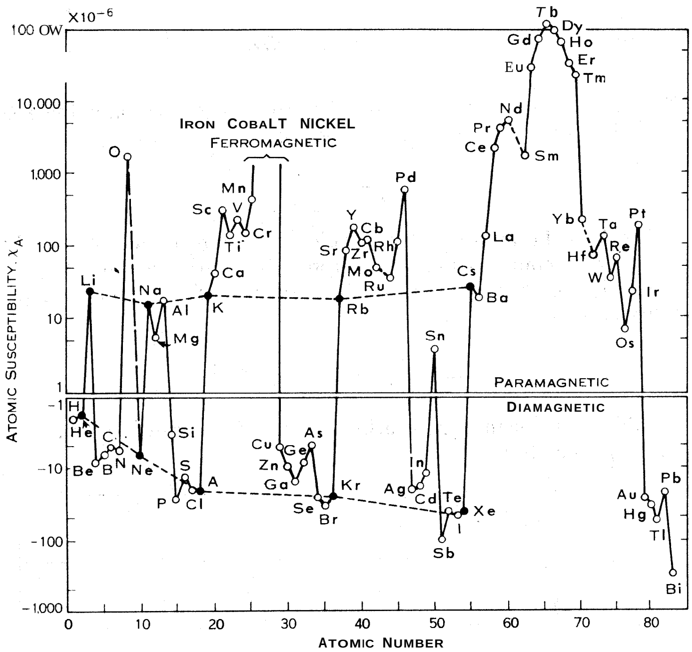

FIG 53.— ATOMIC SUSCEPTIBILITIES OF THE ELEMENTS AT ROOM TEMPERATURE. DOTTED LINES CONNECT ALKALI METALS (PARAMAGNETIC) AND RARE GASES (DIAMAGNETIC)

simple atoms and molecules and has been moderately successful for the rare monatomic gases helium, neon. argon, krypton and xenon. and for molecular hydrogen, H,. For helium. theory indicates an atomic susceptibility ($\times$ 10⁶) of 1.65 to 1.90, depending on the method of calculation; G. G. Havens' measured value is 1 9 1 For hydrogen the calculated and observed values are 2.10 and 2.01. For the other elements listed, both theoretical and measured susceptibilities vary over a greater range.

Positive ions of the alkali and alkaline earth metals and of the halogens have the rare gas structure and can also be treated theoretically. The lack of precision in the calculation arises in the approximate nature of wave functions and the effective molecular charge assumed.

2. Compounds.— Most salts are diamagnetic because the ions of which they are composed (*e.g.,* Na^+ and Cl^-) have the completed electron shells characteristic of the rare gases and consequently have no permanent magnetic moment. Measurements are made either on solid salts or on solutions, and the susceptibilities of the separate ions can be deduced from a series of such measurements. There is some ambiguity in separating the susceptibility of the salt into its component parts, and there is also some change with concentration and state of aggregation, but each ion has a value of χ_A that is approximately constant. The observed increase of χ_A with the number of electrons. n, is to be expected according to simple theory. In ions having the same number of electrons but a different nuclear charge. as in the series I-. Xe, Cs^+ and Ba^{++}, the diamagnetic susceptibility decreases numerically with increasing charge because the larger charge draws the electrons closer to the nucleus and so diminishes the value of $\Sigma\overline{r^2}$ of Langevin's equation.

The principle of additivity of the diamagnetism of ions may be extended to include also the more complex ions NO_3^-, SO_4^{--}, PO,---, NH_4^+ and others. Values for these are less certain than those for the simple ions already considered.

In his early comprehensive experiments (1908–13) P. Pascal found that the molecular susceptibility of many organic compounds is the sum of the susceptibilities of the atoms composing them, plus additional terms characteristic of the various bonds occurring in the molecule.

While the Langevin theory is not very illuminating when applied to a simple diatomic molecule like H_2, quantum mechanics can be called upon provided the wave functions are known with sufficient accuracy. In the expression for χ_M there is a term, always positive. added to the negative term of the Langevin equation.

Van Vleck and N. H. Frank have used the wave functions of molecular hydrogen to calculate both terms of the expression, and found them to be -4.66×10^{-6} and $+\ 0.51 \times 10^{-6}$. The net result of $-4.1j \times 10^{-6}$ may be compared favourably with the experimental values ranging from about -3.9 to -4.0×10^{-6}.

Calculation of heavier diatomic molecules cannot be carried out so rigorously, and the approximate wave functions generally used for these substances give too high a value of χ_M. Our knowledge of gases is also limited by the fact that measurements are difficult to make with accuracy.

XII. PARAMAGNETISM

The paramagnetism of the materials examined by Curie was dependent on temperature. the susceptibility decreasing with increasing temperature. Subsequently it was found that there is a large class of weakly paramagnetic substances for which the susceptibility is practically independent of temperature (fig. 54); this class includes many of the metallic elements when, and only when, they are in the solid conducting state. and the paramagnetism of these materials is due to the conduction electrons. This kind of paramagnetism is referred to as meak paramagnetism, whereas the former class has strong paramagnetism and is due to a permanent magnetic moment of the component atoms or molecules.

The origin of the two kinds of paramagnetism is shown schematically in fig. 56, where the curved lines represent electron shells in an atom. The outer line is broken to indicate that the electrons in this shell are loosely bound and become conduction electrons in a solid metal or valence electrons in a compound. In a metal the spins of a portion of these electrons can be changed by an applied field in a way that can be explained by quantum mechanics, and therefore give rise to weak paramagnetism as shown, for example, by metallic sodium. Most of the other shells have their full complement of electrons! and the magnetic moments due to their orbital and spin motions are self-neutralizing so that they contribute only diamagnetism to the atom. On the other hand some of the shells in some atoms are incomplete and therefore have a resultant moment that is large compared with the spin of the conduction electrons or the diamagnetic moment of the closed shells. Such incomplete shells occur notably in the iron group and rare earth group of elements, also in the palladium and platinum groups, and all of these show strong paramagnetism. In the extreme cases of the rare earth elements dysprosium and holmium, the fourth shell (fig. 56) contains electrons whose spin and orbital moments combine to give the largest magnetic moment of any atoms.

Before discussing the experimental results further it is desirable to outline the classical and quantum theories of strong paramagnetism, and the quantum theory of meak paramagnetism.

1. Langevin Theory.— Curie found that his measurements at various temperatures could be expressed by the law now known by his name:

$$\chi_M = C_M/T,$$

in which T is the absolute temperature and C_M the Curie constant characteristic of the substance. The classical theory of this kind of paramagnetism was developed by Langevin who investigated mathematically the behaviour of an ensemble of magnetic

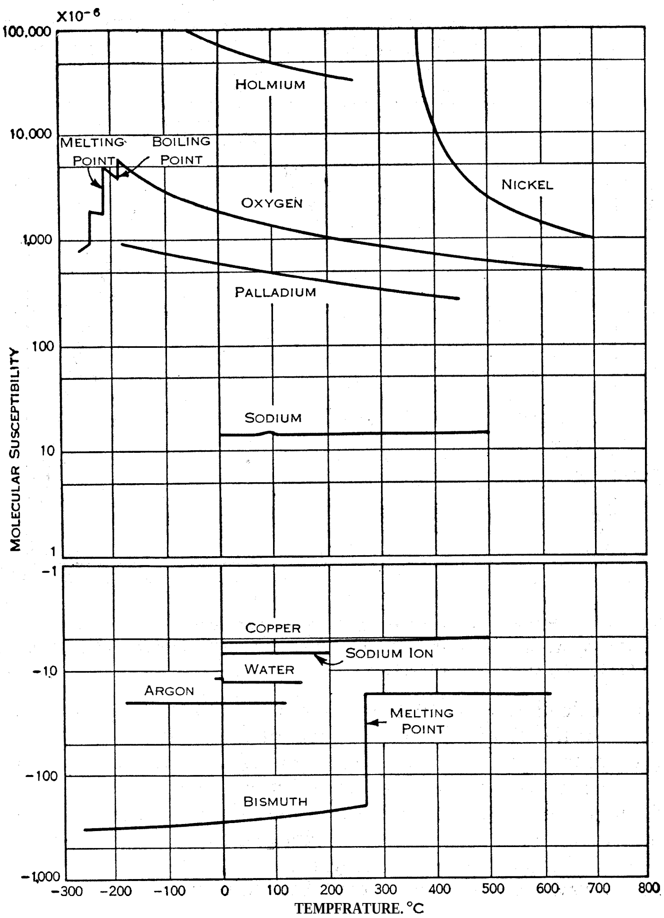

FIG. 54.— VARIATION OF ATOMIC OR MOLECULAR SUSCEPTIBILITY WITH TEMPERATURE FOR SOME REPRESENTATIVE MATERIALS

Susceptibilities of diamagnetic and weakly paramagnetic substances are normally independent of temperature, those of strongly paramagnetic substances decrease with increasing temperature

dipoles, each of moment μ_M, in a field of strength H. The effect of the field is to cause alignment, the thermal agitation to destroy this alignment. Assuming that the molecules are far enough apart so that their mutual forces can be neglected, the energy due to the field is

$$W=\mu_M H \cos \theta$$

for each dipole oriented so that its moment μ_M makes the angle θ with H. If the ensemble is subject to thermal agitation, the principles of statistical mechanics (Boltzman's equation) show that at any temperature, T, the number of dipoles oriented in the solid angle $d\omega$ about the direction θ, is proportional to

$$e^{-W/kT}d\omega=e^{(\mu_M H \cos\theta)/kT}d\omega.$$

For all the molecules the average value of the moment in the direction of the field. $\bar{\mu}_M$, is calculated, and the ratio of this to the total moment, or the moment when all magnets lie parallel, is found to be

$$\frac{\bar{\mu}_M}{\mu_M}=\operatorname{ctnh}\frac{\mu_M H}{kT}-\frac{kT}{\mu_M H}.$$

This is Langevin's equation of paramagnetism. At ordinary temperatures $\mu H << kT$, and this equation may be expanded in series form:

$$\frac{\bar{\mu}_M}{\mu_M}=\frac{\mu_M H}{3kT}-\frac{1}{45}\left(\frac{\mu_M H}{kT}\right)^3+.$$

Now the moment of a gram molecule is $N\bar{\mu}_M$ and the molecular susceptibility is then $\chi_M=N\bar{\mu}_M/H$, so that at ordinary temperatures, where the first term of this equation is sufficient, we have

$$\chi_M=\frac{N\bar{\mu}_M}{H}=\frac{N\mu_M^2}{3kT}=\frac{C_M}{T}.$$

This is Curie's law, with the Curie constant given by

$$C_M=N\mu_M^2/3k.$$

Thus Langevin's work explained Curie's law and showed how the moment per molecule could be determined from the results of experiment.

2. Quantum Theory. — The advent of quantum theory has changed our notions of atomic structure in fundamental ways, and our interpretation of paramagnetic phenomena in several particular ways now to be discussed under four headings.

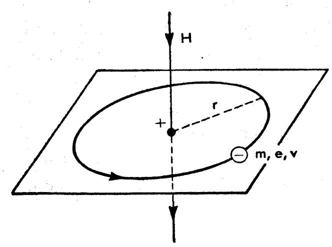

FIG. 55.— ELECTRON VELOCITY

Velocity of electron is changed by application of field **H** so that induced magnetic moment is in direction opposite to that of field

1. Langevin assumed that any orientation of magnetic moment with respect to an applied field is possible; quantum theory requires that only discrete changes of angular momentum are possible, and this imposes restrictions on the orientations of magnetic moment, As a result the Langevin equation of paramagnetism is replaced by a more complicated expression. In the simplest case, when an atom contains a single electron free to change its direction of spin. there are just two possible orientations — those parallel and antiparallel to the field—and the function becomes

$$\bar{\mu}_M/\mu_M=\tanh(\mu_M H/kT)=\mu_M H/kT+\ldots,$$

the last part being applicable when HIT is not too large. When many orientations are possible the function approaches Langevin's as a limit.

2. There is a natural unit for magnetic moment, the Bohr magneton, substantially equal to the moment of one electron spinning about its own centre. Its value is

$$\beta=eh/4\pi mc=9.27\times10^{-21}\text{ erg/gauss.}$$

Here e is the charge and m the mass of the electron, h is Planck's constant and c the velocity of light. It is convenient to convert susceptibility data to the apparent number of Bohr magnetons per atom, by dividing the moment per atom, determined from Langevin's expression for the Curie constant, by β.

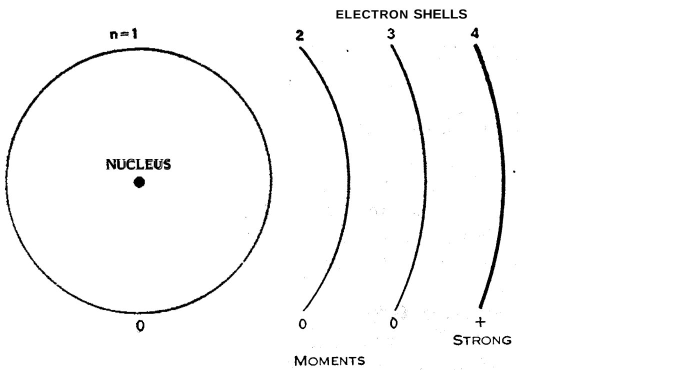

FIG. 56.— PARAMAGNETISM OCCURS WHEN INNER SHELL IS INCOMPLETE (HEAVY LINE) AND THEREFORE HAS PERMANENT MOMENT (STRONG PARAMAGNETISM), OR WHEN ELECTRONS OF OUTER SHELL (BROKEN LINE) BECOME CONDUCTION ELECTRONS IN METAL (WEAK PARAMAGNETISM)

This number is called the effective Bohr magneton number: $\mu_{eff}=\mu_M/\beta$. In terms of the Langevin theory it may be expressed

$$\mu_{eff}=\frac{\mu_M}{\beta}=\sqrt{\frac{3k\chi_M T}{N\beta^2}}=2.83\sqrt{\chi_M T}=2.83\sqrt{C_M}$$

and can be calculated provided enough is known of the structure of the atom.

3. The effective moment of an atom may change with temperature or field strength in a calculable way, and Curie's law will not then be obeyed. Under certain conditions χ_M will be of the form

$$\chi_M = \frac{N\mu_M^2}{3kT} + N\alpha.$$

Such an expression. with the constant a included, accounts quantitatively for the behaviour of some of the rare earth ions, and is applicable in principle in other cases where, however, it cannot often be worked out in detail.

4. The temperature-independent or weak paramagnetism of many metals (fig. 54) and of some conducting oxides and salts was quite inexplicable on classical theory. Quantum theory. however, provides an explanation by showing that conduction electrons, behaving as an electron gas, have just this observed character, as previously stated. Comparison of theory with experiment is discussed below.

The applications of these items to substances of various types will now be considered.

3. Rare Earths. — The ions of the rare earth elements cerium (58) to .ytterbium (70) are good examples of strongly paramagnetic substances. The permanent magnetic moment is due to the 4f subshell of the 4th electron shell in the usually trivalent ions. This inner shell is protected by the outer shells from the influence of neighbouring atoms and so the assumptions underlying the theory are fairly well satisfied.

Ionic susceptibilities are deduced from measurements on solutions and on solid salts and oxides, by subtracting the contributions of water and other ions. The susceptibilities decrease with increasing temperature, as expected. except that χ_M for the samarium ion Sm^{+++} is almost constant above room temperature and Eu^{+++} shows an almost constant susceptibility at low temperatures.

Calculation of the susceptibilities of the rare earth ions by quantum mechanics is one of the important successes of the Van Vleck theory (fig. 57), based on the earlier work of F. Hund. Both terms of the last equations above, those dependent on and independent of temperature. were derived quantitatively from theory. and the unusual change of χ_M with temperature for samarium and europium satisfactorily explained.

Rare earths in metallic form have large susceptibilities, and gadolinium and dysprosium are ferromagnetic at low temperatures. Values of $\chi_A \times 10^6$ are more than 100.000 for terbium and dysprosium at room temperature. Important deviations from Curie's law are observed, and a law of the form

$$\chi_A = C/(T-\theta)$$

is closely followed. This is the Curie-Weiss law applicable to many solid paramagnetics. particularly those in which the magnetic cores of the atoms are under the influence of magnetic or electric fields of nearby atoms: and the Langevin assumptions, therefore. not satisfied. For gadolinium, as for the other ferromagnetic elements. 0 is approximately the Curie point (see *XIII. Theory* of *Ferromagnetism* below), but the existence of θ in the Curie-Weiss equation does not mean necessarily that the material will be ferromagnetic below the temperature $T=0$; rather, the law breaks down before this point is reached.

4. Ions of the Iron Group.——Strong paramagnetism occurs also in the ions of the elements lying between scandium and copper, and is most marked in the ions of manganese. iron and cobalt. The moments of the ions are generally less than those of rare earth ions, because the shell responsible for the paramagnetism is smaller and has only 10 instead of 14 electrons when filled.

In calculating the moments from quantum theory the method used for the rare earths is not at all successful, as shown by the broken line of fig. 58. Results of calculations made with other assumptions are shown by the solid lines (a) and (b), and it is seen that the observed values lie between these curves. Stoner has indicated the reason for this. The shell responsible for the moment is the outermost shell of the ion and so is subject to the influence of surrounding ions. These affect the orbital motions in a way difficult to calculate, but if the effect is severe only the spin moments will be influenced by the magnetic field and curve (a) results. On the other hand if the interaction between neighbouring ions is weak, the orbital motions will be affected and curve

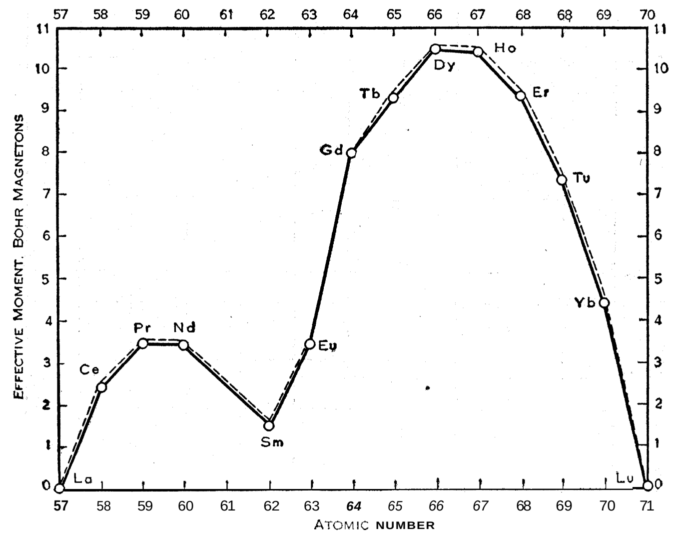

FIG 57 — EFFECTIVE MOMENT OF THE TRIVALENT IONS OF THE RARE EARTH ELEMENTS AT ROOM TEMPERATURE. BROKEN LINE SHOWS VALUES CALCULATED BY VAN VLECK THEORY

(b) is calculated; the further assumption is here made that the energy of thermal agitation is capable of changing the distribution of electron spins in the unfilled shell, an assumption cbnsistent with known facts concerning the structures of these ions. When the influence of surrounding ions on the unfilled shell is moderate, the actual ionic moments may be expected to lie between the two theoretical limits, as in fact they do.

5. Paramagnetism at Low Temperatures. — At ordinary

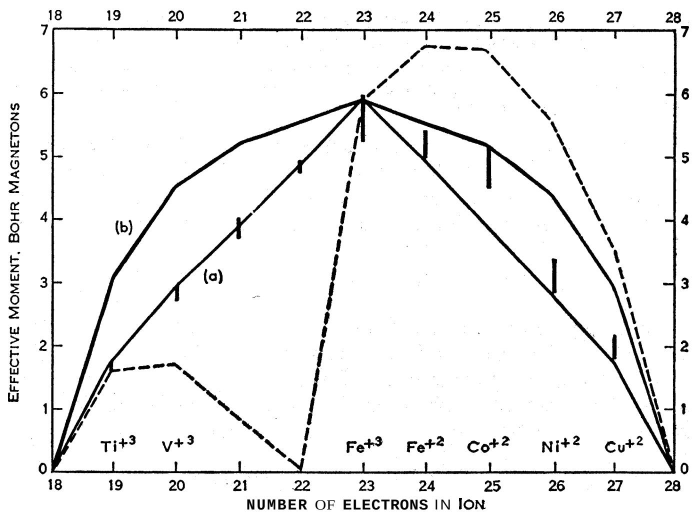

FIG. 58.— EFFECTIVE MOMENT OF IONS OF IRON GROUP OF ELEMENTS. PLOTTED AGAINST NUMBER OF ELECTRONS IN ION. VERTICAL LINES INDICATE RANGE OF OBSERVED VALUES. CONNECTING LINES THEORETICAL VALUES BASED ON DIFFERENT ASSUMPTIONS

temperatures the Langevin equation may be represented with sufficient accuracy by the first term of the series expansion, as noted above. However, at low temperatures and in strong fields $\mu_M H/kT$ may be so large that the complete equation. or its quantum equivalent, must be used. Under these conditions the susceptibility is no longer independent of the field strength, and the magnetic moment of the material approaches a limiting value corresponding to alignment of the molecular magnets parallel to the field.

The first experimental test of this phenomenon was carried out at temperatures down to 1.3° K. and field strengths up to 22,000 oersteds, and the results confirmed the theory in a satisfactory manner. A slightly different relation was predicted by quantum theory, and this agrees with experiment entirely within the limits of accuracy of the experiments.

The magnetic behaviour of certain paramagnetic salts is important in the attainment of very low temperatures. A temperature just 0.0014° above absolute zero was attained in 1951 using the paramagnetic salt chrome aluminum alum.

6. Paramagnetic Gases.—>lost monatomic gases. such as those in the eighth column of the periodic table, are diamagnetic because they have complete electron shells and. therefore, no residual magnetic moments. Metal vapours, however, have monatomic molecules in which the single electron in the outer shell should give rise to paramagnetism. Measurements on such vapours are difficult, but potassium and thallium are reported to be paramagnetic and the former obeys Curie's law over a limited range of temperatures and has a susceptibility, according to the rather inaccurate measurements, corresponding approximately to a single uncompensated electron ($\chi_M = 0.375/T$).

Molecules containing more than one atom are generally diamagnetic because they contain an even number of electrons whose moments neutralize each other. A well-known exception to this rule is oxygen (O_2). This gas follows Curie's lam ($C_M = 1.00$) except at high pressures when the Curie-Weiss law is obeyed, with the constant θ·small and negative. Liquid oxygen also follows the Curie-Weiss law, and the susceptibility increases with decreasing temperature through the solidification point.

The molecular susceptibility of nitric oxide has been measured from 20 to −160° C. (below its normal boiling point) and the effective Bohr magneton number, μ_{eff}, found to vary by about 15% over this range of temperature. Accurate calculation of μ_{eff} and its variation with temperature was carried out by Van Vleck, who based his work on the electronic structure derived from spectroscopic data. The close agreement found between calculated and observed values is a tribute to the adequacy of the theory.

7. Paramagnetism of Free Electrons.— The weak temperature-independent paramagnetism of many of the metals (fig. 53 and 54) was inexplicable on the Langevin theory, according to which all paramagnetism should decrease with increase in temperature. According to modern theory the conduction electrons of a metal have spin moments that can be oriented slightly by a magnetic field. In the simplest case, with one free electron per atom, quantum theory predicts an atomic susceptibility of $1.88 \times 10^{-6} (A/d)^{2/3}$, where A is the atomic weight and d the density in g./cm.^{3}; there is also a smaller diamagnetism predicted by quantum theory, equal to one-third the paramagnetic contribution when the electrons are free.

In actual metals the electrons are not wholly free but are partially bound to the atoms, and are influenced by the so-called correlation and exchange forces, quantum mechanical in nature. Also, the ionic core of the atom has an important diamagnetic contribution to the susceptibility. These various components have been calculated for sodium, and when summed they come within about 10% of the observed susceptibility. For other elements the calculations are less satisfactory.

The paramagnetic contributions of the electrons will vary with the nature of the metal and the diamagnetism of the ionic cores will be different for different atoms, and it is easy to see qualitatively that these and other factors will cause some metals to be weakly paramagnetic. others weakly diamagnetic. The order of magnitude of the susceptibility is explained by theory; more exact calculations must await further quantitative development of atomic theory.

8. Ferromagnetic Materials Above the Curie Point.—A11 materials that exhibit ferromagnetism are paramagnetic when they are heated above the Curie temperature. As the temperature continues to increase. the susceptibility decreases continually according to the Curie-Weiss law for strongly paramagnetic substances, unless there is a change in the phase structure of the material. If the Curie-Weiss law were followed exactly, a straight line would be obtained when $1/\chi_A$ is plotted against the temperature. The data for iron, cobalt and nickel show some variations from the expected linear relations. Definite breaks in the curve for iron are caused by changes in its crystal structure at temperatures of 910° and 1,400° C.

One should be able to calculate from the slope of each of these lines the magnetic moment per atom. and compare this with the moment calculated from the saturation magnetization determined at lower temperatures when the material is ferromagnetic. For nickel the ferromagnetic moment is 0.61 Bohr magnetons per atom. and the moment calculated from the Curie constant is 1.6 in the same units. Similar discrepancies occur for iron and cobalt. These results show that there is not an integral number of electron spins per atom; therefore the atoms will not all have the same moment at any instant. This means that the calculation of magnetic moment from the Curie constant cannot properly be made by the relation used. Modifications of the theory are necessary.

9. Paramagnetic Resonance.— Experiments on resonance at high (microwave) frequencies are carried out in the same way for paramagnetic substances as for ferromagnetic materials! as described above (X. *Magnetization in Alternating* Fields: fig. jo–jz). Resonance occurs when the frequency of the high-frequency field is

$$f = MH/(2\pi J),$$

H being the strength of thesteady magnetic field and M and J the magnetic and mechanical moments of the atom (see fig. 50). This may also be written:

$$f = g\beta H/h,$$

β being the Bohr magneton, h Planck's constant, and g the spectroscopic splitting factor which is 2.00 for electron spin and 1.00 for the orbital motion of the electron.

In solids the electron orbits in a given atom are generally fixed by the strong electrostatic fields of neighbouring atoms so that only the spin moments of the electrons are able to precess in an applied magnetic field. However, the coupling between spin and orbital motion prevents the spin from being perfectly free, and the value of g departs from the value 2.00. The amount of departure gives information about atomic forces and interactions in the solid state, and is a specific property of the material.

In a crystal the spin-orbit coupling depends on the direction in which the steady magnetic field is applied with respect to the crystal areas. Consequently the g values determined with differently oriented fields give additional valuable information about the fields of force in solids.

The nucleus of an atom may itself have a magnetic moment. This is expressed in nuclear magnetons, which are smaller than Bohr magnetons by a factor of 1,840. Nuclear moments precess in a magnetic field, and nuclear magnetic resonance is quite analogous to paramagnetic resonance. The data obtained are useful in studying nuclear structure.

10. Antiferrornagnetism.— Thereis a class of materials that are paramagnetic as judged by their small positive susceptibility, whose behaviour is interpreted in terms of a negative molecular field, or the tendency of neighbouring atomic magnets to be arranged antiparallel. This is illustrated in fig. 7(C). A typical member of this class is manganous oxide. MnO. for which the susceptibility is plotted against temperature in fig. 59. The temperature of the susceptibility maximum is called the antiferromagnetic Curie point or the Néel point; below this temperature there is antiparallel arrangement but above it the thermal agitation destroys the regular arrangement of atomic moments and the material behaves like a normal paramagnetic substance (fig. 7[A]).

The spatial orientations of the atomic moments have been determined for a number of antiferromagnetic substances with the aid of neutron diffraction. Some of the best known antiferromagnetic materials are chromium. copper chloride, ferrous fluoride, manganous oxide and nickel oxide; about jo were known in the late 1950s. Néel points are known to vary from less than 1° to 800° above absolute zero.

Generally in these materials the force bringing about the antiparallel arrangement between the atomic moments (*e.g.*, between Mn ions in MnO) is the quantum mechanical force of exchange, acting from one magnetic atom (Mn) through the intermediate nonmagnetic oxygen atom to the next magnetic atom. Such indi-

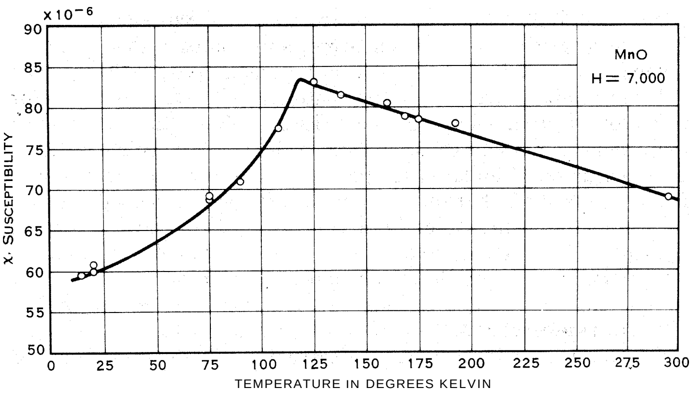

FIG. 59.— SUSCEPTIBILITY OF MnO AS DEPENDENT ON TEMPERATURE. TYPICAL OF ANTIFERROMAGNETIC SUBSTANCE. TEMPERATURE OF MAXIMUM IS NÉEL POINT (H. BIZETTE. C. F. SQUIRE. B. TSAI)

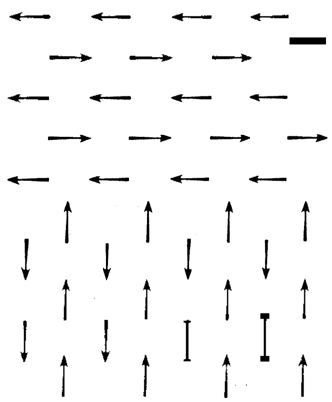
rect action has been designated by H. A. Kramers as superexchange.

It is supposed that antiferromagnetic materials form domains in much the same way as ferromagnetic materials. Such a formation, including one "wall." is shown schematically in fig. 60.

XIII. THEORY OF FERROMAGNETISM

The first requirement of a ferromagnetic material is that the atoms of which it is composed have permanent magnetic moments. The magnetic moment of an atom is due to the electrons which it contains, since the nuclear contribution is negligible. An electron possesses a magnetic moment because of its spin, and may have an additional moment by virtue of its orbital motion.

A second requirement of ferromagnetism is the existence of some kind of interatomic force that maintains the magnetic moments of many atoms parallel to each other. Without such forces the atoms would be disordered by thermal agitation and the moments of neighbouring atoms would neutralize each other, and the large magnetic moment characteristic of ferromagnetic material would not exist. The material would then be merely paramagnetic.



FROM FERROMAGNETISM, R M BOZORTH BY COURTESY OF D VAN NOSTRAND CO, INC, 1951–53

FIG 60 —DOMAIN STRUCTURE OF ANTIFERROMAGNETIC MATERIAL DOMAIN WALL IS NOT AS SHARP AS INDICATED

Our knowledge of these interatomic forces and of the structure of the atom now permits a general description of the origin of ferromagnetism. The following steps in the theory may be enumerated: (1) the ultimate magnetic particle is the spinning electron, and a change in magnetization is fundamentally due to a change in the directions of spin of certain electrons, not to any appreciable extent to a change in their orbital motions; (2) in iron, cobalt and nickel the electrons responsible for ferromagnetism lie in the incomplete third shell of these atoms. In complete shells the electrons are arranged symmetrically so that the spins neutralize one another and the combined moment is zero; (3) in ferromagnetic materials the spins of neighbouring atoms are held parallel by strong quantum mechanical forces. whereas in the atoms of other substances the forces usually tend to make the spins of neighbouring atoms antiparallel and self-neutralizing. The circumstances under which these quantum forces effect parallel orientations and form ferromagnetic domains, or antiparallel orientations that lead to paramagnetism or antiferromagnetism, will be discussed in the following paragraphs. Before considering these steps in modern theory in detail, however, it is appropriate to recall the earlier theories and their development.

1. Early **Theories.**—Ewing was one of the first to attempt to explain ferromagnetic phenomena in terms of the forces between atoms. He assumed with Weber that each atom was a permanent magnet free to turn in any direction about its centre. The interatomic forces holding neighbouring atoms parallel were assumed to be the usual magnetic forces known to act between large-scale bar magnets. The **I,** H curve and hysteresis loop were calculated for a linear group of such magnets and were determined experimentally using models having as many as 130 magnets arranged at the points of a plane square lattice. The calculations for a linear chain show that as the field is gradually increased in magnitude from zero there is at first a slow continuous rotation of all the magnets together, then sudden change in orientation and finally a further continuous rotation until the magnets lie parallel to the field. The **I,** H curves calculated for such a group of magnets resemble in general form the actual curves of iron; they show a permeability first increasing. then decreasing, and saturation and hysteresis.

G. S. Mahajani calculated the magnetic potential energy of a group of magnets arranged in space in the same way that the iron atoms are arranged in a crystal. In agreement with Ewing's theory the magnets tend to be parallel, and some directions in the space array are more stable or preferred than others. On the other hand our present knowledge of the structure of atoms and crystals makes it clear that such magnetic furces between atoms are not large enough to maintain the magnetic moments of neighbouring atoms parallel, as they must be if ferromagnetism is to exist. Such weak forces would readily be disturbed by the thermal motion of atoms at room temperature and even at temperatures a few degrees above absolute zero.

It is now well established that there are very powerful forces, not contemplated when Ewing made his model and proposed his theory, which maintain the dipole moments of neighbouring atoms parallel. These are the electrostatic forces of exchange which will be discussed in connection with the quantum theory.

2. Molecular Field Theory.—In order to understand how atomic forces give rise to ferromagnetism it is desirable to review briefly Weiss's theory of ferromagnetism, which introduces a so-called molecular field that presently will be identified with the nature of these forces. Using an approach different from Ewing's, Weiss did not attempt to explain the nature of the interatomic forces but treated them empirically by assuming that they exerted a powerful effect which aided the applied field in lining up the atomic moments. This is an extension of Langevin's theory of a paramagnetic gas, which culminated in a formula relating the magnetization, **I,** to the field strength, H, and the temperature, T—the hyperbolic cotangent law,

$$\frac{I}{I_0}=\operatorname{ctnh}\frac{\mu_A H}{kT}-\frac{kT}{\mu_A H},$$

referred to in XII. Paramagnetism above. In deriving this, the assumptions are made that the elementary magnets, each of moment μ_A, are subject to thermal agitation and momentarily may have any orientation with respect to the direction of the field, and that they are too far apart to influence each other. Quantum theory alters the first of those assumptions by stating that in such an ensemble of elementary magnets (atoms) there will be only a limited number of possible orientations, in the simplest case only two, one parallel and the other antiparallel to the direction of the field. In this case the equation corresponding to Langevin's is

$$\frac{I}{I_0}=\tanh\frac{\mu_A H}{kT}.$$

Weiss assumed that there exists in a ferromagnetic material a molecular field, proportional to the intensity of magnetization, that aids the magnetic field already present. He therefore replaced the H of Langevin's equation by $H+NI$, calling N the molecular field constant. The resulting equation,

$$\frac{I}{I_0}=\tanh\frac{\mu_A(H+NI)}{kT},$$

is perhaps the most important in the theory of ferromagnetism. It indicates that even in zero field there is still a magnetization of considerable magnitude, provided the temperature is not too high. Putting $H=0$ and $\theta=\mu_A NI_0/k$, this equation reduces to

$$\frac{I}{I_0}=\tanh\frac{I/I_0}{T/\theta}.$$

This purports to specify the magnetization at zero applied field by a function that is the same for all materials, when the mag-

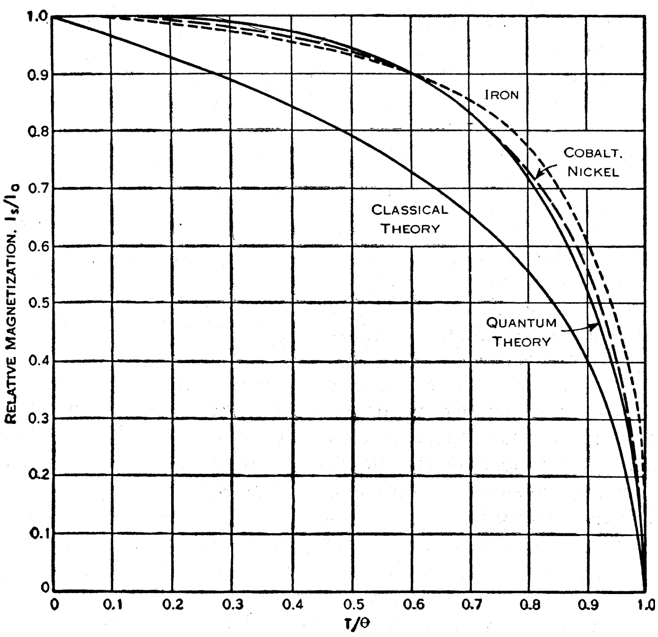


FIG. 61.— SATURATION MAGNETIZATION AS DEPENDENT ON ABSOLUTE TEMPERATURE IN RELATIVE UNITS. SOLID CURVES ARE THEORETICAL. FOR CLASSICAL (WEISS) AND QUANTUM THEORIES

netization is expressed as a fraction of its value at absolute zero (I,) and the temperature as a fraction of the Curie temperature (θ) on the absolute scale. This magnetization v. temperature relation, plotted as the upper solid line of fig. 61, means that at all temperatures below 0 the intensity of magnetization has a definite value even when no field is applied.

According to this conception the I of the last equation represents the magnetization of a domain, and is determined experimentally by measuring the magnetization of a specimen when all domains are parallel; *i.e.,* at saturation (I= I,). This equation should then be written

$$\frac{I_s}{I_0}=\tanh\frac{I_s/I_0}{T/\theta}.$$

It is well known, however. that a piece of iron may be apparently unmagnetized at room temperature. Weiss explained this by formulating the domain theory, already described above, according to which each part of a ferromagnetic material is magnetized to saturation, the magnetic moments of the separate parts being oriented in different directions so that the over-all effect is zero.

These relations are also important for ferromagnetic materials above the Curie point, when they are paramagnetic. Then I is small compared to I_0 and we may write

$$\frac{I}{I_0}=\frac{\mu_A(H+NI)}{kT}.$$

If we put $\theta=\mu_A NI_0/k$ as before, and $C=I_0\mu_A/k$, this becomes

$$I=\frac{CH}{T-\theta},$$

the Curie-Weiss law. Thus θ is explained by the existence of the molecular field, *NI,* that aids the applied field, H, in orienting the elementary magnets. However, as pointed out above, the fact that a paramagnetic substance follows this law does not mean necessarily that it will become ferromagnetic at temperatures below $T=\theta$.

3. Quantum Theory.— The nature of the molecular field was unknonn to Weiss when he developed his theory; he knew only that its power in orienting the elementary magnets was equal to that of a magnetic field of millions of oersteds (in iron, NI is as high as 7×10^6 oersteds). A rational explanation of this was first proposed in 1928 by Heisenberg who showed that it can be explained in terms of the quantum mechanical forces of exchange (see QUANTUM MECHANICS) acting between electrons in neighbouring atoms. Imagine two atoms some distance apart. each atom having a magnetic moment of one Bohr magneton due to the spin moment of one electron. **A** force of interaction, the exchange force already referred to, has been shown to exist between them in addition to the better-known electrostatic and (much weaker) magnetic forces. It is known that such quantum forces are negligible, as one would expect, when the atoms are two or three times as far apart as they are in crystals. It is supposed also, on the basis of discussions by Slater and by Bethe, that as two atoms are brought near to each other from a distance, these forces at first cause the electron spins in the two atoms to become parallel (positive interaction). As the atoms are brought nearer, the spin moments are held parallel more firmly until at a certain distance the force diminishes and then becomes zero; and with still closer approach, the spins set themselves antiparallel with relatively strong forces (negative interaction). In the curve of fig. 62 the energies corresponding to these forces are shown as a function of the distances between atoms.

The interaction curve was drawn originally for atoms with definite shell radii and varying distances from atom to atom. It may equally well be used for a series of elements if we take account of the different radii of the shell in which the magnetic moment resides. The criterion of interaction for the metals of the iron group is the radius, R, of the atom (half the internuclear distance in the crystal) divided by the radius, *r,* of the 3d shell, in which the magnetic moment resides. In fig. 62 this ratio R/r has been used as abscissa and the elements chromium to nickel have been given appropriate positions on the curve. Slater showed that the ratio R/r is larger in the ferromagnetic elements than in other elements having incomplete inner shells, and that the point at which the curve crosses from the nonferromagnetic to the ferromagnetic region is near $R/r=1.5$. This also explains why manganese becomes ferromagnetic when the atoms are separated by abnormally large distances as they are in the Heusler alloys and some compounds.

FIG. 62.—FORM OF INTERACTION CURVE. INTERACTION MEASURED AS CURIE (OR NÉEL) POINT, θ, IN ° K.

4. Atomic Structure of Ferromagnetic Substances.— It has already been pointed out that the fundamental magnetic particle is the spinning electron. One might think that the orbital motions of the electrons in the atom would also contribute to ferromagnetism, as a result of their magnetic moments, but it

has been established that when the magnetization is altered all that changes is the direction of the spin of certain of the electrons in the atoms—the orbital motions remain practically unchanged. The experimental basis for this conclusion is the determination of the ratio of angular momentum to magnetic moment; this ratio is found, in the experiments of S. J. Barnett and others, to be appropriate to the electron spin and definitely not to the orbital moment.

The electrons that are responsible for the magnetic properties of iron, cobalt! nickel and their alloys lie in a definite shell in the atom. As shown in fig. 63, there are four shells or regions, more or less well defined, into which all the electrons circulating about the nuclei of these atoms may be divided when the atom is separated from its neighbouring atoms, as it is, for example, in a gas. Two of these shells are subdivided as shown. When the atoms come closer together to form the solid metal, the fourth or outermost shell of each becomes disrupted, and the two elec-

FIG. 63.— ELECTRONSHELLS

Shells in (A) free iron atom, (B) Fe^{+++} ion. Unfilled third shell is responsible for magnetic moment. Electrons of outer 4s shell of isolated atoms become "free" electrons in the metallic state

trons which comprised it wander easily from atom to atom and are the "free" electrons responsible for electrical conduction. The electrons in the outer part of the third shell are those responsible for the ferromagnetic moment. Some of these electrons spin in one direction and some in the opposite, as indicated, so that their magnetic moments neutralize each other partially but not wholly, and the excess of those spinning in one direction (+) over those spinning in the other (−) causes each atom as a whole to behave as a small permanent magnet.

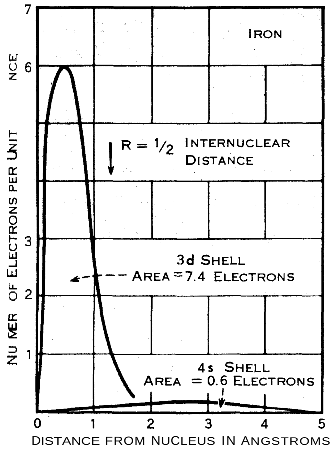
The average moment of the atom in a ferromagnetic material may be determined from the saturation magnetization. I_0, at the absolute zero of temperature by dividing I_0 by the number of atoms in a cubic centimetre. Expressed in Bohr magnetons, β, this number is

$$n_B = \frac{I_0 A}{N\beta d},$$

A being the average atomic weight, N Xvogadro's number and d the density. Moments of iron, cobalt and nickel atoms, so calculated, are

Fe	2.22 Bohr magnetons
Co	1.70
Ni	0.61

The meaning of these nonintegral values may be discussed in either of two different ways used for many problems of the solid state. In the Heisenberg method of approach the atoms have their own electrons (some atoms necessarily more than others), and the disturbing effect of the interaction between neighbours is estimated as well as possible. The other approach, followed by Bloch, Stoner and others, is to consider the metal as composed initially of ions and free electrons, and to calculate the way in which the ionic fields modify the behaviour of the electrons, making them less free. According to the latter or "collective electron" description both the 3d and 4s shells of iron, cobalt and nickel atoms are incomplete and there is a distribution of electrons between them determined by the specific nature of the atomic fields. The calculations indicate that in iron the electrons in these shells are distributed (on the average) about the nuclei as indicated in fig. 64. The 3d shell is a rather dense ring of electrons, as contrasted with the 4s shell which extends farther from the nucleus, so far that in the solid the shells of neighbouring atoms overlap considerably.



FROM "FERROMAGNETISM," R. M. BOZORTH, BY COURTESY OF D. VAN NOSTRAND CO., INC., 1951–53

FIG. 64.—DISTRIBUTION OF ELECTRONS IN THE 3d AND 4s SHELLS IN IRON

The above description of electron distributions in their relation to ferromagnetism is supported by experiments on the alloying of nickel with copper, zinc and other elements. The substitution of one copper for one nickel atom in the lattice is equivalent to adding one electron to the alloy. This electron seeks the place of lowest energy in the alloy and finds it in the 3d− shell of a nickel atom rather than in the copper atom to which it originally belonged. This lowers the magnetic saturation of the alloy by one Bohr unit, since the added electron in the 3d− shell just neutralizes the moment of one in the 3d+ shell. Addition of more copper to nickel decreases the average moment until the empty spaces in the 3d− shell are just full; this should occur when 60% of the atoms are copper, and then the magnetic saturation at 0° K. should be just zero. The theory is well confirmed by the data (fig. 65). When divalent zinc, having two available electrons per atom, is added to nickel the 3d shell is filled twice as fast as when monovalent copper is added, again in accordance with theory, and metals of higher valences behave accordingly.

5. Theory of Ferrites.—The relation of the atomic moments and interaction to atomic structure and interatomic distance are well illustrated by the properties of the ferrites. Nickel ferrite, for example, has the chemical composition represented by $NiO.Fe_2O_3$ or $Ni^{++}Fe_2^{+++}O_4^{--}$. The crystal structure is determined mainly by the oxygen ions, which are much larger than the metal ions and form a close-packed cubic array. Among the oxygen ions there are two kinds of openings in which the metal ions lie. In one kind of position (the A position) the metal ions are equidistant from four oxygen ions arranged at the corners of a tetrahedron; in the other kind (B position) the metal ions are surrounded by six equidistant oxygen ions placed at the corners of an octahedron. In the magnetic ferrites $NiFe_2O_4$, half of the iron ions, Fe^{+++}, are in the A sites. the other half and all of the divalent ions. Ni^{++}, are in the B sites.

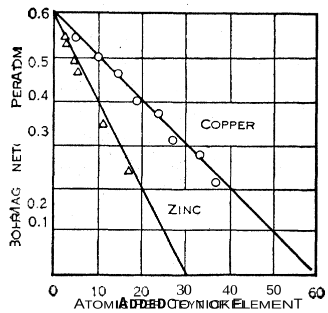


FIG. 65.—REDUCTION IN MAGNETIC MOMENT PER ATOM OF NICKEL

Reduction is caused by adding copper (with one extra electron per atom) or zinc (two per atom). Extra electrons go into unfilled shell and therefore decrease its moment (V. Marian)

The magnetic moments of the metal ions can be deduced from the number of electrons in the atom, as shown in the diagram of fig. 63. The spin moment of Fe^{+++} is five Bohr magnetons, that of Ni^{++} is two.

L. Néel showed that in the magnetic ferrites the interactions between the ions in the A and B sites are antiferromagnetic in nature so that the moments of A ions are antiparallel to those of the B ions. Since the moments are not equal the material is ferromagnetic (*see* fig. 7[D]). In the nonmagnetic zinc ferrites it is knonn that the Zn^{++} ions are on the A sites and all of the Fe^{+++} on the B sites. In magnetic $NiFe_2O_4$ and nonmagnetic $ZnFe_2O_4$ we can represent the situation as follows:

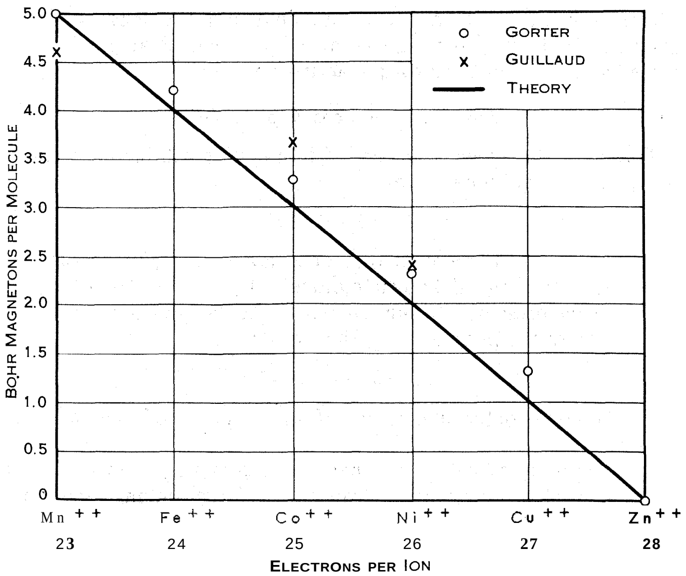
	Tetrahedral A sites	Octahedral B sites		Net moment (n_B)
Fe (NiFe)O_4:	Fe^{+++}	Ni^{++}, Fe^{+++}	O_4^{--}	
Moments:	$\overrightarrow{5}$	$\overleftarrow{2}$ $\overleftarrow{5}$		2
Zn(FeFe)O_4:	Zn^{++}	Fe^{+++} Fe^{+++}	O_4^{--}	
Rloments:	o	$\overleftarrow{5}$ $\overrightarrow{5}$		o

the moments being expressed in Bohr magnetons per molecule. The net moment of $NiFe_2O_4$ is then expected to be two Bohr magnetons. Experimentally E. W. Gorter found 2.3. At room temperature $ZnFe_2O_4$ has random directions of the Fe^{+++} moments, but below 10° K. the Fe^{+++} ions go into an antiparallel arrangement and so show a weak antiparallel or negative interaction.

Similarly one can estimate the moments for the other ferrites in the series Mn, Fe, Co, Ni, Cu, Zn with increasing atomic number. One expects the molecular moments to be just those of the divalent ions of these elements, because the two Fe^{+++} ions in the A and B positions cancel each other. Using the known moments of the divalent ions and plotting the molecular moments of the corresponding ferrites, we obtain the straight line of fig. 66. The observed moments, derived from the saturation magnetization at 0° K., are shown as points. The small discrepancy between calculated and observed moments has been attributed to the moments resulting from the orbital motions of the electrons.

The agreement betneen theory and observation shows that we have a good understanding of the atomic structure and interatomic interactions in simple ferrites.

An interesting and useful material is made by combining a small amount of nonmagnetic zinc ferrite with magnetic manganese



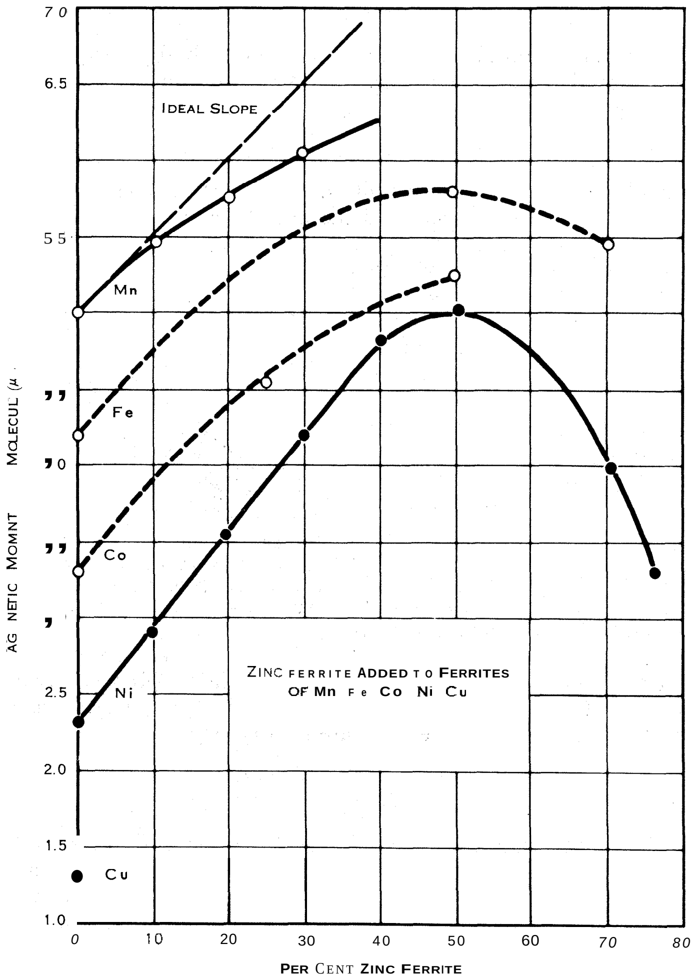
FROM RECENT ADVANCES IN PHYSICS M H SHAMOS & G M MURPHY (ED), BY COURTESY OF NEW YORK UNIVERSITY PRESS 1956

FIG 66 — THEORETICAL AND MEASURED MOLECULAR MOMENTS OF FERRITES OF IRON-GROUP ELEMENTS

ferrite. One can calculate the magnetic moment of a mixture of 90% $MnFe_2O_4$ and 10% $ZnFe_2O_4$ as follows:

	Tetrahedral A sites	Octahedral B sites		Net moment (n_B)
$MnFe_2O_4$:	Mn^{++}	Fe^{+++},Fe^{+++}	O_4^{--}	
Moments:	$\overrightarrow{5}$	$\overleftarrow{5}$ $\overleftarrow{5}$		5
$ZnFe_2O_4$:	Zn^{++}	Fe^{+++},Fe^{+++}	O_4^{--}	
Moments:	o	5 random 5		o
0.9 $MnFe_2O_4$ 0.1 $ZnFe_2O_4$	$Zn^{++}_{0.1}$, $Mn^{++}_{0.9}$	$Fe^{+++}_{0.9}$, $Fe^{+++}_{1.1}$	O_4^{--}	
Moments: o	$\overrightarrow{4.5}$	$\overleftarrow{4.5}$ $\overrightarrow{5.5}$		5.5

If, therefore, some $ZnFe_2O_4$ is added to $MnFe_2O_4$, the Zn^{++} ions will go in the A positions and the Fe^{+++} will remain in the B



FROM RECENT ADVANCES IN PHYSICS M H SHAMOS & G. M MURPHY (ED), BY COURTESY OF NEW YORK UNIVERSITY PRESS 1956

FIG 67 — OBSERVED CHANGE IN MOMENT OF SEVERAL FERRITES BY ADDITION OF ZINC FERRITE. IDEAL THEORETICAL INCREASE IS APPROACHED FOR SMALL ADDITIONS

positions. The net moment of the chemical mixture is found to be 5.5, an increase of 0.5 over that for $MnFe_2O_4$. As long as added Zn^{++} ions go into the A positions we should expect the moment to rise as indicated by the upper broken line of fig. 6; (ideal slope), which has this same increase of 0.5 Bohr magneton for each addition of 10% of $ZnFe_2O_4$. Actually the experiments of E. W. Gorter and C. Guillaud give the data of fig. 67 for additions of $ZnFe_2O_4$ to several of the simple ferrites. The first additions give curves starting with the ideal slope. Eventually the moments of ions in the A positions are too weak to influence the moments of ions in the B positions and the mixture becomes nonmagnetic like pure $ZnFe_2O_4$.

XIV. MEASUREMENT OF MAGNETIC QUANTITIES

1. Basic Relations.—As a prelude to a discussion of the production and measurement of magnetic fields, and the measurement of magnetization, it is desirable to consider quantitatively the fields and forces excited by currents and magnets. These may be discussed according to the following list: (1) the fields produced by magnets; (2) the fields produced by currents; (3) the force on a magnet in a field; (4) the force on a current in a field; (5) the electromotive forces produced in coils by changes in induction within them. It is on these relations that most of the measurements of induction and field strength are based.

Field of a *Magnet*—Consider a bar magnet NS (fig. 68) of pole strength m and interpolar distance l and therefore magnetic moment $M=lm$. Using the fundamental relation according to which the field strength varies inversely as the square of the distance, d, from a pole,[1]

$$H=m/d^2, \qquad (1)$$

and adding vectorially the fields produced by both poles it may be shown that the field strength at distance r from the centre of the magnet is given by

$$H=(M/r^3)\sqrt{1+3\cos^2\theta}$$

provided r is large compared with l. Here θ is the angle between the axis SN of the magnet and the line OP drawn from its centre to the point. P, at which the field is observed. The direction of the field at this point is defined by φ, the angle it makes with OP prolonged. and is determined by

$$2\tan\varphi=\tan\theta.$$

A graphical construction based on this relation may be made easily by trisecting OP so that OC$=\frac{1}{2}$ CP. drawing CD at right angles to OP to cut SN produced at D. Then DP is the direction of the field at P. Here. as elsewhere in this article. H is expressed in oersteds, B in gausses, dimensions in centimetres, forces in dynes and currents in amperes.

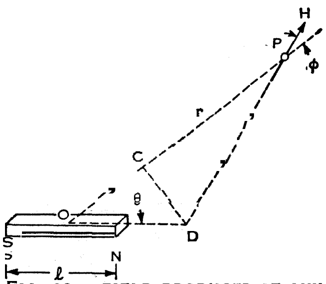


FIG. 68.—FIELD PRODUCED AT ANY POINT P BY PRESENCE OF BAR MAGNET NS DEPENDS ON DISTANCE R AND ANGLE θ

Important special cases are the end-on position (first Gaussian position) for $\theta=0$, and the broadside position (second Gaussian) for θ =go°. For these the fields are respectively

$$H_1=(2M/r^3)(1+l^2/2r^2),$$
$$H_2=(M/r^3)(1-3l^2/4r^2).$$

When two magnets are placed very close together end to end, with opposite poles m_1 and m_2 separated by a distance. d, small romnared mith the extent of the surfaces. the two magnets are attracted with a force that may be very strong. For each portion of one of the nearby surfaces the corresponding part of the other has an attraction given by the fundamental relation

$$F=\frac{m_1 m_2}{d^2}.$$

Summing for the effect of all parts of one surface on all parts of the other one can obtain

$$F=AH^2/8\pi$$

proportional to the pole area, A, but independent of the distance betneen as long as this is small.

Fields Produced by *Currents*.—The simplest way of producing a magnetic field of known strength and direction is by the use of a long coil or solenoid of wire. The field is parallel to the axis of the coil, and when a current of i amperes flows in the windings (having n turns per centimetre) the field strength within the coil is

$$H=4\pi ni/10. \qquad (2)$$

When many layers of wire are used in a solenoid that is not very long in comparison mith its diameter. the field strength varies mith the position. and can be calculated with the help of the appropriate formula.

When a field is produced by the current in a long straight wire of radius a, the direction of the field is everywhere at right angles to the wire axis, and at distance x from the axis the field strength is

$$H=\frac{2i}{10x}$$

outside the wire, while inside it the field strength is

$$a=\frac{2ix}{10a^2}.$$

To create a relatively uniform field in a large volume Hermann von Helmholtz proposed the arrangement of two thin circular coaxial coils of diameter $2a$ and axial separation a. At the centre of symmetry, 0, the field strength is

$$H=0.899\ Ni/a.$$

N is the total number of turns of wire in each coil.

Other forms of coils may be used. and the strength and direction of the field calculated by summing the fields due to each current element. The magnitude of the field dH caused by a current i flowing in an element of mire dl cm. long, at a point r cm. from the current, is given by the equation

$$dH=(i/10r^2)\ dl\ \sin\theta,$$

θ being the angle between the direction of the current and that of the line, r, connecting dl to the point. The direction of the field is at right angles to both the current and r.

Force *on Magnet* in Field.—The force on a single magnetic pole of strength m in a field of strength H is

$$F=Hm$$

dynes acting parallel to the field. In a uniform field a magnet of moment dl' is acted on by a torque tending to turn the magnet upon an axis at right angles to its length and to the field so that it will lie parallel to the field. The magnitude of this torque is

$$L=M'H\sin\alpha$$

where a is the angle between the field and the length of the magnet. If the field is produced at P by a magnet of moment M placed at O (fig. 68), the torque acting on M' is

$$L=MM'\sqrt{1+3\cos^2\theta}\ (\sin\alpha)/r^3.$$

If a pivoted magnet is suspended in a field it will have a natural period of oscillation equal to

$$T=2\pi\sqrt{K/MH}$$

seconds, if K is the moment of inertia about its point of suspension. If an additional known moment of inertia. k, is added to that already present. without changing the magnet moment, and this increases the period to T_1, the expression

$$MH=4\pi^2k/(T_1^2-T^2)$$

can be used to determine either H or M provided the other is known.

In a nonuniform field a magnet will experience a translational force as well as a torque, because the force pulling one pole parallel to the field will be opposed by a larger force caused by a larger field acting on the other pole. If the gradient of the field is dH/dx, the force on a magnet of moment M is

$$F=MdH/dx.$$

This may be expressed more accurately by the relation

$$F_x=M_x\frac{\partial H_x}{\partial x}+M_y\frac{\partial H_y}{\partial x}+M_z\frac{\partial H_z}{\partial x}$$

[1]This relation applies exactly when the magnet is surrounded hy a vacuum; when the surrounding medium is air a very small modification may be necessary. When surrounded by a medium of permeability μ the law is $H=m/\mu d^2$.

in terms of the x, y and z components of H and M. When the moment is induced by the field and is therefore

$$M = Iv = \kappa Hv,$$

the force acting on the volume, v, is

$$F = \kappa vH dH/dx. \tag{3}$$

Force on Current in Field.—When a current i flows in an element of wire of length dl in a field of strength H, a force acts on the wire of magnitude

$$F = Hidl(\sin\theta)/10. \tag{4}$$

Here θ is the angle between dl and H, and the direction of the force is at right angles to both. In two long parallel straight wires carrying currents the field of each acts on the current in the other to produce an attractive force if the currents are in the same direction, a repulsive force if they are antiparallel, of magnitude

$$F = 2ii'/(100a)$$

dynes per centimetre length of wire.

Electromotive Force Due to Changing Flux.—When an electric circuit encloses a changing magnetic flux, φ, an electromotive force is generated in the circuit proportional to the time rate of change of flux, $d\varphi/dt$, and to the number of times, N, the circuit threads the flux. Thus if N turns of wire are wrapped around a piece of iron of cross-sectional area A, and a change in the induction, B, is produced in the iron, a voltage is produced at the ends of the wire equal to 10^{-8} NA times the rate of change of induction in gausses per second:

$$E = 10^{-8}\, NA\, dB/dt.$$

The total change in B that has occurred in a specified time may be evaluated by integrating this equation with the result

$$B = 10^{8}\int E\, dt/NA. \tag{5}$$

2. Common Methods.—Ballistic *Method* With Ring.—In determining magnetization curves and hysteresis loops the ballistic method, employing a ring specimen, is generally the most satisfactory. H. A. Rowland used this method in 1873, and was the first to express the results of measurement in an absolute system. A ring is cut with a radial thickness small compared with its diameter and two uindings of wire are applied (fig. 69) ; a secondary winding (S), usually consisting of many turns of fine wire, is wound close to the specimen and connected to a ballistic galvanometer or fluxmeter (G), and a primary winding (P) of turns evenly spaced is applied and connected to a current source.

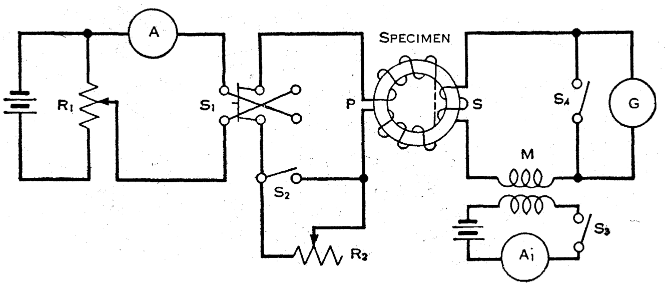

FIG. 69.— DIAGRAM OF METHOD OF MEASUREMENT OF B AND H IN RING SPECIMEN

Current in primary winding P is controlled by resistances R_1 and R_2 and switches S_1 and S_2 and is read on meter A. Secondary winding S is connected through mutual inductance M to ballistic galvanometer G. A_1 and S_3 are used for calibration

In the primary circuit means are provided for adjusting the current and for changing it rapidly from one value to another in the same or opposite direction. In the secondary circuit a mutual inductance (M) with an air core is provided for calibration and a switch for short circuiting the galvanometer. The field strength, H, is calculated according to equation (2) from the number of turns and the dimensions of the coil and the current indicated by the ammeter (A).

When H is changed suddenly from one value to another the resulting change in B induces a voltage in the coil S and causes

TABLE IV.—*Demagnetizing Factors, $N/4\pi$, for Rods and Ellipsoids Magnetized Parallel to Long Axis*

100	.00036	.000430	.00776
200	.000090	.000125	.00390
joo	.000014	.0000236	.001567
1,000	.0000036	.0000066	.000784
2,000	.0000009	.0000019	.000392

a deflection of the galvanometer that is proportional to the change in B, according to equation (5) above (the ballistic galvanometer has a deflection proportional to $\int$Edt provided the voltage impulse occurs in an interval of time short compared with the natural period of oscillation of the galvanometer coil and mirror). Since ballistic measurements always involve differences one must start with a known value of B. The most common procedure for accomplishing this is first to reduce the magnetization to zero, or demagnetize the core, by subjecting it to an alternating field of high strength and gradually reducing the amplitude to zero. To determine a point such as M in fig. 70, current corresponding to H_1 is applied and reversed several times with the galvanometer short-circuited. to establish a steady cyclic state, and then the galvanometer is connected in and the deflection for reversal of H_1 noted. This deflection then corresponds to a change in B of $2B_1$, and B_1 can easily be calculated from the constant obtained by calibration. The point M on the normal magnetization curve is thus established and other points on the curve are determined similarly.

To determine a point, N, on a hysteresis loop the field is alternated several times between the points of the loop (*e.g.*, MM'), then H, is changed suddenly to $-H_2$ and the deflection noted and the corresponding change in B is subtracted from B_1, already determined, to give the value of $-B_2$ at N. By varying H_2, a sufficient number of points on the whole loop can be obtained.

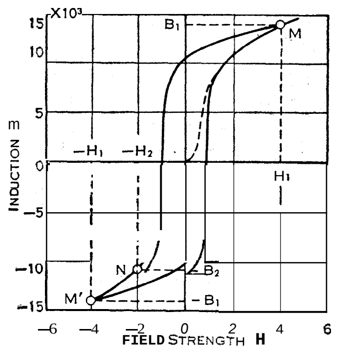

FIG. 70.— HYSTERESIS LOOP ILLUSTRATING BALLISTIC METHOD OF MEASUREMENT OF B

When field strength is changed from H_1 to $-H_1$, B changes from B_1 to $-B_1$, and galvanometer deflection measures this change in B

The ring specimen is not adapted to rapid testing, for some time is consumed in machining the ring and in winding it with wire. However, several methods are available for the rapid application of turns. Stiff wires may be held in fixed positions and arranged so that the ring will slip over many of them at once, the nires being connected together by a plug-and-socket arrangement or with mercury contacts to make a single circuit. Also, toroidal winding machines are made that apply more than 25 turns a second to a closed ring.

Ordinarily the ballistic galvanometer and ring specimen are used for fields of intermediate strength. When the field strength is high, *e.g.*, 1,000 oersteds, the number of turns in the primary winding, or the current through it, must be large and the consequent heat generated interferes with the measurements. If the field strength is too low many turns must be wound on the secondary in order to obtain a sufficiently large galvanometer deflection, and this process is tedious and under some circumstances there may not be enough space available inside the ring. In very low fields A.C. methods should be considered.

Rod *Specimens;* Demagnetizing *Factors*.—The ballistic method may be used with a straight specimen in the form of a rod, this being magnetized with the same procedure as that used for a ring. The specimen may easily be slipped into a long solenoid previously prepared. and the secondary winding or search coil should be placed around a small central portion of the specimen. Under these circumstances the more difficult quantity to determine is the field strength, because the field created by the solenoid will be disturbed by the magnetic poles of the specimen. The field created by the specimen itself is called the demagnetizing field, δH, and is proportional to the intensity of magnetization. It is usually specified by the. demagnetizing factor, N, which depends on the ratio length/diameter of the rod:

$$AH = NI.$$

The field acting on the middle of the rod is then the resultant of the field in the solenoid. H,. and the demagnetizing field, δH, and (when I is replaced by $(B-H)/4\pi$) is

$$H = H_0 - \frac{N}{4\pi}(B-H).$$

Values of $N/4\pi$ have been determined by a number of experiments and selected values are given in Table IV.

The term effective permeability, μ', is often applied to the ratio B/H_0, and its relation to the (true) permeability, μ, can be derived from the above equation:

$$1/\mu = 1/\mu' - N/4\pi$$

by considering $N/4\pi$ to be negligibly small compared with one. The relation between μ and μ' for rods of various dimensional ratios m = length/diameter is shown graphically in fig. 71. It is apparent that rods having dimensional ratios as large as 1,000 must be used to determine accurately the value of the permeability when it is more than 100,000.

In rods the induction varies from place to place in the bar, decreasing from the middle toward the ends. It is only when the specimen is in the form of an ellipsoid that the induction is uniform throughout. In specimens of such form the demagnetizing factor may be calculated accurately from the lengths of the three axes of the ellipsoid, and the direction of the induction determined. Equations are given below for the two most useful cases: (1) the prolate ellipsoid having the major axis m times the two equal minor axes, and magnetized parallel to its major axis; and (2) the oblate ellipsoid or ellipsoidal disk having two long axes each m times the short axis, the specimen being magnetized parallel to a long axis.

$$\text{Prolate: } \frac{N}{4\pi} = \frac{1}{m^2-1}\left[\frac{m}{\sqrt{m^2-1}}\log_e\left(m+\sqrt{m^2-1}\right)-1\right],$$

$$\text{Oblate: } \frac{N}{4\pi} = \frac{1}{2}\left[\frac{m^2}{(m^2-1)^{3/2}}\arcsin\frac{\sqrt{m^2-1}}{m} - \frac{1}{m^2-1}\right].$$

Values of $N/4\pi$ for various values of m are given in Table IV.

Yokes and Permeameters.—When the specimen is in the form of a straight rod or tube or tape the demagnetizing field may be partially or completely annulled by connecting the tao ends, outside the magnetizing solenoid. nith magnetic material of high permeability and large cross-sectional area. Such a yoke may be used for specimens of high dimensional ratio, and measurements made with considerable accuracy.

More often, in the testing of permanent magnets or commercial materials in the form of bars or strips. it is desirable to use a yoke with a relatively short specimen and in this case the demagnetizing field must be taken into account or annulled in some way. One way that has been satisfactorily used to accomplish both of these things is to measure the field with a ballistic galvanometer connected to a coil (H-coil) of many turns placed in the magnetizing coil near the middle of the specimen but not surrounding it (fig. 72), and at the same time to magnetize the yoke nith the current that passes through the magnetizing coil. The turns through which this current passes are adjusted to overcome the reluctance of the yoke and the air gaps that exist at each end of the specimen no matter how much care is taken to obtain good joints at these points. The search coil used in determining B is wound on the middle of the specimen as usual.

A further step toward increased accuracy was taken in the

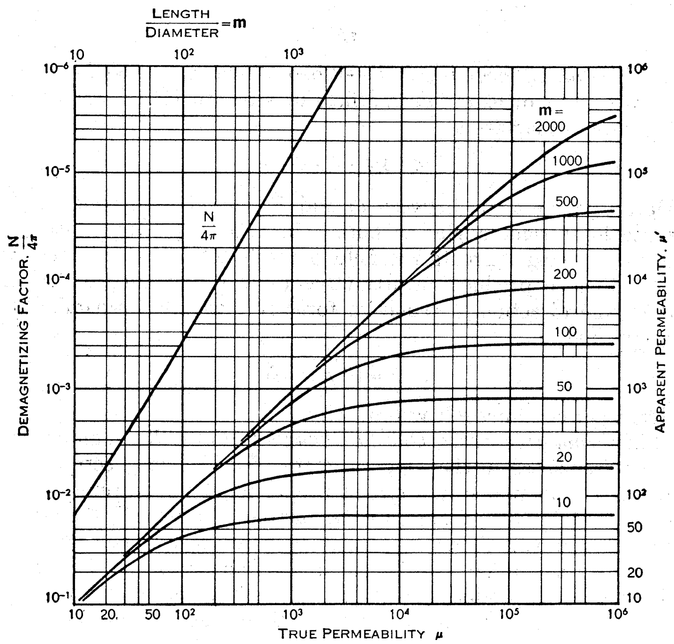

FIG. 71.— CHART FOR CONVERTING APPARENT TO TRUE PERMEABILITY. μ' TO μ, OF CYLINDERS OF GIVEN RATIO M OF LENGTH TO DIAMETER. ALSO DEMAGNETIZING FACTORS. $N/4\pi$

construction of the Burrows and the Niwa permeameters. These use auxiliary magnetizing and search coils to effect a uniform magnetization of the specimen by compensating for the air gaps that must be present. The induction is determined with a ballistic galvanometer.

Other methods of testing with a yoke mere proposed by F. P. Fahy and by **A.** Koepsel and these have been used extensively for routine testing of samples of standardized materials of moderate or low permeability. In the Fahy permeameter B and H are determined with the help of coils extending the full length

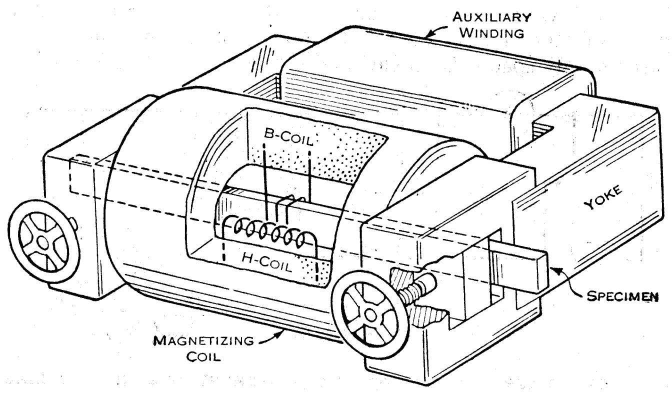

FIG. 72.— SIMPLE YOKE METHOD OF COMPENSATING DEMAGNETIZING EFFECT OF ENDS OF SHORT SPECIMEN

of the specimen and connected to a galvanometer. An auxiliary magnetizing coil is used on the yoke. The Koepsel permeameter has the advantage of being a direct-reading instrument since it requires no galvanometer. To indicate the induction in the specimen a coil of wire is placed on a delicate bearing in an air gap in the yoke. and when a constant current is passed through this coil it deflects in accordance with equation (4) by an amount proportional to the field strength in the gap, which in turn depends on the flux in the specimen.

In determining the magnetic properties of materials in high fields, of the order of *300* to 10,000 or more! it is usually desirable to use some kind of an electromagnet (*q.v.*) to create the field. One good method for determining B and H is shown in fig. *73*. The specimen S is placed in the air gap of an electromagnet EM and surrounded by a small coil B, preferably a short single layer of fine wire. This is connected to a sensitive fluxmeter G_B, the deflection of which is a measure of the flux change when the field of the electromagnet is changed.

The field strength acting on the specimen is measured by a Chattock potentiometer; this is made of many turns of fine wire, C, wound evenly on a flexible nonmagnetic form which is bent into a semicircular shape and placed against the specimen near the ends of the coil B. The deflection of the fluxmeter G_B measures the change of field strength as the coil C is brought from zero field into its place against the specimen.

A high-H permeameter was also designed by R. L. Sanford and E. G. Bennett for measurements of B in high fields.

Alternating Current *Methods.*—The principal uses of A.C. testing methods are for determining (1) permeability and energy losses of thin sheet at low inductions, usually not more than a few hundred gausses, using an inductance bridge; and (2) energy losses at high inductions, usually $B=15{,}000$, using the Epstein method.

A diagram of the inductance bridge is shown in fig. *74*. Current of the desired frequency, f, is supplied by an oscillator and fed to opposite corners of the bridge through a transformer and a thermal ammeter, A. Two equal fixed resistances R_1 constitute two arms of the bridge, and in the others are the specimen, S, and variable inductance L and resistance R. When the bridge is balanced by adjusting L and R until no voltage is detected by the phones P or other instrument connected as shown through a transformer and amplifier, then L and R are equal to the inductance and A.C. resistance of the winding enclosing the specimen. The permeability can be calculated from L and the dimensions of the specimen, the field strength from the current through the core winding and the energy loss in the specimen from the resistance R, correction being made for the losses in the copper wire. In another common modification of the Maxwell bridge the variable inductance L is removed and a variable condenser is connected in parallel with the variable resistor.

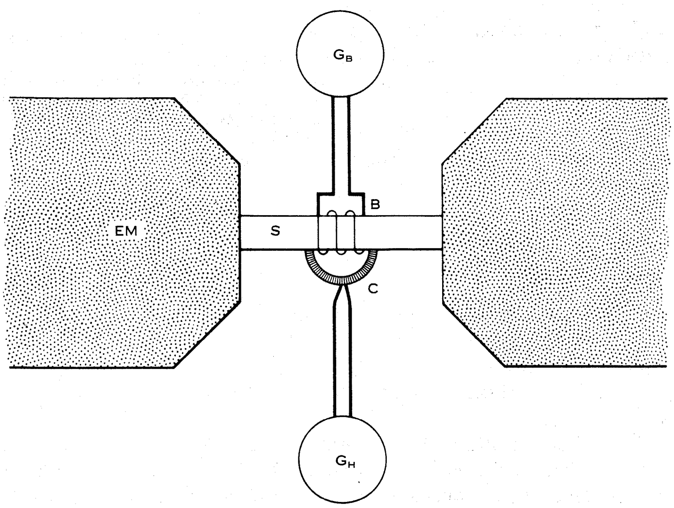

FIG. 73 — MEASUREMENT OF SPECIMEN S AT HIGH VALUES OF H
Induction is measured with coil B connected to fluxmeter G_B, H is measured with Chattock coil C. H is changed with current through electromagnet EM

To save the application of many turns of wire to the specimen, necessary nhen low inductions are measured. G. E. Kelsall has used a device indicated schematically at K in fig. 74. Instead of connecting the windings of a specimen directly to one arm of the bridge, in the usual way, there is substituted a transformer having a many-turn primary and a single-turn secondary. This turn is wound on the specimen also, and the bridge is balanced as before. The core of the transformer is made of high quality laminated material and has low losses which, however, must be taken into account and subtracted from the bridge measurement to obtain the loss in the specimen. This instrument has been adapted for use at high temperatures as well as at ordinary temperatures.

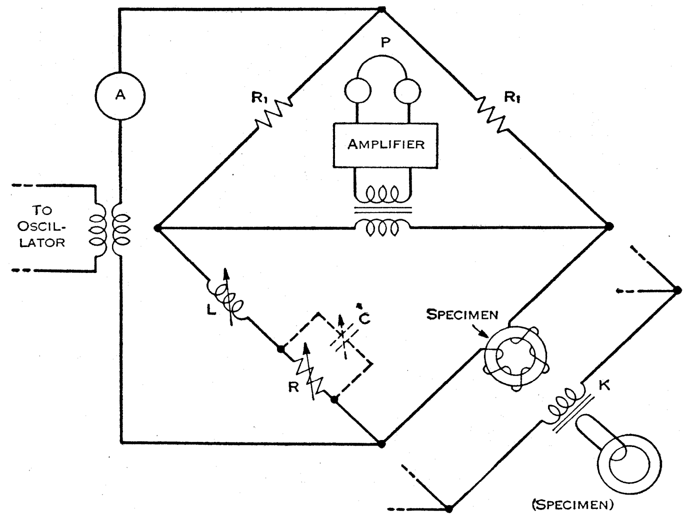

FIG. 74. — INDUCTANCE BRIDGE
The bridge measures resistance and inductance of winding surrounding specimen. Alternatively, L may be omitted and a variable condenser, C, inserted in parallel with R. Specimen may be connected through transformer K having single-turn secondary looped with specimen

In interpreting the permeability and energy losses measured by A. C. methods one must consider the apparent reduction of permeability due to skin effect or shielding caused by eddy currents. and the separable losses attributable to eddy currents and hysteresis. These data obtained with the A.C. bridge are especially important in the study of materials used in communication engineering where small magnetic fields are important in the transmission of weak or undistorted signals.

The Epstein or Lloyd-Fisher apparatus is used primarily for measuring magnetic losses in material for power and other transformers operating at high inductions. The material in the form of strips is built into a hollow square. An alternating field is applied. in one winding, to magnetize it to a high induction measured by the voltage induced in a second winding, and the loss is indicated by a wattmeter connected to the circuits of both windings (fig. 75). Both windings are placed evenly on forms with square sections. and four such forms are placed to form a hollow, square. The strips are slipped into the forms and carefully clamped at the corners after being abutted or overlapped there. Standard specifications control the manner of cutting and stacking the specimens, of correcting for the air flux in the coils and of taking into account the wave form of the exciting current. Measurements are commonly made at $B=15{,}000$ and at a frequency of 60 cycles/sec. in the U.S. and 50 cycles/sec. in England.

In principle a simple method of testing a specimen by A.C. is by determining the current-voltage characteristics of a specimen having tuo uindings. the current being a measure of H and the voltage a measure of *B*. Several ways have been used for accomplishing this. involving potentiometric measurements or rectification. From the results one can determine not only *B* and H, but also by taking account of the phase can determine the total energy loss in the material.

3. Special Methods. — Methods other than those described may be used advahtageously for special investigations.

Measurements of very small quantities of materials, of single crystals in definite directions, of paramagnetic or diamagnetic solids, liquids or gases all require specific arrangements for obtaining results of high accuracy with a minimum of effort.

Years ago the intensity of magnetization of a specimen was usually measured by the torque it exerted on a small magnetic needle of known moment suspended nearby. The deflection of a light beam by a mirror attached to the delicate suspended system is still a very sensitive indicator of the state of magnetization of a specimen under investigation, but for most purposes the uncertainty in the positions of the magnetic poles of the specimen makes the magnetometer an instrument of low precision.

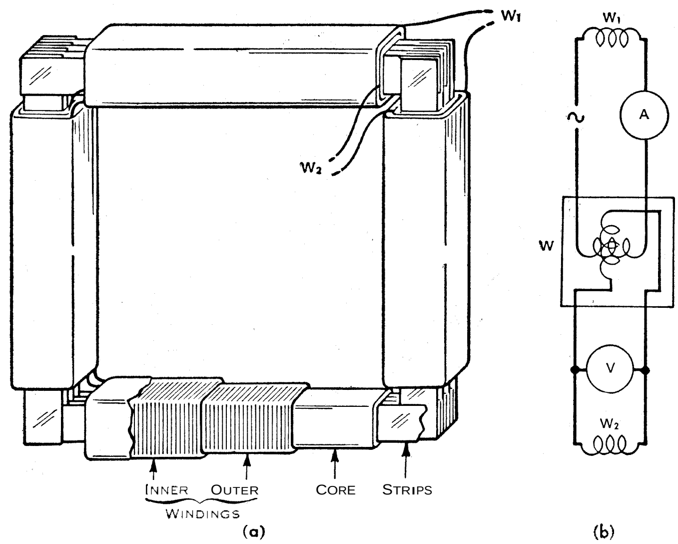

FIG. 75.— EPSTEINOR LLOYD-FISHER APPARATUS
This apparatus measures power dissipated in a specimen formed from strips. Coils, form wound as shown in (a), are connected as shown at (b) to voltmeter V and wattmeter W. Same coils are also used for ballistic measurements

In principle the magnetometer measures field strength at a known distance from the poles of the specimen. in accordance nith equation (1), $H=m/d^2$. It has been used recently for measuring, with not too great accuracy, the magnetic properties of very small specimens in the form of fine wires or thin films deposited by evaporation or electrodeposition.

Measurements of weakly magnetic substances usually depend on the translational force exerted on a magnetized body in a nonuniform magnetic field. Faraday suspended the material to be measured between the poles of an electromagnet, displaced from the central position so that the field gradient was large, and used a torsion balance to measure the force pulling the material toward the stronger part of the field or repelling it therefrom. This method was developed by P. Curie and used in his classical researches on the effect of temperature on paramagnetic and diamagnetic materials.

When the field gradient is dH/dx, the force on material of magnetic moment M is MdH/dx dynes, and when expressed in terms of susceptibility and volume (equation [3]) the force is

$$F=\kappa vHdH/dx.$$

The force is zero at the central position between the poles of the magnet because here dH/dx is zero, and the force is a maximum at some point and falls off again toward zero at points distant from the magnet.

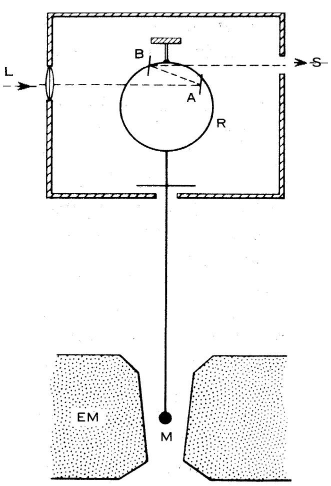

FIG. 76.—SUCKSMITH BALANCE
Specimen M is pulled into electromagnet and strains ring R by amount measured by deflection of light beam LS after reflection from mirrors AB

To avoid the laborious mapping of the field to determine the product HdH/dx, and the careful setting of the sample at a given position, C. Chéveneau proposed that the magnet be moved until the sample deviates a maximum amount from its zero position against the restoring force of a torsion balance. The deflection is then proportional to the susceptibility and to the maximum value of HdH/dx, and the proportionality factor is determined by calibration with a substance of known susceptibility.

An ingenious quick-reading device was designed by W. Sucksmith and is shown schematically in fig. 76. The specimen M is suspended from a ring R which is made of a flexible strip of metal that deforms when the specimen is pulled into the inhomogeneous field of the electromagnet EM. The deformation of the ring is measured with a beam of light L reflected from two mirrors AB to a scale S. The force that deforms the ring is proportional to the intensity of magnetization of the specimen; the constant of calibration is obtained using a magnetic material of known magnetization. The method is applicable to ferromagnetic and paramagnetic substances.

A further method of measuring magnetization in high fields is the method of extraction. used first by Weiss and R. Forrer. The specimen is placed in the field of an electromagnet and then suddenly removed. During removal it induces a voltage in a coil that is fixed to the magnet, and the integrated voltage. proportional to the magnetization of the specimen, is measured by a ballistic galvanometer.

The force exerted upon a magnetic material in an inhomogeneous magnetic field is also the basis of the methods of L. Gouy and G. Quincke for measuring the susceptibilities of liquids. There are numerous modifications of the original methods and adaptation has been made to the measurement of gases. The force on the liquid in the field is measured by its rise in a capillary tube, against the force of gravity. A simple modification is shown diagrammatically in fig. 77 which shows the poles of an electromagnet producing a high field at the surface of the liquid, the movement of which is measured by a microscope when the field is applied or removed. In using the method for gases a standard liquid of known susceptibility is employed and the gas fills the remainder of the tube. The force on the gas, caused by the field. adds vectorially to that on the liquid and the displacement of the meniscus is a measure of the resultant.

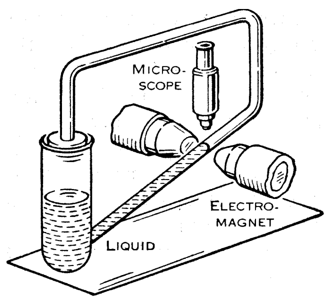

FIG. 77.— DETERMINATION OF SUSCEPTIBILITY OF LIQUID
Displacement of the liquid's meniscus in a capillary tube when the field of an electromagnet is applied in direction at right angles to tube is noted (with microscope) (L. Gouy, G. Quincke)

The force on a column of liquid (or gas) extending from a place where the field is H_1 to where it is H_0 may be obtained by integration of equation (3) to give

$$F=\kappa A(H_1^2-H_0^2)/2,$$

A being the cross-sectional area of the column. If a column of liquid (susceptibility κ_1) is opposed by a column of gas (susceptibility κ_2), the relation becomes

$$F=(\kappa_1-\kappa_2)A(H_1^2-H_0^2)/2.$$

Usually H_1 is the field strength directly between the poles of the magnet at the boundary between liquid and gas, and H_0 at the other end of the column is negligibly small. The susceptibility of gases has also been measured with the aid of a sensitive torsion balance.

The measurements of the saturetion induction of ferromagnetic materials were made with great accuracy by Weiss and his students in fields up to 20.000 oersteds, at temperatures ranging from about $-250°$ to $+800°$ C. For this purpose they used some modification of the scheme shown in fig. 78, in which the force is produced by a field gradient as in the Faraday method, but is measured as a translation instead of a torsion. Such a pendulum magnetometer has a light horizontal beam with the specimen mounted at one end in a region of high field gradient. The force due to the field is annulled by adjusting a current in a solenoid in which is a plunger attached to the other end of the beam, and the point of zero deflection is indicated by a tilting mirror.

Other methods of measurement in strong fields deserve brief mention. H. DuBois measured the intensity of magnetization by observing the rotation of the polarization of light reflecting from a magnetized surface (Kerr effect). The strength of a field can be measured by noting the change in the electrical resistance of

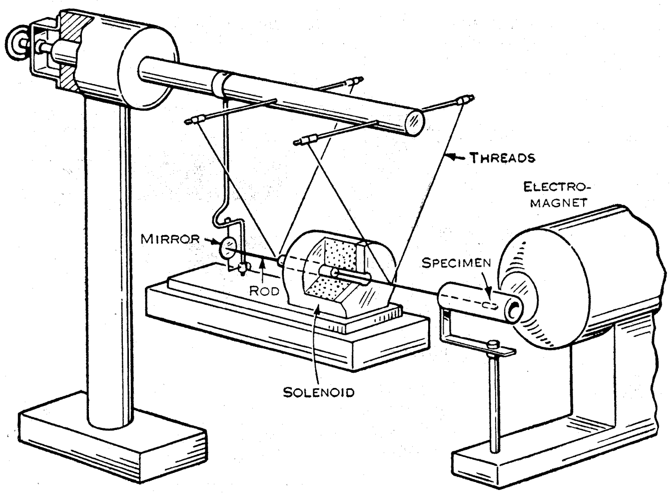

FIG. 78.—PENDULUM MAGNETOMETER

Specimen is hung from threads on light frame. Inhomogeneous field of electromagnet (half of which is shown) causes horizontal motion of frame, detected by tilting of mirror. Motion is compensated by magnetic plunger in solenoid, current through which is measure of magnetization of specimen (P. Weiss and G. Foex)

a bismuth wire immersed in the field or by observing the force (opposing gravity) produced on a conductor carrying a known current (equation [4]). Special methods have been devised for measuring the magnetic properties of materials in which these vary with direction. as in single crystals.

In weak fields, such as that of the earth. the methods of geomagnetism can be used (see GEOMAGNETISM). In 1936 an apparatus was constructed for measuring and recording rapid changes in fields as small as one gamma (10^{-5} oersted), and during and after World War II this method was developed to even higher sensitivity (10^{-7} oersted). A piece of high-permeability material is subjected to an alternating field of moderate amplitude, and if an additional steady field (that to be measured) is also present an alternating voltage of twice the exciting frequency will be produced and can be amplified and recorded. Its amplitude is proportional to the field strength to be determined.

The strength of high fields is now measured with high accuracy with the use of nuclear resonance. In principle this is the same as ferromagnetic resonance described above (X. *Magnetization* in Alternating Fields) except that the magnetic moment of the nucleus is much smaller than that of the electron so that the frequency of resonance is correspondingly lower, and for the nuclei of the hydrogen and lithium atoms. which are most used for measurement, this frequency lies in the radio-frequency range. The measurement of the field strength is then reduced to the measurement of a radio frequency, and this can readily be done with a precision of a few parts in 1,000,000. 4 material containing hydrogen or other nuclei, whose constants are known with high accuracy, is placed in the field to be measured, the weak radio-frequency field is applied at right angles to the principal field and the frequency is varied until resonance occurs.

A number of curve tracers have been made for taking magnetization curves and hysteresis loops so that a permanent accurate record may be obtained in a short time. Among the more accurate and convenient of these is the device of P. P. Cioffi. For the investigation of magnetic properties at high frequencies special techniques of some complexity must be used. MAGNETITE or MAGNETIC IRON ORE, a member of the spinel group of minerals with the formula Fe_3O_4 (or $FeFe_2O_4$), is an important ore of iron found in commercial quantities in northern Sweden, Norway and Rumania and in the Ural mountains; in the United States—New York, New Jersey, Pennsylvania and Utah (and in some of the ores of the Lake Superior district). It is a black, opaque mineral with metallic lustre. Hardness, about 6. Specific gravity, 4.9 to 5.2. Streak, black. Magnetite, also known as the loadstone, is strongly magnetic and frequently polar and has been known from very early times for this remarkable property which was described by Pliny (see also MAGNETISM: History). It crystallizes in the cubic system, in which it occurs usually in octahedra, and is frequently twinned. There is no distinct cleavage.

Magnetite is a mineral of wide distribution, especially as a constituent of igneous rocks, both intrusive and volcanic. It appears to have crystallized from the magma at an early period of consolidation, and marginal segregation has led in many cases to the formation of ore deposits. Being a mineral not prone to decomposition, it is also found in detrital deposits, sometimes in a concentrated form, as magnetite sand. The existence of pseudomorphs of magnetite after hematite (*q.v.*) and vice versa, however, prove that these minerals may be converted into one another by a change in the state of oxidation. Oxidation and hydration in the zone of weathering lead to limonite (*q.v.*). Titaniferous magnetite or titanomagnetite is a variety containing titanium. It consists of an intergrowth in various proportions of the minerals magnetite and ilmenite (*q.v.*).

MAGNETO, HIGH-TENSION. The magneto is a special application of the electric generator employed where the output of energy required is very small. It is used to furnish energy for ignition of compressed gases in various types of internal-combustion engines. The elements of construction comprise a permanent magnetic field, an armature rotated within that field, a circuit breaker and a distributing mechanism which serves to convey the generated voltage to a desired point. The low-tension magneto consists merely of a permanent magnet of inverted U form and, rotating between its poles, a shuttle-wound armature containing a number of turns of comparatively coarse wire, as shown in fig. 1.

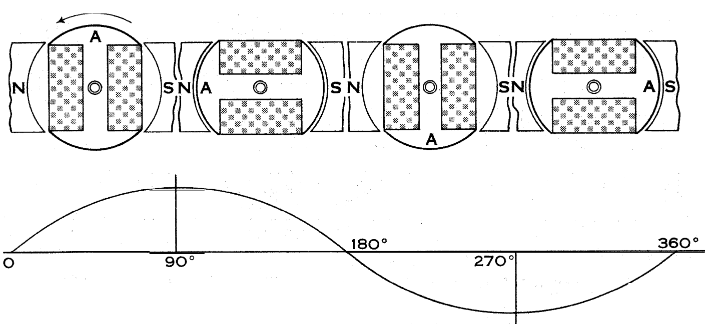
FIG. 1.—SIMPLE MAGNETO SHOWING MAGNET PRIMARY WINDING

The changes of flux in the armature core, caused by its rotation in the permanent field, generate in the armature winding an electromotive force, the magnitude of which is proportional to the field strength, the speed of rotation and the number of turns of wire on the armature. As the armature core rotates into a position in a plane nith the flux lines, the flux in the core increases to a maxi-



BY COURTESY OF J H CROWNE

FIG. 2.—SIMPLE ELECTRIC WAVE FORMED IN A MAGNETO, SHOWING POSITION OF THE ARMATURE AND THE CURRENT PHASE FOR EACH POSITION

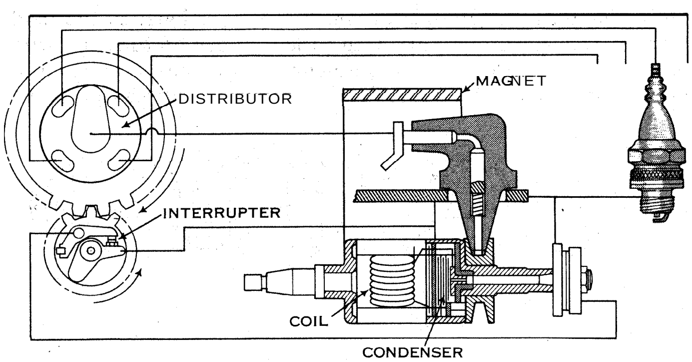
mum. As the rotation progresses, the flux in the core decreases for one-half cycle. In the second half cycle, the coil direction is reversed with relation to the flux.

The generated electromotive force, consequently, is alternating in direction and magnitude and follows the variation of flux in the core. The change of electromotive force with change of position of the armature is shown in fig. 2. The low-tension magneto has been used in conjunction with an induction coil as an ignition source, the coil serving to transform the voltage to a value sufficient to cause a spark across the terminals of a spark plug.

High-Tension Magneto Construction.—The high-tension magneto has a secondary winding, comprising a great many turns of fine wire superimposed upon the primary winding. The primary winding is short-circuited by means of an auxiliary device during the building up of the field in the armature core. When the energy in the primary circuit has reached a maximum, this circuit is opened, and at the same instant, as a result of the rotation of the armature, the magnetic field is removed. The energy of the primary winding is discharged through the secondary, and as a result of the ratio of primary to secondary turns, a considerable increase in voltage is effected. This value may vary between 7,500 and 18,000 v. The high-tension magneto when employed as a source of ignition for gas engines is operated synchronously with the engine by direct connection.

Fig. 3 shows the construction of a shuttle-armature type of high-tension magneto. The circuit breaker is operated by means of a cam, upon which the bumper, or cam follower on the breaker bar, bears. Since the armature is directly connected to the engine, the frequency of the discharges through the secondary circuit is thus determined. (A shuttle armature, having two poles, can generate two spark discharges per revolution.) The distributor serves to convey the voltage to each of the spark-plug cables, in a desired sequence. Operating in synchronism with the armature, from which it is driven by means of a gear and pinion, the brush or firing pin of the distributor arm makes contact with a segment in the distributor block each time the secondary discharge occurs. By this means, the high-tension energy is carried to each spark plug in order. For a four-cylinder engine, the distributor block carries four segments, and since the shuttle armature generates two sparks per revolution, the gear ratio between armature and distributor is 2:1. The primary and secondary windings are common at one point and are there connected to the frame of the magneto. The return circuit of the secondary is thus completed through the body of the engine. The contact points of the circuit breaker, or interrupter, are made of an arc-resistant alloy.

An improvement in magneto design was offered in the inductor-type instrument in which the coil is stationary and the flux changes are brought about by means of magnetic shunt segments which rotate between the magnet poles and bridge between them and the coil core. A cross-sectional drawing of this type is shown in fig. 4. By the use of four rotor segments, spaced 90° apart, four

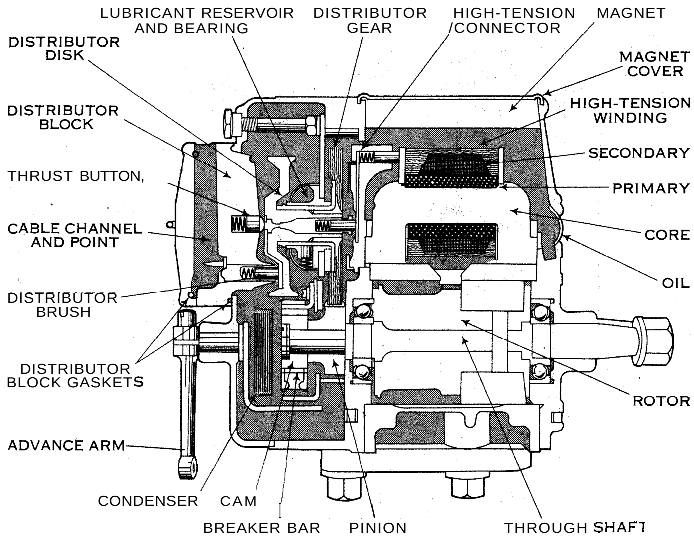


BY COURTESY OF J H. CROWNE

FIG. 3.—UNIT COIL FOR GASOLINE MOTOR IGNITION SYSTEM

sparks per revolution may be generated. In addition, the flux direction through the coil core is reversed each quarter revolution. The direction of current through the contact points of the interrupter is thus alternated, and the excessive point pitting, caused by a unidirectional arc is eliminated.

In order to vary the time of occurrence of the spark in the engine cylinder, the magneto cam, or the circuit breaker, is made



BY COURTESY OF J H CROWNE

FIG. 4.—CROSS SECTION OF INDUCTOR MAGNETO

rotatable through part of a revolution, and is connected, by means of a linkage, to a convenient advance-retard lever. This makes it possible to alter the relationship between the engine crankshaft and the magneto, and to ignite the charge either before or after the piston has reached its dead centre position. Since the spark intensity of a magneto varies directly with engine speed, there is available an increase of energy at high speed when the requirements for ignition are most severe. At low speeds of rotation such as accompany the cranking or starting of automotive engines, the magneto will sometimes fail to produce a voltage sufficient to spark across the gap. There have been in use various impulse devices, such as "impulse couplings," which serve to couple the magneto to the engine and to accelerate its rotation in starting.

The magneto is employed on aircraft engines, where the highest engine efficiency must be maintained; on tractor engines, motorcycles, marine engines and to a great extent on motorbuses and motor trucks. Stationary engines are also magneto equipped. Minor commercial uses are found in the igniting of blasting charges (detonafors), in igniters, for oil or gas burners; and, in conjunction with neon lamps, as stroboscopic indicating instruments.

MAGNETOCHEMISTRY. Iron is strongly attracted by a magnet; the iron is said to be ferromagnetic. There are few ferromagnetic materials, but all other substances experience either a weak attraction or a very weak repulsion by a magnet. Substances thus weakly attracted to a magnet are said to be paramagnetic, those repelled are diamagnetic. The measure of the attraction or repulsion is called the magnetic susceptibility. Magnetochemistry is the application of magnetic susceptibilities, and of closely related quantities, to the solution of chemical problems.

There are four major applications of magnetism to chemistry. These are (1) testing for traces of certain kinds of impurities in various substances; (2) the study of free radicals; (3) examination of inorganic solids with a view to finding their structures; and (4) the study of complex compounds. These four applications will be described more fully in the following paragraphs.

Magnetic susceptibility balances may be made very sensitive for the detection of paramagnetic impurities in diamagnetic substances, and especially so for ferromagnetic impurities. Three examples will be cited. The sand used for making glass must often be as free as possible from iron. Use of the magnetic balance will often detect a very small trace of such impurity and the measurements may be made in such a routine fashion as to be simpler and cheaper than any other method of detection. Similarly, traces of iron or of other ferromagnetic substances may be detected in metals such as magnesium. A third analytical application is in measuring the concentration of oxygen in mixtures of gases. The magnetic method is a convenient analytical tool for a variety of chemical and metallurgical operations.

The second use of magnetic measurements is in the study of free radicals. These substances, of which triphenylmethyl is an example, are of very considerable theoretical interest to chemists. Most chemical substances have an even number of electrons, and are diamagnetic, but free radicals have an odd number of electrons, and are paramagnetic. Magnetic susceptibility measurements may be used to establish the presence of free radicals, to estimate their amount and to follow the chemical changes which they undergo, all in a very satisfactory manner.

A field of much interest and promise is the application of magnetic methods to the study of inorganic solids, particularly those solids of interest in catalysis. The possibility of relationships between catalytic activity on the one hand and magnetic properties on the other has interested many workers. It cannot be denied that those chemical elements, such as chromium and nickel, which show the most pronounced catalytic activity are the elements which show the most interesting magnetic effects. This is not to say that all catalytic activity is caused by magnetism, but rather that catalysis and magnetism may, in some cases at least, have some common underlying basis.

In a few cases it is possible to predict whether or not a substance will sho catalytic activity, solely on the basis of magnetic measurements. Superactive catalysts, and catalysts showing undesirable side effects, may not infrequently be identified through use of the magnetic method.

The final application which mill be mentioned is to complicated compounds, of which hemoglobin will serve as an example. Hemoglobin is the red matter in blood. It serves in the blood as the carrier of oxygen. Hemoglobin is composed in part of a complex compound containing iron. This substance is paramagnetic. When hemoglobin takes up oxygen, as it does in passing through the lung tissues, it becomes diamagnetic. From this change it is possible to draw conclusions concerning the spatial arrangement of the various atoms which make up the molecule of hemoglobin. Conclusions may also be drawn as to the mode of linkage between the hemoglobin and the oxygen. Similar studies have been made on a very wide range of complex compounds containing iron, nickel, cobalt and many other elements. See MAGNETISM; CATALYSIS.

MAGNETOMETER, an instrument for measuring a magnetic force. Although the term is often applied to any instrument for measuring the external field caused by a magnet, it has become attached more specifically to instruments for measuring the earth's magnetism. Such instruments can be used for measuring the intensity of one or more components. the direction of the total field vector or one of its components. In practice, usually one of the intensity components is measured together with the direction of the total field vector, and the field or other components are then computed.

Magnetometers can be classified as (1) absolute magnetometers; (2) relative magnetometers; and (3) variometers. Absolute magnetometers measure the magnetic force without reference to any other standards except those of mass. length and time. Relative magnetometers require comparison with absolute instruments to determine certain fundamental constants that can be determined only with great difficulty, or occasionally not at all; or involve the use of standards of electric current, resistance or voltage. Variometers are used for measuring the variations in the force from time to time between two points in space. A set of variometers for recording time variations of the magnetic field is called a magnetograph.

The absolute magnetometers in use at the majority of magnetic observatories are those that measure the horizontal intensity of the earth's magnetic field by the classical method of C. F. Gauss. Gauss's method permits the measurement of the intensity through two experiments. The first observation is the determination of the period of oscillation of a magnet. The magnet is suspended on a fibre of negligible torsion in a closed housing free from air currents. The period of oscillation is measured, and is a function of the strength of the magnet, its magnetic moment and the strength of the horizontal component of the field. In the second experiment, this magnet is used to deflect a second magnet suspended in a similar manner. Gauss made these deflection observations by keeping the magnet in a fixed position at right angles to the magnetic meridian. Johann von Lamont later revised this procedure, and by means of a theodolite magnetometer could keep the two magnets at right angles during the experiment. In the first experiment, ihe relationship between the values of the horizontal field and the magnet are expressed as:

$$MH = \frac{4\pi^2 I}{T^2}$$

where H is the horizontal intensity of the earth's field; M is the moment of the magnet; I is the moment of inertia of the magnet and supporting holder; and T is the time of one oscillation.

The moment of inertia of the magnet and its support cannot be computed readily because the shape is irregular and dissimilar materials are used. It is therefore determined experimentally by attaching a cylindrical bar or ring whose moment of inertia can be computed from its dimensions and mass.

In the second experiment, folloning Lamont's method. the relationship between the field and the deflection angle is:

$$\frac{H}{M} - \frac{2}{r^3 \sin \delta}$$

where H and M are as above; r is the distance between the centres of the two magnets; and δ is the deflection angle. By combining these two equations, the final value is:

$$H^2 = \frac{87r^2 1}{T^2 r^3 \text{ sins}}$$

In practice. various corrections are applied to allow for the effects of torsion in the fibre. induction in the magnets, coefficients of distribution of magnetism in the magnets, temperature coefficients of the magnet and the deflection bar, etc. Errors are kept down to 0.00008 gauss.' where one gamma (y) is $\frac{1}{100.000}$ gauss.

Relative magnetometers are finding increased usefulness for magnetic survey work and as control instruments at magnetic observatories. The reliability of these instruments has been greatly enhanced by virtue of the new magnetic steels and by the use of modern techniques in measuring electrical quantities on some instruments that operate on electromagnetic principles.

One of the most nidely used relative magnetometers, known as the QHM (quartz horizontal magnetometer), was developed by D. La Cour of the Danish Meteorological institute. It consists of a magnet with an attached mirror suspended by a quartz fibre. It operates on the principle of balancing the torque exerted on the magnet by the earth's horizontal magnetic field against the torque exerted by the fibre when twisted through exactly 2π (360°) radians. The torsion coefficient of the fibre and the moment of the magnet are so related that for the value of horizontal intensity in most latitudes. $HM > 2\pi\phi$ (H is horizontal intensity; M, the moment of the magnet: ϕ, the coefficient of torsion). The suspended system is so arranged that when the magnet is in the magnetic meridian, the mirror is perpendicular to the axis of the telescope attached to the instrument. The image of the scale in the Gaussian eyepiece of the telescope may be viewed through the mirror. and the telescope set perpendicular. To make a measurement, the instrument is first set in the magnetic meridian by bringing the central mark on the scale into coincidence with its image as seen in the mirror. The magnet is left unclamped and the instrument is then rotated slowly through an angle $2\pi + \delta$ to coincidence of the two lines. The instrument is then rotated in the opposite direction through an angle $4\pi + \delta$ to coincidence. The horizontal intensity is then given by:

$$H = \frac{2\phi}{M \sin 6} = \frac{C}{\sin \delta}$$

C is a constant determined by comparison with standard instruments. Corrections must be applied for the temperature coefficients of the magnet and the quartz fibre.

The QHM is also widely used at fixed observatories for the determination of the magnetic declination by sighting at a mark whose azimuth is known.

A companion instrument of the QHM is the BMZ (magnetometric zero balance) for measuring the vertical intensity. It is similar to the local vertical intensity variometer in principle. The instrument is equipped with two auxiliary magnets, the upper one for establishing the mean value at which the instrument will operate, and a lower magnet used to reach a balanced condition. The indicating or balanced magnet is made from one piece of magnet steel and consists of the magnet, mirror and steel knife-edges. The knife-edges of the magnet rest on cylindrical quartz bearings. A small telescope with Gaussian eyepiece similar to that used in the QHM is used to determine the balanced or horizontal position of the magnet. The observation is made by freeing the balanced magnet and rotating, about a horizontal axis, the lower or turn magnet. The angle through which this lower magnet must be turned to reach a balance is a measure of the vertical intensity. The constants of the instrument must also be determined by comparison with standard instruments. Corrections are applied for the temperature coefficients of the two magnets.

Electromagnetic Magnetometers.—Electromagnetic instruments constitute a large class of relative magnetometers. They all depend upon the comparison of the magnetic field of the earth with the magnetic field produced by a coil through which a measured electric current is flowing. As the electrical standards are accurate to about 1 part in 100,000, they are inferior to the accuracy of standards of length and time. These electromagnetic types of instruments are gradually replacing the older magnetometers and are becoming increasingly important.

The sine galvanometer designed by S. J. Barnett consists of a Helmholtz coil (a system of circular coils giving a uniform field near the axis between them) with the windings in spirals upon a marble cylinder. The dimensions of the coil are accurately measured so that the field produced by this coil can be computed. A small magnet is suspended at the centre of the coil for determining the magnetic meridian as well as the resultant direction after the field from the coil is applied.

In making the measurement, a fixed current is applied and the sine galvanometer is rotated about its vertical axis until the resultant field (*i.e.*, between the coil and the horizontal component of the earth's field) is perpendicular to the axis of the coil. The sine of the angle (6) between the axis of the coil and the direction of the earth's field is a measure of the horizontal intensity and is given by:

$$H = \frac{Ci}{\sin 6}$$

in which i is the current and C is the coil constant which has been accurately calculated from the measurements of the dimensions of the coil.

The Schuster-Smith coil magnetometer, used extensively in England and Canada, is similar to the sine galvanometer except that the current applied to the coil is adjusted so that the field produced by the coil is slightly greater than the horizontal component of the earth's magnetic field. The coil is then turned on its vertical axis nearly 180° with the direction of the earth's magnetic field until the suspended magnet is at right angles to the magnetic meridian. Then $H = H_c \cos \propto$, where H is the value of the horizontal component of the earth's field, H_c is the field produced by the coil and $\propto$ is the angle between the magnetic meridian and the axis of the coil.

Other electromagnetic instruments have been designed for the measurement of the vertical intensity, such as the instrument designed by D. W. Dye, a counterpart of the Schuster-Smith magnetometer. The coil is a Helmholtz system on a precision-ground marble form, similar to the coils of the instruments mentioned above. The current in the coil is adjusted till the magnetic field at the centre just nulls the vertical intensity. Then: $Z = Ci$, where Z is the vertical intensity of the earth's magnetic field; C is the coil constant determined from measurements of the dimensions of the coil; and i is the current. A number of devices have been applied for determining the condition of neutralization of the component being measured. In the Dye coil magnetometer, a small flat coil free to swing about a horizontal axis is used. A comparatively strong alternating current, of frequency equal to that of the mechanical resonance vibration of the coil, is applied to the coil through the suspension wires. This coil acts as a small magnet except that the axis is being continually reversed by the alternating current. The coil will vibrate about the suspension under the action of the vertical magnetic field, except when the earth's vertical component has been exactly nulled by the field of the Helmholtz coil.

Another type of null indicator for the electromagnetic instruments is a small coil rotating about a suitable axis within the fixed coil. The output from this coil is usually amplified and the output from this amplifier fed into a suitable detector. This method is capable of high accuracy, since the coupling between the fixed coil and the rotating coil may be calculated accurately to correct for their finite dimensions.

Military requirements of World War II led to the development of a number of devices usable as null detectors which employed a new principle. These detectors depend upon the ability of very weak fields to produce magnetic saturation of certain alloys of iron, nickel and cobalt. If an alternating and symmetrical magnetic force is applied lengthwise to a rod of suitable dimensions and composition, the magnetic flux changes in the rod will be symmetrical. But if there is a small ambient magnetic field parallel to the rod, the flux changes will exhibit pronounced asymmetry. The sensitivity of this effect is sufficiently great that it may be used for the detection of extremely small fields.

Several different methods have been devised for applying this principle to the measurement of magnetic fields. In one of these methods, an alternating magnetomotive force is applied to the permeable material through a coil. Asymmetrical flux changes in the material are revealed by the appearance of voltages in the exciting coil at twice the frequency of the exciting current, voltages which may be filtered out and measured. Another device employs two such units with the axes parallel, side by side or in line, the exciting coils being connected in series opposition. A connection is made between the bridge connecting the two coils and the transformer winding which energizes the coils. When there is no ambient magnetic field, there is no voltage across this bridge, but if there is an ambient field, the flux changes in one element lead those in the other in phase so that sharp voltage peaks occur on each half cycle. In another type of detector, the two elements have a secondary coil wound about them which, when the proper adjustments are made, picks up only the asymmetrical flux changes which appear as voltages across the secondary. Electronic circuits are used with all these types of instruments to amplify and detect the output voltages, although the last type of instrument has been used successfully with a conventional galvanometer as the detecting member.

Although the greatest sensitivity may be realized when these devices are used as null detectors, they may be used as direct reading instruments to measure the intensity of any component of the field. In most cases, however, the major part of the components of the field to be measured is neutralized by electric currents or balanced out by application of biasing voltages applied to the detecting circuit.

These detectors possess several advantageous characteristics: they comprise no moving parts which are subject to errors resulting from accelerations; they may be mounted in one place and the readings taken in another; they are fast in operation and response; and their outputs may be readily applied to operate various control devices. Electronic control circuits employed to excite the elements and to amplify and detect their outputs are rugged. By suitable amplification' small changes in the ambient magnetic field may be made to produce large deflections of rugged recording meters. These characteristics make the induction-type detectors particularly suitable for use on aircraft.

Originally intended for the detection of submarines during World War II, these devices later found extensive application in geophysical prospecting. The great mobility of aircraft and their ability to fly over areas which are accessible for ground surveys only with great difficulty encouraged the use of these induction-type instruments for geophysical surveys. To escape magnetic effects of the plane, the measuring and orienting mechanism is sometimes mounted in a "bird" which is trailed well beneath the plane, the control circuits and indicating meters being mounted within the plane and connected to the bird by electric cables.

In most geophysical surveys conducted on the ground, the vertical component of the intensity is measured since that component uniquely defines the magnetic potential over the area being investigated, subject to certain limitations. Measurements of total intensity do not uniquely define a magnetic potential. However, if the variations in total intensity caused by the magnetic anomaly being surveyed are small relative to the total intensity of the earth's uniform field. a satisfactory solution can be derived.

Nuclear Resonance Magnetometer. — After the end of World War II there was considerable work accomplished on the various nuclear resonance phenomena that are associated with a magnetic field. One of the first instruments developed using these new methods was a nuclear resonance magnetometer, frequently termed a proton precessional magnetometer. The instrument consists essentially of a means of initiating precession of protons having gyromagnetic properties in a magnetic field. Nuclei may have spin or angular momentum. and will act like small gyroscopes. In a constant magnetic field the nucleus. having a magnetic moment, may be expected to behave like a compass needle. But because of the spin. the behaviour of the nucleus is slightly more complex. The system has angular momentum and a torque caused by the interaction between the nuclear magnetic moment and the external field Since the value of the angular momentum of the nucleus is fixed, the only possible change caused by the torque is a change in orientation. This orientation of the angular momentum vector changes steadily. but always maintains a constant angle with the magnetic field, so that the momentum vector moves on the surface of a cone with axis parallel to the magnetic field. This motion is commonly called precession, and is exactly similar to that of a gyroscope acted on by gravity, the axis making a constant angle with the vertical as it precesses. Just as friction or other damping causes the gyroscope to assume a position of lowest potential energy in the gravitational field, so the damping forces acting on the nucleus eventually suppress the precession and allow the nuclear magnetic moments to line up nith the magnetic field. The time required for these damping forces to act has been called the relaxation time and may be of the order of microseconds or minutes depending on the material used for the sample.

In the nuclear precession magnetometer. the nucleus is polarized in a direction at an angle to the earth's magnetic field. When this polarizing current is suddenly cut off, the protons precess back to the normal (ambient) magnetic field. The frequency of precession is directly related to the strength of the magnetic field being measured. The instrument consists essentially of a sample containing protons and a coil of wire wound around this sample. The sample may be nater or a hydrocarbon such as kerosene. When a strong direct current is applied to the coil, the protons are magnetized or oriented in this new direction. The current is then cut off rapidly, and the protons start precessing back to their normal direction The coil previously used for polarizing the sample is now connected to an amplifier and suitable electronic counter, and the frequency of precession is measured. This frequency is directly related to the strength of the magnetic field.

$$H = Cf$$

where H is the value of the magnetic field; f is the frequency of precession; and C is a constant.

In 1950 A. Kastler, in Paris, suggested the technique of optical pumping for orienting nuclei and for detecting nuclear magnetic resonance signals in gases at low pressures. This technique has been developed and expanded and is the basis of a type of magnetometer capable of measuring extremely low fields of the order of a few gammas.

The magnetometer consists in its simplest form of a light source, a filter to pass only one of the strong optical lines in the spectrum of the alkali metal being used, a device to circularly polarize the light, an absorption cell and a photocell to monitor the light transmitted through the cell. The light beam is oriented roughly parallel to the magnetic field. Under proper conditions, the atoms will tend to line up with their magnetic moments along the direction of the magnetic field. In this condition, the atoms will absorb less light than normally, and the amount of transmitted light will be greater than if the atoms were randomly oriented. If a radio-frequency field is now applied at right angles to the magnetic field, and at a frequency corresponding to the Zeeman transitions, the atoms will become disoriented, and the amount of light transmitted will decrease. If the applied radio frequency is swept through the resonance value, the resonant frequency will be observed as a dip in the output of the photocell. The above instrument has been used successfully to measure the earth's magnetic field and the results have been of the same order of accuracy as the proton precessional magnetometer or the electromagnetic types of instruments.

MAGNIFICAT, the *Canticum beatae Mariae Virginis,* the song of praise of Mary in the house of Zacharias, with which she answered the greeting of Elizabeth: "Magnificat anima meum Dominum."

It constitutes the most important canticle of the vesper service in the Roman Catholic Church and of the evening office in the Anglican Church. Besides having been set to plain song melodies in all the eight church modes, it has received countless settings by later composers.

MAGNITUDE of a star is the measure of its brightness adopted in astronomy. The higher the number expressing the magnitude the fainter the star. A step of one magnitude corresponds to a decrease in light intensity in the ratio 2.512:1, so that five magnitudes correspond to a decrease in the ratio 100:1. The absolute magnitude of a star is the apparent magnitude it would have if placed at a standard distance of ten parsecs or about 33 light-years.

The bolometric magnitude is an analogous measure of the heat intensity of a star.

See PHOTOMETRY. CELESTIAL; STAR.

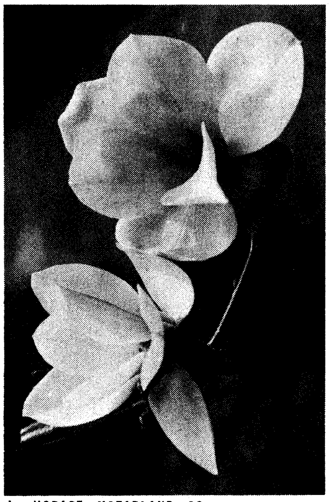
MAGNOLIA, the type genus and one of nine genera of the botanical family Magnoliaceae, named for Pierre Magnol (1638–1715), professor of botany at Montpellier, France. It includes about 75–80 species. in two centres. about 50 in the old world (Japan to the eastern Himalayas, south to Java) and about 25 in the new world (southern Ontario, the eastern United States, the Greater Antilles and Mexico to Venezuela).

Magnolias are trees or shrubs with persistent or deciduous simple leaves with stipules. Most magnolias bear showy, fragrant, white to pink or purple or green to yellow flowers singly at the tips of the branches. The perianth is composed of 9–15 petallike tepals in series of 3 each; the 3 outermost are differentiated as sepals in some species. The numerous stamens and carpels are borne spirally on the elongated floral axis. The conelike fruit is composed of the many carpels. each of which splits along the outer side releasing two scarlet to pink seeds which dangle by slender threads. Essential-oil cells give most tissues of the plant a spicy fragrance when crushed.

Eight species, cultivated as ornamentals in both the United

States and England, are native to eastern North America. Five are closely related trees or shrubs with rather large deciduous leaves clustered near the tips of the branches (whence the name umbrella tree) and large white flowers: *Magnolia fraseri,* of the southern Appalachians; M. *pyramidata,* with a Gulf coast distribution; M. *tripetala,* the original umbrella tree; the spectacular *M. macrophylla,* with leaves up to three feet long (the largest in the genus); and *M. ashei,* restricted to western Florida. Closely related to these are three Asian species, all in cultivation: *M. obovata* (Japan), *M. officinalis* (eastern China) and *M. rostrata* (northwestern Yünnan and adjacent areas). The best-known American magnolia is *M. grandijlora* (bull bay), a handsome evergreen tree bearing large white flowers, native to the southeastern coastal plain but cultivated in other warm temperate areas. Excepting the tenderer *M. delavayi* (from Yünnan), *M. grandijlora* is the only hardy evergreen species. *M. virginiana* (sweet bay), with small, white, very fragrant flowers and leaves whitened beneath, has a wide range along the coastal plain (Massachusetts to southernmost Florida and Texas), and was the first magnolia to be grown in England (1688). M. *acuminata* (called cucumber tree, from the appearance of the young fruits) is a large deciduous tree which occurs from Ontario and New York to Florida, Missouri and Arkansas. Its green to yellow flowers are in striking contrast with those of its only close relative, the purple-flowered *M. liliflora* of China.

More than half of the Asian magnolias are evergreen trees and shrubs of the tropics, and only about 20 are suitable for cultivation in temperate areas. Among the hardy and showy ornamental species are the Chinese *M. denudata* and *M. liliflora* and the Japanese M. *stellata,* M. *kobus* and *M. salicifolia.* Unfortunately, *M. sprengeri, M. sargentiana* and *M. campbellii,* among the most beautiful trees in the genus, are far less hardy. In all of these species, flowering occurs before the leaves appear, in contrast with the American species which flower with or after the unfolding of the leaves.



J. HORACE MCFARLAND CO.

LARGE WAXY BLOSSOMS OF A HYBRID MAGNOLIA (MAGNOLIA SOULANGIANA)

No wild hybrids of *Magnolia* have been found, although a number of garden hybrids are known. Probably' the most widely cultivated of any of the Asian group is *M. soulangiana,* a hardy and vigorous hybrid (originated near Paris, 1820) of the white-flowered *M. denudata* and the purple M. *liliflora.*

Magnolias prefer well-drained but moist, rather loamy, slightly acid (pH 6) soil. Propagation is by layers, cuttings, grafts or seeds. The seeds have a short period of viability, especially if allowed to dry out, and usually a period of moist cold is necessary to promote germination. Attempts to send seeds from Asia to England were mostly unsuccessful until the practice of coating the seeds with paraffin was tried; the storage and transport of seeds in bags of polyethylene film is a more modern development.

Much attention has been focused on *Magnolia* as one of the most primitive of living flowering plants, particularly on account of the woody habit, the numerous, free and spirally arranged floral parts, the primitive stamens and the single-grooved pollen grains. Although the group is undoubtedly ancient (more than 80 fossil "species" have been described) and formerly had a much wider distribution in the northern hemisphere, a number of other extant flowering plants show evolutionarily much more primitive structures. Some of the species of the genus *Drimys* (of the family Winteraceae) appear to combine more numerous primitive features than any other known group of flowering plants.

(C. E. W.)

MAGNUS, OLAUS (Swedish OLAF MANSSON) (1490–1557), Swedish ecclesiastic and author of an influential history of Scandinavia, was born at Linkoping in Oct. 1490. A Catholic priest, he went to Rome in 1523, during the Swedish reformation, and thereafter lived in exile, first in Danzig and later in Italy, with his brother Archbishop Johannes Magnus (1488–1544), on whose death he was appointed Catholic archbishop of Sweden. After 1549 he was also director of St. Brigitta's, a religious house in Rome.

Magnus died in Rome, Aug. 1, 1557.

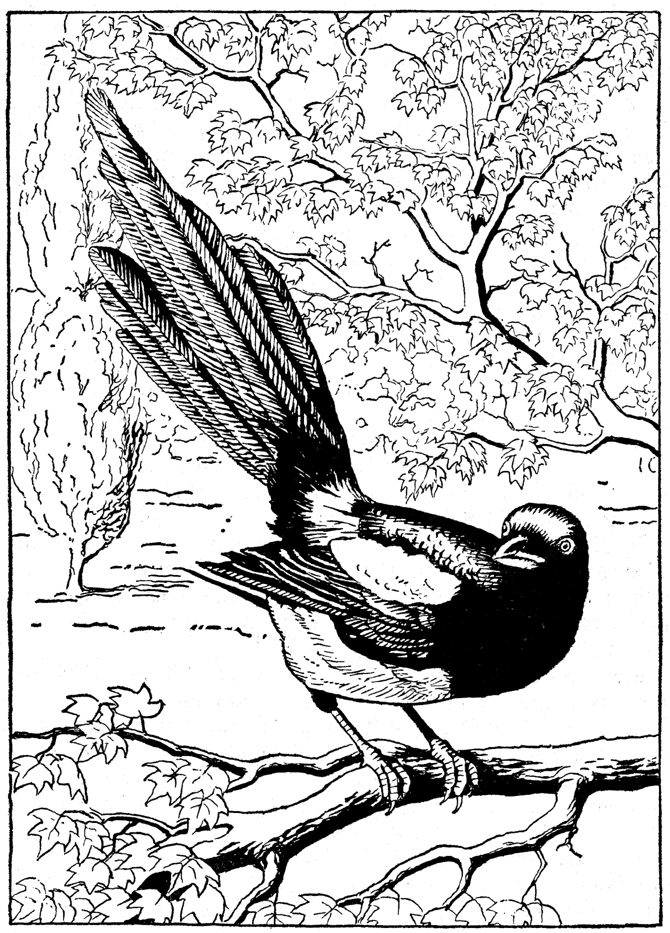
Olaus Magnus' *Carta marina* (1539) was the first detailed map of Scandinavia with any pretensions to accuracy. His foremost work, however, is the *Historia de gentibus septentrionalibus* (1555), a history of the northern peoples inspired by humanist historiography and imbued with patriotic warmth, which gives a picture of the countryside and people of Sweden on the threshold of a new era. It appeared in many editions and translations during the 17th century—the first English translation being the *History of the Goths, Swedes and Vandals* (1658)—and for long influenced the European idea of the Scandinavian people. (S. H. L.)

MAGNUSSON, ARNI (1663–1730), Icelandic historian and antiquarian. was born in Vestland, Ice., on Nov. 13, 1663, and died at Copenhagen, Den., on Jan. 6, 1730. He studied theology at Copenhagen, and in 1696, on his return from a visit to Germany, was appointed to the post of secretary of the secret archives. In 1701 he was elected professor of Danish antiquities and the next year was sent on a royal mission to Iceland, where he stayed ten years. collecting documents relative to the history of that country which he bequeathed to the university of Copenhagen. Magnusson's most important works are: *Incerti auctoris Chronica Danorunz, et praecipue Islandiae* (Leipzig. 1695); and *Testamentum Magni regis Norvegiae* (Copenhagen, 1719). *See* also his letters, *Arne Magnusson's Private Brevveksling* (Copenhagen, 1920).

MAGO, the name of several Carthaginians. (1) The reputed founder of the military power of Carthage, fl. 550–500 B.C. (Justin xviii. 7; xix. 1). (2) The youngest of the three sons of Hamilcar Barca. He accompanied Hannibal into Italy, and held important commands in the great victories of the first three years. After the battle of Cannae (216 B.C.) he sailed to Carthage to report the successes gained. He was about to return to Italy with strong reinforcements for Hannibal when the government ordered him to go to the aid of his other brother. Hasdrubal, who was hard pressed in Spain. He carried on the war there with varying success in concert with the two Hasdrubals until, in 209, his brother marched into Italy to help Hannibal. Mago remained in Spain with Hasdrubal, the son of Gisco. In 207 he was defeated by M. Iunius Silanus, and in 206 the combined forces of Mago and Hasdrubal were scattered by Scipio Africanus in the decisive battle of Silpia. Mago maintained himself for some time in Gades, but afterward received orders to carry the war into Liguria. He wintered in the Balearic Isles, where the harbour Portus Magonis (Port Mahon) still bears his name. Early in 204 he landed in Liguria, where he maintained a desultory warfare till in 203 he was defeated in Cisalpine Gaul by the Roman forces. Shortly afterward he was ordered to return to Carthage, but on the voyage home he died of wounds received in battle. (3) The name of Mago is also attached to a great work on agriculture brought to Rome and translated by order of the senate after the destruction of Carthage. The book was regarded as a standard authority, and is often referred to by later writers.

MAGOON, CHARLES EDWARD (1861–1920), U.S. lawyer and government official, was born in Steele county, Minn., on Dec. 5, 1861. He had one year of college education at the University of Nebraska, Lincoln, and then studied law in Lincoln, where he subsequently practised from 1882 to 1899. From 1899 to 1904 he was legal adviser to the bureau of insular affairs of the war department, during which time he compiled the valuable and detailed *Report on the Legal Status of the Territovy . . . Acquired by the United States during the War with Spain* (1900). Two years later his interpretations of U.S. law, as it affected possessions acquired after the Spanish-American War, uere gathered and published as *The* Law *of Civil Government in Territory Subject to Military Occupation* (1902). This work became of value to administrative personnel in the Philippine Islands. From 1905 to 1906 Magoon was governor of the Panama Canal Zone as well as U.S. envoy to the Republic of Panamá. He served as provisional governor of Cuba from 1906 to 1909 at a critical period in the history of the island. Among other changes which took place during his administration. the scourge of yellow fever was almost entirely eliminated. He died in Washington on Jan 14, 1920.

MAGPIE or **Pie,** a bird once abundant throughout Great Britain. but later much scarcer, though after World War I its numbers increased. It did not reach Ireland until the 15th century, but is no common enough in that country. This species is extending its range where not molested.



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY

THE MAGPIE (PICA PICA OR PICA RUSTICA)

In Norway, the magpie is very tame, nesting in the gardens even of town houses. but in Britain persecution has made it shy, and most people know it only as a captive in a wicker cage. where its vivacity and natural beauty are lessened or lost. At large, few European birds possess greater beauty, the pure white of its scapulars and inner web of the flight feathers contrasting vividly with the deep glossy black on the rest of its body and wings, while its long tail is lustrous nith green, bronze and purple reflections. The pie's nest is a wonderful structure, placed either in trees or bushes and massively built. Its foundation consists of stout sticks, turf and clay, wrought into a deep, hollow cup, plastered with earth and lined with fibres; around this is erected a basketlike outwork of thorny sticks, forming a dome over the nest, and leaving a hole in the side for entrance and exit. Herein are laid from six to nine eggs, of a pale bluish green freckled with brown and blotched with ash colour. The magpie, in common with the raven, the jay and many birds of prey, has a remarkable capacity, when its mate is killed, for obtaining a new mate within a day or two. In the case of the pie and the jay, a large gathering of birds of the species is said to appear on the scene, and apparently the new mate is selected from these.

The pie belongs to the crow family and is scientifically termed *Pica pica.* The typical subspecies inhabits Europe, northwest Africa and Asia, and is replaced in western North America by the subspecies *Pica pica hudsonia.* In California *P. nuttalli* is distinguishable by its yellow bill and the bare yellow skin round its eyes.

MAGSAYSAY, RAMON (1907–1955), Philippine soldier and political leader. who as secretary of defense and president reduced the communist-led Hukbalahap (Huk) movement after World War II. Born on Aug. 31, 1907, at Iba in Zambales province on Luzon, the son of a schoolteacher, blacksmith and farmer, he worked his way through the University of the Philippines at Manila (1927–31) and José Rizal college, from which he received a degree in 1933. Rising from his first job as an automotive mechanic, he became by 1941 branch manager (later general manager) of a transportation company whose buses were commandeered by U.S. forces after Japan invaded the Philippines.

He fought with U.S. forces until before the surrender of Bataan, when he joined the western Luzon guerrilla forces, becoming commanding officer of the Zambales military district in 1945. He fought with U.S. forces until the liberation and afterward was appointed military governor of Zambales province. Discharged from military service in 1946, he was elected to two terms in congress for Zambales (1946–50). In 1950 Pres. Elpidio Quirino appointed him secretary of defense. The Huks, then at the height of their power. derived much support from the peasants. who felt the local constabularies oppressed them as representatives of the landlords. Magsaysay replaced the constabulary with army units, reformed the army and fought the Huks, offering them '.complete force or complete fellowship!'; to those who surrendered he gave land and tools. In 1953 he resigned as secretary of defense and from the Liberal party and joined the Nationalist party, charging President Quirino with obstruction of his anti-Huk campaign and a corrupt administration.

The Nationalist party nominated Magsaysay to oppose Quirino for the presidency; Magsaysay won the election and was inaugurated Dec. 30. for a four-year term. He also served as secretary of defense until May 1954, when the surrender of the Huk leader Luis Taruc climaxed the anti-Huk campaign. Despite Magsaysay's great personal popularity, congressional and intraparty opposition slowed the progress of his program of land and governmental reform. His opponents considered his friendship with the United States extreme. but he held firm in foreign policy. In July 1955 congress gave the president power to break up large landed estates and carry out basic land reform; in August a Nationalist party convention completely endorsed the president's program and nominated a slate of candidates to remove the president's strongest opponents in congress. This slate won in November, but congressional opposition to his reform measures continued.

Magsaysay died in an airplane crash on March 17, 1957 while returning from Cebu City to Manila. and was succeeded by Carlos P. Garcia, vice-president and foreign minister.

See Carlos P. Romulo and Marvin M. Gray, *The Magsaysay Story* (New York, 1956).

MAGWE, a district and division of Burma. In 1941 the division included the district of Thayetmyo, Minbu, Magwe, Pakôkku and Pakôkku hill tract and the Chin hills district. The district has an area of 3,724 sq.mi.; pop. (1941) 559,926. Magwe may be divided into two portions: the low, flat country in the west. forming part of the surrounding valley, and the undulating high forested ground in the east forming part of the Pegu

Yomas, which at some parts reaches a height of 1,500 ft. In the heart of the district there is a low fertile plain which is about 45 mi. from north to south and as much as 30 mi. wide in places. The railway from Pyinmana runs through this plain and beyond. The chief streams are the Yin and the Pin, which form the northern boundary. The only perennial stream is the Yanpe. The annual rainfall averages about 27 in. The maximum temperature rises to a little over 100° F. in the hot season, and falls to an average minimum of 53° F. and 54° F. in the cold season. Rice is the staple product, and considerable quantities are exported. Sesame, maize and millet are also cultivated, as well as cotton, while an important crop in the sandy soil is peanuts.

In this district are included the well-known Yenangyaung and Chauk oil fields. A block of 80 sq.mi. was demarcated by the government as the area of the Yenangyaung oil fields but only about 2 or 3 sq.mi. were occupied by the actual field and the bulk of the production was from an area of only $1\frac{1}{4}$ sq.mi. The state lands were leased to the Burmah Oil company but two large blocks in the richest part (the Beme and Twingôn reserves) were reserved for the hereditary Burmese owners called *twinsa*. Although there were still some primitive hand-dug wells in modern times. nearly all the native owners sold their rights to companies operating with modern plant. Hence it was in these reserves that competition between the competing companies proved extraordinarily keen, though methods of working were closely supervised by government agents.

A great advance has been made by electrifying the field. The oil was sent by pipe line to the refineries at Syriam near Rangoon.

MAGYARS, the name of the people called in English Hungarians. Though they have become physically assimilated to the western peoples. linguistically they belong to the Finno-Ugrian (*q.v.*) group within the Ural-Altaic (*q.v.*) family of languages. Before World War I they formed barely half the population of Hungary, but were by far the largest and most compact of all its racial groups. Magyar was the official language of Hungary, the official name of which (*Magyarország*, or "country of the Magyars") enshrined the Magyar claim to predominance. The Magyars themselves sometimes applied the name *Magyarország* to Hungary "proper," excluding Croatia-Slavonia, the whole kingdom being called *Magyarbirodalom*, the Magyar monarchy or realm.

Hungary. as constituted now, does not include the whole of the *Magyarország*. (W. A. P.)

MAHAN, ALFRED THAYER (1840–1914), U.S. naval officer and historian, an early exponent of sea power, was born on Sept. 27, 1840, at West Point, N.Y., where his father was professor of military engineering at the U.S. Military academy. Columbia college and the U.S. Naval academy at Annapolis, Md., qualified him for the U.S. navy, in which he served 40 years. He saw active service in the Civil War and when 21 designed a "mystery ship" and volunteered to command it. After acting as lecturer on naval history and strategy at the naval war college, he became its president in 1886. An indefatigable student with a prodigious memory, he steeped himself in the strategy of Antoine Henri Jomini, Napoleon and Nelson and made critical analyses of the conclusive battles of the world on land and sea. *The Influence of Sea Power Upon History, 1660–1783*, published in 1890, was inspired by a conviction that the historic significance of the control of the sea had never been fully revealed. It was followed in 1892 by *The Influence of Sea Power Upon the French Revolution and Empire, 1793–1812*. These classic works were widely acclaimed by naval men, statesmen and scholars and have been credited with stimulating the growth of navies between 1900 and 1914. No previous writer had so convincingly argued the case for the dominating influence of sea power. The famous trilogy was completed by *The Life of Nelson* in 1897.

Mahan was recognized as an authority on naval strategy, especially in Great Britain, and his doctrines have been said to have governed the naval political thought of the world. Degrees were conferred upon him by Oxford and Cambridge universities in 1894 and later by leading U.S. universities. He commanded the cruiser "Chicago" in European waters. 1893–95, and served on the naval war board during the Spanish-American War of 1898 and as delegate to The Hague peace conference in 1899. In 1900 he was awarded the Chesney gold medal for his three works. which were translated into several foreign languages. He was president of the American Historical association in 1902 and chairman of a commission on naval affairs in 1908.

Mahan, who excelled as a strategist rather than as a tactician, attempted chiefly to make clear the paramount importance of the sea as a decisive factor in history. He analyzed the elements of sea power in all its bearings, military. national, territorial and commercial. With masterly touch he dissected the strategic features of the Caribbean. He stressed the interdependence of the military and commercial control of the sea and held that commerce dominates war. In *The Interest of America in Sea Power, Present and Fziture* (1897) and in most of his 20 volumes he sought to arouse his countrymen to a realization of their maritime responsibilities. He doubted the infallibility of arbitration in international disputes and in Anglo-U.S. naval supremacy saw the surest hope of peace.

Mahan died on Dec. 1, 1914, having foretold the defeat of the Central Powers and the surrender of the German navy. Discussion of sea power compels recourse to his works, which are invaluable to students of international affairs. *(See* SEA POWER.)

For a complete list of works and bibliography *see* Charles Carlisle Taylor, *The Life of Admiral Mahan* (1920). (C. C. TAY.; X.)

MAHANADI ("The Great River"), a river of India rising 25 mi. S. of Raipur, in Madhya Pradesh. Taking a northerly direction, it receives the Seonath above Seorinarayan. Turning east. it is augmented by drainage of the hills of Uprora, Korba and the ranges separating Sambalpur from Chota Nagpur. At Padampur it turns south past Sambalpur to Sonpur and flows toward the Orissa hills, piercing them by a gorge. It reaches the Orissa delta at Naraj and, traversing Cuttack district, falls into the Bay of Bengal. The Mahanadi drainage area is about 74,516 sq.mi., and in flood its maximum discharge exceeds 1,500,000 cu.ft. per second. In dry weather the discharge dwindles to 500 cu.ft. per second. An early (1863) project to store and use the flood waters was a financial failure. It did, however, save the lowland from threats of famine and was thus the first truly protective canal project in India. A weir at Rudri on the upper Mahanadi, supplemented by a reservoir in a tributary valley, irrigates 300,000 ac. around Raipur on the Chhattisgarh plain. (T. HER.; X.)

MAHAR, the name of a servile caste in the Deccan, India. Their special function, apart from that of scavenger, is to act as village watchman, as guardian of the village boundaries and as public messenger. In some parts they are also weavers of coarse cotton cloth.

MAHARASHTRA, a state of the Republic of India, with Bombay as its capital city. It has, according to 'the redefined boundaries laid down in the Bombay Reorganization act, 1960, an area of 118,884 sq.mi. and a population (1961) of 39,504,294. When India became independent in 1947, the province long known as Bombay Presidency became Bombay state. The following year a number of former princely states (notably Baroda) were merged into the new state, and on Nov. 1, 1956, the major reorganization of the states of peninsular India resulted in the addition of large parts of the former Hyderabad and Madhya Pradesh. From 1956 to 1960, with an area of 190,668 sq.mi. and a population of 48,265,622 (1951), Bombay was the largest state in area in the republic and second in population. In the north it comprised most of the Gujarati-speaking peoples and in the south most of the Marathi-speaking. It was on this linguistic basis that the state was split into two on May 1, 1960, with Gujarat in the north and a state that was at first named Maharashtra in the south. The latter resumed the name Bombay a few weeks later, but before the end of the year, despite opposition, the central government declared Maharashtra the official name. As now defined, with minor boundary adjustments, this comprises 26 districts, which are, in effect, all those parts of India where Marathi is the dominant language. It stretches along the west coast between the former Portuguese territories of Damão and Goa. comprising an area known as the Konkan (*q.v.*), and far inland beyond Berar and the city of Nagpur to include the districts of Bhandara and Chanda. It is bordered by Gujarat and Madhya Pradesh in the north and east and by Andhra Pradesh and Mysore on the south.

Physical **Geography.**—Maharashtra comprises the coastal strip backed by the high crest of the Western Ghats beyond which is a rolling plateau with flat-topped hills indicating the presence of the successive lava flows, almost horizontal, of the Deccan basalts, formerly known as traps. The lavas cover practically the whole surface; the underlying complex of metamorphic rocks is rarely seen. Spurs from the Western Ghats reach the coast, which renders north-south communication difficult; neither motor road nor railway has been constructed through the west coast districts south of Bombay city. The coast is rock-bound and dangerous when the southwest monsoon is blowing onshore There are havens for small vessels, but there is only one major inlet, that protected by the island on which Bombay city has been built and which is one of the most magnificent and spacious harbours of Asia.

The climate shons the typical monsoon regime of cool dry season with light northeasterly minds from the land (about November to February), the hot dry season of March, April and May followed by the rainy season when the southnest monsoon blows directly against the west coast and Western Ghats. Apart from preliminary showers (mango showers) in May and early June, the rains break suddenly about mid-June. The Konkan is very wet; no part receives less than 80 in., while Mahabaleshwar, in the Western Ghats, with an annual average of more than 250 in., has one of the highest recorded rainfalls in the world. The winds lose their moisture in rising to cross the Ghats, and eastward on the plateau the average rainfall declines rapidly so that over most of the plateau districts it is less than 40 in. a year. The coastal districts enjoy equable temperatures, monthly averages ranging, as at Bombay city, only a few degrees above or below 80° F. A range of more than 20° between day and night temperatures is unusual. Stations like Poona, high up on the plateau but sufficiently near its edge to get a good rainfall, benefit from the elevation to be cooler throughout the year but remain equable. Mahabaleshwar, at 4,534 ft., has long been used as a hill station. Eastward on the plateau, with the lower rainfall, both daily and annual ranges of temperature increase.

The wet coastal districts have swift mountain torrents, sometimes with spectacular waterfalls when in spate but greatly hindering land communication and useful mainly for floating down timber. Except in the extreme north, where it is trenched by the westward-flowing Tapti, most of the plateau is drained by seasonal, eastward-flowing tributaries of the Godavari and Krishna in broad open valleys. Many rise very close to the edge of the plateau, the crest of the Western Ghats, which varies from 2,500 to 4,500 ft. in height. with some points exceeding 5,000.

The basaltic lava flows of the plateau break down into the famous regur or black cotton soil of India. It is a heavy, dark, almost black, clayey loam, which holds moisture well and is especially suited to Indian varieties of cotton and to dry zone grains. Some irrigation is practised in the broad open valleys, but care has to be taken in the use of irrigation water as the soil easily becomes a pasty mud.

The natural vegetation of the state reflects in the main the amount of rainfall. There are evergreen rain forests of large trees on the wet western slopes of the Ghats, giving place to a somewhat narrow but valuable belt of the monsoon forests, leafless in the dry season but including teak and the useful sal tree (*Shorea* robusta), and then eastward to the scrub forests and savanna lands so typical of much of the plateau. (L. D. S.)

History. — The present state comprises more than the ancient Maharashtra, which did not include the Konkan coastal strip and did not stretch so far south as Pandharpur, the celebrated Vaishnava shrine, nor as far east into the Deccan. For the history of early dynasties who ruled over this area between the 6th and 10th centuries A.D., see CHALGKYA; RASHTRAKUTA. By the beginning of the 13th century Maharashtrians or Mahrattas, speaking the forerunner of Marathi, were infiltrating into regions occupied previously by Telugu- and, more notably, Kanarese-speaking peoples. With the exception of the Konkan, which tended to be rich and easygoing, all Maharashtra, including the Ghats, was hard and severe, and the earliest ruling families of which there is any record were occupied largely in invading and attempting to exploit wetter, easier regions, such as Gujarat, Vengi and the Tamil country. Patronage of religion, letters and architecture was virtually unknown until in the 13th century, under the Yadavas, success outside Maharashtra brought an accumulation of resources. Poona was, and remains, in the cultural heart of the country. Under the Yadavas, too, Maharashtrian schools of Vaishnavism became prominent.

After the defeat of the last Yadava by the troops of the sultan of Delhi in 1310, a period of unrest followed, during which Maharashtra was partitioned between the sultanates of Ahmednagar and Bijapur, two of the successor states of the Bahmani (*q.v.*) empire. When the sultanates were absorbed by the Moguls, some Maratha officials attempted to carve out separate fiefs and to challenge Muslim authority. For the rise of Hindu autonomy in this area and for the history of the period of Maratha ascendancy and of the Maratha Wars, see MAHRATTAS.

The essence of Maharashtra has been its possession of a common language, and an active, restless people. Participation in Hindu Sanskritic culture came rather late but was embraced the more fervently for that reason. The feelings of independence, and even superiority to the inhabitants of the easier, wealthier regions in the north, west, east and southeast, can be explained on historical grounds. The neighbours to the south were equally poor but not equally successful. Maharashtrians show no great aptitude for commerce and have no great artistic traditions, but the blending of cultures, particularly in Bombay and similar centres, has ushered in a more fruitful era. (See also INDIA: History.)

(J. D. M. D.)

Population, Administration and Social Conditions. — At the 1961 census the population was 39,504,294. There are many Adibasi communities in the state, like the Agaris, the Warlis, the Katkaris, the Thakurs of the Thana and Kolaba districts, the Bhils of West Khandesh and the Gonds of Vidarbha. who live in dense forests or on the mountain perches of the Western Ghats.

The state is divided into the following 26 districts, which are grouped in 4 divisions: Khandesh (East and West), Nasik, Thana, greater Bombay, Kolaba. Ratnagiri (Bombay division); Ahmednagar, Poona, Satara (North and South). Kolhapur, Sholapur (Poona division); Aurangabad, Parbhani, Bhir, Osmanabad, Nanded (Aurangabad division); Buldana, Akola, Amravati, Yeotmal, Wardha. Nagpur, Chanda, Bhandara (Nagpur division).

There are more than 380 towns and nearly 36,000 villages in the state. The more important cities and towns with their populations at the 1951 census, are as follows: Bombay (2,839,270; [1961] 4,146,491); Poona (480.982; [1961] 721,134); Nagpur (449,099; [1961] 643,186); Sholapur (226.050; [1961] 337,544); Kolhapur (136,835; [1961] 187,306); Nasik (97,042; [1961] 130,834); Akda (89,606); Amravati (87,099); Ahmednagar (80,873; [1961] 118,266); Ulhasnagar Camp (80,861); Jalgaon (68,412); Poona cantonment (59.011); Kalyan (58,900); Bhusawal (54,346); Sangli (50,287); Thana (50,155; [1961] 101,103). (S. CH.)

With about one-eighth of the population attending educational establishments and about 30% of the people literate, Maharashtra is one of the educationally advanced states of India. In 1958–59 there mere 45,000 schools and higher educational institutions, including five universities — Bombay, Nagpur, Poona. Marathwada and Shreemati Nathibai Damodar Thackersey Women's university. Free compulsory primary education for children between the ages of 7 and 11 is available in all villages with a population of more than 1,000 in western Maharashtra. The Marathi (*q.v.*) language and its various dialects are widely spoken.

Nearly 900 hospitals and dispensaries generally provide free medical aid. Under the contributory social insurance plan many industrial workers in greater Bombay and the Vidarbha region are protected against sickness, maternity and employment injury.

Maharashtra is one of the pioneer states in providing welfare facilities for children. including the care and rehabilitation of juvenile delinquents and destitute and neglected children. Welfare centres offer recreational, cultural and educational facilities to industrial workers. Under a Sarvodya plan, free educational facilities and medical aid are available to backward classes and tribal people. (S. B. L. N.)

The Economy.—Rice, which occupies about 10% of the cultivated area, is grown mainly in the small alluvial basins that lie between the hills of the west coast; on the plateau cotton sometimes predominates. followed by wheat on the better lands, but the great staples in the poorer parts are jowar and bajra. Oilseeds, fodder and grain occupy large areas. Sugar cane is more local, and coconuts are typical only of the coast. The Konkan is famed for its mangoes and cashew nuts. Forests of the varied types mentioned in *Physical Geography* cover large areas; products include timber, fuel, sandalwood, bamboos and grasses.

Production of manganese ore is of major importance. Other minerals include limestone and salt, which is produced in some coastal areas by evaporation.

Maharashtra can claim to be the most industrialized state in India, with about 8,000 registered factories employing two-thirds of 1,000,000 workers. Bombay city is the great centre! but the former dominance of the cotton textile industry has given place to a marked diversification. with general and electrical engineering, a considerable motion-picture industry, the making of rayon fabrics, ceramics, glassware (especially at Ogalewadi), drugs, chemicals, antibiotics (at Pimpri, near Poona). soap, sugar and agricultural implements and pumps (at Kirloskarvadi) and the refining of oil (at Thana). There are government printing works at Nasik and hydroelectric plants at Khopoli. Bhivpuri, Bhira and Koyna and a thermal power station at Trombay.

With an excellent harbour and highly developed industries: Bombay city is an important trading entrepdt for the whole of India. To the east of the city lies one of the relatively easy passes through the Ghats, which facilitated the early construction of railway links with other parts of India. Under the railway grouping of 1947 Maharashtra is served by three of the systems: the Western railway northward into Gujarat, the Central from Bombay eastward and the Southern southeastward to Madras. The state has 2,656 mi. of railway line. The use of motor transport as a feeder to the railways continues to extend with the metaling and tarring of roads. The Konkan is the only part of the state not well served with rail and road. Bombay city has an international airport, and much use is made of local air services. (L. D. S.)

MAHASARAKHAM, a province on the Khorat plateau in northeast Thailand. Area 2,224 sq.mi. Pop. (1960) 496,970. The chief crops are rice: cotton, sugar cane, tobacco. maize and beans. The province is relatively isolated from modern influences and traditional Thai-Lao folk dances, music and religious ceremonies are still widely performed. The capital, Mahasarakham town (pop. [1960] 15,680), lies in the Chi river valley, 41 mi. by motor road from Banphai located on the Khorat-Nongkhai rail line. Locally called Ban Talat, "market town," it is a trading centre for the neighbouring provinces of Kalasin and Roiet, which are still farther from the railroad. (G. W. SK.)

MAHAVAMSA, the *Great Chronicle,* a history of Ceylon from the 5th century B.C. to the middle of the 5th century A.D., written in the 6th century in Pali verse by Mahanama of the Dighasanda hermitage, shortly after the close of the period with which it deals.

In point of historical value it compares well with early European chronicles. In India proper the decipherment of early Indian inscriptions was facilitated to a great extent by the data found only in the Mahavamsa. It was composed on the basis of earlier works written in Sinhalese! which are now lost, having been supplanted by the chronicles and commentaries in which their contents were restated in Pali in the course of the 5th century. The particular one on which this Mahavamsa was mainly based was also called the Mahavamsa, and was written in Sinhalese prose with Pali memorial verse interspersed. The extant Pali work gives legends of the Buddha and the genealogy of his family; a sketch of the history of India down to Asoka; an account of Buddhism in India down to the same date; a description of the sending out of missionaries after Asoka's council, and especially of the mission of Mahinda to Ceylon; a sketch of the previous history of Ceylon; a long account of the reign of Devanam-piya Tissa. the king of Ceylon who received blahinda and established Buddhism in the island; short accounts of the kings succeeding him down to Duttha Gamani (Dadagamana or Dutegemunu); then a long account, amounting to an epic poem, of the adventures and reign of that prince. a popular hero born in adversity, who roused the people and drove the Tamil invaders from the island. Finally, there are short notices of the subsequent kings down to the author's time.

The Mahavamsa mas the first Pali book made known to Europe. It was edited in 1837 with English translation and an elaborate introduction by George Turnour. then colonial secretary in Ceylon. Its vocabulary was an important part of the material utilized in R C. Childers' *Pali Dictionary.* Its relation to the sources from which it drew was carefully discussed by various scholars and in special detail by M'ilhelm Geiger. It was agreed that it gave a reasonably fair and correct presentation of the tradition preserved in the lost Sinhalese Mahavamsa; that, except in the earliest period. its list of kings with the years of each reign was complete and trustworthy; and that it gave throughout the view, as to events in Ceylon, of a resident in the Great Minster at Anuradhapura. (T. W. R. D.; X.)

MAHAVIRA, VARDHAMANA JNATRIPUTRA (6th century B.C.), a contemporary of Buddha, was the 24th and last *tirthankara* ("prophet") of the Jains (*q.v.*) and the founder of the present form of their creed. Mahavira is an honorary title meaning "great hero." According to Jain tradition, his dates were 599–527 B.C., but the two Jain sects, Svetambaras and Digambaras, differ in their accounts of his life, which is confused with many legends. The historical facts are that he was born in Vaisali, the younger son of a king named Siddhartha and of his wife Trisala. He married a noble lady by whom he had a daughter, but at the age of 30 he renounced the world and for 12 years led a life of self-mortification as a wandering beggar, even discarding his clothes. At the end of this period he reached the state of omniscience, and for the rest of his life he taught his doctrines to his ascetic disciples and to an ever-increasing number of laymen. Although he was of a reserved nature, his personality seems to have left a deep impression.

His teaching was a systemization of that of Parsva, the 23rd *tirthankara,* who is said to have lived about 250 years previously. Recensions of some of Mahavira's discourses are extant in the sacred books of the Jains, written in Prakrit dialects, their final redaction dating probably from the 5th century AD. It is uncertain how far any of the sayings there attributed to him are genuine: the Svetambaras acknowledge their authenticity but the Digambaras deny it. As, however, the doctrines of the two sects differ only in matters of minor importance and bear the stamp of a very archaic mode of thinking, it seems not improbable that their leading ideas may go back to his teaching.

MAHAYANA (GREAT VEHICLE) is one of the two major schools of Buddhism (*q.v.*), the other being Theravada. As a "vehicle," *i.e.,* conveyance, it is "great" because it teaches, by its cardinal doctrine, the broad path to salvation: all sentient beings possess the Buddha-nature and hence are capable of attaining enlightenment. The Mahayana aspect of Buddhism, which is followed in Tibet, China and Japan, probably developed during the two centuries before the Christian era, with its starting point very likely furnished by the speculations on the nature of the Buddha developed by the Mahasanghikas, the group of dissident monks who broke away from the orthodox community at the second great Buddhist council, at Vesali (northeast India) c. 383 B.C. According to this school, the Buddha was no longer a human teacher but a *lokottara* or supramundane being who appeared on earth in an apparitional form as Sakyamuni *(see* GAUTAMA BUDDHA).

Doctrine.—Since the Mahayana teaches the universal salvation of all sentient beings, the path leading to this salvation must be simplified. The Mahayana stresses the importance of faith and devotion to the Buddha and the Bodhisattvas, and love for all creatures, manifested by compassion and charity. According to the Lotus (Saddharma Pundarika) Sutra, one of the important Mahayana scriptures, anyone who hears the Master's teachings, who worships an image or relic of the Buddha or who makes a statue even of sand will attain enlightenment; according to the Pure Land (Sukhavativyuha) Sutra, it is necessary only to utter the name of the Buddha Amitabha in loving adoration.

The Mahayana scriptures were composed mainly in Sanskrit (in contrast to the Theravadin, in Pali) and survive largely in Tibetan and Chinese translations.

One of the notable differences between the Theravadin and Mahayana aspects lies in their conception of the Buddha. In the Mahayana there is little of the man left; he has become a transcendental being. a Supreme God above all gods, who has lived for countless ages in the past and will continue to live forever in the future. As the embodiment of the absolute and eternal truth, he is neither born nor dies but lives and works eternally. leading all his followers also to the eternal life. However, to save errant mankind. he appeared on earth as Sakyamuni to preach a doctrine of salvation; he did this not once but countless times in the past and will continue to do so in the future.

As a result of this development, the historical Buddha, Sakyamuni, receded farther and farther into the background, while speculations about the eternal Buddha began to assume increasing importance Such speculations eventually led to the formulation of the doctrine of the *Trikaya* or the triple body of the Buddha. According to this doctrine, as elucidated in its fullest form by Asanga (4th century A.D.), the triple body consists of the *Dharmakaya* (Body of Essence, or Unmanifested Body), *Sambhogakaya* (Body of Communal Enjoyment, or Subtle Body) and *Nirmanakaya* (Body of Magical Transformations, or Earthly Body). The *Dharmakaya* is the only real body of the Buddha; it connects and unites all the Buddhas of the past with those of the future. Though there are many Buddhas, there is only one *Dharmakaya,* which is devoid of all determinations, free from all opposites and embodied in all bodies. The universe becomes, but the *Dharmakaya* remains forever. When it is called upon to fulfill the vows of the Bodhisattva. it then appears as the *Sambhogakaya,* the body in which the Buddha enjoys his full majesty, virtue and knowledge and which the Bodhisattvas are privileged to witness. A marvelous symphony of light and sound, this body preaches the Mahayana *sutras* on Vulture peak, one of the hills encircling Rajagaha, capital of the ancient kingdom of Magadha in eastern India. Lastly, to explain the appearance of a Buddha like Sakyamuni on earth, there is the *Nirmanakaya,* which is a fictitious creation of the eternal Buddha made to conform to the ways of man.

Between the realm of pain which is human and the realm of beatitude which is the Buddha. a connection is established by a class of deity called Bodhisattva — literally a being destined for enlightenment — the doctrine of which is one of the distinguishing features of the Mahayana. The Bodhisattva is an ever-compassionate, warm and merciful being, always ready to assist anyone in need of help, who delays his entry into Nirvana until he has rescued all sentient beings from the sea of misery. He is able to do this by a new doctrine developed by the Mahayana, that of the transfer of merits, according to which the Bodhisattva transfers to less fortunate creatures some of the merits he has accumulated through his long career of spiritual advancement. There are a number of great Bodhisattvas, who are usually regarded as personifications of different aspects of the Buddha's virtues: Manjusri represents wisdom, Avalokitesvara the compassionate glance, Samantabhadra all-round excellence. Of these, Avalokitesvara (Kuan-yin in Chinese, Kwannon in Japanese) is the most prominent, for he abrogates the law of *karma* by going to the deepest hell to lighten the misery of creatures there, and he is ever ready to help people faced with the dangers of fire. flood, demon and the sword. For reasons not fully clear, this Bodhisattva is best known in China and Japan in a female form as the goddess of mercy, the patron deity of women who desire children.

Theravada and Mahayana also differ in their understanding of the concept of Nirvana (*q.v.*). In the Mahayana, Nirvana means the thorough comprehension of the sameness of *samsara* — that is, the phenomenal world of human experience, with its suffering and unrest — and Nirvana — that is, the experience of spiritual freedom and enlightenment. Therefore the enlightened Bodhisattva does not think of passing from *samsara* into Nirvana. The nirvanic state is present in all of us, but we do not realize it because of our ignorance. When all imaginings about the dualism of *samsara* and Nirvana cease, when there is a complete cessation of mental constructions, then the individual is said to have attained Nirvana or perfect Buddhahood.

Within the Mahayana there arose a development called Tantrayana or Mantrayana — Tantrayana because its basic literature is designated as *tantras,* meaning esoteric literature, Mantrayana because it emphasizes *mantras* or mystic syllables. In this phase, an esoteric consecration into the mystic circle or *mandala* — in which sexual symbolisms, liturgy and rites play a prominent role — is a necessary component of soteriology. Developed originally on the borders of India, the Tantrayana attained its most luxuriant growth in Tibet. For a brief period during the 8th century it gained a foothold in China, but it soon disappeared, presumably because the prevailing Confucian ritualistic principles did not countenance mixture of the sexes. (See also TIBETAN BUDDHISM.)

Schools. — The two main Mahayana schools in India were the Madhyamika (Doctrine of the Middle Path) and the Vijnanavada (Doctrine of Mere Ideation). The former, founded by Nagarjuna (2nd century A.D.), stresses the doctrine of *sunyata,* interpreted as emptiness by some and relativity by others. By this, Nagarjuna meant that a thing can be identified only by its relation to another thing; without these relations, it becomes meaningless. Therefore, a thing is said to be empty because it does not possess an independent reality, for it depends upon causes and conditions for its existence, and when these causes and conditions disappear, the thing also disappears. Thorough comprehension of the doctrine of *sunyata* leads to *prajna,* intuitive wisdom or nondual knowledge. When one achieves *prajna,* one reaches the state of absolute truth, which is beyond thought and conception, unconditioned and indeterminate. On the one hand, this absolute truth is said to transcend phenomenon, but on the other hand it is also said to be immanent and identical with it. The understanding of the phenomenal world, where *karma* prevails, is said to constitute the second or relative level of truth. The Vijnanavada holds to the dictum that this world is mere ideation. The external world is a fabrication of human consciousness, hence an illusion. The only true reality is mind or consciousness.

The Madhyamika school was introduced into China in the early 5th century by Kumarajiva; the Vijnanavada was first propagated by the Indian monk Paramartha in the middle of the 6th century, though the chief exponent of this school was Hsiian-tsang during the 7th century. Although both schools were studied, they never became so popular as the other Mahayana schools developed in China, such as the Hua-yen, T'ien-t'ai, Pure Land and Ch'an (Zen [*q.v.*] in Japanese). The Hua-yen or Wreath school, with its principles of interpenetration and intermutuality, emphasizes the relationship between one phenomenon and another and maintains that since all phenomena are manifestations of the one immutable noumenon they are in perfect harmony with one another. Followers of the T'ien-t'ai school, on the other hand, concentrate their attention on the relationship between the noumenon and phenomenon and say that the whole and the part are identical with each other in accordance with their doctrine of the threefold truth, emptiness, temporariness and the mean. All things lack reality, hence they are empty. However, a thing, though empty, enjoys a temporary existence as phenomenon. The fact that a thing is both empty and temporary at the same time constitutes the middle truth. In the Pure Land school. faith and devotion to Amitabha, presiding Buddha of the Western Paradise, accompanied by utterance of his name, are the main prerequisites for rebirth in that ideal Buddha-land. The Ch'an or Meditation school would do away with all literature and images and endeavour to attain a direct, instantaneous realization of the inner essence that is the Buddha-nature in man.

Of these four schools, the first two, being more philosophically inclined, did not gain so wide a following among the populace as did the Pure Land and Ch'an. The teachings and practices of the Pure Land were so simple that even the illiterate could understand them, hence this school became the dominant one in China from the time of the T'ang dynasty (7th–10th centuries). As for the Ch'an school, its de-emphasis of the scriptures, images, rituals and metaphysical speculations appealed to the practical tendencies of the Chinese. Its approach to enlightenment was direct, plain and concrete. The Ch'an masters spoke in the everyday colloquial language the ordinary Chinese could understand. It did not antagonize Confucian thought. for it insisted that monks do productive work. It had a close affinity to Taoism in its nonattachment to worldly objects and its mystic appreciation of nature. Being elastic and comprehensive enough to adapt itself to the Chinese environment, it prospered in China.

All these schools were in turn introduced into Japan with very little doctrinal change by Japanese monks after the beginning of the 7th century, and in their new home in that country they were to enjoy a long period of growth and development. For a study of Mahayana Buddhism as it is practised in the modern world, it is therefore necessary to go to Japan (see JAPAN: The People: *Religion*).

MAHDI (Arab., "he who is guided aright"), a title assumed by the third Abbasid caliph (see CALIPHATE). According to Moslem traditionists Mohammed declared that one of his descendants, the imam of God. who would fill the earth with equity and justice, would bear the name of al-mahdi. The Sunnis hold that this mahdi has not yet appeared. The name of mahdi is also given by the Shi'ites to the last of the imams of the house of Ali, who disappeared mysteriously about 874. It was under the name of al-mahdi that Mokhtar proclaimed Ali's son Mohammed as the opponent of the caliph Abdalmalik and, according to Shahrastani. the doctrine of the mahdi, the hidden deliverer who is one day to appear and fill the oppressed world with righteousness, first arose in connection with a belief that this Mohammed had not died but lived concealed at Mt. Radwa, near Mecca, guarded by a lion and a panther. The belief in the appearance of the mahdi readily lent itself to imposture. Of the many pretenders to this dignity known in all periods of Moslem history the most famous was the first caliph of the Fatimite dynasty in north Africa: Obaidallah al-Mahdi, who reigned from 909 to 933. After him was named the first capital of the dynasty. the once important city of Mahdia (*q.v.*). Another great historical movement, headed by a leader who proclaimed himself the mahdi (Mohammed ibn Abdallah ibn Tumart), was that of the Almohads (*q.v.*).

In 1881 Mohammed Ahmed ibn Seyyid Abdullah (*q.v.*), a Dongolese, proclaimed himself al-mahdi and founded in the eastern Sudan the short-lived empire which was overthrown by an Anglo-Egyptian force at the battle of Omdurman in 1898. Concurrently with the claim of Mohammed Ahmed to be the mahdi the same title was claimed by, or for, the head of the Senussi, a confraternity powerful in many regions of north Africa.

MAHDIA (also spelled MEHDIA, MEHEDIA, etc.), a port of Tunisia, on the coast between the gulfs of Hammamet and Gabès. 47 mi. by rail S.S.E. of Sousse. Pop. (1956) 10.832. Mahdia is built on a rocky peninsula which projects eastward about a mile beyond the normal coast line, and is not more than a quarter of a mile wide. The extremity of the peninsula is called Ras Mahdia or Cape Africa — Africa being the name by which Mahdia was designated by Froissart and other European historians during the middle ages and the Renaissance. In the centre of the peninsula and occupying its highest point is a citadel (16th century); another castle farther west is now used as a prison and is in the centre of the native town.

The European quarter and the new port are on the southwest side of the peninsula. The small artificial harbour is available for small boats only; steamers anchor in the roadstead about a quarter of a mile from the shore. On the southeast, cut out of the rock, is the ancient harbour, or cothon. There are manufactories of olive oil.

Mahdia occupies the site of a Phoenician settlement on which grew a Roman centre, name unknown. After the Arab conquest of north Africa the town fell into decay. It was refounded in 912 by the first Fatimite caliph, Obaidallah al-Mahdi, after whom it was named. It became the port for Kairawan and was for centuries a city of considerable importance. largely because of its great natural strength and its position on the Mediterranean. It carried on an active trade with Egypt, Syria and Spain. The town was occupied by the Normans of Sicily in the 12th century, but after holding it for about 12 years they were driven out in 1159 by the Almohades. In 1390 a joint English and French force vainly besieged Mahdia for 61 days. In the early part of the 16th century the corsair Dragut seized the town and made it his capital, but in 1550 the place was captured by the Spaniards, who held it until 1574. Before evacuating the town the Spaniards dismantled the fortifications. Near to Mahdia, about 3 mi. N.E. of the lighthouse, were found in the sea in 1908 at a depth of 528 ft. the remains of an ancient galley. of Athenian construction, laden uith objects of art, and sunk in the 1st century A.D. Beautiful statues of bronze and many fragments found by divers are gathered together in the Alaoui museum at Tunis.

MAHÉ, a former French settlement within Malabar district, Kerala, India, situated in 10° 43' N. and 75° 33' E., at the mouth of the Mahé river. Area 23 sq.mi.; pop. (1955) 20,261. It was the only French possession on the west coast of India and was subordinate to the commissioner in Pondicherry. A popular movement in favour of Mahé's union with India began on April 9, 1954; after a series of disturbances the French administration withdrew on July 15 and Mahé was transferred de *jure* to the republic of India on Nov. 1, 1954.

MAHESHWAR, a town in Nimar district, Madhya Pradesh state, India, on the north bank of the Narbada (Nerbudda). Pop. (1951) 7,525.

Though of great antiquity, and also of religious sanctity, it is chiefly noted as having been the residence of Ahalya Bai, the famous queen of the Holkar dynasty during the last half of the 18th century.

MAHI, a river of western India. which rises in southwestern Madhya Pradesh and, after flowing through southern Rajasthan, enters the Gujarat and falls into the sea by a wide estuary near Cambay; total length, about 350 mi.; estimated drainage area, 17,000 sq.mi.

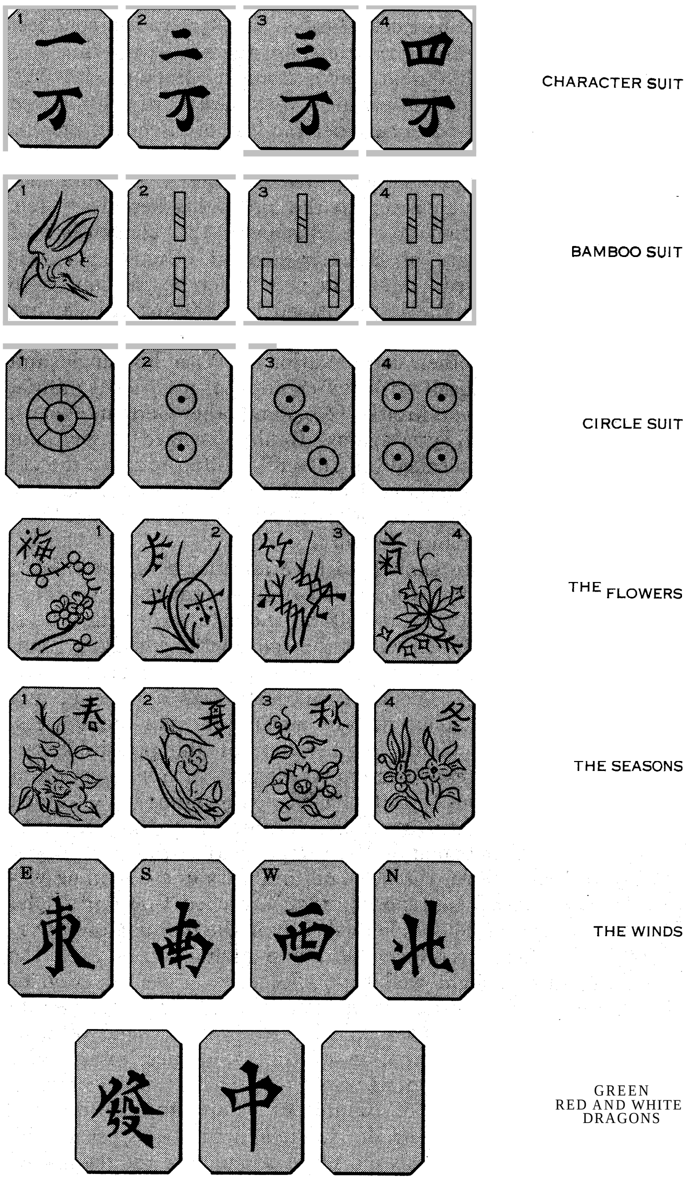
MAHILLON, VICTOR CHARLES (1841–1924), Belgian musical scholar and authority on wind instruments. The son of Charles Mahillon (1813–87), the founder of a firm of wind-instrument makers, he was born in Brussels, March 10, 1841, and entered his father's business (1865). As curator of the museum of the Brussels Conservatoire, he formed a collection of over 1.500 instruments of which he published an analytical catalogue (1880–1922), containing demonstrations of the theories of instrument construction and a methodical classification of ancient and modern instruments. He had copies made of rare instruments, and adapted some of them, notably the Bach trumpet. for modern use.

Mahillon published Les *Éléments* d'acoustique *musicale* et *instrumentale* (1874), and numerous monographs on instruments and organized concerts of historical works played on old instruments.

Mahillon died at St. Jean, near Cap-Ferrat, June 17, 1924.

See E. Closson, *La Facture des instruments de musique en Belgique* (1935).

MAH-JONGG, a western version of a Chinese game, is played with 136 or 144 tiles or *p'ais,* similar to dominoes but engraved with Chinese symbols and characters and divided into suits and honours. A fad in England, the United States and Australia in the mid-1920s, the game was revived in the U.S. after 1935 but never regained its initial popularity. The game that came to be known as mah-jongg is probably of 19th-century origin. Before World War I, each Chinese province had its own style of play and dialect name for it. Signifying "sparrow" or hemplike bird, the name has been variously transliterated as *ma tsiang, ma chiang, ma cheuk* and *ma ch'iau.* The sparrow or a mythical "bird of 100 intelligences" appears on one of the tiles. The name mah-jongg was coined and copyrighted by Joseph P. Babcock, a U.S. resident of Shanghai who is credited with introducing mah-jongg to the west after World War I. He wrote a modified set of rules,



TILES OF COMMON **SUITS** AND HONOURS USED IN MAH-JONGG

A full set contains 144 tiles, divided into 6 suits; sometimes only 5 are used

gave English titles to the tiles and added index letters and numerals familiar to western card players.

Pieces.—Modern mah-jongg sets are usually made of plastics instead of bone or ivory. A full mah-jongg set contains 136 or 144 tiles depending on whether the flowers or seasons are used. Some sets include 20 flowers. The pieces are named and numbered as follows:

1. Bamboos, numbered 1 to 9, four of each number.......36 tiles
2. Circles, numbered 1 to 9, four of each number..........36 tiles
3. Characters, numbered 1 to 9, four of each number.......36 tiles
4. Honours, 4 red dragons, 4 green, 4 white dragons.......12 tiles
5. Winds, 4 east winds, 4 south winds, 4 west winds, 4 north winds..............................16 tiles

136 tiles

In addition:

6. Flowers and seasons, 4 of each or 8 of either............8 tiles

144 tiles

The bamboos are often called sticks or bams, the circles dots, the characters cracks or craks. The set also includes two dice, a quantity of tokens or plastic chips used for scorekeeping and a rack for each player whereon he can place 14 tiles with their faces visible only to himself.

The Game.—The usual game is for four, each playing for himself (there are no partners). The object of play, similar to that of the rummy card games, is to obtain sets of tiles. There are three kinds of sets: "chow," a run or sequence of three tiles of the same suit in numerical order; (2) "pung," a sequence of three like tiles of the same suit and rank, three dragons of the same colour or three identical winds; and (3) "kong," a pung plus the fourth matching tile. The winner is the first player to hold a complete hand; *i.e.,* four sets and a pair of like tiles (14 tiles). The strategy of mah-jongg, like that of rummy, is both offensive and defensive: to complete a "woo" or winning hand as quickly as possible; to block other players by not discarding tiles useful to them; and to build a high-scoring hand. Beginning with "east wind" (who collects or pays double according to whether he or another player wins), each player draws his "hand" and places it in his tile rack, east taking a total of 14 tiles and the others 13. The flowers or seasons are not counted as part of a 13-tile hand; on drawing such a tile, the player immediately "grounds" it face up and draws another tile. East begins the play by discarding one tile, reducing his hand to 13. Thereafter, the other players, in counterclockwise rotation, each draw one tile, which may be the last discarded tile or a loose tile from the "wall" (comparable to stock in rummy). Any player, regardless of whether it is his turn, may claim the previous discard if it completes his set. (If two or more players claim the same discard, there is a detailed order of precedence.) The losing players settle with the winner and with each other according to the accepted schedule of values for the sets or combinations of sets. A concealed set held in the hand scores differently from an exposed set on the table.

Under certain rules, exceptionally complete hands or "limit hands," picturesquely named "the three scholars," "four small blessings," etc., are scored differently. In U.S. play the emphasis on limit hands eventually far exceeded that under Chinese rules until high scores were accented over playing skill. A certain school of players restricted the winning hand to a very narrow list and made the flowers wild. Various other innovations followed. One was the "clear-handed" rule: woo hand may contain only tiles of one suit plus honours. The conflict led to publication of *Laws for Mah-Jongg* (1925) by Babcock and others, giving an option between the Chinese game and the clear-handed variant. Shortly after, the Mah-Jongg fad collapsed.

In 1937 Viola Cecil organized the National Mah Jongg league in the U.S. to standardize a new version of the game. Its innovations included the "Charleston," or exchange of tiles between players before the start of play, and the use of 22 flower tiles (wild or jokers except in certain winning hands).

Cecil, *Maajh* (1941), *The New Mah Jongg* (1945); Kanai Shozo, *Mah Jongg for Beginners* (1952); Dorothy S. Meyerson, *"That's It": A New Way to Play Mah Jongg* (1937). (P. FR.)

MAHLER, **GUSTAV** (1860–1911), Austrian composer and conductor, was born at Kalischt, Bohemia, July 7, 1860. From 1885 onward he conducted in Prague, Budapest, Hamburg and London, becoming director of the Vienna Opera in 1897. By unremitting zeal and tireless enthusiasm he brought the Viennese opera to a high state of perfection, but the strenuous work which he exacted from all earned him the name of "the tyrant" and made him many enemies, and in 1907 he was obliged to resign his post. He immediately received the offer of a conductorship in the U.S., which he visited for three seasons, returning in 1911 to Vienna, where he died on May 18. Mahler reflected to some extent in his works the classical tradition inherited from F. Schubert and A. Bruckner. In addition to over 40 songs, he wrote nine symphonies and part of another, all planned on a gigantic scale for an orchestra nearly doubled in strength.

MAHLSTICK, a stick with a soft leather or padded head, used by painters to support the hand that holds the brush. The word is an adaptation of the Dutch *maalstok* (*i.e.,* the painter's stick), from *malen,* to paint.

MAHMUD I (1696–1754), sultan of Turkey, the son of Mustafa II, succeeded his uncle Ahmed III in 1730. A peace-loving man, he played no part in the wars of his reign. He was under the influence of his two successive chief eunuchs, both named Beshir Aga. The first died in 1746; the second was assassinated in 1752 at Mahmud's instigation to appease the janissaries and the ulema. During this reign Turkish diplomacy was conspicuously skilful, partly as a result of what had been learned from a French convert to Islam, the comte de Bonneval (called Ahmed Pasha), who also did much to westernize the army. Mahmud died of heart disease in 1754.

(See TURKEY: History.) (G. L. L.)

MAHMUD II (1785–1839), sultan of Turkey, was the son of Abdul-Hamid I, and succeeded his brother, Mustafa IV, in 1808. He had shared the captivity of his ill-fated cousin, the former sultan Selim III, whose efforts at reform had ended in his deposition by the janissaries. The reforming efforts of the grand vizier Bairaktar, to whom he had owed his life and his accession, broke down on the opposition of the janissaries, and Mahmud had to wait for more favourable times. Meanwhile the empire seemed in danger of breaking up. In 1812 the war with Russia was closed by the treaty of Bucharest, which restored Moldavia and the greater part of Walachia to the Ottoman government, but left a number of burning questions, both internal and external, unsettled. The preoccupation of the sultan with Ali (*q.v.*) of Janina gave their opportunity to the Greeks, who in 1821 began their war of independence (see GREEK ISDEPENDENCE, WAR OF). The rising in the north was easily crushed; but in the south the Ottoman power was hampered by the defection of the seafaring Greeks, who had manned the Turkish navy.

After three abortive campaigns Mahmud was compelled, infinitely against his will, to summon to his assistance the already too powerful pasha of Egypt, Mohammed Ali (*q.v.*), whom he had already employed to suppress the rebellious Wahhabis in Arabia. The disciplined Egyptian army, supported by a well-organized fleet, rapidly accomplished what the Turks had failed to do; by 1826 the Greeks were practically subdued on land, and Ibrahim was preparing to turn his attention to the islands. But for the intervention of the Powers and the battle of Navarino Mahmud's authority would have been restored in Greece. After in vain attempting to obtain an apology for "the unparalleled outrage against a friendly power" he issued on Dec. 20, 1827, a solemn *hatti* sherif summoning the faithful to a holy war. This, together with certain outstanding grievances and the pretext of enforcing the settlement of the Greek question approved by the Powers, gave Russia the excuse for declaring war against Turkey. After two hardly fought campaigns (1828, 1829) Mahmud was at length, on Sept. 14, 1829, compelled to sign the peace of Adrianople. From this moment until his death Mahmud was, to all intents and purposes, the "vassal of Russia," though not without occasional desperate efforts to break his chains. (For the political events of the period see TURKEY: History.)

The attitude of, the sultan to Mohammed Ali must now be considered. This was determined throughout by his overmastering hatred of the upstart pasha, of whom he had stooped to ask aid and who in Sept. 1832 began to defy his will (see MOHAMMED ALI); the importance of this attitude lies in the fact that, as the result of the success of Mahmud's centralizing policy and notably of the destruction of the janissaries (*q.v.*), the supreme authority, hitherto limited by the practical power of the ministers of the Porte and by the turbulence of the privileged military caste, had become concentrated in his own person.

This omnipotence of the sultan in deciding the policy of the government was in striking contrast with his impotence in enforcing his views on his subjects and in his relations with foreign powers. Mahmud, in spite of—or rather because of—his well-meant efforts at reform, was hated by his Moslem subjects and stigmatized as an "infidel" and a traitor to Islam. Of this hatred he was fully conscious; he knew that his subjects, even many of his own ministers, regarded Mohammed Ali as the champion of Islam against the "infidel sultan"; he suspected the pasha, already master of the sacred cities, of an intention to proclaim himself caliph in his stead. This, together with the weakness caused by military reforms but recently begun, drove him to rely on the aid of Russia. The long tradition of French friendship for Turkey had been broken in 1830 by the conquest of Algiers. Austria was, for the time, but the ally of the tsar.

On Aug. 9, 1832, Mahmud made, through Stratford Canning, a formal proposal for an alliance with Great Britain, which Lord Palmerston refused to consider for fear of offending France. Mahmud bitterly contrasted the fair professions of England with the offers of effective help from Russia. His old ally having deserted him, he accepted the aid of his hereditary foe. The Russian expedition to the Bosporus, the convention of Kutakia and the treaty of Hunkiar Iskelesi (Unkiar Skelessi; July 8, 1833) followed. Mahmud was under no illusion as to the position in which the latter placed him toward Russia, but his fear of Mohammed Ali and his desire to be revenged upon him outweighed all other considerations. With his single aim in view he busied himself with the creation of a national militia, with the aid of count von Moltke (*q.v.*) and other German officers. In 1834 the revolt of Syria against Ibrahim seemed to give him his opportunity. He pleaded the duty of a sultan to go to the aid of his subjects when oppressed by one of his servants; but the Powers were obdurate, even Russia, much occupied in affairs nearer home, leaving him in the lurch.

Mahmud was astute enough to take advantage of the offense given to the Powers by Mohammed Ali's system of monopolies, and in 1838 signed with Great Britain, and afterward with others, a commercial treaty which cut at the root of the pasha's system. A few months later his passionate impatience overcame his policy and his fears. The hand of death was upon him, and he felt that he must strike now or never. In vain the Powers, now united in their views, warned him of the probable consequences of any aggressive action on his part. On his sole initiative he sent instructions to Hafiz Pasha, commanding the Ottoman troops concentrated at Bir on the Euphrates, to advance into Syria. The fatal outcome of the campaign that followed he did not live to hear. When the news of Ibrahim's overwhelming victory at Nezib (Nizib) (June 24, 1839) reached Constantinople, Mahmud lay unconscious. He died early in the morning of July 1.

Mahmud's efforts to reform the whole administration after the European pattern might well have succeeded, given a period of peace and enough first-rate men to help him. He was, despite his hasty temper, a kindly man, sincere, energetic and of high intelligence. By his extirpation of the janissaries, one of the greatest obstacles to reform, he paved the way for the *tanzimat* of 1839. He set an admirable example of loyalty to subordinates, and his abolition (1826) of the sultan's right to confiscate the property of deceased officials did much to enhance the dignity of public service. (W. A. P.; X.)

MAHMUD NEDIM PASHA (c. 1818–1883), Turkish statesman, was the son of Nejib Pasha, former governor general of Baghdad. He was successively undersecretary of state for foreign affairs, governor general of Syria and Smyrna, minister of commerce and governor general of Tripoli; minister successively of justice and of marine (1869); grand vizier in 1871 and 1872 and in 187j and 1876. He was high in favour with Sultan Abd-ul Aziz and fell much under the influence of Count Nicholas Ignatiev, the forceful Russian ambassador, before the war of 1877–78, his subserviency to Russia earning for him the nickname of "Mahmudoff." His administration was most unsuccessful, and he was largely responsible for the issue of the decree suspending the interest on the Turkish funds. He was minister of the interior from 1879 to 1883.

MAHMUD OF GHAZNI (971–1030), son of Sabuktagin, Afghan conqueror, was born on Oct 2, 971. His fame rests on his repeated invasions of India. His military capacity, inherited from his father, Nasir ud-Din Sabuktagin. was strengthened by youthful experience in the field. Sabuktagin, a Turki slave of Alptagin. governor of Khurasan under 'Abd ul-Malik I ibn Nuh of the Samanid dynasty of Bukhara, early brought himself to notice. (See SAMANIDS) He was raised to high office in the state by Alptagin's successor, Abu Ishak, and in A.H. 366 (AD. 977), by the choice of the nobles of Ghazni, he became their ruler. He soon began to make conquests in the neighbouring countries, and in these wars he was accompanied by his young son Mahmud.

In 994 Mahmud was made governor of Khurasan, with the title of saif *ud-daula* ("sword of the state"), by the Samanid Nuh II. Two years later his father Sabuktagin died in the neighbourhood of Balkh, having declared his second son, Ismail, uho was then with him, to be his successor. As soon as Ismail had assumed the sovereignty at Balkh, Illahmud, who was at Nishapur, addressed him in friendly terms, proposing a division of the territories held by their father at his death. Ismail rejected the proposal and was immediately attacked by Mahmud and defeated Retreating to Ghazni, he there yielded and was imprisoned, and Mahmud obtained undisputed power as sovereign of Khurasan and Ghazni (997).

The Ghaznevid dynasty is sometimes reckoned by native historians to commence with Sabuktagin's conquest of Bost and Kosdar (978). But Sabuktagin, throughout his reign at Ghazni, continued to acknowledge the Samanid suzerainty, as did Mahmud also, until 999, when after driving the Samanid forces out of Khurasan he received from Kadir, caliph of Baghdad, a khzlat (robe of honour). with a letter recognizing his sovereignty and conferring on him the titles *yamīn* ud-daula ("right hand of the state") and *amīn ul-millat* ("guardian of the faith"). From this time it is the name of the caliph that is inscribed on Mahmud's coins. together with his own new titles.

The new honours received from the caliph gave fresh impulse to Mahmud's zeal on behalf of Islam, and he resolved on an annual expedition against the idolaters of India. He could not quite carry out this intention, but a great part of his reign mas occupied with his Indian campaigns. In 1000 he started on the first of these expeditions, but he went no farther than the hill country near Peshawar. Mahmud's army first crossed the Indus in 1001, opposed by Jaipal, raja of Lahore. Jaipal was defeated, and Mahmud, after his return from this expedition. is said to have taken the distinctive appellation of *ghāzi* ("valiant for the faith"), but he is rarely so-called. On the next occasion (1005) Mahmud advanced as far as Bhera on the Jhelum, when his adversary, Anang-pal, son and successor of Jaipal, fled to Kashmir. The following year saw Mahmud at Multan. When he was in the Punjab at this time he heard of the invasion of Khurasan by the Ilek khan Nasr I, ruler of Transoxiana, whose daughter Mahmud had married. After a rapid march back from India, Mahmud repelled the invaders. The Ilek khan, having retreated across the Oxus. returned with reinforcements and took up a position a few miles from Balkh, but was defeated by Mahmud.

Mahmud again entered the Punjab in 1008, this time for the express purpose of chastising Sukhpal, who, having become a Moslem and been left by Mahmud in charge of Multan, had relapsed to Hinduism. The Indian campaign of 1009 was notable. Near the Indus Mahmud was opposed again by Anang-pal, supported by powerful rajas from other parts of India. After a severe fight, Anang-pal's elephants nere so terror-stricken by the fire missiles flung among them by the invaders that they turned and fled, the whole army retreating in confusion and leaving Mahmud master of the field. Mahmud, after this victory, pushed on through the Punjab to Nagar-kot (Kangra) and carried off much spoil from the Hindu temples to enrich his treasury at Ghazni. In 1011, after a short campaign against the Afghans under Mohammed ibn Sur in the hill country of Ghor, he marched again into the Punjab. The next time (1014) he advanced to Thanesar, between the Sutlej and the Jumna.

Before beginning his inroad into Hindustan he had to march north into Khwarizm (Khiva) against his brother-in-law Mamun, who had refused to acknowledge Mahmud's supremacy. The result was as usual. and Nahmud, having committed Khwarizm to a new ruler, one of Mamun's chief officers, returned to his capital. Then in 1018, with a very large force, he proceeded to India again, extending his inroad this time to the great Hindu cities of Muttra on the Jumna and Ranauj on the Ganges. He reduced the one, received the submission of the other and carried back great stores of plunder. Three years later he went into India again, marching over nearly the same ground, to the support, this time, of the raja of Kanauj, who, having made friendship with the Mohammedan invader on his last visit, had been attacked by the raja of Kalinjar. But Mahmud found he had not yet sufficiently subdued the idolaters nearer his own border, between Kabul and the Indus; and the campaign of 1022 was directed against them and reached no farther than Peshawar. Another march into India the follouing year was made direct to Gwalior.

The next expedition (1025) is the most famous of all. The point to which it was directed was the temple of Somnath on the coast of the Gujarat peninsula. After an arduous journey by Multan and through part of Rajputana, he reached Somnath and met with a very vigorous but fruitless resistance on the part of the Hindus of Gujarat. Moslem feet soon trod the courts of the great temple. The chief object of worship that it contained was broken, and the fragments kept to be carried off to Ghazni. For the more recent story of the Somnath gates see SOMNATH.

After the successes at Somnath, Mahmud remained several months in India before returning to Ghazni. Then in 1026 he crossed the Indus once more into the Punjab. His brilliant military career closed with an expedition to Persia. in the third year after this, his last, visit to India. The Indian campaigns of Mahmud and his father were almost, but not altogether, unvarying successes. The Moslem historians touch lightly on reverses. And, although the annals of Rajputana tell how Sabuktagin was defeated by one raja of Ajmere and Mahmud by his successor, the course of events which followed shows how little these and other reverses affected the invader's progress. A vast cycle of legends soon grew up over blahmud's exploits in India and more especially over the expedition to Somnath. Yet Mahmud's Indian conquests, striking and important in themselves, were, after all, in great measure barren, except to the Ghazni treasury. Mahmud retained no possessions in India under his own direct rule. But after the repeated defeats, by his father and himself, of two successive rajas of Lahore, the conqueror assumed the right of nominating the governors of the Punjab as a dependency of Ghazni, a right which continued to be exercised by seven of his successors. And for a time, in the reign of Mas'ud II (1098–1114), Lahore was used as the residence of the reigning Ghaznevid sovereign.

Mahmud died at Ghazni in 1030, the year following his expedition to Persia. He is conspicuous for his military ardour, his ambition. strong will, perserverance, watchfulness and energy, combined with great courage and unbounded self-reliance. But his tastes were not exclusively military. His love of literature brought poets and men of learning to his court, and the site of the ancient city of Ghazni still has remains of his monuments.

See *Cambridge* History *of India,* vol. *3* (1928); M. Nāzim, *The Life and Times of Sultan Mahmud of Ghazna* (1931).

MAHOGANY is the foremost cabinetwood of the world and one of the most valuable timbers in tropical America. It is the product of the genus Swietenia, family Meliaceae. First discovered of the three species is West Indies mahogany (Swietenia mahagoni), native in the Bahamas, Cuba, Jamaica, Hispaniola and southern Florida. More important commercially. is Honduras mahogany (Swietenia *macrophylla)* of southern Mexico, Central America and South America, found in Colombia, Venezuela and the upper Amazonian region of Peru, Bolivia and western Brazil.

Mahogany trees are scattered through wet tropical forests and are grown in plantations and for shade and ornament around the world. The alternate pinnate leaves have 4 to 12 paired, shiny, pointed leaflets with the two sides unequal. Many small greenish-yellow 5-petaled flowers are borne in clusters. The distinctive hard, pear-shaped seed capsules split into five parts from the base upward, releasing many winged seeds. The wood characteristically is rich reddish brown, especially after exposure, though when freshly cut ranges from light pink to golden brown. It is fine-textured with scattered pores and often with a highly attractive figure. such as stripe, mottle. fiddleback and. from forks, the famous crotch and swirl. Oi uniformly high grade, it is easily worked, takes a beautiful polish, stains and glues readily and is strong and durable.

The oldest surviving use oi carved mahogany is in the cathedral at Santo Domingo, built 1514–40. Hernán Cortés in 1521 adapted it for shipbuilding. One of the first recorded uses in England was at Nottingham castle in 1680. For fine furniture, mahogany became popular in the early part of the 18th century, when cabinetmakers began to carve decorations on this strong wood. Other uses include cabinetwork, television cabinets, paneling, veneers, plywood, molded plywood boat hulls, yacht interiors, working models and foundry patterns. In World War II mahogany served for PT boats and aircraft.

The word mahogany, usually with a descriptive or geographic qualification: has been applied to nearly 200 species. Khaya, or African mahogany, is obtained from the genus Khaya (mostly Khaya iuorensis; family Meliaceae) in West Africa, mainly Ivory Coast: Ghana and Nigeria. Wood of related genera. for example sapele (*Entandrophragma cylindricum*). also has been marketed as African mahogany. The trade name Philippine mahogany has been applied to red lauans (*Shorea negrosensis, S. polyspermn*—also called tangile, and related species) irom the Philippine Islands belonging to the dipterocarp family (Dipterocarpaceae). The U.S. Federal Trade commission has approved the names African and Philippine mahogany but otherwise restricts mahogany to woods of *Swietenia.*

In western North America several species of shrubs and small trees of cercocarpus, genus *Cercocarpus* (fam. Rosaceae, *q.v.*), with hard, fine-grained, reddish wood, are known as mountain-mahogany. Lemonade sumac (*Rhus integrifolia*), a handsome evergreen shrub or small tree of southern California and Mexico, has been called mahogany sumac or mahogany. (E. L. L.)

MAHONE, WILLIAM (1826–1895), U.S. soldier and senator, was born near Monroe, Va., on Dec. 1, 1826. In 1847 he graduated at the Virginia Military academy and. having studied civil engineering, became chief engineer of the Norfolk and Petersburg railway. At the outbreak of the Civil War he became lieutenant colonel of Virginia volunteers in the Confederate army. and soon after colonel of the 6th Virginia infantry. He participated in most of the battles of the peninsula and those around Petersburg, winning a reputation for his hardy campaigning. He was commissioned brigadier general in March and major general in August 1864. He afterward commanded a division in Ambrose B. Hill's corps. After the war he again turned to railway affairs and became president of the Norfolk and Tennessee. He became the leader of the readjuster party in Virginia! was an unsuccessful candidate for governor in 1878, but in 1880 was elected U.S. senator, which position he held until his defeat in 1887. He died at Washington, D.C.. on Oct. 8, 1895.

MAHONIA, a genus of unarmed evergreen shrubs (family Berberidaceae), closely allied to the barberry (*q.v.*) and considered by some as a section of *Berberis.* The mahonias differ from the true barberries mainly in having compound leaves and a calyx of nine sepals. There are about jo species of *Mahonia,* found chiefly in Asia, western Sorth America and Central America. Several are cultivated for their ornamental ioliage, flowers and fruit, including the Oregon grape (*q.v.*); the Japanese mahonia (*M. japonica*), native to China; and *M. fortunei,* also native to China and named after the English traveller, Robert Fortune.

MAHONY, FRANCIS SYLVESTER (1804–1866), known as "Father Prout," Irish priest and author, son oi a woollen manufacturer. was born in Cork) Ire.: in 1804. His classical education was chiefly obtained at a Jesuit college at Amiens, and after studying in Paris he entered the Jesuit college at Rome and was admitted into the Society of Jesus. He served in Switzerland and at Clongoweswood, Ire.. where he was prefect of studies and subsequently master of rhetoric. There he was involved in scandals that led to his resignation. On going to Italy he was told at Florence that he was expelled from the society. He obtained priest's orders at Rome in 1832, and returned to Ireland, later officiating in the chapel of the Bavarian Legation in London. He joined William Maginn, and about 1834 began to contribute his celebrated "Prout Papers" to *Fraser's Magazine.* These consist of episodes in the life of the parish priest "Father Prout," and dialogues after the model of "Christopher North." Of his poetic writings. his "Bells of Shandon" has always been greatly admired. His verse tends to show that with all his sarcastic and cynical wit his genius had also its tender, serious and sentimental side. In 1846 Mahony became correspondent at Rome to the *Daily News,* and his letters from that capital give vivid pictures of the first years of the reign of Pius IX. He died in Paris on May 18, 1866.

An edition of his works, by Charles Kent, was published in 1881.

MAHOUT, an elephant driver. The mahout sits on the elephant's neck and directs him by voice and by the use of a goad called ankus.

MAHRATTAS or **MARATHAS.** The Mahrattas are a mixed people inhabiting Central India irom Gwalior to Goa. Their religion is Hinduism and their language is Marathi. Their origin is obscure. hut they seem to have entered India beiore Mahmud of Ghazni with his Mohammedan horde conquered Indian states in the early 11th century. The real iounder of the Mahrattas as a power was Sivaji Bhonsla (1627–80). He gradually succeeded in compelling the independent chiefs to acknowledge his suzerainty, and drawing upon their military resources he subdued much of the territory of the emperor of Delhi. In 1674 he was proclaimed maharajah of the Konkan, and he instituted a levy of a fourth of the land revenues. Sivaji was succeeded by his son; Sambaji, in 1680. and in 1689 the latter was captured and put to death by Aurangzeb (*q.v.*). Thereafter, there being no stable rule, the peshwas or chief ministers indulged their ambitions to the full and the Mahrattas began to decline, being divided among themselves.

Sivaji's successor was merely a titular monarch, the peshwa becoming the hereditary ruler. These peshwas were Brahman by faith and gradually the struggle became one between the military and religious powers. In the early 18th century the five Mahratta states of Baroda, Gwalior, Indore, Nagpur and the "dominions of the Peshwa" were constituted. Owing to internal strife the East India company was forced to intervene. When, in 1739, Nadir Shah invaded the empire of Delhi the peshwas saw an opportunity of seizing further territory from the mogul emperor. In 1761 their power was almost irretrievably destroyed in their defeat by Ahmad Shah, ruler of Afghanistan, at the battle of Panipat. In 1779 began a series of wars between the Mahrattas and the British and the names of Wellesley and Lake are famous in connection with the brilliant victories over the soldiers of Indore, Nagpur and Gwalior in the third Mahratta War (1803–05). The efforts of these officers resulted in the accession of much territory to the British flag. In 1817 the Mahratta peshwa united with Nagpur and Indore in attacking the British forces. and the result was the annexation of the peshwa's territories to the presidency of Bombay. Later. Indore and Xagpur were annexed by the British and the state of Gwalior was brought under British control in the middle of the 19th century. In modern times the rulers of the Mahratta states took special titles, the ruler of Indore being known as Holkar of Indore, Sindia of Gwalior, and Gaikwar of Baroda. These are family names.

MAHSEER (*Barbus mosal*), a large-scaled barbel of the rivers of India. attaining a weight of over 100 lb. and celebrated as a sporting fish.

MAI, ANGELO (1782–1854), Italian cardinal and philologist, was born of humble parents at Schilpario in the province of Bergamo. Lombardy. on March 7, 1782, was made a cardinal in 1838. and died at Castelgandolfo on Sept. 8, 1854. He was educated at the Collegium Romanum. and aiter teaching at Orvieto and elsewhere was made custodian of the Ambrosian library at Milan in 1813. He went to Rome in 1819 as chief keeper of the Vatican library.

It is on his skill as a reader of palimpsests that Mai's fame chiefly rests. To the period of his residence at Milan belong: Fragments of Cicero's *Pro Scauro, Pro Tullio, Pro Flacco, In Clodium et Curionem, De aere alieno Milonis, De rege Alexandrino* (1814); *M. Corn. Frontonis opera inedita, cum epistolis item ineditis, Antonini Pii, Marci Aurelii, Lucii Veri et Appiani* (181j; new ed., 1823, with more than 100 additional letters found in the Vatican library); portions of eight speeches of Quintus Aurelius Symmachus; fragments of Plautus; the oration of Isaeus *De hereditate Cleonymi;* the last nine books of the *Antiquities* of Dionysius of Halicarnassus, and a number of other works. *M. Tullii Ciceronis de republica quae supersunt* appeared at Rome in 1822; *Scriptorum veterum nova collectio, e vaticanis codicibzis edita* in 1825–38; *Classici scriptores e vaticanis codicibus editi* in 1828–38; *Spicilegium romanum* in 1839–44; and *Patrum nova bibliotheca* in 1845–53.

MAIA. (1) In Greek mythology, the eldest of the Pleiades, the seven daughters of Atlas and the Oceanid Pleïone, mother of Hermes (*q.v.*). (2) An obscure Roman goddess, also called Maiesta, the cult partner of Volcanus; commonly confused with (1) in poetry and later cult.

MAIDA, a village in the province of Catanzaro, Calabria, near the Gulf of Sant' Eufemia, It., 210 mi. S. of Naples. Pop. (1951) 4,603. The battle of Maida on July 4, 1806, is memorable as the first of many successes in the Napoleonic Wars gained by British infantry in line over French infantry attacking in column. Adm. Sidney Smith had landed Gen. Sir John Stuart with about 5,000 men to help the Calabrian guerrillas. Gen. E. Reynier swiftly brought 6,000 French; Poles and Swiss to Maida. Each general meant to fight, and each engaged his leading unit before the rest of his force could wheel into action on the flank.

The French 1st light infantry, described by the French general, Joachim hlurat, in 1802 as a "superb regiment," attacked in two columns, between which rode Gen. Compere, a noted leader of light troops, confident of breaking the English as he had broken the Neapolitans four months before. Col. J. Rempt faced them with seven companies of light infantry in line two-deep, thus able, as Sir Charles Oman observed, to fire 700 shots against 240 from the front of the 1,600 French. On the third volley, at 20 yd., the French broke; Compere was taken, wounded, in the British line; Rempt charged the fugitives, and the 1st infantry lost 430 prisoners as well as 42; killed and wounded. On their flank this disaster and the fire of Col. W. P. Acland's brigade shattered the next French column, 42nd line, as quickly, though with less loss, and Acland, advancing, took 250 prisoners from a Polish regiment. With three regiments beaten Reynier was forced to retreat; the engagement developing on his right flank between Gen. Antoine Digonet's and Gen. Sir Galbraith Cole's brigades became a rearguard action and ended when a belated British battalion appeared on the flank. Reynier fled north, having lost 2,000 men. and it was a year before he regained Reggio. The battle had no other result. as Stuart had at once turned south, cleared some posts and returned to Sicily.

See Sir C. Oman, Studies in *the Napoleonic Wars* (London, 1929; New York, 1930). (I. D. E.)

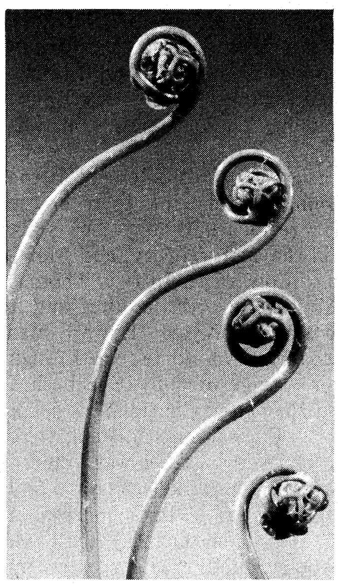
MAIDAN, a term used in Morocco and other parts of the Arabic-speaking east for an open space, usually in front of a palace. It is used generally in the middle east to signify an open plain; *e.g.,* Maidan park, Calcutta. It is a common part of place names in Afghanistan and Iran.

MAIDEN or MAID, a young unmarried girl. Maid is a shortened form of maiden. O Eng. *nzaegden,* which represents a diminutive of a Teutonic word meaning "young person," of either sex. An old English word "may," meaning a kinsman or kinswoman, and also a virgin or girl, represents the original. In early usage maiden as meaning virgin is frequently applied to the male sex, thus. in Malory's *Morte d' Arthur,* Sir Percyvale is called a "parfyte clene megden."

The title of maid of honour is given to an unmarried lady attached to the personal suite of a queen. The custom of sending young girls of noble or good birth to the court of a prince or feudal superior, for the purpose, primarily, of education, goes back to early feudal times, and is parallel with the sending of boys to act as pages and squires to the feudal castles. The regular establishment of maids of honour (*filles d'honneur*) appears first in the French court. As an institution they were suppressed in the reign of Louis XIV, at the instigation of Mme. de Montespan — who had been one of them — and their place was taken by the *dames de palais.* In the English court. this custom of attaching maids of honour to the queen's person was no doubt adopted from France. At the present day a queen regnant has eight maids of honour, a queen consort four. They take precedence next after the daughters of barons, and where they have not by right or courtesy a title of their own, they are styled "Honourable."

THE SCOTTISH MAIDEN was an instrument of capital punishment formerly in use in Scotland. It is said to have been invented by the earl of Morton, who is also said to have been its first victim. But the maiden was first used at the execution of the inferior agents in the assassination of David Rizzio (1566) and hlorton was not beheaded till 1581. The maiden was practically an early form of guillotine. A loaded blade or axe moving in grooves was fixed in a frame about 10 ft. high. The axe was raised to the full height of the frame and then released) severing the victim's head from his body. At least 120 suffered death by the maiden, including the regent Morton, Sir John Gordon of Haddo, President Spottiswood, the marquis and earl of Argyll. In 1710 it ceased to be used; it is now preserved in the museum of the Society of Antiquaries of Scotland, in Edinburgh.

MAIDENHAIR, the common name for the plants of a large genus of ferns, *Adiantum,* comprising about 200 species of dainty shade-loving forms with shiny black or purplish stipes and thin delicate fronds or leaf blades, either simple or divided icto fan-shaped segments or pinnules. Sori are marginal, short, borne on the underside at edge of the more or less altered margin of the pinnule, the margin reflexed to form a kidney-shaped indusium. The genus is largely of tropical America, nith a few species in temperate North America. *A. capillus-veneris,* Southern maidenhair or Venus' hair. occurs in temperate and tropical America, in the warmer parts of the old world and is a popular plant in greenhouses *A. pedatum,* a larger and beautiful fern. grows in woods from Nova Scotia to Alaska and southward from Florida to Texas. Adiantum is the ancient name. meaning unwetted, the foliage shedding raindrops.



ROCHE

MAIDENHAIR. UNOPENED FRONDS

Maidenhair tree is the popular name for *Ginkgo biloba,* a remarkable and handsome gymnospermous tree, the fan-shaped leaves of which with their forked veins resemble those of the maidenhair ferns. *See* GINKGO OR MAIDENHAIR TREE; GYMNOSPERMS. (J. M. BL.)

MAIDENHEAD, a municipal borough in the Windsor parliamentary division of Berkshire, Eng., on the Thames, 12 mi. N E. of Reading by road. Pop. (1951) 27,145. Area 7.8 sq.mi. Edward I gave a grant of pontage in aid of Maidenhead bridge in 1297 and in 1451 Henry VI incorporated the guild of the Brethren and Sisters of Maydenhith to keep the bridge in order; Elizabeth I in 1581 substituted for it a corporation. The present bridge is of stone and dates from 1772. It carries the London traffic over the Thames. In the 18th century a considerable river trade was done in malt, meal and timber; today Maidenhead is a residential and holiday town with much boating in the summer and with some light industries, such as engineering and the making of precision instruments, preserves and confectionery. There are research laboratories in the district. The railway bridge, designed by Isambard Brunel and built in 1838 has one of the largest brick spans in the world. The governing charter of the town until the 19th century was that of James II (1685).

MAID MARIAN, a personage incorporated in the English legend of Robin Hood (*q.v.*). She seems to have been an essential feature of the morris dance, and in the may-game was paired sometimes with Robin Hood, but oftener with Friar Tuck. The well-known pastoral play of Adam de la Hale, *Jeu de Robin et Marion,* and the many French songs on the subject, account for the association of the names. In the ballads on Robin Hood her name is only twice mentioned, but there is a late ballad, by a certain S. G. (F. J. Child, *English and Scottish Ballads,* i, 219), which tells how Maid Marian sought Robin in the forest disguised as a page, and fought with him for an hour before she recognized him by his voice. S. G. was perhaps acquainted with the two plays, written in 1598, of *The Downfall* and *The Death of Robert Earl of Huntingdon,* by Anthony Munday and Harry Chettle. In *The Downfall,* Matilda Fitz Walter escapes from the persecution of King John by following her lover to Sherwood forest, where they take the names of Robin Hood and Maid Marian. Perhaps this tale has some connection with the romance of the outlaw, Fulk Fitz Warin. Matilda or Mahaud, widow of Theobald Walter, escaped from John's solicitations by marrying the outlawed Fulk and following him to the forest. There were in semihistorical legends three Matildas pursued by King John, of whom particulars are given by H. L. D. Ward in his *Catalogue of Romances* (i. 502). Their several histories were fused by the Elizabethan dramatists, and associated with the Maid Marian of the morris dance who up to that time had probably only a vague connection with Robin Hood.

MAIDSTONE, a market town and municipal borough and the county town of Kent, Eng., in the Maidstone parliamentary division, about 41 mi. E.S.E. of London by road. Pop. (1951) 54,035. Area 9.3 sq.mi. There is evidence of Roman rural settlement, but the name Maidstone (Meddestane in Domesday Book; later Maeghan stane), probably meaning "the Maiden's stone," is presumably Saxon.

At the time of the Domesday survey the town belonged to the archbishop of Canterbury, and from the reign of John to the Reformation the archbishops had a residence there. The shire moot was held on Penenden heath in the 11th century, and Maidstone was an assize town in the reign of Edward I. In 1537 Thomas Cranmer exchanged the manor of Maidstone with the king, and it was granted by Edward VI to Sir Thomas Wyat. Edward also incorporated the town but this charter was forfeited through Wyat's rebellion. A second charter was granted by Elizabeth I (1559), others by James I (1604 and 1619) and Charles II (1682), and a new one by George II (1747). Four fairs, still held, were granted by the charter of 1559. A Thursday market was granted by Henry III to Archbishop Boniface, and a market every second Tuesday in the month by charter of George II. A cattle market on Monday and a produce and general market on Tuesday are held.

The manufacture of linen and woolen goods was increased by Walloons, who settled there in 1567, and was succeeded by papermaking, later the chief industry of the district. Maidstone is also the principal grain centre in the county. The cultivation of hops has been carried on since the 17th century, and there are large breweries and maltings. Other industries are confectionery, quarrying for Kentish ragstone, agricultural implement making, iron founding, and manufacturing hop bags, matting, sacking, etc., besides cement and lime works. The water traffic on the Medway is comparatively small.

Archbishop Boniface in about 1260 established a hospital there (Newark) for poor travelers, the chapel of which, with modern additions, is St. Peter's church. The demolition of the parish church of St. Mary. which had existed from Norman times, was begun in 1395 by Archbishop William Courtenay, who erected on the site the present church of All Saints. The remains of Courtenay's college of secular canons are interesting late 14th-century architecture. The grammar school was founded in 1549 and endowed with the estates of the local Corpus Christi fraternity, then dissolved; the medieval hall remains, but the school is in modem buildings on a new site.

A municipal museum, with public library, was opened in 1858 in a Tudor building, which is also the headquarters of the Kent Archaeological society. A museum of carriages, the only one of its kind in the British commonwealth was opened in 1946. From Saxon times down to 1830 executions and all the great county meetings took place on Penenden heath, a common enclosed in 1882 as a public recreation ground. In 1929 the corporation bought the Mote estate of 558 ac. and converted it into a public park and housing estate. A new courthouse was opened in 1937. The borough has its own courts of quarter sessions and summary jurisdiction.

MAIDU. This Indian group, of Penutian (*q.v.*) stock, lived in California east of the Sacramento river. Dialectically it comprises three divisions, northwestern, northeastern and southern or Nisinan; but a physiographically founded cultural cleavage into Maidu of the valley, foothills and mountains is more significant. The valley division was wealthiest and most advanced, and together with the Patwin west of the Sacramento had developed the Hesi form of the Kuksu cult, a spirit-impersonating religion with initiating societies, which appears to mark the culminating point of central Californian culture. The name Maidu, pronounced Mydoo, means "people." The population, which was originally from 8,000 to 10,000, had declined to 1,100 (including mixed bloods) by the end of the first decade of the 20th century.

MAIL: *see* ARMS AND ARMOUR; POST AND POSTAL SERVICES.

MAILLART, ROBERT (1872–1940), Swiss engineer, renowned for his pioneering work in reinforced-concrete flat-slab construction and the unsurpassed beauty and elegance of his bridges, was born in Bern. Switz., June 2, 1872. He was educated at the Federal Institute of Technology, Zurich (1890–94); then worked in France with François Hennebique. who had the first reinforced-concrete construction firm. In 1902 Maillart founded his own engineering firm in Zurich. He went to Russia in 1912, where he constructed factories and warehouses in Kharkov. Riga and St. Petersburg (Leningrad) for Swiss companies. After the Russian Revolution he returned to Switzerland financially ruined. In 1919 he again founded an engineering firm and continued construction until his death in Ziirich on May 4, 1940.

Among Maillart's works are bridges, spun airily over space, belonging to the purest expression that the modern era has been able to achieve. They include the Tavanasa bridge (1905), span 170 ft.; Salginatobel bridge (1929–30), span 307 ft.; Thur bridge (1933), span 240 ft.; a bridge over the Arve river near Geneva (1936–37), span 187 ft.: and bridges at Lachen (1940) and over the Simme river (1940). His was the first mushroom column, flat-slab construction, for a warehouse in Ziirich (1910).

See E. B. *Mock, The Architecture of Bridges* (1949). (S. GN.)

MAILLOL, ARISTIDE (1861–1944), French sculptor, whose primary importance rests on his monumental studies of the nude, was born at Banyuls-sur-Mer, Rousillon, on Dec. 8, 1861. At first a painter, he studied at Perpignan and, from 1882 to 1886, in Paris with Alexandre Cabanel. Like many young artists at this time, he then abandoned easel painting, taking up tapestry and wood carving and, about the turn of the century, began to work on a grand scale in clay, marble and bronze. At that time Maillol began to be influenced by the "synthesist" movement of Paul Gauguin (*q.v.*) and to some extent by his powerful wood carving, and by Maurice Denis and his concern with statuesque calm, order and unity at the expense of detail.

This equipment was strengthened in the first decade of the 20th century by a reappreciation of the archaic art of Greece (which Maillol visited in 1909); and it gave his work qualities which at once distinguished it from the intensely emotional and disrupted forms of Auguste Rodin, then powerfully influential.

Closely based on the living model, Maillol's work is nonetheless formal and he is preoccupied with over-all unity and balance. The emotional force of his work depends on disciplined relationships of mass and direction, and this control distinguishes it again from Rodin's frequent dependence on accidental effects of surface. Among Maillol's large works are the reclining figure of

"Fame" in the Tuileries gardens, Paris (a monument to' Paul Cézanne); the war memorials at Elne, Céret and Port Vendres; the standing figure of "Flora" (1911), based on a study of the Olympian sculptures; and the "Crouching Woman" made for his friend Count Kessler. There is a portrait head of Auguste Renoir (1907), between whose sculpture and Maillol's there is an affinity. He also worked in high-relief in stone and made fine terra-cotta statuettes, and his drawings and the book illustrations of his late years are of high quality. He died after a road accident near his birthplace in Oct. 1944. (D. C. T. T.)

MAILLY, LOUISE JULIE, COMTESSE DE (1710–1751), mistress of Louis XV of France, was the daughter of Louis, marquis de Nesle. She was the eldest of three sisters who succeeded one another as favourites of the king. In 1726 she married her cousin, Louis-Alexandre de Mailly. Although Louis XV had paid her attentions from 1732, she did not become titular mistress until 1738. She did not use her position to enrich herself, but she did have some influence in politics, being a patroness of Charles Fouquet, duc de Belle-Isle.

She was supplanted by her sister, the duchess of Châteauroux, and obliged to leave court in 1742.

MAIL-ORDER BUSINESS. In mail-order business, a retail commercial enterprise carried on primarily by mail, customers order from illustrated catalogues, circulars or advertisements in periodicals. Orders are placed by mail, filled from stock and usually delivered to the customer by parcel post, freight or express. In metropolitan communities, the general mail-order house may deliver the merchandise directly by truck.

By far the largest number of the hundreds of mail-order companies in the United States are small specialty sales firms. There are also numerous department stores which do a significant volume of business through their mail-order departments. The great bulk of the total mail-order business, however, is done by a few firms selling general merchandise lines. The largest and most advanced of mail-order companies are Sears, Roebuck and Co. and Montgomery Ward and Co., Inc.

Responding to major population shifts, the large mail-order companies established hundreds of retail stores across the country in the years after 192j. By mid-century the retail store sales volume of the largest firms exceeded that of their mail-order divisions. In addition to conventional over-the-counter selling, these retail stores characteristically include facilities for customers wishing to order goods through catalogues. In certain areas, catalogue offices have also been established where sample merchandise is displayed and where customers may order by mail after inspecting the samples. Another development in mail-order distribution in the large companies is that of the telephone ordering service, particularly popular in urban areas. Customers may select merchandise and order directly by telephone.

Mail-order operations have been known in the U.S. in one form or another since colonial days, but not until the latter part of the 19th century did this form of distribution assume a significant role in domestic trade. The great agricultural expansion in the U.S. together with the completion of the continental railroad network combined to provide a basic opportunity for a new form of distribution. The general merchandise mail-order houses developed to take advantage of the favourable market situation which was being inadequately serviced by conventional retailing outlets in rural areas. One of the impelling forces leading to the original success of the mail-order companies in rural markets was that they brought a variety of merchandise to the isolated farm buyer at comparatively low prices. Its great growth was stimulated by a postal rate structure which encouraged the wide dissemination of the early mail-order papers and later the distribution of catalogues. The establishment of the parcel-post system in 1913 added another important auxiliary to the continued expansion of mail-order operations.

Of significant importance in encouraging the growth of the early mail-order companies was the general antagonism U.S. farmers felt toward middlemen. The American Grange was especially vocal in expressing the resentment of the agricultural population toward what farmers considered the excessive size of distributors' trading margins. The early advertising copy of the mail-order companies capitalized effectively upon this unfavourable attitude of many farmers toward the merchant class, and the earliest years of Montgomery Ward and Company saw a close association between the company and the Grange. Members of the Grange were given special inducements to trade with Montgomery Ward when the company was founded in 1872.

The established mail-order houses came to be uniformly respected by both their customers and their competitors for adopting policies of full guarantees on merchandise and liberality in making adjustments. Although the companies were leaders in the movement for accurate and informative advertising of essentially reputable merchandise, this was not always the case. Indeed, the early years of the business were marked by something less than a high standard of ethics and by intensive advertising campaigns which attempted to exploit every possible opportunity to glorify the merchandise and to impel the incautious customer to buy. Modern mail-order catalogues, however, are nearly models of propriety and truthfulness in advertising.

The most successful mail-order companies have enjoyed certain sources of economy which are common to large-scale merchandising. They buy in large quantities; they frequently order merchandise manufactured to their own specifications: and in many cases they arrange for the production of their orders on a schedule which permits the supplier to sell at lower margins than he would otherwise demand. In some cases the large Arms contract for the entire output of particular manufacturers, and occasionally the mail-order company is completely integrated in terms of ownership of factory outlets, although this is not common.

Apart from the economies of large scale buying and selling, the mail-order operation offers certain opportunities for operating economies, since the mail-order plants themselves are essentially warehouses and may be located in relatively low rent areas. Further economies are achieved in the handling and shipping of merchandise. Orders to the mail-order company correspond to customers in the retail store, but the mail-order house has the advantage that the number of orders (or customers) at any given time of the day can be controlled. Under the schedule system originated by Sears. Roebuck and Co., the largest of all mail-order houses, orders are scheduled every 20 minutes, and the quantity in any 20-minute period depends upon the number of orders received during the day.

One mail-order firm in the mid-1950s was receiving more than 5,000 lbs. of first-class mail at all of its branches in an average day. This represents a total of approximately 300,000 letters. The mail is weighed before it is taken out of the sacks in which it arrives, and the company is able to determine the number of orders on the basis of the weight of the day's incoming mail. A thousand pounds of mail averages 55,000 letters, of which experience indicates a given percentage constitutes orders. Long experience has also demonstrated that the volume of orders received in the morning mail is a reliable index of what the day's order load will be. Given such information at the beginning of the day, it is possible to fix shipping times on a regular schedule and to pass orders along to the various merchandise departments at a rate which will keep them running at a steady pace.

Machines and mechanical aids of many types are employed. Man power is eliminated wherever a machine will be more efficient. Machines open the mail at the rate of 450 letters per minute. Pneumatic tubes, endless belt conveyors, chutes and electric trucks are used in the distribution of orders to the numerous merchandise departments into which the mail-order house is organized. Paralleling these mechanical facilities, personal effort is organized along highly specialized lines.

Throughout the entire system of buying, handling and shipping, substantial savings of time and money are achieved, which are reflected in the retail prices found in the mail-order catalogue, the primary selling instrument of the important mail-order firms.

The mail-order houses contributed substantially to improving the efficiency of retail distribution in the United States. Perhaps more important than any other single service was their effect in breaking the local monopolies of retail stores in once isolated areas by providing rural buyers with a feasible means for purchasing a wide variety of merchandise at relatively low prices.

While company sales volume of the largest mail-order firms is enormous, the relative importance of mail-order sales to retail trade in general is not great. Mail-order sales constituted less than 1% of the total retail sales volume in the United States in the mid-1950s.

MAIMANA, a town and khanate of Afghan Tui-kistan. The town is situated 100 mi. S.W. of Balkh, and only about 25 mi. from the frontier of Russian Turkistan. It is about two-thirds the size of Herat, square built and surrounded by a ruined wall and moat. The khanate was long in dispute between Bukhara and Kabul, but in 1868 Abdur Rahman laid siege to the town, and it was compelled to come to terms.

Its political status as an Afghan province was definitely fixed by the Russo-Afghan boundary commission of 1885. The inhabitants are chiefly Czbegs.

MAIMBOURG, LOUIS (1610–1686), French Jesuit and historian, an energetic defender of Gallican liberties in his *Traitd historique de l'établissement et des prerogatives de l'Église de Rome et de ses évêques* (1685; new ed., 1831). Born at Nancy on Jan. 10, 1610, he entered the Society of Jesus at the age of 16. His works include *Histoire du lutheranisme* (1680) and *Histoire du calvinisme* (1682), which was useful to the French government as propaganda for the revocation of the Edict of Nantes. His defense of French liberties in his *Traitk* was bitterly resented by Pope Innocent XI, who ordered the Jesuits to expel him. Louis XIV granted him a pension and a retreat at the abbey of St. Victor, Paris. He died on Aug. 13, 1686.

His works were published in 14 volumes (1686–87).

MAIMING, mutilation, a physical injury which involves the loss of, or incapacity to use, a bodily member. Maiming or mutilation is and has been practised by many peoples with various ethnical and religious significances, and was a customary form of punishment on the principle of an "eye for an eye." *(See* MUTILATIONS AND DEFORMATIONS.)

In law "maiming" was made a criminal offense; the old law term employed for a special case of maiming of persons was mayhem (*q.v.*), an Anglo-French variant form of the word. The punishment incurred for maiming of cattle in Great Britain was set at 13 to 14 years of penal servitude. Malicious injury to other animals was made a misdemeanour punishable on summary conviction. For a second offense the penalty was set at imprisonment with hard labour for more than 12 months under the Malicious Damage act of 1861. In both British and U.S. law maiming means the permanent injury of the animal; mounding or otherwise mistreating an animal is a separate offense.

MAIMON, SALQMQN (*c.* 1754–1800), Jewish philosopher who was acknowledged by Kant to be the most acute of his critics, was born about 1754 at Nieswiez in Polish Lithuania and was married off by his father at the age of 11. He gained a remarkable proficiency in Hebrew, studying outside the conventional limits of the Talmud, and acquired a particular reverence for Maimonides (*q.v.*), in whose honour he took the surname Maimon instead of the original patronymic Ben Joshua. In 1770 he estranged himself from his orthodox coreligionists by a commentary on Maimonides' *Guide of the Pevplexed.* Eight years later he left Poland for Konigsberg to begin a life of material insecurity and wandering over northern Europe only terminated in 1790 when he was offered the retreat on the estate of Count Adolf Kalkreuth at Nieder-Siegersdorf (Silesia), where he died on Nov. 22, 1800.

Nearly all Maimon's philosophical works were published during the years 1790–1800, including the two by which he is best remembered: the autobiography edited for him as *Salomon Maimons Lebensgeschichte* by Karl Philipp Moritz (1792); and *Versuch über die Transcendentalphilosophie* (1790), formulating his objections to Kantian philosophy. In this work Maimon seizes upon the fundamental incompatibility of a consciousness which can apprehend, yet is separated from, the thing-in-itself. That which is object of thought cannot be outside consciousness; just as in mathematics $\sqrt{-1}$ is an unreal quantity, so things-in-themselves are *ex hypothesi* outside consciousness, that is to say, unthinkable. The Kantian paradox he explains as the result of an attempt to explain the origin of the "given" in consciousness. The form of things is admittedly subjective; the mind endeavours to explain the material of the given in the same terms, an attempt which is not only impossible but involves a denial of the elementary laws of thought. Knowledge of the given is, therefore, essentially incomplete. Complete or perfect knowledge is confined to the domain of pure thought. to logic or mathematics. Thus the problem of the thing-in-itself is dismissed from the inquiry, and philosophy is limited to the sphere of pure thought. The Kantian categories are, indeed, demonstrable and true, but their application to the given is meaningless and unthinkable.

By this critical skepticism Maimon takes up a position intermediate between Kant and Hume. Hume's attitude to the empirical is entirely supported by Maimon. The causal concept, as given by experience, expresses not a necessary objective order of things, but an ordered scheme of perception; it is subjective and cannot be postulated as a concrete law apart from consciousness.

Maimon's other published norks include *Philosophisches Wörterbuch* (1791); *Uber die Progressen der Philosophie* (1793); *Versuch einer neuen Logik* (1794); and *Kritische Untersuchungen uber den menschlichen Geist* (1797).

See Hugo Bergman (ed.), *The Autobiography* of *Solomon Maimon,* with useiul commentary (1954).

MAIMONIDES (MOSES BEN MAIMON) (1135–1204), also known from his initials, with his title rabbi, as RAMBAM, Jewish philosopher, physician and master of rabbinic literature, was born in Córdova, Spain, of an illustrious Jewish family and educated by his learned father. When Córdova fell to the Almohades in 1148 and the position of the Jews became intolerable, the family emigrated first to Morocco, then for a short while to Palestine and finally to Egypt. Maimonides eventually settled in Fostat, a suburb of Cairo, where he attained the position of *nagid* or accredited leader of Egyptian Jewry. He was appointed court physician to Saladin and was invited by King Richard I to come to England but refused the invitation.

Maimonides' greatest work in the rabbinic field is his *Mishneh Torah,* a kind of *summa theologiae* of Judaism, composed in an elegant and concise Hebrew, arranged in 14 books and offering a systematic presentation of the entire content of the rabbinic tradition. It was preceded by his *Commentary on the Mishnah* and by the *Book of Commandments,* both written in Arabic. The *Mishneh Torah* secured for Maimonides a commanding position in the development of rabbinic law and represents the first of a series of authoritative codes. From his early youth, Maimonides was attracted to Aristotelian philosophy as taught by al-Farabi and by Avicenna. At the age of 16 he composed a *Treatise on the Terminology of Logic;* and his *Commentary on the Mishnah* embodies a fair amount of philosophy, especially in the *Eight Chapters* prefacing his comments on the tractate *Aboth.* The same applies to his code, which opens with an outline of his metaphysics and ethics. His celebrated *Guide of the Perplexed* contains the ripe fruit of his philosophical thinking and exercised considerable influence on both Jewish and Christian scholasticism. Written in Arabic, it seeks to interpret the biblical and rabbinic theology in terms of Neoplatonic Aristotelianism.

The first book of the *Guide* discusses the figurative meaning of anthropomorphic expressions applied to God in the Scriptures and examines the propriety of the various types of attributes or predications of God. The essence of God can be neither defined nor described. Existence is not something added to, but implied in, the essence of God. The *via negativa* is the only admissible way of speaking about God's essence; that is to sap, me can deny all positive statements about God which imply a deficiency. But we may also admit "attributes of action" such as justice. love, etc.. seeing that they do not touch upon the mystery of His hidden essence and describe only God's relation to the world in terms of cause and effect. The first book concludes with a comprehensive statement of the principles of the Arabian Mutakallimun (Kalamists) and their refutation. The second book proves the existence of God by the argument of the unmoved mover and by the distinction between the necessary and the possible and between the necessary and the contingent. Aristotle's cosmology is accepted in outline, and the separate intelligencies of Neoplatonic Aristotelianism moving the celestial spheres are identified with the angels of Scripture. Aristotle's doctrine of the eternity of the world Maimonides finds less acceptable, not because it contradicts the plain meaning of Scripture (this could, if necessary, be interpreted allegorically) but because it runs counter to the fundamental biblical notion of a God not bound by necessity and creating the world freely. Maimonides makes the point that unless we allow for the free operation of God's will the irregularities in the planetary motions cannot be explained. The second book also discusses the nature of prophecy: the prophets of the Bible are described as combining intellectual insight with the strongest imagination; their visions represent intuitive intellections concerning the spiritual world and their dreams future events. Following al-Farabi's The Model State and Avicenna's discussion of prophecy, Maimonides sees in the type of the prophet a kind of Platonic philosopher-king, the lawgiver of the ideal state. The third book treats of the nature of evil, of providence, of design in nature, of the historical background of the biblical ritual (this section is important as an early essay in comparative religion) and of moral virtues as steppingstones to the contemplative life. See also JEWISH PHILOSOPHY.

Editions of the Guide are: by S. Munk, Arabic text with French translation and valuable notes, 3 vol. (1856–66), English translation by M. Friedlander, 3 vol. (1881–85), and reissue, 1 vol. (1925), and German translation by A. Weiss, 3 vol. (1923). There is also an English translation of selected passages by C. Rabin, with introduction and commentary by J. Guttmann (1952).

Other texts include the Treatise on the Terminology **of Logic,** edited with English translation by I. Efros (1937–38); Eight Chapters, English translation by J. I. Gorfinkle (1912); and sections from the *Mishneh* Torah in English translation by M. Hyamson (1949 et seq.).

See bibliographies compiled by J. L. Gorfinkle in I. Epstein (ed), *Moses Maimonides, 1135–1204,* pp. 229–248 (1935); and by G. Vajda in *Jüdische Philosophie,* pp. 20–24 (1950). (A. AN)

MAIN, a river of Germany, 32j mi. long and the most important right-bank tributary of the Rhine. It has two sources, the Weisse blain (White Main) vhich rises in the granitic rocks of the Fichtelgebirge, and the Rote Main (Red Main), which, rising on the eastern slope of the Jurassic rocks of the Frankish Jura, flows past Bayreuth. They unite near Kulmbach after which the river, flowing northwest keeps to the Trias, and flows round the north end of the Frankish Jura to Bamberg. There it receives its chief tributary, the Regnitz (left), and enters upon its middle course. Flowing amid vine-clad hills it passes Würzburg, and thence, dividing the forest-clad ranges of the Spessart and the Odenwald, reaches Gemiinden. There it is joined by the Frankish Saale (right) and turning abruptly south, receives at Wertheim the beautiful Tauber (left). From the latter it proceeds due north to Aschaffenburg, whence passing Frankfort it joins the Rhine just above Mainz. It is navigable from the confluence of the Regnitz for barges and other small craft, and through the Ludwigs canal is connected with the Danube. See RHINE.

MAIN, power or strength; *e.g.,* the expression "with might and main" (Lat magnus, "great"). "The main." the high open sea. is for 'main sea," **cf.** "mainland," the principal part of a territory excluding islands and sometimes far-projecting peninsulas. The "Spanish main" was the mainland of the northeast coast of South America, stretching from the Orinoco to the isthmus of Panama, and the former Spanish possessions in Central America bordering on the Caribbean sea, or more loosely, the Caribbean sea itself. The principal pipe or cable for gas, water, electricity, etc., is called the main.

MAINA (or MANI) and **MAINOTES,** a district and people of the Peloponnesus. the modern Morea. Maina is the country occupied by the mountain range of Taygetus from Sparta to Cape Matapan, the ancient Taenarum. It is now divided between the modern districts Oetylos and Gythion. It contained over a hundred villages. The Mainotes claim to descend from the Spartans, and probably represent the Eleuthero Laconians delivered by Rome from the power of Sparta, as is suggested by traces of ancient Greek in their dialect and by their physical type. They did not become Christians till the 9th century.

Their country being a natural fortress, they were able to defend themselves against the Byzantine emperors, the barbarian invaders, the Latin princes of Achaea of the house of Villehardouin, and the Turks. As their country is also poor and maritime, they were early tempted to piratical adventure. Gibbon has referred to "the inhuman pillage of all that is shipwrecked on their rocky shore." Their neighbours gave their country the name of "Kakoboulia"—the land of wicked counsels. The passes of their mountains and their villages were fortified, so leading to their favourite epithet, Maina Polypyrgos—"many-towered." On the western side are the remains of feudal keeps, erected by William II. de Villehardouin (1245–1278) and other Latin princes of Achaea. From the 15th till the 17th century they recognized as head chiefs a family which claimed to belong to the Comneni of Trebizond. But the real power was in the hands of chiefs, a turbulent and martial aristocracy. Feuds were enduring and ferocious.

In the 18th century the family of Mavromicheli (Black Michael), in lower Maina, established a general headship after much strife and many murders. The Mainotes rose against the Turks at Russian instigation in 1770 and managed to gain virtual independence in 1777. During the Greek war of independence the Mainotes were led by Petros (Petro Bey) Mavromicheli. "the king of Maina," who undoubtedly cherished the hope of establishing a principality for himself. The freedom of Greece, for which he had fought in his own way, was the ruin of his ambition. He found the new order less compatible with his schemes than the Turkish dominion, and was imprisoned by the Greek president Capodistrias (see KAPODISTRIAS, IOANNES ANTONIOS), who was in revenge murdered by the Mavromichelis. The family were finally content to become courtiers and officials in the reign of King Otho I. In the 19th century Maina was but little affected by civilization, except so far as navies prevented piracy.

See W. Martin Leake, *Travels in the Morea* (1830); M. E. Yemeniz, "La Maina," in *Revue des deux mondes* (March 1, 1865); and Philipson, "Zur Ethnographie des Peloponnes," in *Petermanns Mittheilungen, vol. 36* (Gotha).

MAINAN, an independent linguistic stock of South American Indians, so called from the Mainas, one of its important tribes. This stock occupies a considerable area in north-eastern Peru, on the north side of the Marañon between the lower Pastaza and Tigre rivers, and south of it on the Samiria and lower Huallaga rivers, extending to the Mayo, and westward to the Potro. The Jeberos (Xeberos), often confounded with the Jivaran (*q v.*), are members of this group. The tribes of this stock were sedentary agriculturists, pottery and textile makers, and greatly given to taking enemy heads, shrinking and preserving them as do the Jivaros. They now retain little of their original culture.

See F. de Figueroa, "Relación de las Misiones . . . *en el Pais de los Maynas,"* vol i (1904).

MAINE, SIR HENRY JAMES SUMNER (1822–1888). English jurist and historian, a pioneer in the study of comparative law. was born on Aug. 15, 1822. He was educated at Christ's hospital and Pembroke college. Cambridge, where he excelled in classical studies. From 1847 to 1854 he was professor of civil law at Cambridge university and also began lecturing on Roman lan at the Inns of Court, the legal centre in London. These lectures formed the groundnork for his first book. Ancient **Law** (1861; new ed. 1930), which made his reputation at one stroke. Its object was "to indicate some of the earliest ideas of mankind. as they are reflected in ancient law. and to point out the relation of those ideas to modern thought." Historical in approach and objective in method, the work drew upon Roman law, systems of both western and eastern Europe, laws of India and primitive law in order to trace and define basic concepts. Although some of his statements necessarily were modified or invalidated by later research, Maine helped put the study of comparative jurisprudence on a sound historical footing. *Ancient Law* also was influential in political theory and, because of its controversial theories on primitive law, in anthropology.

From 1863 to 1869 Maine was a legal member of the council of the governor general in India. where he was largely responsible for plans for the codification of Indian law. He also served as vice-chancellor of Calcutta university. Upon his return to England he became, in 1869, the first professor of historical and comparative jurisprudence at Oxford and, in 1887, professor of international law (a subject that occupied his later years) at Cambridge. The recipient of many honours during his lifetime, he died on Feb. 3, 1888, at Cannes, Fr.

Maine's other books include *Village Communities in the East and West* (1871); *Early History of Institutions* (1875); *Dissertations on Early Law and Custom* (1883); *Popular Government* (1885). *See* also JURISPRUDENCE, COMPARATIVE: *Influence of Philological Research.*

MAINE, an old French province, bounded north by Normandy, east by Orléanais, south by Touraine and Anjou and west by Brittany. Under the Romans it consisted of two *civitates* in the Provincia Lugdunensis Tertia—the Civitas Cenomannorum and the Civitas Diablintum, whose chief towns were Le Mans and Jublains. These two *civitates* were united during the barbarian period and formed a single bishopric, that of Le Mans, suffragan to the metropolitan see of Tours. This diocese corresponded under the Merovingians and Carolingians to the Pagus Cenomanensis and in the feudal period to the county of Maine. In the 16th century the county of Maine, with the addition of Perche, formed a military government—the province of Maine. Since 1790 this province has been represented approximately by the *départements* of Sarthe and Mayenne, the respective capitals of which are Le Mans and Laval. In 1855 the bishopric of Laval was separated from that of Le Mans. Roger (*c.* 892–*c.* 898) was perhaps the first hereditary count of Maine. In the 12th century Maine was attached to Anjou (*q.v.*) until 1204, when it was united to the royal domain. In 1246 it was given, with Anjou, by Louis IX to his brother Charles (Charles I of Naples). Again united to France in 1328, it was given in 1356 as an appanage to Louis, second son of King John II, and did not return to the French crown until 1481, after the death of Charles II, count of Maine. During the Hundred Years' War, Maine was taken in 1425 by the English, who lost it in 1448.

MAINE, popularly called the "Pine Tree" state, is the most northeasterly state of the United States and the largest state in New England; it was admitted to the union in 1820 as the 23rd state. It is bounded on the northwest by the Canadian province of Quebec; north and east by New Brunswick; south-southeast by the Atlantic ocean; and west by New Hampshire. It has an area of 33,215 sq.mi., 2,203 sq.mi. being water surface; in size it ranks 39th among the states.

The state capital is Augusta (*q.v.*). The white pine is the state's official tree, the white-pine cone and tassel the state flower and the chickadee the state bird. The flag is a blue field upon which is embroidered the state's coat of arms.

PHYSICAL GEOGRAPHY

Physical Features.--Maine lies between the extremes of approximately 43" 4' and 47° 28' N. lat. and 66° 57' and 71" 7 W. long. Considering the area as a whole, the surface of Maine is a gently rolling upland, above which rise mountain peaks, isolated and in clusters, and below which are numerous river valleys. The highest peak is Mt. Katahdin (5,268 ft.), other high mountains being Saddleback mountain (4,116 ft.), Mt. Abraham (4,039 ft.), Mt. Bigelow (4,150 ft.) and Mt. Blue (3,187 ft.). A little north of this line of mountain peaks is the water parting which divides the state into a north slope and a south slope. The north slope, though hilly in the middle and west, is so poorly drained that swamps abound in all sections. The south slope, which contains nearly all the mountains and is generally more hilly, has a mean descent toward the sea of about seven feet to the mile.

During the period of the great continental glaciation, Maine was overrun by the glacial icecap, which left more than 1,600 lakes scattered throughout the state. Few other states have so many large lakes of such beauty, and they contribute largely to a constant supply of water power, for which the rivers of southwest Maine are exceptionally well adapted. Moosehead lake (about 117 sq.mi.) is the largest lake in Maine and the largest inland body of water wholly in New England; the Kennebec river is its principal outlet. Other lakes, such as the Rangeleys, the Chesuncook and Twin lakes, on the Penobscot, and the Grand lake, at the headwaters of the St. Croix river, equal Moosehead's picturesque setting.

Another important feature of Maine's physiography is the irregular coast line with its numerous islands and bays and many good harbours. The shortest distance between extremities of the coast is only 225 mi., but because of projections and indentations the coast line measures about 2,500 mi. West of the mouth of the Kennebec river are marshes and low grassy islands, but east of the river the shore becomes much bolder and rises in precipitous cliffs. Casco, Penobscot and Passamaquoddy bays are representative of the capacious and well-protected harbours.

The principal river systems of Maine are the St. John on the north slope and the Penobscot, Kennebec, Androscoggin and Saco, with numerous falls and rapids, on the south slope.

Climate.—The climate of the state is moist and rather cold. The precipitation is about 42.5 in. annually and is distributed very evenly throughout the year, 10 to 11 in. of rain or its equivalent in snow falling each season. The snowfall varies from about 60 in. on the coast to more than 100 in. on the north slope, the average for the state being about 83 in. The summers are short, with a growing season of only about 4½ months. The mean summer temperature is about 62° F., the mean winter temperature approximately 20° F. The mean annual temperature for the entire state is 42° F.

Soil.—The soil types, though exceedingly varied, are in general poor, as a result of glaciation. The most productive area of the state is the potato-growing region in Aroostook county.

Vegetation.—Maine once was famous for its virgin stands of white-pine trees, and there still exist great numbers of white pine, fir and spruce. Among the other kinds of trees are hemlock, balsam fir, red and burr oak, white and yellow birch, sugar and mountain maple, box elder, tamarack, red spruce, white cedar, black willow, aspen poplar, beech, white or American elm (especially typical of New England), mountain ash and wild fruit trees. The flowers and blossoming shrubs are those that are common to the north temperate zone. Among the more widely distributed ones are the anemone, all kinds of asters, wild bergamot, bittersweet, black-eyed Susan, clover, daisy, blue flag, goldenrod, many varieties of lilies and the trailing arbutus. Devil's-paintbrush, pinks, rhodoras, wild roses and violets also grow in profusion.

Animal Life.—Perhaps the most numerous of the wild animals common to Maine are deer. more than 40,000 of which are killed annually by hunters. Others are black bear, beaver, red fox, otter, mink, weasel, squirrel, rabbit, porcupine, muskrat, woodchuck and wildcat. Game birds native to the state include the Canada goose, wood duck, ruffed grouse, pheasant and many others. Other birds are the American eagle and varieties of owls and loons, and, among songbirds, robins, orioles, bobolinks, kingbirds, swallows and chickadees. Trout, pickerel and salmon are plentiful in the lakes; coastal fish include tuna, cod and flounder.

Parks, Memorial Sites and Recreation.—Established in 1919 as Lafayette National park, with headquarters at Bar Harbor, Acadia National park is the only national park in New England and the oldest east of the Mississippi river. Baxter State park, in the northern Maine wilderness, has Mt. Katahdin as its chief attraction. Other state parks of interest include Aroostook State park. near Presque Isle, and Fort Knox State park, at Prospect, on the site of a fortification built after the Aroostook War. Among the memorial sites are Fort Edgecomb memorial, on Davis Island, built in 1808 to defend Wiscasset harbour; Fort Machias memorial, off which the British schooner "Margaretta" was captured early in the Revolutionary War; Fort McClary memorial, the first recorded fortification of the Massachusetts bay colony on the Maine side of the Piscataqua river; Fort George memorial, at Castine, which has earthworks and fortifications built by the British in 1779; Fort William Henry memorial. at Bristol: and Fort Popham memorial, at Phippsburg, on a site fortified during the Revolutionary War and the War of 1812 and meant to guard the entrance to the Kennebec river.

Maine's position as a favourite resort for summer vacationists dates from about 1870. when camps, summer hotels and boardinghouses began to multiply throughout the state. Maine is now one of the nation's leading vacation spots.

HISTORY

Discovery and Settlement. — Most historical scholars believe that Maine was sighted by Norsemen about A.D. 1000. but for lack of definite evidence the credit of discovering Maine passes to others. John Cabot probably saw Maine on his second voyage to the new world in 1498. Among the explorers of the 16th and early 17th centuries who reached hlaine were Giovanni da Verrazano (1524), Pierre du Guast, Sieur de Monts (1604), George Weymouth (1605) and John Smith (1614). Smith explored and mapped the coast and gave to the country the name New England.

At the time of these early explorations there were probably at least 25,000 Indians of the Algonkin group living in Maine, separated from the main body of Algonkins by their bitter enemies the Iroquois. They lived in semipermanent villages along the main rivers and subsisted on fish, game and a primitive agriculture, which featured corn and other garden vegetables. Property was owned in common. The manner of government varied from tribe to tribe.

In 1603 De Monts received from the king of France a grant of all the land between the site of Philadelphia and Newfoundland, and in 1604 he established a colony on St. Croix Island. at the mouth of the St. Croix river. Samuel de Champlain, the geographer of the expedition, explored the Maine coast, ascended the Penobscot and Kennebec rivers and discovered and named Mount Desert Island, on which Bar Harbor is now located. Bitter cold and scurvy reduced the St. Croix colony to less than one-half its original size by spring, when it was decided to relocate at Port Royal (now Annapolis Royal, Nova Scotia). In 1605 George Weymouth explored the St. George river area, captured five Indians and carried them to England, where three of them lived for a time in the family of Sir Ferdinando Gorges, who was to become the leader in founding Maine. In 1607 the Plymouth company, of which Gorges nas a member, sent out a colony, numbering 120 persons, under the direction of George Popham and Raleigh Gilbert. The colony was established at the mouth of the Kennebec river in August, but because of insufficient supplies about three-fifths of the company returned to England in December. Popham died during the winter and Gilbert assumed command. The next spring the news of the death of one of the colony's chief sponsors and a rich inheritance for Gilbert, together with the hardships of the winter, caused the colonists to abandon the settlement and return to England. In 1613 the French Jesuits Pierre Biard and Edmond Masse began the construction of a mission station on Mount Desert Island, but the station was destroyed by Sir Samuel Argall, acting under the instructions of the English at Jamestown. Va.

Proprietary Period and Massachusetts Ownership. — In 1620 the Council for New England, successor to the Plymouth company, obtained a grant of the country between 40" and 48° N., extending from sea to sea; and two years later Gorges and John Mason received the land between the Merrimack and Kennebec rivers under the name Province of Maine. In 1629 the territory was divided, with Gorges taking the portion between the Piscataqua and Kennebec rivers. In the early 1630s numerous land grants were made in the vicinity of Kittery, Wells, York, Saco, Scarboro and Falmouth (Portland), and permanent settlements were established. In 1635 the Council for New England surrendered its charter, but Gorges kept the land which had been granted to him, calling it New Somersetshire. In 1639 he procured a royal charter investing him with feudal powers. His charter, however, conflicted with other grants by the Council for New England; his authority was contested especially by George Cleeve, whose Lygonia patent issued by the council extended along the coast from the Kennebunk to the Kennebec.

Simultaneously, Massachusetts, fearing the royal authority in Blaine, reinterpreted its charter so as to make its northern boundary an east-west line 3 mi. N. of the source of the Merrimack river. This meant that blassachusetts laid claim to land as far east as Casco bay, or almost the whole of settled Maine. Massachusetts received the allegiance of Maine towns between 1652 and 1658. In 1677 Massachusetts purchased the claims of the Gorges family for £1,250 and held the province as a proprietor until 1691, when, by the new Massachusetts charter, hlaine mas extended to the St. Croix river and made an integral part of Massachusetts.

Maine was subjected to the rigours of six wars (known collectively as the Indian Wars) between 1675 and 1763. In four of these the French were active allies of the Maine Indians against the English. During the first three wars the English were virtually driven from Maine, but the tide turned permanently in their favour after the treaty of Utrecht in 1713.

During the American Revolutionary War, in 1775, the town of Falmouth (Portland) was burned as a reprisal for its defiance of British law. Benedict Arnold marched through Maine on his expedition to Quebec (1775), and the first naval engagement (the battle of the "Margaretta") of the Revolutionary War occurred off Machias. An attempt by the Americans to recapture Castine, which the British had occupied in 1779, was a dismal failure. From 1807 to 1812 the embargo and nonintercourse laws were a severe blow to Maine's shipping industry, and eastern Maine was occupied by the British with only token resistance in the War of 1812.

Statehood.—Maine was generally well governed by Massachusetts, but geographical separation, a heavy debt, unequal representation in the legislature and different economic and political policies (Maine was largely Democratic and Massachusetts Federalist) created a desire for independence even before the close of the Revolutionary War. After the War of 1812 the independence movement gained momentum, and in 1816 Massachusetts authorized separation if a popular vote gave a majority of five to four for separation. As the vote was only 11.969 yeas to 10.347 nays, the advocates of separation were unsuccessful A source of strong opposition to separation was removed in 1819 when congress rearranged the customs districts so that coasting vessels from Maine, as a separate state, would not have to enter and clear on every trip to or from Boston. Consequently, separation measures were carried by large majorities that year, and a constitution was framed by a convention that met in Portland in October. The constitution nas ratified by toun meetings in December and Maine applied for admission into the union. Because of the controversy then current in congress concerning the admission of Missouri as a slave state. Maine's admission became an important national issue. Finally by an act of March 15, 1820, Maine was admitted, its admission being a part of the Missouri Compromise (*q.v.*).

Boundary Dispute. — The northeast boundary of the state, which forms the northeast boundary of the United States, was long a matter of serious controversy between the United States and Great Britain. The treaty of 1783 ending the Revolutionary War identified the boundary in part as extending along the middle of the St. Croix river to its source, from there due north to certain highlands and along the highlands "to the north-westernmost head of Connecticut river." The dispute concerned just what the St. Croix river was and the location of its source and which highlands nere to mark the boundary. The exact location of the St. Croix and its source nas established by a commission provided for by the Jay treaty of 1794, but identifying the highlands proved to be a more difficult problem. Maine claimed that the highlands referred to overlooked the St. Lawrence river, but Great Britain contended that they were in the vicinity of Mars hill. The king of the Netherlands was chosen as arbitrator, and in 1831 he returned a decision unfavourable to Maine, causing the federal senate to withhold its assent. The disputed area thus became the scene of a disturbance known as the Aroostook War in 1838–39. Maine erected forts along the line it claimed, and the federal government prepared to resist British efforts to exercise exclusive jurisdiction. War seemed inevitable until Gen. Winfield Scott, who had been sent to take command on the Maine frontier. was able to arrange a truce whereby both sides withdrew their armed forces in favour of a civilian posse. Three years later the Webster-Ashburton treaty was effected, whereby Maine and Great Britain divided the disputed territory virtually in half.

19th-Century Politics. — From 1820 until 1854 Maine was classed as a Democratic state, although Whig governors were elected in 1837, 1840, 1852 and 1853. With its prohibitory laws of 1846 and 1851, Maine pioneered in regulating the liquor business. As a result of the prohibition and slavery questions there was a party disintegration between 1850 and 1855, followed by the supremacy of the Republican party from 1856 to 1878. In the latter year no gubernatorial candidate received a majority of the votes as required by the constitution and consequently a Democratic-Greenback fusion in the legislature declared the Democratic candidate, Alonzo Garcelon (1813–1906), governor. The electorate again failing to select a governor the following year. Governor Garcelon and his council counted out Republicans and replaced them with fusion candidates in the legislature. On Jan. 3, 1880, the supreme court declared the governor and council in error in counting in a fusion majority, but on Jan. 7 the governor swore in a legislature with 78 fusion and only two Republican members; the governor's term having expired, the president of the senate, James D. Lamson, became governor ex-officio. On Jan. 12 the Republicans, whose organized legislature was declared legal by the supreme court, seized the legislative chambers and chose as governor Daniel F. Davis. Former Governor Joshua L. Chamberlain was largely responsible for the peaceful solution of the difficulty which had had the state on the edge of civil war for a number of weeks, and ultimately Republican legislators and a Republican governor took office. In 1880 the Democrats and Greenbackers united and elected their candidate, but after 1882 Maine was strongly Republican until 1910.

Modern Times. — In 1910 the Democrats elected a governor and also in 1914, but Republicans again dominated politics otherwise until the 1930s. Louis Brann, Democrat, was elected in 1932 and re-elected in 1934, but Franklin D. Roosevelt failed to carry the state. In 1933 Maine voted for the repeal of the 18th amendment (prohibition) and in 1934 repealed its own prohibition statute. The high hopes held for the Passamaquoddy bay hydroelectric project were dashed in 1936 when congress discontinued funds for it though President Roosevelt favoured it. In 1950 a Canadian-U.S. commission indicated that detailed study must be made before the project's revival as a joint undertaking would be possible. After World War II several army and navy airfields in Maine were closed, but construction of the huge Loring air base at Limestone was undertaken. The Presque Isle, Bangor and Brunswick air bases were reactivated in 1951 and became increasingly important in the national defense system.

Maine's traditional Republicanism was shaken in 1954 when Democrat Edmund S. Muskie won the governorship; he easily won re-election in 1956, and in 1958 he became the state's first popularly elected Democratic U.S. senator. Adding to the Democratic trend was the election in 1956 of a Democratic congressman, Frank Coffin, who was re-elected in 1958 and joined by another Democratic congressman, James C. Oliver, to give the Democrats two of Maine's three seats in the house. Clinton A. Clauson, Democrat, won election that year as Maine's first four-year-term governor; on his death in 1960, however, he was succeeded by the Republican president of the state senate, John Reed. In the 1960 elections Reed defeated Coffin for the governorship and at the same time, Maine's three house seats were returned to Republican control.

GOVERNMENT

Maine was long noted as the only state to hold elections in September, but a constitutional amendment approved by the voters in 1957 moved its election day to the November date of other states, effective in 1960. The state has had only one constitution, ratified in Dec. 1819. It admits of amendment by a two-thirds vote of both houses of the legislature, followed by a majority vote of the electorate at the next election; or, as provided by an amendment adopted in 1875, the legislature may by a two-thirds vote of each house summon a constitutional convention. Among the more important amendments adopted have been those which granted the franchise to the Indians, authorized a $20,000,000 bond issue for a state industrial mortgage program, changed the election date from September to November and established the four-year term for governor.

Executive. — The governor is the only executive officer of the state elected by popular vote. There is no lieutenant governor, the president of the senate succeeding to the office of governor in case of a vacancy. There is also a council of seven members elected by the legislature (not more than one from any one senatorial district), whose sole function is to advise the governor. His power of appointment is unusually extensive, but the advice and consent of the council (instead of that of the senate as in other states) are required for his appointments. He appoints judges, medical examiners and notaries public, besides all other civil and military officers for whose appointment neither the constitution nor the laws provide otherwise. His removal power extends even to the locally elected sheriffs and county attorneys. Besides the seven members of the council, the secretary of state, the treasurer, the attorney general, the commissioner of agriculture and the auditor are elected by the legislature.

Legislative. — The legislature meets on the first Wednesday in January in odd-numbered years. It is composed of a senate of 33 members and a house of representatives of 151 members. Members of each house are elected for terms of two years, senators by counties roughly on the basis of one for each 30,000 inhabitants, and representatives approximately according to the population of towns and cities, with a maximum of seven for any one municipality. In 1908 a constitutional amendment provided for referendum and initiative by the people.

Judiciary. — At the head of the judicial branch is the supreme judicial court, which consists of a chief justice and five associate justices appointed by the governor and council for terms of seven years. The court's chief function is to hear appeals on points of law, but it renders advisory opinions when requested by the governor, council or either branch of the legislature. Below the supreme court is a seven-member superior court, whose members are also appointed for seven-year terms. Each judge goes on cir-, cuit in various counties as assigned by the chief justice of the supreme court. The superior courts are the only jury courts in Maine. They hear appeals from the local courts and hear the more important civil and criminal cases as courts of first instance.

Local Government. — The principal units of local government are the town (or toanship), the plantation, the county and the city. As in other parts of New England, the town or city is the most important of these. At the regular town meeting, ordinarily held in March, the electorate of the town assembles, decides what shall be done for the town during the ensuing year, elects officers to execute its decisions with limited discretion and votes money to meet the expenses. The principal officers are the selectmen (usually three), town clerk, assessors, collector, treasurer, school committee and road commissioner. Maine is the only state in the union that retains what is known as the organized plantation. This is a gokernmental unit organized from an unincorporated township having at least 200 inhabitants, and its principal officers are the moderator, clerk, three assessors, treasurer, collector, constable and school committee. The city-manager form of government was introduced in Maine in 1917 in the city of Auburn. The county is an intermediate organization between the state and the towns, to assist chiefly in the administralion of justice, especially in the custody of offenders. Its officers are three commissioners, a treasurer, a register of deeds, a judge of probate, a register of probate, a clerk of courts, a county attorney and a sheriff.

Finance. — Before 1912 the state constitution forbade the borrowing of money in excess of $300,000, except for the suppression of a rebellion, for war purposes or for repelling an invasion. In

that year an amendment to the constitution was adopted allowing the state to incur a debt not exceeding $2,000,000 for state highway purposes. Between 1912 and 1935, 12 amendments dealt with state debt and bond issues, gradually increasing the debt limit. An amendment adopted in 1950 removed all debt limitations and permitted bonds to be issued at the discretion of the legislature. by a two-thirds vote of each house, subject to popular referendum.

In order of importance, the chief sources of state funds in the second half of the 20th century were federal grants, gasoline tax, liquor, registrations and drivers' licences, general property tax, cigarette and tobacco taxes and public utility and insurance company taxes. These accounted for about three-fourths of the operating funds. Revenue was more than $100,000,000 annually, about 20% of which was from federal grants. Lacking an income tax or general sales tax. the state had a narrow tax base until 1951, when the legislature enacted a general 2% sales tax (exempting, however, food). In 1957 the rate was increased to 3%. With the additional revenue thus provided, the state was able to increase substantially its services, particularly in the fields of education and health and welfare. At that time, expenditures were about $110,000,000 annually. The bonded debt was nearly $40,000,000. The major expenditures were for highways, health and hospitals, education, and public welfare. Total expenditures nearly doubled between 1950 and 1960, but revenues maintained a similar pace. Per capita income had risen from $1,188 in 1950, nearly $300 below the national average, to $1,768 in 1959.

POPULATION

The census of 1820, the year Maine entered the union, revealed that the state had a population of 298,335. This placed it 11th among the 27 states and territories that then composed the union. The population was classified as a little more than 97% rural. The decade between the censuses of 1790 and 1800 was the period of most rapid growth—the population showed an increase of 57.2% in 1800 over that of 1790. At mid-19th century the state had a population of 583,169 (86% rural) and was 16th in population among the 37 states and territories. During the decade between 1860 and 1870 Maine's population declined by about 0.2%. In 1900 the population mas 649,466 (66% rural) and ranked the state 31st in the union. The 1950 population figure was 913,774 (35th among the states), 51.7% of which was urban. In 1960 Maine had a population of 969,265, an increase of 55,491 or 6.1% over 1950. The total urban population for 1960 was 497,114 or 51.3% of the total. The standard metropolitan statistical area of Portland had a population of 120,655 in 1960, an increase of 713 over 1950. The population per square mile in 1960 was 29.2, as compared with 49.6 for the United States as a whole.

Distribution by colour and nativity in 1950 was as follows: 91.5% native white; 8.1% foreign-born white; and 0.3% nonwhite. Of the foreign-born white population, 38.1% mere French Canadians, 35% were other Canadians. 6.1% were born in Great Britain and 2.8% in Ireland. Of the total population, 10.2% was 65 years old or over. Of the population 14 years old and over, 51.2% was in the labour force.

EDUCATION

Public Schools.—The first school in Maine was a mission established in 1696 by Father Sebastian Rasle on the Kennebec river. Other Jesuit missions were shortly afterward established at Passamaquoddy and at Indian Island. The first town school was established at York in 1701. Characteristic of the early days of education in Maine were the "moving schools," which traveled from place to place, remaining only a few weeks in one location. Greater organization was introduced in 1789 when Massachusetts, of which Maine was then a part, adopted a law requiring liberal instruction for all children and college training for all teachers. When Maine became a separate state in 1820, its educational system was patterned after that of Massachusetts. In 1828 the income from certain state lands was designated a public-school fund. Legislation passed in 1873 provided for the creation of free public high schools; education was made mandatory in 1875.

The state department of education is administered by a commissioner selected by an unpaid state board of education, consisting of ten members serving five-year overlapping terms. The department supervises the distribution of state subsidies to local areas on the basis of complex legislative formulas, designed to secure uniform minimum standards and to aid the less wealthy communities. The department exerts considerable control over school-building design, curriculums, teaching methods and teacher training, certification and placement. It is also responsible for education in the unorganized toanships where there is no local government. Still further, it groups towns and small cities into unions which are administered by locally chosen superintendents of schools. Towns and cities retain considerable local autonomy in school affairs. A sizable quantity of school-building districts mere created by special legislative acts to allow municipalities to circumvent the constitutional debt limit (usually 5% of the assessed valuation).

In 1957 the legislature passed the Sinclair bill, designed to encourage the formation of school districts and the consolidation of small high schools. At that time Maine had more than 125 high schools with fewer than 100 pupils.

Children between the ages of 7 and 15 are reauired to attend school. The free public elementary and secondary schools are supplemented by numerous parochial schools and more than 50 private schools and academies. At mid-20th century Maine was spending about $222 annually per pupil, or about $70 less than the national average.

Higher Education.— The state department of education (see above) administers four state teachers' colleges, at Gorham, Farmington, Machias and Presque Isle; a normal school at Fort Rent; and a trade school, the Vocational Technical institute, at South Portland. The state also operates a maritime academy at Castine.

Chief among the state-controlled institutions of higher learning is the University of Maine, at Orono, established in 1865 as the State College of Agriculture and the Mechanic Arts; the name was changed to University of Maine in 1897. The university is composed of schools and colleges of arts and sciences, agriculture, home economics. technology and education, forestry, nursing. and physical education and athletics. In 1957 the university absorbed the Portland junior college, after which the latter nas operated as a branch under the name of the University of Maine in Portland. In addition to the two campuses, the university maintains educational centres at Presque Isle, Auburn-Augusta and Machias. More than 4.000 students are enrolled annually, and the faculty numbers over 300.

Among the private institutions of higher learning is Bowdoin college, founded in 1794 at Brunswick (*q.v.*). Other colleges are Bates college (Lewiston, nonsectarian, 1864) and Colby college (Waterville, nonsectarian, 1813).

HEALTH AND WELFARE

The state's welfare activities were co-ordinated in 1931 by an act establishing the department of health and welfare. The department was composed of three bureaus, health, welfare and institutional service. having authority over the state's welfare program. In 1939 the legislature removed control of state institutions from health and welfare to a new department of institutional service.

The penal and reformatory institutions consist of the state prison, at Thomaston; the reformatory for men, at South Windham; the reformatory for women, at Skowhegan; the state (reform) school for boys, at South Portland; and the state (reform) school for girls, at Hallowell; the state schools are not places of punishment, but reformatories for delinquent boys from 8 to 16 years of age and girls from 6 to 16 years of age who have been committed by the courts for violations of law, or, in the case of girls, who by force of circumstances or association, are "in manifest danger of becoming outcasts oi society." The inmates in these schools get instruction in various trades and occupations so as to be able to earn a living when discharged.

Paupers formerly were cared for chiefly by touns and cities, those nholly dependent being placed in almshouses and those only partially dependent receiving aid in their homes. Federal-state funds for old-age assistance, aid to dependent children, aid to the blind and aid to the permanently and totally disabled are administered by the department of health and welfare. Unemployment compensation is administered by an employment security commission of three members.

The mental and charitable institutions maintained by the state are. the Augusta State hospital, at Augusta; Bangor State hospital, at Bangor; Central Maine sanatorium, at Fairfield; Pineland Hospital and Training School for the Feeble-minded, at West Pownal; Military and Naval Children's home, at Bath; and the Maine School for the Deaf, at Portland.

THE ECONOMY

Agriculture. — Agriculture is less important than it once was in Maine, the number of farms having declined from around 50,000 at the time of World War I to about 23,000 in the second half of the 20th century. Maine ranks first among the states in potato production, with Aroostook county as the leading producing centre. Production usually amounts to more than 60,000.000 bu. annually. To avoid a one-crop economy Aroostook county has begun raising peas, oats and beef cattle. Other important state crops are corn, barley, hay, beans, McIntosh apples and blueberries. Market gardening is important in the area around Portland. Dairying has long rivaled potatoes in importance. The most significant agricultural development after World War II was the raising of poultry, especially broilers. In ten years the number of broilers raised multiplied more than five times, to more than 50,000,000. Belfast is the centre of the industry.

Industry. — The construction of wooden ships was a principal industry in Maine until the middle of the 19th century, with some building of wooden (principally "downeasters" and schooners) and steel ships continuing, especially during World Wars I and II. Bath remains the chief centre of this activity. Cotton, woolen and paper mills, built in large numbers in the 19th century, were located on rivers to take advantage of the abundant water power. Sawmills were numerous from early colonial days. Later a variety of woodworking industries was established. After World War I there began a decline in textile manufacturing, which continued after World War II. Paper mills, shoe factories and food processing plants replaced the textile factories. The paper and textile industries were the leaders in the value of their products, but the leather products industry, especially shoes, employed the largest number of persons.

Minerals. — Maine formerly produced bricks, lime, granite and slate in sizable quantities, but output of these materials has dwindled. The state's principal mineral products in order of value are cement (New England's only cement plant is located at Thomaston), sand and gravel, stone, sheet mica and feldspar (about 25% of all the feldspar produced in the U.S.), with an average annual value in excess of $12,000,000. Maine. however, produces less than 1% of the total mineral output of the U.S.

Fisheries. — Fishing is an important coastal industry, affording employment to about 10% of the state's population. The catching and packing of young herring under the trade name of sardines represents the largest annual catch but is greatly exceeded in value by the lobster catch. Other fish of commercial importance include cod, haddock, hake, pollack, mackerel, ocean perch, alewives and flounders. Clams, sea scallops and crabs are also abundant in Maine waters. A rapidly growing activity is the collection of bloodworms and sandworms for bait. Average annual landings at Maine ports in the second half oi the 20th century totaled about 300,000,000 lb. valued at approximately $20,000,000. Lobsters alone accounted for about 55% of these revenues.

Forestry. — More than iour-fifths of the land area of Maine is forested (after Alaska the largest per capita acreage in the nation), and more than one-half of the land area is unorganized territory, nith no local government and few permanent inhabitants. A forest district tax on timberlands finances fire protection and other services performed by the Maine forest service.

Lumbering has always been Maine's chief industry. In colonial days Maine pine trees uere the chief source of masts for the British navy. In the 19th century the forests sustained the many shipyards, and Maine was long the leading producer of wooden ships in the United States. In the 20th century the same forests supplied pulpwood for the paper mills and lumber for the building trades. The annual production of pulpwood in the second half of the 20th century was more than 1,900.000 cords and that of lumber exceeded 500,000,000 bd.ft. Hardwoods, such as maple, beech and birch. were also widely used to make plywood, spools, dowels, toothpicks, skis, furniture, toys and novelties. Wood-using industries employed more than one-third of the wage earners of the state.

Transportation and Communications. — The southwestern part of the state, where the manufacturing, quarrying and much of the older agricultural district are located, always has had satisfactory means of transportation either by water or rail. The first international railroad in North America, the Atlantic and St. Lawrence (now a part of the Canadian National system), connected Portland and Montreal in 1853. During the American Civil War the chief railroad system in Maine was begun when the Maine Central was formed out of two short-line railroads connecting Lewiston and Bangor. It was not until the last decade of the 19th century that the forests, farmlands and summer resorts of Aroostook county nere reached by rail. In the second half of the 20th century, following considerable contraction, particularly in the less populous areas, the total railway mileage was slightly more than 2,000. Formerly there were five narrow gauge lines (two feet between the rails) and numerous electric lines operating in the state, but they have all become defunct. Many branch rail lines have been abandoned and passenger service on the Maine Central ceased in 1960.

Maine's coast line has many excellent harbours. The Kennebec river is navigable for coast vessels to Augusta, and the Penobscot to Bangor. For decades steamboats regularly plied between Maine ports and Boston, New York and several Canadian ports, but none have operated since just before World War II. In 1956 the Canadian National railways instituted a daily ferry service between Bar Harbor, on Mount Desert Island, and Yarmouth, Nova Scotia. This service proved attractive to the tourists who annually visit Mount Desert Island and Acadia National park.

Maine is connected with the other states by commercial airlines. Plane and auto transportation have all but eliminated rail passenger service and drastically reduced rail freight traffic. Modern highways have been built in many parts of the state, including a turnpike running from the state capital, Augusta, to the New Hampshire line Highways totaled more than 20,500 mi.

MAINE DE BIRAN, MARIE FRANÇOIS PIERRE GONTHIER (1766–1824), French philosopher, was born at Bergerac, Fr., on Nov. 29, 1766. The name Maine he assumed from an estate called Le Maine which belonged to his father. Maine de Biran entered the king's lifeguards and defended Louis XVI at Versailles on Oct. 5 and 6, 1789. He then retired to his estate at Grateloup, near Bergerac, and pursued his studies in mathematics and philosophy until, after the fall of Robespierre, he entered public life as an administrator in the de'partement of the Dordogne. He became a member of the Corps Législatif in 1809 and was among those who expressed public opposition to Napoleon in 1813. After the Restoration he became treasurer to the chamber of deputies. He died in Paris on July 16. 1824.

Maine de Biran first became known in the intellectual world as one of the Idéologues. These philosophers developed the antimetaphysical and empiricist aspects of Locke's philosophy in the manner of Etienne de Condillac; and Maine de Biran's philosophical importance consists in his gradual and detailed discovery of the inadequacies of this point of view. His diary, in which he commented on his administrative and political activities as well as on his philosophical reading, throws valuable light on the thoughts and struggles of a diffident philosopher forced to play a decisive part in politics. Both as philosopher and as diarist his interest is in the inner life of man.

His first important philosophical writing and one of the few published during his lifetime was *Influence* de *l'habitude sur* la *faculté* de *penser* (1802; Eng. trans. by M. D. Boehm, Baltimore, 1929). In it, developing an idea of Destutt de Tracy's, he stresses the role of the will in our perception of the physical world and argues that the result of becoming habituated on a being that possessed only sense-experience would be that it would lose consciousness altogether. These themes of the importance of the will and of the impossibility of analyzing the self entirely in terms of sensation and feeling were developed in later works. In his *Mémoire sur* la *décomposition* de la *pensée* (1804). Maine de Biran criticizes Descartes for confusing the self considered as subject with the self considered as a substance in the natural world and is thus led to suppose that the methods appropriate to the study of nature are incapable of revealing the essence of selves or subjects. In his Essai *sur* les *fondements* de la *psychologie* (1812), Maine de Biran concluded that there is a "hyperorganic" element in the self, even though "my body and myself form a single being." In his *Nouveaux essais* d'anthropologie (1823–24) he describes the self as developing through an animal, purely sensitive phase (vie *animale*) to a human phase of will and freedom (vie humaine) and culminating in experiences which transcend humanity (vie de *l'esprit*).

BIBLIOGRAPHY.—There is an incomplete edition of his works by Victor Cousin, 4 vol. (Paris, 1834–41), and another, *Oeuvres ine'dites,* by *E.* Naville, 3 vol. (Paris, 1859). A complete edition was begun by P. Tisserand in 1920. Other texts are the *Journal intime,* ed. by A. de La Valette Monbrun, 2 vol. (Paris, 1927–31); and the *Oeuvres choisies,* ed. by *H.* Gouhier (I'aris, 1942). *See* also: P. Tisserand, *L'Anthropologie de Maine de Biran ou la science de l'homme intérieur* (Paris, 1909); V. Delbos, *Maine de Biran et son oeuvre philosophique* (Paris, 1931); G. Le Roy, *L'Expérience de l'effort et de la grâce chez Maine de Biran* (Paris, 1938); Gerhard Funke, *Maine de Biran: philosophisches und politisches Denken zwischen Ancien Régime und Bürgerkönigtum in Frankreich* (Bonn, 1947); Henri Gouhier, *Les Conversions de Maine de Biran* (Paris, 1947). (H. B. A.)

MAINE-ET-LOIRE, a de'partement of western France, formed in 1790 for the most part out of the southern portion of the former province of Anjou, and bounded north by the departments of Mayenne and Sarthe, east by Indre-et-Loire, southeast by Vienne, south by Deux-Sèvres and Vendée, west by Loire-Inférieure, and northwest by Ille-et-Vilaine. Area 2,787 sq.mi. Pop. (1954) 518,241. The department includes the course of the Authion and the lower course of the Maine, with its feeders, the Loir, Sarthe, Mayenne and Oudon, on the right bank of the Loire; as well as those of the Layon, Evre and Divatte on the left. The Val d'Anjou, followed by the Loire, forms a zone of rich meadows, market gardens and orchards from east to west. The west of the department is floored by Palaeozoic rocks and granites of the Armorican system, but east of the line of the Sarthe the rocks are chiefly cretaceous, with tertiary capping on the somewhat higher ground between the rivers. The name Val d'Anjou belongs strictly to the eastern part of the Loire valley in the department. The climate is mild. The mean annual temperature of Angers is about 54°; the rainfall is between 23 and 24 in. annually. The frequent fogs, combined with the peculiar nature of the soil in the southeast of the department, are highly favourable to meadow growths. The winter colds are never severe, and readily permit the cultivation of certain trees which cannot be reared in the adjoining departments.

The chief cereals grown are wheat: oats and barley, and potatoes and mangels also give good returns. Much hemp is grown in the valley of the Loire, and the vegetables, melons and other fruits of that region are of the finest quality. Good wine is produced at Serrant and other places near Angers, and on the right bank of the Layon and near Saumur, famous for its sparkling white wine. Cider apples, and fruit generally, are produced. Woodland, chiefly of oak and beech, covers large tracts. The fattening of cattle is an important industry round Cholet, and horses are reared. There are important slate quarries near Angers, tufa is worked in the river valleys, and freestone and other stone, iron and coal are also found. The manufactures include linen and woollen stuffs. The department is served by the railways of the State and of the Orléans company. The Mayenne, the Sarthe and the Loire, together with some of the lesser rivers, provide about 130 mi. of navigable waterway. In the southeast the canal of the Dive covers some 10 mi. in the department.

There are four arrondissements—Angers, Cholet, Saumur and Segré, with 34 cantons and 381 communes. Maine-et-Loire belongs to the académie (educational division) of Rennes. to the region of the IX army corps (Tours) and to the ecclesiastical province of Tours. Angers (*q.v.*), the capital, is the seat of a bishopric and of a court of appeal. Other important places are Cholet. Saumur and Fontevrault. For architectural interest there may also be mentioned the châteaux of Brissac (17th century), Serrant (1jth and 16th centuries). Montreuil-Bellay (14th and 15th centuries), and Ecueillé (1jth century), and the churches of Puy-Notre-Dame (13th century) and St. Florent-le-Vieil (13th, 17th and 19th centuries). the last containing the fine monument to Charles Bonchamps, the Vendean leader, by David d'Angers. Gennes has remains of a theatre and other Roman remains, as well as two churches dating in part from the 10th century. Ponts-de-CC, an interesting old town built partly on islands in the Loire, is important. because until the Revolution its bridges formed the only way across the Loire between Saumur and Nantes.

MAINE RIVER, France, is a right-bank tributary of the Loire (*q.v.*) which it enters at La Pointe below Angers. The Maine itself (7 mi. long) is formed from the confluence of the Mayenne, Sarthe and Loir rivers. The Mayenne, rising in the hills of Normandy, flows south past Laval through the hilly pastoral country of the easternmost part of the crystalline Armorican massif. The Sarthe and its tributary the Huisne, which joins it at Le Mans, rise in the hills of the Perche. Before joining the Mayenne, the Sarthe receives the Loir, flowing westward from the margins of the limestone platform of Beauce. The dry, sandy platforms of Maine. which the Sarthe and Loir traverse, are far from fertile and carry much woodland! but the broad river valleys, with their alluvial floors, are exceptions as strips of rich cultivation, including orchards and vineyards at their northern limit. Below Angers, the Maine valley enters the wide alluvial trench of the Loire, there known as the Val d'Anjou. The navigable waterway of the lower Loire is continued by the Maine, and the Mayenne is navigable by small craft as far as Brives and the Sarthe less satisfactorily to Le Mans. (AR. E. S.)

MAINPURI, a town and district in the Agra division of Uttar Pradesh, India. The town (pop. 1951, 22,932) consists of two separate parts, Mainpuri proper and Mukhamganj. Jaswant Rao Holkar plundered and burned part of the town in 1804, but was repulsed by the local militia. After the British occupation the population rapidly increased and many improvements mere carried out. The Agra branch of the Grand Trunk road runs through the town, forming a wide street lined on both sides by shops. which constitute the principal bazaar. Mainpuri has a specialty in the production of carved wooden articles inlaid with brass wire. The American Presbyterian mission manages a high school in the town.

The DISTRICT OF MAINPURI lies in the central Doab. Area, 1,680 sq.mi. The population (1951) was 993,890. It consists of an almost unbroken plain wooded throughout with mango groves, and isolated clumps of *bábul* trees occasionally relieve the bareness of its saline *usar* plains. On the southwestern boundary the Jumna flows in a deep alluvial bed, sometimes sweeping close to the high banks which overhang its valley, and elsewhere leaving room for a narrow strip of fertile soil between the river and the upland plain. The district is watered by two branches of the Ganges canal.

Mainpuri anciently formed part of the great kingdom of Kanauj, and after the fall of that famous state it was divided into a number of petty principalities, of which Rapri and Bhongaon were the chief. In 1194 Rapri was made the seat of a Moslem governor. Mainpuri fell to the Moguls on Baber's invasion in 1526, passed, toward the end of the 18th century, into the power of the Marathas, and finally became a part of the province of Oudh. When this part of the country was ceded to the British in 1801 Mainpuri town became the headquarters of the extensive district of Etawah, which was in 1856 reduced by the formation of Etah and Mainpuri into separate collectorates.

MAINTAINED PRICE: *see* PRICE MAINTENANCE.

MAINTENANCE AND CHAMPERTY. In English law maintenance is the maintaining or assisting a party, with money or otherwise, to prosecute or defend an action in which the maintainer has no legitimate interest. The law allows a master to assist his servant. near relations to support each other, the charitable to assist the poor, and persons having an interest even contingent in the subject matter or principle involved in a suit to assist a party to it. Other maintenance is a criminal offense and a civil cause of action. In theory, even if the maintained action succeeds so that a party is assisted only to secure his legal due. the unsuccessful party can sue the maintainer if he can prove that he has suffered damage (*Neville* v. London *Express Newspaper Ltd.*, 1919. *A.C.* 368), but this is seldom if ever possible since the damages and costs which he is compelled to pay flow from his own wrong and not from the maintenance. If the maintainer is to be rewarded by receiving some part of the subject matter of or some profit from the suit the bargain is the criminal offense of champerty. (S.)

United States.—Maintenance and champerty as defined by the common law are still generally criminal in the United States. The criminal aspect of maintenance and champerty has now little significance, but the concepts retain their vigour in rendering unethical the conduct of a particular attorney or illegal contracts between attorneys and clients concerning remuneration for services rendered in the prosecuting of a suit. The charging of legal fees contingent upon success is technically champerty, but the strict definition has relaxed as the social necessity of such a practice has become increasingly apparent. The common law doctrines that made illegal all champertous agreements were consequently greatly modified by judicial decision. A few states followed the so-called Massachusetts rule which made illegal an agreement by an attorney that he shall receive a specific share in the proceeds of the suit but considered an agreement legal which merely provides for a larger fee in the event of success. The majority of states follow the rule that champerty of itself does not make the agreement illegal unless it is accompanied either by maintenance in the form of an agreement that the attorney will bear the expenses of the suit, or by a provision binding the client not to compromise or release the claim without the consent of the attorney. The fact that such rules consider the form and not the substance of the agreement has led to the modern view held by a few states, namely that neither technical champerty nor maintenance invalidates the contract but its validity is to be determined by a consideration of whether the particular agreement induced the litigation and revealed an overreaching of the client by the attorney. Many states unfortunately have allowed an attorney whose agreement for fees is invalid because of champerty or maintenance to recover reasonable fees from his client, thus permitting him to charge any fees that he may desire in the first instance and in the unusual event of litigation assuring him no matter what the final outcome a reasonable compensation. The champertous character of an agreement between attorney and client can be availed of only by the parties to it, and no defendant can successfully defend the claim against him by proving that the plaintiff is prosecuting it under a champertous agreement.

The ease with which the practices of champerty, maintenance and barratry or the stirring up of vexatious litigation eluded both the criminal law and the restraining influence of doctrines rendering contracts between lawyers and clients illegal led in the large cities to the practice of ambulance chasing. Unscrupulous attorneys eager to solicit business in negligence cases employ runners who keep track of accidents with the aid of police. newspaper reporters. doctors, etc., and by appearing on the scene shortly after the accident manage to inveigle the victims into engaging them to prosecute their claims. Needless litigation over minor and often spurious injuries is thus aroused. In Minnesota by virtue of a statute, which was declared unconstitutional, attorneys sought to bring within the jurisdiction of Minnesota courts claims for injuries arising out of railroad transportation which may have occurred a thousand or more miles from the place of trial merely on the ground that the railroad maintained a freight and passenger agent in the state although it operated no trackage within the state. nor was the plaintiff a resident of the state. Similar attempts have been made in other states to facilitate the trial of accident cases remote from the place of their occurrence so as to harass the defendent into a settlement irrespective of the merits of the plaintiff's claim by the prospect of the costs that he would incur in bringing his witnesses to the place of trial. (J. M. LA.)

MAINTENON, FRANÇOISE D'AUBIGNÉ, MARQUISE DE (1635–1719), the second wife of Louis XIV, was born in a prison at Niort, on Nov. 27, 1635. Her father, Constant d'Aubigné, was the son of Agrippa d'Aubigné, the friend and general of Henry IV, and had been imprisoned as a Huguenot malcontent, but her mother had the child christened a Catholic. After the release of d'Aubigné the family went to Martinique. There the father died. Mother and child returned to France. where Françoise was surrendered to a Protestant relative who is said to have converted her to Protestantism. She was removed by an order of state to Catholic guardianship, and reconverted. She and her mother were penniless, and the girl married (1652) Scarron, the famous wit, to whom she was more nurse than wife. He died in 1660. Anne of Austria continued his pension to his widow, and even increased it to 2,000 livres a year, which enabled her to entertain and frequent literary society. After Anne's death the pension was continued by the king on the intercession of his mistress, Madame de Montespan, who put her in charge of the children whom she bore to Louis. In 1674 the king determined to have his children at court, and their governess who had now made sufficient fortune to buy the estate of Maintenon, accompanied them. In 1678 her estate at Maintenon was raised to a marquisate. Mme. de Montespan's jealousy mas aroused by these favours, and Mme. de Maintenon's position was almost unendurable until Mme. de Montespan left the court. Madame de Maintenon now became the king's mistress "en titre." The queen declared she had never been so well treated as at this time, and eventually died in Mme. de Maintenon's arms in 1683. In 1684 Mme. de Maintenon was made first lady in waiting to the dauphiness, and in the winter of 1685–1686 she was privately married to the king by Harlay, archbishop of Paris, in the presence, it is believed. of Père la Chaise, the king's confessor, the marquis de Montchevreuil, the chevalier de Forbin, the marquis de Louvois and the valet, Bontemps. No wrltten proof of the marriage is extant, but that it took place is nevertheless certain. Her life during the next 30 years can be fully studied in her letters.

Her political influence has probably been exaggerated, but it was supreme in matters of detail. The ministers of the day used to discuss and arrange all the business to be done with the king beforehand with her, and it was all done in her cabinet and in her presence, but the king in more important matters often chose not to consult her. Such mistakes as, for instance, the replacing of Catinet by Villeroi may be attributed to her, but not whole policies—notably, according to Saint-Simon, not the policy with regard to the Spanish succession. Even the revocation of the edict of Nantes and the dragonnades have been unjustly laid to her charge. Her influence was on the whole a moderating and prudent force. Her social influence was always exercised on the side of decency and morality.

Side by side with this public life, she passed a happier existence as the foundress of St. Cyr. Mme. de Maintenon was a born teacher; and she had always wished to establish a home for poor girls of good family placed in such straits as she herself had experienced.

As soon as her fortunes began to mend she started a small home for poor girls at Ruil, which she afterward moved to Noisy, and which was the nucleus of the splendid institution of St. Cyr, which the king endowed in 1686, out of the funds of the abbey of St. Denis.

She was in her element there. She herself drew up the rules of the institution and examined every minute detail. She befriended her pupils in every way, and often turned her attention from the weariness of Versailles or of Marly to her "little sisters" at St. Cyr. It was for them that Jean Racine wrote his Esther and his *Athalie.*

Because he managed the affairs of St. Cyr so well, Michel Chamillart was made controller general of the finances. The later years of her power were marked by the promotion of her old pupils, the children of the king and Mme. de Montespan, to high dignity between the blood royal and the peers of the realm, and it was doubtless under the influence of her dislike for the duke of Orleans that the king drew up his will, leaving the personal care of his successor to the duke of Maine, and hampering the duke of Orleans by a council of regency, an arrangement which mas overthrown by the parlement after the king's death. The regent Orleans visited her at St. Cyr and continued her pension of 48,000 livres.

She spent her last years at St. Cyr in seclusion but an object of great interest to visitors to France, all of whom, however, with the exception of Peter the Great, found it impossible to get an audience with her.

On April 15, 1719, she died and was buried in the choir at St. Cyr. She bequeathed her estate at Maintenon to her niece, the only daughter of her brother Charles and the wife of the maréchal de Noailles.

Her *Lettres historiques et édifiantes* (7 vols.) and her *Correspondance générale* (4 vol., 1888), were edited by Th. Lavallée. Saint-Simon's account of the court in her day i: contained in vol. xii of his *Mémoires. See* also Mademoiselle d'Aumale's *Souvenirs sur Madame de Maintenon,* ed. Comte d'Haussonville and G. Hanotaux, 3 vol. (1902–04); A. Geffroy, *Madame de Maintenon d'après sa correspondance authentique,* 2 vol. (Paris, 1887); A. de Boislisle, *Paul Scarron et Françoise d'Aubigné d'aprbs des documents nouveaux* (1894); É. Barnard, *Madame de Maintenon and Saint-Cyr* (1934); Maud Cruttwell, *Madame de Maintenon* (1930).

MAINZ (Fr. Mayence), a city and episcopal see of Germany, which grew up on the left bank of the Rhine, almost opposite the influx of the Main; the city has spread also to the right bank of the river. It lies at the junction of the important main lines of railway from Cologne to Mannheim and Frankfurt-on-Main, 25 mi. W. of the latter. Pop. (1950) 88,369, of whom two-thirds are Roman Catholic.

History.—Mainz was a pre-Roman settlement at which, about 13 B.C., Nero Claudius Drusus, the stepson of Augustus, erected a fortified camp; the *Castellum Mattiacorum* (the modern Kastel) on the opposite bank was afterward added to it, the two being connected with a bridge at the opening of the Christian era. The earlier name became latinized as Maguntiacum, or *Mogontiacum,* and a town gradually arose around the camp, which became the capital of Germania Superior. During the Volkerwanderung Mainz suffered severely, being destroyed on different occasions by the Alamanni, the Vandals and the Huns. Christianity seems to have been introduced into the town at a very early period; and a church already stood there in the 4th century. In the 6th century a new Mainz was founded by Bishop Sidonius. In the middle of the 8th century under St. Boniface it became an archbishopric, and to this the primacy of Germany was soon annexed. Charlemagne, who had a palace in the neighbourhood, gave privileges to Mainz, which rose rapidly in wealth and importance, becoming a free city in 1118. In 1160 the citizens revolted against Archbishop Arnold, and in 1163 the walls of the city were pulled down by order of the emperor Frederick I.

In 1244 certain rights of self-government were given to the citizens; and in 1254 Mainz was the centre and mainspring of a powerful league of Rhenish towns. In 1462 there was warfare between two rival archbishops. The citizens espoused the losing cause and were deprived of their privileges. Many of the inhabitants were driven into exile, and these carried into other lands a knowledge of the art of printing, which had been invented at Mainz by Johann Gutenberg in 1450.

During the Thirty Years' War Mainz was occupied by the Swedes and by the French. In 1792 the citizens welcomed the ideas of the French Revolution; they expelled their archbishop, and opened their gates to the French troops. Mainz was ceded to France by the treaty of Campo Formio in 1797, and again by the treaty of Lunéville in 1801. In 1814 it was restored to Germany and in 1816 it was handed over to the grand duke of Hesse. After World War I it was occupied by Allied troops. During World War II it was bombed by the British.

Architecture and Trade.—The cathedral is a Romanesque edifice with numerous Gothic additions and details. It was originally erected between 975 and 1009, but has since been repeatedly burned down and rebuilt. and in its present form dates chiefly from the 12th, 13th and 14th centuries. The whole building was restored by order of Napoleon in 1814, and another thorough renovation was made later. Other noteworthy churches are those of St. Ignatius (18th century), with a finely painted ceiling; of St. Stephen, built 1257–1328 and restored after an explosion in 1857; and of St. Peter (18th century). These churches were renovated after World War II. The old electoral palace (1627–78), a large building of red sandstone, now contains a valuable, collection of Roman and Germanic antiquities. Among the other principal buildings are the former palace of the grand duke of Hesse, built in the 1730s as a lodge of the Teutonic order, and the government buildings. A statue of Gutenberg, by Bertel Thorwaldsen, was erected at Mainz in 1837. Mainz still retains many relics of the Roman period, the most important of which is the Eigelstein; this monument is believed to have been erected by the Roman legions during the 1st century B.C. in honour of the illustrious general Drusus. It stands within the citadel, which occupies the site of the Roman castrum. A little to the southwest of the town are the remains of a large Roman aqueduct, of which more than 60 pillars are still standing.

The University of Mainz. founded in 1477, was suppressed following the French Revolution in 1798. It was revived in 1946 under the name of the Johannes Gutenberg university.

The site of Mainz would seem to mark it out naturally as a great centre of trade, but the illiberal rule of the archbishops and its military importance seriously hampered its commercial and industrial development. It is now, however: the chief emporium of the Rhenish wine traffic, and also carries on an extensive transit trade in grain, timber, flour, petroleum, paper and vegetables. The principal manufactures are leather goods, furniture, carriages, chemicals, musical instruments. cement and boots. Other industries include brewing, shipbuilding and printing. Mainz is the capital of the *Land* Rhineland-Palatinate.

The Archbishopric of **Mainz,** dating from 747, was one of the seven electorates of the Holy Roman Empire, and became a powerful state during the middle ages. retaining some of its importance until the dissolution of the empire in 1806. Its archbishop was president of the electoral college, archchancellor of the empire and primate of Germany. The lands of the electorate were on both banks of the Rhine; their area at the time of the French Revolution was about 3,200 sq.mi. The archbishopric was secularized in 1803, two years after the lands on the left bank of the Rhine had been seized by France. Some of those on the right bank were given to Prussia and to Hesse; others were formed into a grand duchy for Karl von Dalberg. The archbishopric itself was transferred to Regensburg, and Mainz became a bishopric only.

MAIR, ALEXANDER WILLIAM (1875–1928), Scottish classical scholar. was born on June 9, 1875. at Deerhill, Banff. After a distinguished career at Aberdeen and Cambridge he was appointed (1899) assistant professor and (1903) professor of Greek at Edinburgh university.

He was an unusually able and meticulous scholar of the Cambridge school, and a highly successful teacher. His chief works were his editions and translations of Hesiod, Callimachus. Lycophron and Oppian (the last-named being unpublished at his death). He also wrote a biography of PLINY and LUCIAN, as well as several other articles for the *Encyclopædia Britannica.*

He was burned to death by an accident in his study on Nov. 12, 1928.

MAIRET, JEAN **DE** (1604–1686), French dramatist, was born at Besançon, and died there on Jan. 31, 1686. His own statement that he was born in 1610 has been disproved. He went to Paris to study at the Collège des Grassins about 1625, in which year he produced his first piece *Chriséide et Arimand,* followed in 1626 by *Sylvie,* a "pastoral tragi-comedy." In 1634 appeared his masterpiece, *Sophonisbe,* which marks, in its observance of the rules, the beginning of the "regular" tragedies. Mairet was one of the bitterest assailants of Corneille in the controversy over *The Cid.* It was perhaps his jealousy of Corneille that made him give up writing for the stage. He was appointed in 1648 official representative of the Franche-Comté in Paris, but in 1653 he was exiled for a short time by Mazarin. His other plays include *Silvanire ou la Morte-vive,* published in 1631 with a preface on the observance of the unities, *Les Galanteries du duc d'Orsonne* (1632), *Virginie* (1633), *Marc-Antoine* (1635) and *Le Grand et dernier Solyman* (1637).

See G. Bizos, *Etude sur* la *vie et les oeuvres de Jean de Mairet* (1877). *Sophonisbe* was edited by K. Vollmoller (Heilbronn, 1888), and *Silvanire* by R. Otto (Bamberg, 1890).

MAIRONIS (1862–1932), Lithuanian poet, whose real name is Jonas Mačiulis, was born at Pasandvaris, in the Kaunas (Kovno) district. In 1909, Maironis was appointed rector of the Kaunas seminary and in 1922 became a professor and deacon of the theological faculty of the Kaunas University which he helped to found. His songs are sung all over Lithuania. His famous poem *Young Lithuania* describes the national rebirth; *Our Sufferings* is a poem descriptive of the Lithuanian national ripening and conquest of independence; his *Magdalen* of *Raseiniai* castigates the national vices, while his Polish poem *Znad Biruty* appeals to the Polonised Lithuanian nobility. His dramatic works include *Where is Salvation? The Death of Kestutis,* and *Vytautas with the Crusaders,* the two last being historical plays of the 14th century. Maironis also translated the *Rigveda* into Lithuanian.

MAISTRE, JOSEPH DE (1754–1821), French diplomatist and polemical writer, was born at Chambéry on April 1, 1754. His family was an ancient and noble one, and is said to have been of Languedocian extraction. The father of Joseph was president of the senate of Savoy, and held other important offices. Joseph himself, after studying at Turin, entered the civil service of Savoy, finally becoming a member of the senate. In 1786 he married Françoise de Morand. The invasion and annexation of Savoy by the French Republicans made him an exile. He betook himself to the neutral territory of Lausanne. There, in 1796, he published his *Considérations sur la France.* In this he developed his Legitimist views, based on his religious convictions. The philosophism of his day was his lifelong aversion.

Charles Emmanuel now summoned de Maistre to Turin; he followed the king to Sardinia, and in 1802 he was appointed envoy extraordinary and minister plenipotentiary at St. Petersburg During these years he only published a single treatise, on the *Principe générateur des Constitutions;* but he wrote his best and most famous works, Du *Pape* (written in 1817) and its continuation, *De L'église gallicane* and the *Soire'es de St. Pétersbourg,* the last of which was never finished. *Du Pape,* written from the standpoint of papal absolutism, is a treatise on the relations of the sovereign pontiff to the Church, to temporal sovereigns, to civilization generally, and to schismatics, especially Anglicans and the Greek Church. The *Soirées de St. Pe'tersbourg* deals with the fortunes of virtue and vice in this world. It contains two of De Maistre's most famous pieces, his panegyric on the executioner as the foundatior. of social order, and his acrimonious, and in part unfair, but also in part very damaging, attack on Locke. Besides these works he wrote an examination of the philosophy of Bacon, some letters on the Inquisition, and, earlier than any of these, a translation of Plutarch's "Essay on the Delay of Divine Justice," with somewhat copious notes. After 1815 he returned to Savoy, and was appointed to high office. He died on Feb. 26, 1821, at Turin. Most of the works mentioned were posthumous, and it was not till 1851 that a collection of *Lettres et opuscules* appeared.

Joseph de Maistre was one of the most powerful, and by far the ablest, of the leaders of the neo-Catholic and anti-revolutionary movement. He regarded the temporal monarchy as an institution of altogether inferior importance to the spiritual primacy of the pope. He was by no means a political absolutist, except in so far as he regarded obedience as the first of political virtues, and he seldom loses an opportunity of stipulating for a tempered monarchy. But the pope's power is not to be tempered at all, either by councils or by the temporal power or by national churches, least of all by private judgment. The absolute necessity of order was, doubtless, the first principle of this thinker, who will invite comparison with Hobbes. The anarchic tendencies of the Revolution in politics and religion offended him. Moreover, he was profoundly and accurately learned in history and philosophy and the superficial blunders of the *philosophes* irritated him as much as their doctrines. To Voltaire he shows no mercy.

Of the two works named as his masterpieces, *Du Pape* and the *Soirées de St. Pétersbourg,* editions are extremely numerous. So complete edition of his works appeared till 1884–87, when one was published at Lyons in 14 volumes. This had been preceded, and has been followed, by numerous biographies and discussions: C Barthélemy, *L'Ésprit de Joseph de Maistre* (1859); *R.* de Sézeval, *Joseph de Maistre* (1865); *L. I.* Moreau, *Joseph de Maistre* (1879); F. Paulhan, *Joseph de Maistre et sa philosophie* (1893); *L.* Cogordan, "Joseph de Maistre" in the *Grands écrivains français* (1894); F. Descostes, *Joseph de Maistre avant la révolution* (1896), and other works by the same uriter; J. Mandoul, *Un Homme d'ttat italien: Joseph de Maistre et la politique de la maison de Savoie* (1900); *E.* Grasset, *Joseph de Maistre* (1901); *L.* Arnould, *La Providence et le Bonheur d'après Bossuet et Joseph de Maistre* (1916); C. Besse. *Le paradox celebre de J. de Maistre sur la guerre* (1916); *M.* Jugie, *J. de Maistre et l'église Gréco-Russe* (1922); and F. Vermale, *Notes sur J. de Maistre inconnu* (Chambéry, 1921).

MAISTRE, XAVIER DE (1763–1852), younger brother of Joseph de Maistre, was born at Chambéry on Nov. 8, 1763. He served in the Piedmontese army, and wrote his delightful fantasy, *Voyage autour de ma chambre* (published 1794) when he was under arrest at Turin in consequence of a duel. On the annexation of Savoy to France, he left the service and took a commission in the Russian army. He served under Suvarov in his victorious Austro-Russian campaign and accompanied the marshal to Russia. He shared the disgrace of his general, and supported himself for some time in St. Petersburg by mmiature painting. But on his brother's arrival in St. Petersburg he was introduced to the minister of marine. He was appointed to several posts in the capital, but also saw active service, mas wounded in the Caucasus, and attained the rank of major general. He died at St. Petersburg on June 12, 1852. Besides the *Voyage* already mentioned, Xavier de Maistre's works (all of which are of very modest dimensions) are *Le Lépreux de la citd d'Aoste* (1811); *Les Prisonniers du Caucase* (182j), *La Jeune Sibe'rienne* (1825) and the *Expddition nocturne*, a sequel to the *Voyage autour de ma chambre* (1825).

His works, with the exception of some brief chemical tractates, are included in the collections of Charpentier, Garnier, etc., and in his *Oeuvres ine'dites*, 2 vol., 1877.

See Sainte-Beuve's *Portraits contemporains*, vol. iii; A. Berthier, *Xavier de Maistre* (1920); C. de Bultet, *Aperçu de la vie de Xavier de Maistre* (1919).

MAITLAND, EDWARD (1824–1897), English humanitarian writer, was born at Ipswich on Oct. 27, 1824, and was educated at Caius college, Cambridge. With Anna Kingsford (1846–88), the supporter of vegetarianism and antivivisectionism, he brought out *Keys of the Creeds* (1875), *The Perfect Way: or the Finding of Christ* (1882) and founded the Hermetic society in 1884. After her death he founded the Esoteric Christian Union in 1891, and wrote her *Life and Letters*. He died on Oct. 2, 1897.

MAITLAND, FREDERIC WILLIAM (1850–1906). English jurist and historian, son of John Gorham Maitland, was born on May 28, 1850, and educated at Eton and Trinity, Cambridge. He was called to the bar (Lincoln's Inn) in 1876, and became a thoroughly competent equity lawyer and conveyancer, but finally devoted himself to comparative jurisprudence and especially the history of English law. In 1884 he was appointed reader in English law at Cambridge, and in 1888 became Downing professor of the laws of England. Though handicapped in his later years by poor health, his intellectual grasp and wide knowledge and research gradually made him famous as a jurist and historian. He edited numerous volumes for the Selden society, including *Select Pleas for the Crown, 1200–1225, Select Pleas in Manorial Courts* and *The Court Baron;* and among his principal works were *Gloucester Pleas* (1884), *Justice and Police* (188j), *Bracton's Note-Book* (1887), *History of English Law* (with Sir F. Pollock, 1895; new ed., 1898); *Domesday Book and Beyond* (1897), *Township and Borough* (1898), *Canon Law in England* (1898), *English Law and the Renaissance* (1901), the *Lzfe of Leslie Stephen* (1906). His writings are marked by vigour and vitality of style, as well as by the highest qualities of the historian who recreates the past from the original sources; he had no sympathy with either legal or historical pedantry. He died at Grand Canary on Dec. 19, 1906.

See P. Vinogradoff's article on Maitland in the *English Historical Review* (1907); Sir F. Pollock's in the *Quarterly Review* (1907); G. T. Lapsley's in *The Green Bag* (1907); A. L. Smith, *F. W. Maitland* (1908); H. A. L. Fisher, F. W. *Maitland* (1910).

MAITLAND, SIR RICHARD (LORD LETHINGTON) (1496–1586), Scottish poet, lawyer. statesman and compiler of an important collection of Scottish verse. "Manly Maitland," as he was called in an epitaph, was the son of Sir William Maitland of Lethington, who was killed at Flodden. He studied law at St. Andrews and Paris, served James V and was keeper of the Great Seal (1562–67) under Queen Mary. Although he went blind about 1561, he remained active as a judge until 1584 and busied himself with writing and collecting Scottish poetry. He died on March 20, 1j86. Maitland's poems reflect the troubled condition of Scotland in his time. Many have social and political themes, which they treat sometimes satirically, sometimes with the meditative seriousness of an old and blind man who loves his country and who asks his more fanatical and intolerant contemporaries, "How suld our commonweill endure?" They have frequently a nice and laconic strength and a metrical expressiveness, both reminiscent of his English contemporary, Sir Thomas Wyatt. Maitland included his own poems in his valuable collection of Scottish poetry known as the *Maitland Folio Manuscript* (begun about 1570), and his daughter added others when she compiled the smaller anthology called the *Maitland Quarto Manuscript* (1586). The 183 leaves of the folio and the 138 leaves of the quarto also contain a selection of works by Robert Henryson, William Dunbar, Gavin Douglas and other poets of the period. Maitland's services to Scottish history and literature were commemorated by the foundation of the Maitland club in 1828 to continue their study.

Smith, *Specimens of Middle Scots* (1902); the Maitland Club's editions of Maitland's *Poems* (1830) and his *Historie and Chronicle of the Hous of Seytoun* (1829). *See* also G. Eyre-Todd, *Scottish Poetry of the 16th Century* (1892).

(E. G. M.)

MAITLAND (MAITLAND OF LETHINGTON), **WILLIAM** (*c.* 1528–1573), Scottish statesman, eldest son of Sir Richard Maitland (1496–1586) (*q.v.*), was educated at St. Andrews and in 1558 became secretary of state to the regent, Mary of Lorraine. In 1559, however, Maitland threw in his lot with the lords of the congregation. He was sent to Elizabeth I for assistance and worked consistently for a union between the two crowns. In 1561 he was appointed secretary of state, and for about six years he directed the policy of Scotland and enjoyed the confidence of Mary Queen of Scots. John Knox was consistently antagonistic to him, and their encounter in the general assembly of 1564 is famous.

Maitland was doubtless concerned in the conspiracy against David Rizzio, and after Rizzio's murder was obliged to leave the court and was himself in danger of assassination. In 1567 he was again at Mary's side. He was a consenting party to the murder of Darnley, although he had favoured his marriage with Mary, but the enmity between Bothwell and himself was one of the reasons which drove him into the arms of the queen's enemies, among whom he figured at Langside.

He was one of the Scots who met Elizabeth's representatives at York in 1568; there he showed a desire to exculpate Mary and to marry her to the duke of Norfolk. but he was arrested in Sept. 1569 because of his share in the Darnley murder. He was delivered from his captors by a ruse on the part of his friend Sir William Kirkcaldy of Grange. Maitland now became the leader of the remnant which stood by the cause of the imprisoned queen, and with Kirkcaldy held Edinburgh castle against the regent Morton. The castle surrendered in May 1573 and on June 7 or 9, 1573, Maitland died at Leith.

"Secretary Maitland" was a man of great learning with a ready wit and a caustic tongue. He placed his country above the claims of either the Roman Catholic or the Protestant religions. Among the testimonies to his abilities are those of Queen Elizabeth I, of William Cecil and of Knox.

See J. Skelton, *Maitland of Lethington* (1894); A. Lang, *History of Scotland*, vol. ii (1902).

MAITLAND, a city of New South Wales, Austr., situated in the lower valley of the Hunter river, 20 mi. N.W. of Newcastle. Maitland is subject to flooding. but its suburbs, East Maitland, Morpeth, Tenambit. Lorn, Telarah and Rutherford are on high ground to the east and west. Pop. (1954) 21,331. In the adjacent farming area, mixed farming is extensively practised, as well as dairying and beekeeping. Lucerne, maize, millet, potatoes and vegetables are grown. Maitland is the market centre for stock and the local abattoir processes meat for local. metropolitan and export markets. Industries include the manufacture of rayon and textiles, clothing, bricks. tiles, pipes and light engineering. There are bus services to all centres within 30 mi. and the city is within the Newcastle suburban train service, while daily express train services link the district with Sydney and the northern half of New South Wales.

Cessnock (pop. [1954] 14,417) lies 18 mi. S.W. of Maitland and is the market town of the south Maitland coalfields. which cover an area of about 100 sq mi.. and contain some 1,640,000,000 tons of reserves. In the mid-1950s the average annual production was 9,000,000 tons of excellent quality coal. Cessnock is also the centre of a good agricultural district.

MAITREYA, the name of the bodhisattva nho is to be the next future Buddha. In accordance with the Hindu theory of recurrent cycles of the universe, Buddhism held that its truths have been repeatedly taught by Buddhas. who arise in succession, and that the doctrine after its decay and disappearance will be again realized and taught by other Buddhas in the future. A cycle in which no Buddha appears is called empty, but in this cycle there are to be five, or according to some schools 1,000. Four have already appeared, and the fifth is to be Maitreya (Pali, *Metteyya).*

The theory of recurrent Buddhas may not be primitive, but it certainly arose before the close of the Pali Canon, as Metteyya is twice mentioned there *(Digha-nikaya,* no. 26, *Buddhavamsa,* ch. 27), and the belief became established in all schools. According to the *Lalita-vistura* Maitreya was appointed vicegerent in the Tushita heaven when Gotama left it to become Buddha. He is sometimes represented in Mahayana sutras as being present as a bodhisattva at the Buddha's discourses.

MAITTAIRE, MICHAEL (1668–1747), English bibliographer, was born in France but went to England with his parents. who were Huguenots, after the revocation of the Edict of Nantes in 1685. He was educated at Westminster school and at Christ Church college, Oxford, after which he taught at Westminster (1695–99) and at a school of his own. For a time he was tutor to Philip Stanhope. Lord Chesterfield's natural son. He died in London, Sept. 7, 1747.

His works include: *Annales typographici* ab *artis inventae origine ad annum 1557 cum appendice ad annum 1664* (1719–41), still consulted by bibliographers; *Graecae linguae dialecti* (1706), originally written. as was his *English Grammar* (1712), for the use of Westminster school and surviving as a textbook for generations of schoolboys in J. Seager's translation (1831) from the Leipzig edition (1807); editions of classical texts (1713–25); and *Historia typographorum aliquot Parisiensium* (1717).

MAIWAND, a village of Afghanistan, jo mi. N.W. of Kandahar. It is chiefly notable for the defeat inflicted on a British brigade under General Burrows by Ayub Khan on July 27. 1880, during the second Afghan War *(see* AFGHANISTAN). Ayub Khan, Shere Ali's younger son. who had been holding Herat during the British operations at Kabul and Kandahar, set out toward Kandahar with a small army in June 1880, and a brigade under General Burrows was detached from Kandahar to oppose him. Burrows advanced to the Helmund, opposite Girishk, but was deserted there by Shere Ali, the wali of Kandahar, and had to retreat to Kushk-i-Nakhud. In order to prevent Ayub passing to Ghazni, Burrows advanced to Maiwand on July 27 and attacked Ayub, who had already seized that place.

The Afghans, who numbered 25,000, outflanked the British. the artillery expended their ammunition, and the native portion of the brigade got out of hand and pressed back on the British battalion. The brigade was completely routed and had to thank the apathy of the Afghans for escaping total annihilation. Of the 2.476 British troops engaged, 934 were killed and 175 wounded or missing. This defeat necessitated Sir Frederick Roberts' famous march from Kabul to Kandahar.

MAIZE (CORN or INDIAN CORN), the principal food plant of America. The word maize, derived from the Arawak Indian word *má-hiz,* was formerly preferred in international usage since corn, the term by which the plant is known in the United States and Canada, was in many countries synonymous with grain and was applied to any cereal. The botanical name is *Zea mays.* The Spanish equivalent, maiz, is still used in the Spanish-speaking countries of America, but elsewhere in the world wherever English is commonly spoken the word maize is giving way to corn. In southwestern United States maize means specifically a variety of sorghum, milo maize. *See* CORN. (P. C. MF.)

MAJANO (MAIANO), **BENEDETTO DA** (1442–1497), Italian sculptor, was born at Majano, near Florence. His earliest surviving work is the shrine of S. Savino (1468–70) in Faenza cathedral. Between 1470 and 1475 he was engaged on the altar of Sta. Fina in the Collegiata at S. Gimignano, in a chapel designed by his elder brother Giuliano (1468) and decorated with frescoes by Domenico Ghirlandaio. The connection between Benedetto da Majano and Domenico Ghirlandaio is reflected in the five narrative reliefs in Benedetto's masterpiece, the pulpit in Sta. Croce in Florence (probably 1472). A bust of Pietro Mellini (Museo Nazionale, Florence) by whom the pulpit was commissioned, is dated 1474, and reveals the same accumulation of naturalistic detail as is found in the male portraits of Ghirlandaio. The ornate decorative parts of the Sta. Croce pulpit are of great distinction, and have a counterpart in the marble doorway of the Sala dei Gigli in the Palazzo Vecchio, Florence.

After this time Benedetto was employed on two major works for the church of Monte Oliveto in Naples, the tomb of Mary of Aragon (d. 1470), begun by Antonio Rossellino, and an altarpiece of the Annunciation (1489). Concurrently he was employed by Filippo Strozzi, of whom he made a portrait bust (marble in the Louvre, Paris; terra cotta in the Kaiser Friedrich museum, Berlin) and whose tomb in Sta. Maria Novella, Florence, he completed after 1491. His last major works, the altar of S. Bartolo in S. Agostino at S. Gimignano (1493–9j) and an unfinished group representing the "Coronation of Ferdinand of Aragon" (Museo Nazionale) show some decline in quality.

As a sculptor Majano occupies a place above Mino da Fiesole and below Andrea del Verrocchio, and his work depends for its effect less on invention and originality than on unfailing taste and an exceptionally high level of technical skill. He was also an architect.

Majano died on May 24, 1497.

See L. Dussler, *Benedetto da Majano* (1924). (J. W. P.-H.)

MAJESTY, that is, awe-inspiring greatness, in particular the attribute of divine or sovereign power. The ancient Romans spoke of the majesty *(maiestas)* of the republic or of the Roman people, violation of which entailed a charge "of injured majesty," *crimen laesae mniestatis; i.e.,* of *lèse-majesté* or treason *(q.v.).* Under the principate the majesty of the state was transferred to the emperor's person, whose *maiestas augustalis* was protected from disrespect by extension of the law of treason. An early example of the modern usage of the term as an honorific form of address occurs in a letter of Q. Aurelius Symmachus to Theodosius I, whom he calls "Tour Majesty," after which it becomes frequent in addresses to the western emperors (cf. the *megaleiotes* of the Byzantines).

In the middle ages the Holy Roman emperors had "majesty" from the time of Louis the Pious; but kings *(e.g.,* Henry II of England), popes, cardinals and archbishops also enjoyed it occasionally; and we even find Hugh, count of Champagne, referring to his own in a letter to the monks of Saint-Remi (1114) and the citizens of Ghent ascribing it to Philip the Good, duke of Burgundy (1453). In these instances, however, one of the parties to the communication recognized the other as his superior: no precedent was therefore established for solving the problems that obstructed diplomacy when the emperor proved unwilling to accord "majesty" to other sovereigns who claimed it. Having withheld it from Francis I of France at the signing of the treaty of Cambrai (1529), Charles V eventually allowed it to him at the peace of Crepy-en-Laonnois (1544), with the distinction however that Charles's "majesty" was there specified as "Caesarean" while Francis' was only "Royal." The kings of Spain, on the other hand, managed to retain the "majesty" acquired when Charles was both king of Spain and emperor.

Embarrassments recurred (notably in the preliminaries of the peace of Westphalia) until the solution adumbrated in 1344 was generally adopted in the 18th century, when the "majesty" of the several kings was determined by qualification with the special epithets that the papacy had given them as kings: the king of France, then, as "Most Christian king," became "His Most Christian Majesty"; the king of Spain, "His Catholic"; and the king of Portugal, "His Most Faithful." Maria Theresa, during the War of the Austrian Succession, had "Apostolic Majesty" as undisputed successor of the "Apostolic kings" of Hungary; later, their right to the empire established, she and her successors had "Imperial and Apostolic."

The sovereign of the United Kingdom is "His" or "Her Britannic Majesty" for international purposes. "His Majesty" is usually enough for any ruler within his own realm but may be amplified: "His Sacred" (16th–17th century), "His Most Gracious" and "His Most Excellent Majesty" are English forms.

MAJLÁTH, JÁNOS or JOHN, COUNT (1786–1855), Hungarian historian and poet, was born at Budapest on Oct. 5, 1786. First educated at home, he subsequently studied philosophy at Eger (Erlau) and law at Gyor (Raab), his father, Count Joseph Majláth, an Austrian minister of state, eventually obtaining for him an appointment in the public service. Majláth devoted himself to historical research and the translation into German of Magyar folk tales and of selections from the works of the best of his country's native poets. Moreover. as an original lyrical writer and as an editor and adapter of old German poems, Majláth showed considerable talent.

During the greater part of his life he resided either at Budapest or Vienna, but a few years before his death he moved to Munich, where he fell into a state of destitution and extreme despondency. Seized at last by a terrible infatuation, he and his daughter Henriette, who had long been his constant companion and amanuensis, drowned themselves in the Lake of Starnberg, a few miles southwest of Munich, Jan. 3, 18jj.

Of his historical works the most important are the *Geschichte der Magyaren*, 5 vol. (1828–31; and ed., 1852–53) and his *Geschichte des österreichischen Kaiserstuats*, *j* vol. (1834–50). Noteworthy among his metrical translations from the Hungarian are the *Magyarische Gedichte* (1825) and *Himfy's auserlesene Liebeslieder* (1829; 2nd ed., 1831). A valuable contribution to folklore appeared in the *Magyarische Sagen, Märchen und Erzählungen*, 2 vol. (1825; 2nd ed., 1837).

MAJOLICA, a name properly applied to a species of Italian ware in which the body is coated with a tin enamel, on which a painted decoration is laid and fired. It is also applied to similar wares made in imitation of the Italian mare in other countries. The word in Italian is *maiolica*. *See* POTTERY AND PORCELAIN.

MAJOR (or MAIR), **JOHN** (1470–1550), Scottish theological and historical writer, was born at Gleghornie, near North Berwick. He was educated at the school of Haddington, where John Knox was later a pupil. After a short period spent at Cambridge (at God's house, afterward Christ's college) he entered the University of Paris in 1493, studying successively at the colleges of St. Barbe, Montaigu and Navarre, and graduating as master of arts in 1496. Promoted to the doctorate in 1505, he lectured on philosophy at Montaigu college and on theology at Navarre.

He visited Scotland in 151j and returned in 1518, when he was appointed principal regent in the University of Glasgow, John Knox being one of those who attended his lectures there. In 1522 he moved to St. Andrew's university, where in 1525 George Buchanan was one of his pupils. He returned to the College of Montaigu in 152j but was once more at St. Andrcn's in 1531, nhere he nas head of St. Salvator's college from 1534 until his death in 1550.

Major's voluminous writings may be grouped under *(a)* logic and philosophy, *(b)* Scripture commentary and *(c)* history. All are in Latin. all appeared between 1503 and 1530 and all nere printed at Paris The first group includes his *Exponabilia* (1jog), his commentary on Petrus Hispanus (150j–1506), his *Inclitarum artium libri* (1506, etc.), his commentary on Joannes Dorp (1504, etc.), his *Insolubilia* (1516, etc.), his introduction to Aristotle's logic (1521. etc.), his commentary on the ethics (1530) and, chief of all, his commentary on Peter Lombard's *Sentences* (1509, etc.); the second consists of a commentary on Matthew (1518) and another on the Four Gospels (1529); the last is represented by his famous *Historia Majoris Britanniae tam Angliae quam Scotiae per J.M.* (1521).

In political philosophy he maintained the Scotist position that civil authority mas derived from the popular will, but in theology he was a scholastic conservative, though he never failed to show his approbation of Gallicanism and its plea for the reform of ecclesiastical abuses. He hoped to reconcile realism and nominalism in the interests of theological peace.

Major claimed that the historian's chief duty is to write truthfully, and he was careful to show that a theologian might fulfill this condition.

The *History*, on which his fame now rests, was reprinted by Freebairn (1740) and was translated in 1892 by Archibald Constable for the Scottish History society. The latter volume contains a full account of the author by Aeneas J. G. Mackay and a bibliography by Thomas Graves Law.

MAJOR, a military rank standing above captain. Originally, the term was used adjectivally in the title sergeant major, the "third principal officer in a regiment" (Ward, 1639), now the major. In the 16th and 17th centuries there was a similarity between the duties of the sergeant, sergeant major and sergeant major general, in that they attended to the drill and administration of a company. a regiment and an army. respectively. In conversation, sergeant major was abbreviated to major and sergeant major general to major general. whence the modern titles of major and major general derive. In the case of sergeant major the sergeant was dropped about 1660, although in some quarters it lingered for several years.

In the 17th century the duties of a major were a combination of those now performed by the major (second in command) and sergeant major, but on the introduction of adjutants he mas relieved of much of the routine work. The brigade major corresponds in a higher sphere to the adjutant of a battalion Such expressions as town major and fort major indicate the purpose of the appointment.

The rank of major has always been below that of lieutenant colonel. In a regiment commanded by a colonel, he was the third in command; in a battalion commanded by a lieutenant colonel, he was second in command. In the larger organizations of the 20th century a regiment might have three or more majors, each commanding a battalion.

Drum major was an ancient title in the British service and was adopted by the U.S. army early in its history. The drum major was responsible for training the regimental drummers and often had the additional functions of regimental postman and banker. The title sergeant major was introduced as a noncommissioned rank in the British service early in the 18th century and was elevated to warrant rank in 1881. In the U.S. army it has usually indicated the principal administrative noncommissioned officer of a unit, the chief assistant to its adjutant.

See also INSIGNIA, MILITARY; OFFICERS. For the musical meaning of the term major *see* HARMONY. (F. P. T.)

MAJORCA, the largest of the group of Spanish islands in the Mediterranean sea known as the Balearic Islands (*q.v.*). Pop. (1950) 339,948; area, 1,405 sq.mi. On the northwest the coast is precipitous, but on the other sides it is low and sloping. On the northeast the chief bays are those of Alcudia and Pollensa, while on the southwest is the still more important bay of Palma. In the northwest a chain of mountains runs parallel with the coast and attains its highest elevation in Silla de Torrellas (4,741 ft.). Majorca has typical limestone scenery. Some oi the valleys, such as those of Valldemosa and Sóller, have luxuriant vegetation. There are marble quarries, those near Santañy being celebrated; while lead, iron and cinnabar have also been obtained. Coal is found at Renisalem. Selva, Santa Maria and elsewhere.

The inhabitants are principally engaged in agriculture. Old pine woods have in many places given way to the olive! the vine and the almond tree, to fields of wheat and flax or to orchards

BY COURTESY OF SPANISH TOURIST OFFICE

ONE OF THE FAMOUS 1,000-YEAR-OLD OLIVE TREES OF MAJORCA

of figs and oranges.

Inca is the centre of the oil district. The wines are light but excellent, especially the Muscatel and Montona. Brandy is made and exported; woolen and linen cloths are woven; the silkworm is reared and its produce manufactured; and canvas, rope and cord are largely made. The four principal roads are those from Alcudia, Manacor, Sóller and Andraitx to Palma, the capital. The main railway line runs from Palma to Manacor and Alcudia. There is regular communication with Barcelona and Alicante.

The principal municipalities include — besides Palma (133,397), Felantix (11,860) and Manacor (18,702), which are described in separate articles—Andraitx (4,303), Inca (12,247), Lluchmayor (10,041), Pollensa (8,541), Santañy (5,260), Sóller (9,279) and La Puebla (10,321).

MAJORIAN (IULIUS VALERIUS MAIORIANUS), emperor of the west from 457 to 461. After the deposition of Avitus Majorian was declared emperor by the regent, Ricimer. After repelling an attack by the Vandals upon Campania (458), he prepared a large force to invade Africa. Having defeated and concluded an alliance with Theodoric the Visigoth, at the beginning of 460 he crossed the Pyrenees for the purpose of joining the powerful fleet which he had collected at Carthagena. The Vandal king Gaiseric, however, succeeded through the treachery of certain officers in destroying the Roman fleet. Majorian thereupon made peace. But his ill-success had destroyed his military reputation. A mutiny inspired by Ricimer broke out in Lombardy, and on the 2nd of August 461 Majorian was forced to resign. He died five days afterward, either of dysentery or by violence.

Majorian was the author of a number of laws, appended to the Theodosian Code. Of these the most interesting is that forbidding the use of ancient monuments as quarries for building material.

See Sidonius Apollinaris, *Panegyric of Majorian (Chronica Minora,* ed. Mommsen, vol. 1, 2, 3) ; Edward Gibbon, *Decline and Fall,* ch. xxxvi (where an outline of the "novels" of Majorian is given) ; J. B. Bury, *Later Roman Empire,* ch. iii.

MAJORITY: *see* INFANT.

MAJUBA (properly AMAJUBA, Zulu for "the hill of doves"), a mountain in the Drakenberg, of northern Natal, South Africa, rising 7,046 ft. above the sea and more than 2,000 ft. above the level of the surrounding country. It overlooks the pass over the Drakenberg known as Laing's Nek, is 8 mi. S. of the Transvaal border and 18 mi. N. of the town of Newcastle. The railway from Durban to Johannesburg skirts the base of the mountain. During the Boer War of 1880–81 Majuba was occupied on the night of Feb. 26, 1881, by about 600 British troops under Sir George Pomeroy Colley.

On the following morning the hill was stormed by the Boers under Piet Joubert and the British routed, Colley being among the slain.

MAKAH, the Indians of Cape Flattery, Washington, the only group of Nutka affiliation in the United States. Bold canoemen, they paddle far out on the ocean to harpoon whales. Their culture, of general North Pacific coast type, has closest resemblance to that of the Quileute and Nutka.

MAKARAKA ("Cannibals"), a Negroid people of central Africa, related to the powerful Azande or Niam-Niam race, occupying the Bahr-el-Ghazal west of Lado. They came originally from the country of the Kibas, north of the Welle. They are a reddish-black, with nose less flat and cheekbones less prominent than the ordinary Negroes, and they do not extract the incisors. Their long silky hair is built up in the most fantastic form by means of vegetable substances. They are well known for strength and staying power.

See W. Junker, *Travels in Africa* (1890–92).

MAKARSKA (Ital. *Macarsca*), the chief town of an administrative district in Croatia, Yugo. Pop. (1953) 2,547, chiefly Serbo-Croatian. Makarska is a steamship station and has a brisk trade in wine, grain and fruit.

Under the name of Mocrum, Makarska was a thriving Roman city, and a bishopric until 639, when the town was destroyed by the Avars. Its bishopric was revived in 1320, but merged in that of Split (Spalato) in 1830.

MAKART, HANS (1840–1884), Austrian painter, who became the most celebrated painter of the great bourgeois epoch in Vienna, was born in Salzburg on May 29, 1840. He got his decisive training in Munich under Karl von Piloty, the leading historical painter at that time. He gave himself over entirely to a superficial, idealized historicalism, even in his portraiture, taking the 16th-century Venetians, Van Dyck and Rubens, as his models in composition and colour. Makart lived in Vienna from 1869 and died there, Oct. 3, 1884. In 1879, when he was at the peak of his fame, he undertook to design the festal procession which was to celebrate the silver wedding of the emperor Francis Joseph I and the empress Elisabeth.

Makart's art, with its riotous, decorative grandiloquence, was in general the kind which is destined to fade quickly. But it is not difficult to recognize in many details and in individual works no small talent as a painter and an unusual gift for colour.

Important works are in the galleries of Vienna, Berlin, Hamburg and Stuttgart. He also executed a series of decorative lunettes for the Kunsthistorisches museum in Vienna. His great historical pictures include "Caterina Cornaro" (1873), "The Entry of Charles V Into Antwerp" (1878) and "The Plague in Florence" (1867–68); other works are "The Burg Theatre Actress Charlotte Wolter as Messalina" (1876) and "The Triumph of Ariadne" (1873).

See Emil Pirchan, *Hans Makart* (1954). (F. NY.)

MAKEMIE, FRANCIS (*c.* 1658–1707/08), American colonial Presbyterian clergyman and leader in forming the first American presbytery, was born in County Donegal, Ire., about 1658 and was educated at the University of Glasgow. In 1682 he was ordained by the Presbytery of Laggan, Ire., to go to America in response to a plea from a Colonel Stevens in Maryland. Makemie preached in Somerset county, Md., and in the Barbados for a number of years, supplementing his meagre income by trading. About 1690 he married the daughter of a wealthy merchant of Accomack, Va., and took up residence there. A year later he was in London, where he was associated with Increase Mather of Boston, with whom he had corresponded for several years, and with other Presbyterian and Congregationalist leaders.

For ten years he preached and traded between Accomack and the Barbados, and sought also to unite the various struggling Protestant churches of these areas in a common cause. However, Anglican attempts to silence him by arrest, and a severe controversy with George Keith, first a Quaker and then an Anglican zealot, awakened Makemie to the peril of the Dissenting churches in the colonies. His ties with the Boston ministers were continued, and in 1706 Makemie seems to have been the leading spirit in uniting several scattered churches and pastors in Virginia, Maryland, Pennsylvania and New Jersey into a presbytery. The following year Lord Cornbury of New York imprisoned Makemie and a colleague, John Hampton, for preaching on Long Island without licences. After several months of imprisonment, and a long and costly trial, Makemie was acquitted. Cornbury was soon recalled to London. Thereafter the provisions of the Toleration act in England were claimed by all Dissenters in the American colonies. In his trial Makemie had been aided by the Boston Congregationalist ministers, leading Dissenting ministers in London and prominent New York citizens.

Makemie's death occurred in late 1707 or early 1708. Six of his several controversial and sermonic publications are extant.

OTIS SKINNER (1858–1942) IN VARIOUS RÔLES ILLUSTRATING CONTRASTS IN MAKE-UP

1. As Charles Surface in "The School for Scandal"
2. Portraying Hajj in "Kismet"
3. As Sancho Panza in Cervantes' "Don Quixote"
4. As Falstaff in "Henry IV."
5. Otis Skinner without make-up
6. As he appeared in "Mister Antonio"
7. As Denis Roulette in "Sire"
8. As Falstaff in "Merry Wives of Windsor"
9. As Philippe Bridau in "The Honor of the Family"

MAKE-UP (STAGE, MOTION PICTURE AND TELEVISION). As long as dramatic exposition has existed it has presumably been accompanied by some form of masquerade for the purpose of transforming the actor into the part he portrays. Use of make-up actually dates to earliest historical times.

Primitive Make-Up.—A suggestion of the simplicity and crudeness of the earliest devices of make-up may be found in the religious rites of primitive races in modern times. The Patagonians, whose only form of dramatic movement was the swaying of their bodies and a monotonous mumbling of incantations, made up for the occasion by smearing their faces with chalk. Among the Australian aborigines, uho rank somewhat higher in the ethnological scale, ritual ceremonies are enhanced by bodily adornments of wreaths, flowers and feathers worn over greased bodies and faces daubed with white clay.

The Aleutian Indians use painted wooden masks representing demons and sea animals for their mystic rites. while the natives of the South Sea islands dress their heads uith helmetlike structures, into which are built masks of wood, reeds, tortoise shell and human skulls, sometimes decorated with vegetable substances to represent hair. Some of these islanders, like the members of the Areoi societies, discarded the mask and impressed their spectators by painting their faces red and their bodies black. The Indians of North America, besides decorating their bodies and faces with variously hued war paints, were accustomed to behold their medicine man dressed for rituals in the skin and head of elk, bear, wolf or panther.

STAGE

Early.—The Chinese and Siamese theatre not only handed down old tradition of masks, but made use of grotesquely painted faces of blue, green, ochre, vermilion and ghastly white for demons and spirits. For the official ceremonies of the ancient Egyptians wigs were worn by kings and priests. Excavations dating back to 5000 B.C. reveal that eye and face paints also were widely used. Persian warriors wove strands of jute into their marcelled beards.

In the procession of Dionysus (out of which grew the Greek drama) the god was represented with long hair and beard: two small horns projecting from his forehead, while the reeling Bacchantes appeared with faces smeared with wine dregs or mulberry juice. Some of the followers in the train portrayed dead souls clad in shrouds with their faces covered in white lead.

Medieval.—For miracle plays of the 14th century and onward actors made up with startling realism as animals, devils, saints and angels. bluch ingenuity in facial disguise was used in a medieval play called *The Acts of the Apostles*, wherein the spectators saw the eyes of St. Matthew drawn out of his head and Simon Magus change his face several times. In an early English Passion play, Christ and the Apostles wore gilt wigs and the evil spirits appeared with bodies painted a reptilelike green, huge horns of oxen and rams ornamenting their heads.

Renaissance.—A favourite farce actor in Paris during the reign of Henry IV was known as Gros Guillaume. His face make-up consisted of a thick coating of flour which, at comic moments, he sent flying into the eyes of his fellow actors by puffing out his fat cheeks; on his chin he wore a piece of white lamb's skin, representing a beard. The popular commedia dell' arte (*q.v.*) of the Italian theatre of the 16th and 17th centuries was performed by actors masked always in the typical grotesquerie of Pierrot, Harlequin, Pantaloon, Scaramouche, Capitano, etc. The white face of the modern circus clown is a direct inheritance from the Pierrot, who in the 18th century discarded the mask and powdered his face with flour.

The English stage of Elizabeth I did away with the mask as a means of facial make-up. Instead of the set expressions of the disguised Harlequins and Pantaloons, actors mere seen as human beings with their natural faces or appropriately painted, bearded and wigged as the character called for. Cosmetics were applied simply and obviously as there was no artificial lighting to soften disguise deficiencies. The theatre of Molière encountered few make-up difficulties. The customary long ringlets of the court were worn whatever the period of the play, whether Roman or contemporary and the only beard necessary was the partly shaved mustache of the prevailing mode.

Later.—The ignoring of archaeological verity in make-up was characteristic of the English stage until after the time of David Garrick who, for nearly every character, wore the white court wig of George 111 and as Romeo appeared as a British gentleman of his day. The art of make-up was but little studied before the beginning of the 19th century. Costume was clumsy and wigs and beards for character parts were of crude material. The early method of acting Shylock was as a comedy part that roused audiences to laughter. Thomas Doggett, a celebrated Shylock, wore a ridiculous red wig and beard lor the part. The first actor to redeem the character from buffoonery was Charles Macklin, who presented him as si'nister and black-bearded. Since Macklin, actors have varied the aspect of Shylock according to their fancy. A well-remembered portrait was that of Henry Irving whose Jew was the picture of an elderly aristocrat.

The stage lighting of the period was dim and ineffectual, first by candles, later by smoking oil lamps, and in its twilight crudity passed unnoticed. As illuminating gas and calcium lights were introduced the necessity arose for greater circumspection in appearance. Make-up material, however, was still somewhat elemental and natural appearing heads and complexions a rarity.

(0. SK.; M. F.)

Modern.——With the introduction of Edison's electric light into the theatre came the need for new make-up materials and more skillful techniques of application. Crude, inartistic effects no longer could be hidden under the revealing light of electricity. A new era of realism was dawning. Stick grease paint, a revolutionary invention, soon made its first appearance, and by 1890 the demand for stage make-up had warranted its manufacture on a commercial scale.

The importance of modern stage make-up cannot be overemphasized. If it were not used, the performer quickly would discover that the lighting system of the stage actually had absorbed all the colour from his complexion. Therefore, make-up is necessary to restore this colour and define the features of the face to insure a natural appearance. It also helps the player to look and feel the part, and for most character interpretations it is absolutely essential. Standardized charts show the correct shades of straight make-up for various types of men, women and children.

MOTION PICTURES

During the early days of motion pictures, specially created make-up for the new medium was not available. Players who wore make-up at all borrowed both materials and techniques from the stage. Characters invariably were standard types: hero, heroine and villain. The hero and heroine were heavily made up with painted lips, chalk-white faces and dark eye make-up. The villain depended only upon long "moustachios" and heavily painted black eyebrows. Stick grease paint of the theatre, however! was not satisfactory. Necessarily heavy applications made it impossible for the actor to appear natural looking in close-ups and the limited range of colours failed to meet requirements of motion-picture lighting and photography.

The first make-up designed expressly for motion pictures was created by Max Factor and introduced in 1910. This mas a light, semiliquid grease paint in jars: made available in a precisely graduated range of tan-tone shades, suitable for the lighting and orthochromatic film emulsion of that period. A short time later, this new grease paint became the first make-up to be introduced in sanitary tubes. Prior to 1928, there were no established standards for motion-picture lighting or the selection of make-up colours. But with the advent of panchromatic film and incandescent lights on the sets, a complete gradation of make-up shades was created which allowed every player, from fairest blonde to darkest brunette: to appear true to type on the screen. In Feb. 1928, the Society of Motion Picture Engineers conducted a special series of tests for the purpose of standardizing the type of film, lighting and colours of make-up that proved most effective for motion pictures. Obviously, the principal consideration was given to the appearance of the players and it was quickly determined that make-up colours used for the former orthochromatic film, as well as the old method of arc lighting, would have to be changed. As a result of these experiments, Max Factor created a completely new range of make-up colours, which he presented to the motion-picture industry as Panchromatic Make-Up. For this achievement, he won a special Academy award.

The main make-up requisite used by a film player is the foundation colour, which panchromatic make-up supplies in 11 distinctive tones. ranging from a faint tan to a warm brown. With this standardized scale also including lip rouges in proportionate tones of dark red, as well as lining colours and eye shadow in panchromatic shades. the player can co-ordinate make-up colours with lighting and photographic conditions and usually be certain of uniformly correct screen results.

Motion-picture make-up is both a corrective art and a creative art. Make-up always must be applied skillfully, delicately and subtly so that facial expression will have natural freedom. The inexperienced should remember that the camera lens! particularly in close-ups, magnifies the face many times larger than life size. Consequently, every complexion flaw or crudely applied make-up artifice is clearly discernible. As a corrective art, make-up serves to cover blemishes, provide the face with a smooth, even colour tone for the most effective photography, clearly define the facial features for more visibly expressive action, make the player appear more attractive and insure a uniform appearance before the camera. As a creative art, make-up enables the player to take on the appearance of almost any type of character. It can be his means of achieving a distinctive "screen personality." It can make the young appear to age believably and the old appear to look young again. Countless special make-up devices, effects and tricks are available. Tears can be produced by blowing fumes from a menthol tube into the eyes. Weird or comedy effects may be created by blocking out teeth with black tooth enamel. Scars are realistically made with a simple brush application of collodion.

Wigs, hairpieces and mustaches also are an integral part of the motion-picture make-up art and the ancient art of wigmaking has kept pace with the general advancement and perfection of make-up. The modern hairpiece and wig is made of human hair. Each individual strand of hair is tied, one by one: with a special ventilating needle into a lacelike foundation, which is stretched over a wooden wigblock sculptured in the size and shape of the head contours. The most artistic beards and mustaches usually are achieved through the use of crepe hair. which comes in various shades and is applied with spirit gum. The bald or balding actor necessarily relies upon a hairpiece as a means of regaining a youthful appearance, but players of all ages and types depend upon hairgoods to achieve realistic characterizations. In 1937, the film production *Marie Antoinette* called for 903 ornately fashioned white wigs and 1,200 less elaborate wigs for peasant extras. Another period movie, *Forever Amber* required 4,402 wigs. In Cecil B. DeMille's *The Ten Commandments,* approximately 7,500 hairpieces, including beards and mustaches, were used.

Make-Up for Colour Films.—The introduction of colour to motion pictures brought make-up problems of the most serious nature. Existing grease paint made some players appear to have yellow jaundice. Other faces became bright red, blue or green on the screen. As colour film processes were perfected, the need for a new type of make-up became mandatory. The problem was not one of merely developing new colours. Entirely new materials had to be created. After first testing a liquid make-up, which did not prove satisfactory, experiments were started in a completely new field of make-up principles. This resulted in the introduction of a spectacularly successful solid make-up, applied with a moist sponge, known as Pan-Cake Make-Gp. Instead of covering and concealing skin surfaces, the new material could be applied in a light. transparent film of colour. It was first used in *Vogues of 1938* and later in *The Goldwyn Follies.* For the first time in history audiences saw players who appeared realistic and lifelike enough to convey the impression that they might at any time step down from the screen into the theatre. Soon Pan-Cake Make-Up started replacing grease paint to a large extent even for black-and-white films. Another highly successful material, perfected for colour motion-picture use, was a creamy foundation in semisolid stick form called Pan-Stik. Make-up charts show the correct colours to use for each type of colour film.

Basic techniques of make-up application are virtually the same for black-and-white and colour photography, except that the latter demands even greater skill and perfection in application methods for the most realistic results.

TELEVISION

As early as 1932, special make-up had been created for television. This was the result of exhaustive, practical tests conducted in collaboration with the pioneer Don Lee experimental television station, W6XAO, in Los Angeles. In all, four major phases of technical development have occurred in the evolution of this make-up. The first creation was a light-coloured monotone make-up. Next came the "painted Indian" effect, employing multiple make-up colours. which televised most naturally during the intermediate period of television. This was followed by the development of the modern TV-N series of colours in Pan-Cake and Pan-Stik foundations for black-and-white television. The fourth step was the creation of special materials and shades for colour television.

Although 11 shades (TV-IN to TV-11N) of make-up were available for black-and-white television in the latter 1950s, the average foundation make-up needs for the medium could be fulfilled with six colours—TV-4N to TV-9N. Colours in the lower numbers are light pastel pinks and beiges. In the higher numbers, they are tan, brown and dark brown. TV-IN, for instance, would provide an extremely white face while TV-11N would give the darkest possible complexion effect. Without make-up. the performer cannot expect to have an attractive complexion on television. Light complexions become ghostly white. Dark complexions look dirty. Men who may be closely shaved still appear to be in need of a shave. Everyday make-up shades used by women televise too light or too dark and ordinary lipstick colours usually wash out. Screen make-up shades are equally unsatisfactory.

For colour television, various new materials and countless variations of colours had to be tested. The very success of the medium is largely dependent upon the naturalness, accuracy and believability of the human skin tones it reproduces. It might be relatively unimportant if a green dress appeared blue on a colour-receiving set, but a performer with a green face would be ludicrous. The problem is doubly complicated because faces must look lifelike on colour television and at the same time appear natural in the simultaneous black-and-white telecasts. Like make-up for black-and-white television. the make-up used for colour television is specifically designated as the CTV series and ranges from CTV-1W to CTV-12W in Pan-Cake Make-Up and Pan-Stik.

(M. F.)

MAKING-UP PRICE. A term used in the London and other British stock exchanges to denote the price at which speculative bargains are carried over from one account to the next. The carry-over of a "bull" position in Eries, for example, implies a sale for cash and a simultaneous repurchase for the new account, both bargains being done at the making-up price, fixed at noon on carry-over day, in accordance with the market price then current *(see* STOCK EXCHANGE). The term is also used in New York, where the making-up prices are fixed at the end of a day's business. in accord with the U.S. system of daily settlements.

MAKÓ, the capital of Csongrád county, Hungary, a typical market town of the Hungarian plain situated near the right bank of the Maros. Cereal cultivation and stock raising are important activities on its fertile communal lands and there are several flour mills in the town, but its chief specialization is the growth of vegetables, particularly onions for which it is famous. Pop. (1957 est.) 34.000 mun.

MAKONNEN, RAS TAFAWI (1891–), **a** king of

Abyssinia, "King of the Kings of Ethiopia, Lion of Judah, the Elect of God," born July 17, 1891, was great-grandson of Haile Melekot, King of Shoa, and son of a distinguished soldier and diplomat. He was educated by the French mission at Harrar. In 1912 he married Waizero Manin, granddaughter of Ras Michael, his eldest son being born July 27, 1916. When on Sept. 27. 1916, the dissolute Lej Yasu was dethroned and his aunt, Zauditu. proclaimed empress, Tafari, her cousin, was appointed regent, heir to the throne, and Ras (prince) of Rases. Ras Michael, Yasu's father, was defeated on Oct. 27. Yasu rallied his father's army, but it surrendered at Magdala in Dec. 1917. Yasu was imprisoned in 1921.

In order to gain authority independently of the empress Zauditu, Ras had himself proclaimed king, Nov. 7, 1928. After Zauditu's death he formally mounted the throne on Nov. 2, 1930, as Emperor Haile Selassie I. He continued his work of modernization, secured the admission of Abyssinia to the League of Nations in 1923, and toured European capitals in 1924.

Difficulties with England over control of the Nile waters were soon overshadowed by disputes with Italy. In spite of the arbitration agreement of 1928 and the action of the League of Nations, hostilities broke out late in 1935 with Italy, ending in the flight of the emperor from Addis Ababa, May 1, 1936; occupation of the capital by the Italians, May 5; and the proclaiming of King Victor Emmanuel as emperor of Abyssinia.

In May 1941 Haile Selassie returned to Addis Ababa. Great Britain recognized his nation as a sovereign state on Jan. 31, 1942, and provided financial aid to reconstruct the country.

(J. Sw.; X.)

MAKRAN (MEKRAN), the coastal region of southeastern Persia and southwestern Pakistan, extending along the Gulf of Oman for about 600 mi. from Ras (cape) el-Kuh to Las Bela (southern Baluchistan). The long lateral valley of the Kej (Kech) river and the name Makran are associated in early geographies: thus the Kei-Macoran of Marco Polo is the Makran of todav. The name is applied in particular to a former province of Persia and to one of the Baluchistan states.

Makran's long sandy coastline is broken by the magnificent cliffs of Malan, the headlands of Ormara and Gwadur, the precipitous coast of Jebel Zarain (near Pasni), the bays of Charbar (Chahbar) and Gwatar, and the inlet near Ras Maidani. Northward is a band of parallel ridges with narrow valleys between. The normal relief of southwestern Baluchistan is somewhat emphasized in Makran. The volcanic action that preceded the upheaval of recent strata and the folding of the edges of the interior highlands is evidenced by occasional boiling mud volcanoes. The coast is indented by several harbours: Ormara. Khor Kalmat, Pasni, Gwadur and Charbar are all rather difficult of approach because of the sand bar apparently extending all along the coast — probably the remains of a submerged ridge. They are all subject to lively surf under certain wind conditions. Gwadur, which with about 300 sq.mi. of hinterland belongs to the sultanate of Muscat and Oman, is the most important of them. Except in the Kej (upper Dasht) valley, and that of the Bolida, an affluent of the Kej, there is not much cultivation in Makran. These two picturesque valleys have thick date palm groves, croplands and orchards; yet the surrounding hilly waste is mainly a barren repetition of sun-cracked crags and ridges with parched valleys between. The Rakhshan and Mashkel rivers, sweeping down respectively from the Kalat highlands in Pakistan and the Koh-i-Bampusht uplands of Persia, unite to break through the hills northward and form the lake and swamps of the Hamun-i-Mashkel, and define the northern limits of Makran. In their valleys are narrow strips of very advanced cultivation, especially of dates.

The population has a prominent Arab element, for the Arabs held Makran even before they conquered Sind. There are Negroes on the coast, descended from imported slaves. The Meds of the Indus valley still provide most of the fishing population; they represent the Ichthyophagi ("fisheaters") of Arrian. The old Tajik element of Persia is not so evident in Makran as farther north; and the Karak pirates, whose depredations led to British intervention in the area, seem to have disappeared altogether.

Following the establishment of British control over Kalat earlier in the 19th century (see BALUCHISTAN) the boundary between the Persian and British (now Pakistani) parts of Makran was demarcated by a commission in 1895–96. In 1898 a British force was sent to Makran by sea, because of a rebellion against the khan of Kalat and an attack by Makrani chiefs on a British survey party. A brief campaign ended with the capture of the Kej citadel. Another expedition was needed in 1901 to storm Nodiz.

Makran is served by a fair weather motorable road in the interior uplands and, on the Persian side nearer the coast, by a pack road. The former, coming ultimately from Quetta and Kalat, passes through Turbat, crosses the frontier near Pishin and passes west of Geh before turning north to Bampur; branches run southward to Charbar and from Turbat to Pasni and Gwadur. The pack road runs from the Perso-Pakistan frontier via Charbar to Jask. The Karachi-Bushire telegraph line passes through Gwadur and the other Makran ports.

MAKRAN STATE up to 1948 was feudatory to Kalat, forming the southwesternmost of the five divisions of the khanate. On March 17, 1948, it became independent of Kalat as a result of its chief's separate declaration of accession to the new dominion of Pakistan. In 1952, with Kalat and two other Baluchistan states, it formed the Baluchistan States union (see BALUCHISTAN). With the establishment of the single West Pakistan province in 1955, Makran became in effect one of the four districts of the new Kalat division of that province. Area of Makran 23,196 sq.mi.; pop. (1951) 138,691. The capital is Turbat.

PERSIAN MAKRAN was formerly a separate province, but under the law of territorial division of administration of 1937 was made part of the *ostan* of Kerman and Makran. As a province its capital was Jask, a port once under British control about 130 mi. S.E. of Bandar Abbas.

MAKSOORA, in Mohammedan architecture, the sanctuary or praying chamber in a mosque, sometimes enclosed with a lattice screen; the word is occasionally used for a similar enclosure round a tomb.

MALABAR, a district of Madras state, Republic of India. Geographically the name is sometimes extended to the entire western coast of the peninsula. Properly it should apply to the strip below the Ghats, which is inhabited by people speaking the Malayalam language. a branch of the Dravidian stock, who form a peculiar race, with castes, customs and traditions of their own. It would thus be coextensive with the old kingdom of Chera, including the modern state of Travancore-Cochin and part of Kanara.

The district of Malabar extends for 145 mi, along the coast, running inland to the Ghats with a breadth varying from 25 to 70 mi. The administrative headquarters are at Calicut. Area, 5,844 sq.mi. Malabar is much diversified in its configuration. From the eastward the great range of the Western Ghats, only interrupted by the Palghat gap, looks down on a country broken by spurs, ravines, forests and jungle. To the westward gentler slopes and downs, and gradually widening valleys closely cultivated, succeed the forest uplands, till, nearer the seaboard, the low laterite tablelands shelve into rice plains and backwaters fringed with coconut palms. The coast runs in a southeasterly direction, and forms a few headlands and small bays. In the south there is considerable extent of tableland. The mountains of the Western Ghats, from 3,000 to 8,000 ft. high, run almost parallel to the coast, and along the coast is an almost continuous chain of lagoons or backwaters which have been formed by the action of the waves and shore currents in obstructing the waters of the rivers. Connected by artificial canals, they form a cheap means of transit for a large local trade. Fishing and fish curing is an important industry, coir is manufactured, and there are sawmills, soap and tile works. The forests are extensive and of great value. The population in 1951 was 4,758,342, of whom nearly a third are Moslems.

The staple crop is rice, the next most important products being coconuts, fruits and pepper. Coffee is grown chiefly in the upland tract known as the Wynaad (*q.v.*). The Southern railway crosses the district and runs along the coast from Calicut to Mangalore. The principal seaports are Calicut, Tellicherry and

Cannanore. The principal exports are coffee, coconut products and pepper.

MALABARI, BEHRAMJI (1853–1912), Indian journalist and social reformer, was born in 1853 at Baroda, the son of a poor Parsi in the employment of the state. He was educated in a mission school, but he never obtained an academical degree. Coming to Bombay. he fell under the influence of John Wilson, principal of the Scottish college. He published a volume of poems in Gujarati (1875), and *The Indian Muse in English Garb* (1877), which attracted attention in England. In 1880 he acquired the *Indian Spectator*, which he edited for 20 years until it was merged in the *Voice of India*. In 1901 he became editor of *East and West*. He was an ardent and indefatigable advocate of social reform in India. especially as regards child marriage and the remarriage of widows. It was largely by his efforts. in the press and in tours through the country, that the Age of Consent act was passed in 1891. He died at Bandora, near Botnbay, on July 12, 1912.

He also wrote *Gujarat and the Gujarati's* (1883) and *The Indian Eye on English Life* (1893).

See R. P. Karkaria, *India, Forty Years of Progress and Reform* (London, 1896).

MALABON, a municipality (with 21 *barrios* or districts) of the province of Rizal, Luzon, Philippine Islands, 1 mi. inland from Manila bay and 3 mi. N. of Manila, with which it is connected by a streetcar line. Pop. (1948) 46,455. Malabon is noted for its fish ponds and fisheries and for the manufacture of perfume from the flowers of ilang-ilang trees *(Cananga odorata)*.

Other leading industries are sugar refining, cigar making and the weaving of jusi cloth. Tagalog is the vernacular. Of the inhabitants aged 6 to 19 inclusive, 39.6% were reported in 1939 as attending school, while 75.2% of the population 10 years old and over was reported as literate. Malabon was formerly known as Tambóbong.

MALACCA, a town on the west coast of the Malay peninsula, which with the adjoining territory forms one of the settlements of the Federation of Malaya. and gives its name to the straits that divide Sumatra from the Malaya peninsula. Malacca is administered by a resident commissioner. The population of the town of Malacca in 1939 was about 44,000. In 1952 the population of the territory was estimated at 272,820, of whom Malays numbered 138,814, Chinese 106,779, and Indians and Pakistanis 23,160.

The trade of this once flourishing port has declined, most of the vessels being coasting craft. This is due to the shallowness of the harbour, and to the fact that Penang and Singapore, at either entrance to the straits, draw all the trade and shipping. The area of the territory is 637 sq.mi. The settlement is wholly agricultural. Much of the land has been in the hands of natives, but there is ordinarily a large acreage under rubber *(hevea)*. The settlement is well opened up by roads; and a railway, which is part of the Malayan railway system, was constructed from the town of Malacca to Tampin in the Negri Sembilan. There is a good resthouse at Malacca and a comfortable seaside bungalow at Tanjong Kling, 7 mi. from the town. Malacca is 118 mi. by sea from Singapore and 50 mi. by rail from Seremban, the capital of the Negri Sembilan. In World War II it was occupied by Japan.

History. — Malacca, visited by few ships, was the least important of the three British settlements on the Straits which gave their name to the colony. It has, however, a remarkable history *(see* MALAYA: *History)*. The precise date of its foundation cannot be ascertained, but there is reason to believe that this event took place in the 14th century. The Roman youth Ludovigo Barthema is thought to have been the first European to visit it, some time before 1503; and in 1508 Diogo Lopez de Siqueira sailed from Portugal for the purpose of exploiting Malacca. He was hospitably received, but disagreements with the natives ensued and word was brought to Siqueira that a treacherous attack was about to be made upon his ships. Siqueira sent a native man and woman ashore "with an arrow passed through their skulls" to the sultan, "who was thus informed," says João de Barros, ('through his subjects that unless he kept a good watch the treason which he had perpetrated would be punished with fire and sword." The sultan retaliated by arresting Ruy de Araujo, the factor, and 20 other men who were ashore collecting cargo. Siqueira immediately burned one of his vessels and sailed for Portugal. In 1511 Alphonso d'Albuquerque captured the town. Malacca became a Portuguese possession for 130 years, and was the base of their commercial explorations in southeastern Asia while they enjoyed, and later while they sought to hold, their monopoly in the East. It was from Malacca, immediately after its conquest. that d'Albuquerque sent Antonio d'Abreu on his voyage of discovery to the Moluccas, or Spice Islands, which later were the objective of Ferdinand Magellan's voyage of circumnavigation. Under the Portuguese government St. Francis Xavier started a mission in Malacca, the first Christian mission in Malayan lands.

The Dutch held Malacca from 1641 till 1795, when it was taken from them by Great Britain, and the Dutch system of monopoly in the straits was abolished. The colony was restored to the Dutch in 1818, but six years later it came finally into the hands of Great Britain, being exchanged by a treaty with Holland for the East India company's settlement of Bengkulen and a few other unimportant places on the west of Sumatra. By this treaty the Dutch were precluded from interference in the affairs of the Malay peninsula, and Great Britain from similar action in regard to the States of Sumatra, with the exception of Achin, the right to protect that state being maintained by Great Britain until in 1872 it was finally abandoned by a treaty concluded with Holland. It was not until 1833 that the whole territory was brought under British control.

During World War II it was under Japanese control and became a member of the Federation of Malaya in 1951.

MALACHI, the name assigned to the last book of the Old Testament in English (the last of the "prophets" in the Hebrew Bible), which according to the title (Mal. i, 1) contains the "word of Yahweh to Israel by the hand of Malachi." In form the word means "my messenger." It could be explained as a contraction of Malachiah, "messenger of Yahweh"; but the Septuagint is probably right in not regarding it as a proper name ("by the hand of His messenger"). Not only do we know nothing from internal or external evidence of the existence of a prophet of this name, but the occurrence of the word in the title is naturally explained as derived from iii, 1: "Behold, I send my messenger" (cf. ii, 7). The prophecy must, therefore, be regarded as anonymous; the title was added by the compiler who wrote similar editorial titles to the anonymous prophecies beginning Zech. ix, 1; xii, 1. (Note the use of "burden.")

The contents of the prophecy fall into a series of clearly marked sections, as in the paragraph division of the Revised Version. These apply, in various ways, the truth emphasized at the outset: Yahweh's love for Israel in contrast with his treatment of Edom (i, 2–5). Israel's response should be a proper regard for the ritual of His worship; yet any offering, however imperfect, is thought good enough for Yahweh's altar (i, 6–14). Let the priests, who are responsible, take warning, and return to their ancient ideals (ii, 1–9). Again, the common Fatherhood of God should inspire a right relation among fellow Israelites, not such conduct as the divorce of Israelite wives in order to marry non-Israelite women (ii, 10–16). The prevalence of wrongdoing has provoked scepticism as to righteous judgment; but the messenger of Yahweh is at hand to purge away indifferentism from worship and immorality from conduct (ii, 17–iii, 6). The payment of tithes now withheld mill be followed by the return of prosperity (iii, 7–12). Religion may seem useless, but Yahueh remembers His own, and will soon in open judgment distinguish them from the irreligious (iii, 13–iv, 3 The book closes with an appeal to observe the law of Moses, and with a promise that Elijah shall come before the threatened judgment--probably a later addition.

The topics noticed clearly relate the prophecy to the period of Ezra and Nehemiah, when the Temple had been rebuilt (i. 10; iii. 1, 10), the province of Judah was under a Persian governor (i. 8), and there had been time enough for the loss of earlier enthusiasm. The majority of modern scholars are agreed that the prophet prepares for the work of those reformers (Ezra, 458 *c.;* Nehemiah, 444, 432 B.C.). The priests have fallen into contempt (ii. 9) and have neglected what is still one of their chief trusts, the oral law (ii. 6 *seq.)*. The priestly code of written law, in its present form, was not promulgated until 444 B.C. (Neh. viii.-x.) and it is not presupposed by "Malachi" who writes under the influence of the earlier Code of Deuteronomy only, and must therefore belong to a date prior to 444. The independent character of the attack on current abuses (marriage with foreign women, ii. 11; non-payment of sacred dues, iii. 8) suggests priority to the work of Ezra. The prophecy affords an interesting and valuable glimpse of the post-exilic community, with its various currents of thought and life. The completion of the second Temple (j16 B.C.) has been followed by disillusionment as to the anticipated prosperity, by indifference to worship, scepticism as to providence, and moral laxity. In view of these conditions, the prophet's message is to reassert the true relation of Israel to Yahweh, and to call for a corresponding holiness, especially in regard to questions of ritual and of marriage.

The book is a significant landmark in the religious history of Israel. Its emphasis on the observance of ritual finds fullest development in the Priestly Code, subsequently promulgated; its protest against foreign marriages is made effective through the reforms of Ezra and Nehemiah; the influence of its closing words on later expectation is familiar to every reader of the new Testament (Matt. xvii. 3, 4, 10–13; xxvii. 47, 49; John i. 21, 25).

(H. W. R.)

MALACHITE, a bright green mineral, consisting of a basic copper carbonate. It is one of the commonest ores of copper and perhaps the most conspicuous, being a useful guide in prospecting. It is found in the upper oxidized portions of copper deposits, and is formed by the action of water, air and carbon dioxide on primary copper sulfides, especially where calcium carbonate is present. The soluble copper salts set free by oxidation of the sulfides react with limestone or other carbonates and precipitate the insoluble malachite. The mineral is found in nearly all copper-mining districts; specially fine specimens have come from various mines in Russia, where it has often been used as a polished ornamental stone. Other well-known localities for good specimens have been the Copper Queen mine, Bisbee. Arizona, the old Burra Burra mines. Kooringa, South Australia and southwest Africa.

The composition of malachite is $CuCO_3Cu(OH)_2$. It belongs to the monoclinic system, but rarely forms good crystals, occurring mostly as nodular, botryoidal (grapelike) or reniform (kidney-shaped) masses, with pronounced radial and concentric structure, successive layers often varying much in colour. It may also be quite compact or earthy and often forms thin films or mere stains on rocks. It is very commonly associated with the deep blue azurite (*q.v.*). The density is about 4 and the hardness 3.5–4.0. It is soluble in acids with effervescence. (R. H. RA.)

MALACHOWSKI, STANISLAW (1736–1809), Polish statesman, the younger son of Stanislaw Malachowski, palatine of Posen. He was first elected a deputy to the Diet of 1764, and the Four Years' Diet unanimously elected him its speaker (1788). Malachowski worked tirelessly for reform and to save the republic. He was one of the framers of the constitution of May 3, 1791, exceeding in liberality all his colleagues and advocating the extension of the franchise to the towns and the emancipation of the serfs. In 1807 Malachowski was placed at the head of the executive committee appointed at Warsaw after its evacuation by the Prussians, and when the grand duchy of Warsaw was created Malachowski became president of the senate. In the negotiations with the Austrian government concerning the Galician salt-mines Malachowski assisted the treasury by hypothecating all his estates as an additional guarantee. In 1809 he died at Warsaw.

MALACHY, ST. (c. 1094–1148), otherwise known as Maol-Maodhog (or Maelmaedhog) Ua Morgair, archbishop of Armagh and papal legate in Ireland, was born at Armagh. His father, an Irish clergyman, the *Fearleighlinn,* or lector, at the university, was said to have been of noble family. He was vicar of Archbishop Celsus or Ceallach of Armagh, and carried out many reforms ending to increase conformity with the usage of the Church of Rome. He spent four years with Malchus, bishop of Lismore (in Munster), a strong advocate of Romanism. On his return from Lismore, Malachy undertook the government of the decayed monastery of Bangor (in Co. Down), but very soon afterwards he was elected bishop of Connor (now a small village near Ballymena). After the sack of that place by the king of Ulster he withdrew into Munster; here he was kindly received by Cormac MacCarthy, with whose assistance he built the monastery of Ibrach (in Kerry). Meanwhile he had been designated by Celsus to succeed him in the archbishopric but eventually returned, at his own desire, to the smaller and poorer portion of it, the bishopric of Down. In 1139, Malachy set out from Ireland with the purpose of soliciting from the pope the pallium for the archbishop of Armagh. On his way to Rome he visited Clairvaux, and thus began his friendship with St. Bernard. Malachy was received by Innocent II with great honour, and made papal legate in Ireland, though the pope refused to grant the pallium until it had been unanimously applied for "by a general council of the bishops, clergy and nobles." Nine years later (1148), at a synod of bishops and clergy held at Inis-Patrick (St. Patrick's island, near Skerries, Co. Dublin), Malachy was commissioned to return to Rome and make fresh application for the pallium; he did not, however, get beyond Clairvaux, where he died in the arms of St. Bernard, on Nov. 2, 1148. The object of his life was realized four years afterwards, in 1152, during the legateship of his successor. Malachy was canonized by Clement III in 1190. Malachy reformed and reorganized the Irish Church and brought it into subjection to Rome; like Boniface, he was a zealous reformer and a promoter of monasticism. He opened the first Cistercian monastery in Ireland, five more being soon afterwards established. Several works are attributed to him, but are all probably spurious.

St. Bernard's *Life* of Malachy, and two sermons on his death will be found in J. P. Migne, *Patrologia Latina,* clxxxii, clxxxiii; *see* also the ecclesiastical histories of Ireland by J. Lanigan (1829) and W. D. Killen (1875); *A.* Bellesheim, *Geschichte der katholischen Kirche in Irland,* Bd. *I.* (Mainz, 1890); G. T. Stokes, *Ireland and the Celtic Church* (6th ed., 1907); J. O'Hanlon, *Life of Saint Malachy* (Dublin, 1859); articles in *Dict. Nat. Biog.* and Herzog-Hauck's *Realencyklopädie* fur *protestantische Theologie.*

MALACOSTRACA, the largest subclass of the Crustacea (*q.v.*), including the lobsters, crawfish, crabs, shrimps, prawns, beach fleas, sow bugs and various other crustaceans. They may be briefly defined as Crustacea having the body composed of nineteen somites, all, typically, bearing appendages, the trunk-limbs differentiated into two series, a thoracic of eight and an abdominal of six pairs; and the genital openings of the female on the sixth, those of the male on the eighth thoracic somite. A study of the comparative morphology of the Malacostraca permits us to draw up a scheme for the probable course of evolution of the group which is, at least, not contradicted by our scanty knowledge of its fossil representatives. According to this scheme, the earliest Malacostraca exhibited what has been called the "caridoid facies"; that is to say, they were shrimplike in general form, with a carapace enveloping, but not coalesced with, the thoracic somites, with stalked eyes, biramous antennules, and a scale-like expodite on the antenna, with the thoracic limbs forming walking-legs with swimming exopodites and branchial epipodites and with a tendency for one or more of the anterior pairs to be assimilated to the mouth-parts as maxillipeds; with the abdominal appendages forming biramous swimmerets, except the last pair which are large, lamellar, and form with the telson a "tail-fan."

The earliest fossils that can be definitely referred to the Malacostraca occur in the Carboniferous rocks and present, with little modification, the caridoid facies described above. Some of them (Pygocephalus) have a brood-pouch formed by overlapping plates (oostegrtes) from the bases of the thoracic legs and appear, therefore, to be referable, to the Mysidacea. From the caridoid Mysidacea a series can be traced in which the carapace is progressively reduced, the thoracic exopodites are lost and the eyes become sessile. Although palaeontology gives no help, the steps of this series are indicated by the specialized offshoots which have given the Cumacea, Thermosbaenacea, Tanaidacea and Isopoda. The Amphipoda belong to the same series but their precise place in it is less clear. The other orders of Malacostraca have no brood-pouch and appear to have diverged very early from the primitive stock. Already in Carboniferous times the Syncarida had lost the carapace and had much the same general structure as the recent Anaspides and its allies. Another series in which the carapace coalesced with the thoracic somites gave rise to the great group of the Decapoda, from which the Euphausiacea are perhaps an offshoot. The Decapoda, beginning with caridoid forms, have, in several independent lines, assumed the crablike or "carcinoid facies" by reduction of the abdominal region (Brachyura or true crabs, and crablike Anomura). The Stomatopoda had assumed nearly their typical structure in Jurassic times but their earlier history is unknown.

In the scheme of phylogeny thus outlined no mention has been made of the Phyllocarida, which, in most systems of classification, are ranked as the most primitive Malacostraca, forming a link with the Branchiopoda. They differ from the other Malacostraca in having an additional somite in the abdomen, the telson terminating in a "caudal fork," and a bivalve carapace provided with an adductor muscle. The thoracic limbs are more or less flattened and leaflike and have a general resemblance to the trunk-limbs of the Branchiopoda though a close comparison is difficult. The existing genera, Nebalia and its allies, are believed to show affinity with the fossil Ceratiocaridae, the earliest of which appear in Cambrian rocks and are thus vastly more ancient than any other Malacostraca. Recent work, however, tends to diminish the significance of the differences between Phyllocarida and other Malacostraca, and, in particular, the recognition of a vestigial seventh abdominal somite in certain primitive Mysidacea suggests that the Phyllocarida may, after all, be mose closely related to the Peracaridan series than has been supposed.

The orders composing the Malacostraca may be grouped in the following five divisions, briefly characterized below:

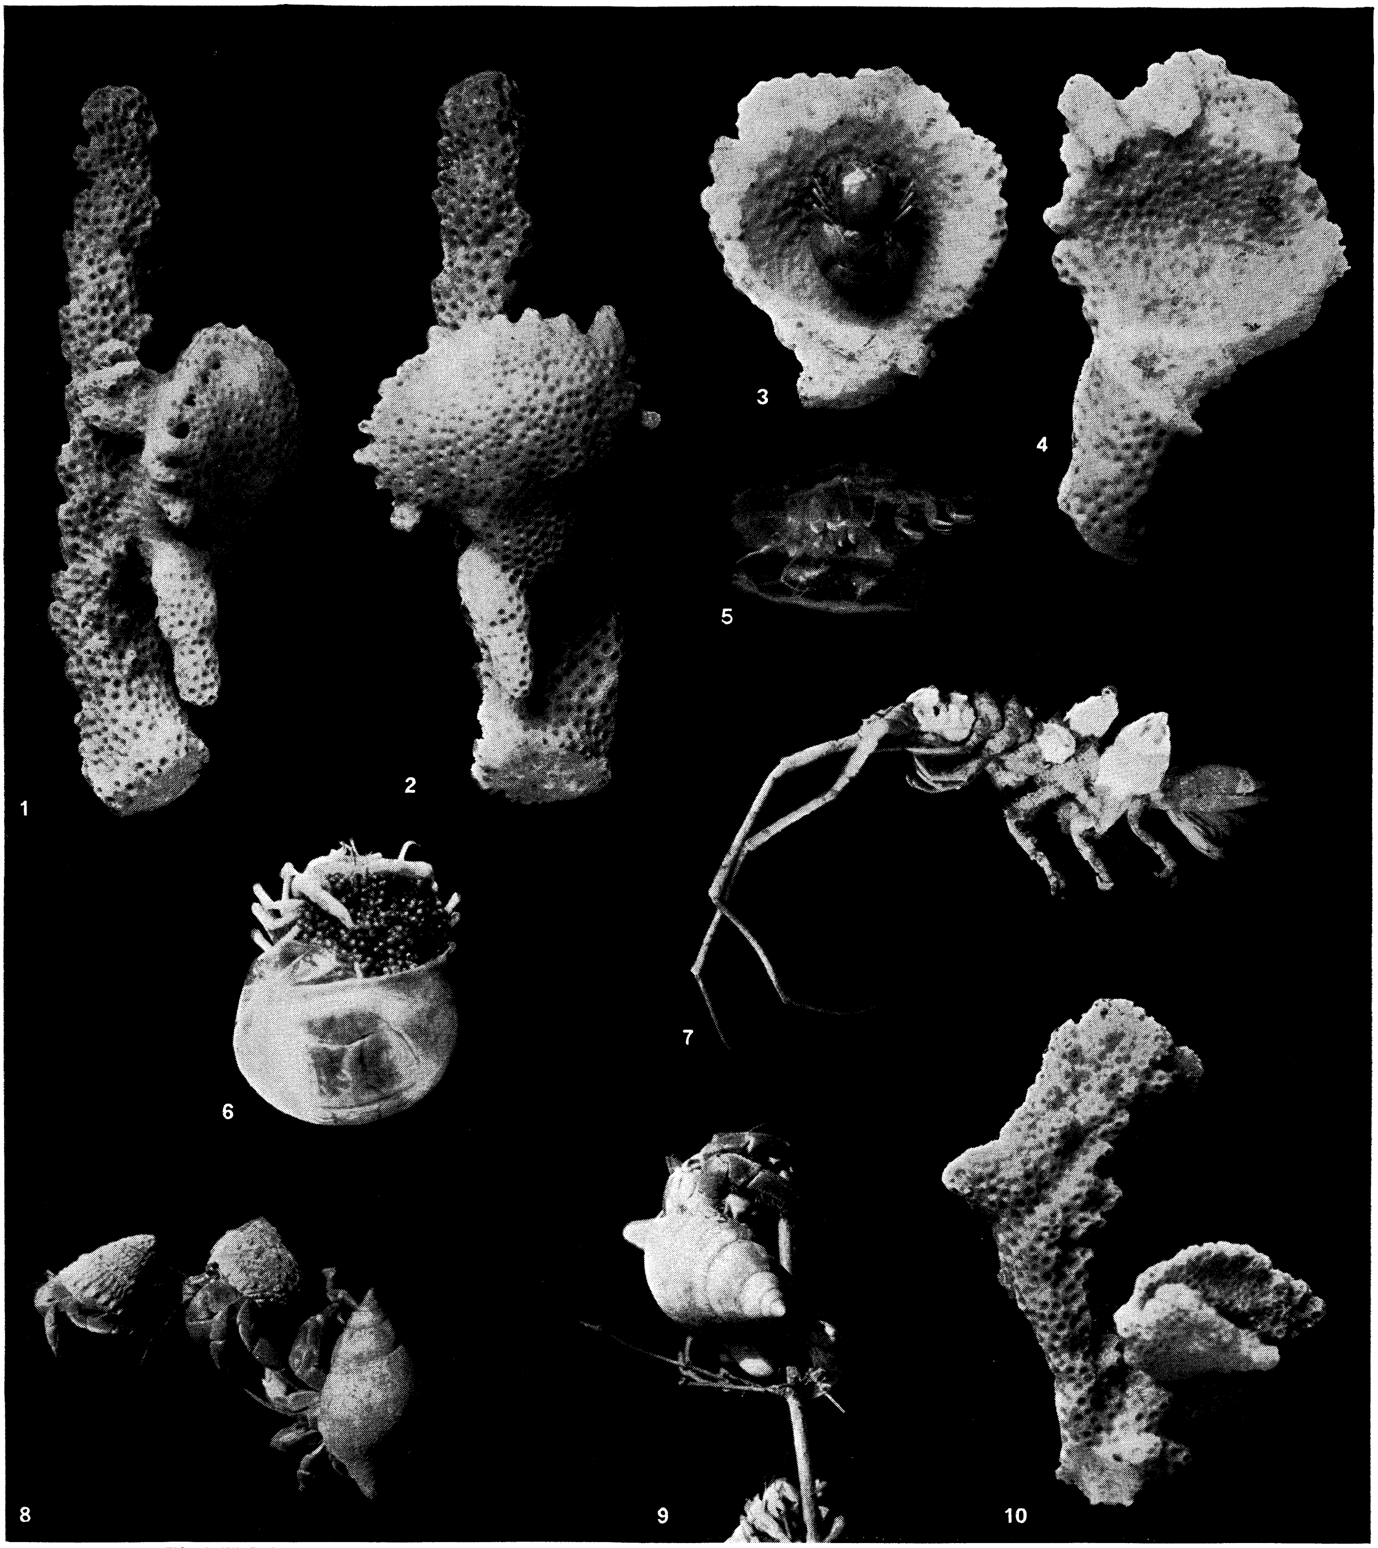
1. Peracarida. A carapace, if present, not fused with more than four thoracic somites; eyes, when present, stalked (Mysidacea, stalks movable; Tanaidacea, stalks fixed) or sessile (Cumacea, Isopoda, Amphipoda). The Mysidacea comprise generally small shrimplike swimming forms, nearly all marine. They are called "opossum" shrimps because of the brood pouch formed of oostegites or plates attached to the coxae of the thoracic legs, in which the young undergo their entire metamorphosis after hatching out as nauplii. Their size range is considerable, running from the tiny *Anchialus* pusillus, $\frac{1}{8}$ in. long, to *Gnathophausia ingens,* which exceeds *6* in. in length. Probably all serve as the food of other animals. Several species occur in fresh-water. One of these is *Mysis relicta,* a widely distributed lacustrine form in the northern hemisphere. Thermosbaenacea includes only the minute, blind, creeping Thermosbaena, found in a hot spring in Tunis. Cumacea are marine mud-burrowers but the males are, to some extent, free swimming. Tanaidacea are also part of the micro-fauna of the sea bottom, less natatory than the Cumacea. Isopoda are a very varied and successful group, creeping, mud-burrowing and sometimes actively swimming in the sea and a few in fresh water. The destructive wood-boring crustaceans are principally isopods. The most widely distributed of them in both Atlantic and Pacific oceans, Limnoria *lignorum,* the "Gribble," is often accompanied by a boring amphipod, Chelura terebrans. Next to the molluscan shipworms, the tiny Gribble ($\frac{1}{8}$ to $\frac{1}{6}$ in. long) is the worst known destroyer of submerged timbers. Infested piling may carry 300–400 individuals to the square inch of surface in favoured localities. An untreated test piece of Oregon fir 5 ft. long by 3 in. square, set in Port Jackson, Australia, was 60% destroyed in six months by a combined attack by Limnoria and Chelura. By the time nine months had elapsed, it was so utterly riddled with the assistance of shipworms, which had by this time invaded the timber, that insufficient material remained to support further ravages by the borers present. Several species of Sphaeroma, though larger ($\frac{3}{8}$ in. long, more or less), also attack wood, but not so generally as *Limnoria,* and less in American than in Australian waters. Sphaeroma quoyana is reported to have honeycombed claystone or "papa rock" used in harbour works in New Zealand to such an extent that blocks of concrete overlaying it sank several feet. Parasitism appears in many different families and leads to extremes of specialization and degeneration. One suborder, Oniscoidea, consists of the terrestrial, air-breathing mood lice. Creeping and swimming forms of Amphipoda, another varied and successful group, abound in fresh water and in the sea. A few sandhoppers or "beach fleas" may become wholly terrestrial. The vast majority of amphipods belong to one suborder (Gammaridea), which includes both free-living and parasitic forms; members of a smaller suborder (Hyperiidea) are planktonic, occur at times in vast swarms, and are consumed in great quantities by seals, cetaceans and other marine animals; a third suborder (Caprellidea) contains the exclusively parasitic family Cyamidae or whale lice.

2. *Phyllocarida.* Sometimes referred to as Leptostraca, this order is characterized in part by a large carapace which is not fused with any of the thoracic somites, stalked eyes and abdomen of seven segments (six in all other Malacostraca). The single order, Nebaliacea, includes only three or four living genera, all marine mud-burrowers, in part scavengers. They are widely distributed in all seas, usually occurring at moderate depths. Some, such as the large Nebaliopsis typica, which attains a length of more than $1\frac{1}{2}$ in., live at depths exceeding 1,000 fathoms. The doubtful affinities of the Phyllocarida are mentioned above.

3. Syncarida. This group possesses stalked eyes but no carapace. A small fresh-water group of limited distribution, to which belong the mountain shrimp (Anaspides) of Tasmania and a few allies in the Australian region, and also the Bathynellidae of central Europe, minute, blind, degenerate, subterranean forms. They appear to be survivors of a group widely distributed in Carboniferous and Permian times.

4. Eucarida. This group is recognized by its stalked eyes and carapace fused dorsally with all thoracic somites. The Euphausiacea are a small group of planktonic, phosphorescent shrimps except for a few living in the deep sea at 1,000 fathoms or more. The pelagic species are of importance as food of whalebone whales. The Decapoda, on the other hand, form the most extensive and diversified of all the orders of Crustacea. It includes the largest representatives of the class and, indeed, of living Arthropoda, and, since many of them are used for food, they are more generally familiar and more thoroughly studied than any other Crustacea. They are classified into two suborders: —Natantia, comprising the shrimps and prawns; and Reptantia, subdivided into four sections, spiny lobsters and their relatives, (Palinura), true lobsters and crayfish (Astacura), hermit and lithodid crabs and their allies (Anomura) and the true crabs (Brachyura). The headquarters of the group is in the sea but many of its members have invaded fresh waters (river prawns and river crabs in the tropics and crayfishes in temperate regions) and although a few are so far terrestrial as to deserve the name of land crabs, and may even climb lofty trees like the Coconut Crab, they pass their young stages in salt or fresh water.

5. Hoplocarida. These differ from all other Malacostraca in having the first antennae and the stalked eyes attached to movably articulated segments of the head. The carapace is small and shallow, fused with two or three thoracic somites, leaving four well-developed somites free. The members of the single order Stomatopoda are sometimes known as "mantis shrimps" from the resemblance of their large prehensile claws to those of the mantis insect. They are exclusively marine, burrowing in sand or lurking



VARIOUS CRUSTACEA MALACOSTRACA

1, 2, 3, 4, 6, 10. Coral gall crab, ***Hapalocarcinus marsupialis*** (Eucarida, Order Decapoda, Section Brachyura) and "house" formed by coral, *Pocillopora* species. This crab occurs in the Indo-Pacific and in South America, on the west coast of Colombia and in the Secas Islands, Panama; specimens photographed are from Port Utria, Colombia. 1. Shows the breathing holes kept open by respiratory streams of water. 3. Opened gall with female. Figs. 1-4 about x 2. 5. Young, partially formed gall. 6. Female x 4 showing egg mass and abdominal "pouch" from which the crab derives its specific name

5. ***Phronima*** (Peracarida, Order Amphipoda, Suborder Hyperiidea) by reflected light, compare with Plate fig. 2, Crustacea. Natural size

7. ***Arcturus baffini*** (Peracarida, Order Isopoda), a North American Arctic species. The female usually carries her young around ***on*** her long antenrae. The figured specimen is an old "granny" which has not moulted for a long time, as it carries several barnacles, ***Balanus*** species (Cirripedia, Order Thoracioa), attached to its back. Natural size

8, 9. Land hermits, ***Coenobita clypeatus*** (Eucarida, Order Decapoda, Reptantia, Section Anomura), common in Florida and the Caribbean region; under favourable circumstances grow to be three or four times the size of the specimens shown here. About x ½

CLAUS, "LEHRBUCH" (JULIUS SPRINGER), (S) FROM SIRS, "CRUSTACEA OF NORWAY" (BERGEN MUSEUM), (4-5) FROH MAYER, "CAPRELLIDEN," (6-7, 10-11) FROM CALMAN, IN "A TREATISE ON ZOOLOGY" (A. & C. BLACK)

VARIOUS CRUSTACEA MALACOSTRACA

1. Diagram of a generalized malacostracan, showing the "caridoid facies"
2. ***Nebalia*** bipes (Phyllocarida, Order Nebaliacea). Appendages show through the transparent shell or carapace. ***Nebalia*** is widely distributed in both the Atlantic and Pacific oceans. About x 12
3. Freshwater amphipod, Garnrnarus ***pulex*** (Peracarida, Order Amphipoda, Suborder Gammaridea), by some called freshwater "shrimp." A widely distributed Palaearctic species ranging from England to Japan and found in some parts of North Africa; does not occur in North America

4, 5. "Skeleton shrimp," ***Caprella eximia*** (Peracarida, Order **Amphipoda,** Suborder Caprellidea); female (fig. 4) and male (fig. 5) from the Pacific shores of Asia. Enlarged x 3

6. Anaspides tasmaniae (Syncarida, Order **Anaspidacea),** found only in rocky pools at high elevations in the mountains of Tasmania. A specimen of maximum size will about equal the dimensions of the figure here given
7. Apseudes ***spinosus*** (Peracarida, Order **Tanaidacea),** female with eggs In "brood pouch" or marsupium. Primarily a Norwegian species, it has been taken off the Irish coast in 725 fathoms

8, 9. ***Diastylus planifrons*** (Peracarida, Order **Cumacea).** 8. Female with eggs in "brood pouch" from the Straits of **Magellan.** About x 7. 9. Same, dorsal view of **cephalothorax**

10. ***Meganyctiphanes norvegica*** (Eucarida, Order **Euphausiacea),** male, common in the cooler parts of the north Atlantic; in immense swarms or schools, called "krill" by Norwegian fishermen and whalers, serves as food of whales. About x 2
11. Opossum shrimp, ***Mysis relicta*** (Peracarida, Order **Mysidacea),** female with brood pouch. A circumpolar species found In the larger freshwater lakes of North America, Europe, and Asia. About x 3%

VARIOUS CRUSTACEA MALACOSTRACA (EUCARIDA, ORDER DECAPODA, REPTANTIA, SECTION ANOMURA)

1, 2, 3. Porcellanid "crabs." 1. Pachycheles rugirnanus, ranging from North Carolina through the West Indies. About x 2. 2. *Porcellana sayana,* ranging from North Carolina through the Caribbean area to Panamá; generally found commensal with hermit crabs in gastropod mollusk shells. About natural size. 3. Megalobrachiurn *poeyi,* ranging from the Bahamas through the West Indies to Colombia. About x 2

4. "Munida" or squat lobster, Munida *evermanni,* known only from deep water (220-225 fathoms) off Puerto Rico. About x 1½

5, 6. Hermit crabs without their usually carried gastropod shells. 5. *Clibanarius* tricolor, found in Bermuda and ranging from Florida through the West Indies to Barbados, a common species. About x 6. 6. Calcinus tibicen, more widely distributed than the preceding species, ranging from Florida to Brazil. About natural size

7. Paralithodes *camtschatica,* Alaskan king crab. Related species are called rock crabs in Europe. Occurring in the north Pacific ocean and the Bering sea, from the shores of Japan and Kamtschatka northward to Bering strait and south to southeastern Alaska. Males are larger than the females, attaining an over-all spread of 4 or 5 ft., with shell or carapace measuring nearly 12 in. in length; weight up to 22 lb.

It is to be noticed in the Anomura that the fifth pair of legs, counting the pincer legs or chelipeds, are much reduced in size and are often hidden under the shell or carapace, as in the king crab, fig. 7. In the hermit crabs the fourth pair of legs, as well, are reduced in size

CRUSTACEA MALACOSTRACA

1. Spiny or rock lobster of the Pacific coast of North America, Panulirus interruptus (Eucarida, Order Decapoda, Reptantia, Section Palinura). The Florida counterpart, *Panulirus* argus, as well as the South African spiny lobster, attains a body length of 18 in. A California spiny lobster weighing 17 lb. has been recorded. About one-Rfth natural size
2. Mantis shrimp, *Squilla* empusa (Hoplocarida, Order **Stomatopoda)** **from** Woods Hole, Mass. Not auite one-half natural size
3. River crayfish, *Cambarus* affinis (Eucarida, Order Decapoda, Reptantia. Section Astacura), from Havre de Grace, Md. About one-half natural size
4. Blue crab of the east coast of the United States. ***Callinectes sapidus*** (Eucarida, Order Decapoda, Reptantia, Section Brachyura), about three-tenths natural sire; fully grown males may attain a shell width of as much as 8¾ in.
5. Edible crab of Pacific coast of North America, also known as the Dungeness crab, Cancer ***magister*** (Eucarida, Order Decapoda, Reptantia, Section Brachyura); attains a shell or carapace width of approximately 8 in.
6. Green crab, or "Joe Rocker," common shore crab of Europe, ***Carçinides maenas*** (Eucarida, Order Decapoda, Reptantia, Section Brachyura), occurring on north Atlantic coast of the United States, Pernambuco, Brazil, Bay of Panama, coasts of Europe and North Africa, Suez Canal, Red Sea, Ceylon, Australia and Hawaiian Islands. About one-third natural size.
7. Stone crab, Menippe ***mercenarıa*** (Eucarida, Order Decapoda. Reptantia, **Section** Brachyura); southern Atlantic and Gulf coasts of United States and Mexico. Attains a width of shell or carapace of 5 in. Like the blue crab, the stone crab is much relished **for food** in the eastern and southern **U.S.**

in crevices in the shallow waters of all the warmer seas. A few go into brackish water. Many species are rare, known only from a few specimens, yet others are found in greater abundance, such as *Squilla investigatoris,* of which 500 were taken in a single haul from 110 fathoms in the Indian ocean. Despite their vicious claws, they have numerous enemies among the fish and octopuses. They are much used fresh or fried for food in the Mediterranean region, in the Philippines, Malaya and elsewhere. In Japan they are cheaper than other edible crustacea. One of the largest stomatopods on record is a Philippine specimen of *Lysiosquilla maculata,* whose body measured slightly more than 1j in. in length.

MÁLAGA, a maritime province of Spain, one of the eight modern subdivisions of Andalusia; bounded on the west by Cidiz, north by Seville and Córdoba. east by Granada, and south by the Mediterranean sea. Pop. (1960 est.) 826.327; area. 2.809 square miles. The northern half of Málaga belongs to the Andalusian plain watered by the Guadalquivir. the southern is mountainous, and rises steeply from the coast. Of the numerous sierras is that of Alhama. separating the province from Granada, rising above 6.800 ft.; its westward continuation in the Sierra de Abdalajis and the Axarquia between Xntequera and Málaga; and not far from the Cadiz boundary the Sierras de Ronda, de Mijas, de Tolox and Rermeja. converging and culminating in a summit of nearly 6,500 ft. The principal river is the Guadalhorce. which rises in the Sierra de Alhama. After a westerly course past Antequera it bends through the defile of Peñarrubia and the *Vega* or Vale of Málaga, falling into the sea near that city. The only other considerable stream is the Guadiaro or Guadalevín, which has the greater part of its course within the province and flows past Ronda. There is an extensive salt lagoon near the northern boundary. The mountains are rich in lead and iron. There are warm sulphurous springs and baths at Carratraca. Large quantities of grapes and raisins, oranges and lemons, figs and almonds, are exported. The oil and wines of Málaga are also esteemed. After 1870 the manufacture of beet and cane sugar developed into an important industry. The fisheries are important. The province is traversed by the Córdoba-Málaga railway. The nationalists occupied the province during the civil war of 1936–39.

Málaga, the capital (mun. pop. [1960] 318.102), Antequera ([1950] 43.576), Vélez-Málaga (31,948), Ronda (30,653) and Coin (20.183) are described in separate articles.

MÁLAGA, the capital of Málaga province, an episcopal see and a port of southern Spain, is situated on the Mediterranean, about 75 mi. N.E. of Gibraltar. It lies on the left bank of the Guadalmedina ("river of the city") at the eastern end of the fertile Málaga plain near the slopes of Mt. Gibralfaro. a western spur of the Axarquia (or Málaga hills). The surrounding amphitheatre of mountains protects Málaga in winter from cold north winds; in summer the weather is mild. Pop. (1960) mun., 318,102.

Málaga, as a city founded by the Phoenicians. is mentioned by Strabo. Pliny the Elder and Ptolemy. After passing from Carthaginian rule. it became an ally of Rome and, later, a municipality. In the 6th century the Visigoth Leovigild took Málaga, and it remained in the hands of the Visigoths for two centuries. being also made an episcopal see. until it fell in 711 to the Arabs. They retained the city. despite Castillian attempts to take it. until finally it fell to Ferdinand and Isabella in 1487 after a long siege.

Málaga was the scene of several disturbances among which were the rebellions of the Moors in 1501, an English naval attack in 1570 and French occupation from 1810 to 1812. On Feb. 8, 1937, the city was captured by the nationalist general Queipo de Llano. In 1878 the local vineyards were stricken by *Phylloxera* and, in 1884, an earthquake and floods did much damage.

The cathedral. built primarily between 1528 and 1782, stands on the site of a mosque; in it are carvings by Pedro de Mena. Málaga's famous churches include those of Santo Cristo, the Iglesia del Sagrario and la Victoria. The provincial museum of fine arts contains paintings by Zurbarán. Guido Reni and other masters including. among the moderns. paintings by Pablo Picasso, who was born in Málaga. There are still remains of the Moorish fortress of Alcazába, while that of Gibralfaro has been made into a museum and garden.

The old port of Málaga can hold 30 large vessels and offers a draft of 30–45 ft. Near it is the Cluh Mediterráneo. a centre for nautical sports, especially during n·inter regattas. The city's exports include a wide variety of local products: the chief imports are petroleum, grains. chemical products. iron and steel. Local manufactures and products include cement. bricks. mosaics, paint, chemical fertilizers, pharmaceutical products. soap. cotton and cotton goods, leather, and food products such as flour, vinegar, sugar, and the well-known Málaga wines, fruits, almonds, fish and shellfish. (A. C. A.)

MALAGASY REPUBLIC: *see* MADAGASCAR.

MALAKAND, an agency of the Peshawar division, West Pakistan, controlled by a political agent residing in the town of the same name. 41 mi. N.E. of Peshawar. The total area of Malakand is 13.419 sq.mi.; the population in 1961 was 1,517,000. The agency includes Chitral, Swat (*qq.v.*) and Dir states, Kalam, the Malakand Protected area and the areas called Swat Ranizai and Sam Ranizai. Malakand is inhibited by *azad* (free) tribes having their own chiefs or *sardars.*

At Malakand is a 20,000-kw. hydroelectric power station, opened in 1938. The Dargai hydroelectric station nearby produces another 20.000 kw. There is a training centre at Batkhelo for woolen textiles and rugmaking. The Malakand pass connects the Mardan and Peshawar districts with the Swat valley. It is traversed by an ancient Buddhist road. (K. S. AD.)

MALALAS (or MALELAS) (Syriac for "orator"). **JOHN** (*c.* 491–578), Byzantine chronicler. was born at Antioch. He wrote a chronicle beginning with the creation and ending with the death of Justinian (565).

It possesses little historical value: it is. however, important as the first specimen of a chronicle written not for the learned but for the instruction of the monks and the common people, in the language of the vulgar. with an admixture of Latin and oriental words. It is preserved in an abridged form in a single manuscript at Oxford.

Fur a full discussion see Krumhachcr, *Geschichte der byzantinischen Literatur,* pp. 332–334 (1897); and the first edition, by E. Chilmead (Oxford. 1691).

MALAN, DANIEL FRANÇOIS (1874–1959), South African advocate of *apartheid* (racial segregation), was born at Riebeck West. Cape Pro ince. on May 22. 1874. He was educated at Victoria college. Stellenhosch, and at the University of Utrecht. Neth.. where he obtained the degree of doctor of theology. He returned to South Africa as a minister of the Reformed Church and in 191j became editor of ***Die*** *Burger,* shortly afterward being elected chairman of the newly formed Nationalist party in the Cape. He was elected to the house of assembly in 1917 and was minister of the interior. health and education during 1924–33.

At the outbreak of World War II Malan supported Gen. James Hertzog's policy of neutrality, and on the general's death in 1942 succeeded him as leader of the opposition to the government of J. C. Smuts. In the 1948 election the Nationalist party obtained a majority and Malan became prime minister. Under his leadership the government carried out an aggressive program of racial segregation with the announced goal of the complete separation of mces. Malan's Nationalist party carried the general elections in 1953, but on Nov. 30, 1954. he retired from politics at the age of 80. He died in Stellenbosch, U. of S. Af., on Feb. 7, 1959.

MALANGE: *see* ANGOLA.

MALAR, a lake of Sweden, extending 75 mi. W. from Stockholm, which lies at its junction with the Saltsjö, an arm of the Baltic sea. The height of the lake normally reaches only one foot above sea level, and its outflow is sometimes reversed. The area is 440 sq.mi., the deepest sounding is 210 ft. It contnlns numerous islands and its outline is very irregular, the mean breadth being about 15 mi., but an arm extends northward for 30 mi. nearly to the city of Uppsala.

The lake is connected by navigable channels with Lake Hjelmar to the southwest and the Baltic to the south, by the Södertelge canal and by two channels at Stockholm. The more important towns, besides Stockholm, are Vesterås on the north, Sodertelge and Eskilstuna near the south shore.

The lake offers a field for recreation fully appreciated by the inhabitants of Stockholm, and many of the businessmen of the capital city have residences on the shores of the lake. On the island of Drottningholm (Queen's Island, named in honour of Catherine, wife of John III) is a palace with a fine park and formal gardens. a summer residence of the royal family, built by Nicodemus Tessin and his son Nicodemus in the second half of the 17th century on the site of the one built by John III at the close of the 16th century. Near Mariefred on the south shore is the picturesque castle of Gripsholm, dating from 1537, built by Gustavus Vasa, containing a large collection of portraits. Strengnas, also on the south shore, became an episcopal see in 1291, when the fine cathedral, later much altered, was consecrated. In the episcopal palace there. a building of the 1jth century later used as a school, Gustavus Vasa was elected to the throne of Sweden in 1523. On the northward arm of the lake is the palace of Rosersberg, later used as a school of gunnery. in a well-wooded park.

On a branch of the same arm is Sigtuna, a village whose ruined churches are a memorial of its former rank among the principal towns of Sweden after its foundation in the 11th century. Remains prove that on Bjorko. an island in the eastern part of the lake, there was a large settlement of earlier importance than Sigtuna. There a cross commemorates the preaching of Christianity by St. Ansgar in 829.

On the northern arm of Lake Mälar, about 10 mi. S. of Uppsala, is the chateau of Skokloster, occupying the site of a monastery, and presented by Gustavus Adolphus to Marshal Herman Wrangel, whose son Charles Gustavus Wrangel stored it with a remarkable collection of trophies from Germany. taken during the Thirty Tears' War, and including a library, an armoury and a great collection of curios.

MALARIA. Malaria is an infection principally of man, apes, monkeys, birds and reptiles. It is caused by several species of Protozoa (one-cell animal organisms). which are classified as blood Sporozoa (suborder Haemosporidiidae) and belong to the single genus *Plasmodium* (*see* PROTOZOA: *Taxonomy*). As far as is known, all are transmitted by mosquitoes.

A given species has a limited ability to infect both vertebrate and mosquito hosts. Thus, *Plasmodium brasilianum* can be transmitted to several species of new world monkeys and marmosets. but has never been successfully transmitted to man or old world monkeys. Only one species, *P. knowlesi,* occurring in monkeys, has been successfully transmitted to man. The culicine genera *Culex* and *Aedes* are the most important transmitters of bird malaria. whereas the genus *Anopheles* is the sole known transmitter of the human species. In a zoological sense, the mosquito in which the parasite undergoes its sexual processes is the definitive host, and man or other vertebrates are the intermediate hosts.

The stages of the malarial parasites which invade mature red cells containing hemoglobin in the vertebrate host have the interesting biochemical habit of splitting hemoglobin into its pigment, heme. and the protein carrier. globin. The parasite utilizes the globin and discards the heme. When the heme accumulates in the red cells and in various organs, it is known as malarial pigment. The same method of producing pigment occurs in infections caused by close relatives of the malarial parasites that belong to the genera *Haemoproteus,* infecting birds, and *Hepatocystis,* infecting monkeys, bats and squirrels. These infections are frequently, but inappropriately, referred to as malaria.

The present article will deal chiefly with the malarial parasites of man. No parasite producing malaria in man has been successfully transmitted to any lower animal except to the chimpanzee and, for very transient infections. to howler monkeys. For this reason, many advances in the knowledge of the human disease have been based on work on several species occurring in birds and monkeys. The discovery of P. *berghei* which infects the Congo tree rat and can be maintained in mice and rats is a promising mid-20th century addition to the available research material.

Clinically, malaria is characterized by periodic paroxysms, popularly known as chills and fever, and a tendency to assume a chronic form with frequent relapses. During World War II marked advances were made in the treatment of the disease as well as the discovery of efficient insecticides which gave promise of removing the disease as one of the leading scourges of the inhabitable world, particularly in the tropic and subtropic areas.

History. — Historically, malaria is one of the most ancient infections known to man, having been noted in some of the earliest records. 5th century B.C., a-hen Hippocrates differentiated the fever into different types: namely! quotidian (daily), tertian (alternate days) or quartan (fever three days apart) types. He further observed that those who drank the stagnant marsh water had large stiff spleens, a characteristic of the disease, and fatal dropsy was common among them. It is not known when malaria first made its appearance in the Americas, but it is highly probable that it was a post-Columbian importation; some rather severe epidemics were first noted in 1493. The origin of the word malaria is not known, although reputedly it refers to *mal* aria, meaning "evil air." There has always been recognition of the association between swampy, marshy areas and the disease, although the exact roles of the mosquito and the parasite were not known until the beginning of the 20th century.

An effective treatment was known long before the cause of the disease was understood. There are many legends which indicate that the countess of Chinchón, suffering from chills and fever, was treated in 1630 with an infusion of the bark of a certain tree in Peru. The reason why the infusion was used is not exactly clear, although certain Jesuits were thought to have learned about it from the natives. Discovery of the countess' diary failed to reveal that she ever had malaria. The fact remains. however, that the tree with the therapeutically active bark mas named for her as the cinchona tree; and from 1700 its most active principle, quinine, was used universally for the treatment of malaria.

The first person known to have described the malarial parasite and to have recognized it as the cause of the disease was Alphonse Laveran in 1880 in Algeria. In 1886 the Italian investigator Camillo Golgi, known best for his studies on the structure of the nervous system, pointed out that the paroxysms are coincident with the segmentation of the blood parasites. Detailed knowledge of the tissue stages came later and represents the work of many investigators. Special mention should be made of the U.S. parasitologists C. G. Huff and F. Coulston. who in 1944 described the complete development of early tissue stages in the avian P. *gallinaceum,* and the English parasitologists H. E. Shortt and P. C. C. Garnham. who with their associates first described in 1948 tissue stages in human malaria.

The discovery of the mosquito transmission of the disease had an involved history which turned into an exciting race toward the turn of the 19th century. The U.S. investigators Theobald Smith and F. L. Kilborne. between 1889 and 1893, had shown that the tick is the carrier of the piroplasm producing Texas fever of cattle and thus laid the basis for the demonstration of the role not only of ticks but also of other arthropods, such as mites, crustacea and especially insects in the transmission of human and animal diseases. Sir Patrick Nanson, British pioneer in tropical medicine, stated in 1894 that he suspected the mosquito to be the vector (carrier) of malaria. In 1898 in India the British physician Sir Ronald Ross proved that bird malaria is transmitted by *Culex* mosquitoes and described the entire development of the parasite in the mosquito. Just the year before, he had seen pigmented cysts in anopheline mosquitoes fed on patients with falciparum malaria. In Nov. 1898 the Italian investigators A. Bignami, G. B. Grassi and G. Bastianelli first infected man by mosquitoes, described the full development in man and noted that malaria is probably transmitted only by anopheline mosquitoes, an observation that continues to hold true. The disease can be transmitted unnaturally by common use of the hypodermic needle, as among drug addicts, or occasionally by blood transfusion from infected donors.

For therapy. a major event was the mass cultivation of strains of cinchona trees giving high yields of quinine alkaloids. This was achieved by the Dutch in the East Indies. In 1891 P. Guttmann and Paul Ehrlich found that methylene blue had a slight therapeutic effect. The shortage of quinine in Germany during World War I led to the research of W. Schulemann and his associates which culminated in the discovery of Plasmochin or pamaquine in 1924. It was made by modifying methylene blue. In 1930 W. Kikuth, in collaboration with W. Mauss and F. Mietzsch, produced Atabrine, which became known as quinacrine or mepacrine. Both compounds are potent antimalarials. The discovery of improved synthetic compounds during World War II by U.S. and British investigators presaged eventual replacement of both quinine and quinacrine.

The vast malaria-control projects conducted in Panamá by William C. Gorgas, who practically eliminated the disease that, with yellow fever, had previously prevented the construction of the canal; the restoration of the Pontine marshes as a place of healthful habitation for the Italians; and the species eradication of *Anopheles gambiae* from Brazil by the Brazilian government, initiated and directed by the Rockefeller foundation! were outstanding events in malaria history. The acute problem in Brazil resulted from the transmission by aircraft or surface craft of an effective vector from Africa that spread over many thousands of acres and was responsible for an epidemic which cost thousands of lives before being eradicated. Although pyrethrum and kerosene sprays had been used to kill the larvae and adults of mosquitoes, their effectiveness was surpassed by DDT (dichloro-diphenyl-trichloroethane), first synthesized in 1874 by O. Zeidler in Strasbourg. In 1939 a small quantity was produced in Switzerland and was found to be lethal for potato bugs. In 1942 it was found to be surprisingly effective against lice, and samples were transported to the United States. The U.S. department of agriculture proved it to be an effective killer not only of lice but also of mosquitoes, flies and fleas.

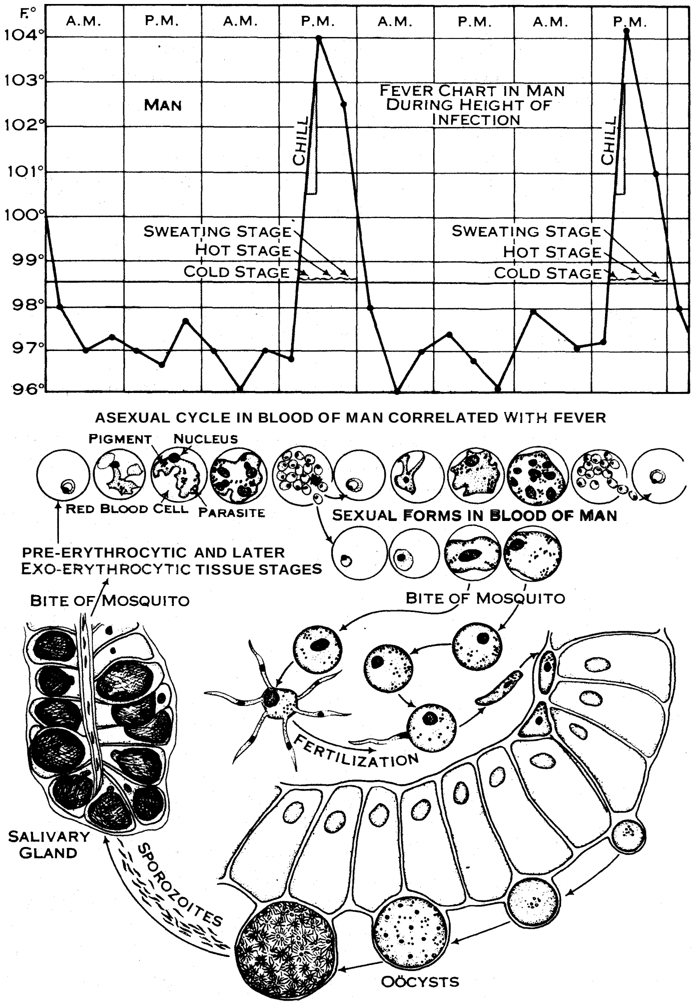
Distribution and Prevalence of Malaria.—Malaria is a world-wide disease, and there are probably more cases of it than of any other infection. It is most common in the tropics, where climatic conditions are favourable for the mosquito and for transmission of the disease throughout the year. As one approaches the poles, it becomes less prevalent, although it has been recorded as far north as Archangel. U.S.S.R. In the continental United States malaria was once a severe menace in the south, the Mississippi river basin and lower California. By mid-20th century it was at its lowest ebb in history; fewer than 500 cases were recorded in 1955. Hyperendemic areas are found in Central and South America, north and central Africa, southern Europe, all countries bordering and the islands of the Mediterranean and the middle and far east. There are some favourable areas still malaria-free because of the absence of mosquito vectors, including such Pacific areas as the Fiji Islands, Hawaii and Guam.

In India it was estimated at mid-century that malaria was still killing 1,000,000 persons annually; in many parts of the world probably the entire population is infected more or less constantly. P. F. Russell estimated that there "are not less than 3,000,000 malarial deaths and at least 300,000,000 cases of malarial fever each year throughout the world." (P. F. Russell, *Bull. New York Acad. Med.*, 19:599–630 [1943]).

Vivax malaria is the most widespread variety, aided by its ability to withstand therapy and remain chronic. Falciparum malaria, the most malignant, requires higher temperatures for optimal development; hence it is confined more closely to the tropical areas. In west Africa, for example, it exists almost to the exclusion of the other varieties. Malaria caused by *Plasmodium malariae* is very prevalent in the Mediterranean area. Instances of this infection persisting without active relapse for 40 years or more have been recorded. Many factors determine the distribution and incidence of malaria, in addition to those of cardinal necessity: the anopheline mosquito, a reservoir of infection and a susceptible human population. These include climate, rainfall, occupation, housing conditions, agriculture, wars, migrations of peoples, economic conditions, etc.

The Parasite.—Four species of the parasite are known to produce disease in man, *P. vivax*, *P. falciparum*, *P. malariae* and *P. ovale*. They cause, respectively, vivax (tertian), falciparum (subtertian or malignant tertian), malariae (quartan) and ovale tertian malaria. Each species has an asexual cycle in the tissues and blood of man and a sexual cycle which starts in the red blood cells of man and is completed in the mosquito.

The accompanying figure illustrates the life cycle of P. *vivax*. The infective stage (sporozoite). which is introduced into man by the bite of the mosquito, initiates a series of generations of pre-erythrocytic stages which occur in tissue cells before parasites invade the red cells. These in turn develop into erythrocytic stages so named because they infect red blood cells. (Except in P. *falciparum*, the pre-erythrocytic stages also give rise to exo-erythrocytic stages which not only can maintain themselves in



MODIFIED FROM W. H. TALIAFERRO, "MICROORGANISMS AND THEIR ROLES IN NATURE,,, "THE WORLD AND MAN," AND FROM C G HUFF. "A MANUAL OF MEDICAL PARASITOLOGY," BY COURTESY OF W. H. TALIAFERRO. C. G. HUFF AND THE UNIVERSITY OF CHICAGO PRESS

LIFE CYCLE OF PLASMODIUM VIVAX IN MAN AND THE FEMALE ANOPHELINE MOSQUITO

The fever curve in man as correlated with the asexual cycle of the parasite in the blood and as correlated with the beginning of the sexual cycle in the blood. The asexual cycle starts with a small parasite (ring stage) possessing a single nucleus. The parasite grows as the original nucleus undergoes successive divisions and finally becomes a segmenter which produces a brood of small parasites (rnerozoites) which can infect new red cells. The completion of the sexual cycle takes place in the mosquito and the sexually fertilized ookinete eventually develops into sporozoites

tissue cells, but also can develop into erythrocytic stages. Since the persistent tissue stages are resistant to most drugs, they probably keep the infection going and relapsing. As far as is known, they do not produce clinical symptoms.)

During the erythrocytic asexual cycle, a young ring stage in P. *vivax* requires two days to grow and develop into a segmenter containing 16 to 24 daughter parasites (merozoites). (Other species produce different numbers of merozoites.) The infected red cells then rupture and each daughter parasite that survives—many die—invades a new red cell. A remarkable aspect of the asexual cycle is that the parasites grow and divide synchronously and therefore at the time of segmentation the parasitized erythrocytes disintegrate in batches and liberate malarial pigment and other residues of parasite and red cell. This process, provided enough parasites are present, produces the typical. regularly recurring malarial paroxysm, which lasts four to ten hours and consists successively of a cold stage (chill), a hot stage and a sweating stage. The cold symptoms of the chill are subjective as they occur after the body temperature is elevated. Between paroxysms, the temperature may be normal or subnormal. The figure shows the relation of the asexual blood cycle and the paroxysms of chills and fever.

A regular tertian fever because of the two-day cycle is produced by P. vivax and P. *ovale.* A quartan fever is produced by P. *malariae.* (Parenthetically. the terms tertian for a two-day interval and quartan for a three-day interval arise from the classical method of including the first and last day of each interval.) The two-day cycle of P. *falciparum* is irregular, and fever may be more or less continuous with chills and sweating at irregular intervals. In this species, only the young rings and sexually mature stages of gametocytes are usually seen in blood smears; the other stages develop in the deeper blood vessels of the body. Infections with one or more species can occur simultaneously. Furthermore, a double brood of tertian parasites can segment on alternate days, giving a daily or quotidian fever. Double or triple broods of the quartan parasite, P. *malariae,* may occur with chills and fever for two days followed by a free day or with fever every day.

After the blood stages have developed asexually about ten days, ring stages similar if not identical to the asexual ones initiate the sexual cycle. The young sexual parasites do not segment but grow into male forms (microgametocytes) or female forms (macrogametocytes), which eventually perish if not taken up by a susceptible anopheline mosquito. In a susceptible mosquito, they undergo maturation and fertilization similar to that of the germ cells of higher animals. The process of forming microgametes (equivalent to spermatozoa in higher forms) is termed exflagellation because the filamentous microgametes behave very much like flagellums as they lash about in freeing themselves from the original gametocyte. After becoming free, a single microgamete fertilizes a macrogamete (equivalent to an ovum). The resulting ookinete (so-called because it actively moves) becomes an oocyst on the outside stomach wall. Within a week or ten days. these oocysts produce scores of sporozoites which are the infective form and which migrate to many parts of the mosquito, including the salivary gland. From this site they are injected by the bite of the mosquito into the vertebrate host and infect new individuals. (See also REPRODUCTION : Dual Hosts.)

Malarial parasites have been difficult to cultivate in the laboratory. Some progress, however, has been made by F. L. Hawking in England and by Eric Ball and Q. M. Geiman in the United States. The parasites remain viable at extremely low temperatures, $-65°$ C., and this characteristic has been utilized to preserve various strains for research.

The Mosquito **Vector.**—Anopheline mosquitoes are the only known vectors of human malaria, and approximately 35 different species perform this function satisfactorily in different parts of the world. These mosquitoes undergo an aquatic larval stage, pupate and hatch into flying adults in about ten days, depending on the temperature of the water. The females require blood meals to produce fertile eggs; the males live on plant juices. According to the species, some prefer animal to human blood, hence are not good malaria vectors. Different species may live preferentially in streams, ponds, hoofprints, tree holes, in shade or sunlight. Usually their flight range is one mile or less from the source of human blood and infection. These mosquitoes are distributed throughout the world, more prevalently in the tropics, but some are present at latitude 50° N. In Ceylon they have been reported at an altitude of 8,000 ft.

The Disease in Man.—The disease in man is recognized by periodic chills and fever, anemia and, later, cachexia (general poor health) and an enlarged spleen. The different patterns of chills and fever have been described above. In falciparum malaria the symptoms are much more severe than in the other varieties. This type may be accompanied by various symptoms depending largely upon the localization of the asexual parasites. Intestinal localization may produce diarrhea and vomiting, and cerebral localization may cause delirium or coma. Only prompt treatment can prevent death in these severe infections.

Diagnosis.—Once clinically suspected, the diagnosis is made by identification of the parasite in stained blood smears. A dehemoglobinized drop of blood can also be stained. The parasites take a characteristic stain, and all stages are easily identified if present and properly stained. There are no satisfactory serological diagnostic tests such as precipitin or agglutination. The complement fixation was shown by L. T. Coggeshall and M. D. Eaton to be reliable when positive, but in many instances known cases failed to furnish more than a weak reaction. The white blood cell (leucocyte) count is usually low and mild anemia is a constant finding. Usually an enlarged spleen can be palpated.

Immunity.—A malaria infection confers a low-grade but specific immunity upon its host after the acute attack has subsided. This acquired immunity in man is of short duration, as a person may have repeated attacks produced by the same organism within a relatively short space of time. In experimental animals the residual immunity following complete eradication of the infection persists only a few weeks. It is held by many that a host is immune to malaria only in the presence of infection. There is no cross immunity in human malaria, as it is frequently observed that a person may have a simultaneous infection with two or more types of malaria. It is highly probable that a person is resistant only to the malaria in his particular locality; for example, it has been shown that a person immune to a strain of vivax malaria in Florida behaves as a normal when exposed to infection from a vivax parasite from Cuba. Immunity is fundamentally antiparasitic, *i.e.*, directed against the parasite. and is not antitoxic. Immunological suppression of the blood infection is chiefly brought about by macrophages (sometimes called scavenger cells) of the spleen and liver and, to a lesser extent, the bone marrow (see discussion of malarial immunity in PARASITISM AND PARASITOLOGY). These organs are the most important of the so-called filter organs of the blood and their macrophages, which are part of the reticulo-endothelial system, are so oriented as to remove material from the blood. The macrophages phagocytose (eat) many parasites and parasitized red cells throughout the infection and especially after the development of acquired immunity due, undoubtedly, to specific antibodies. Moreover. the macrophages themselves markedly increase in number chiefly by development from lymphocytes and monocytes (see PATHOLOGY: *Phagocytosis;* BLOOD: White Blood Cells). Immunity against pre-erythrocytic and exo-erythrocytic stages also occurs in some avian malarias and may occur in n an. It has not been thoroughly studied.

Drug Treatment and Prophylaxis.—Antimalarial drugs may be used either curatively to treat malaria or prophylactically to prevent the disease. Suppressive treatment or clinical cure primarily involves the administration during acute attacks of drugs which will quickly suppress the population of blood asexual parasites so that symptoms disappear. In general, such treatment does not eliminate the exo-erythrocytic stages in the tissues. Continuous suppressive treatment may be used in both uninfected and chronically infected persons to prevent the asexual blood stages from reaching a level at which symptoms appear. The drawback to this type of control (frequently called clinical or suppressive prophylaxis) is that an infection may be acquired during treatment and may flare up after treatment is stopped unless an adequate immunity has been built up. It was the only type of drug prevention available when quinine was the sole antimalarial. Causal prophylaxis occurs only with drugs that prevent the infection by killing or inhibiting the development of sporozoites and pre-erythrocytic tissue stages. Radical cure is brought about by drugs that can eradicate all stages of the parasite, both in the blood and in the tissues. After such a cure, no relapse is possible, but a new infection can take place. It would seem at first glance that only those drugs should be used that give true causal prophylaxis and radical cure. The suppressive drugs, however, often act on the blood parasites much faster than do the curative drugs. Therefore, both kinds of drugs are often prescribed, particularly with vivax malaria, to relieve symptoms quickly and to eradicate the infection eventually. Under certain conditions such as active military operations. suppression (clinical prophylaxis) may be superior to causal prophylaxis. Thus, suppression with drugs allows the development of a low-grade infection during which immunity develops and is maintained under conditions where it is very difficult to maintain an effective dosage level of a causal prophylactic drug.

Treatment of malaria depends upon the species of parasite involved. Entreated vivax and quartan infections eventually subside, but untreated ialciparum malaria may be fatal. In fact, falciparum malaria is responsible for practically all uncomplicated deaths from malaria. It is. however, easier to cure than the so-called benign malarias. During World War II it was radically cured by long-continued treatment with quinacrine. This difference is now generally believed to be due to differences in the persisting tissue stages. Pre-erythrocytic stages of P. *falciparum* are not long lived and give rise only to initial blood stages. whereas those of P. *vivax*, P. *malariae* and *P. ovale* produce, in addition to blood stages, persistent drug-resisting tissue exo-erythrocytic stages that are responsible for long-term relapses. The tissue exo-erythrocytic stages can be eradicated only by a few of the never drugs.

In this connection, it is interesting that a vivax infection. when transmitted by a transfusion of blood from an infected person, can be cured by any effective suppressive drug including quinine because no tissue stages occur.

Older Drugs.—The importance of quinine cannot be overemphasized. Without it many of the most fertile areas of the world would never have been habitable. Its chief shortcoming has been its inability to eradicate such infections as vivax malaria. It may also give rise to partial deafness. Quinine is still the preferred drug throughout the world in spite of the introduction of improved drugs. Quinacrine is highly effective and remains in use. Its disadvantages are that it also does not cure vivax infections, it discolours the skin and, at times, leads to gastric disorders. skin rashes and serious mental disorders. In 1928 the English investigators J. A. Sinton and W Bird discovered in India that the 8-aminoquinoline pamaquine (Plasmochin) would cure vivax malaria as indicated by a greatly reduced relapse rate. The drug was too toxic for wide acceptance, but led directly to the development of other 8-aminoquinolines, The best of these, primaquine. was first found effective in man by Alf S. Alving and his associates.

Later Drugs.—Because of the shortage of quinine and the great demand for quinacrine. an intensive research program was initiated during World War II by the National Research council of the United States. As a result, promising drugs were developed by United States and British investigators. of which four were found to possess superior therapeutic properties.

Chloroquine. 7-chloro-4-(4-diethylamino-1-methylbutylamino)-quinoline, commonly known under the trade name of Aralen, was first synthesized in 1934 by German scientists. It is superior to quinine or quinacrine because it is less toxic, relieves symptoms more quickly by eliminating more rapidly the asexual blood stages and prolongs subsequent latent periods The ultimate total relapse rate, however, is the same for all three drugs.

Amodiaquin, frequently known by the trade name Camoquin. is like chloroquine in being a 4-aminoquinoline. It was discovered in 1946 by J. H. Burckhalter and his co-workers. It is similar to chloroquine in its nontoxicity and effectiveness as a suppressive drug, but it has not been as extensively tested as has chloroquine.

Primaquine. 8-(4-amino-1-methylbuty1amino)-6-methoxyquinoline, is an 8-aminoquinoline that was developed in the United States during World War II. It is much less toxic than the earlier drug, pamaquine, to nhich it is related. Its outstanding characteristic is that it can cure vivax malaria. It is not, however, very active in eliminating the blood parasites. Hence, during an acute attack or during an appreciable parasitemia, it is combined nith an effective suppressive drug such as quinine, chloroquine or amodiaquin. Quinacrine is not used for this purpose as it seems to potentiate, or increase, the toxicity of primaquine. Primaquine in addition has largely replaced pentaquine and isopentaquine, two other 8-aminoquinolines, which were developed a few years earlier by U.S. workers.

The most recent drug, pyrimethamine. 2,4-diamino-5-*p*-chlorophenyl-6-ethylpyrimidine, which goes under the trade name of Daraprin. was first synthesized in the United States and tested there and in England. It is relatively nontoxic and has a marked prophylactic value. Not only is it a suppressive prophylactic to both vivax and falciparum malaria when given at weekly intervals. but it acts as a true causal prophylactic when begun soon enough by arresting the early pre-erythrocytic stages. It is also effective against P. *malariae.*

Pyrimethamine only slowly suppresses acute attacks. It is, therefore, often supplemented by such drugs as chloroquine, amodiaquin. quinacrine or quinine Pyrimethamine has largely replaced the related but less effective drug proguanil (=paludrine), that was earlier developed by English workers.

It is interesting that some of the antimalarial drugs have been found to be effective in other infections. Thus. chloroquine and amodiaquin are used to treat the dysentery amoeba *Endamoeba histolytica* when it has invaded the liver; quinacrine has been found to be active against infections nith some of the intestinal tapeworms and the intestinal protozoan *Giardia lamblia;* and pentaquine, and especially primaquine, are the best suppressive drugs yet found for infections with *Trypanosoma cruzi.*

Acquired drug resistance is an important factor in antibiotic therapy *(see* ANTIBIOTICS; PARASITISM AND PARASITOLOGY: *Chemotherapy).* It does not occur to any appreciable extent with the older drugs and was first noted in the case of proguanil. The resistance of *P. vivax* to proguanil has been raised a thousand times by contact with the drug. Blood stages of both P. *vivax* and *P. falciparum* also become resistant to pyrimethamine.

Control.—The methods of control of malaria are varied according to the habits of the particular mosquito involved. Elimination of all breeding places of *Anopheles* by drainage or filling is essential wherever practical. Human beings should be protected from the bites of mosquitoes. Dwellings should be screened and bed nets used. since most *Anopheles* feed at night. The use of DDT is a major item; it can be used as a spray for dwellings to destroy the adult mosquito. Likewise, when applied as a dust to the surface of water, in breeding places. it will eliminate the larvae.

The problem of mosquito control by DDT is complicated by the development of strains of *Anopheles* which are resistant to DDT or other specific insecticides. One of the most successful insecticides for DDT-resistant mosquitos has been dieldrin (a synthetic chlorinated hydrocarbon also known as compound 49; and Octalox). Some use is also being made of lindane, the gamma isomer of benzol hexachloride.

In some areas it is possible to reduce the reservoir of infection. thus interfering with transmission, by the use of drugs. particularly the later ones. There are other natural methods, such as the introduction of the surface-feeding minnow *Gambusia,* a natural enemy of the mosquito; increasing the salinity of nater near the seaside by tide gates; raising and lowering nater levels; and eliminating protruding vegetation and debris from the breeding places. making it unfavourable to the mosquito. These are but a few of the many applicable methods. (See MOSQUITO: *Control Measures.*)

Blackwater Fever.—Blackwater fever is the most serious and the least understood complication of malaria. It is characterized by a rapidly developing and severe anemia, passage of dark-red to black urine, signs of severe toxicity and a high mortality. It is usually a complication of malaria of the falciparum variety, although occasionally it may appear after an attack of vivax or quartan malaria. The incidence of blackwater fever seems to be in proportion to the amount of malaria in a certain area. Non-immune immigrants in heavily endemic areas are frequent sufferers from this complication. In nest Africa, where blackwater fever is prevalent, it was found to occur once in every 900 attacks of malaria. It seldom appeared in a person until he had had at least four attacks of malaria and had been in the area for six months. The disease, which was relatively uncommon in World War II, is certainly not caused by repeated attacks of vivax malaria because it was not observed by L. T. Coggeshall in more than 5.000 relapsing cases with an average of 14 relapses per patient. This would indicate that repeated reinfection by infected mosquitoes is probably the most important factor. Other predisposing factors are quinine, alcohol, etc.

Symptomatology.—The onset is usually accompanied by single or multiple rigors and extreme prostration. There is no characteristic pattern of fever, although it is usually high, 103° to 105° F. The pulse is rapid, and the patient usually exhibits a considerable degree of pallor. With the hemolytic crisis there is a profound drop in the number of red cells, so that the count may be as low as 2,000,000. Jaundice makes an appearance early in the course of the disease. Vomiting and anemia are frequently observed.

Prognosis and Treatment. — A 50% mortality is approximately the rate to be expected. If the patients are anuric (lacking in the secretion of urine) the rate is muchhigher. Repeated hemolytic crises tend to affect the prognosis adversely. One attack of blackwater fever predisposes to others; the patient should therefore be removed from the endemic malarious area upon recovery. Treatment is entirely supportive.

MALATYA (MALATIEH or ASPUZU), the chief town of a province in Turkey, on the Samsun-Sivas-Diarbekr road, altitude 2,900 ft., situated about 10 mi. S.W. of the junction of the Tokhma Su (medieval Kubakib) with the Euphrates, near the south end of a fertile plain, and at the northern foot of the Taurus. Pop. (1955) 64,880.

Malatya was rebuilt after the earthquake of 1893, and is noted for its fruit orchards. Eskishehr or Old Malatya (Melitene), 5 mi. N E and 3 mi. from the medieval bridge (Kirkgeuz) over the Tokhma Su, has large gardens and many ruined mosques. baths, etc. The earliest site was possibly Arslan Tepe about 2 mi. S. of Eskishehr where two "Hittite" stelae, representing hunting scenes, were found.

Under Titus, Melitene was the seat of the 12th legion; Trajan raised it to a city. Lying in a very fertile country at the focus of important routes, it grew in size and importance, and was the capital of Armenia Minor or Secunda. Justinian, who completed the walls commenced by Anastasius, made it the capital of Armenia Tertia; it was then a great place (Procop., De aed., iii, 4). The town was burned by Chosroes after his defeat there in 577. Taken by the Saracens. retaken and destroyed by Constantine Copronymus, it was recovered to Islam, and rebuilt under Mansur (A.D. 756).

The town changed hands more than once, being reckoned among the frontier towns of Syria (Istakhry, pp. 55, 62). At length the Greeks recovered it in 934, and Nicephorus II. finding the district much wasted, encouraged the Jacobites to settle in it. A convent of the Virgin and the church which bears his name were erected by Bishop Ignatius. Malatya became a great seat of the Jacobites, and was the birthplace of their famous maphrian Bar-hebraeus (or Abu'l-faraj).

At the time of the first crusade the city, being hard pressed by the Turks, was relieved by Baldwin. The city returned to the Turks in 1102 and subsequently became part of the realm of Kilij Arslan, sultan of Iconium.

MALAYA (called by Malays Tanah Malayu; *i.e.*, Malay Land), projects into the China sea and forms the most southerly portion of the continent of Asia. Geographically it begins at the Isthmus of Kra, 10° N., at which point it is only between 40 and 50 mi. wide, and the distance from sea to sea is further diminished by a large irregular salt-water inlet. From the Isthmus of Kra the peninsula extends south with a general inclination toward the east. A line drawn diagonally down the centre from the Isthmus of Kra to Cape Rumenia (east of Singapore) gives the length at about 750 mi. The breadth at the widest point, from Tanjong Penunjok in Trengganu to Tanjong Hantu in the Dindings, is about zoo mi. The peninsula runs into Thailand (Siam) in the north (nhere it is also met by a long. southward-projecting tongue from Burma) and is bounded by the China sea on the east. by the island and strait of Singapore on the south and by the Strait of Malacca on the west.

Politically the northern portion of the peninsula is a continuation of Thailand, and anthropologically must also be so regarded, rather than as a section of Malaya. South of the Thai Malay states, Malaya comprises two political units, both within the British Commonwealth: the Federation of Malaya (which has come to be known as Malaya) and the colony of Singapore. These were formerly divided into the Federated Malay States, the Unfederated Malay States and the Straits Settlements respectively. Malaya and Singapore are dealt with separately below, but it must be realized that they are closely linked both in government and economic interest. (For the city of Singapore see also SINGAPORE.)

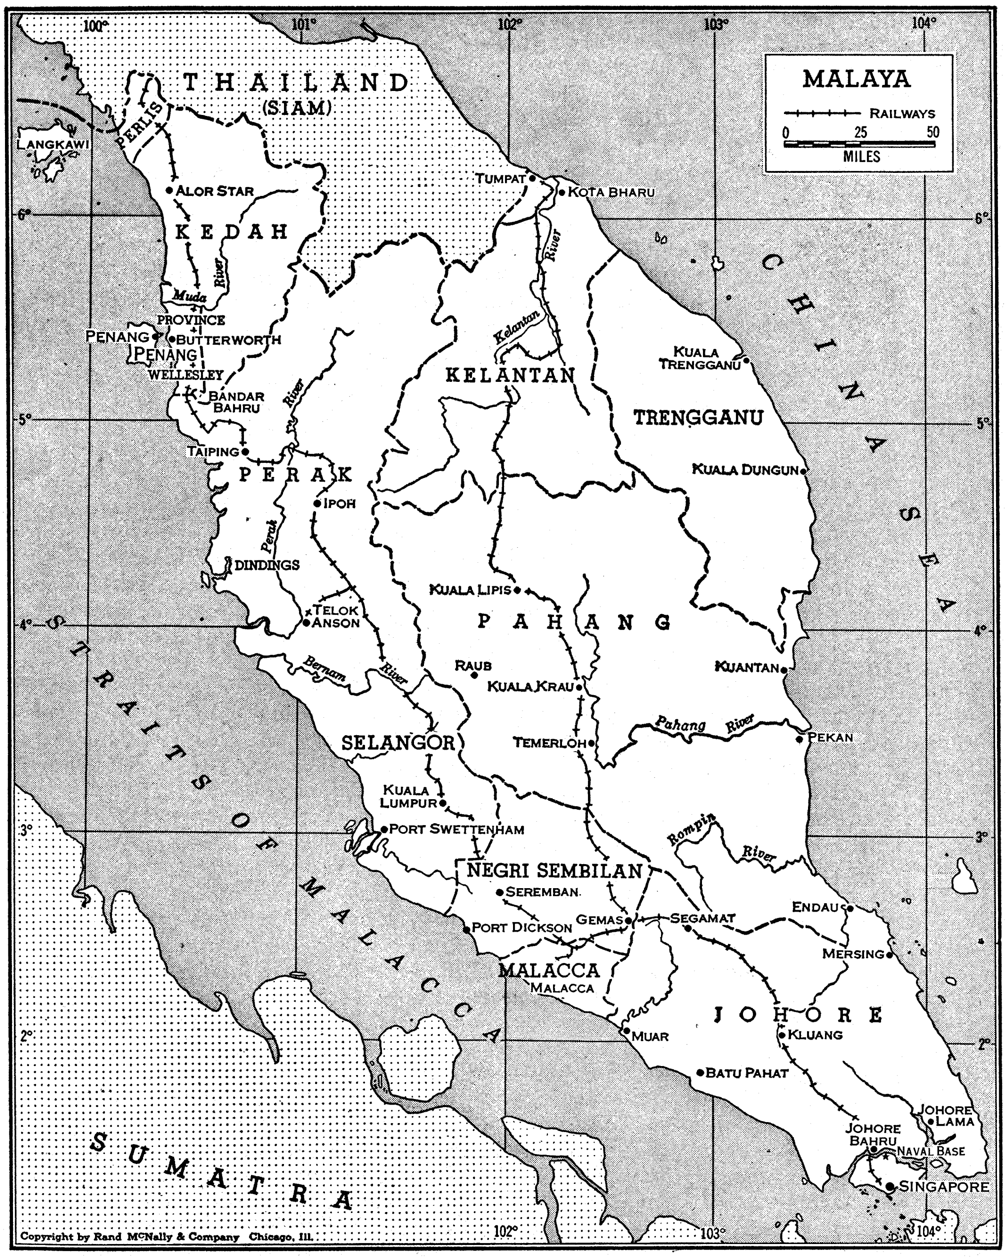
THE FEDERATION OF MALAYA

PHYSIOGRAPHY

Geographical Features. — Malaya is divided into two unequal parts by a range of mountains having a length of 300 mi. and a breadth, in places. of 30 to 40 mi. The highest peak in this range, Gunong Korbu in Perak, is 7,162 ft. and much of the country in the centre of the range is above 4,000 ft. The greater part of Malaya lies to the east of the range and contains two large isolated mountains, Gunong Benom and Gunong Tahan, the latter being the highest mountain in the country (7,186 ft.); both these are in the state of Pahang. Another area of mountainous country lies east and north of these along the border of Kelantan and Trengganu. In the relatively narrow plain to the west of the main range there is a small spur, the Larut hills, in Perak, and an isolated peak, Mt Ophir, is situated near Malacca. In the plains and foothills on both sides of the country precipitous hills or bluffs of limestone are conspicuous features in the scenery. Almost all of them contain caves, some of impressive proportions, and they are more numerous in the north; the most southern of them is the Batu Caves hill near Kuala Lumpur.

The largest river is the Pahang with a length of more than 271 mi. It has many tributaries and the main stream bears different names for different parts of its course; in its headwaters it is the Telom and in its course through the foothills it is named the Jelai. The next river in importance on the east side is the Kelantan which meets the sea very near the Thailand boundary. South of this a number of fair-sized rivers debouch on the coasts of Trengganu and Pahang, and the Endau in its lower course forms the Pahang-Johore boundary. On the west the Perak river rivals the Pahang in size, having a length of 252 mi. It rises in the broadest part of the main range, near the Thailand border, and flows southward between the central mountains and the Larut hills. No other west-coast rivers approach the Perak in size. The Bernam enters the sea a little south of the Perak, and the Muar far to the south in Johore. Much of the land between the mountains and the sea in the west is an alluvial plain, and provides the richest source of tin ore in the country. Rice is grown on this flat alluvial type of country on both sides of the range, mainly in the northern states.

The seacoast on the west side of the peninsula, facing the Malacca strait, includes some sandy stretches and a great deal of mangrove swamp, which is formed wherever rivers and streams meet the sea. The east coast facing the South China sea is very different. There heavy seas pound the shore yearly and mangrove is restricted to within the mouths of some of the rivers. Sloping golden sands. interrputed by rocky headlands and backed by casuarina trees, form the far more attractive east-coast scene. but sandy bars across the mouths of the rivers make them useless as ports and close most of them to navigation altogether during the monsoon period.



Islands are numerous offboth coasts. Offthe west *coast, in the north, are the* Langkawis, *partly of steep limestone and affording beautiful scenery. Penang lies* between *them and the Sembilan Islands offthe Perak coast. In the South China sea islands are scattered* off *the coasts of Johore, Trengganu and Kelantan; many of these are surrounded by beautiful coral reefs. Singapore and many other islands lie offthe tip of the peninsula.*

Geology. — *The conformation of the peninsula is to a great extent the result of a phase of folding and intrusion of igneous rocks dating from post-Triassic: but probably still Mesozoic, times. The strike of the folding and direction of the main intrusions are north-northwest to south-southeast, folio\+-ing the axis of the peninsula. The main range, which lies to the west of the centre of the country. is formed by the largest of these igneous intrusions. East of this another isolated igneous massif. the Benom range, rises to nearly 7,000 ft., and intrusive igneous rocks are also extensively exposed in Trengganu and Kelantan and to the south in Johore. The Mesozoic intrusive rocks are predominantly biotite granites, but hornblende granites, syenites and diorites occur in some parts, while there is considerable variety among the hypabyssal derivatives of all these rocks. It is from this great intrusive series that the mineral* wealth *of the country is derived, the tin, gold, tungsten and other metals that are mined, mainly by exploitation of natural concentrations in alluvial, eluvial and residual deposits.*

The sedimentary rocks older than the granite range from the Lower Carboniferous to the Trias in age. They can be divided into two *main series, an older, largely calcareous, series of Carboniferous and Permian age, consisting of interstratified limestone and shale. and a younger Triassic series of conglomerate. sandstone and shale. Volcanic rocks, chiefly andesitic tuffs, occur in both series and have been named collectively the* Pahang *volcanic series.* Many *of these rocks have been altered by heat and pressure, consequent upon the* folding *and igneous intrusions, and are* now *represented by massive crystalline limestone. schist, phyllite, quartzite and other* metamorphic rocks. *Although the main mountain ranges and peaks are of granite, the highest mountain in the country. Gunong Tahan, is topped bv Triassic auartzite.* Recognizable *fossils are scarce in these* Palaeozoic *and* Mesozoic *rocks. The oldest knonn are from the Kuantan district of* Pahang *and indicate a Loner Carboniferous* (Visean) *age.*

Triassic fossils occur rather more generally and have been found in some quantity on Singapore Island.

No Mesozoic *sedimentary rocks later than Triassic are* known, *and the only deposits so far proved to be of Tertiary age are* coal-*bearing beds. The only operating mine is situated at Batu Arang* in *Selangor The alluvial deposits of the coastal plains are mainly of recent date. Some are raised above sea level and may nell date from the Pleistocene, but* fossil *evidence of their age is almost completely lacking.*

Climate. — *Situated just north of the equator and at no point more than* 100 *mi. from the sea,* Malaya *has a* climate *distinguished principally* by *high humidity and uniform temperature. The prevailing ninds are controlled mainly by the southnest and northeast monsoons, modified by land and sea breezes The effect of the* southwest *monsoon is relatively slight. but the northeast, bloning from about October to February, brings high seas and much rain to the east coast.*

Malaya *is outside the range of typhoons and the local storms* known *as sumatras. though strong and sudden, are never violently destructive.*

Rainfall coincides in intensity with the northeast monsoon on the east side of the country southward to Singapore. In the northwest two *rainfall peaks are discernible, each coinciding in time* with *the transition betneen the monsoons. There is.* however. *no dry season* anywhere *at any time in the year. Average annual rainfall over the* whole *peninsula is probably about* 100 *in. Day temperatures at sea level are generally* between 80° *and go° F. and seldom much exceed the latter figure.* Night *temperatures, especially inland. often fall* below 70° F. *In the hill stations, at about* 4,000 *ft.. temperatures are, of course, lower and may fall at night well below* 60° F.

Vegetation.— The natural vegetation of Malaya consists of the high, continuous evergreen forest called rain forest. It comprises an enormous variety of trees, the tallest mostly belonging to the family Dipterocarpaceae, which furnishes most of the commercial timber of the country.

A notable feature of the rain forest is the universal presence of epiphytic plants. which are mainly of three classes! orchids, aroids and ferns. Of orchids about 800 species are known. Lianes are also present in variety and their ropelike stems are a feature of the jungle. One group of them, the rattans, have exceedingly long, tough. flexible stems, and climb by means of small recurved thorns on the prolonged leaf tips. Rattan forms the basis of an important furniture-making industry and is used for a variety of other purposes.

The biggest known flower, *Rafflesia* arnoldi, which measures 18 in. across. and other species of *Rafflesia* are found parasitic upon the woody stems of the lianes (Vitis).

Large bamboos are also a feature of the lowland and foothill forest and are much used by the aborigines and country people for making containers, rafts for river use and in house building. Palms are abundant and varied. More than 70% of the country is still covered by forest of this type. The mangrove of the coastal belt forms forest of a very distinct type, of great value as a source of firewood. and on the sandy shores coconut palms and casuarina trees are the most conspicuous vegetation.

Fauna.— The zoological affinities of Malaya are rather with the Greater Sunda Islands. Borneo, Sumatra and Java, than with the Asiatic continent. a circumstance derived from the fact that during the Ice Age the whole Sunda shelf was continuous land.

Elephants are still fairly numerous and the large black wild cattle called gaur or seladang are found in the larger forested areas. Two species of rhinoceros are listed in the fauna, the larger of which. Rhinoceros *sondaicus*, may be extinct, but the two-horned *Didermoceros sumatrensis* still exists in small numbers in the remoter hilly areas. The strange parti-coloured Asiatic tapir is not rare. and sambar, barking deer, two species of mouse deer (*Tragulus*) and two of wild pig are among the other ungulates. Carnivores include tiger, leopard (mostly the black variety), clouded leopard and a variety of smaller cats and civets (Viverridae). The large black siamang and two smaller forms of gibbon represent the anthropoid apes, and there are five species of monkeys. There is a single true lemur, the slow loris, and the very interesting and primitive primates called tree shrews (*Tupaia*) are common. Of the smaller mammals. bats. rats and squirrels are present in great variety, the former including the large flying fox (*Pteropus*) with a wing span of four to five feet. In the flying squirrels a membrane of skin between fore and hind limbs serves as a parachute and enables the animal to glide from one tree to a lower point on another. Similarly equipped is the so-called flying lemur (Cynocephalus, sometimes classified as *Galeopterus*), which is not really a lemur, its affinities among the mammals being obscure.

Birds are numerous and varied. Bulbuls, tiny sunbirds, brilliant kingfishers and the black and white magpie robin are familiar garden birds, and a host of others. many seldom seen, live in the forest. Notable among these are the large grotesque hornbills, the magnificent argus pheasant and the brightly coloured trogons and pittas.

Reptiles include the estuarine crocodile of the coastal mangrove and the Malayan gharial (Tomistoma) of the inland swamps. Snakes are numerous but only a small number are venomous and known deaths from snakebite are rare. The largest existing snake, the reticulated python, and the largest venomous snake, the hamadryad or king cobra, are both found. Among the most remarkable reptiles are the flying lizards (Druco and Ptychozoon) which glide from tree to tree as the flying squirrels do. The most familiar ones are the little house geckos which astonish newcomers by their ability to run upside down on the ceiling.

A very large variety of fish is found in the surrounding seas and in the ditches. lakes, swamps and rivers. Important fisheries exist all round the coast. Insects and other invertebrates are diverse beyond computation and many groups are imperfectly known. An example of this diversity is the presence of nearly 900 species of butterflies in the country.

Anthropology.— The indigenous population comprises a majority of Malays and a minority of jungle-dwelling aboriginal people, The distinction between the two is not always sharp and is determined rather by religious belief and custom than by race. The Malays are all Mohammedans. Physically the Malays are a brown-skinned Austro-Asiatic people of very similar type to the Indonesians. Although they are homogeneous it is difficult to speak with certainty of their origin. Some. particularly those of the southwestern states, certainly come from Minangkabau in Sumatra. Many of the Malays are probably descendants of the early settling of various Indonesian seafaring people on the coasts of the peninsula. They occupy themselves chiefly with agriculture and fishing, and speak a language, Malay, which, with minor variations, is uniform throughout the country and which provides a lingua franca over all the Indonesian region.

The greater number of the aborigines live in the jungles of the main range. They can be divided racially into three types: Negritos, small Negroid people; Senoi, slimly built, wavy-haired, relatively fair-skinned people; aboriginal Malays, more stoutly built. dark skinned, with straight or slightly wavy hair. Most of them live by hunting and by a system of shifting agriculture, involving the felling and burning of new areas of jungle each year. They hunt animals of all kinds by trapping and with the blowgun. This is most usually made of a slender bamboo enclosed and supported in a stouter one, about eight feet long. A slender wooden dart with a soft pith butt is shot from the blowgun by a sharp expulsion of the breath; the dart itself inflicts only a trivial wound and to make it effective it is invariably poisoned at the tip; vegetable poisons of two types are used, the brown latex of the Ipoh tree, *Antiaris* toxicaria, and a preparation made from creepers of the genus *Strychnos*. A less common type of blowgun is made like a lead pencil without the lead; two hemicylindrical pieces of wood are carefully grooved and fitted together to form a tube. The traditional weapon of the Negritos (*q.v.*) was the bow, but they have now mostly adopted the blowgun.

Several distinct languages are spoken by the aborigines, and they include words of the Mon-Khmer family, pointing to the origin of these people in the Indochinese region. The word Sakai is often used to comprise all the Malayan aborigines. As it is without exact meaning and is regarded by the people themselves as derogatory, its use should be discontinued.

Archaeology.— Archaeological study in Malaya has shown a long and interesting sequence of Stone Age cultures, but signs of the early Metal Age are scanty. The earliest stone industry is the Tampanian, represented by large, very crude pebble tools comparable with those of the Soan of India, the Pajitanian of Java and others. On typological grounds it can be regarded as probably dating from the Pleistocene, and it has been found only at one site, Kota Tampan in the valley of the Perak river. A mesolithic culture, closely allied to the Hoabinhian of Tongking, is represented by abundant pebble tools in middens in caves and rock shelters. They are usually worked only by flaking on one or both sides of a river pebble, but some are edge-ground. Accompanying them are bones of animals, all of existing species, numerous snail shells and human remains suggesting that the bearers of the culture were of Melanesian type. The Neolithic is represented in Malaya by very diverse and well-made tools of hornstone. almost all having a quadrangular cross section. Adzes are more numerous than any other type. These implements were fashioned by skilful flaking and finished by grinding and polishing, and most of them appear to be the tools of workers in wood rather than weapons of the chase or of war. They are accompanied by great quantities of unglazed pottery, usually ornamented with an impressed pattern of twisted cord (cord marking) and of diverse and often highly artistic forms. The contrast between the cave-dwelling hunters of the Hoabinhian and the apparently peaceful, industrious and artistic neolithic people is striking. Some other industries, represented by round axes and bone tools, have been found, but their relations with the main succession of cultures are obscure.

Early Metal-Age finds include two bronze drums of Dong Son type and a few bronze celts. These are certainly importations as no copper accessible to primitive mining methods exists in Malaya. Peculiar iron implements of a type not known outside Malaya have been found, some of them associated with slab graves (pits lined with slabs of desquamated granite), small glass beads and ill-preserved pottery. The affinities of this assemblage of objects are still in doubt. (M. W. F. T.)

HISTORY

Early Civilizations. — The earliest civilizations of southeast Asia derived their culture from India and more especially from Kalinga (in Orissa) and Palavas (near Madras). Palava inscriptions found in Kedah, Perak and elsewhere suggest a measure of direct Indian influence in Malaya and may date from as early as A.D. 400. More Indian influence, however, was felt indirectly through Sumatra and Java. The Sumatran empire of Sri Vijaya, with its capital at what is now Palembang, seems to have conquered most of Malaya in or before the 7th century. This Sumatran, Buddhist rule may have introduced, among other things, the name Melayu, which the Chinese regarded as another or a later name for Sri Vijaya itself. To the rulers and merchants of Sri Vijaya the Malay peninsula presented itself mainly, no doubt, as a barrier between India and China, forcing trade into a long southward detour which was of benefit to themselves. But this obstacle might be circumvented by crossing it overland at its narrowest point, the Isthmus of Kra, or else farther north at Mergui. This latter crossing would tend naturally to fall under the control of the people inhabiting the Menam Chao Phya river valley, the nearest plain capable of supporting a population of any size. In the earliest 13th century, there was a state called Ligor in northern Malaya but the Mongol invasion of southern China drove out the Thais, who entered what is now Thailand in 1280 and destroyed the Khmer rulers of Kambuja before setting up a new kingdom of their own. For a period, their expansion farther southward was checked by Ligor but they were eventually able to seize Tenasserim, the point at which the trade route crossed the peninsula. Southward from there. the territory which is now Malaya offered to the invader no particular obstacle and Thai rule probably extended over much of the peninsula in the 14th century.

Meanwhile, however, a new empire had arisen in Java, also under the influence of Indian culture. This was the Hindu-Javanese empire of Majapahit, which arose in the second half of the 13th century to challenge and eclipse the influence of Sri Vijaya. Majapahit supremacy continued for a century or more and extended not only over Java and Sumatra but also over southern Malaya. Although the claims of the Javanese and Thais must surely have overlapped, there is no record of conflict and they seem to have divided their spheres of influence in rather the same way as the Thais were later to divide Malaya with the British. From their capital of Aijudhya, the Thai rulers continued to dominate the overland route.

But it was not every merchant who chose to pass that way. The trader who preferred the sea passage between India and China would necessarily pass, as now, the southern tip of the Malay peninsula. More than that, he would tend to time his arrival there at about the change of the monsoon so as to make the best use of the wind system. Once in that vicinity he was near the Spice Islands and also in a position to profit from any trade the peninsula itself might offer. These circumstances all tended to favour the establishment of a port in roughly the area now occupied by the city of Singapore. Where exactly this port was situated remains doubtful and the contention that it occupied the same site as the modern city has become difficult to sustain in view of the almost total lack of archaeological evidence. The straits of Johore and of Singapore had their importance, nevertheless, and were the scene of 14th-century conflict between the local inhabitants and the Javanese. That there were fortified settlements up the Johore river is certain. Elsewhere, farther north, there may have been mining for gold and tin. But all the early history of Malaya is obscure and depends upon the doubtful identification of the place names mentioned by Arab and Chinese travellers.

Whatever the advantages of Malaya in mineral wealth and geographical position, its population remained insignificant and was quite small even in the 20th century. The country was a prey to neighbouring powers and we hear of no native civilization before the rise of Malacca in the middle of the 14th century. According to Malay legend, Malacca was first settled by a Malay chief whose original home (at or near Singapore and perhaps called Tumasuk) had been sacked and destroyed by the Javanese. Malacca is without some of the geographical advantages which such an earlier settlement would have provided but it offered, at that period, a sheltered roadstead, a navigable river, a good defensive position and a supply of fresh water, this last asset being none too common among the mangrove swamps of western Malaya. It also offered an overland line of communication by river, with only a short portage, to Pahang on the east coast. As that coast is unapproachable for sailing craft during the northeast monsoon, the trade of Pahang may have found its way to Malacca for at least half the year. In that trade was included the export of gold as well as tin.

Malacca, the first Malay kingdom, was a dependency of Thailand. to which it paid tribute in gold. But Chinese sources show that efforts were made to establish an alliance on tributary terms with China. These overtures in 1403–11 give us almost the first firm dates in Malayan history. Although effective Chinese help was unlikely, the Malays were emboldened to throw off allegiance to Thailand and even gain control of Pahang and other adjacent territories. The great days of the Malacca kingdom were from about 1450 to 1490 and have certainly lost nothing in the telling. Of prime importance, however, is the fact that the Malacca dynasty had been converted to Islam, probably in the 14th century, and was now influential in spreading Moslem doctrines throughout the peninsula. If the Malays were now Moslem, however, they readily countenanced the resort to Malacca of Hindu, Chinese and other traders. By the end of the 15th century Malacca was a place of sufficient importance to have given its name to the straits and perhaps to the peninsula itself.

Portuguese and Dutch Control. — So completely had Malacca assumed the commercial role of modern Singapore that the Portuguese, arriving in the east by the Cape route in 1498, marked it down for early conquest. It was captured by Alphonso d'Albuquerque in 1511 and absorbed into a Portuguese system designed to control the eastern trade; a system organized from Goa but stretching eventually from Ormuz to Macao. To deflect the trade from the old route (via the Red sea or Persian gulf) to the new oceanic route, possession of Malacca was essential. That city was stormed accordingly in 1511 and fortified against recapture.

The Portuguese exploited to the full the commercial possibilities of Malacca but never succeeded in destroying its native monarchy. Sultan Mahmud of Malacca established a new Malay capital as centre of a kingdom which now comprised Johore and the Riouw archipelago. He thus returned, in effect, to the vicinity of the original Malay city. Of his two sons, one became sultan of Perak. The other built a new capital at Johore Lama, on the Johore river. in about 1530. In the triangular war which continued with the Portuguese and with Achin in Sumatra, Malacca was repeatedly but unsuccessfully attacked. Johore Lama, on the other hand, was captured by the Portuguese in 1584. Recent excavation on this site has revealed a fortified settlement with pottery fragments dating from the 15th to the 17th century. All evidence suggests that, while the town was probably of some importance before 1530, it hardly survived its capture by the Portuguese and soon dwindled to its present status as a village.

Malacca fell to the Dutch and Malays in 1641, long after the Portuguese had lost naval control of the straits. By this date the Dutch had opened a new oceanic route from the Cape to the Straits of Sunda, a route which by-passed the Malacca straits and avoided Malaya altogether. Malacca was a place of reduced importance, therefore, under Dutch rule, with a declining population and trade. Deserted temporarily as a result of Achinese attacks, the Johore kingdom flourished again for a time, only to be sacked once more by the Sumatrans in 1673. Soon after, the royal line in that branch became extinct. The Dutch ruled as much of Malaya as suited them, making a state monopoly of the export of tin and building forts to guard the places of shipment.

British Rule. — The Dutch were unable to prevent the British

East India company from establishing a settlement at Pulo Penang in 1786 and the French wars which broke out in 1793 gave the British the opportunity to capture Malacca in 1795. Province Wellesley was acquired by purchase in 1800. This was followed by the foundation of another settlement at Singapore in 1819 and, in the treaty of London of 1824, the Dutch agreed to cede to the British all rights in Malaya, receiving in return the cession of all British rights in Sumatra. The East India company's establishments at Singapore, Penang, Malacca and Province Wellealey formed collectively the Straits Settlements and were a part of British India until 1867. Penang, originally designed as a naval base, and Malacca enjoyed only a mild prosperity but Singapore grew rapidly and became the base for the British expansion in Sarawak, Labuan and North Borneo. It was no part of British policy during this period to assert more control over the peninsula than would serve to exclude the influence of other European powers.

As a result of local agitation in the years following the Indian mutiny, the Straits Settlements were transferred in 1867 from the control of the government of India to the direct rule of the colonial office. This was a period during which other western powers were making their influence felt in southeast Asia, the French in Indochina, the Spanish in the Sulu archipelago and the Dutch in Sumatra. These last were nearest to Malaya; they were on the borders of Achin by 186j and clearly intending a further advance. International rivalry was intensified when the Suez canal was opened in 1869, bringing the main eastern trade back to its former route through the Straits of Malacca. This altered situation allowed the Singapore and Penang houses of agency to demand an extension of British influence in the Malay peninsula. It needed only a Conservative government to start the movement and such a cabinet took office in Feb. 1874.

Perak, Selangor, Negri Sembilan and Pahang were brought successively under British control (with a resident in each as the native ruler's adviser), with but one occasion for a display of force (during the Perak War of 187j). Two native states, Johore and Kedah, were already so influenced respectively by Singapore and Penang that any more systematic "advice" was for long deemed needless, In 1895 the four protected states were formed into a federation with a resident general at Kuala Lumpur. Up to this period the western states depended for their revenue upon tin mines. worked almost exclusively by Chinese. and communications were first developed between these mines and the coast. Later, the state railway systems were linked with each other, thus tending to unify the federation. The early planting was done by European planters along the line of the railways, coffee giving place to rubber from about 1900. An important result of this development was the recruitment of labour for the estates from southern India. The arrival of Tamil labourers, brought by government-subsidized shipping and protected by special legislation, added a new element to an already mixed population. Indians had not hitherto been present, except in Province Wellesley, in large numbers. The coming of the motorcar led to a rubber boom in 1906 and a bigger boom during and after World War I. Before this, however, in 1909, a treaty signed with Thailand transferred to British protection the states of Kelantan, Trengganu, Kedah and Perlis,' thus fixing the frontier on its present line. These territories were not absorbed into the federation but were governed more loosely as nonfederated states. Relations with Johore were not regulated by treaty until 1914 and even the Federated Malay States were never annexed as British territory.

In the years following World War I and the termination of the Japanese alliance. work began on a scheme for creating a full-scale naval base at Singapore (see below; also SINGAPORE). It was realized that the development of long-range aircraft made a defense of the naval base impossible without a defense of Malaya as a whole. Airfields were constructed in northern Malaya and the beginning of World War II brought to Malaya the troops needed to defend the airfields. When the Japanese attacked the United States and Great Britain in Dec. 1941 there were the equivalent of three and a half divisions of infantry in Malaya but few warships and few modern aircraft. With the temporary loss of sea power, Malaya was open to an invasion by seasoned Japanese infantry. This led to the conquest of Malaya and so to the fall of Singapore in Feb. 1942.

Malaya was occupied by the Japanese during the years 1942–45 and recovered only after the war ended. British prestige had suffered severely during the campaign and afterward, when the entire remaining British population was interned. It was hoped, nevertheless, to recover not merely the former degree of influence but a new and direct control following virtual annexation of the Malay territories in 1946. The constitution of the Malayan union, as thus established, was strongly opposed by the Malays and eventually withdrawn. Following new negotiations another constitution was drawn up and came into force on Feb. 1, 1948. This established the Federation of Malaya with Penang and Malacca included but Singapore was left as a crown colony. Co-ordination between the separate governments of the federation, Singapore and British Borneo was entrusted to a commissioner general whose functions were to be mainly diplomatic and advisory.

Toward Self-Government. — The end of the war with Japan did not bring immediate peace to Malaya, for the only effective local opposition to the Japanese had come from (mainly Chinese) Communists and these were armed and in the field when the Japanese surrendered. These now continued their guerrilla operations. A series of atrocities and attacks on property culminated in the ambush of Oct. 6, 1951, in which Sir Henry Gurney (high commissioner of the federation) was killed. This period of unrest coincided with a postwar boom in rubber and tin, initially caused by the cessation of exports during the previous period of enemy occupation and then intensified by the efforts of the United States to acquire stocks of these materials. Malaya thus served as a dollar-earner for the sterling area in 1949–52, the boom period ending only in 1953. Under the next high commissioner. Lieut. Gen. Sir Gerald Templer, the security forces were more effectively deployed and by mid-1954 Templer was able to relinquish the high commission to his deputy, Sir Donald MacGillivray, and the direction of military operations to a senior army officer. Measures to end the state of emergency included political as well as military action: in 19jj the federal executive council was transformed into a ministerial body and, on July 27, the first elections were held to the federal legislative council, 52 of whose 98 seats were elective. Fifty-one seats were secured by a triple alliance of the principal moderately nationalist community parties, Malay, Chinese and Indian. Tengku Abdul Rahman, leader of the United Malays' National organization (U.M.N.O.) and of the alliance, took on the chief ministry and the portfolio of home affairs. In Jan.–Feb. 1956 he attended a conference in London at which it was agreed that a new constitution providing full independence and self-government for the federation within the commonwealth should be introduced. The Malayan government assumed responsibility for finance. internal defense and security, including the prosecution of the war against the Communists. In December, however, it was made clear that even after independence had been achieved, British forces would be available until terrorism was completely crushed. Food control, which had proved a successful weapon, was tightened. and in 1956 the biggest single success of the emergency, the killing of the deputy secretary general of the Malayan Communist party, took place. On Aug. 5, 1957, MacGillivray signed an agreement providing for the admission of Malaya into the British commonwealth as an independent state on Aug. 31, 1957, and ceding the British settlements of Penang and Malacca to the new federation. Sir Xbdul Rahman was elected monarch at a conference of Malayan rulers on Aug. 3. (C. N. P.; X.)

POPULATION

The Federation of Malaya (area: 50,600 sq.mi.) had a population (1957) of 6,276,915, composed as follows: nine Malay states, Johore (925,919), Pahang (312,978), Negri Sembilan (365,045), Selangor (1,012,047), Kedah (701,486), Perlis (90,834), Kelantan (505,171), Trengganu (278,147), Perak (1,220,633); and two British settlements, Penang (274,325) and Malacca (291,233).

Table I shows the population increase after 1931 (the first census year).

TABLE I.—*Population, 1931–55*

	1931 (census)	1947 (census)	1955 (est.)
Malaysians	1,863,872	2,427,834	3,003,181
Chinese	1,284,888	1,884,534	2,326,498
Indians and Pakistanis	570,987	530,638	729,013
Others	68,011	65,080	93,407
Total	3,787,758	4,908,086	6,152,099

The Chinese predominate in the southwestern states, in Penang and in the commercial and industrial areas whereas there is a bigger percentage of Malays in the north and east and in Malacca.

Religion, Education and Health.—Malaya is basically a Moslem country. the Malays and many of the Indians folloning the Moslem religion. The other major religions practised are the Christian, Buddhist and Hindu.

The problems of education in Malaya are complicated by the fact that it is a multiracial community. The official languages are Malay and English. but many of the Chinese dialects, particularly Cantonese and Hokkien, and south Indian languages, chiefly Tamil. Telugu and Malayalam, are also spoken. Daily newspapers are published in most of the vernacular languages.

Secondary education is only available in schools in which English is the chief language of instruction, which are open to all races. and in some Chinese schools. In 1952 an education ordinance gave legal sanction to the provision of free and compulsory primary education and provided for a new multiracial school, called the National school, with either Malay or English as the medium of instruction, with Chinese and Tamil as subsidiary languages. Later, it was decided to introduce English-medium classes into the vernacular schools, and to discourage the setting up of purely vernacular schools. The policy of encouraging education was hampered by lack of teachers and by lack of funds. It was estimated that by 1954 405% of the population mere literate.

Table II shows the number of pupils enrolled in schools of all types in 1938, 1947, 1954 and 1955. In 1955 there were 4,751 schools of all types. Enrolment in the multiracial English-medium schools did not reflect the proportions of the races in the population: there were 26% Malays, 49.4% Chinese, 22.25% Indians and 2 4% others. From 1949 onward, a noticeable development was the rising number of Malays enrolling in multiracial schools.

The University of Malaya, established in 1949 and centred in Singapore, serves the federation and Singapore and has faculties of arts, science and medicine. There are also two technical colleges.

TABLE II.—*Education, 1938–55*

	1938	1947	1954	1955
English	18,444	52,900	158,485	178,644
Malay	57,144	149,414	349,583	368,017
Chinese	...	193,340	251,124	277,454
Indian	22,915	35,378	44,561	46,247

Principal diseases treated in government hospitals in the federation are malaria, pulmonary tuberculosis, dysentery. diarrhoea and enteritis, pneumonia, bronchitis, beriberi, venereal diseases and enteric fever. A remarkable development during the first half of the 20th century was the success of the campaign against malaria. By the mid-1950s it had ceased to be an indigenous disease; cases admitted to government hospitals continued to fall (from 22,281 in 1947 to 8,577 in 1955) and efforts were directed toward preventing its recurrence, and to fighting tuberculosis, the next most serious scourge of the Malay peninsula.

A ten-year health program was adopted in 1948. By 1955 there were 68 government hospitals, 161 private hospitals, 184 static dispensaries and 77 mobile dispensaries. There were also a maternity hospital and 553 maternity and child welfare clinics, and institutions for the treatment of tuberculosis, venereal disease, leprosy and mental diseases. There is an important Institute for Medical Research at Kuala Lumpur.

CONSTITUTION AND GOVERNMENT

The constitution of the Federation of Malaya dates from 1948 when the Federation of Malaya agreement between the British sovereign and the rulers of the Malay states came into force. The agreement established the federation under the protection of the United Kingdom, the government of the United Kingdom bearing responsibility for defense and foreign relations. In Feb. 1956, it was agreed that a new constitution should be introduced, if possible by Aug. 1957, granting the federation full self-government within the commonwealth. Meanwhile the Malayan government would take over full responsibility for finance, internal defense and security. In Nov. 1956, the high commissioner announced that independence day would be Aug. 1, 1957, and also made immediate amendments to the constitution to allow for Malayanization of the civil service.

The central or federal government is established at Kuala Lumpur. It is composed of the high commissioner, the federal executive council and the federal legislative council. Executive authority is exercised by the high commissioner through the executive council; ministerial responsibility for the work of the various government departments is borne by the members of the executive council, whose members, including the chief minister, are drawn from the political party with the majority in the legislative council, with, in addition, a few official members, who are senior government officers. The legislative council, which is presided over by the speaker, is composed of 98 members of whom 52 are elected. The council has powers to make laws on matters which are clearly defined in the federation agreement. Laws passed by the legislative council require the assent of the high commissioner and of the rulers. The high commissioner retains certain reserve powers to legislate if he considers it in the public interest.

There is established under the federal agreement the conference of rulers comprising the nine rulers of the states and their Malay advisers. This conference, which has no executive authority, meets at least three times a year and provides a channel for consultation between the high commissioner and the rulers and enables the high commissioner to ascertain the views of the rulers on matters of importance.

Under the various state agreements between the rulers and the British sovereign the executive authority in each state is exercised by the ruler aided by the state executive council composed of both official and unofficial members. The authority of the state executive council extends to all matters not within the executive authority of the federal agreement and is generally concerned with the internal administration of the states. In each state there is also a council of state, the composition of which varies but which in each case has a proportion of elected members which, with the nominated unofficial members constitutes a majority; it may pass laws on any subject other than those in respect of which the federal legislative council has the powers to legislate. The assent of the ruler is required before a law passed by the council of state comes into force. The rulers retain certain reserve powers similar to those retained by the high commissioner. The principal officer of the state is the *mentri besar* who is also the president of the council of state and in that capacity is the representative of the state on the federal legislative council.

The settlements of Penang and Malacca were incorporated in the Federation of Malaya under the Federation of Malaya order in council, 1948. The resident commissioner is the chief executive authority and presides over the settlement council which corresponds to the council of state in the states.

The chief executive officer of the state is the *mentri besar,* and of the settlement the resident commissioner. The states and settlements are divided into administrative districts under district officers. Many of the districts are subdivided into subdistricts and *mukims* or parishes, the administration of which is in the charge of an assistant district officer and *penghulus* or *pegawais.*

The executive responsibility for local government rests with the respective state and settlement governments. There are three municipalities, Penang, Malacca and Kuala Lumpur, with elected majorities. There are 22 elected town councils and 242 local councils which are fully elected bodies responsible for the administration of villages and kampongs roughly corresponding to the English parish council. The number of these is steadily increasing.

Legal System.—Generally the legal system of England, as modified and codified for India, is in force in the federation.

The control of executive actions of the courts is maintained by proceedings in the nature of the English writs of habeas corpus, mandamus and the like. The judicial system of the federation comprises a supreme court, divided into the court of appeal and the high court, which has unlimited civil and criminal jurisdiction. There are, in addition, sessions courts and magistrates' courts with limited civil and criminal jurisdiction, from which appeal lies to the high court and thence, conditionally, to the court of appeal. A final appeal from all courts lies to the sovereign in council (the judicial committee of the privy council). The attorney general is the principal legal adviser to the government, and he is also, in his capacity as public prosecutor, responsible for the direction and conduct of all criminal prosecutions.

The Torrens system of land registration of title ***(see*** TORRENS, SIR ROBERT RICHARD) is in force except in the settlements of Penang and Malacca. Most alienated land is held in perpetuity on payment of an annual rent to the government. Land may be alienated to anyone except in Malay reservations where it may not be alienated to non-Malays.

All persons born in the settlements of Penang and Malacca are British subjects, citizens of the United Kingdom and colonies and automatically citizens of the Federation of Malaya. Subjects, whether by birth or naturalization, of the rulers of the Malay states are also citizens of the federation. Citizenship may also be acquired by registration. All citizens of the Federation of Malaya, if not otherwise British subjects, are British-protected persons.

Defense. — The external defense of the federation is the responsibility of the United Kingdom government. In 1956. however, when responsibility for internal defense was transferred to a Malayan minister for internal defense and security, a Federal Armed Services council uas set up, to administer the growing armed forces of the federation.

ECONOMIC CONDITIONS

Agriculture, Forestry, Fisheries. — Malaya produces about 32% of the world's natural rubber. and rubber is its most important commercial crop. About 64% of the total planted area is devoted to it, and its importance to the country's economy is indicated by the fact that in 1954 the net value of rubber exported was M.$859,500,000, 55% of the total value of all exports.

TABLE *111.—Agricultural Crops*

(000 acres)

*1954.

Rubber is grown both on estates, mostly owned by Europeans, and small holdings, owned by Asians. In 1955, of the total planted area under rubber (about 3,500,000 ac.), the estates area was about 2,030,000 ac., and estates produced 352,000 tons of the total production of 637,000 tons.

The growth of the synthetic rubber industry led the Malayan government to take steps to increase efficiency in the rubber industry. Efforts were made to encourage replanting, particularly on small holdings. Estates growing rubber have. in the main, carried out a steady policy of replanting old rubber trees with trees of proved high-yielding capacity. A tax was imposed on the export of locally produced rubber to provide funds for replanting on small holdings. In 1954, a mission of inquiry into the rubber industry (the Mudie mission) reported on the urgency of expanding the area planted to high-yielding rubber. and as a result, legislation was passed to regulate the export duty and to introduce an 11-year replanting program.

Malayan soils are poor judged by the standards of temperate regions. Their productivity depends upon optimum conditions of rainfall and temperature for plant growth, and on intensive weathering continually making available small quantities of plant food. The particular characteristics of the soils and climate and the topography of the country have led to the development of intrinsically simple systems of agriculture well adapted to Malayan conditions, which do not exploit soil resources. Soils that are exposed to the weather deteriorate rapidly and except for Chinese market gardening, which is famed for its soil-building quality, systems of dry-land arable farming have not been developed. The swamps and the flat coastal plains are best utilized for wet paddy, and the higher undulating areas for permanent tree crops.

The percentage of production to consumption of rice is about 50%. Paddy cultivation is almost solely confined to the Malays. After rubber and rice, coconut is the most important crop. Other food crops are tapioca, sweet potatoes, yams, maize, peanuts, cucumbers, etc., and pineapple. Encouragement of pineapple growing on plantations was a feature of post-World War II agricultural policy. Tea is grown in the highlands and lowlands of Malaya, mostly on estates. Tables III and IV show acreages planted and production of the most important crops.

The total volume of timber (excluding poles, firewood and charcoal) produced in the Federation of Malaya in 1955 was 74,279,000 cu.ft. round measure which almost equalled the 1952 record of 74,479,000 cu.ft. Malaya is self-sufficient in timber.

TABLE *lV.—Agricultural Production*

(tons unless otherwise stated)

The majority of the 49,500 fishermen in Malaya are Malays, but the financing and marketing of fish is preponderantly in the hands of the other races. Total production in 1955 was 109,422 tons, of which approximately 25,000 tons came from fresh-water fisheries. Fish is the most important protein element in the local diet.

The Rural and Industrial Development authority was inaugurated in 1951 and incorporated in 1953. Its object is to provide the rural and urban population with means of improving their economic and social standards by means of assistance from the authority and by promoting self-help among the people concerned. The authority's work is proving a great benefit, especially in the rural areas.

Mining. — The Federation of Malaya is responsible for about one-third of the world's production of tin. More than 90% of the ore (cassiterite) is won from alluvial deposits in the states of Perak and Selangor. The commonest methods of mining are by dredges and by gravel pump. Other minerals of economic importance are iron ore, gold, bauxite, ilmenite, columbite. wolfram and scheelite. Table V gives figures of mining production.

TABLE V.—*Mining Production, 1940–55*

(in tons unless otherwise stated)

	1940	1950	1952	1955

Coal . .	781,509	415,777	314,922	206,118
Gold (troy oz.) .	35,689	18,436	19,806	22,838

Finance **and** Trade. — The following is the table of public finance (federal, state and settlement together), 1949–53.

The public debt at the end of 1953 amounted to M.$364,648,245 (approximately M.$63 per head of population). The states and settlements have their oun budgets for local administration.

The main items of revenue are derived from export duties on rubber and tin. import duties on tobacco, beer, spirits. gasoline and textiles and from income tax. The flow of imports depends upon the export earnings, which are largely derived from rubber and tin. There is an old-established entrepôt trade at Penang which is conducted in small vessels trading with northern Sumatra, south and western Thailand and Burma. In 1955 the value of imports was M.$1,543,000 and exports M.$2,360,000. Table VII gives principal exports by commodities. 1947–55.

Table VI.—*Revenue and Expenditure, 1949–53*

*1954.

The standard currency is the Malayan dollar linked to sterling and valued at 2*s*.4*d*. The standard measures are the imperial yard, imperial gallon and imperial pound, though there are local equivalents.

Communications. — The public road system covered 6,354 mi. in 1955, of which 4,403 mi. were macadamized. The main trunk road runs north and south from the Thailand border in Perlis to Johore Bahru. passing through all the state capitals of the nest coast states. An east-west trunk road connects the east coast at Kuantan with the main north-south road 40 mi. N. of Kuala Lumpur. A partially metalled road connects the east coast from Pekan in Pahang north to Kota Bharu in Kelantan.

The Malayan railway, which is government-owned extends for over 1,000 mi. The main line runs from Singapore to Prai on the mainland opposite to Penang and thence up to the Thai border where it connects with the Thai railway system. A line branches off the main line at Gemas in Negri Sembilan and connects with Kota Bharu in Kelantan from where it also connects with the Thai railway system.

The principal ports are Penang and Port Swettenham. Services to and from the United Kingdom are provided by the main shipping companies on the far eastern service. Local companies provide coastal services and services to ports in southeast Asia.

There are civil customs aerodromes at Kuala Lumpur, Ipoh, Taiping, Penang, Alor Star, Kota Bharu, Kuantan and Malacca; 48 smaller airfields can be used for commercial, military and private purposes.

There is a telephone system throughout the country. Most urban areas have an electricity supply. A government-owned broadcasting system broadcasts in most of the languages spoken in the country. (J. H. Lh.)

SINGAPORE

Singapore, the British colony and city which adjoins Malaya, is separated from it only by the narrow Straits of Johore and these are crossed by a causeway, which carries the railway, the main road and the city's water-supply pipe line. The islsnd lies in 1° 1;' N. latitude and 103° 51′ E. longitude and measures 27 mi. from east to west, 14 mi. from north to south. The area of Singapore, including adjacent islands, is 28; sq.mi.

Besides the city of Singapore (*see* Singapore), the island contains the naval base on its northern coast, east of the causeway, a royal air force airfield at Changi and several other and smaller R.A.F. stations. Coastal batteries and other defensive installations are sited mainly on the southern or seaward coast and upon immediately adjacent islands. A large civil airport at Kallang has been superseded by one still larger at Paya Lebar. Industrial development outside the docks area is largely confined to the main road which crosses the island toward the causeway, other parts of the island being either suburban or rural and only lightly populated. West of the town and inland from Pasir Panjang lies a large area devoted to military barracks. supply depots and hospitals.

Physiography

In its geography, geology, fauna and flora Singapore Island is merely a small sample of Malaya (*see* above). The highest hill, Bukit Timah, rises to only 581 ft. and the rivers are small and end. where they are not canalized. in mangrove swamps. Of the Malayan geological formations only the Triassic shales and sandstones and the hlesozoic igneous rocks are exposed, and these are overlain in places by alluvium. some of nhich is raised above sea level. There are no metalliferous deposits on the island. but granite is quarried on a large scale and Triassic shales are used for brickmaking. When A. R. Wallace visited Singapore in the 1850s he remarked that on an average a man was killed by tigers every day. Now the largest mammals are monkeys. civets and mouse deer. Birds are numerous and most species are protected by law. An area of about 12 sq.mi. in the centre of the island, surrounding the three reservoirs, is preserved as a catchment area and felling of trees and hunting and shooting are forbidden in it. There a fairly representative sample of the smaller animal life of southern Malaya, reptiles, insects and the like. is to be found. Most of the jungle in this area is secondary — that is, it has grown up after felling — but a most interesting and valuable relic of the primary forest is preserved on Bukit Timah hill, which is coextensive with the catchment area. (M. W. F. T.)

History

There is believed to have been a port in the vicinity of Singapore in the 12th–13th centuries but there is little evidence to show either its position or extent. Malay sources allude to a town destroyed by the Javanese in the 14th century. and it was a study of these sources which encouraged the modern founder of Singapore to choose a site nhich he identified with that formerly occupied. Whatever the truth of this matter, it is certain that Singapore Island was scarcely inhabited at the beginning of the 19th century. It belonged then to the sultan of Johore whose remaining territories comprised also the Riouw archipelago. Pahang and what is now Johore proper, all supposed to be under Dutch protection. The Dutch control over the East Indies was weakened during the French wars of 1793–1815 n-hen. the Netherlands being under the control of France. one Dutch colony after another came to be occupied by British troops. Eventually, in 1811, Java itself was taken and Stamford Raffles placed there as governor. The Dutch East Indies were returned to the Netherlands nhen peace was made but Raffles, now lieutenant governor of Benkulen in Sumatra. was anxious to prevent the Dutch regaining or extending their influence in the Malay archipelago. He persuaded the governor general of India to allow him to found a new British settlement near the southern entrance to the Straits of Malacca. This was done in 1819, the island of Singapore being the place chosen although not the site originally preferred. Dutch protests ended in a general agreement in 1824 (the treaty of London) by nhich Benkulen was yielded in exchange for Malacca and a line agreed upon dividing the British and Dutch spheres of influence. Raffles had established Singapore as a free port and the town grew rapidly for several years, attracting much of its trade from the Dutch ports and some from Penang. The East India company lost its monopoly of the China trade. however, in 1833, and with it such interest as it had previously shown in Singapore. The port suffered again from the establishment of Hong Kong in 1831 and thenceforward enjoyed only a moderate prosperity until about 1870 The opening of the Suez canal. and with it the replacement of sailing vessels by steamships, brought about a transformation in the port's activities. This was represented in the first place by the development of the Tanjong Pagar docks, and, in the second place, by the accumulation in Singapore of coal for naval purposes which had, in turn, to be protected by batteries. With the development of the resources of the Malay states. Singapore added to its existing entrepôt trade a partial monopoly of Malayan exports and imports. The Straits Trading company set up its vast tin-smelting works on the island of Pulau Brani, to which came most of the tin ore from the mainland. Docks and warehouses multiplied and the port rapidly became a world-famous centre of commerce. Its prosperity was marked by the construction of government buildings, town hall, supreme court. hospitals and schools. It was the seat of government for the Straits Settlements as a whole and the governor was also, before World War II, high commissioner for the Federation of Malaya.

In 1921 began the construction of the naval base, situated between Singapore Island and the mainland. Modern coastal defenses were developed from about 1932 and these. with the necessary airfields. led to Singapore's being termed a fortress. It scarcely deserved that title on its landward side where, obviously, the defense of the naval base could not be conducted from the island itself. When the Japanese oifensive of 1942 drove the commonwealth forces back into Singapore Island hopes centred on the possibilities of a protracted siege defense and the arrival of a relieving army by sea. But in effect there was nothing left to defend. With enemy artillery in South Johore and enemy land-based aircraft within easy striking distance, the naval base, the commercial harbour and the Singapore airfields were all practically useless. However. the British government was reluctant to surrender a base on nhich so much had been spent. The result was not only an order to defend the island to the end but the arrival at the last moment of another infantry division, too late to do much more than swell the total of prisoners.

The Japanese offensive began on Feb. 8, 1942, the Straits of Johore proving no greater obstacle to the invaders than several rivers they had already crossed. A landing mas made in the northwest part of the island and the defenders were driven back toward Singapore town. their withdrawal allowing the island's reservoirs to fall into enemv hands. Lieut. Gen. A. E. Percival was authorized to surrender; this he did unconditionally on Feb. 15. With forces consisting partly of troops which were exhausted by a fighting withdrawal from northern Malaya and partly of troops which were unacclimatized, there was little more he could have done. There can be no doubt that a defense of Singapore, street by street and house by house (destroying the town and most of its population in the process) would have done more to uphold British prestige in the east. But humanitarian motives prevailed and Singapore passed more easily into Japanese hands, remaining a Japanese base until the end of the war. It was then recovered more or less intact save for the naval base installations, wrecked before the surrender or damaged by Allied bombing afterward.

In 1946, with the transfer to the federation of the settlements of Penang and Malacca, Singapore Island became a crown colony. Singapore received its royal charter as a city in 1951. The naval base played a part in refitting warships taking part in the Korean war hut there was unrest among the workers. In 1955 the colony's executive council became a council of ministers, and on April 2 the first general elections were held to a newly constituted legislative assembly, 2j of whose seats were elective. A "labour front," left-wing and "anticolonial" (but anticommunist), emerged as the main group in the assembly, with 10 of the elective seats. Its leader, David Marshall. a moderate socialist. assumed the chief ministry and the commerce portfolio. A conflict with the governor about the latter's discretionary powers ended in a compromise, by which the legal status of the governor's discretionary powers was unaltered. but he was instructed to exercise them only according to the advice of the chief minister. In April–May 1956 Marshall took part in a London conference at which he urged Singapore's desire for self-government. Negotiations broke down over the problem of responsibility far internal security if Singapore became a self-governing member of the commonwealth, and Marshall resigned in June, being succeeded by Lim Yew Hock, the president of the Labour front. On April 11, 1957, an agreement was signed in London outlining terms for a constitution granting Singapore internal self-government. A date for relaxation of controls was to be decided by Jan. 1, 1958. (C. N. P.)

Population

At the census of the colony of Singapore taken in Sept. 1947 the population numbered 940.824. Pop. (1957 census) 1,466,800.

BY COURTESY OF BRITISH INFORMATION SERVICES

WASHING CASSITERITE. TIN ORE. AT AN OPEN-PIT MINE ON THE WEST COAST OF MALAYA. THE ORE IS SMELTED AT PENANG AND SINGAPORE

Singapore's position as a focal point for the trade of southeast Asia made the growth of a mixed population inevitable. In 19jj it was estimated that there were 927,981 Chinese (76% of the total), 148,520 Malaysians, 94,295 Indians and Pakistanis, 18,305 Europeans, 11,684 Eurasians and 11,803 others. The influx of Chinese and Indians followed the establishment of British rule in 1819. The population at the first census in 1824 numbered 10,683 persons of all nationalities. By 1860 it had risen to 81,734 but with a significant majority (more than 50,000) of Chinese. In 1919 the population within the municipal limits was estimated at 305,000 persons. In 1931 it was 559,945, of which 74.9% was Chinese. During the slump of 1928 to 1933 immigration was reduced and a system of quotas for the entry of aliens introduced. The quota did not prove effective in obtaining the right type of immigrant, and from 1934 to 1938 the net increase in population was 648,000 persons, mostly males. During the Japanese occupation of Malaya. transportation of large numbers of workers out of Singapore took place compulsorily. After the war the influx began again and by 1946 it became desirable to introduce selective immigration. In August entry was prohibited except to those who could contribute to the commerce and industry of the colony, and those who could provide specialized services not available locally.

Social Services.—In 195j it was estimated that 862,222 persons lived in the city and about 340,000 in the rural area of Singapore. This large concentration of population in the city area, barely 3 mi. in radius, as well as the shortage of good agricultural land, has made the provision of social services very important and has restricted development of food production. For the years 1955–59, the government intended spending Mal. $150,000,000 as capital expenditure on social development. The medical plan was to cost about Mal. $52,000,000 from 1951 to 1960. By 1955 buildings costing Mal. $5,000,000 had been built. To staff these, 100 doctors and 1.000 nurses were recruited and trained.

The governments of the Federation of Malaya and Singapore agreed on the future development of the University of Malaya and guaranteed a part of the funds. The medical: arts and science faculties were to be sited in Singapore while those for agriculture and engineering would be established in the federation. Because of the difficult conditions prevailing in China and the lack of higher Chinese education in the federation and the colony, the Chinese community in Malaya founded in 1954 a second university in Singapore, the Nan Yang university. The well-known Chinese writer Lin Yutang was elected its first chancellor. By April 1955, however, relations had deteriorated between the governing body and the faculty, who resigned as a body. The project was put in abeyance. Legislation was passed in 1954 for the establishment of a polytechnic college.

Constitution and Government

The Japanese surrendered Singapore to the British in 1945. On April 1, 1946, the British military administration of Malaya came to an end and at the same time the Malayan union and the colony of Singapore came into being. The United Kingdom secretary of state for the colonies announced in May 1947 that a legislative council with an unofficial majority would be set up. It was to comprise the governor: 9 official and 13 unofficial members, of whom 6 mould be popularly elected. An elections ordinance was brought into force in July 1947 providing universal adult suffrage for all British subjects resident in the colony. In March 1948. 63% of the registered voters went to the polls. Fifteen candidates were nominated. five representing the Progressive party (the only party then formed) and ten standing as independents. Three of each group were returned.

In 1951 the number of popularly elected members was increased from six to nine. In the same year the legislative council elected an unofficial member to be its vice-president and take the chair in the governor's absence. Two unofficial members were also elected to the executive council, thus linking the two councils together. After 1951 the legislative council consisted of the governor as president, 4 ex-officio members, 5 nominated officials, 4 unofficial members and 12 elected members. Of those elected. nine were chosen by popular ballot and three by the principal chambers of commerce. The four other unofficial members were nominated by the governor to represent important interests not otherwise represented.

In 1953, the governor appointed a constitutional commission under Sir George Rendel, a senior British diplomat. In Feb. 1954 the commission recommended a system of automatic registration of voters and the establishment of a mainly elected legislative assembly with a speaker. The assembly was to comprise 25 popularly elected members. 3 ex-officio members and 4 members nominated by the governor. The majority party in the assembly was to form a council of nine ministers. with the governor as president. Six of the nine were to be from the elected members of assembly with the leader of the majority party as chief minister. The remaining three were the ex-officio members. Elections for the assembly were held in April 1955 and out of the 25 elective seats the Labour front obtained 10, more than any other group, and was thus able to form a ministry.

The municipal affairs of the city are in the hands of a council under a civil servant as president. The council was established by royal charter in 1951, being then incorporated from a municipal commission into a city council. Of the 27 members of this council, 18 are elected by popular franchise and 9 nominated by the governor. Outside the city boundaries the island is administered by a rural board which includes representatives of village committees.

Economic Conditions

Finance and **Commerce.**—The basis of Singapore's prosperity is its entrepôt trade. The colony is a free port and the only customs duties are those levied on spirits, tobacco and petroleum. The biggest revenue earner, however, is income tax, which was introduced in 1948

The monetary unit is the Malayan dollar, the value of which was fixed in 1906 at *2s.4d.* sterling. Currency is circulated under a currency agreement of Jan. 1, 1952, between the governments of the Federation of Malaya, Singapore. Sarau-ak, North Borneo and Brunei. The currency commissioners have the sole right to issue notes and coin in these five territories and, as a backing for the currency, they manage a fund consisting of sterling securities.

During 1950–5j revenue was buoyant as a result of favourable trading conditions. After World War II Singapore enjoyed a trade boom. In 1948 the value of total trade was £285,000,000 as against £118,000,000 in 1946 and £81,000,000 in 1938. The peak of the boom was 1951 when trade totalled £901,000,000. The prices of rubber and tin are the main factors which govern trade. The boom of 1950–51 was mainly caused by increased world prices for these two commodities resulting from the outbreak of the Korean war. A high proportion of Singapore's postwar trade mas conducted with the United States and the British commonwealth. They were the main suppliers of the colony's imports of manufactured goods. Trade also expanded with Indonesia, Thailand, Borneo, Sarawak and Indochina, though, after 1952, the introduction of import restrictions by the governments of a number of these territories hampered the growth of the colony's trade.

Communications. — Singapore has a natural deep-water harbour. free of mud and shoals, with excellent dock and wharf facilities. Dock accommodation includes five graving docks. Deep-water wharves totalled 13,500 ft. in 1955, and there was at that date storage for about 1,800,000 sq.ft. of cargo. Air services on all the international routes are provided by the major airline companies. Kallang airport, in the city area: opened in 1937, was replaced in 19jj by a larger and more up-to-date one at Paya Lebar to the northeast. It was large enough for any aircraft likely to be used on international routes. Good road and rail services connect the colony with the Federation of Malaya. About 16 mi. of dock railways enable bulk carriage of the valuable entrepôt commodities, *e.g.* rubber, palm oil; latex. etc., between Singapore and the mainland. (G. E. Bs.)

MALAYALAM, one of the four literary languages of the

Dravidian family, is spoken on the west coast of southern India. It developed out of Tamil between the jth and the 10th centuries. In general it differs from Tamil in the absence of personal terminations in the verb. The colloquial and even more the literary language uses many words borrowed from Sanskrit. There were estimated to be 14,000,000 speakers at mid-20th century.

See *Linguistic Survey* of *India*, vol. iv (1906) ; R. Caldwell, *Comparative Grammar* of *the Dravidian Languages* (1913). (M. B. E.)

MALAY ARCHIPELAGO, also known as Malaysia and the East Indies. the largest group of islands in the world, consisting of the more than 3,000 islands of Indonesia and the 7,000 islands and unnamed rocks of the Philippine group. New Guinea is usually arbitrarily included in the Malay archipelago while the Andaman and Nicobar Islands in the northnest and the Bismarck archipelago in the east are not. The principal islands and groups of Indonesia include Sumatra. Java. Borneo (Kalimantan), Celebes (Sulawesi), the Lesser Sunda Islands and the Moluccas, including Halmahera. The Philippines include the large islands of Luzon in the north and Mindanao in the south. with the Visayan group between. For political divisions, see the Table in Population, below.

The archipelago extends along both sides of the equator for a longitudinal distance of more than 3.800 mi. and is 2,200 mi. in its greatest north-south dimension. The festoons of islands with their enclosed seas are situated between the Pacific and Indian oceans. Stretching from the mainland of Asia to Australia. the archipelago is separated from mainland Asia in the west by the 30-mi. Strait of Malacca, from Formosa in the north by the 100-mi. Bashi channel and from Australia by the 100-mi. Torres strait.

This island bridge is an area of physical and cultural transition between Asia and Australia. Due to its transitional nature and physical fragmentation, the region is one of great variety in physical landscape, climate, vegetation, animal life. land use and stage of economic development. The different peoples, their distinct cultures, myriad languages and many religions add to this diversity. The region has been subject to Indian, Chinese. Australian, Melanesian and European influences, all contributing to its cultural multiformity.

PHYSICAL GEOGRAPHY

Geology and Physical Features. — Structurally the Malay archipelago divides into three parts: the Sunda platform, the Sahul shelf and the area of recent tectonic activity which lies between the two. The Sunda platform is a stable continental extension of mainland southeast Asia. Most of the platform is covered by shallow seas averaging less than 2j fathoms. Borneo and parts of Java, Sumatra and associated islands are sections of the platform above sea level. These are areas of worn-down mountains of old metamorphic rock and are of complex geologic origin. The Sahul shelf, of which New Guinea and related islands are a part, is an extension of the Australian continent similar in structure to the Sunda platform and also covered by shallow seas. Between these stable continental platforms is a zone of recent tectonic activity: faulted and folded steep young mountain systems arranged in long mountain ranges or chains of islands. The main arc runs from Burma through the line of the Andaman and Nicobar Islands, forms the main ranges of Java, Sumatra and the Lesser Sunda Islands and then curves back through the Moluccas to Celebes. A circumpacific arc runs southward through the Philippines, through Halmahera and eastward along New Guinea. Other arcs run from the Philippines to Celebes and from the Philippines to Borneo. Around Celebes is a confused area of fragmented arcs and downfaulted basins.

Tectonic activity is characterized by frequent earthquakes, more than 1,500 a year occurring on the island of Banda in the Moluccas. Along the fracture lines associated with Tertiary folding are found a string of volcanic peaks, dating from the Late Tertiary and Quaternary. There are more than 300 cones, of which jo are still active. Volcanic cones are scattered through the Philippines, northern Celebes and the Moluccas, and form the impressive chain of peaks which dot the Lesser Sunda Islands and march majestically down the length of Java and Sumatra. Eruptions are often of the explosive type but the benefits from volcanoes far outweigh the harm. The ejecta and ash weather into extremely fertile soil; the forest-covered permeable ash cones collect and store rainfall which is later made available for agriculture by surface streams.

Associated with the arcs are deep offshore trenches or basins. More than 20 are located in the area between the continental shelves and are occupied by deep seas. many over 2,500 fathoms deep. Coral growth reaches its greatest development in the Great Sunda reef which marks the edge of the Sunda platform off the east coast of Borneo. Coral reefs and atolls are found throughout eastern Indonesia and the southern Philippines.

The mountainous nature of the islands plus the generally high annual rainfall results in many short, steep-gradient rivers with erosive power. On the islands which lie on the continental shelves. the rivers deposit eroded, material in the shallow surrounding seas and rapidly build extensive flood plains and deltas. Across these lowlands develop long rivers, such as the Musi in Sumatra, the Kapuas and Barito in Borneo and the Sepik and Fly in New Guinea. The islands which rise steeply from the deep seas between the continental shelves have little opportunity to build coastal plains and deltas in the surrounding deeps; level lowlands are limited and the rivers are usually short and steep.

Climate. — The Malay archipelago lies entirely within the tropics and, with the exception of the northern islands of the Philippines, within 10° of the equator, which bisects the major islands of Indonesia. Because of this equatorial location, temperatures are high, averaging 80° F. The annual variation in temperatures is only a few degrees at the equator, but increases away from the equator to about 20° F. in northern Luzon. Annual variation in temperature is modified by the maritime influence of the surrounding seas. Temperatures are also modified by elevation, and many hill stations such as Baguio (*q.v.*) in Luzon and Prapat in Sumatra have been established in the highlands to take advantage of the lower average temperatures.

The variable element in the climate is rainfall, which ranges from more than 320 in. annually on exposed mountain slopes in Sumatra and Java to less than 20 in. in rain-shadow areas of western Celebes and the Lesser Sunda Islands. Most of the archipelago averages more than 80 in. of rainfall well distributed through the year. but the total decreases and the length of the dry season increases from central Java eastward through the Lesser Sundas and from Mindanao northward in the Philippines. Timor, in the Lesser Sunda Islands, has a dry season of more than six months per year. There is also great local variation in rainfall depending on elevation, relief and wind direction.

Another climatic element is the typhoon. More than 20 of these storms arise each year in the Southwest Pacific from July through November and then swing westward and northward, bringing violent winds and heavy rains to the Philippines north of Mindanao.

The region is usually under the effect of the doldrums or intertropical front. a zone of convergence of the northeast trade winds from north of the equator and the southeast trades from the southern hemisphere. Rising moist air in this zone of convergence results in heavy rainfall. This frontal zone of convergence moves north and south with the seasons. The proximity of the two continents of Asia and Australia further influences the wind pattern and consequently the rainfall pattern of the archipelago. During the northern hemisphere winter the northeast trades are reinforced by cold air masses from a high-pressure area over the middle of Asia. Thus reinforced. the northeast trades sweep over the islands toward the low-pressure centre in Australia and this is known as the northeast (or northwest) monsoon. In the northern hemisphere summer this pattern is reversed and the southeast (or southwest) monsoon results. Most islands receive rainfall from both monsoons.

Vegetation.——The natural vegetation of the islands reflects their transitional climatic nature and differences in total rainfall and its annual distribution. Throughout most of the area heavy rainfall and high temperatures result in continuous, rapid plant growth of great variety. Evergreen tropical rain forest with a great variety of large dipterocarps covers areas with ample rainfall. In drier areas there is a semideciduous monsoon forest, including such trees as teak and eucalyptus. This forest has seasonal rather

than continuous growth. Other forest types include coastal forests (mangrove. nipa palms, pandanus), swamp forests and mountain forests. There are more than 150 species of palms, including the coconut, lontar, sugar, sago and areca palms, and bamboo is found in all parts. Large areas of the natural forest have been repeatedly cleared and dominated by cogon grass (*Imperata cylindricn)*.

The flora of the Malay archipelago is probably the most varied in the world. More than 30,000 species of trees, shrubs and grasses belonging to more than 2,500 families have been recorded. This wealth of different species is the result of the heavy rainfall, long growing period, relief! variety of environments and the position of the Malay archipelago as a bridge between Asia and Australia. Mingling of the flora and the fauna of these two continents takes place in the islands. Some species have undergone a complex evolution as a result of geologic changes; island groups have been joined together, then separated. then rejoined. increasing the almost unimaginable diversity and complexity of plant and animal life.

Animal **Life.**—While the fauna of the archipelago is very rich, there are few large animals. Elephants, tigers, rhinoceros, wild cattle, tapir and orangutan are all part of the Asian fauna. They are unevenly distributed on the islands of the Sunda platform and indicate differing periods of connection between these islands. Of the Australian fauna, kangaroos are found in New Guinea and other marsupials have moved beyond the Sahul shelf as far as Timor and Celebes. Some of the islands in between have endemic species, such as the anoa or dwarf buffalo and the giant monitor lizard or "dragon" of Komodo Island near Flores in the Lesser Sundas. Insects and birds have wider distribution, and the archipelago has probably the richest insect and bird life of the world. Particularly notable are the large longicorn beetles, the giant butterflies. the exotic birds of paradise, argus pheasants and myriad-coloured cockatoos.

The transitional flora and fauna of the area early attracted the attention of naturalists and after extensive work in 1854–62 A. R. Wallace attempted to fix a line between the Asian fauna and that of Australia. Later work established that Asian species extend to the edge of the Sahul shelf and that the area between represents a zone of mixing, transition and local evolution.

For a more detailed discussion of the geography of the archipelago, *see* the articles dealing with separate islands or island groups such as JAVA; MOLUCCAS; SUMATRA; etc.

NATURAL RESOURCES

Agriculture. — The raw material wealth of the Indies is legendary and brings to mind rare spices and precious metals. Of the great variety of resources the most important is agricultural production, which provides employment for almost 90% of the population. Productive agricultural areas are based on favourable water and soil conditions. Most islands have ample water in all seasons. but the Lesser Sunda Islands from Sumbawa eastward are chronically short of water and large areas support only extensive grazing. Eastern Indonesia and the northern Philippines suffer severe seasonal drought.

Most upland soils are of weathered lateritic types of low fertility. Tree crops can be grown on some lateritic soils and shifting cultivators also make temporary use of these areas. The intensively cultivated irrigated rice areas are on the fertile alluvial soils of river valleys, deltas and coastal swamps. Basic volcanic rocks: ash and mudflows develop into fertile soils and support intensive cultivation in parts of Sumatra, Java and Bali.

The agricultural economy is varied. Shifting hill cultivators raise subsistence dry crops of rice and corn in upland areas. The majority of the rural popuiation are sedentary cultivators, usually growing irrigated rice; but sometimes corn, yams or cassava as their principal food crop. Many commercial crops such as rubber and tobacco. although introduced on plantations, are now grown by these sedentary small holders. The small holder produces most of the region's sugar, copra. pepper, nutmeg. spices, kapok, sago. tobacco and abacá. The plantations, introduced in the colonial period and located principally in Sumatra and Java, provide valuable exports of rubber, palm oil, sisal, cinchona and tea, as well as some cofiee. tobacco and copra.

Other Resources. — Forests provide valuable resources in timber and in rosins, rattans and other gathered forest products. Timber exports are particularly important in the less-developed economies of Sarawak. North Borneo, Mindanao, Sumatra and Indonesian Borneo. Fishing and livestock production are important for domestic consumption only.

Petroleum is the principal mineral deposit of the archipelago. exploited in Sumatra Indonesian Borneo. Brunei and western New Guinea (Irian) Production in the 1960s was only 3% of the world total but was important in the petroleum-poor areas of Asia. Tin mines on Singkep. Bangka and Billiton provide about 20% of the norld's production. Deposits of bauxite are available in the Riouw archipelago and iron ore is mined in the central Philippines. Nickel is found in Celebes, and gold. chrome manganese and copper in the Philippines Coal resources throughout the archipelago are limited and of only fair quality; hydroelectric power potential is great although little developed.

Manufacturing is not greatly developed. Most important are handicraft industries and industries engaged in primary processing of agricultural and mineral products for export. Light manufacturing is expanding with spinning mills, paper. glass, soap and cigarette factories as well as some heavy industry. For a more detailed consideration of the economy, *see* the articles on each major island or island group. (L. A. P. G.)

ANTHROPOLOGY

Prehistory.—The prehistory of the area goes back to Pleistocene deposits in Java. where several exceedingly primitive manlike beings. collectively known as *Pithecanthropus erectus*, have been found. In strata of the third interglacial appear Neanderthal-like humans, there known as *Homo soloensis;* while in still later horizons the fossil remains of Wadjak man seem to be related to the modern Australoids. On the mainland, skeletal remains give evidence of a Negroid physical type which in Late Paleolithic (Mesolithic) times was moving eastward into the Pacific toward New Guinea. No groups of large Negroes now exist in southeast Asia but remnant bands of Pygmy blacks, known as Negritos or Semang. are found in the Andaman Islands. the Malay peninsula and the Philippines. The Neolithic or New Stone Age introduces a new. non-Negroid physical type, possibly of a Veddalike people which once occupied the coasts from southern India and Ceylon eastward into Malaysia. The Senoi (Sakai) of the Malay peninsula and minor groups in Sumatra, Celebes and some eastern islands of the archipelago appear to be related to this once widespread population. (*See* VEDDA; SENOI.)

Pygmies and **Senoi.**—The Pygmies are nomadic hunters and food gatherers who roam the jungles in small unorganized bands. They build only frail shelters and have scanty bark-cloth garments and few permanent possessions. The Senoi combine a limited agriculture n-ith hunting. in which they employ the blowgun and poisoned darts. Their typical dwelling is a one-room structure raised high above the ground on piles. but some communal houses appear. Each settlement is under a headman — usually an elder—who exercises a limited authority. Considering the simplicity of their material culture, the Senoi have a rather intricate set of religious beliefs, including superior beings. wandering spirits and life after death. An unorganized group of individuals. called *halak*, deals with the spirit world by means of ceremonies and magic rites. The Senoi are of slight build. with rather long heads and angular faces. Skin oolour is light reddish-brown; hair is dark and wavy and when worn uncut falls to the shoulders.

Proto-Malays. — The dominant population of Malaysia appears to have entered the area from the mainland, probably by following the river courses which spread south and southeast from the Tibetan borders. The character of the country did not permit mass migration but there was a steady drift of a people much like the Malay, although of stockier build, longer heads, heavier features and with wavy hair. Because of their earlier appearance and their evident relationship to the Malays they are known as Proto-Malays. As they advanced they drove out or absorbed most of the aboriginal peoples. They were followed by an infiltration of a related but more definitely southern Mongoloid physical type. Amalgamation of the two produced the present-day Malayan. Isolated groups of the Proto-Malays are found on the mainland, while powerful tribes such as the Igorot-Ifugao of the northern Philippines, the Tenggerese of Java, the Toradja of the Celebes and in less pure strain the Batak of Sumatra still remain.

Malays. — The Malayan peoples spread over the mainland nearly to the borders of China, down the peninsula and out into the Pacific until they had occupied Formosa, the Philippines, Borneo and Indonesia. In later centuries, as they became competent seafarers. they went east to the coasts of New Guinea, while to the west they reached and colonized Madagascar off the coast of Africa. On the continent, except for the peninsula, they were eventually dispossessed or absorbed by incoming peoples such as the Mon-Khmer, Thai, Burmese and Assamese. Even there small islands of Malay-speaking groups still exist. Both Malay and Proto-Malay speak dialects of Malayo-Polynesian. (See MALAY LANGUAGE.)

The typical Malay is of slight build; men are about 5 ft. 4 in., women slightly shorter. They have brachycephalic heads, broad faces and noses of medium size. The Mongolian (epicanthic) fold of the eye is common; the chin is prominent. Skin colour ranges from olive to a reddish-brown; eyes and hair are dark and the latter ranges from straight to wavy. In both the Proto-Malay and the Malay there is evidence of Caucasian mixture, probably due to crossing in the interior homeland.

The early Malayan kampong (village) was a small, largely self-sufficient unit. Bamboo and thatch houses of one or two rooms were raised high above the ground on piles. Close to the settlements mere plots of rice, sweet potatoes, taro and in some places spices. Always coconut and betel nut palms were nearby. Industries consisted of weaving, mat- and basketmaking, handmade pottery and ironworking. Such a village was governed by a headman and a council of elders, but there was no higher, organized rule. Religion was highly developed around a belief in spirits, some good, some bad, some ancestral, some self-existing through time. Contact with the spirit world was through mediums who, in trances, conducted elaborate ceremonies for the general welfare. A rich folklore gave the background for the religious beliefs as well as for the near-universal practices of magic and head-hunting. Today the bilateral family, with inheritance and descent in both lines, is typical but a highly specialized variant type exists among the Menangkabau of Sumatra and in some other areas. There is found a clan and phratry system with inheritance and descent through the female line. In such areas the long house or community dwelling is prevalent. (*See* also MALAYS.)

Other Elements. — Early in the Christian era Indian traders and petty princes entered the area in search of spices. Soon they set themselves up as rulers. Out of such beginnings empires arose (see History, below). Indian influence became dominant at the higher levels; elaborate courts were established together with Buddhistic and Brahmanistic rites. The Indian epics, given a local setting, became the literature of the people. During this period there was some intermarriage between the newcomers and the upper-class natives. Into this situation came Arabian traders and teachers who in a short time succeeded in introducing the religion of Mohammed. Only in Bali did the Indian religion persist, but the cultural influence of India ,is still strong in Malaysia. In the Philippines, Christianity, introduced by the Spanish, resisted the spread of Islam.

The 15th century witnessed the appearance of the colonizing powers of Europe. Their influence has been great, especially as related to the economic life. In the Philippines, Spain wrought great changes and succeeded in establishing the only Christian population in Asia. European exploitation of such natural resources as tin and rubber called for manpower, a need answered in part by the introduction of Chinese and south Indian labourers. Chinese contacts had begun in Malaysia by the jth century but extensive immigration did not start until after the advent of the European powers. With settled conditions and opportunities for gain there was a great influx of Chinese! in some areas as traders and shopkeepers, in others as settlers or as coolie labourers. In the Malay peninsula and Singapore they were so successful that many remained and came to constitute about half the population. Another important element, especially in the peninsula, is the south Indian (Tamil), who came primarily as a labourer on the estates. Indians make up about 10% of the population. On the peninsula a pluralistic society emerged, composed of Malays, who are Mohammedans; Chinese, mostly Buddhists; and south Indians, with Hinduism dominant. Because of the differences in religion, language and economic activities, there has been little intercommunication and few community interests are shared. (F.-C. CE.)

HISTORY

The Hindu **and** Moslem Periods. — Indians — merchants and political refugees — arrived in Indonesia prior to the Christian era. The immigration continued for seven centuries but the number was never large. They intermarried with the Indonesian aristocracy and their descendants formed the governing class. The immigrants deeply affected government and religion and exerted their greatest influence in Java and Sumatra. From there the new culture spread to Bali and the Moluccas, with some traces in Borneo and Celebes.

While the majority of the immigrants were Hindus, some were Buddhists. The two religions coexisted without persecution and provided the models for architecture and sculpture. Chinese traders arrived about the same time as the Indians but had little influence on Indonesia.

The two most powerful kingdoms between the 5th and 9th centuries were Srivijaya (Criwidjaya) and Sailendra (Cailendra). The former, with its capital at Palembang in Sumatra. included part of Sumatra and the Malay peninsula and was a commercial and naval power. The Sailendra dynasty ruled in central Java during the 8th and 9th centuries; under it Indian art reached its highest development in, for example, the Buddhist temple at Borobudur. Later. eastern Java became the most powerful kingdom and in the late 13th century King Kertanagara conquered part of Sumatra, Borneo, Bali and several of the Moluccas. After an interlude of civil war and the intervention of a Chinese fleet and army sent by Kublai Khan. Vijaya (Widjaya) became king in 1294. He founded the empire of Majapahit, whose strength rested upon sea power and control of the spice trade. The empire finally collapsed in the late 1jth or early 16th century. (*See* JAVA and SUMATRA for a more detailed history.)

The decay of Majapahit was hastened by the spread of the Moslem religion, introduced by traders. In 1292 Rlarco Polo visited the islands and found that the northern tip of Sumatra had been converted to Islam. From there it spread gradually through the islands until Hinduism survived only in Bali. The process of conversion was still in progress when the Portuguese arrived, and their efforts to substitute Christianity for Islam had little effect.

The Portuguese and Spanish. — In 1511 a Portuguese expedition under Antonio d'Abreu was dispatched to find a route to the Moluccas and Banda Islands; then famous for their cloves and nutmegs. The explorers reached Amboina and Ternate, after gaining some knowledge of Java, Madura, Sumbawa and other islands. In 1514 a second Portuguese fleet arrived at Ternate, n-hich became the centre of Portuguese enterprise in the archipelago. In 1529 a treaty was concluded between Spain and Portugal by which the boundary between the Spanish and Portuguese spheres was fixed at 17° E. of the Moluccas; the Philippines were included within the Spanish sphere.

Portuguese traders frequented the coast of Java and established a trading port in Sumatra, but annexed no territory in either. Farther east they founded numerous forts and factories, notably in Amboina, Banda, Celebes and Halmahera. Ternate remained the seat of the governor of the Moluccas, the highest official in the archipelago. Portuguese power in the east was weakened by administrative corruption and by incessant war with native states, notably Bintang and Xtjeh (Achin); bitter hostility was aroused by the attempts of the Portuguese to establish a commercial monopoly and to convert their subjects and 'allies.

The Dutch and English, 1595–1674. — The Dutch came to the east to avenge the injuries inflicted on their country by the Spaniards and to break the commercial monopoly of the peninsular states. They already possessed a large interest in the spice trade, for the Portuguese, having no direct access to the principal European markets, sent cargo to the Netherlands for distribution by way of the Scheldt and Rhine. The Dutch now sought to monopolize not only the distribution but the production of spices. The first Dutch fleet, under the command of Cornelius Houtman, reached Sumatra in 1596. In 1602 the Dutch East India company (*q.v.*) was incorporated, and for nearly two centuries played the chief part in the history of Indonesia. The Dutch were the stronger power at sea. They attacked the Portuguese in Ceylon (1602), and defeated a powerful fleet off Banda. In 1608 they forced the Portuguese to assent to an armistice for 12 years, and in 1609 Pieter Both was chosen as first governor general of Netherlands India. In 1611 the headquarters of the Dutch was changed from Bantam to Jakarta (*q.v.*), which in 1619 was renamed Batavia and became the Dutch capital. (The name Jakarta was restored in 1949.)

Meanwhile the English East India company extended its operations to the archipelago. After 1611 the commercial rivalry between the Dutch and British became acute, and commissioners met to arrange for co-operation between the Dutch and British companies and the maintenance of a joint fleet. But neither company could restrain its agents from aggressive action and many fresh causes of dispute arose. The treaty of defense lapsed in 1637. The Dutch company opened up trade with Japan and China and prosecuted the war against Portugal with great vigour.

A new war between Great Britain and the Setherlands broke out and was terminated by the treaty of Westminster in 1674. Thenceforward the British company devoted its energies chiefly to the development of its Indian possessions, while the Dutch were left supreme in the archipelago.

The system of practical slavery enforced on the native races provoked an insurrection throughout Java, in which the Chinese settlers participated; but the Dutch maintained naval and military forces strong enough to crush all resistance, and by 1749 they were practically supreme in Java.

British Occupation, 1811–16.—The Netherlands Indies were at this time part of the Napoleonic empire, with which Great Britain was at war. A British naval squadron captured Amboina, Banda and Ternate in 1810. and in 1811 a strong fleet captured Java. Thomas Stamford Raffles (*q.v.*) was appointed lieutenant governor and introduced many important changes in the departments of revenue, commerce and judicature. In 1816 the Setherlands Indies were returned to the Dutch, in accordance with the treaty of Vienna.

Restoration of Dutch Power, 1816–1940.—The history of the archipelago was changed by Raffles' occupation of Singapore in 1819 to prevent the Dutch from acquiring a monopoly of trade throughout Malaya and with China. Questions between Great Britain and the Netherlands were settled by treaty in 1824. The Dutch were given freedom of action in Sumatra, while the Malay peninsula was recognized as within the British sphere of influence.

The extension of Dutch political power—notably in Java, Sumatra, Celebes, the Moluccas, Borneo, the Lesser Sunda Islands and New Guinea—involved several wars with various native states. A large expedition mas sent to Lombok in 1894 and almost the whole of that island was incorporated in the Dutch dominions. A 30 years' war with Atjeh (*see* SUMATRA) began in 1873.

While the Dutch were consolidating their authority, other countries were acquiring interests in the archipelago. Immigration from China and Japan steadily increased. In 1841 Sir James Brooke (*q.v.*) established British sovereignty in northwest Borneo. In 1885 New Guinea was divided between Great Britain, Germany and the Netherlands. The Spanish-American War of 1898 resulted in the cession of the Philippines to the United States. Australian and Japanese trade in the archipelago was stimulated by the establishment of the Australian commonwealth (1901) and by the Russo-Japanese War (1904–05).

The effect of World War I was to deprive Germany of the northern part of New Guinea, which was administered under mandate by the commonwealth of Australia. The division of Timor between Portugal and the Netherlands was reminiscent of the struggles of past centuries; the Dutch-Portuguese treaty in 1904 settled all outstanding questions (see TIMOR). Apart from the Philippines, the Malay archipelago was before World War II almost wholly in the hands of the British and the Dutch.

After World War 11.—In World War II almost the entire Malay archipelago was brought under Japanese control. After Japan capitulated, the Indonesian republic was proclaimed on Aug. 17, 1945, and, following more than four years of Dutch-Indonesian hostilities, the transfer of sovereignty from the Netherlands to the United States of Indonesia took place on Dec. 27, 1949. On Aug. 17, 1950, the unitary Republic of Indonesia was proclaimed (see INDONESIA). The commonwealth of the Philippines obtained full independence on July 4. 1946, and became a republic (*see* PHILIPPINES, REPUBLIC OF THE).

See also the articles on the other political units in the archipelago. (K. G. J.; C.H.; E.S.; G. W.O.)

POPULATION

The population of the Malay archipelago is over 116,000,000, almost 5% of the total world population (see Table).

The distribution of population shows great variation in density. The most densely settled parts of Java have a rural population of more than 4,000 per square mile while the adjacent island of Borneo averages less than 5 persons per square mile and has large areas without population. This reflects the productivity of land and many historical and cultural factors.

About 80% of the Indonesian and Philippine population is rural. After World War II and independence there was a pronounced movement to the cities, resulting in the rapid growth of such urban areas as Jakarta and Manila (*qq.v.*). Almost 40% of the population is under 20 years of age, accelerating the already rapid rate of annual increase of 2% in Indonesia and the Philippines. Population pressure is severe in parts of Java and Madura in Indonesia. In the Philippines northwest Luzon as well as several islands in the Visayan group suffer population pressure.

Migration, both voluntary and government sponsored, has resulted in the settlement of Javanese in southern Sumatra, around Medan in northeastern Sumatra and along the southern coasts of Borneo. Filipinos from Luzon and the Visayan Islands have settled on sparsely populated Mindanao. Some have migrated outside the Malay archipelago: Indonesians to Malaya and Filipinos to Hawaii and the United States. But migration alone is an ineffective and temporary solution to population pressure. There are areas of the Malay archipelago where additional settlement is possible but continued rapid population increase will pose many problems. *See* also references under "Malay Archipelago" in the Index volume. (L. A. P. G.)

Area and Population

Political Unit	Area (sq.mi.)	Population
Indonesia	575,893	84,432,141*

(L. A. P. G.; F.-C. CE.)

MALAY LANGUAGE is one of the Malayo-Polynesian (Austronesian) languages *(q.v.).* It is most closely related to Menangkabau in west Sumatra and perhaps connected with it by the varied dialects of south and west central Sumatra sometimes called Middle Malay. It is next most closely related with other Malayo-Polynesian languages of Sumatra: Java and Borneo and the Cham languages of Vietnam. It is the native language of about 9,000,000 people distributed over the Malay peninsula, the east coast of Sumatra, the entire coast of Borneo and the smaller islands that lie between these areas, the Riouw archipelago, Bangka, Billiton, the Great Natuna Islands, etc. The local varieties differ noticeably from each other, but not as much as from the native Malay of Jakarta and that of Amboina.

The dialect of highest prestige is that of the Riouw Islands and the southern Malay peninsula. It is regarded as the basis of the standard Malay of the Federation of Malaya and also of the Bahasa Indonesia ("Indonesian language") or Indonesian, which is the official language of the Republic of Indonesia. A Malay pidgin often called Bazaar Malay *(mdlayu pasar* "market Malay") developed as a lingua franca in the East Indian archipelago probably before the arrival of the Portuguese. This pidgin varies somewhat locally. The variety used by the large Chinese colonies of Malaya and Indonesia is called Baba Malay. The formation of Bazaar Malay is no doubt due to the dominant position held successively by Palembang. Tumasik (old Singapore'). Malacca and Singapore as the centre of trade between the East Indies and other countries. The Java form of Bazaar Malay was used by the Dutch as the colonial language. The movement for Indonesian independence adopted Malay in 1927. As the variety of Malay spoken by most of the members of this movement, the same Java form had a noticeable influence on present standard Indonesian. The Japanese sponsored an Indonesian more like standard Malay and this has continued as the Indonesian standard. The European words in standard peninsular Malay are mainly from English whereas those of Indonesian are from Dutch. Another difference is the increase in Indonesian vocabulary fostered by the Indonesian government.

The earliest records in Malay are Sumatran inscriptions of the late 7th century in a Pallava (south Indian) alphabet. Such an alphabet is used in the so-called *renchong* script of southern Sumatra (Bengkulu, Palembang). With the coming of Islam in the 14th century, Malay became the local language of religious commentaries in converted Sumatra and in the Malay-speaking areas. An Arabic alphabet was developed for these commentaries and this orthography is still used in Malaya and parts of Sumatra for Malay. This alphabet is called Jawi *(huruf jawi* "Jawi letters"), perhaps because Java (Malay *Jawa)* dominated Sumatra and large parts of the peninsula at the time of the conversion.

An orthography with Latin letters was constructed by English scholars and has been used in some publications. The standard Indonesian orthography uses Latin letters, but since its basis was constructed by the Dutch, it differs from its Malay counterpart. After the modifications introduced by the Indonesian government the difference between the two Latin orthographies involved chiefly four letters: Malay *ch, j, ny, y* = Indonesian *tj, dj, nj, j,* respectively.

The Malay of the southern peninsula distinguishes the syllabics *i, e, è, ĕ, a, u, o, ò* and the nonsyllabics *k, g, ng, ch, j, ny, t, d, n, p, b, m, y, w, r, l, s, h, q.* Syllabics appear nasalized *(tãõn* "town") or unnasalized *(taon* "year") ; *è* appears in loan words *(bèk* "bag"). Likewise *k* is final only in loan words; romanized final *k* (= Jawi *qāf)* or apostrophe (= Jawi *hamzah)* correspond to a glottal stop (q) in pronunciation: *r* is a velar spirant. In pronunciation *ĕ* appears for final orthographic *a,* and *e* and *o* for orthographic *i* and *u* commonly appear before final consonants (in disagreement with the standard orthography) : *apĕ* "what," *baeq* "good," *bagos* "fine,!' orthographic *apa, baik, bagus.* Stress as well as pitch is part of the phrase structure and is conditioned by the shape of the words rather than the particular words.

Malay has a number of parts of speech. The chief ones are particles and full words of which only the latter appear with attributes. The particles are exclamatory *(e.g., wah* "gosh"), prepositional *(e.g., di* "at," *kd* "to"), conjunctional *(e.g., jang* "that," *kalau* "if," *kavdna* "because") and attributive *(e.g., chuma* "only"). The full words are nouns *(e.g., rumah* "house," *saja "I")* and verbals, the latter being further classified as adjectives *(e.g., bĕsar* "big"), numerals *(e.g., satu* "one") and verbs *(e.g., bĕli* "buy," *pdrgi* "go"). As predicator a noun has the negative *bukan (itu bukan rumah* "that is not a house") whereas a verbal has *tidak (saya tidak pdrgi* "I did not go"). An adjective follows the noun it modifies *(rumah bĕsar* "a big house"). A numeral precedes the noun it modifies *(satu rumah* "one house'!). Usually there is a choice between a simple numeral as above and a compound numeral *(sĕbuah rumah* "a house") ; in such cases the simple numeral calls particular attention to the number *(dua rumah* "two houses." *duabuah rumah* "some two houses").

A noun is followed by a noun which modifies it; such a modifier is either descriptive *(orang mĕlayu* "[person Malay] a Malay") or partitive-possessive *(rumah kawan saja* "[house friend my] my friend's house"). A passive verb is followed immediately by the agent *(itu dibdli orang* "[that bought person] that was bought by somebody"): although more commonly in Malay and less frequently in Indonesian a phrase with the preposition *oleh* is found *(itu dibdli oleh kawan saya* "that was bought by my friend"). Subject and predicate are in most cases invertible with a difference in emphasis; besides *dia kawan saya* "he is my friend," there is also the more emphatic *kawan saya dia.* Many common constructions of Malay resemble those of English *(e.g.,* prepositional: *di rumah saya* "at my house"; verb goal: *bdli rumah* "buy a house").

Words are simple. complex or compound. Simple words contain a single meaningful element: *nama* "name." Complex words contain at least two meaningful elements which differ as affix and root: *e.g., namakan* "to name." Compound words contain at least two meaningful elements neither of which is an affix: *rumah-makan* "(house-eat) restaurant." Longer sequences resemble one or the other type of word.

There is a fair variety of affixes among which doubling *(e.g., nama-nama* "names") is to be counted. Nouns and adjectives are inflected for number (but noncompulsorily) : *rumah* "house." *rumah-rumah* "houses"; *panas* "hot," *panas-panas* "hot" (pl.). Transitive verbs have a passive *(di-bĕli* "be bought") and active *(mĕm-bĕli* "buy") and a simplex which appears in commands *(bdli* "Buy!") and in other constructions. Various affixes appear in derivation, such as doubling *(e.g.,* with nouns "an analogue of": *jari* "finger," *jari-jari* "spoke," with verbs "diffusely, persistently": *bĕrlari* "run," *bĕrlari-lari* "run around, keep running").

Various affixes appear in derivation and very often these have ill-defined or varied meanings. There are two common suffixes: *-kan* (forms transitive verbs) and *-an (makanan* "food," *makan* "to eat"). The suffix *-i* is very rare in colloquial Malay *(lalui* "pass, traverse," *lalu* "go past") but is common in literary Malay and in very wide use in Indonesian. The number of prefixes is much larger *(e.g., bdr-, tĕr-, pĕng-, mĕng-, kd-).* Combinations of affixal elements are found that resemble the addition of a prefix and a suffix or prefix and doubling or the like without, however; showing the meaning of these as separate elements; *e.g., kĕmauan* "desire," *mau* "want," *kdkuningkuningan* "tinted yellow," *kuning* "yellow," *sĕchĕpatchĕpatnja* "as fast as possible," *chĕpat* "fast."

The combinations of elements in analyzable words are usually transparent. The chief exceptions are the active prefix (*mĕng-*) and others which behave like it. For these the shape of the combination depends on the initial of the following element as it would otherwise appear. If the initial of the base is *p, t,* k, or *s,* then a corresponding nasal appears at the seam (potong "cut," *mĕmotong; tipu* "deceive:" *mĕnipu; kirim* "send," *mĕngirim; sapu* "sweep," *mĕnyapu*), otherwise the initial appears with the nasal it determines (*e.g.,* angkat "lift," *mĕngangkat;* bawa "bring," *mĕmbawa;* chari "seek," mdnchari).

All Malay literature postdates the arrival of Islam. Its original form is believed to have been poetry, probably the *pantun.* The other poetic genre is the sja ir. In it are written long poems, religious, historical and dramatic. The latter are no longer popular. The extensive prose literature consists largely of lengthy novels (*hikajat*), most of which are reworkings of Javanese drama literature, the *wayang.* Some also have a Persian or Arabic background. "Moslem legends," stories from the Koran, are also widely read. The historical novel is represented by *Hang* Tuah, the story of a hero who travels through many lands encountering known figures from Javanese history. The best known of the works classifiable as "historical writing" is the *Sĕdjarah* Malayu (1612). A series of funny stories utilizes the mouse deer (kantjil, *pĕlanduk*) as the chief character. The flow and variety of Malay literature greatly increased as a result of independence, particularly in Indonesia, where many revolutionaries had literary aspirations.

MALAYO-POLYNESIAN LANGUAGES (also known as the AUSTRONESIAN LANGUAGES) are a family of related languages with about 110,000,000 speakers in Madagascar, southern Vietnam, the Malay peninsula, Indonesia, the Philippine Islands, Formosa, New Guinea, the Melanesian, Micronesian and Polynesian islands and New Zealand. In pre-Columbian times this was the most widespread language family, extending from the Malagasy of Madagascar to the Rapanui of the Easter Islanders. The number of Malayo-Polynesian languages is more than 300 and perhaps exceeds 500 (depending upon the way in which languages are distinguished from dialects). They constitute 10%–15% of all languages in the world. The vast majority of speakers are in the Philippines and Indonesia, the island of Java containing somewhat less than half. There are four large countries in which a Malayo-Polynesian language is the official language or one of the official languages: Malay in the Federation of Malaya, Indonesian in the Republic of Indonesia, Tagalog in the Republic of the Philippines and Malagasy in the Malagasy Republic.

The Malayo-Polynesian languages are widely, but falsely, thought to be phonetically and grammatically simple. Malay and the Polynesian Ianguages do have relatively simple phonemic systems, but their grammatical structures are not particularly simple. On the other hand a language like that of Yap shows complicated phonemic and grammatical structures.

The itfalayo-Polynesian languages were once a single language. The original undifferentiated language became diversified locally, and the hundreds of Malayo-Polynesian languages are the result. The features of the original language, called Proto-Malayo-Polynesian, can only be inferred by comparing the modern forms.

Although the classification of the members of the family has not been completed, some close relationships seem to be observable. Most of the Philippine languages appear to be closely related to each other. With these are often grouped the Chamorro language of Guam and the language of the Palau Islands. The languages of western Indonesia (*e.g.,* Malay, Achinese, Minangkabau, Batak, Sundanese, Javanese, Balinese and some of the languages of Borneo) seem closely related to each other, to the Cham languages of southern Vietnam and to Malagasy. The languages of the Carolines with the exception of Palau, Chamorro (see above) and Yapese are closely related to each other and more distantly to Ponapean. Gilbertese and Marshallese. These are likewise closely related to the Polynesian language (*q.v.*). Since the languages of Micronesia and Polynesia are closely related to some of the languages of Melanesia (*e.g.,* the Banks Islands and northern New Hebrides), and since those of the Philippines are probably related to those of western Indonesia, some scholars postulate two subgroups of Malayo-Polynesian: Eastern and Western. The languages of eastern Indonesia and of New Guinea resemble those of Melanesia, but are not clearly of either subgroup.

Not all of the languages in the vast island area demarcated above are Malayo-Polynesian. Most of the languages of New Guinea are non-Malayo-Polynesian. The Malayo-Polynesian area is limited to a large region near the isthmus connecting the northwest peninsula nith the main body of New Guinea and the northern (both of the northwest peninsula and the main body) and eastern coasts. Non-Malayo-Polynesian languages are spoken in the northern two-thirds of Halmahera, in Alor and Timor in Indonesia and in the Solomon Islands in Melanesia.

The most likely next of kin of the Malayo-Polynesian languages is the Thai family. The generally accepted hypothesis regarding the Malayo-Polynesian migration states that it came from the continent of Asia via the Malay peninsula and the neighbouring chain of islands to the Pacific. Madagascar was probably settled from Borneo in the first part of the 1st millennium A.D., not long after the Indians came to the Malay archipelago. The latter found the forerunners of the contemporary languages there, and these were no doubt already different from the forerunners of the Malayo-Polynesian languages elsewhere (except Madagascar). Thus the migration must have been well under way by then, perhaps for more than 2.000 years. The connection with the Thai family, however, is not beyond a reasonable doubt.

MALAYS, a people of southeast Asia.

It is thought that the neolithic ancestors of the Malays (Proto-Austronesians, Proto-Malays, Mongoloid Indonesians or Malaysians) descended from Yunnan province, southern China, between 2500 B.C. and 1500 B.C. down the valley of the Mekong river to the Malay peninsula and so to Indonesia and on to Madagascar and Easter Island. They had already cultivated the banana, sugar cane, millet and rice, domesticated the pig and buffalo and could count up to a thousand. They were boatbuilders and fishermen as well as hunters and agriculturists. They built houses of bamboo or wood on piles, made pottery in great variety and erected megaliths to dead chiefs. These early peoples were head-hunters. Then, about the beginning of the Christian era, came Indian immigrants who spread their cultural influence along with Buddhism, Saivism and Vishnuism, until, between the 13th and 15th centuries, Islam ousted all religions except in Bali, which remained Hindu, and the Philippines. where the Spaniards introduced the Roman Catholic faith. The modern or Deutero-Malays are the primitive Malay with foreign strains derived from intermarriage with Chinese from Chou times down to the Malay conversion to Islam, and with Indians, Siamese and Arabs. The Malay groups bore many local names until, probably in the 13th century, they got their generic name from Jambi, also called Melayu, in Sumatra.

Religion and Folklore.—Relics of animism survive in the Malays' fear of malignant spirits of the soil and jungle, in dread of banshees hostile to pregnant women and in respect for sacred places, rocks and trees, holy persons and sacred animals though, except in remote hamlets, these superstitions now count for no more than a European's dislike of walking under a ladder. The thousand years of Hindu influence left behind ceremonials for weddings and the installation of rulers, many Sanskrit terms especially at courts, even the word raja denoting an Indian rank, and a host of gods and demons for the invocations of the obsolescent shaman.

In 1292 Marco Polo found Islam established on the north coast of Sumatra by missionaries from the Coromandel coast; early in the 15th century the rulers of Malacca embraced it, and from there it was carried to Java, Borneo and other islands until -outside the Philippines and Bali—almost all peoples of Malaysia became orthodox Moslems of the school of Shafi'i.

After conversion to Islam, the Arabic script with some Persian additions and three new letters took the place of earlier alphabets based on Sanskrit. Malay translations of the Ramayana and Mahabharata gave way to the early romances of Islamic heroes, Alexander the Great, Amir Hamzah, Mohammed Hanafiah and to Moslem stories, such as the Tales of a Parrot, as well as many Moslem treatises on religion from the Persian and Arabic. Malay is now written either in Arabic or Romanized script.

Social and Political Structure.—Except in the state of Negri Sembilan in southwestern Malaya, where a matrilineal system derived from the Menangkabau (*q.v.*) prevails, the Malay reckons descent and relationships bilaterally. through both male and female lines. Separation and divorce are relatively easy and common. Husband and wife both have property rights in case of divorce or the death of a spouse. Women traditionally are active and influential in economic affairs, often carrying on trade and handling money matters. In the state of Kelantan in northeastern Malaya, one-quarter of the women earn a regular income and one-half are employed from time to time. In the Malay village or kampong, often located along coasts or streams, the rather widely dispersed houses are separated by fruit trees and vegetable gardens. The village economy revolves about rice or rubber cultivation and fishing. While men do the heavy work, women sell garden produce or cooked food and plant and harvest rice. Women also may weave or make floor mats and baskets, wash for alluvial tin or gold. tap rubber or teach in schools.

The Malay is still a handy man rather than a specialist in any trade, but he was not slow to plant rubber after the plant was introduced early in the 20th century and has adjusted himself to an industrial age.

Hinduism gave the Malay, instead of tribal chiefs, territorial rulers, who in theory took the advice of high court officials and governed through district chiefs. These rulers, as incarnations of Hindu gods, tended to wield absolute power down to the British period. Its source forgotten, a political structure of 4 great, 8 major and 16 minor chiefs, whose numbers were determined by astrological notions centring round the Hindu Olympus. Mahameru, survived to modern times.

The main class division is between raja and commoner, though within both there are degrees based on 'birth, means, profession and personal characteristics. The gap between the two main classes is bridged by a ruler's being able to marry a woman of any class though raja women lose social standing unless they marry a raja or a Sayid (*i.e.*, descendant of the prophet Mohammed). Before the British period, there were also slaves who might have. been Malay debt-bondsmen, criminals, or pagan aborigines or Africans bought by pilgrims to Mecca. As a Moslem, a Malay may marry a Christian or a Jew but not a polytheist or a pagan, unless conversion to Islam has occurred.

All classes and national groups meet on the football field. The Malays enjoy all forms of sport within their means—football, swimming, boat racing, physical drill. The capital invested under British protection in tin and rubber provided revenue for an educational system extolled before World War I as unrivalled in Asia outside Japan, and for a medical service that abolished cholera, yaws. beriberi and smallpox and confined malaria to remote rural areas. Better health and changed social and political conditions have stopped the notorious amok or homicidal mania; suicide among Malays is almost unknown and serious crime very rare. Far from conservative, the Malay has welcomed innovation in custom, law, medicine, politics and dress, whether introduced by Hindu, Moslem or the European.

Costume and Weapons.—Except for a bark loincloth and a blowpipe for killing game, the early Malay had neither clothes nor weapons. The men's coat, bearing a Persian name, and the skirt (sarong) worn by both sexes came from India. Malay trousers may have been copied from the Chinese but have an Arabic name, as also has the velvet cap now worn by all males; the rice planter's sun hat was brought from Yunnan and the elaborately tied headkerchief (now seen only on ceremonial occasions) probably was of Hindu origin. The usual jacket for Malay women in the peninsula is a coat of cotton or silk, knee-length and pinned with three brooches, which was introduced by the Portuguese in the 16th century. Women wear this jacket, or a more modern short jacket, with the sarong down to their ankles. For formal dress a man nears trousers covered from waist to knee by the sarong. The most prized sarongs, heavily interwoven with gold thread, come from Batu Bara and Palembang in Sumatra, though silk sarongs of mottled patterns and interwoven with gold thread are made in Trengganu and sarongs of modern type in Kelantan. Most sarongs are imported, the silk ones from Sumatra, the cotton ones from Pulicat, India, for men and from Java for women.

The two-edged Malay dagger or kris came from Java, though its prototype belongs to the Bronze-Age culture of Dongson in Annam. It is never represented on early Indo-Javanese sculpture. By the end of the 13th century it had changed from a one-piece weapon to a dagger nith a separate hilt of gold, ivory or wood, carved to represent Vishnu's bird the Garuda, or a Hindu demon Raksasa or rarely Hanuman the monkey god. The blade became wavy to represent serpents or Nagas. Bronze knives of 1000 B C. from Anyang in China and bronze knives from Ordos in Mongolia together with the kidney-shaped guard of the Scythian sword are identical with the shape and guard of the small Malay dagger known as the "pepper crusher," The needs of piracy led to the Bugis (Celebes) sundang, or short swords with blades straight or wavy and cockatoo hilts There is a great variety of wood knives. A finger knife for cutting rice stalk by stalk has a stone prototype unearthed in Tonkin

MALBONE, EDWARD GREENE (1777–1807), U.S. artist generally regarded as the greatest of American miniaturists, was born at Newport, R.I., in Aug. 1777. Largely sell-taught, he began his professional career in Providence, R.I., at seventeen and quickly developed a remarkably fine technique. A man of agreeable manners, diligent and blessed with what Washington Allston called "the happy talent . . . of elevating the character without impairing the likeness," Malbone was during his short career the most sought-after miniaturist of his day in Providence, Newport, Boston. New York city. Philadelphia and Savannah. His career was cut short by tuberculosis, of which he died at Savannah, Ga.. on May 7, 1807.

Many of his miniatures have survived and are highly prized for their delicacy of drawing, richness of colour and convincing characterization. He had no formal pupils, but freely advised other artists, notably Charles Fraser, William Dunlap and John Wesley Jarvis.

See Ruel P. Tolman, *Life of Edward Greene Malbone* (1957).

(D. H. W.)

MALCOLM, the name of four Scottish kings.

MALCOLM I. king 943–954, received Strathclyde from Edmund, king of the English, in terms of a treaty of alliance in 945.

MALCOLM II, grandson of Malcolm I, was king from 1005 to 1034 and frequently invaded northern England. By the battle of Carham (*c.* 1016 or 1018?) he finally secured Lothian for Scotland.

MALCOLM III (Canmore), great-grandson of Malcolm II, became king after the defeat of Macbeth at Lumphanan and ruled from 1058 to 1093. He had spent several years of his youth in exile at the court of Edward the Confessor and after the Norman Conquest gave asylum in Scotland to Edgar the Aetheling and his sisters: one of whom, Margaret (*q.v.*), he married in 1070. He did homage to William the Conqueror at Abernethy in 1072, giving his eldest son as a hostage and receiving lands in England. His frequent raids into England caused the building of castles at Newcastle-upon-Tyne and Carlisle.

A visit to William Rufus at Gloucester in 1092 only worsened their relations, so that Malcolm the next year led his last invasion, reaching Alnwick where he was killed with his son Edward. In his reign English influence increased and the southern parts of his kingdom grew in importance, the first mention being found of Dunfermline and Edinburgh as royal residences. On his death a Celtic reaction carried his brother, Donald Bane, to the throne. By his first wife. Ingibiorg, he had a son, afterward Duncan II; by his second, St. Margaret, six sons (of whom Edgar, Alexander and David in turn succeeded to the throne) and two daughters, Matilda (married Henry I of England) and Mary (married Count Eustace of Boulogne).

MALCOLM IV (the Maiden), born 1142, eldest son of Henry, earl of Huntingdon, succeeded his grandfather, David I, in 11j3. His treaty with Henry II of England in 1157 fixed the boundary of the kingdoms at the Tweed and Solway. He was knighted by Henry during the Toulouse campaign of 1159. He died at Jedburgh on Dec. 9, 116j.

(New York and London, 1947); P. Hume Brown, *History of Scotland*, 3 vol., vol. i. (New York and London, 1911). (E. W. M. B.-M.)

MALCOLM, JAMES PELLER (1767–1815), engraver and antiquary, was born in Philadelphia, Pa., in Aug. 1767, the son of a merchant. He first studied at a Quaker school in Philadelphia and later in Pottstown. Pa., his family having moved there to avoid the dangers of the Revolutionary War.

After the war he returned to Philadelphia to study art. He later attended schools of the Roval academv. London. He abandoned his original intention of becoming a painter, concentrating instead on engraving. He compiled and illustrated a number of books on various historical and topographical subjects and contributed illustrations to magazines in England, where he spent the last half of his life.

His works include *Londinium Redivivum, or an Antient History and Modern Description of London,* a parochial history published in four volumes, the work being completed in 1807; *Excursions in the Counties of Kent, Gloucester, Hereford, Monmouth, and Somersetshire . . . Illustrated by Descriptive Sketches* (London, 1807); *Anecdotes of the Manners and Customs of London, From the Roman Invasoin to the Year 1700, Illustrated by Eighteen Engravings* (London, 1811); and *An Historical Sketclz of the Art of Caricaturing, With Graphic Illustrations* (London, 1813).

Malcolm died in London on April 5, 181j.

His autobiography was published in the *Gentleman's Magazine,* May 181j.

MALCOLM, SIR JOHN (1769–1833), Anglo-Indian soldier, diplomatist, administrator and author, was born in Dumfriesshire, Scot., on May 2, 1769, the son of a farmer. He received a cadetship in the Indian army at the age of 12, and in April 1783 he landed at Madras, shortly afterward joining his regiment at Vellore.

He held various important appointments in India from 1792. In that year, having for some time studied Persian, he was appointed to the staff of Lord Cornwallis as Persian interpreter. Two years later, however, he was compelled by ill health to leave for England.

On his return to India in 1796 he became military secretary to Sir Alured Clarke, commander in chief at Madras, and afterward to his successor Lord Harris. In 1798 he was appointed by Lord Wellesley assistant to the resident at Hyderabad. In that capacity he distinguished himself by the manner in which he gave effect to the difficult measure of disbanding the French corps in the pay of the nizam.

In 1799 began his lifelong friendship with Col. Arthur Wellesley. In the course of the same year he acted as first secretary to the commission appointed to settle the Mysore government, and before its close he was appointed by Lord Wellesley to proceed as envoy to the court of Persia for the purpose of counteracting the policy of the French by inducing that country to form a British alliance. Arriving at Teheran late in 1800. he was successful in negotiating favourable treaties, both political and commercial, and returned to Bombay by way of Baghdad in May 1801.

He then for some time held the interim post of private secretary to Lord Wellesley, and in 1803 was appointed to the Mysore residency. At the close of the Mahratta War in 1804, and again in 1805, he negotiated important treaties with Sindhia and Holkar, and in 1806, besides seeing the arrangements arising out of these alliances carried out, he directed the difficult work of reducing the immense body of irregular native troops.

In 1808 Malcolm was again sent on a mission to Persia. After his return to England he wrote his *History of Persia* (2 vol., 1815). On his return to India in 1817 he was appointed by Lord Moira his political agent in the Deccan; as brigadier general under Sir T. Hislop he took'a distinguished part in the victory of Mehidpur (Dec. 21, 1817), as also in the subsequent work of settling the country.

In 1821 he returned once more to England, where he remained until 1827, when he was appointed governor of Bombay. His influence in this office was directed to the promotion of various economical reforms and useful administrative measures. Leaving India for the last time in 1830, shortly after his arrival in England he entered parliament as member for Launceston and opposed the Reform bill. He died on May 30, 1833.

Besides the work mentioned above, Sir John Malcolm published *Sketch of the Political History of India since . . . 1784* (in 1811 and 1826); *Sketch of the Sikhs* (1812); *Observations on the Disturbances in the Madras Army in 1809* (1812); *Persia, a Poem*, anonymous (1814); *A Memoir of Central India* (2 vol., 1823); and *Sketches of Persia*, anonymous (1827). A posthumous work, *Life of Robert, Lord Clive,* appeared in 1836. See *Life and Correspondence of Sir John Malcolm,* by J. W. Kaye (2 vol., 1856).

MALDA, a district, formerly oi British India, in the Rajshahi division of Bengal. In the partition of India in 1947, two-fifths of the area and about one-third of the population became part of East Pakistan. The remaining three-fifths of area (1,429 sq.mi.) and two-thirds of population (1951, 937,580) went to the state of West Bengal in India. The former British district was divided into two almost equal parts by the Mahananda river, flowing from north to south. The tract between the Mahananda and the main stream of the Ganges is an alluvial plain of sandy soil and great fertility. The eastern half of the former British district is a slightly elevated region. called the Barind. The soil here is a hard red clay; and the whole is sparsely populated. Agricultural prosperity centres on the Mahananda, where mango orchards extend continuously along both banks; the mangoes of Malda have a wide reputation and demand. The principal industry is the production of silk. The weaving of piece goods has declined, but the rearing of silkworms and the export of ram silk and silk thread are carried on upon a large scale.

Malda supplied three capitals to the early Mohammedan kings of Bengal. The sites of Gaur and Pandua exhibit the most interesting remains to be found in the lower valley of the Ganges; the site of Tanda, the capital from about 1564 to 1595, was washed away by floods in 1826 and no trace of it remains. (*See* GAUR.)

Malda was connected with the East India company for many years. As early as 1676 there was a factory there, and in 1770 the city of English Bazar was fixed upon for a commercial residency.

MALDEN, a city in Middlesex county, Mass., U.S., on the Malden river, a branch of the Mystic river, 5 mi. N. of Boston.

It is almost surrounded by Melrose, Revere, Everett and Medford (*qq.v.*), with the Middlesex Fells (a state reservation) forming its northwest boundary.

When first settled. mainly by Puritans, on the north side of the Mystic river, Malden was part of Charlestown (*q.v.*) and was known as the Mystic Side. It was incorporared as the town of Mauldon (for Malden, Eng., the home of some of the early settlers) in 1649 and was chartered as a city in 1881. Its bicameral council was abolished in 1958 in favour of a single chamber council. Of historic interest is Bell Rock Memorial park, named ior the bell which in colonial times summoned the people to worship or sounded alarms in times of danger, with a Civil War Soldiers and Sailors monument at its summit.

Malden is a residential community with some industrial development and is also an important suburban Boston shopping centre. Manufactures include rubber footwear, electronic and radio parts, aircraft engine parts, metal cans, paints, drugs, knitted clothing and foods. Pop. (1960) 57,676. (L. G. H.)

MALDEN AND COOMBE, a municipal borough in the Kingston upon Thames parliamentary division of Surrey. Eng., is about 10 mi. S.W. of London: it lies immediately south of Richmond park. Pop. (1951) 45.566. Area 4.9 sq.mi. Walter de Merton, lord chancellor of England, founded a college there in 1264 for the maintenance of 20 scholars at Oxford, where Merton college was founded about two years later. From 1894 to 1936. when they were incorporated as a borough, Malden and Coombe were governed by an urban district council. The district is mainly residential. but there are a few small factories.

MALDIVE ISLANDS, an archipelago of coral islets in the Indian ocean. forming a chain between 7° 6' N. and 0° 42' S. It lies 400 mi. S.W. of Ceylon. and some 300 of the numerous islands in the 17 Maldivian atolls are inhabited. In the extreme south are the isolated atolls of Addu and Fua-Mulaku, separated from Suvadiva by the Equatorial channel. which is itself separated from the main chain of atolls by One-and-a-half-degree channel. Thence the chain continues northward to the Eight-degree channel. beyond which lies Minicoy, 71 mi. from the nearest point of the Maldives and 110 mi. from that of the Laccadives to the north. The main part, north of One-and-a-half-degree channel. consists of a series of banks either surrounded or studded all over with reefs.

Aiter the Portuguese. from about 1518 onward, had attempted many times to establish themselves on the islands by iorce. and after the Maldivians had endured frequent raids by the Mopla pirates of the Malabar coast. they began to send tokens of homage and claims of protection (the first recorded being in 1645) to the rulers of Ceylon. Formerly a dependency of Ceylon. the Maldive Islands are now a sultanate, and a protected state of the United Kingdom. In 1956 the population of the Maldives was 81,950. The people have been classed in four ethnological divisions. (1) Those of the atolls north of the Kardiva channel. There the people are more vigorous than their less warlike southern neighbours. They annually visited the coasts of India or Ceylon. and often married Indian wives, thus acquiring distinct racial characters of an approximately Dravidian type. (2) Those of the central division, under the direct rule of the sultan, and more exposed to Arab influences. They formerly traded with Arabia and Malaysia. and many Arabs settled among them, so that they betray a strong strain of Semitic blood in their features. (3 and 4) The natives of the southern clusters, who have had little communication with the Central Mali. people, and probably preserve more of the primitive type, approximating in appearance to the Sinhalese villagers of Ceylon.

The language is a dialect of Sinhalese: but indicating a separation of ancient date, and many of the Maldivians read Arabic with considerable fluency. They are an intelligent and industrious people. More than half of the men earn their livelihood as fishermen. Coir making is the industry second in importance. The finest quality of coir is found in the Tiladummati atoll. A large number of the people arc also engaged in the manufacture of lace. The chief exports of the islands, besides coir, are coconuts, copra, millet and fruit.

Minicoy atoll, belonging to India, with the numerous wrecks on its reefs. and its lighthouse, is a familiar sight to seafarers in these waters. The atoll is growing outward on every side, and at one place it rises 19 ft. above sea level. The population. which numbers 3.804 (1931), is divided into five castes, of which the three highest are pure Maldivians, the lower two the same as in the Laccadives, All are centred in a village opposite Mou Rambu Point. on the west or lagoon side; but most of the men are employed with the Lascar crews on large vessels plying in the eastern seas.

See F. W. Hockley, *A Short Account of the People, History and Customs of the Maldive Archipelago* (1935).

MALDON, a market town, municipal borough and port, in the Maldon parliamentary division of Essex, Eng., on the south side of the Blackwater, 10 mi. E. of Chelmsford by road. Pop. (1951) 9,726. Area 7.5 sq.mi. Finds of prehistoric objects indicate early settlement, and an earthwork, of which traces exist, may be Saxon or Danish. The Anglo-Saxon Chronicle relates that Edward the Elder established a "burh" there about 921. Maldon was more remarkable for its fortress than for its commercial importance. In 991 it was the site of a battle fought by Byrhtnoth, earldorman of Essex, against Danish marauders who were victorious. The incident is commemorated in an Old English poem, *The Battle of Maldon.* It remained a royal town up to the reign of Henry I and thus is entered as being on *terra regis* in Domesday Book. Henry II granted the burgesses their first charter in 1171. Maldon was incorporated by Philip and Mary in 1554. The church of All Saints dates from 1056, the Moot hall, formerly D'Arcy's tower, was built in the reign of Henry VI, and the Plume library, founded by Thomas Plume, archdeacon of Rochester, before 1704. Maldon has many summer visitors and there are foundries, timber and flour mills, an oyster fishery and some shipping.

Beeleigh abbey, 1 mi. W., a Premonstratensian house founded about 1180, is a residence in which the beautiful Early English chapter house. the warming house and dormitory are incorporated.

MALEBRANCHE, NICOLAS (1638–1715), French philosopher of the Cartesian school, the youngest child of Nicolas Malebranche, secretary to Louis XIII, and Catherine de Lauzon. sister of a viceroy of Canada. was born at Paris on Aug. 6, 1638. Deformed and constitutionally feeble, he studied theology at the Sorbonne, and in 1660 he joined the congregation of the Oratory. In 1664 he read Descartes's *Traité de l'homme (De homine)*. After ten years' study of the works of Descartes he produced the famous *De la recherche de la vérité où l'on traite de la nature de l'esprit de l'homme et de l'usage qu'il en doit faire pour éviter l'erreur dans la science* (1674; Eng. trans., 1694–95), followed at intervals by other works, both speculative and controversial. Like most of the great metaphysicians of the 17th century, Malebranche interested himself also in questions of mathematics and natural philosophy, and in 1699 was admitted an honorary member of the Academy of Sciences. During his later years his society was much courted, and he received many visits from foreigners of distinction. He died on Oct. 13, 1715; his end was said to have been hastened by a metaphysical argument in an interview with Bishop Berkeley. For Malebranchc's place in the history of philosophy, *see* CARTESIANS. His other works include *Conversations métaphysiques et chrétiennes* (1677; Eng. trans., 1695); *Traite' de la nature et de la grâce* (Amsterdam, 1680; Eng. trans., 1695); *Méditations chrétiennes et métaphysiques* (1683); *Traité de morale* (Rotterdam, 1684; Eng. trans. by Sir J. Shipton 1699); several polemical works against Arnauld from 1684 to 1688; *Entretiens sur la métaphysique et sur la religion* (1688); *Traite' de l'amour de Dieu* (1697); *Entretiens d'un philosophe chrétien et d'un philosophe chinois sur l'existence et la nature de Dieu* (1708); *Réflexions sur la prémotion physique* (1715).

BIBLIOGRAPHY.—There are collected editions of Malebranche's works by Jules Simon (Paris, 1842; 1853–59; and 1871) and by D. Roustan and P. Schrecker (Paris, 1938 ff.). MALENKOV, GEORGI MAXIMILIANOVICH (1902–), Soviet statesman, was born at Orenburg (Chkalov), Russia, on Jan. 8, 1902. He joined the Communist party in April 1920. After the civil war, he studied at Moscow Higher Technical college and was secretary of the Communist students' organization. In 1925 he was appointed personal secretary to Joseph Stalin. In 1930 he was organizing secretary of the Moscow section of the party. In March 1934, before the purges of 1936–38, Stalin appointed him member of the Orgburo and head of the personnel department. The 18th congress of March 1939 elected him member of the central committee of the All-Union Communist party which, in turn, appointed him one of the five secretaries. On Feb. 21, 1941, he became a substitute member of the Politburo and on June 30. 1941, a member of the State Defense committee. For organizing aircraft production during World War II he was awarded in 1943 the title of Hero of Socialist Labour and the Order of Lenin. On March 19, 1946, he was appointed one of ten full members of the Politburo and one of the deputy chairmen of the council of ministers. Besides Stalin, only Malenkov was simultaneously a member of the government and of the three key party bodies: Politburo, Orgburo and secretariat. On Sept. 22–23, 1947, he and Andrei A. Zhdanov were Soviet delegates at the conference at Wilcza Gora, Poland, at which the Cominform was created. At the 19th congress of the Communist Party of the Soviet Union (as it was now called). Malenkov read the main report (Oct. 5, 1952) and was elected member of a commission of 11 to revise the party program (Oct. 13) as well as of the new central committee of 125 (Oct. 14). On Oct. 16 the last-named elected him to the new key party bodies a 25-member presidium and a 10-member secretariat. On March 6. 1953, the day after Stalin's death. a reorganization of the Soviet party and state was announced: the party presidium was reduced to ten. with Malenkov heading the list; the secretariat. to five. with Malenkov as first secretary (eight days later he resigned from that post). He became chairman of the council of ministers and the number of deputy chairmen was reduced to five. with Lavrenti P. Beria in the first place. The changes mere approved by the supreme soviet of the C.S.S.R. on March 15. Beria, who had proposed Malenkov's appointment as chairman of the council of ministers, was later denounced by Malenkov for "criminal actions" and executed in 1953. On Feb. 8, 1955, Malenkov resigned, assuming responsibility for failure of the agriculture program and calling for further development of heavy industry. N S. Khrushchev, who had been appointed first secretary of the Communist party, nominated Malenkov's successor, Marshal Nikolai Bulganin, who, under various titles, had been in charge of the armed forces for more than ten years.

MALESHERBES, CHRETIEN GUILLAUME DE LAMOIGNON DE (1721–1794), French law reformer and statesman, was born at Paris on Dec. 6. After completing his historical and legal studies, he became *conseiller* of the parlement of Paris at the age of 24 and premier president of the *cour des aides* in 1750. In the same year, his father, Guillaume de Lamoignon, who had just become chancellor, placed him at the head of the French press-censorship as *directeur de la libvaivie.* Malesherbes held this appointment till 1768 and in him the philosophers found an understanding critic and unofficial protector. His enlightened views and his friendly relations with the foremost French writers of the time, including Voltaire, Rousseau and Diderot, made it possible for the *Encyclopédie* to continue to appear, and even for works which had been printed abroad to evade the censorship to circulate inside France.

Malesherbes was a prominent member of the opposition to the abolition of the parlements in 1771, and was exiled to his estates at St. Lucie. After the restoration of the parlements under Louis XVI, Malesherbes resumed his presidency of the *cour des aides,* but resigned on becoming secretary of state for the *maison du roi* on July 21, 1775. In this ministerial position. which carried with it responsibility for the police. ecclesiastical affairs a considerable part of the provincial government of France and the capital, Malesherbes gave disinterested, but hardly energetic, support to the reforming activities of Turgot. He devoted himself to the cause of prison reform and did much to control the abuses of the system of *lettres de cachet* (*q.v.*). On Turgot's fall from power. Malesherbes resigned office on May 12, 1776, and, for the rest of his life took no prominent part in politics, though he held office again in 1787–88. In retirement he travelled in Switzerland, Germany and Holland. cultivated his literary and botanical interests, and campaigned for the recognition of the civil status of Protestants in France. His intellectual distinction brought him membership of the Academy of Sciences (1750), the Academy of Inscriptions (1759) and of the Académie Française (1775).

Malesherbes re-emerged from his retirement in Dec. 1792 in order to offer his services to Louis XVI. on trial before the Convention. He assisted Tronchet and de Sèze in the conduct of the defense and broke the news of the verdict to the king. He was arrested in Dec. 1793, condemned to death by the Revolutionary Tribunal for counter-revolutionary activities and guillotined, with his daughter. son-in-law and grandchildren, on April 22. 1794.

Alison, *Lamoignon de Malesherbes, Defender and Reformer of the French Monarchy* (New Haven, Conn., 1938).

(A. Gn.)

MALHERBE, FRANÇOIS DE (1555–1628), French poet, critic and translator, was born at Caen, the eldest son of another François de Malherbe, *conseiller du roi* in the magistracy of Caen. He himself was educated at Caen, at Paris, at Heidelberg and at Basle. At the age of 21 he entered the household of Henri d'Angoulême, grand prior of France, the natural son of Henry II. He served this prince as secretary in Provence, and married there in 1581 Madelaine de Coriolis. After his patron's death he lived partly in Provence and partly in Normandy for many years, but very little is known of his life during this period. He was presented by his countryman. the Cardinal Du Perron, to Henry IV. and was at last summoned to court and endowed after one fashion or another. It is said that the pension promised him was not paid till the next reign. His father died in 1606, and he came into his inheritance. From this time forward he lived at court, corresponding affectionately with his wife, but seeing her only twice in some 20 years. His old age was saddened by a great misfortune. His son, Marc Antoine, a young man of promise. fell in a duel in 1626. His father used his utmost influence to have the guilty parties brought to justice, but he died before the suit was decided (it is said in consequence of disease caught at the camp of La Rochelle, whither he had gone to petition the king). Malherbe's first poem *Les Larmes de Saint Pierre* appeared in 1587. His poetical work is scanty in amount. The beautiful *Consolation à Duperier* (*c.* 1599), in which occurs the famous line—

"Et rose, elle a vécu ce que vivent les roses—"

the odes to Marie de' Medici and to Louis XIII, and a few other pieces comprise all that is really worth remembering of him. His prose work is much more abundant, not less remarkable for care as to style and expression, and of greater positive value. It consists of some translations of Livy and Seneca, and of a very large number of interesting and admirably written letters, many of which are addressed to Peiresc, the man of science of whom Gassendi has left a delightful Latin *Life.* It contains also the *Commentaire sur Desportes,* in which Malherbe's minute and carping style of verbal criticism is displayed on the great scale.

The personal character of Malherbe was far from amiable, but he exercised, or at least indicated the exercise of, a great and enduring effect upon French literature, though by no means a wholly beneficial one. The lines of Boileau beginning *Enfin Malherbe vint* are rendered only partially applicable by the extraordinary ignorance of older French poetry which distinguished that peremptory critic. But the good as well as bad side of Malherbe's theory and practice is excellently described by his contemporary and superior Regnier, who was animated against him, not merely by reason of his own devotion to Ronsard but because of Malherbe's discourtesy toward Regnier's uncle P. Desportes, whom the Norman poet had at first distinctly copied. These are the lines:—

Cependant leur savoir ne s'étend nullement
Qu'à régratter un mot douteux au jugement,
Prendre garde qu'un *qui* ne heurte une diphthongue,
Epier si des vers la rime est brève ou longue,
Ou bien si la voyelle à l'autre s'unissant
Ne rend point à l'oreille un vers trop languissant.

. . . .

C'est proser de la rime et rimer de la prose.

This is perfectly true, and from the time of Malherbe dates that great and deplorable falling off of French poetry in its more poetic qualities, which was not made good till 1830. Nevertheless the critical and restraining tendency of Rialherbe was not ill in place after the luxuriant importation and innovation of the *Pléiade;* and if he had confined himself to preaching greater technical perfection, and especially greater simplicity and purity in vocabulary and versification. instead of superciliously striking his pen through the great works of his predecessors. he would have deserved wholly well. As it was, his reforms helped to elaborate the kind of verse necessary for the classical tragedy, and that is the most that can be said for him.

Malherbe's works were published two years after his death. He left behind him an unenviable reputation for acerbity in his relations with his contemporaries. but his influence as a critic was great and far reaching. He represents the reaction against the innovations of the Pléiade and the beginning of the strict French classical school.

The chief authorities for the biography of Malherbe are the Vie *de Malherbe* by his friend and pupil Racan, and the long *Historiette* which Tallemant des Réaux has devoted to him. The standard edition is that of Ludovic Lalanne, 5 vol. (1862–69).

MALIBRAN, MARIE FÉLICITÉ (1808–1836), operatic singer. daughter of Manuel Garcia (q v), was born in Paris on March 24, 1808. Her father was then a member of the company of the Théâtre des Italiens. and she accompanied him to Italy and London. She possessed a soprano voice of unusual beauty and phenomenal compass, which was carefully cultivated by her father.

Mme. Malibran was only seventeen when she was suddenly asked to take Pasta's place in *The Barber of Seville* at Covent Garden. She was engaged for the remaining six weeks of the season. and then appeared in New York in *Othello, The Barber of Seville, Don Juan, Romeo and Juliet, Tancred.* Her gifts as an actress were on a par with her magnificent voice: and her gaiety made her irresistible in light opera. although her greatest triumphs were obtained in tragic parts. She married a French banker of New York, named Malibran, who was much older than herself. The marriage was an unhappy one, and Mme. Malibran returned alone to Europe in 1828, when she began the series of representations at the Théâtre des Italiens, which excited an enthusiasm in Paris only exceeded by the reception she received in the principal towns of Italy. She was formally divorced from Malibran in 1835, and married the Belgian violinist, Charles de Beriot. She died on Sept. 23, 1836.

MALINES (Flemish, MECHELEN), an ancient and important city, and the seat since 1559 of the only Belgian archbishopric. Pop. (19jj est.) 63,293. It is on the Dyle in the province of Antwerp, about half-way between Antwerp and Brussels. The archbishop is the primate of the country. The archbishop's palace is in a picturesque situation, and dates from the creation of the see. The fine cathedral dedicated to St. Rombaut was begun in the 12th and finished early in the 14th century, and modified in the 15th after a fire. The massive tower of over 300 ft., which is described as unfinished because the original intention was to carry it to joo ft., is its most striking external feature. The cathedral contains a fine altar-piece by Van Dyck. The old palace of Margaret of Austria, regent for Charles V, has been preserved and is now a court of justice. In the church of Our Lady (16th century) is Rubens' masterpiece "the Miraculous Draught of Fishes," and in that of St. John is a fine triptych by the same master. Malines, although no longer famous for its lace, carries on a large trade in linen, needles, furniture and oil; it is a great junction for the lines Ghent-Liége and Antwerp-Brussels and has large state railway-works.

The lordship of Malines was conferred as a separate fief by Pippin the Short on his kinsman Count Adon in 754. In the 9th century Charles the Bald bestowed the fief on the bishop of Liége, and it passed to Philip the Bold, of Burgundy, in 1384. During the religious troubles of the 16th century Malines suffered greatly, and in 1572 it was sacked by Alva's troops during three days. In the wars of the 17th and 18th centuries it was besieged many times and captured by the French, Dutch and English on several occasions. The French finally removed the fortifications in 1804, since which year it has been an open town.

Malines was bombarded three times during World War I and seriously damaged. The law courts, restored shortly before the war, the school of music, and the picturesque houses round the Yzeren Leeh were ruined, and the south side of the cathedral of St. Rombaut and the chimes badly damaged. The Cloth Hall, also restored before the war, was, afterwards, used as the Town hall. Conferences were held there, 1921–25, between Cardinal Mercier, Archbishop of Malines, and some dignitaries of the Church of England, to further a reunion of the churches.

In World War II, the British first met the Germans near Malines. Its fall led to the capture of Antwerp and Brussels.

MALINKE, the name of a tribe, formerly commonly called Negroid, of west Sudan. Malinké is a general term covering many individual divisions of speech and tribe. The languages spoken are divided into (1) Malinké proper (Eastern Malinké), used throughout the length of the Upper Niger above Bamako and between Niger and Bafing; (2) Xasonké, usually called Northern Malinké in the Kayes region; (3) Western Malinké on the Gambia and (4) Southern Malinké on the edge of the dense forests. These languages belong to the Nigero-Senegalese group of tongues, as does the lingua franca of the region Kãgbe or "white language."

MALINOWSKI, BRONISLAW KASPER (1884–1942), Polish-born British anthropologist, one of the leading figures in the development of modern social anthropology, was born on April 7, 1884, in Cracow. Attracted to anthropology by Frazer's *The Golden Bough,* he studied at the University of Cracow (Ph.D., 1908), Leipzig university and the London School of Economics, where he successively became lecturer. reader and first professor (1927–42) of social anthropology. His analyses of Melanesian society, based upon four years of field work in the Trobriand Islands and northwest Melanesia (1914–18), set a standard of depth and comprehensiveness that revolutionized field research and gained him a world-wide reputation. His functional approach to the study of societies, which he saw as integrated systems of institutions subserving basic and derived needs, drew into the discussion of anthropological theory specialists in a wide range of human studies from law to psychology, and did much to obtain a secure position for anthropology in British university curriculums. He also was a pioneer in applied anthropology, and many of the British advances in colonial administration stemmed from the inspiration he gave scholars and administrators from Africa and Asia. His talent attracted to his seminars almost all the leading British specialists of the first half of the 20th century.

From 1939 until his death at New Haven, Conn., on May 16. 1942, Malinowski was visiting professor of anthropology at Yale university.

His studies include *The Family Among the Australian Aborigines* (1913); *Argonauts of the Western Pacific* (1922); *Sex and Repression in Savage Society* (1927); *Coral Gardens and Their Magic,* 2 vol. (1935); *The Foundations of Faith and Morals* (1936); and, posthumously, *A Scientific Theory of Culture* (1944); *The Dynamics of Culture Change* (1945); *Magic, Science and Religion* (1948).

See M. Gluckman, *Analysis of the Sociological Theories of B. Malinowski* (1949); and P. Murdock, "Bronislaw Malinowski," *Amer. Anthrop.,* vol. xlv (1942), with bibliography. (H. N. C. S.)

MALIPIERO, G. FRANCESCO (1882–). Italian composer. was born in Venice on March 18. 1882. He studied under Marco Enrico Bossi in Venice, and in 1902 followed him to Bologna. Later he went to Paris, but his strong individuality prevented him from attaching himself to any school. In 1921 he was appointed professor of composition at the Royal Conservatory of Parma.

Malipiero, one of the most advanced of Italian composers, aimed at the perfect fusion of music and drama, and his experiments in this direction aroused great interest and much criticism. In *Pantea,* a symphonic drama for a dancer with invisible chorus and orchestra, the dancer's movements represent, it is claimed, the "moods of the soul." *Sette Canzoni,* perhaps his best achievement, was included with the two dramas *La morte delle maschere* and *Orfeo* in a trilogy under the title *L'Orfeide.* It is divided into episodes, each with a *canzone* as its central feature and mimic action for the setting. But this *canzone* is not a song created for stage requirements but one which has a natural place in scenes of real life. Other dramatic works are: *Ellen e Fuldano, San Francesco d'Assisi, Sogno d'un tramonto d'autunno, Canossa* and *La mascherata delle principesse.* Symphonies written by him include *Impressione dal vero* (2 sets, 1911, 1914), *Ditirambo tragico* (1917), *Armenie* (1917), *Per una favola cavalleresca* (1921) and *Oriente immaginario.*

MAL-LARA, JUAN DE (?1524–1571), Spanish humanist remembered for his *Filosofia Vulgar* (1568), a commentary on Spanish proverbs, was born at Seville, studied at Salamanca (1538) and at Barcelona under the Valencian rhetorician Francisco de Escobar, returning to Salamanca in 1548. He founded a famous grammar school at Seville, where he died in 1571. His *Filosofia Vulgar* is based on the *Adagia* of Erasmus, whose ideas influenced Mal-Lara, and whose text he follows, avoiding, however, all contentious problems. It shows keen observation, apt reporting of anecdote and picturesque detail, wide learning and enlightened criticism of manners and customs and is valuable both as an authoritative work on proverbs and as an encyclopaedia of folklore. He also wrote many plays, now lost, of which three, including the *Comedia Locusta,* are praised by name by contemporary writers.

See F. Sánchez Escribano, *J. de Mal-Lara: su vida y sus obras* (1941).
(I. M. G.-LL.)

MALLARME, STÉPHANE (1842–1898), French poet and theorist, was born at Paris, on March 18, 1842. His life was simple and without event. His small income as professor of English in a French college was sufficient for his needs, and, with his wife and daughter, he divided the year between a fourth-floor flat in Paris and a cottage on the banks of the Seine. His Tuesday evening receptions, which did so much to form the thought of the more interesting of the younger French men of letters, were almost as important a part of his career as the few carefully elaborated books which he produced at long intervals. *L'Après-midi d'un faune* (1876) and other fragments of his verse and prose had been known to a few people long before the publication of the *Poésies complètes* of 1887, in a facsimile of his clear and elegant handwriting, and of the *Pages* of 1891 and the *Vers et prose* of 1893. His remarkable translation of poems of Poe appeared in 1888, "The Raven" having been published as early as 1875, with illustrations by Manet. *Divagations,* his own final edition of his prose, was published in 1897, and a more or less complete edition of the *Poésies,* posthumously, in 1899. He died at Valvins, Fontainebleau, on Sept. 9, 1898. All his life Mallarmé was in search of a new aesthetic, and his discoveries by the way were often admirable. But he was too critical ever to create freely, and too limited ever to create abundantly. His great achievement remains unfinished, and all that he left towards it is not of equal value. There are a few poems and a few pieces of imaginative prose which have the haunting quality of Gustave Moreau's pictures, with the same jewelled magnificence, mysterious and yet definite. His later work became more and more obscure, as he seemed to himself to have abolished limit after limit which holds back speech from the expression of the absolute. Finally, he abandoned punctuation in verse, and invented a new punctuation, along with a new construction, for prose. Patience in the study of so difficult an author has its reward. No one in our time has vindicated with more pride the self-sufficiency of the artist in his struggle with the material world. To those who knew him only by his writings his conversation was startling in its clearness; it was always, like all his work, at the service of a few dignified and misunderstood ideas. (A. SY.)

MALLEABLE CAST IRON: *see* CAST-IRON.

MALLECO, an inland province of southern Chile, lying between the provinces of Bio-Bio and Cautin. Area 5,512 sq.mi.; pop. (1952) 159,419. It is in the rainy, forested region of southern Chile, inhabited to a considerable extent by Araucanian Indians. Gold placer mining has attracted some attention, but the output is small. Principal industries are cattle and wheat raising and timber cutting. The state central railway crosses the province, and the capital (Angol) is served by a branch line.

MALLET or MALLOCH, **DAVID** (?1705–1765), Scottish poet and dramatist, the son of a farmer, was born in Perthshire, probably in 1705. He went to school in Edinburgh, and in 1720, to Edinburgh university, where he made the friendship of James Thomson, author of *The Seasons.* Short poems by Mallet appeared in the *Edinburgh Miscellany,* and in Allan Ramsay's *Tea Table Miscellany,* in which his ballad "William and Margaret" was published in 1724. In this year he changed his name from Malloch to Mallet. He travelled for several years as private tutor to the duke of Montrose's sons: and in 1742 through Pope's influence was appointed secretary to the prince of Wales. For his services as a pamphleteer for the Tory party. Lord Bute gave him a lucrative sinecure in 1760. He died on April 21, 1765. In 1740, in collaboration with Thomson. Mallet produced the masque *Alfred* (containing the patriotic song "Rule, Britannia"); in 1751 after Thomson's death, he published a new version, claiming that it was almost entirely his own work.

A collection of his *Works* appeared in 1759 (3 vol.). His *Ballads and Songs* were edited by F. Dinsdale, with notes and a biographical memoir, in 1857.

MALLET DU PAN, JACQUES (1749–1800), French journalist, was born near Geneva. Voltaire obtained him a professorship at Cassel, which he soon resigned. He joined Simon Linguet (*q.v.*) in London, in the production of his *Annales politiques* (1778–80), and during Linguet's imprisonment in the Bastille (1781–83) continued them himself. Linguet resented this, and Mallet du Pan changed the title of his publication to *Mémoires historiques* (1783), which he incorporated with the *Mercure de France* in Paris from 1783. He sided with the Royalists at the Revolution. and was sent by Louis XVI on a mission to the German princes (1791–92). His antirevolutionary pamphlets, and an attack on Bonaparte and the Directory resulted in his exile in Berne (1797). In 1798 he went to London and founded the *Mercure britannique.* He died at Richmond, Surrey, on May 10, 1800. Mallet du Pan was a pioneer of modern political journalism.

Mallet du Pan's *Mémoires et correspondance* was edited by A. Sayous (1851). *See* also B. Mallet, *Mallet du Pan and the French Revolution* (1902).

MALLING, EAST and **WEST,** two villages in the Malling rural district of Kent, Eng.. respectively 4 mi. and 6 mi. W. N.W. of Maidstone. Pop. (1951) East Malling 3.258; West Malling 3,357. East Malling is known for its horticultural research station specializing in experiments in fruitgrowing. The mansion of Bradbourne is now the headquarters of the station. There are also large paper mills in the village. At West Malling are remains of Malling abbey, a Benedictine nunnery founded in 1090 by Gundulf, bishop of Rochester. The remains, partly incorporated in a modern building, include the Norman west front of the church, the Early English cloisters. the chapter house and gatehouse (the chapel of which is restored to use). Gundulf also built himself a residence. of which St. Leonard's tower survives. The village has a long cricketing tradition.

MALLOPHAGA, an order of insects comprising the biting or chewing lice; minute, wingless forms parasitic on birds and mammals. They are sometimes treated as a suborder along with Anoplura, the sucking lice, to form the order Phthiraptera. About 2,800 species are recorded. with many more. especially among the bird lice. still undescribed. Their life cycle is spent on the feathers or hair of the host, though one genus lives in the throat pouches of pelicans and cormorants.

The eggs. attached to the feathers or hairs, or occasionally laid inside quill feathers, give rise to young which pass through three nymphal stages which resemble the adult. A single bird or mammal species may be parasitized by one or more (sometimes as many as 15) species of biting lice. They often show host-specificity, being unable to survive on any but their own or a related host. Their present distribution suggests that they became parasitic at an early stage in the evolution of their hosts and evolved with them so that: with some exceptions due to subsequent transference having taken place, related hosts are parasitized by related biting lice; a particular genus may be restricted to one group of birds, and a particular species may be found on only one species of bird or on a group of related species.

Biting lice on birds feed on feathers or feathers and blood, the blood sometimes being taken from the shafts of the developing feathers; some live on blood alone and their normal chewing mandibles may then be adapted to piercing the skin. Probably all species of birds have biting lice. Preening keeps down the numbers, and birds with damaged bills are often particularly heavily infested because they cannot preen themselves properly. Normally. lice do no damage, but if they are too numerous the irritation may cause the bird to damage itself by scratching and may even interfere with egg production and fattening in poultry.

Biting lice parasitic on mammals feed on skin secretions and skin debris; it is uncertain whether they eat hair. They are less widespread than those of birds, comprising fewer genera and species. and occur on marsupials, primates, rodents, land carnivores. hyraxes and ungulates. The elephant louse, *Haematomyzus,* if of questionable affinity, is usually considered to belong to the Mallophaga. *See* LOUSE.

See M. Rothschild and T. Clay, Fleas, Flukes *and* Cuckoos, 3rd ed. (1957). (T. CL.)

MALLOW, a town and watering place of County Cork. Ire., on the Blackwater. 144½ mi. S.W. from Dublin, and 21 N. from Cork by the Great Southern railway. Pop. (1961) 5,520. The town possesses a tepid mineral spring and a spa house. There are manufactures of mineral water and condensed milk, corn mills and tanneries.

Mallow received a charter of incorporation from James I. Its name was originally Magh Allo, that is, Plain of the Allo (the old name used by Spenser for this part of the river), and the ford was defended by a castle, built by the Desmonds, the ruins of which remain. A bridge connects the town with Ballydaheen. Mallow is a centre for salmon fishing on the Blackwater.

MALLOW is any plant of the family Malvaceae, especially of the genera *Hibiscus* (*q.v.*) and *Malva,* the latter embracing about 30 species of annual and perennial herbs. widely distributed throughout the northern hemisphere. The mallows possess the kidney-shaped one-celled anthers which characterize the Malvaceae (*q.v.*). The petals also are united by their base to the tube formed by the coalesced filaments of the stamens. The special characters which separate the genus *Malva* from others most nearly allied to it are the involucre, consisting of a row of three separate bracts attached to the lower part of the true calyx. and the numerous single-seeded carpels disposed in a circle around a central axis, from which they become detached when ripe. The flowers are mostly white or pinkish. never yellow, the leaves radiate-veined and more or less lobed or cut. Three species are found in Britain. The musk mallow (*Malva moschata)* is a perennial herb with five-partite, deeply cut leaves and large rose-coloured flowers clustered together at the ends of the branched stems and is found growing along hedges and borders of fields. blossoming in July and August. It owes its name to a slight musky odour diffused by the plant in warm dry weather when it is kept in a confined situation. The round-leaved dwarf mallow (*Malva neglecta*) is a creeping perennial growing in waste sandy places, with roundish serrate leaves and small pinkish-white flowers produced in the axils of the leaves from June to September. It is common throughout Europe and the north of Africa, extending to western and northern Asia. The common mallow (*Malva sylvestris*), the *mauve* of the French, is an erect biennial or perennial plant with long-stalked roundish-angular serrate leaves, and conspicuously axillary reddish-purple flowers. blossoming from May to September. Like most plants of the order it abounds in mucilage, and hence forms a favourite domestic remedy for colds and sore throats. The aniline dye called mauve derives its name from its resemblance to the colour of this plant. Besides the foregoing, three other species have become naturalized in various parts of North America.

FROM GROOM, "ELEMENTARY BOTANY" (G. BELL AND SONS)

VERTICAL SECTION OF COMMON MALLOW (MALVA SYLVESTRIS) FLOWER

The marsh mallow *(Althaen officinalis*), the *guimauve* of the French. belongs to the same genus as the hollyhock (*q.v.*). (For rose mallow, *see* HIBISCUS.) The mallow of Scriptures, Job xxx, 4, has sometimes been identified with Jew's mallow *(Corchorus olitorius*), a member of the allied family Tiliaceae. but more plausibly with *Atriplex halimus,* the sea orache of Europe. Once widely used in medicine, mallows are no longer considered of value.

MALMÉDY, a small town acquired by Belgium from Germany through the treaties after 1918, lying in a wild and deep basin, on the Warche, 20 mi. S. of Aachen by rail via Eupen. Pop. (1955 est.) 5,941. (See EUPEN-ET-MALMÉDY.)

MALMESBURY, JAMES HARRIS, 1ST EARL OF (1746–1820), English diplomatist, was born at Salisbury on April 21, 1746, the son of James Harris, the author of *Hermes.* Educated at Winchester, Oxford and Leyden, he became secretary in 1768 to the British embassy at Madrid, then minister ad *interim,* and in 1772 minister plenipotentiary to the court of Prussia. In 1777 he was transferred to the court of Russia, where he made his reputation, for he managed to get on with Catherine in spite of her predilections for France, and steered adroitly through the accumulated difficulties of the first armed neutrality. He was made a knight of the Bath in 1778, but in 1782 returned home because of ill health, and was appointed by his friend Fox to be minister at The Hague. He furthered Pitt's policy of maintaining England's influence on the continent by the arms of her allies, and held the threads of the diplomacy which ended in the king of Prussia's overthrowing the republican party in Holland, which was inclined to France, and re-establishing the prince of Orange. He was created Baron Malmesbury of Malmesbury (Sept. 1788), and permitted by the king of Prussia to bear the Prussian eagle on his arms and by the prince of Orange to use his motto *"Je maintiendrai."* He returned to England, and seceded from the Whig party with the duke of Portland in 1793; in that year he was sent by Pitt, but in vain, to try to keep Prussia true to the first coalition against France. In 1794 he was sent to Brunswick to solicit the hand of the unfortunate Princess Caroline for the prince of Wales. In 1796 and 1797 he was at Paris and Lille vainly negotiating with the French Directory. In 1800 he was created earl of Malmesbury and Viscount Fitzharris of Heron Court in the county of Hants. He was now consulted by successive foreign ministers, trusted by men of the most different ideas in political crises and was above all the confidant, and for a short time after Pitt's death almost the political director, of Canning. Lord Palmerston, who was his ward, derived many of his ideas on foreign policy from him. Malmesbury died on Nov. 21, 1820, and was succeeded as 2nd earl by his son James Edward (1778–1841), undersecretary for foreign affairs under Canning.

Malmesbury published only an account of the Dutch revolution and an edition of his father's works, but his important *Diaries* (1844) and *Letters* (1870) were edited by his grandson.

MALMESBURY, JAMES HOWARD HARRIS, 3RD EARL OF (1807–1889), English statesman, was born on March 25, 1807, in London, and educated at Eton and at Oriel college, Oxford. Member for Wilton in 1841, when he succeeded to the title, Malmesbury first became prominent after the Conservative split over the corn laws in 1846 as a staunch old-fashioned Tory and active supporter of Lord Stanley, later Lord Derby, under whom he served as foreign secretary in 1852 and 1858–59. Despite his lack of experience, Malmesbury, who was naturally pacific and dubious of Palmerstonian methods, proved adequate to a difficult task. Francophile through inclination and his acquaintance with Napoleon III, he concentrated upon improving Anglo-French relations. He was the first to recognize the establishment of the second Empire; over the Italian question he attempted, with little success. 'to combine neutrality, tempered by a preference for the Habsburg position, with benevolence toward France. Though never holding executive officeagain. Malmesbury remained a respected and influential figure in Conservative circles. From 1866 to 1868 and from 1874 to 1876, he was lord privy seal; he died on May 17, 1889, at Heron Court, Hampshire.

Malmesbury's political career owed much to his friendship with Derby, and to the paucity of talent in his party after the secession of the Peelites. Cosmopolitan in his tastes and connections, his casual if extensive knowledge of European problems and personalities was his main qualification for the foreign office, although his performance there surprised the critics. In 1884 he published his entertaining Memoirs *of* an Ex-Minister, a valuable source for a crucial period in the history of the Conservative party.

(A. F. T.)

MALMESBURY, a market town and municipal borough in the Chippenham parliamentary division of Wiltshire, Eng., 22 mi. N.E. of Bath by road. Pop. (1961) 2,606. It stands on a ridge between the Salisbury Avon and its tributary. the Inglebourne. Maildulph, a Scottish or Irish monk, built a hermitage near the site of the modern Malmesbury in about 635. This formed the nucleus of the later abbey, of which Aldhelm, his pupil, became the first abbot. Aethelstan, who was buried there, rebuilt and endowed the monastery, and there William of Malmesbury (*q.v.*) was brought up from childhood. A Benedictine abbey church was built on this site in the 12th century and part of it, restored in 1928 by Sir Harold Brakspear, is now the parish church. The nave is transitional Norman and Decorated and the south porch is Norman. At the time of the Dissolution, the abbey and its lands were bought by a rich clothier. The abbey church was fitted with looms for weaving, and later presented to the townspeople to replace their decaying parish church. All that remains of the latter is the tower which contains the town clock and the abbey bells. In the market square stands a fine market cross of the 16th century, borne upon an octagonal battlemented basement. The 13th-century hospital of St. John of Jerusalem survives as fragments in a corporation almshouse.

The town grew up around the abbey and at the time of the Domesday Survey it was one of the only two boroughs in Wiltshire. The building of a castle by Henry I (pulled down in the 13th century) gave further impetus to the growth of the town. Following many earlier charters. the first charter of incorporation was granted in 1635. The borough returned two members to parliament from 129j to 1832 and one member from then until 1885. Thomas Hobbes, the philosopher, was born there in 1588. From the middle ages to the 1750s the town possessed a considerable cloth manufacture, and silk industries flourished during the 19th century. Today it has an agricultural trade and firms making electronic and radar and strip-lighting equipment.

MALMÖ, a seaport of Sweden, chief town of the county (*län*) of Malmohus, on a small bay of the sound, 384 mi. S.S.W. of Stockholm by rail. Pop. (1800) 38,054; (1960) 228,878.

Malmö (Malmhauge, Malmey, Malmoye, Malmoughe), sometimes called Ancona Scanorum or Ellenbogen, first appears in history about the middle of the 13th century. During the Hanseatic period it was the most important commercial town on the sound, but in the 16th and 17th centuries greatly lost ground because of the decay of its herring fisheries and the rise of its rival, Copenhagen, Den. It began to revive in the late 18th century.

It is connected with Copenhagen, 17¼ mi. N.W., by steam ferry, the sound being kept open in winter by an icebreaker. It is also the first important station in Sweden on the Berlin-Stockholm route, which crosses the sea between Sassnitz in Rügen and Trelleborg 20 mi. S.E. of Malmö. The town formerly had strong fortifications, of which only the citadel (Malmöhus) remains; in it the earl of Bothwell was imprisoned by Frederick II of Denmark for some time after his departure from Scotland in 1567. The town hall (1546, largely restored in 1864) contains a handsome chamber, the Knutssal, formerly used by the council of the guild of Canute. The church of St. Peter (*Peterkyrka*) dates in part from 1319. Malmö is second to Stockholm as an industrial centre. There are breweries and large works for the manufacture of machinery, among which are the Kockum mechanical works, with yards for the construction of vessels of war, and others; of cotton and woollen goods, rubber factories, sugar factories, gloves, chocolate, sweetmeats and tobacco. Malmö is a free port. It has a large export trade in grain, timber, cattle, flour, butter, cheese, matches, wood pulp, etc. The imports are coal, manufactures, cotton, chemicals, iron, herring, manures, grain, etc. The harbourage includes an outer harbour of 22-ft. depth, and two inner basins admitting vessels of 21-ft. draught, with dry dock and patent slip. Malmö returns four members to the second chamber of the *riksdag* (parliament).

MALMSEY is a strong, sweet wine that is made mainly in Madeira. Originally it was a Byzantine wine exported from Monemvasia, a village on a small island in the bay of Epidaurus, Peloponnesus, the name of which was corrupted in medieval Latin into *Malmasia,* whence the English form of the word. In the 16th century any strong, sweet dessert wine from Greece, the Greek archipelago, Italy or elsewhere in the Mediterranean was called malmsey—the best came from Iraklion (Candia), Crete, which for a long time had a monopoly. (C. C. H. F.)

MALNUTRITION. Maintenance of proper nutrition (*q.v.*) depends primarily on the provision of appropriate quantities of all the nutrients. Wrong proportions among these quantities results in a condition of malnutrition; an insufficient total amount of nutrients results in undernutrition, of which condition the extreme degree is starvation. Malnutrition also may be caused by impaired physiology as, for example, in certain diseases, even though the dietary intake may be adequate. Such malnutrition, usually called conditioned malnutrition, is a problem of clinical medicine and will not be discussed in this article.

Various meanings have been applied to the word malnutrition. While its literal meaning is "faulty or imperfect nutrition," the word is frequently used only to describe deficiencies. Malnutrition may also result. however, from excessive food intake. This is particularly evident in the case of excessive consumption of calories, but there is also reason to suppose that excessive consumption of carbohydrates and fats, quite apart from calories, may produce various forms of malnutrition. Obesity, the result of this type of unsatisfactory nutrition, is associated with much ill-health and in severe cases with a greatly increased mortality rate. In this review the word malnutrition will be used in its literal meaning and will be applied to conditions caused by deficiencies and excesses in the supplies of nutrients.

Detecting Malnutrition.— Various types of evidence indicate malnutrition. Presumptive or suggestive evidence includes vital statistics (growth rates. maternal mortality, infant mortality, etc.) and statistics of national available food supplies. Statistics, however, have many serious limitations as diagnostic evidence. Vital statistics, for example, reflect the collective effects of disease, environment and many factors of which nutrition is only one.

Indirect evidence must be supplemented by more specific information from nutrition surveys. The basic method is clinical appraisal combined with dietary surveys. Simple laboratory tests may usefully supplement the basic method. Clinical assessment includes a general inspection and a detailed inspection. The former includes the appearance of health, intelligence and vitality or their opposites conveyed to the mind of the examiner. The detailed examination includes inspection of the eyes. skin, mucous membranes, bones and subcutaneous deposits of fat. These body areas are those most likely to manifest evidences of undernutrition, deficiency disease and obesity.

DISORDERS OF MALNUTRITION

Nutrition surveys have revealed alarming evidence of malnutrition. the problems varying in different parts of the world. In underdeveloped areas the deficiencies, such as undernutrition, protein malnutrition, anemia, nutritional disorders of the eye and beriberi, are predominant. In regions in which food supplies are abundant and economic levels high, overnutrition is the main problem.

Deficiency States

A nutritional deficiency may be caused by anything that diminishes the availability of a nutrient or nutrients to the tissues. Thus. although adequate amounts may be eaten, there may be a failure of the body tissues to absorb nutrients, or over-rapid excretion may occur. Deficiency states are frequently multiple, hence the clinical picture is often complex.

General Undernutrition or Chronic Partial Starvation. —In places where. or in times when. food is scarce. cases of starvation occur due to insufficiency but not entire lack of food. Diets are predominantly rich in carbohydrates and deficient in most of the other nutrients. Further, coarse and unfamiliar food may be eaten, causing indigestion and diarrhea. The clinical symptoms presented by the afflicted vary with the nature of the food available. The commonest disturbances are low basal metabolic rate, slow pulse, lowered blood pressure, suppression of menses in women. dry, coarse. cold skin, bloodshot eyes, insomnia and fractures from osteoporotic changes in the bones. Nutritional edema. burning sensations in the feet and hands and sore mouth with increased salivation are common symptoms in chronic starvation. Classification of the possible degrees of undernutrition is given in the table.

Degrees of Undernutrition

State of undernutrition	Weight loss (% underweight)	Effect on functions and characteristics
Slight	10	No serious functional deterioration
Moderate	10–20	Substantial change, but condition often compatible with light or moderate work
Severe	20–30	Profound changes—may be able to do light work but condition is potentially serious
Extreme	more than 30	Patient grossly abnormal—rarely capable of any useful work
Very extreme	50	Severe and often fatal

The simplest way of treating starvation is to get the patient to take easily digested, highly nutritious food. The first to be given should be skimmed milk and well-strained vegetable and meat soups; glucose should be added to the milk. As soon as the patient is able to digest these, the diet can be gradually expanded to include whole milk, lean meat. fish, vegetables and fruits.

Protein Malnutrition.— Protein deficiency is widespread in many parts of the world, particularly in the tropics. Kwashiorkor, a form of protein malnutrition commonly occurring in infants and young children who have been fed on a diet low in protein and composed mainly of foods rich in carbohydrates, has been recognized in many parts of the world, particularly in Xfrica, India, Indonesia. southeast. Asia and Central and Latin America. The main characteristics are retarded growth and development, apathy and anorexia. edema: pellagroid skin lesions, alterations in skin and hair pigmentation. fatty liver and diarrhea. There may be signs of associated vitamin deficiency.

Protein malnutrition is found in a continuous range from the classical forms in which calories are adequate, even abundant, to those in which there have been a severe calorie deficit and considerable wasting. The latter type is often called marasmic kwashiorkor.

Treatment of patients suffering from protein malnutrition is essentially dietetic. The protein-rich diet may consist of a mixture of powdered skim milk and suitable forms of carbohydrate such as ripe bananas. As soon as the digestive function will permit, return should be made to a well-balanced normal diet suitable for the child's age, since milk alone will not satisfy calorie and other requirements. In areas where kwashiorkor is prevalent a long time would be required before adequate supplies of animal protein could be provided; hence, attention is focused upon improving the quality of protein of vegetable origin, as from soybeans, peanuts and legumes.

Nutrition and Anemia.— Anemia constitutes a public health problem of great magnitude, particularly in the underdeveloped and tropical areas of the world. Malnutrition underlies most of the anemias in these areas, affecting particularly expectant and nursing mothers, infants and young children. Deficiency anemias are classified as (1) deficiency in nutrients (iron and protein) necessary for the formation of hemoglobin (nutritional deficiency anemia); and (2) deficiency in such substances as folic acid and vitamin B_{12}, necessary for red cell formation. (See Anemia.)

Nutritional Deficiency Anemia.—The symptoms may be vague or concrete. The patient may complain only of unusual fatigue or a feeling that he is "run down." Nausea and vomiting, laboured breathing. headache and dizziness may develop after the anemia has continued for some time. The number of red cells may be low or near'normal. but they are pale and small; the hemoglobin concentration is low. Anemia is corrected by supplements of iron, given as ferrous sulfate.

Pernicious Anemia.—This disease, due to a deficiency of vitamin B_{12}, usually occurs after the age of 40. Numbness and tingling of the hands, yellowing of the skin and a burning sensation in the mouth are the first signs. Diarrhea. loss of appetite. loss of weight and weakness also are common complaints. Later the patient begins to suffer from shortness of breath. Eventually, if given no treatment, the patient becomes exhausted and finally comatose. There is a marked decrease in the red blood cell count, and a number of immature blood cells appear in the blood. Other characteristic symptoms include a decrease in the hydrochloric acid of the stomach and disturbances of the central nervous system. An unexplained phenomenon is the periods of remission during which the patient becomes almost symptom-free. The diet for pernicious anemia is a normal diet that contributes to the patient's general nutrition. supplemented by vitamin B_{12}.

Vitamin A Deficiency.—Clinical signs and symptoms include night blindness. xerophthalmia (producing dry, dull eyeballs), softening of the cornea and dermatosis characterized by eruptive lesions of the hair follicles with keratinization. Each of these manifestations may occur alone or in combination with other signs and symptoms. Treatment is with daily supplements of vitamin A, which causes prompt regression of night blindness and xerophthalmia.

Riboflavin Deficiency.— This deficiency is prevalent throughout practically all the underdeveloped world, especially among infants and children in areas where other deficiency diseases are endemic. Manifestation of this deficiency involves the eyes. lips and skin. There is vascularization of the cornea, circumcorneal infection and. later, development of opacities. Angular lesions on the lips at the corners of the mouth (cheilosis) appear. The lesion of the skin is of the seborrheic type with flaking and greasiness over a reddened base. Milk and organ meats, the rich natural sources of riboflavin. should be prescribed but other water-soluble vitamins should be given as well.

Beriberi.— This is a chronic disease endemic among people who subsist almost entirely on polished rice. Though it may be due to multiple deficiencies, the most important is that of vitamin B_1 (thiamin). Three types of beriberi have been described: (1) dry, characterized by multiple peripheral neuritis with muscular atrophy; (2) wet, where edema is present; and (3) cardiac or acute. with cardiovascular changes. Manifestations of thiamin deficiency are loss of appetite, nausea, gastrointestinal disturbances, degenerative changes in heart muscle and multiple neuritis. Treatment consists in supplying thiamin daily by mouth or injection. (See Beriberi.)

Pellagra. — This chronic disease due to deficiency of niacin is found principally among maize-eating populations, who are particularly predisposed because the principal protein of maize, zein, lacks tryptophan, an amino acid the body can convert into niacin. The symptoms characteristically involve the skin, the gastrointestinal tract and the nervous system, forming the classical clinical triad of dermatitis, diarrhea and dementia. The skin lesions tend to appear bilaterally symmetrically on the areas of the body exposed to sunlight. Treatment consists in giving niacin daily in divided doses with supplements of yeast, liver by injection and thiamin and riboflavin to combat the deficiency of the other B vitamins. *(See* PELLAGRA AND RELATED DISORDERS.)

Other Deficiency Diseases. — The occurrence of other deficiency diseases is now relatively uncommon. These include scurvy, due to a lack of vitamin C (ascorbic acid); rickets (*q.v.*), a manifestation of vitamin D deficiency; goitre, due to iodine deficiency: and hypovitaminosis K, which accounts for the occurrence of hemorrhagic disease of the newborn.

See also VITAMINS.

OVERNUTRITION

In most of the highly developed countries of the west, overweight in adults probably represents the commonest form of malnutrition. The prevalence of overweight and obesity is accompanied by increased mortality from a number of degenerative diseases, one of which is arteriosclerosis, a leading cause of death in many technically developed and well-fed countries *(see* ARTERIES, DISEASES OF).

The exact point at which obesity begins is difficult to define, but as a general rule a person is considered obese when the body weight increases by 20% above the average weight of healthy persons aged 25 and of the same height. This average weight at age 25 is termed desirable weight.

The immediate cause of obesity is the consumption of food providing calories in excess of energy requirements. However, there are multiple remote causes related to factors that cause an inappropriately positive calorie balance and eventually an inappropriately high body lipid content. The possible roles of genetic factors, hypothalamic lesions, hormonal disturbances and increased peripheral glucose utilization, which have afforded a means of study of obesity in experimental animals. do not seem to apply broadly in explaining the pathogenesis of obesity in man; obesity is generally regarded as a psychosomatic disorder of multiple cause featuring a disturbance in the mechanism that matches food intake to energy expenditure.

The most useful treatment for obesity is diet therapy — a reducing diet that should supply an intake of calories substantially less than an obese person's customary food intake (1,000 to 1.200 cal. per day) but that should contain at the same time adequate quantities of protein and the various nutrients. Exercise increases the energy requirement and stimulates basal metabolism and is, therefore, a special factor in the management of obesity. The psychological aspect is also particularly important; the pleasure of eating usually influences greatly the desire for food and may be seized upon to replace other satisfactions of living. An effort must be made to discover the cause of a person's emotional disturbance before demanding his co-operation in a reducing diet. Some substitute for the satisfaction obtained from food must be found.

CAUSES AND PREVENTION

There are a number of distinct causes of malnutrition, most of which are interrelated. The fundamental causes include agriculture, economics and social and cultural factors.

Only about one-third of the population of the world has an adequate available food supply. The areas in which deficiency diseases predominate are technically underdeveloped and agricultural yields are low. In certain countries the amount of arable land available per head of population is small. Where the population is dense, pressure on land available for cultivation is high. In many cases the growth of the population is outstripping the supply of food that can be produced at existing levels of agricultural development. In areas where such conditions obtain, the population must depend on consumption of direct products of the soil. Land must be devoted largely to such major staples as rice, maize, cassava, millets and wheat that give a high calorie yield per unit of area. Green and leafy vegetables, for example, are important "protective" foods, yet the calorie yield per acre is so low in comparison to that of the major staples that many parts of the morld cannot afford to grow them.

Throughout the underdeveloped parts of the world, therefore, the diets of the people contain a predominance of cereals or tubers or both. Other foods, and particularly foods of animal origin, are included in the diet in relatively small amounts. Diets that contain so high a proportion of cereal are inevitably deficient in terms of modern standards of nutrient requirements, thus leading to malnutrition. Typically, adults seem to survive quite well on even these predominantly cereal diets; it is among the more vulnerable groups — infants, preschool children, pregnant and nursing women — that malnutrition first appears. Improvement in agricultural practices, in varieties of crops, in storage practices, in transportation and marketing arrangements are fundamental to prevention of malnutrition in these areas of the world.

Moreover, people in these areas usually depend for their existence almost entirely on agriculture in the broad sense of this term; industry on a large scale has not been developed. Economic levels, therefore, are low and people cannot afford to buy foods to supplement the staple cereal. Families that purchase their food must spend a high proportion of the family income — often 70% or more — in obtaining their present meagre and ill-balanced diet. Until their economic condition is improved, such families cannot afford to buy supplementary foods in sufficient quantity even when they are available. Another way in which poverty influences diet is in forcing small producers to sell more expensive protective foods of which they are themselves in need in order to be able to buy the staple foods and other essentials.

With poverty go illiteracy and ignorance, and in such circumstances the improvement of food habits through education is difficult. Social systems have important effects on food habits and nutritional problems. For example, it is common to find a system of priority within families that gives the father the first choice of available food; the mother comes second and the children last. Food taboos, unsound food beliefs and food practices are encountered: there are groups who have eggs but will not eat them, regarding egg eating as a sign of greed; the main and cheapest source of animal protein in some areas, dried fish, may be thought to cause worms and "bad eyes"; there are groups who believe that cow's milk is not a proper food for children; and in some communities the taking of milk by girls and especially by married women has powerful emotional connotations. Food habits also are affected by religion.

While awaiting the slow improvement in agriculture and economy, malnutrition can be alleviated by nutrition education. The fundamental aim of nutrition education should be to improve utilization of existing resources. Teaching and practical demonstration should aim at countering food taboos; increasing local production of food, use of appropriate methods of preserving foods, and selection of well-balanced low-cost diets composed of locally available foods; introducing methods for the preparation of food based upon good hygiene and sound nutritional principles; and preparing correct diets for infants and young children.

The predominantly cereal diets of many areas of the world also can be improved by enrichment with certain vitamins, minerals and certain amino acids such as lysine. In the past this was not feasible economically, but improvements in the production of many synthetic nutrients now make it possible. Thus, the protein of wheat and rice can be substantially improved by the addition of lysine, giving great promise for future decrease'in protein malnutrition.

MALOCELLO, LANCILOTO ("LANZAROTE, the 'Lancelot Maloisiel' of the French"), leader of the first of modern European oceanic enterprises. This was a Genoese expedition, which about 1270 seems to have sailed into the Atlantic, rediscovered the "Fortunate Islands," or Canaries, and made a settlement in one of the most northerly isles of this archipelago, still known (after the Italian captain) as Lanzarote. "Lancarote" is said to have been killed by the Canarian natives; but the castle built by him was standing in 1402–04, when it was utilized for the storage of grain by the French conquerors under Gadifer de la Salle. Malocello's enterprise is probably not unconnected with the great Genoese venture of 1291 in search of a waterway to India.

Canaries, p. 177; M. A. P. d'Avezac in vol. vi, part ii, of *L'Univers*, pp. 1–41 (*Iles* africaines de *l'océan* atlantique); C. R. Beazley, Dawn of Modern Geography, iii, 411–413, 449, 451 (1906).

MALOLOS, a municipality, capital of Bulacan province, Philippines, lies on a flat, poorly drained plain, about 20 mi. N.W. of Manila. During the revolution against the U.S. the insurgent congress met there and framed the "Malolos constitution," by virtue of which the constitutional Philippine republic was proclaimed on Jan. 23, 1899. The insurgent leader, Emilio Aguinaldo, established his headquarters in Malolos and it served as the insurgent capital until it was captured by U.S. forces in March 1899.

Malolos is an important trading centre in a heavy rice- and vegetable-producing region. Major fish-pond areas are located south and west of the administrative centre.

The municipality lies astride the main highway leading north through the central plain northward from Manila and is also bisected by the rail line to the Lingayen gulf. Pop. (1959 est.) 47,507. (R. E. HE.)

MALONE, EDMUND (1741–1812), Irish Shakespearian scholar and editor, was born in Dublin, on Oct. 4, 1741, the son of a barrister and a member of the Irish house of commons. He was educated at Trinity college, Dublin, and was called to the Irish bar in 1767. On the death of his father in 1774 he went to London, where he frequented literary and artistic circles. He frequently visited Samuel Johnson and was of great assistance to James Boswell in revising and proofreading his Life, four of the later editions of which he annotated. He was one of Sir Joshua Reynolds' executors, and published a posthumous collection of his works (1798) with a memoir. Horace Walpole, Edmund Burke, George Canning, Lord Charlemont and, for a time, George Steevens, were among Malone's friends. Encouraged by the last two he devoted himself to the study of Shakespearian chronology, and the results of his Attempt to Ascertain the Order in Which the Plays of Shakespeare Were Written (1778) are still largely accepted. This was followed in 1780 by two supplementary volumes to Steevens' version of Johnson's Shakespeare; and this again, in 1783, by an appendix volume.

The seven years (1785–92) were devoted to Malone's own edition of Shakespeare in 11 volumes.

Malone published a denial of the claim to antiquity of the Rowley poems (see CHATTERTON, THOMAS), and in this (1782) as in his branding (1796) of the Ireland manuscripts (see IRELAND, WILLIAM HENRY) as forgeries, he was among the first to guess and state the truth. His elaborate edition of John Dryden's works (1800) with a memoir, was another monument to his industry, accuracy and scholarly care. At the time of his death, on April 25, 1812, Malone was at work on a new octavo edition of Shakespeare, and he left his material to James Boswell the younger; the result was the edition of 1821 — generally known as the Third Variorum edition — in 21 volumes.

A memoir of Malone by James Boswell is included in the *Prolegonzena* to the edition of 1821. See also Sir J. Prior, Life oj Edmund *Malone* (1860).

MALONIC ACID crystallizes **in** large colourless plates, dissolving readily in water, alcohol or ether, and melts at 135.6° C. Although the sparingly soluble calcium malonate occurs in beetroot, the acid itself, $HO_2C.CH_2.CO_2H$, is generally produced by laboratory methods, such as the oxidation of malic acid or the hydrolysis of cyanoacetic acid, $CN.CH_2.CO_2H$. When carefully heated at 140°–150° C., malonic acid partly decomposes into acetic acid and water, but 10%–12% undergoes dehydration with formation of carbon suboxide, C_3O_2.

The outstanding importance of malonic acid in systematic chemistry arises from the varied syntheses which can be effected with its ethyl ester, diethyl malonate, commonly called malonic ester, $CH_2(CO_2C_2H_5)_2$. This ester, usually prepared by passing hydrogen chloride into a solution of cyanoacetic acid (obtained from chloroacetic acid) in absolute alcohol, is a colourless fragrant liquid boiling at 198° C. Its very reactive methylene group, CH,, is instrumental in effecting syntheses of higher mono- and dibasic acids. The replacement of one hydrogen of this methylene group by sodium gives sodiomalonic ester; this on treatment with an alkyl iodide gives the ester of the corresponding alkyl malonic acid. In the presence of sodium ethoxide the esters of malonic acid and diethylmalonic acid undergo condensation with urea to furnish respectively barbituric and diethylbarbituric acids, the latter being the well-known soporific drug veronal (see BARBITURATES). By a similar condensation with urea ethylphenylmalonic ester yields the drug phenobarbital.

MALORY, SIR THOMAS (d. 1471), translator and compiler of the famous English classic, the Morte *d'Arthur*. Previous to the publication of G. L. Kittredge's monograph, *Who* Was Sir Thomas *Malory?* the identity of this writer remained an unsolved problem. Of direct evidence we have very little; in the concluding passage of the book the author asks the prayers of the reader for "Syr Thomas Maleore knyght," and states that the book was ended "the ix yere of the reygne of Kyng Edward the fourth." Caxton, who printed Morte *d'Arthur* after Malory's death, in his preface (1485) says that he printed the book "after a copye unto me delivered whyche copye Syr Thomas Rlalorye dyd take oute of certeyn bookes of frensshe and reduced it in to Englysshe."

Kittredge identifies Caxton's Malory with Sir Thomas Malory, knight, of Newbold Revell (or Fenny Newbold), M.P. for Warwickshire in 1445. He had served in France, in the retinue of the earl of Warwick. He is almost certainly the "Thomas Malorie, miles," who, on account of his part in the Wars of the Roses was excluded with several others from the operation of a pardon issued by Edward IV. When Sir Thomas Malory's widow died in 1479 she was in possession of his hereditary estates in Northamptonshire and Warwick, so that it seems clear that Sir Thomas must have conveyed them to her in his lifetime probably for fear of confiscation.

On two occasions, in 1451 and 1452, Humphrey, duke of Buckingham was commissioned to arrest Thomas Malory, knight, and bring him before the king and council "to answer certain charges," in the first case with respect to the rights of the monks of Axiholme in Kirby Monachorum, the parish which contained Malory's estate of Newbold Revell. (See Calendar of Patent Rolls, 1446–52, p. 476, and 1452–61, p. 61.)

Malory's Morte *d'Arthur* is an abridged compilation of the great body of Arthurian romance in its latest form. The Merlin, Tristan, Lancelot, Queste and *Mort Artus* are all represented, the only branch omitted is that dealing with the "early history" of the Grail, the Joseph of *Arimathea* and Grand S. Graal. But we do not yet know whether Malory himself was responsible for this selection, or whether he found it ready to hand in a manuscript, the "Frensshe Booke" to which he often refers. Medieval copyists, at the instance of their patrons. did make compilations from the various romances within their reach, such as *e.g.,* the enormous codex 112 (*fonds Franç*) of the Bibliothèque Nationale, which includes large sections of the Tristan, the Lancelot, and the Merlin suite. Taking into consideration alike what Malory retains and what he omits. it seems most probable that he mas in possession, not of complete copies of the romances, but of one or more volumes of compilations from these sources.

The Morte *d'Arthur* represents the Arthurian cycle in the period of its decadence; nor does Malory in any way endeavour to overcome the difficulties caused by the juxtaposition of a number of independent (and often contradictory) versions; but the diversity of sources is harmonized and wrought into a whole by the great charm of Malory's style; simple, direct, idiomatic, yet musical and dignified, it has lent to the relations between Lancelot and Guenevere a character of truth and vitality lacking in his predecessors. Malory took the Arthurian story in its worst and weakest form, and he imparted to it a moral force and elevation which the cycle, even in its earlier and finer stage, had, save in the unique case of Von Eschenbach's *Parzival,* never possessed. *Morte d'Arthur* was the first English prose epic, and formed one of the chief foundations of English prose.

See G L Kittredge, "Who Was Sir Thomas Malory?", *Harvard Studies and Notes in Philology and Literature,* vol. v (1897); and *Sir Thomas Malory* (1925); *Morte d'Arthur,* ed by Oskar Sommer (an exact reproduction of the original text in 2 vol.)—vol iii a study on *The Sources of Malory.* The sections on *Lancelot* and *Queste* are unfcrtunately very inadequate; for these see *The Legend of Sir Lancelot,* Grimm Library, vol. xii. (J.L.W.; X.)

MALOU, JULES EDOUARD XAVIER (1810–1886), Belgian statesman, one of the leaders of the clerical party, was born at Ypres on Oct. 19, 1810. He mas minister of finance in the coalition ministry of J. B. Nothomb in 1844. and formed with B. T de Theux a Catholic cabinet in 1846, which was overthronn in the Liberal victory of 1847. Malou then became a member of the senate, and his party only regained ascendancy in 1870. The extreme clerical ministry of Baron d'Anethan retired in Dec. 1871 after serious rioting in Brussels, and Malou was the real, though not the nominal, head of the more moderate clerical administrations of De Theux and Aspremont-Lynden (1870–78). After the fall of the ministry in 1878 he adopted a·frankly clerical policy. and when he became chief of a new government in June 1884 he proceeded to undo the educational compromise of his predecessors in the Frère-Orban ministry. His legislation in favour of the Catholic schools caused rioting in Brussels, and in October the king demanded the retirement of Jacobs and Woeste, the members of the cabinet against whom popular indignation was chiefly directed. Malou retired. and died at Wolume Saint Lambert, in Brabant, on July 11, 1886. He was a financier of great experience. A list of his works is given in Koninck's *Bibliographie nationale de Belgique.*

MALOUET, PIERRE VICTOR, BARON (1740–1814), French publicist and politician, was born at Riom (Puy-de-Dôme) on Feb. 11, 1740. He entered the civil service and was employed successively at the French embassy in Lisbon, in the administrative department of the duc de Broglie's army, as commissary in San Domingo (1767–1774), and after his return to France, as commissary general of the marine. He was sent to carry out plans of colonization in French Guiana in 1776, but superseded in 1779. He became intendant of Toulon, and in 1789 nas returned to the states-general. He emigrated to England in Sept. 1792, but later tried and failed to obtain permission to assist in the defense of Louis XVI. In 1801 Napoleon restored him to his position in the civil service, and sent him to Antwerp as commissioner general and maritime prefect. He entered the council of state in 1810, but offended the emperor by his plain speech, and was disgraced in 1812. Louis XVIII made him minister of marine at the Restoration, and he died on Sept. 7, 1814.

For accounts of his domestic and colonial policy see *Collection de ses opinions a l'Assemblée Nationale,* 3 vol. (1791–92); and *Collection de mémoires et correspondances officielles sur l'administration et notamment sur la Guiane française et hollandaise,* 5 vol. (1802).

MALPIGHI, MARCELLO (1628–1694), Italian physiologist, the founder of microscopic anatomy, was born on March 10, 1628, at Crevalcore near Bologna, where he graduated in medicine in 1653 and where he became lecturer in 1656. A few months later he nas appointed to the chair of theoretical medicine at Pisa, but after four years he returned to Bologna. In 1662 he was appointed professor primarius at Messina. After a further four years he again returned to his native university, and spent the next 25 years there. In 1691 he moved to Rome as private physician to Innocent XII, and he died there on Nov. 30, 1694. Shortly before his death, he drew up a long account of his academic and scientific labours, correspondence and controversies, and committed it to the charge of the Royal Society of London, which published his autobiography in 1696.

Malpighi was one of the first to apply the microscope to the study of animal and vegetable structure, and his discoveries were of major importance. Although Harvey had correctly inferred the existence of the capillary circulation, he had never seen it; it was reserved for Malpighi in 1661 (four years after Harvey's death) to see for the first time the blood coursing through a network of small tubes on the surface of the lung and of the distended urinary bladder of the frog. This discovery was given to the world in two letters, *De pulmonibus,* published at Bologna in 1661 and often reprinted. These letters contained also the first account of the vesicular structure of the human lung, and they made a theory of respiration possible for the first time.

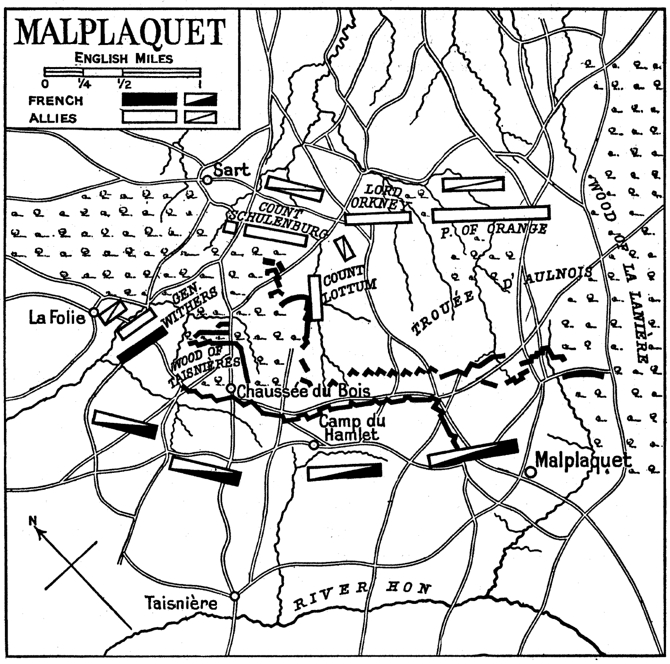
Malpighi's next achievement was a demonstration of the plan of structure of secreting glands. He maintained that the secretion was formed in terminal acini standing in open communication with the ducts. The name of Malpighi is still associated with his discovery of the mucous character of the lower stratum of the epidermis, of the vascular coils in the cortex of the kidney and of the follicular bodies in the spleen. He was the first to attempt the finer anatomy of the brain, and described the distribution of gray matter and of the fibre tracts in the cord, with their extensions to the cerebrum and cerebellum, with great accuracy, though from his microscopic study of the gray matter he concluded that it was of glandular structure and that it secreted the "vital spirits." At an early period he applied himself to vegetable histology, and became acquainted with the spiral vessels of plants in 1662. His *Anatomia plantarum,* published in 1672, included the *Observationes de ovo incubato,* which gave one of the best accounts (with good plates) of the development of the chick. His *Diss. epist. de bombyce* (1669) elaborately described the structure and metamorphosis of the silknorm.

Malpighi also wrote *Epistolae anatomicae Marc. Malpighii et Car. Fracassati* (1662), on the tongue, brain, skin, omentum, etc.; *De viscerum structura: exercitatio anatomica* (1669); *De structura glandularum conglobatarum* (1689). *Opera posthuma, et vita a seipso scripta* (1697) with preface and additions was published at Amsterdam in 1700. An edition containing all his works except the last two was published in London in 1686.

See Logan Clendening, *Source Book of Medical History,* pp. 209–217 (1942).

MALPLAQUET, a village of France in the Nord *département,* close to the Belgian frontier and about 10 mi. S. by E. of Mons, famous as the scene of the battle, Sept. 1709, between the Allies under the duke of Marlborough and Prince Eugkne and the French commanded by Marshal Villars, in which the former were victorious. The country to the west and south of Mons is enclosed by a semicircular wall of woods and broken ground, through nhich there are only two important gaps — that of Jemappes (*q.v.*) (famous in 1792) to the west, and that of Aulnois, in which stands the village of Malplaquet, to the south. In the latter gap and the woods on either side Villars took up his position facing northeastward, on Aug. 29 (Sept. 9). The forces present, over 90,000 on each side, were exceptionally large, and the French army in particular represented the spirit of its nation to a degree unusual in the armies of that time. Villars was the best general in the service of Louis XIV and the veteran Marshal Boufflers, though senior to him, had volunteered to serve as his second in command. Marlborough and Eugkne lay uith their army between Mons and the French camps, uhich were almost within cannon shot. Marlborough's own wish mas for an immediate battle, but he was opposed by the Dutch deputies at his headquarters, and even by Eugkne, so that it was only on Aug. 31 (Sept. 11) that the attack actually took place. Villars had made full use of his respite. The French right stood at the fringe of the wood of Lanière, the left was strongly posted in the midst of the wood of Taisnikre, and across the $2\frac{1}{2}$ mi. of open ground between the woods the position was entrenched with several successive lines of works. The troops were almost equally distributed along the whole line as usual, and the cavalry was massed in rear of the infantry. In the Allied army the mounted troops were also kept back, but for the most part distributed to the various infantry commands.

The intention of Marlborough and Eugkne, when on the morning of the battle they examined this formidable position, was to deliver the main attack upon the French left wing, combining the assaults of several columns on its front and flanks. In this quarter the French not only held the interior of the wood but also were thrown forward so as to occupy the edges of its north-eastern salient, and upon the two faces of this salient Count Lottum with the Prussians, and Count von der Schulenburg with the Austrian infantry were to deliver a convergent attack, while farther to the Allied right a column under the English general Withers was detached to make a wide turning movement through the woods. Marlborough took command on the right, Eugène on the left. The centre, which was intended only to observe the enemy until the decision had been forced at the wood of Taisniiire, consisted of Lord Orkney's British corps and the prince of



FROM FORTESCUE, "HISTORY OF THE BRITISH ARMY" (MACMILLAN)

PLAN OF THE BATTLE OF MALPLAQUET. SEPT. 9-10. 1709

Orange's Dutch contingent. The salient of the Taisniiire wood was duly attacked, after a heavy cannonade, on its two faces by the Prussians and Austrians about 9 A.M. They encountered a sterner resistance than in any of the battles and combats of the past seven campaigns, for on this field the defenders were fighting, not as hitherto for the interests of their king, but to defend their country, and the regiments of Picardie and Champagne which held the salient were the oldest and most famous of the French line. Lottum attacked again and again without success, until three British battalions had to be sent to reinforce him, and Marlborough placed himself with a corps of cavalry in close support. At last the entrenchments were stormed. Schulenburg had by this time fought his way through the woods and undergrowth, and the united force pressed back the French. Still, so stubborn was the defense and so dense the wood that the impetus of the assault died away and the troops on both sides broke up into small disconnected bodies, fighting too fiercely to be amenable to superior control.

But the French were not reinforced from their right wing as Villars expected. The prince of Orange, far from merely observing the hostile right as he had been ordered to do, committed his corps. very early in the battle, to a serious assault upon it, which Boufflers repulsed with enormous loss. The Dutch infantry never recovered from its casualties on this day, and the memory of Malplaquet was strong even at Fontenoy nearly 40 years afterward. The only advantage to the Allies was that Boufflers did not dare send reinforcements to the hard-pressed left wing. Because of this the attackers made steady progress in the wood of Taisnikre. Villars launched the "Irish brigade" to check the advance of the Allies, and this famous corps charged into the forest. Villars, Eugkne and Marlborough personally led their troops in the encounter which followed. Eugène was wounded, but refused to quit the field. Villars was more seriously hurt, and after trying in vain to direct the fighting from a chair was carried insensible from the field. At this crisis General Withers, who commanded the force that had been ordered to turn the French extreme left, appeared on the scene. The British 18th regiment (Royal Irish), encountering the French Royal Irlandais, put them to the rout, and Villars' counterstroke was at an end. The French maintained themselves on this side only by the aid of troops drawn from the centre and right, and this gave the Allied centre the opportunity which the prince of Orange had so rashly anticipated. The great attack over the open was carried out, in spite of the previous repulse, with the greatest determination. Preceded by 40 guns, the corps of the prince of Orange and Lord Orkney swiftly carried the first line of works. The Allied cavalry then pushed out to the front, and horse, foot and artillery were combined in the last advance. Boufflers's cavalry masses, coming into play for the first time, fought hard, and the struggle fluctuated with the arrival of successive reserves on either side, but in the end, shortly before 3 P.M., Boufflers (who had been in command since Villars's fall) decided to retreat. The Allies had no troops left intact for the pursuit, and those engaged had expended their last efforts. Moreover Boufflers, experienced soldier as he was, drew off his men before they had lost their order and discipline.

Thus this "very murdering battle" as Marlborough called it—the last and greatest pitched battle of the war—was almost barren of results. The Allies lost not less than 20,000 men, or nearly a quarter of the whole force, the 30 battalions of the Dutch infantry losing half their numbers. On the French side there were some 12,000 casualties.

MALT is a food product prepared from cereal grain by allowing partial germination to modify the seeds' natural food substances. Except for wrinkling of the husk, malt has mostly the physical appearance of the grain from which it was prepared. Malt itself is seldom a constituent of human food. It is rather an extract or the result of an enzymatic digestion by malt that is found in "malted" foods. Hence the term is frequently but erroneously applied also to a concentrated sirupy aqueous extract of malt. The starch of malt is mellower and more soluble than that of the original grain. Its protein has become partially hydrolyzed. The enzymes (*q.v.*) developed during the malting process are responsible for its industrial importance.

Any cereal grain may be converted to malt by germination but barley (*q.v.*) is the favoured grain and has been hybridized to improve its malting quality wherever it is grown. Rye, wheat, rice and, to an even lesser extent, corn are malted in some countries, usually as a result of tax complications or legal restrictions protecting native farm products.

Uses.—The largest bulk of malt is used in the manufacture of beer (see BREWING) and most of the extractives in beer are derived from malt. Hence the flavour of beer is predominantly the result of the malt from which it was made. From 30 to 50 lb. of malt are used to make a barrel of beer, depending upon its strength and the use of adjunct starches.

The next most important use of malt is in the production of distilled alcohol for both beverage and industrial purposes. It is used in this case almost entirely for its enzymatic ability and is hence specially prepared as a high-diastatic or distiller's malt. The diastase of malt converts starches, obtained from corn, potatoes or other economical sources, into sugars which are then fermented to alcohol and concentrated by distillation. Distiller's malt is also used in the production by fermentation (*q.v.*) of other solvents such as acetone, butanol and other higher alcohols.

Malt extracts are either sirupy concentrates or dry powders resulting from the evaporation of strained mashes of malt and water, sometimes including added starchy materials. The malt contributes maltose (a sugar not as sweet as cane sugar), dextrins, soluble protein and vitamins, especially of the B complex, to these materials. The extracts are used to impart a "malted" flavour to confections and food mixtures. Many special baby foods are prepared in a similar manner. If milk is added before drying the resulting powder is the familiar malted milk. Frequently these products are made so as to retain diastatic activity and are offered as aids to digestion. Diastatically active malt extract is used by bakers to improve the fermentation of their dough, thereby influencing the texture of their products.

While malt contains enzymes other than those capable of hydrolyzing starch. it owes its importance primarily to this ability. Starch sizing applied in the processing of textiles may be removed by enzymatic solubilization utilizing a malt extract as the source of amylase.

Method of Manufacture. — Malt production is a controlled and limited germination initiated by adding moisture and arrested by removal of the moisture before the young plant grows out of the seed covering. Production thus depends upon the life processes inherent in a dormant seed. The first step after the barley has been cleaned and sorted as to kernel size is to steep it in water for about 24 hours until the kernel has absorbed from 40% to 45% moisture. This absorption awakens the embryo and causes the life processes to begin. The dampened grain is then moved to a germinating apparatus, which may be a revolving drum or a rectangular open tank equipped with slow-moving agitators. In the second half of the 20th century a few smaller establishments still spread the grain on a floor and turned it by shoveling.

In either system a means is devised to conduct cooled and moistened air through the mass of sprouting grain and a gentle method of moving the grains is provided so as to prevent matting of the roots. Carbon dioxide is thus removed along with heat developed during the process. Growth and modification of the starchy constituents of the original grain are controlled through manipulation of temperature and moisture within the "piece," as the batch of grain is called.

During germination, enzymes are activated particularly along the scutellum, a membrane separating the embryo, which is largely proteinaceous, from the endosperm or starchy portion of the kernel. These enzymes include cystase, phytase, amylases, phosphorylases, proteases and, in fact, all those which the embryo plant will use in breaking down the food material stored in the endosperm and building it into root and eventually stem structures. These enzymes permeate the endosperm, converting the contained flinty starch into a softer and more soluble form. Some of this starch is hydrolyzed to maltose and dextrose, which are phosphorylated and then pass through the scutellum where they are reconverted to starch in the rootlets that push out at the bottom of the kernel. An incipient stalk called the acrospire also grows upward from the embryo along the side of the kernel inside the hull and will eventually erupt from the top of the kernel to become the aboveground structure of a normal plant if the process is allowed to continue.

Since it is the enzymes and the partially converted starch that are desired, rather than a new growing plant, the growth or germination is stopped in malting when the acrospire has grown to or slightly beyond three-quarters of the kernel length. During this time the rootlets have generally attained a length of about an inch and the endosperm has been rendered entirely mellow. This change may take from four to nine days depending upon the temperatures permitted and the use for which the malt is intended.

When the desired amount of modification has been attained the biological processes are stopped by the simple expedient of removing the moisture necessary to sustain them. This cutoff is accomplished in a kiln, the floors of which are perforated to permit an upward current of dry, heated air to dry the grain. There are many kiln designs and many ways of operating them to control the rate of moisture removal and the amount of heating that is given. Timing and heat intensity govern the amount of caramelization and other changes that are associated with the development of both flavour and colour. Additional flavours are often imparted by the character of the fire used. For example, malt intended for Scotch whisky is dried over a fire to which peat is added. The ensuing smoke is taken up by the malt.

Distiller's malts and others retaining highest enzymatic activity are kilned at low temperatures, around 120° F., to preserve as much of the biological ability as possible. Consequently such malts are pale in colour and have little flavouring value. Some kernels retain the ability to grow. Those malts that are to be used primarily for flavouring or colouring qualities are kilned at temperatures in excess of 200° F. and retain little enzyme action. Malt intended for both enzymatic and flavouring purposes is finished off at intermediate temperatures.

Historical. — The processes of malting, brewing and baking have been closely entwined for a longer period of time than is covered by recorded history. Each was well known and developed into a triple industry or special activity in Egypt at the time of the Pharaohs. Records left by all of the ancient agricultural civilizations indicate that these arts had developed long before. Consequently the origin is resigned to the realm of Egyptian mythology. Osiris, the god of light, health and agriculture, taught man to malt as a preliminary step to brewing an alcoholic beverage that might allow him to escape the woes of the world. Man simultaneously discovered the leavening power of fermenting beer.

Since the sprouting of grain and fermentation will occur even without man's guidance. it may be safely assumed that early man sampled and liked a fermenting watery supernatant that he found over stored grain that had become drenched by rains. By observation, many deductions, experiments and, no doubt, a few temporary illnesses he learned to control the process of malting.

Except for more accurate understanding of the biochemical changes involved, which led to better control, and for mechanical improvements, the malting process and its related processes of brewing and baking have remained unchanged.

In the period around 3000 B.C. spelt, wheat and barley were thrashed and winnowed by hand labour and stored in granaries for subsequent use. The biblical story of Ruth is a familiar reference to this though much more detailed and earlier information is contained in pyramid findings and in the Egyptian Book of *the Dead*.

To prepare malt from this grain it was spread upon a flat surface in a pile perhaps about knee high and watered liberally until rootlets began to appear — after about two days. Water would then be added only to keep the pile moist and the grain would be turned by wooden shovels to keep the pile from overheating. Exact elements of control are unknown but it is possible that traditional tests of biting, kernel flexibility, buoyancy and the like may have had their origin this far back.

The first processes probably utilized green or undried malt for further processing, and earliest attempts at drying must have included spreading in relatively thin layers in the sun. Certainly the arid climate of Egypt at least contributed to very early adoption of dry air currents.

Throughout ancient history and into the middle ages few changes in even the methods of manipulation occurred. The European monasteries and the princely households continued to malt the available grain and, with the necessity of using heated kilns to dry the product in colder and more humid environments, the control of flavour was introduced.

As in other arts, control did not really improve until adequate means of measuring conditions developed. Uniformly scaled thermometers were introduced in the early 18th century. Other instruments followed and were adopted by the maltster-brewers. Barley became the favoured grain to malt and was ruled the only permissible grain for beer in Hamburg in the 12th century.

Not until 1873 was a satisfactory substitute for the hand labour of floor malting devised. In that year Nicholas Galland introduced a mechanical system termed the pneumatic method. While power-driven machinery had been put to use in many other industries before this, even including other brewery operations, no device had been gentle enough to both agitate and protect the grain during its germinating. Galland provided a rectangular compartment having a perforated false bottom that would allow passage of water or air but not of grain. A series of revolving augers reached into the grain to turn it as a rope drive supplied power which also enabled the entire agitator assembly to traverse the length of the compartment on a rack-and-pinion arrangement.

Shortly thereafter the rotating-drum system was introduced. From that time on further improvements were rapidly adopted; electric power, controlled speeds, oil- and gas-fired kilns, artificial refrigeration and volume handling were among the major innovations. None of these have, however, contributed new biological processes. The methods but not the process changed.

These improvements have altered the complexion of the industry substantially. At one time every brewer malted his own grain. Now the greater number of them buy malt from large separate maltsters, although a few of the larger breweries continue to malt much of their own requirements. This specialization has led to expansion in the use of malt for other purposes, to the more economical accomplishment of the changes, to the establishment of research laboratories devoted solely to malting problems and to greater support for barley-improvement programs of benefit to the barley growers.

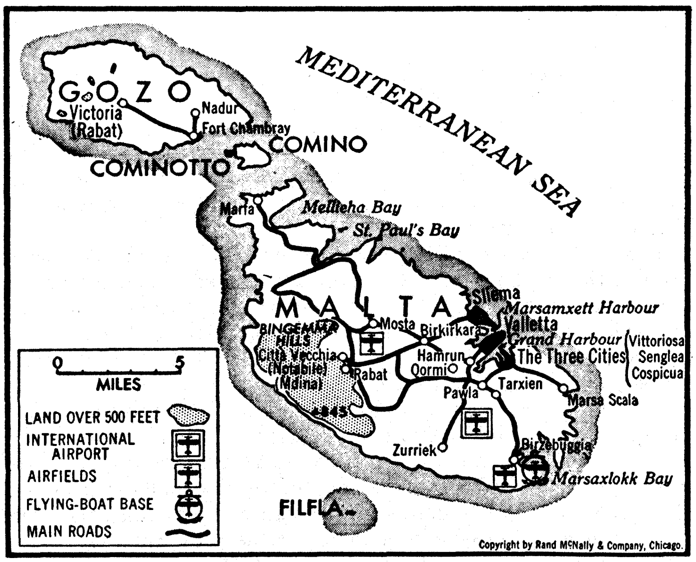
(R. I. T.)

MALTA. The Maltese islands are situated between Europe and Africa, in the central channel which connects the eastern and western basins of the Mediterranean sea. The group belongs to the British Commonwealth and consists of Malta. 95 sq.mi., Gozo (*q.v.*) 26 sq.mi., Comino, 1 sq.mi., and the uninhabited rocks called Cominotto and Filfla.

Malta (lat. of Valletta observatory 35° 53′ 55″ N.. long. 14° 30′ 45″ E.) is about 60 mi. from the nearest point of Sicily, 140 mi. from the mainland of Europe and 180 mi. from Africa; it has a magnificent natural harbour.

Malta is about 17 mi. long by 9 mi. wide; Gozo is 9 by $4\frac{1}{2}$ mi. This chain of islands stretches 29 mi. from northwest to southeast. On the southwest the declivities toward the sea are steep, and in places rise abruptly some 400 ft. from deep water. The general slope of these ridges is toward the northeast, facing Sicily and



PRINCIPAL TOWNS, ROADS AND AIR BASES OF THE MALTESE ISLANDS

snow-capped Etna, the source of cool evening breezes. The Bingemma hills, rising 750 ft., are nearly at right angles to the axis of the main island and the geological "Great Fault" stretches from sea to sea at the foot of these hills. The island has no river or lake. There are good anchorages in the channels between Gozo and Comino, and between Comino and Malta. In addition to the harbours of Valletta (*q.v.*), there are in Malta, facing northeast, the bays called Mellieha and St. Paul's, the inlets of Sliema, of Madalena, of St. Julian and of St. Thomas; on the southeast there is the large bay of Marsaxlokk (Marsa Scirocco). There are landing places on the southwest at Fomh-il-rih and Miggiarro. Mount Sceberras (on which Valletta is built) is a precipitous promontory, about 1 mi. long, pointing northeast. It rises out of deep water; well-sheltered creeks indent the opposite shores on both sides. The waters on the southeast of Valletta form the "Grand Harbour," having its entrance between Fort Ricasoli and Fort St. Elmo. The series of bays to the northwest, approached between the points of Tigné and St. Elmo, is known as Marsamxett (Marsamuscetto) harbour.

PHYSICAL FEATURES

Geology. — The Maltese islands consist largely of Tertiary limestone, with somewhat variable beds of crystalline sandstone, greensand and marl or blue clay. The series appears to be in line with similar formations at Tripoli in Africa, Cagliari in Sardinia, and to the east of Marseilles. To the southeast of the Great Fault the beds are more regular and descend from coralline limestone through greensand, marl or blue clay and sandstone to crystalline limestone. The lower limestone probably belongs to the Tongrian stage of the Oligocene series, and the coralline limestone to the Tortonian stage of the Miocene. The beds are not folded. The general dip of the strata is from west-southwest to east-northeast. North of the Great Fault and at Comino the level of the beds is about 400 ft. lower.

Mammalian remains found in Pleistocene deposits are of exceptional interest. Among the more remarkable forms are a species of hippopotamus, the elephant (including a pigmy variety), and a gigantic dormouse. In the coralline limestone the following fossils have been *noted: — Spondylus, Ostrea, Pecten, Cytherea, Arca, Terebratula, Orthis, Clavagella, Echinus, Cidaris, Nucleolites, Brissus, Spatangus;* in the marl the *Nautilus zigzag;* in the greensand shells of *Lenticulites cornplanatus,* teeth and vertebrae of Squalidae and Cetacea; in the sandstone, *Vaginula depressa, Crystallaria, Nodosaria, Brissus, Nucleolites, Pecten burdigallensis, Scalaria, Scutella subrotunda, Spatangus, Nautilus, Ostrea navicularis* and *Pecten cristatus.*

The blue clay forms, at the higher levels, a stratum impervious to water, and holds up the rainfall, which soaks through the spongy mass of the superimposed coralline formations. Hence arise the springs that run perennially, several of which have been collected into the gravitation water supplies of the Vigna-court and Fawara aqueducts. The larger part of the water supply is pumped from strata at about sea level.

Climate. — The climate is, for the greater part of the year, temperate and healthful. During the winter the weather is pleasantly cool and sometimes cold, owing to the strong winds, but there is much bright sunshine, and the air is clear and invigorating. The thermometer records an annual mean of 66° F. Between June and September the temperature ranges from 75° to 90° F.; the mean for December, January and February, the three coldest months, is 56° F., the mean maximum being 65.5° F. and the mean minimum 46.6" F. Pleasant northeast winds blow for an average of 150 days a year, cool northerly winds for 31 days, east winds for 70 days, west for 34 days.

The northwest "gregale" (Euroclydon of *Acts* xxvii. 14) blows about the equinox, and occasionally, in the winter months, sometimes with almost hurricane force for three days together; it is recorded to have caused the drowning of 600 persons in the harbour in 1555. This wind was a constant menace to shipping at anchor; the breakwater on the Monarch shoal was designed to resist its ravages. The sirocco, an enervating southeast wind, blows at intervals during the summer months, causing close, damp and misty weather.

The regular tides are hardly perceptible, but, under the influence of barometric pressure and wind, the sea level occasionally varies as much as 2 ft. Rainfall is irregular; it averages 17 in., varying from 12 to 27 in. in the year. However, rainfall is uncertain, and periods of drought have extended over three years. Snow is seen once or twice in a generation; hailstorms occur.

Flora. — The calcareous nature of the rocks and soils and the fact that the water contains lime excludes the calcifuges from the Maltese flora. Many of the plants are xerophytic. The vegetation is of the Mediterranean type, and most of the species found in the Maltese islands also occur in Sicily and Italy, though African and Iberian species as well are found. Of the trees, none of which grows to any great size, the commonest is the carob which is indigenous and was extensively cultivated in the first half of the 19th century but largely destroyed during World War I; since then it has had government protection. The elm, white poplar and some willows grow in the valleys with wild pear and hawthorn. The almond and prickly pear are naturalized, and on Gozo and Comino the chaste tree (Vitex *agnus-castus*) is a common native shrub. The fig is native in Malta and the vine, bay and olive have been cultivated for centuries. The many rock plants growing near the sea include Inula crithmoides, Crithmum *maritimum*, Crucianella maritima, saltwort, sea campion, sea heath, spurge and marram grass. On the rocks inland kidney vetch, medic, thyme, Lotus, *Cistus*, Helianthemum, etc. are found. After the spring rains Colchicum, Crocus and *Scilla*, buttercups and dandelions, etc., burst into bloom. and in the autumn lady's tresses and squills flower. The summer annuals include heliotrope, spurge, Linaria and Inula and, along the watercourses, Lythrum, *Polygonum*, convolvulus, etc. A plant endemic to Malta is Centaurea crassifolia. The parasitic "Malta fungus" (Cynomorium coccineum), which has bright red flowers and was once valued for medicinal purposes, is also found in Tunisia, Sicily, Crete, Iran and the Canary Islands.

Fauna. — The indigenous mammals consist of weasels, hedgehogs and bats (the little horseshoe and the long-eared); rabbits, rats and mice have been introduced. There are seals and porpoises in the surrocnding seas. Among the few indigenous birds are the blue solitary thrush, which is prized for its song, the spectacled warbler, two species of shearwaters and the jackdaw.

The great variety of bird visitors includes bee eaters, rollers and hoopoes, vultures, eagles, swans, ospreys, robins. blackbirds, thrushes, swallows, cuckoos and skylarks; among those that stay to breed are owls, linnets, buntings and the rock pigeon.

There are species of lizards, a turtle and a tortoise, two species of snakes (imported) and the painted frog, which is used for food. In the surrounding waters tunny, mackerel and bonito arrive at intervals in huge shoals; brill is the commonest of the flatfish; there are also herrings, sardines and anchovies, tench, flying fish, perch and mullet, remora and many kinds of gurnard.

The commonest of the 17 species of butterflies breeding in the islands is the cabbage white which often causes much damage and arrives in swarms in spring and autumn. Locusts migrate to breed where there is more moisture; large numbers of ladybirds often arrive in the spring from Sicily and other insects include cockroaches, beetles, plant bugs, grasshoppers, flies, dragonflies, moths, bees, Rasps and ants. Crabs, lobsters. crayfish and other crustacea, and mollusca, chiefly limpets, mussels, cuttlefish and octopus, are used for food. The commonest of many zoophytes (sponges, polyzoans and hydroids) is Anthea cereus. (ST.; X.)

ARCHAEOLOGY

There is no conclusive evidence for Palaeolithic man in Malta, since the identification of the two teeth from Ghar Dalam as those of Homo neanderthalensis is doubtful and at all events they do not seem to have been found associated with the rich Pleistocene fauna of hippopotamus and elephant in the cave.

The same site, however, produced shards of pottery which represent the earliest Neolithic colonists of the island, related to those from the Mgarr temple (see below) and to the Stentinello type in Sicily. Similar pottery occurs in the earliest Neolithic levels of the Arene Candide cave in Liguria. But the most notable evidence of prehistoric man in Malta is afforded by the monumental stone buildings usually known as temples and by the huge rock-cut collective tomb or hypogeum at Hal Saflieni. The best-preserved of the temple structures are at Hal Tarxien, Hagar Qim, Mnajdra and Mgarr in Malta, and at Ggantija on Gozo; less striking remains of similar buildings exist at Borg in Nadur, Kordin, Skorba and elsewhere.

The temples are built of the local limestone, though fine *Globigerina* limestone was sometimes brought from several miles away, especially where fine-dressed surfaces or decorative carvings were demanded. The plans of the buildings are based on the theme of apsidal chambers, usually in pairs, opening from an axial passage or central court, and the whole complex is enclosed in a massive stone revetment, roughly oval in plan, with a concave façade and forecourt at the entrance. The evidence implies that the majority of the apsidal chambers were roofed by first carrying several courses of corbelled vaulting above the slabs forming the walls and then laying large flat capstones across; but it is uncertain whether some of the very large chambers (*e.g.* at Mnajdra) were in fact roofed in stone, as the large span presents great technical difficulties, and it is likely that the courts giving access to the chambers were always open to the sky, though in both instances temporary coverings of hides or textiles could have been used. The standard of building, with its fine dry jointing and carefully dressed surfaces, is of high technical quality; and in certain of the temples, probably relatively late in any sequence of construction, there is elaborate surface decoration of low-relief carving (either as naturalistic animal friezes or as spiral patterning) or of close-set pitting apparently made with a drill. Although all the free-standing temples are now ruined and roofless, the interior detail of the rock-cut chambers at Hal Saflieni and models of temples or their façades from Mgarr and Hal Tarxien give evidence for reconstructing the roofs on the lines suggested.

In addition to the low-relief carving, there is a large series of figures carved in the round, usually representing obese females and ranging from specimens a few inches high to a statue (of which the lower part alone survives) of a woman in a flounced skirt at Hal Tarxien which is well over life-size; at Hal Tarxien too is an enormous bowl carved out of solid stone. There is evidence that much, if not all, of the carving and ornament was originally painted, and at Gigantia traces of interior wall plaster with red paint on it were recovered. In the Hal Saflieni hypogeum, elaborate spiral patterns are painted in red in certain of the chambers.

Although the hypogeum was certainly used for a vast series of collective burials, its function need not have been wholly or primarily sepulchral, and there is no evidence that the temples were used primarily for burial. But their affinities in architecture and in planning are certainly with collective burial vaults, either rock-cut or built above ground of large stones, which are known from many areas in the western Mediterranean and belong to the beginning of the 2nd millennium B.C. The Maltese temples have yielded a rich series of pottery finds, of which the earliest is the incised white-filled ware of Mgarr, allied to that of Stentinello. There follow wares with fine ornament scratched on them and filled with red or white colouring matter in techniques characteristic of early Southeast Italian, Ligurian and South French neolithic pottery, and this style may in part be an imitation of Italian neolithic painted pottery — shards of painted ware were indeed found at Mgarr and elsewhere. The latest neolithic pottery includes volute or spiral patterns, and these, especially the similar patterns in stone carving, seem likely to be related to the Mycenaean world in the late 17th or 16th centuries B.C. The figure-sculpture and animal reliefs again is something which points to the eastern Mediterranean for origins. The use of the sling in Neolithic Malta (attested by sling stones) may imply Aegean contacts.

At Hal Tarxien, at a period when the original temple was deserted, a cremation cemetery with many burials was established within the precincts. With the burials was pottery of a style quite dissimilar from that of the earlier sites; and there were also bronze or copper flat and flanged axes and flat riveted knife daggers. Although these metal types are primitive in themselves. a cremation cemetery in the central Mediterranean region can hardly be earlier than those which appear to be the prototypes of this form of burial, in Anatolia and Syria, belonging to the 14th century B.C. and later. This then would give some sort of a terminus ad quem for Hal Tarxien, likely to have been deserted by about the 12th or 13th century B.C. at the earliest; and this, taken in conjunction with the western Mediterranean affinities already mentioned, would seem to indicate that the whole range of Maltese neolithic temples and allied structures would lie within the centuries after 2000 B.C.

The Maltese Bronze Age is represented not only by the Hal Tarxien cemetery but also by pottery finds at Borg in Nadur, at Bahrija and at other sites in the island. The Borg in Nadur pottery, from a settlement site within a probably contemporary defensive wall across a promontory, is exactly paralleled by the Thapsos red ware of Sicily dated by Mycenaean imports to the 14th century B.C. and later. A shard of Late Helladic III pottery from Borg in Nadur confirms this dating.

There are rock-cut tombs attributable to the Maltese Neolithic period at Attard and at Busbisija (Mosta). A small inhumation cemetery of five graves at Ta Trapna iz-Zghejra (Zebbug) revealed a novel type of pottery not represented in the temples or in other tombs, but probably early in the local Neolithic sequence.

There is a blank in Maltese prehistory after the Bronze Age until the coming of Punic colonists in the second half of the 1st millennium B.C. Numerous Punic tombs show the island to have been an important colony; their range of date may extend to that of the Roman occupation.

A remarkable type of antiquity in the island is that of the so-called "cart-ruts," pairs of parallel grooves worn into the rock and having a span of about $4\frac{1}{2}$ ft. It seems that these ruts could not have been made either by cart wheels or, because of the relatively sudden curves in many of them, by sledges: the best suggestion is that they were worn by a primitive form of "slide car" of a type still surviving in parts of Europe, in which the load is dragged on a pair of poles joined at their forward end (water carried in skins would be a likely burden). At one point the line of a pair of ruts crosses the mouth of a Punic tomb shaft in such a manner as to suggest that the tomb was the later feature; this is the only piece of dating evidence that can be adduced, except that at Birzebbuga another pair runs under a shallow inlet of the sea, showing that some marine transgression has taken place since its use.

(S. PT.)

HISTORY

Until recent times Malta's megalithic monuments were considered to be the best proof of a Phoenician settlement in the islands. Although modern archaeology has established that these were built by prehistoric man, many historians still believe that the Phoenicians sought refuge or settled in Malta at some period of their travels throughout the Mediterranean. Up to a few centuries ago remains of two temples were extant; some held that these were Phoenician dedicated to Melkart (Hercules) and Astarte (Juno). The old temple of Juno was mentioned by Ptolemy, the geographer, Cicero and Valerius Maximus. Old historiographers record the existence of scattered remains of alleged Phoenician origin. but these have since disappeared. In Phoenician times Malta (Melita) must have been a prosperous trading centre and an independent colony. Greek inscriptions, coins and works of art found in the island induced authors to state that the Maltese islands passed through Greek hands after the Phoenician period. This theory has recently found many adversaries who are only prepared to admit a strong Hellenic influence over the islands.

In the 6th century B.C. the Carthaginians landed at Malta and several Punic coins and inscriptions seem to belong to this period. Historians write that Carthaginian rule was very harsh and that oppressive tribute was levied. This would explain why in 218 B.C. the Maltese gave up the garrison to T. Sempronius in circumstances described by Livy (xxi, 51). This led to Malta and Gozo being granted by the Romans the privileges of a *municipium*. Cicero refers to the Maltese as *socii;* they coined their own money, had the right of sending ambassadors to Rome and of controlling their own domestic affairs. The islands thus attained the highest form of liberal government known in those times and their prosperity is attested both by Cicero and also by Diodorus Siculus. The latter arites of the beauty and ornamentation of Maltese houses, and to this day remains of palaces and dwellings, foremost among which is the Roman villa at Città Vecchia, indicate a high degree of civilization and wealth. When forced to select a place of exile. Cicero was at first attracted to Malta (Ad *Atticum,* iii, 4; x, 1, 8, 9) over which he had ruled as quaestor in 75 B.C.

The most important event in Maltese history occurred in A.D. 60 when the apostle St. Paul was shipwrecked in the bay which now bears his name; according to tradition and to St. Chrysostom (*Hom.* 54) he converted the inhabitants to Christianity. Publius was "chief of the island" and is said to have become the first Christian bishop of Malta. The site where the cathedral at Citti Vecchia stands is reputed to have been the residence of Publius, where the first miracle was wrought (Acts xxviii, 7, 8). Outside the walls of Notabile there are the Maltese catacombs (4th and 5th century A.D.) which are strikingly similar to those of Rome and which were used as places of burial. Malta was not affected by the Greek schism and remained steadfast in its allegiance to Rome.

On the final division of the Roman dominions in 395, Malta was assigned to the empire of Constantinople and it seems to have undergone the same fate as Sicily; some hold that it was conquered by the Vandals and Goths in the 5th century-and reunited to the empire by Belisarius in 533. In August 870 the Arabs made themselves masters of Malta, massacred the Greek garrison and sold the Greek population to the native inhabitants. Unable to garrison the island with a large force, the Arabs cleared a zone between the central stronghold, Medina (Citti Vecchia), and the suburb called Rabat, to restrict the fortified area. Many Arab coins, some Kufic inscriptions and several burial places were left by the Arabs; they did not establish their religion but they gave to Malta their language, some place names and a few customs. The old belief that the Maltese language is a direct heritage of ancient Phoenician has been scientifically disproven by latest researches in Maltese linguistics. Since Arab times, however, Maltese has been so largely influenced by the Siculo-Italian and other European languages that it may be considered in many respects to stand alone as an independent language.

In 1091 Count Roger the Norman (son of Tancred de Hauteville), then master of Sicily, came to Malta with a small retinue and he was hailed as deliverer by the inhabitants. According to tradition, Roger gave the Maltese their national colours, the white and red. Under the Normans the dominion of the church was re-established and bishops were appointed. The Arabs were allowed to remain on the island as vassals until 1245 or 1249 when they were expelled by Frederick II, the Swabian; upon the extinction of the Norman line, the Swabian house of Hohenstaufen had succeeded to the throne of Sicily. Gradually, feudal customs asserted themselves, and from 1192 these islands were granted as a fief to great officers of state or illegitimate descendants of the sovereign. One of these officials was Henry Piscatore, count of Malta, grand admiral of Sicily, whose glorious exploits at sea are recorded by historians.

The battle of Benevento (1266) decided the fate of southern Italy, and Malta passed under Charles of Anjou. In Fort St. Angelo the revolt of the memorable Sicilian Vespers (1282) was planned out, and beneath the same fort the Angevin fleet was defeated (1283) by Peter III of Aragon to whom the Maltese transferred their allegiance. The Maltese suffered under the feudal lords who used to receive Malta as a marquisate or countship, and in 1397, at the request of the Maltese, King Martin I incorporated the islands in perpetuity in the royal desmesnes. When Alphonso V of Aragon was in urgent need of money, he broke Martin's charter by pledging the islands (1420) to a viceroy of Sicily, Antonio Cardona. for 30,000 gold florins. The Maltese paid the debt, but the islands were given to Gonsalvo di Monroy for the same sum in 1425. A revolt, organized and directed by the commune, against Monroy's rule (1427) led the king to incorporate Malta once more in the royal domains by a charter of June 20, 1428, and the Maltese were given authority to resist, by force of arms, any intermediate lord that the sovereign might attempt to impose.

The Normans had improved considerably the political and economic condition of Malta, and they raised it to municipal status. The political organization was similar to that of the large cities of Italy: the *università,* or commune, had a great deal of control over internal affairs. It was a representative body essentially constituted to defend the ancient laws and privileges of the Maltese. It had wide powers including the election of its officers (capitano di verga, jurats, etc.), the appointment of judges and the sending of ambassadors to the foot of the throne to treat with the king. as was done in the revolt of 1427; it even taxed itself and its members. It was as liberal and democratic a body as any in Europe in the middle ages.

The knights of St. John, having been driven from Rhodes by the Turks, obtained the grant of Malta, Gozo and Tripoli in 1530 from the emperor Charles V, subject to a reversion in favour of the emperor's successor in the kingdom of Aragon should the knights leave Malta, and to the annual tribute of a falcon in acknowledgment that Malta was under the suzerainty of Spain. The Maltese at first challenged the grant as a breach of the charter of King Alphonso, but eventually welcomed the knights. The grand master de l'Isle Adam, on entering the ancient capital of Notabile, swore for himself and his successors to maintain the rights and liberties of the hfaltese. The order took up its abode on the promontory guarded by Fort St. Angelo on the southern shore of the Grand Harbour, and. in expectation of attacks from the Turks, began to fortify the neighbouring town called the Birgu (Vittoriosa). The knights lived apart from the hfaltese and derived their principal revenues from estates of the order in the richest countries of Europe. They accumulated wealth by war or by privateering against the Turks and their allies. In 1551 the African Arabs ravaged Gozo after an unsuccessful attempt on Malta.

Soliman I then prepared to conquer Malta and exterminate the order; the knights and the Maltese were expecting the attack. The great siege of hfalta, which made the island and its knights famous and checked the advance of Mohammedan power in southern and western Europe. began in May 1565. The fighting men of the defenders are variously recorded as being between 6,100 and 9.121: the roll comprises one English knight. Sir Oliver Starkey. The Mohammedan forces were estimated as being between 29,000 and 38,500. The sultan placed his troops under the veteran Mustafa. and his galleys under his youthful relative Piali; he hesitated to make either supreme and ordered them to await the arrival of Dragut with his Algerian allies. before deciding on their final plans. Against Mustafa's better judgment. Piali induced the council of war to attack St. Elmo. in order to open the way for his fleet to an anchorage, safe in all weathers, in Marsamuscetto harbour. This strategical blunder was turned to the best advantage by the grand master. Jean Parisot de la Valette, who so prolonged the most heroic defense of St. Elmo that the Turks lost 8,000 killed, besides many wounded, before exterminating the 1,200 defenders, who fell at their post. In the interval Dragut was mortally wounded, the attack on Notabile was neglected, valuable time lost, and the main objective (the Borgo) and St. Angelo left intact. The subsequent siege of St. Angelo and its supporting fortifications was marked by the greatest bravery on both sides. The knights and the Maltese fought for death or victory, without asking or giving quarter. Finally. Mustafa abandoned the siege on Sept. 8. The order thus reached the highest pinnacle of its fame, and new knights from the flower of the nobility of Europe flocked to be enrolled therein; La Valette refused a cardinal's hat, determined not to impair his independence. He made his name immortal by making Valletta a magnificent example of fortification, unrivalled in the world.

Throughout the 16th and 18th centuries the knights harassed Turkish commerce and took part as an allied Christian power in the great victory of Lepanto (1571). With the growth of wealth and security the martial spirit of the order began to wane and so also did its friendly relations with the Maltese. The civil government became neglected and disorganized, licentiousness increased and riots threatened. In 1722 the Turkish prisoners and slaves, then very numerous, formed a conspiracy to rise and seize the island, but premature discovery was followed by prompt suppression.

In 1768 the Jesuits were expelled and their property confiscated; Grand hlaster Emmanuel Pinto converted their university into one of general study. Castle St. Angelo and the fort of St. James mere, in 1775, surprised by rebels clamouring against bad government; this rising is known as the Rebellion of the Priests, from its leader, Mannarino. The last but one of the grand masters who reigned in Malta, Emanuel de Rohan. restored good government. abated abuses and promulgated a code of laws. On the death of de Rohan the French knights disagreed as to the selection of his successor, and a minority were able to elect, in 1797, a German of weak character, Ferdinand von Hompesch, as the last grand master to rule in Malta. Napoleon Bonaparte had arranged to obtain Malta by treachery, and he took possession with little resistance in June 1798; after a stay of six days he proceeded with the bulk of his forces to Egypt, leaving Gen. Claude Henri Vaubois in command with 4,000 troops.

Toward the close of the rule of the knights in Malta feudal institutions had been shaken to their foundations, but the transition to republican rule was too sudden and extreme for the people to accept. Among other laws Bonaparte enacted that French should be the official language; that 30 young men should every year be sent to France for their education; that all foreign monks be expelled; that no new priests be ordained before employment could be found for those existing; that ecclesiastical jurisdiction should cease; that neither the bishop nor the priests could charge fees for sacramental ministrations, etc. Stoppage of trade and absence of work (in a population of which more than half had been living on foreign revenues of the knights) followed the defeat of Bonaparte at the Nile and the failure of his plans to make Malta a centre of French trade.

An attempt to seize church valuables at Notabile was forcibly resisted by the Maltese, and general discontent broke into open rebellion on Sept. 2, 1798. The French soon discovered to their dismay that, behind the rubble walls of every field, the Maltese were unassailable. The prospect of an English blockade of Malta encouraged the insurgents. of whom Canon Francesco Caruana became the most prominent leader. The Maltese formed a provisional government and an assembly. Lord Nelson was appealed to and he sent his Portuguese allies to blockade the island; later, the British fleet took over and. after visiting the island. Nelson left Capt. Alexander Ball, R.N. (later Adm. Sir Alexander Ball), in command. On Feb. 9, 1799, the Maltese assembly appointed Ball as its president and head of government and troops; the British flag was hoisted side by side with the Neapolitan. Nelson still upheld the contention that the king of Sicily (as successor to Charles V in that part of the former kingdom of Aragon) mas the legitimate sovereign of Malta. After 14 months British troops were landed and suffered no casualties. Few Maltese lives were lost in actual combat, but famine and sickness killed thousands. Finally, after a siege of two years, the Maltese with the help of their British, Portuguese and Neapolitan allies forced the French to surrender. The treaty of Amiens (1802) provided for the restoration of the island to the order of the knights of St. John; against this the Maltese strongly protested, realizing that it would be followed by the re-establishment of French influence. The assembly drew up its famous Declaration of Rights in the first article of which the king of Great Britain was acknowledged as sovereign of Malta on certain conditions, such as that he should maintain the Roman Catholic religion and observe the constitution to be established by the assembly. Sir Alexander Ball governed Malta as civil commissioner from 1802 until his death in 1809.

Rather than give up Malta, England renewed the war with France, and in 1813 the British government accepted the offer made by the Maltese and acknowledged them as British subjects; the treaty of Paris (1814) ratified the compact. Sir Thomas Maitland was appointed governor and commander in chief in the Mediterranean aith absolute powers and he introduced many important reforms. The Maltese continued to petition for political liberties, and trial by jury for criminal cases was established in 1829. An advisory council of government, composed of nominated members, was constituted by letters patent in 1835, but this measure only increased the agitation for a representative legislature. Freedom of the press and many salutary innovations were brought about by the recommendations of John Austin and George Cornewall Lewis (later Sir George Lewis), royal commissioners, appointed in 1836. The chief government posts in the civil service were opened to the Maltese. sinecures abolished, legal procedure was simplified and the police established on an English footing. Queen Adelaide visited Malta in 1838 and founded the Anglican collegiate church of St. Paul. Sir F. Hankey as chief secretary was for many years the principal official of the civil administration. In 1847 Richard More O'Ferrall was appointed civil governor. In June 1849 a legislative council was constituted with ten nominated and eight elected members. The Crimean War brought great wealth and commercial prosperity to Malta. The appointment of military governors was reverted to in 1858. The administration was largely confided to the chief secretary with real power, at times, in the hands of the crown advocate. Between 1854 and 1868 the criminal, commercial and civil laws were codified. Much of this work was carried out by the crown advocate, Sir Adrian Dingli, who later became chief justice and president of the court of appeal.

An executive council was established in 1881 and the franchise extended in 1883. The director of education was determined to carry out reforms prejudicing the privileged status of the Italian language in the island and he met with stiff opposition from Fortunato Mizzi, a lawyer, and his nationalist'party. Count Gerald (later Lord) Strickland joined forces with Mizzi and together they succeeded in obtaining for Malta the constitution of 1887, which established a legislative council consisting of 14 elected and only 6 official members. The Maltese were overjoyed to see the end of a period of government by presidential casting votes and official ascendancy. All those elected, including Strickland, were supporters of Mizzi's party. After a few months Strickland accepted a government post, and in 1889 he was made chief secretary. During the 1890s there was widespread agitation respecting the laws as to mixed marriages, the Maltese relying on the Roman canon law, part of the law of Malta, and the English on the common law of England. The Holy See was consulted on the subject of civil marriage, but the question could not be settled to the satisfaction of both parties. In 1898, on opposite sides of the table, Mizzi and Strickland headed violent disputes in the legislative council on the language question, taxation and other subjects. The bitter duel culminated in a council motion, passed by the elected majority. asking for the removal of Strickland from office. In 1902 he was promoted governor of the Leeward Islands. Mizzi would not yield ground on the language question, and when, in 1903, the constitution was repealed, bureaucratic government with an official majority was again fully re-established for all local affairs.

During World War I the Maltese provided a garrison for the island, many seamen for naval ships as well as labour battalions for service at Gallipoli and Salonika. In addition, Maltese did excellent work in various hospitals. Postwar economic difficulties and agitation for constitutional reform led to violent rioting in Valletta on June 7, 1919. A national assembly was constituted similar to that set up in 1798 against the French, and a draft constitution for responsible government was drawn up. In 1921 a self-governing constitution, based upon the dyarchical principle, was granted by letters patent. Members of the senate and house of assembly were to be elected by proportional representation; judges, appointed by the governor in council, could be removed only by a joint address from both houses of the legislature; debates might be conducted in English. Italian or Maltese, but all official entries were to be in English or Italian. English was declared the official language of the administration, and Italian the official language of record in the law courts. During the Nationalist administration the two sides of the dyarchy worked the constitution with little friction.

In 1927 the Strickland ministry took office. Serious politico-religious trouble arose between government and church, and this brought in the Vatican and the British foreign office. The constitution was suspended in 1930, but restored in 1932. The Nationalists were elected to power, letters patent amending the constitution provoked an atmosphere of recrimination. and in 1933 a second suspension followed. Then, by letters patent, Italian lost its position as an officiallanguage and as the language of the courts. In 1936 the constitution was revoked; powers were vested in the governor aided by an executive council of ex-officio and nominated members. until limited representation without responsibility was granted by the 1939 constitution. A council of government of 20 members was created, 10 being elected, with 2 nominated and 8 official members; the governor had a casting though not an original vote. Thus was the clock put back 90 years.

After Italy entered World War II in 1940 Malta became subject to ceaseless aerial attacks by both German and Italian bombers from bases in Sicily. nithin 20 min. flying time. The island, which was 1,000 mi. from the nearest British position. became of the very first importance as a base of operations. For three years Malta was defended by both the garrison and the people. At the height of the siege it was possible to send supplies of aviation gasoline and munitions to Malta only by submarine, while additional fighter aircraft of the Royal Air force were flown to the island from the decks of distant carriers; food became very scarce. Despite the hardships, civilian morale stood high. On April 15, 1942, George VI awarded the George Cross "to the Island Fortress of Malta to bear witness to a heroism and devotion that will long be famous in history." This was the first time that a medal had been conferred upon any part of the British Commonwealth. The siege ended in 1943: by June 30 of that year 1.436 civilians had been killed, 3,415 wounded or injured and about 37,000 buildings destroyed or damaged. The British government awarded more than £31,000,000 to Malta as compensation for war damage.

Government after World War 11.—In 1947 self-government was once more granted to Malta. As in 1921 the constitution was based on the dyarchical system. It provided for a legislative assembly of 40 members elected by proportional representation; suffrage was extended to women; the official languages were to be English and Maltese. In the first election, Labour obtained 24 seats and, among other innovations, introduced income tax.

In 1949, following a split within the Labour party, a Workers party was formed. This gave the chance to the Nationalists to secure at the next election the greatest number of seats in the assembly, although they did not obtain a working majority. From 1951 until 1954 the island was administered by a coalition government of members belonging to the Nationalist and Workers parties. The fifth election under the present constitution was held in Feb. 1955. The reunited labour front was returned to power with 23 seats, while the other 17 seats went to the Nationalists. These two parties were divided on a constitutional issue: the Labour party favoured integration with Great Britain, or, alternatively, self-determination; the Nationalist party aimed at fully responsible government within the British Commonwealth.

(W. B. Pn.; A. G.)

THE PEOPLE

The upper classes have Norman, Spanish and Italian blood. The knights of St. John, commonly called "of Malta," were drawn from the nobility of Roman Catholic Europe. They took vows of obedience and celibacy. At the time of the British occupation there mere about two dozen families bearing titles of nobility granted or recognized by the grand masters, and descending by primogeniture. No government has ever recognized papal titles in Malta.

In appearance the Maltese are a handsome race, about middle height, well built and sturdy; they are less dark than the southern Italians. The women are generally smaller than the men, with black eyes, fine hair and graceful carriage. Their national head-dress, called the faldetta, is like a large nun's hood made of black cloth stiffened with whalebone. It falls over the shoulders like a shawl. Its origin is Arabic. The Maltese are a thrifty and industrious people, prolific and devoted to their offspring, good-humoured, quick-tempered and impressionable. Their religion is Roman Catholic.

Language.——For the most part the people have no racial affinities in Europe and, high and low, all speak Maltese among themselves, a tongue akin to Arabic with a sprinkling of Sicilian vocabulary and idioms. It is, however, different from the Italian language; the latter is spoken with a peculiar intonation by about one-sixth of the population. However, although Maltese was the medium of daily intercourse and business in the island, it had no

official standing until 1933, the two official languages being English and Italian. In 1934 letters patent removed Italian from its position as one of the two official languages and provided that "the English language, as the official language of the British Empire, and the Maltese language, as the language of the people of Malta, shall be the official languages of Malta." (See History.)

Emigration. — The phenomenal congestion of population gives interest to records of its growth. In the 10th century there were 16,767 inhabitants in Malta and 4,514 in Gozo; estimates made at the arrival of the knights (1530) varied from 15,000 to 25,000, and at the end of their rule (1798) the population was estimated at 100,000. Subsequently the population more than doubled, and in the 20th century there was a net average increase of more than 2,500 a year. Including Gozo and Comino, the civil population in 1957 was 319,620 (1948 census: 305,991), giving a density of 2.620 to the square mile, as compared with 547 in the United Kingdom. Emigration, mainly to Australia and also to the U.K., Canada and the U.S., has reduced the overcrowding. (X.)

In 1948 a Passage Assistance agreement between the governments of Australia and Malta came into force, and between Jan. 1948 and Dec. 1953, 16,482 emigrants benefited by the assistance given under the agreement. In addition, the government of Malta assisted a further 6,121 emigrants to Canada and the United Kingdom. The net total number of emigrants during this period was 31,415, of whom 16.038 went to Australia, 6,357 to Canada, 6,450 to the United Kingdom, 4,442 to the U.S., and 118 to other countries. It has been estimated that 12,000 emigrants a year should leave the islands over a period of 10 years in order that Malta could overcome its serious economic difficulties.

Education. — Primary education is compulsory (since 1946) and free in government schools. In 1953 there were 112 government primary schools with an enrolment of 42,623, 6 government secondary schools (enrolment 1,837), 3 government technical schools (enrolment 347), 8 state-aided private schools (enrolment 2,675), and 6j other private schools (enrolment 11,516). The Royal University of Malta, founded in 1769, had an enrolment of 29j men and 32 women. It grants degrees in divinity, law, medicine. architecture, engineering, dental surgery, pharmacy, arts and science. There were three technical schools and one tailoring school and two teacher training colleges.

About the middle of the 19th century a mixed system of both English and Italian, called pari passu, was adopted as the basis of Maltese education. This was followed by a new system whereby the pupils were first taught to read, write and do arithmetic in Maltese and. at a senior stage, either English or Italian. Later, the teaching of Italian in all grades again became general, and it was not until 1923 that the teaching of that language was abolished in the infant schools and in the first and second years of the elementary schools. In 1933 the teaching of Italian was discontinued in all grades of the elementary schools, both Maltese and English being taught in all government educational institutions, and the department of education produced textbooks of Maltese history. told in the Maltese language. A British institute was founded in Valletta in 1939 to impart a knowledge of British history. language, literature and music, and British ways of living and thinking.

Towns and Villages. — The capital is named after its founder, the Grand Master de la Valette, but from its foundation in 1566 it has been called Valletta (pop. 1957 census, 18,202). It contained the palace of the grand masters, the magnificent auberges of the several subdivisions or "Langues" of the order, the unique co-cathedral of St. John with the tombs of the knights and magnificent tapestries and marble work, a fine opera house and hospital. During World War II attacks by Italo-German aircraft inflicted damage to these and other historic buildings beyond possibility of restoration. Before Italy surrendered in 1943, about three out of every four houses in Valletta were damaged or demolished.

Malta is an important naval and air base and one of the headquarters of the British Mediterranean fleet. There are great naval docks, refitting yards, magazines and stores in the Grand Harbour at Valletta.

Between the inner fortifications of Valletta and the outer works, across the neck of the peninsula. is the suburb of Floriana. To the southeast of Valletta, at the other side of the Grand Harbour, are the cities of Senglea. Vittoriosa and Cospicua; this group is often spoken of as "The Three Cities."

The old capital, near the centre of the island, is variously called Città Vecchia, Notabile and (in Maltese) Mdina (*q.v.*), (the population of Citta Vecchia was 823 and of its suburb Rabat 18,792 in 1957); there are the catacombs and the ancient cathedral of Malta.

Across the Marsamxett (Marsamuscetto) harbour of Valletta is a considerable modern town called Sliema with a population (1957) of 23,399.

Malta had eight hospitals and Gozo six in the mid-1950s. There are also district medical officers, health visitors and midwives.

ECONOMICS

Agriculture. — About a quarter of the population of the Maltese islands depend for their livelihood on agriculture. There is no room for heavy agricultural machinery or implements owing to the smallness of the plots cultivated. The hoe is therefore the most commonly used implement, but in 1943 the department of agriculture introduced threshing machines, which became popular, and the rotary cultivator made an appearance. For the most part the fields are composed of terraces around which the soil has been walled up along the contours of the hills, with enormous labour. to save it from being washed away. Owing to the operation of the laws of inheritance, farms are nearly always divided into separate strips of land not adjacent to each other.

The grain crops are wheat and barley (frequently sown together), and the principal fodder crops are green barley and a tall leguminous plant called sulla (Hedysarum coronarium), with beautiful purple blossoms. Vegetables of all sorts are easily grown, and a rotation of these is raised on land irrigated from wells and springs. Potatoes and onions are grown for export at seasons when they are scarce in northern Europe. Grapes are extensively cultivated (chiefly for wine making but also for table use). Cumin seed is produced for export, while tomatoes, oranges, figs, apricots, nectarines and peaches grow to perfection. Animal husbandry is also of some importance. The Large White pig population made the islands self-sufficient in regard to pork. A herd of pedigree cattle was flown from the United Kingdom in order to upgrade the local cattle, and British Saanen goats have been imported to improve the local breed. Fishing occupied about 1,000 persons in 1951.

Industries. — To assist exports and reduce the import of manufactured goods an Encouragement of New Industries act was passed in 1925 (later amended) granting certain concessions to new industries. The making of buttons, gloves, pipes, boots and shoes, meat products, crown corks, wadding, plastics, beer, nylon stockings and matches have been the main industries. Two very old ones, for which Malta has long been famous, lace and silver filigree work, have been hard hit by the purchase tax in the United Kingdom. Homespun cloth is still made locally.

Commerce. — The economy of Malta has grown much beyond its natural resources on account of its strategic importance and the commercial value of its harbours and airports. The requirements of the ever-increasing population have nearly all to be imported. Food, drink and tobacco account for almost half the imports, while raw materials and manufactured articles make up the balance. By far the most important export item is potatoes (about £250,000 sterling annually); others include gloves, buttons, pipes, crown corks and beer. The main overseas markets are Italy and the United Kingdom.

The small area of the Maltese group of islands, the limitations of their agriculture and the inevitably restricted nature of their manufacturing activities combine to preclude any very large economic development. The agricultural produce of the island can support the dense population only for three months in the year; the balance of foodstuffs and necessaries has to be paid for by the purchasing power of the armed forces stationed there, and by work done for the forces in the dockyard and elsewhere and for visitors and tourists. Relatives at home also receive large remittances from Maltese abroad; and interest from investments outside the islands and accumulated capital furnish margins to adjust the adverse balance.

Money, Weights and Measures. — Government of Malta currency notes and British coin are the sole legal tender. Bank of England notes ceased to be legal currency in 1939 The chief banks are the National Bank of Malta, Barclays bank and Scicluna's bank (a private institution). Local weights and measures include the ratal or rotolo. 1.75 lb.; the wizna. 8.75 lb.; the qantar, 175 lb.; the qasba. 82.5 in.. the xiber, 10.3 in.; the tomna, .278 ac. The tomna is also a measure of capacity for dry goods (.0625 quarters). Imperial measures are used for most commercial purposes.

Communications. — Malta is an important shipping centre. There are two main ports, Grand Harbour and Marsamxett. The R.A.F. aerodrome at Luqa and R.A.F. flying-boat base at Marsaxlokk (Marsa Scirocco) are used also for civilian air services. There are small airfields at Hal Far and Ta Qali. In 1955 there were 423 mi. of first-class roads. and there is a ferry service between Malta and Gozo.

The only railway line ceased operation in 1931 and motor omnibuses serve all towns and villages.

Telegraphic communication is maintained with Europe and the rest of the world. There is a government-controlled telephone service in Malta and Gozo. See Index references under "Malta" in the Index volume. (W. B. PN.; W. H. IS.)

MALTA FEVER or MEDITERRAKEAN FEVER is an infectious disease prevalent for many centuries in Mediterranean countries. Mortality is not high, but prolonged and exhausting fever, tendencies to chronicity and relapse and disabling sequelae make it a dreaded disease. Decimation of military garrisons on Malta and Gibraltar led many British physicians to study this illness. In 1887 David Bruce discovered the causative organism in the spleen of a patient who died and named it *Micrococcus melitensis.*

In 1905 T. Zammit, a member of the Mediterranean Fever commission headed by Bruce, found the infection prevalent in goats and transmitted to man by milk.

In 1918 Alice Evans, noting similarities between the organism causing Bang's disease or contagious abortion in cattle (then called *Bacillus abortus*) and that causing Malta fever, predicted a human disease caused by *Bacillus abortus.* In 1924 Chester Keefer reported a case of Malta fever caused by *Bacillus abortus,* thus confirming Evans' prediction. Subsequently, these organisms were reclassified as species of the genus *Brucella,* the organism of Malta fever being named *Brucella melitensis* and that of Bang's disease *Brucella abortus*. *Brucella suis,* a third species, causes disease primarily in swine.

All three species cause similar human disease. The infection in both man and animals is called brucellosis (*q.v.*).

MALTE-BRUN, CONRAD (MALTE CONRAD BRUUN) (1775–1826), one of the leading French geographers and the author and co-author of several extensive geographies, was born on Aug. 12, 1775, at Thisted, Den. A supporter of the French Revolution, he was banished from Copenhagen in 1800 for his political verses and pamphlets. Eventually he established himself as a journalist and geographical writer in Paris. His writings include volumes one through six of the *Précis de la géographie universelle* (1810–29). He originated the *Annales des voyages* in 1808. Malte-Brun took a broad view of geography, regarding it as complementary to natural history and as intimately related to the history. customs and institutions of mankind.

Malte-Brun was a founder of the Société de Geographie of Paris in 1822, the first modern geographical society. He died in Paris on Dec. 14. 1826.

His second son. Victor Adolphe Malte-Brun (1816–1889), followed his father's career of geographer. His special interest was the course of exploration, especially in Africa and the arctic. (G. R. CE.)

MALTESE CROSS: *see* CROSS AKD CRUCIFIXION.

MALTESE LANGUAGE, the only Semitic tongue officially written in the Latin alphabet, is a modern Arabic vernacular closely related to the western (Tripolitan, Algerian) Arabic dialects. In its phonetics, morphology, syntax and vocabulary it shows the strong influence of an earlier, later and continuing Sicilian (Latin) form of speech (cf. Maltese: *il-maktur*, "the handkerchief"; Sicilian: *maccaturu*). The contention that Maltese is descended from an ancient native Phoenician tongue current in the island at the time of the Roman occupation in 216 B.C. and continuing until A.D. 870, the date of the Saracen conquest, is completely untenable on cultural, historical and linguistic grounds.

The Maltese of Gozo has interesting archaisms.

MALTHUS, THOMAS ROBERT (1766–1834), English economist, was born in 1766 at the Rookery near Guildford, Surrey, a small estate owned by his father, Daniel Malthus, d~was a friend and one of the executors of Rousseau. After being privately educated, Malthus entered Jesus college, Cambridge, where he was a contemporary of S. T. Coleridge. He was ninth wrangler in 1788 and was elected to a fellowship in 1793.

Malthus took orders in 1797, and held for a short while the curacy of Albury in Surrey. In 1798 he published the first edition of his great work, *An Essay on the Principle of Population as It Affects the Future Improvement of Society, with Remarks on the Speculations of Mr. Godwin, M. Condorcet, and Other Writers*. This was followed five years later by the second greatly enlarged and amended edition of his work in 1803; he published several subsequent revised editions, the sixth and last during his lifetime appearing in 1826. In 1805 Malthus married, and soon after, was appointed professor of modern history and political economy in the East India company's college at I-Iaileybury.

He died there on Dec. 23, 1834.

Malthus' *Essay on Population* grew from some discussions with his father respecting the perfectibility of society. His father shared the theories on that subject of Condorcet and Godwin, but his son maintained that the realization of a happy society will always be hindered by the miseries consequent on the tendency of population to increase faster than the means of subsistence. His father, struck by his views, asked him to put them in writing, and then, after he had done so, recommended that the manuscript be published.

The first edition is in the nature of a long pamphlet, brilliantly written and with a marked felicity of phrase and illustration. It put forward the view that population. when unchecked, increases in a geometrical ratio while subsistence increases only in an arithmetical ratio, and Malthus asserts as a fact that population always increase's up to the limits of the means of subsistence. Population is prevented from increasing beyond these limits by the positive checks of war, famine and pestilence and by the influence of misery and vice. From this theory Malthus drew the important practical conclusion for the England of his day that the existing poor-law system, with its indiscriminate doles and bounties upon large families, was utterly to be condemned as tending to aggravate the very evils which it was supposed to remedy. The publication of the *Essay* roused a storm of controversy, and bitter abuse was hurled at Malthus from the most diverse quarters. Undaunted by the attacks to which he was subjected, he set to work to collect material bearing on the rates of increase of population in all times and countries, and five years later published the second edition of his *Essay* in an entirely different form. In its new guise the *Essay* is a long, soberly worded and scholarly treatise, full of detailed facts and statistics and abundantly documented. Nor was it the form alone that underwent a change. While maintaining his "principle" of population—the universal tendency of population to outrun the means of subsistence—he allowed the question of the mathematical ratios to fall rather into the background. But, above all. he introduced a most important modification into his original doctrine by recognizing the existence, in addition to the positive checks to the increase of population, of a preventive check which he termed "moral restraint." By this term Malthus understood the postponement of the age of marriage, accompanied by strict sexual continence. It may be noted that the views and methods advocated by those modern upholders of small families, who call themselves Neo-Malthusians, would have received nothing but condemnation from Malthus. The introduction of the notion of moral restraint, coupled with the realization that subsistence did not necessarily mean merely the bare necessaries for existence, give a more hopeful colour to Malthus' views as set out in the later editions of his work. Nevertheless. he remained rather pessimistic in his general outlook on the possibilities of the future progress of mankind. for he lacked complete confidence that the human race would be willing to regulate its numbers by the exercise of prudence and restraint. Failing that, the positive checks which had operated in the past. with all the vice and misery that follow in their train, would continue to do so in the future.

It would be scarcely fair to convict Malthus of error on the ground that he failed to foresee the astonishing development of transport and colonization which took place in the 19th century and nhich increased so enormously the area from which foodstuffs and raw materials could be drawn during that period or that he underestimated the importance of the reactions of industrial progress upon the output and cost of production of agricultural produce. He does, however, appear to have supposed that the great increase in British population taking place in his time was caused by a supposed increase in births resulting from bounties and other economic changes; subsequent research has shown that the birth rate was not rising and that the great increase of population was solely the result of the fall in the death rate. His view that an improvement in standards of living will cause a geometrical increase of population. and thus a subsequent reversion to subsistence conditions, may be accepted, subject to the proviso that the birth rate remains at its previous level. Thus, in many parts of the east the Malthusian "principle" is still in operation. But his view that better conditions mould, besides reducing deaths. also stimulate births has not been borne out by experience. In many parts of the world the birth rate. despite the existence of living conditions far more favourable than those in the England of Malthus. has fallen below the replacement level, and in these parts the preoccupation is not the chance of overpopulation but that of race extinction. This error does not, however, diminish the importance of Malthus' work. He remains the pioneer in the fundamental treatment of demographic problems; certain of his assumptions have to be modified, but the new situation is likely to increase, not diminish, the esteem in which his work is held and the amount that it is studied.

A chance reading of the *Essay,* in which the phrase "struggle for existence" struck an answering chord, stimulated Charles Darwin to find the key to biological change in the process of natural selection brought about by this struggle for existence.

Malthus was also a writer of considerable importance for the development of economic theory. The close friend and correspondent of David Ricardo, he not merely stimulated the latter but himself made independent contributions to the theory of value. He is generally credited with being the first writer to formulate the law of diminishing returns as applied to agriculture. though he did not call it by this name and perhaps himself failed to realize the full significance of this conception. He combated the rigid Ricardian labour cost theory of value. Although it is the general view that he was not the equal of Ricardo in his power of economic analysis and that his thinking in this field was at times confused, he has supporters who claim to find in his work an anticipation of the modern theory of "effective demand."

Besides his great work, the first edition of which was reprinted by the Royal Economic society in 1926, Malthus wrote *Observations on the Effect of the Corn Laws: An Inquiry into the Nature and Progress of Rent; Principles of Political Economy; and Definitions in Political Economy.* His views on rent were of real value.

MALTON, a market town and urban district in the North Riding of Yorkshire, Eng., 16½ mi. N.E. of York, stands on rising ground on the north bank of the river Derwent and is connected by bridge with Norton on the opposite bank in the East Riding. Pop. (1951) 4,236; area 6.3 sq.mi. Malton lies in the Malton or Kirkham gap between the Vale of Pickering and the Vale of York.

A Roman camp east of the town, occupied from A.D. 72 to the end of the 4th century, has been identified with Derventio of the Antonine Itineraries. Excavations after World War II revealed the remains of a Romano-British village. Malton has a museum of Roman and pre-Roman remains found locally. The church of St. Mary at Old Malton. 1 mi. N.E. of the town, was attached to a Gilbertine priory founded in 1150; the magnificent nave is mainly transitional Norman and Early English.

Agricultural equipment is manufactured, and there is brewing and flour milling. Important race-horse training stables are in the neighbourhood, and there are limestone quarries. Cattle markets dating from the 13th century and still belonging to the lord of the manor are held on Fridays and Saturdays, and a fair is held at Michaelmas.

Six miles southwest of Malton are the small but beautiful remains of Kirkham priory, an Augustinian foundation of 1121. Castle Howard, designed by Sir John Vanbrugh as a seat for the Howard family. lies 5 mi. to the southwest.

MALTZAN, HEINRICH VON, BARON ZU WARTENBURG UND PENZLIN (1826–1874), German traveller. was born on Sept. 6, 1826, near Dresden. After extensive travels in North Africa and the Levant, he succeeded in 1860 in making the pilgrimage to Mecca, which he afterward described in *Meine Wallfahrt nach Mecca* (Leipzig, 1865), but had to flee for his life to Jidda without visiting Medina. He died by his own hand at Pisa.

His works include *Drei Jahre im Nordwesten von Afrika* (Leipzig, 1863); *Reise nach Sudarabien* (Brunswick, 1873); *Reise in Tunis und Tripolis* (Leipzig, 1870), which contains a collection of Punic inscriptions; and an edition of A. von Wrede's *Reise in Hadramaut* (Brunswick, 1870).

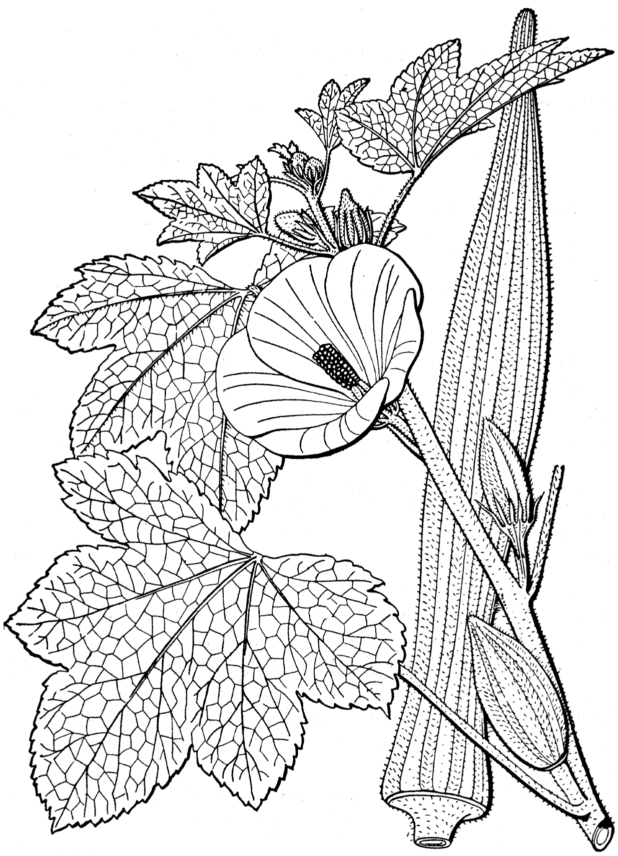
MALUS, ÉTIENNE LOUIS (1775–1812), French physicist, who made important discoveries concerning the polarization of light, was born at Paris on June 23, 1775. Dismissed without receiving a commission from the military engineering school at Mézières. because he was regarded as a suspected person (1793), Malus entered the French army as a private soldier. He was later sent to the newly established École Polytechnique in Paris, and after three years at the school was admitted into the corps of engineers. In 1798 he joined the Egyptian expedition, remaining in the east until 1801.

After his return, he held official posts successively at Antwerp, Strasbourg and Paris and did research in optics. He published a paper in 1809 covering his discovery of the polarization of light by reflection. The discovery gave impetus to the optical investigations of natural crystals by Sir David Brewster and others. In the following year Malus published a memoir on the theory of double refraction in crystals.

Malus died in Paris on Feb. 23, 1812.

MALUS: *see* APPLE; CRAB APPLE.

MALVACEAE, a large and economically important family of flowering plants. It contains 4j genera with about 900 species, and occurs in all world regions except the coldest. the number of species increasing toward the tropics. The most conspicuously useful plant is cotton *(Gossypium)*. It is represented in Britain by three genera: *Malva,* mallow; *Althaea,* marsh mallow; and *Lavatera,* tree mallow. In the United States there are about 20 genera, the best-known ones, after *Gossypium,* being *Althaea* (marsh mallow and hollyhock), *Malva* (mallow). *Sida Abutilon* (Indian mallow or velvet-leaf), and *Hibiscus* (rose mallow, and also okra or gumbo). The plants are herbs, as in the British mallows, or, in the warmer parts of the earth, shrubs or trees. The leaves are alternate and often palmately lobed or divided; the stipules generally fall early. The leaves and young shoots often bear stellate hairs and the tissues contain mucilage-sacs. The



HIBISCUS (HIBISCUS ESCULENTUS), SHOWING UPPER PART OF FLOWERING PLANT (ANNUAL) AND AN UNRIPE FRUIT

regular, hermaphrodite, often showy flowers are borne in the leaf-axils, solitary or in fasicles, or form more or less complicated cymose arrangements. An epicalyx formed by a whorl of three or more bracteoles is generally present just beneath the calyx; sometimes, as in *Abutilon,* it is absent. The parts of the flowers are typically in fives; the five sepals, which have a valvate aestivation, are succeeded by five often large showy petals which are twisted in the bud; they are free to the base, where they are attached to the staminal tube and fall with it when the flower withers. The very numerous stamens are united into a tube at the base, and bear kidney-shaped one-celled anthers which open by a slit across the top. The large spherical pollen-grains are covered with spines. The carpels are one to numerous; when five in number, as in *Abutilon,* they are opposite the petals, or, as in *Hibiscus,* opposite the sepals. In the British genera and many others they are numerous, forming a whorl around the top of the axis in the centre of the flower, the united styles rising from the centre and bearing a corresponding number of stigmatic branches. In *Malope* the numerous carpels are arranged one above the other in vertical rows. One or more anatropous ovules are attached to the inner angle of each carpel; they are generally ascending but sometimes pendulous or horizontal; the position may vary, as in *Abutilon,* in one and the same carpel.

The flowers are protandrous; when the flower opens the unripe stigmas are hidden in the staminal tube and the anthers occupy the centre of the flower; as the anthers dehisce the filaments bend backwards and finally the ripe stigmas spread in the centre. Polination is effected by insects which visit the flower for the honey, which is secreted in pits one between the base of each petal and is protected from rain by hairs on the lower margin of the petals. In small pale-flowered forms, like *Malva rotundifolia,* which attract few insects: self-pollination is found, the style-arms twisting later to bring the stigmatic surfaces' into contact with the anthers.

Except in *Malvaviscus* which has a berry, the fruits are dry. In *Malva (see* MALLOW) and allied genera they form one-seeded schizocarps separating from the persistent central column and from each other. In *Hibiscus* and *Gossypium* (the cotton-plant), the fruit is a capsule splitting loculicidally. Distribution of the seeds is sometimes aided by hooked outgrowths on the wall of the schizocarp, or by a hairy covering on the seed, an extreme case of which is the cotton-plant where the seed is buried in a mass of long tangled hairs—the cotton. The embryo is generally large with much-folded cotyledons and little endosperm.

The largest genus, *Hibiscus,* contains 160 species, which are widely distributed chiefly in the tropics; *H. Rosa sinensis* is a well-known greenhouse plant. *Abutilon* (*q.v.*) contains 120 species, mainly tropical; *Lavatera,* with 20 species, is chiefly Mediterranean; *Althaea* has about 15 species in temperate and warm regions, *A. rosea* being the hollyhock (*q.v.*); *Malva* has about 30 species in the north-temperate zone. Several genera are largely or exclusively American.

MALVASIA (Gr. *Monemvasia,* "city of the single approach"; Ital. *Napoli di Malvasia;* Turk. *Mengeshe* or *Beneshe)* on the east coast of the Morea, Greece, contiguous to the site of the ancient Epidaurus Limera, of which it took the place; one of the principal fortresses and commercial centres of the Levant during the middle ages, still represented by considerable ruins and a town of about j50 inhabitants. So extensive was its trade in wine that the name became familiar throughout Europe as that of a special kind—Ital. *Malvasia;* Span. *Malvagia;* Fr. *Malvoisie;* Eng. *Malvesie* or *Malmsey.* The wine was not of local growth, but came from the Cyclades, and Malavisi province of Crete.

The Byzantine emperors valued Malvasia as a fortress in the Morea, and rewarded its inhabitants for their fidelity by unusual privileges. The emperor Maurice made the city (previously dependent in ecclesiastical matters on Corinth) an archbishop's see, and Alexius Comnenus, and more especially Andronicus II (Palaeologus) gave the Monembasiotes freedom from all sorts of exactions throughout the empire. It was captured after three years' siege by Guillaume de Villehardouin in 1248, but retained its liberties and privileges, and was restored to the Byzantine emperors in 1262. It placed itself under Venice from 1463 to 1540, when it was ceded to the Turks. In 1689 it was the only town of the Morea which held out against Morosini, and his successor Cornaro only succeeded in reducing it by famine. In 171j it capitulated to the Turks, and on the failure of the insurrection of 1770 the leading families were scattered abroad. As the first fortress which fell into the hands of the Greeks in 1821, it became in the following year the seat of the first national assembly.

See Curtius, *Peloponnesos*, ii, 293 and 328; Castellan, *Lettres sur la Morée* (1808), for a plan; Valiero, *Hist. della guerra di Candia* (Venice, 1679), for details as to the fortress; W. Miller in *Journal of Hellenic Studies* (1907).

MALVERN, an urban district in the South Worcestershire parliamentary division of Worcestershire, Eng., 9½ mi. S.W. of Worcester by road. Pop. (1951) 21,505. Area 11.6 sq.mi. It lies mainly on the eastern slopes of the Malvern hills, which run north and south for 9 mi. and rise from the Severn valley to a height of 1,395 ft. in the Worcestershire Beacon. The hills are administered by the Malvern Hills conservators and part of the southern end of the range is under the protection of the National Trust. Malvern chase, originally a crown land and forest, was granted to the earl of Gloucester by Edward I. An ancient trench along the summit of the hills, known as the Red Earl's dyke, is the boundary between Worcestershire and Herefordshire.

The name Malvern is collectively applied to a number of former villages and hamlets built around the hills. The principal town is Great Malvern, lying beneath the Worcestershire Beacon. In early times Malvern was an ecclesiastical settlement, and at Great Malvern was the Benedictine priory which arose in 1085 out of a hermitage endowed by Edward the Confessor. The priory church of SS. Mary and Michael is a cruciform Perpendicular building, with a Norman nave and font. It is famous for its 15th-century glass and encaustic tiles; the great window in the north transept was presented by Henry VII in 1502.

Little Malvern, with remains of a Benedictine priory, now a parish church, lies at the foot of the Herefordshire Beacon, which is crowned by extensive and well-preserved hill fortresses of Iron Age date. Maivern Link, West and North Malvern, on the hills, and Malvern Wells! are also in the district.

Malvern is now an educational centre, with Malvern college for boys founded in 1862, a college for girls and a school of art. It is also a health and holiday resort with a theatre and winter gardens (in which is a large ballroom often used for conferences) and with a swimming pool in the park adjoining. Among its few industries, the chief one is the manufacture of mineral waters.

MALVY, LOUIS JEAN (1875–1949), French Socialist-Radical politician, was born at Figeac, Fr., Dec. 1, 1875. In 1906 he entered the chamber as a Socialist-Radical and was an under-secretary in the Monis and Caillaux cabinets (1911), minister of commerce and postal services under Doumergue (Dec. 1913) and minister of the interior in the Viviani ministry (June 1914). He retained this post under Briand and Ribot. On July 22, 1917, Clemenceau charged him with lax administration in dealing with defeatists and agitators, and he resigned on Aug. 31. His resignation brought about the fall of the Ribot cabinet. In October Léon Daudet brought against him a general accusation of treason. A commission, appointed at Malvy's own suggestion, decided on behalf of the chamber that the senate, sitting as a high court, should pronounce judgment on all the stated charges. On Aug. 6, 1918, the high court acquitted Malvy of the charge of treason, but found him guilty of *forfaiture* (*i.e.*, culpable negligence in the performance of his duties as minister of the interior from 1914–17) and sentenced him to banishment for five years, which he passed in Spain. Re-elected to the chamber in 1924, he represented France at the negotiations with Spain (June–July 1925) for joint action against Abd el-Krim; and in Oct. 1925 he became president of the finance commission of the chamber.

Malvy again became minister of the interior in the Briand cabinet of March 1926; but his appointment roused old and bitter controversies and, although the deputies voted in support of the government after attacking Malvy in a stormy sitting, he resigned on the ground that his presence in the cabinet deprived it of support.

Malvy was elected chairman of the finance committee of the chamber in 1928 and again in 1932, serving until 1940. He died in Paris, June 9, 1949.

See Albert, *Le Procès Malvy* (1920); and E. Gomez Carillo, *Mystère de la vie et de la mort de Mata Hari* (1925).

MALWA, a historic province of India, which gave its name to one of the political agencies into which Central India was divided under British rule. Strictly, the name is confined to the hilly tableland, bounded south by the Vindhya range, which drains north into the Chambal river; but it has been extended to include the Narbada valley farther south. From the Junagadh rock inscription it may be inferred that, in the 2nd century A.D., Rudradaman, the greatest of the western satraps, ruled over Avanti, that is, both eastern and western Malwa. It formed part of the Gupta empire and was later annexed by Harsha. In the 9th century it was absorbed by the Gurjara-Pratiharas between whom and the Rashtrakutas of the Deccan the Narbada formed a fluctuating frontier. The first records of a local dynasty are those of the Paramaras, a Rajput clan, who ruled for about four centuries (800–1200) with their capital at Ujjain and afterward at Dhar.

The Mohammedans invaded Malwa in 1235 and in 1401 Dilawar Khan Ghori founded an independent kingdom, which lasted till 1531. In 1561 Malwa was annexed to the Mogul empire by Akbar. On the break-up of that empire, Malwa was one of the first provinces to be conquered by the Marathas, when it became a cockpit for fighting between the rival Maratha powers, and the headquarters of the Pindaris or irregular plunderers. The Pindaris were extirpated by the campaign of Lord Hastings in 1817, and the country was reduced to order by Sir John Malcolm.

Malwa is traditionally the land of plenty, in which sufferers from famine could take refuge. But in 1899–1900 it was visited by drought, followed by plague.

MALWA is also the name of a large tract in the Punjab, south of the Sutlej river, which is one of the two chief homes of the Sikhs, the other being known as Manjha. It includes the districts of Ferozepore and Ludhiana (Punjab state, India), together with the cis-Sutlej states of Patiala, Jind, Nabha and Maler Kotla (now districts of Punjab). (C. C. D.)

MAMARONECK, a village in Westchester county, N.Y., U.S., is located on Long Island sound, about 5.5 mi. N.E. of the Bronx. Its name derives either from Mamaronock, a Wekquaeskeck (Mohican) chief, or from an Indian word meaning "where the fresh water meets the salt." Although part of a larger area acquired by the Dutch West India company in 1640, the site of Mamaroneck was resold by its Indian inhabitants on September 21, 1661, to John Richbell, an English merchant from Massachusetts bay. In 1698 Caleb Heathcote, later mayor of New York city, purchased Mamaroneck from Richbell's widow. More than a century iater James Fenimore Cooper resided in Heathcote Hill (De Lancey manor house) for several years and there wrote The Spy, Mamaroneck is a suburban community, with a fine marina and Harbor Island park. Major manufactures include metal-spraying equipment, electronic components, water heaters and tanks; lighting fixtures and metal stampings. It became an incorporated village in 1895 and adopted a mayor-village manager system of local government in 1931. For comparative population figures see table in NEW YORK: Population. (M. D. HH.)

MAMELI, GOFFREDO (1827–1849), Italian poet and patriot, born at Genoa of a noble Sardinian family, studied law and philosophy at the University of Genoa. He was wholeheartedly devoted to Mazzini; among other patriotic poems he wrote a hymn to the Bandiera brothers, and in the autumn of 1847 a song called "Fratelli d'Italia," which as Carducci wrote, "resounded through every district and on every battlefield of the peninsula in 1848 and 1849." Mameli served in the national guard at Genoa, and then joined the volunteers in the Lombard campaign of 1848, but after the collapse of the movement in Lombardy he went to Rome, whence he sent the famous despatch to Mazzini: "Roma! Repubblica! Venite!" Although wounded in the engagement of April 30 for the defense of Rome, he at once resumed his place in the ranks, but on June 3 he was again wounded, and died in the Pellegrini hospital on July 6, 1849. Mameli was called "the Tyrtaeus of the Italian revolution."

MAMELUKE, or MAMLUK, the name given to a series of Egyptian sultans, originating (1250) in the usurpation of supreme power by the bodyguard of Turkish slaves first formed in Egypt under the successors of Saladin. See EGYPT: History.

MAMERTINI, or "children of Mars," the name taken by a band of Campanian (or Samnite) freebooters who about 289 B.C. seized the Greek colony of Messana at the northeast corner of

Sicily, after having been hired by Agathocles to defend it (Polyb. i. 7. 2). The members of the expedition are said to have been the male children born in a particular spring of which the produce had been vowed to Apollo (see SAMNITES), and to have settled first in Sicily near Tauromenium. An inscription survives (R. S. Conway, Italic Dialects, 1), which shows that they took with them the Oscan language as it was spoken in Capua or Nola at that date, and the constitution usual in Italic towns of a free community (*touta*) governed by two annual magistrates (meddices). On the Roman conquest of Sicily the town secured an independence under treaty (Cicero, *In* Verr. 3. 6. 13). The inhabitants were still called Mamertines in the time of Strabo (vi. 2. 3).

See also Mommsen, *C.I.L.* x.

MAMERTINUS, CLAUDIUS (fl. c. A.D. 360), Roman official, was the author of a panegyric on the emperor Julian delivered at Constantinople in A.D. 362 in the form of a gratiarum actio (thanksgiving) for the orator's elevation to the consulship. Mamertinus had already held high office under Julian's patronage, and later he was governor of Italy, Africa and Illyria under Valentinian, but his career was terminated in A.D. 368 by a charge of embezzlement. Two earlier speeches in the collection of *Panegyrici* Latini (*see* below) are ascribed in certain manuscripts to a Mamertinus who cannot possibly be identified with Julian's Claudius Mamertinus. These were delivered, probably at Trier, in honour of the emperor Maximian; the first, probably in A.D. 289. on the anniversary of the foundation of Rome, the second, a birthday panegyric. in A.D. 291. All three speeches are important historical documents for their periods.

See W. Baehrens (ed.), *XII Panegyrici Latini* (1911); *E.* Galletier, *Panégyriques latins,* vol. iii (1955) and vol. i (1949) in which the two panegyrists are discussed respectively. (W. S. Ms.)

MAMMALIA, a term invented by Linnaeus (1758) to include that class of animals in which the young are brought forth alive and nourished with milk from the mother's breasts (mammae). Typical examples are the dog, cow, rabbit, monkey, man. Whales are also mammals, although externally fish-like in appearance. Hair (*q.v.*) is a typical mammalian structure. Mammals, like birds, are "warm-blooded" or homoeothermal animals, that is, they differ from "cold-blooded" or poecilothermal forms, such as fishes, amphibians and reptiles, in their superior ability to regulate their own body temperature, so that in spite of wide variations in the temperature of the surrounding medium the body temperature of a typical mammal is maintained in health at a high level and within the relatively narrow limits that are best adapted to the needs of the animal. Some of the most characteristic features of mammals are the expression of the relatively high pace maintained by the vital processes. Here may be mentioned the flexible skin, together with the sweat glands and sebaceous glands, the diaphragm; the complex lungs and heart.

The origin of the mammals lies among the extinct mammal-like reptiles of the Triassic age. The subject may be divided into the following headings, I. Nutrition; II. Locomotion; III. Control Systems; IV. Reproduction; V. Rise of the Mammalian Orders; VI. Continental Dispersal of Orders.

NUTRITION

Jaws and Teeth. — The main divisions of the digestive tract (see GASTROINTESTINAL TRACT) are already established in the vertebrates below mammals; indeed the digestive organs and processes (see NUTRITION and DIGESTION) in the most primitive mammals have been inherited directly from their premammalian ancestors. In typical mammals the most striking morphological advances beyond the reptilian grade are the jaws and teeth.

Mammals are distinguished from lower vertebrates by the fact that the mandible, consisting on each side of a single element (corresponding with the dentary bone of lower vertebrates), articulates directly with the squamosal without the intervention of the quadrate and articular which form the functional mandibular joint in the lower vertebrates. Early embryos of man, and many other mammals, show the dentary of each side forming on the outer side of the stout cartilaginous lower jaw, which corresponds with the Meckel's cartilage or core of the lower jaw of lower vertebrates. The back of this in the embryo mammal ends in a well-developed joint corresponding to the joint between the quadrate and articular elements of the lower vertebrates. As development proceeds the dentary grows upward and establishes a new joint with the squamosal bone of the skull, while the old reptilian joint dwindles in size, pulls away from the dentary bone, and gives rise to the joint between the malleus and incus of the middle ear, which are thus vestiges of the articular and quadrate of lower vertebrates.

In the higher mammal-like reptiles of the Triassic of Russia and South Africa the adult dentition was already differentiated into four kinds of teeth: incisors, canines, premolars and molars; the premolars and molars were cuspidate and in some genera had acquired accessory basal spurs and additional cusps; moreover, the teeth were set in sockets and in some the cheek teeth show an incipient division of the single roots, while the dentition as a whole was reduced to two sets corresponding to the deciduous and permanent dentitions of mammals.

Specialization of Teeth. — The food of mammals, like that of lower vertebrates, may be either chiefly proteids, or chiefly carbohydrates, or a mixture of the two. The pure proteid eaters are typically fierce rapacious forms, in which the digestive tract, the prehensile and masticatory apparatus and the locomotor machinery are all designed for aggression. On the other hand, the carbohydrate feeders are peaceful herbivorous creatures, who spend most of their time in consuming and storing away great quantities of relatively innutritious food.

The anatomical and physiological differences between these two extreme types, *e.g.,* the cat and the cow, are largely correlated with this fundamental contrast in food habits. The cat as a proteid eater receives its food in a highly concentrated and elaborate form. Consequently its digestive tract is relatively short and simple, the stomach is not subdivided and the gastric juice shows a high percentage of hydrochloric acid.

On the other hand, the cow, representing the extreme carbohydrate-feeding type, normally has in its stomach from 14 to 18% of its own total weight in bulky herbaceous food, which contains a great amount of cellulose. The cow's digestive juices are unable to dissolve this indigestible food, but the cow produces an enormous quantity of saliva, which softens the food. By regurgitating and chewing the cud it mashes up the food in preparation for the fermentation caused by the anaerobic bacteria and infusoria in its stomach. In this way the mass gradually becomes fit for digestion by the long digestive tract.

The differences in diet between the cat and the cow are reflected in the differences in their dental mechanism and associated parts of the skull, as set forth in the following table.

	Cat	***Cow***
Jaws:	Short, powerful, wide, for strong vertical movements	Long, slender, narrow, for oblique side swing
Incisor teeth:	Present in both jaws	Absent in upper jaw, replaced by pad
Lower incisors:	Sharp, for piercing, holding and tearing flesh	Blunt, opposed to pad, for cropping grass
Canines:	Prominent, for killing and dragging the prey	Upper canines absent; lower canines incisor-like, for cropping grass
Crowns of premolars and molars:	Compressed, blade-like, for shearing flesh and cutting bones	Crescentic, long-crowned for chewing the cud
Articular condyle of lower jaw:	Placed far down, on level with teeth; to produce a scissors effect, the back teeth engaging first	Placed far above the level of teeth; to bring all the cheek teeth on one side into play at once
Ascending branch of lower jaw:	Very large, for attachment of powerful temporal muscle	Slender, for small temporal muscle
Body of jaw:	Massive, for attachment of powerful masseter muscle	Slender, for attachment of slender masseter muscle

	Cat	Cow
Method of cutting up food:	Into large chunks, with a few powerful bites	Into many very small bits, with many strokes of the jaw

Relatively few mammals attain either of these extreme specializations, the majority subsisting on a more or less mixed diet.

Incisors and Canine Teeth.—The front teeth of mammals are adapted, according to the nature of the food, into insectivorous, carnivorous, gnawing, omnivorous, frugivorous, browsing, grazing, piscivorous and various derived and mixed types.

In the more primitive insectivorous forms the incisors ($\frac{3}{3}$ on each side in primitive placentals and $\frac{5}{4}$ in primitive marsupials) are small nipping teeth, suitable for catching insects, the lower centrals slightly procumbent, the crowns simple with blunt points or slightly sharp edges. In the cat the incisors are fairly primitive in form but are nearly vertical, so giving a more powerful bite.

In rodents the incisors become long-crowned. curved, flattened cylinders with chisel-like edges growing continuously from persistent pulps. In the lower Oligocene forerunners of the Proboscidea (*q.v.*) or elephants (*Moeritherium*), one pair of upper incisors and one pair of lowers are moderately enlarged and adapted for cutting and plucking vegetation from the ground. In *Palaeomastodon* the next higher stage, the upper incisor tusks are much enlarged; through the development of a proboscis, they no longer oppose the lower incisors but function as levers and weapons. In certain later mastodons and elephants the lower incisors are gradually eliminated and the upper incisors attain great size, reaching in the extinct *Elephas ganesa* to 10 ft. 8½ inches.

A reduction or loss of the incisors has frequently occurred in animals with a protrusile tongue, as in the sloths, anteaters, etc

In the horse family, which are grazers, both the upper and lower incisors have become long-crowned, with cup-like insinkings from the incisal surface of the crown. This arrangement strengthens the tooth for cutting off siliceous grass stems, while the long crown insures a long period of use.

In the cow, representing the browsing and grazing ruminant artiodactyls. the upper incisors and canines have been replaced by a horny pad, the lower incisors and lower canines have spatulate cro ns arranged in a semicircle, adapted, with the horny pad above, for plucking herbage.

The canine teeth of carnivores are peculiarly fitted for killing living prey. This type of tooth culminates in the great canines of the extinct sabre-tooth tigers. On the other hand, in herbivorous forms the canine teeth are either reduced or adapted to some other function, as in the lower canines of ruminants above mentioned, or the upper canines or fighting tusks of the boar.

Deciduous or Milk Teeth.—In mammals the true molars, although erupting late, appear to belong to the same series as the deciduous incisors, canines and premolars, but have long lost their permanent successors. Since as soon as the young animal is weaned it usually feeds upon the same food as its parents, it will be obvious that it usually needs a functional set of teeth of the same general kind as those of its parents but smaller. Thus the milk teeth are usually not notably different from the permanent set The presence of the milk teeth makes it possible for the permanent teeth to grow to any desirable size before eruption, teeth once erupted no longer grow except at the roots. Usually the hindmost milk teeth are more molariform than the permanent teeth that replace them, apparently because the young animal needs such teeth where the bite is the strongest.

Dental Formulae.—With few exceptions the right and left sides of the jaws have the same numbers of incisors, canines, premolars and molars respectively. Consequently the "dental formula" as ordinarily written represents only one side of the whole dentition and the total number of teeth is equal to twice the sum of the numbers in the "formula." The adult dental formula of man, for example:

$\left(I\frac{2}{2}\ C\frac{1}{1}\ P\frac{2}{2}\ M\frac{3}{3}\right)$, is simply an abbreviated form of:

Incisors: upper, 2 / lower, 2 Canines: upper, 1 / lower, 1 Premolars: upper, 2 / lower, 2

Molars: upper, 3 / lower, 3

The following dental formulae illustrate the progressive reduction as we pass from the more primitive forms to the highly specialized dentition of the cat:

Typical pantotherian mammal of Jurassic age	$\left(I\frac{?4}{4}\ C\frac{1}{1}\ P\frac{4}{4}\ M\frac{7?}{8?}\right)\times 2=66$
Typical polyprotodont marsupial (Opossum)	$\left(I\frac{5}{4}\ C\frac{1}{1}\ P\frac{3}{3}\ M\frac{4}{4}\right)\times 2=50$
Modern insectivore (Gymnura) . .	$\left(I\frac{3}{3}\ C\frac{1}{1}\ P\frac{4}{4}\ M\frac{3}{3}\right)\times 2=44$
Modern dog	$\left(I\frac{3}{3}\ C\frac{1}{1}\ P\frac{4}{4}\ M\frac{2}{2}\right)\times 2=40$
Modern cat	$\left(I\frac{3}{3}\ C\frac{1}{1}\ P\frac{3}{3}\ M\frac{1}{1}\right)\times 2=32$

On the other hand, a secondary increase in number of molars occurs in several groups. Thus in anthropoids and man a fourth molar is sometimes developed. The high number of simple teeth in the toothed cetaceans is the result'of degenerative specialization.

Molars.—Primitive insectivorous molars are small and bear V-shaped cusps with sharp little blades; in shearing types the molars are reduced in number but are large, with one or two long blades; in omnivorous types either the cusps become rounded, often connected with other cusps by low ridges as in anthropoid apes and man, or they become conic and multiplied in number as in the wart-hog; or the whole crown becomes a swollen mass with low cusps as in the bear; in herbivorous types the molar crowns acquire crests and hillocks, arranged in patterns characteristic of the different species.

In 1883 E. D. Cope observed that the teeth and skeletons of the carnivores and primitive ungulates of the Lower Eocene were far less dissimilar than those of their modern descendants, and especially that, while the patterns of their upper molars were already diversified, there were three main cusps or elevations, two on the outer and one on the inner side of the upper molars, evidently homologous in both carnivores and herbivores. This mas the "tritubercular" upper molar type of the Eocene mammals. A fourth main cusp on the hinder inner side of the upper molars could be seen in earlier stages of evolution in the carnivores and in more advanced stages in the primitive herbivorous mammals.

In the lower jaws Cope observed that in both carnivores and herbivores each lower molar tended to conform to a type in which the tooth crown was divided into two moieties arranged in tandem: the first or anterior moiety (the *trigonid)* elevated and supporting a triangle of cusps, of which the chief lay on the outer side of the crown, the other two on the inner; the second or posterior moiety (the *talonid*) depressed below the trigonid, consisting chiefly of a central concavity flanked on the inner and outer sides by single cusps. This central type of lower molar Cope called *tuberculo-sectorial.* Among recent mammals the tuberculo-sectorial pattern may still be seen in the lower molar teeth of civets, opossums, hedgehogs and other flesh-eating and insectivorous mammals.

H. F. Osborn (1558) gave names to the principal cusps of the upper and lower molars, as follows:

Upper Molar		*Lower Molar*	
Trigon		*Trigonid*	
Antero-internal: (pr)	Protocone	Antero-external: (prd)	Protoconid
Antero-external: (pa)	Paracone	Antero-internal: (pad)	Paraconid
Postero-external: (me)	Metacone	Postero-internal: (med)	Metaconid
		Talonid	
Talon		Pcstero-external: (hyd)	Hypoconid
Postero-internal: (hy)	Hypocone	Postero-internal: (end)	Entoconid

Both Cope and Osborn sought to trace the origin of the tritubercular molars of Eocene mammals back to the "single reptilian cone" of the earliest reptiles. For details of molar evolution *see* H. F. Osborn, *The Origin of the Mammalian Molar Teeth to and from the Trtiubercular Type* (1907) and W. K. Gregory, *The Origin and Evolution of the Human Dentition* (1922).

LOCOMOTION

Origin of the Mammalian Locomotor Apparatus.—The locomotor machinery of mammals, like that of other vertebrates, involves four closely interconnected systems: (1) the motor elements proper; (2) the passive or supporting elements; (3) the combustion; (4) the activating, controlling and directive system.

The motor elements include the striped or red muscle cells and the parts built up from them, muscle fibres, muscles and muscle systems (*see* MUSCLE AND MUSCULAR SYSTEM). The supporting elements include: *(a)* the sheaths and connective tissue surrounding the active elements; (b) the tendons that attach the muscles to the bones; (c) the ligaments that tie the parts of the skeleton together and (d) the articulated bony skeleton, including the backbone, skull, ribs, sternum, pectoral and pelvic girdles and limb bones. The locomotor apparatus of mammals, like that of lower vertebrates, is typically adapted for quadrupedal progression by running on relatively open ground, though many forms have learned to progress in special ways: leaping, climbing, volplaning and even flying, swimming, digging, tunneling. But no matter how elaborate the locomotor mechanism may be, it has all been evolved from the simple crawling mechanism of the earliest amphibians, and this in turn from the undulatory movements of certain air-breathing, lobe-finned fishes of Devonian age.

When the earliest amphibians crawled up out of the water the fore and hind paddles were bent downwards to assist the wriggling movement of the body. At first, the limbs sprawled widely. In such forms the humerus, or first segment of the skeleton of the forelimb, had a very short shaft and widely-expanded ends. There was a sharp bend at the elbow and the radius, or front forearm bone, articulated on the under side of the humerus rather than on its further end. Similarly in the hind-limb, the femur was short and was held widely out from the body.

But in the extinct mammal-like reptiles of the Permian and Triassic of South Africa and Russia the skeleton of the pectoral and pelvic girdles and limbs progressively approaches the mammalian type. Their limbs were adapted for running rather than crawling; the body was lifted well above the ground and the trackway became narrower so that the feet gave a more direct support to the weight. In the later mammal-like reptiles the feet were small and short, and from the reduction in the number of phalanges or toe-joints, to the mammalian number (three in each toe, except the first, which has two) we may infer that the fore-feet were at least partly "digitigrade," *i.e.*, raised off the ground at the wrist. So too the humerus of the cynodonts, or higher mammal-like reptiles, approached the lower mammalian types, and from the form and position of its joint surfaces we may infer that the angle at the elbow was opening out toward the mammalian condition.

The Fore-Limb.—The typical mammalian shoulder-girdle exhibits a distinct advance beyond that of the cynodont reptiles in the following features: (1) complete loss of all parts of the outer shoulder-girdle except the clavicles; (2) the scapula has an anterior shelf or extension supporting the supraspinatus muscle; (3) the dorsal part of the supracoracoid muscle mass has extended upward on to the scapula to give rise to the supraspinatus and the infraspinatus muscles; (4) the coracoid has become greatly reduced and has lost its contact with the sternum; (5) the anterior coracoid plate has disappeared or become vestigial; (6) the interclavicle has disappeared. All these changes have been associated with the raising of the body and the drawing-in of the fore-limbs so that the feet could be planted beneath the body. The egg-laying monotremes now the lowest of existing mammals, are still largely reptilian in the anatomy of the shoulder-girdle.

The remaining elements of the primitive mammalian fore-limb, the humerus, radius and ulna, carpus, metacarpus and digits, were derived with only minor changes from those of the cynodonts.

The Hind Limb.—The primitive mammalian ilium has apparently been derived from that of the cynodonts through the pronounced narrowing of the region above the root of the tail, accompanying the reduction of the tail muscles. The result of this and other changes has been to narrow and lengthen the gluteal area on the back of the ilium and to extend the area on the front inner surface for the origin of the iliacus muscle, so that the primitive mammalian ilium has become a narrow trihedral rod, with well defined iliacus, gluteal and sacral planes.

Meanwhile the femur has undergone corresponding changes in the passage from crawling to running habits. In the primitive crawling types the short stout femur projected widely from the body, its head, or surface for articulation with the pelvis, was a broad oval set directly on top of the shaft; there was a large deep pit for the insertion of the obturator muscles on the under-side of the femur below the head, and a high ridge for the adductor muscles, also on the under-side of the shaft. In primitive mammals, the femur is long, slender, with a cylindrical shaft, the head is globular, set off at a sharp angle and separated from the shaft by a well-defined neck; there is a large flange (greater trochanter) on the outer upper part of the shaft, the proximal pit (or digital fossa) is small, the primary adductor ridge is lost and there is a process, the lesser trochanter, not found in reptiles.

In primitive reptiles the bend between the lower end of the shank and the foot was not sharp; the two main bones of the tarsus, the astragalus and calcaneum, were flat, more or less circular elements located in the same general plane; the calcaneum did not project backward to form a heel-bone. In the running foot of the typical mammal, on the other hand, there is a sharp bend between the shin-bone and the instep, the astragalus and calcaneum are highly differentiated, the former resting upon the latter, the one forming a pulley for the tibia, the other a heel or lever for the powerful muscles of the shank.

Adaptive Radiation of the Limbs.—Among existing mammals the monotremes are adapted for burrowing and swimming but these are the habits of refugees from direct, above-ground competition with higher types. Among marsupials the primitive forms were arboreal, much like the existing opossums, and these gave rise to the numerous ground-living forms adapted for running, leaping and digging. W. D. Matthew has argued that the little-known primitive placental mammals of the early Cretaceous were also arboreal, inasmuch as many of their descendants in the Lower Eocene had five-toed spreading hands and feet, partly divergent thumbs and great toes, and a primitive skeleton not unlike that of an opossum. However, the evidence for arboreal derivation is less decisive than in the marsupials.

Scampering Types.—Small mammals in general have what may be called the scampering habit,—the ability to scurry away quickly in time of danger, without any pronounced specializations of the skeleton for running; and it seems safe to assign this habit to the pre-Eocene insectivorous ancestors of the placentals. From such a scampering type, with small semi-plantigrade hind feet and semi. digitigrade forefeet, adaptive radiation for different habits has brought about profound modifications of all parts of the skeleton.

Cursorial Types.—In quadrupedal running or cursorial forms length and rapidity of stride, combined with strength and endurance, are the great desiderata. The lower segments of the limbs become long, rod-like, angulated compound levers for striking the hard ground and catapulting the body forward; the principal muscles are bunched at the upper parts of the limbs and transmit their pulls through long cord-like tendons that pass over smooth pulley-like surfaces and are inserted into the lower segments of the leg. In extreme forms the foot is longer than the humerus, which gives great speed but requires great muscular strength.

The long narrow feet in running forms have parallel rather than spreading digits; rising on its toes, the animal finally runs on its enlarged hoofs alone. The thumb and great toe are reduced in size and raised off the ground; later they disappear, as do the fifth or outer digits of the fore- and hind-feet. In the perissodactyls or odd-toed ungulates the middle or third digit in both feet becomes predominant, in the horses finally forming the sole functional axis of the foot, the second and fourth digits being reduced to slender splints. In the artiodactyls, on the other hand, after the loss of the first digit the others become paired, the inner and outer digits, II. and V., being smaller, while III. and IV. are larger; in the final stages II. and V. become reduced and almost disappear, while III. and IV. become very long and fuse into the cannon-bone.

As the fore-and-aft movements of the limbs become emphasized, the elbows and knees are turned outward as little as possible; twisting movements diminish. Consequently the shoulder-girdle tends to lose the clavicle and the acromial process of the scapula disappears. In connection with the predominant fore-and-aft movements there are hinge-like joints between the humerus and the forearm, at the wrist and between the metacarpals and the digits.

The scapula is variously shaped: V-shaped in the swift-running artiodactyls, with vertically extended fossa for the infraspinatus muscle; it is usually at least as long as the humerus, which is relatively short with a projecting greater tuberosity for the attachment of the powerful shoulder muscles. The olecranon process of the ulna becomes a broad thickened lever for the insertion of the massive and powerful triceps; the strong tendon of the biceps passes through a broad channel in the humerus.

These and many other detailed adaptations for swift running have been worked out independently in many families and even in different orders of mammals, notably among the numerous plains-living ungulates, as in the horses of the northern world, the extinct pseudo-horses or smaller litopterns of Patagonia, the antelopes and deer. The less advanced stages are seen among the carnivorous hunters such as wolves and certain of the extinct creodonts, as well as in the marsupial wolf (Thylacinus) of Australia. Even some of the plains-living rodents, such as the chinchilla, show cursorial adaptations in the limbs. The ilium in cursorial types is a strongly braced T-shaped bone supporting the thick deep gluteal muscles which are inserted nearly at right angle to the long axis of the femur.

Graviportal or Strzding Types.—Given an abundant food supply, many lines of evolving animals exploit the opportunity of becoming larger, living longer and leaving a larger progeny. These conditions have tended to transform slender speedy animals into great lumbering brutes. In these heavy-bodied forms the lateral or transverse growth components increase relatively faster than the linear ones; slender bodies and narrow limbs and feet become broad and robust. This is clearly seen in such races as the extinct titanotheres, the rhinoceroses and other lines of ungulates, in which the earlier forms have slender narrow feet, the later ones broad short feet.

In such cases the extent to which the earlier cursorial adaptations are disguised by the overlying graviportal changes depends inter alia upon how early the graviportal tendencies gain the ascendancy. When the graviportal tendency supervenes immediately upon the short-footed scampering stage, so that the cursorial stage is passed by, we have the extreme graviportal modifications illustrated in the Eocene Amblypoda and to a less extent in the elephants. The excessively short-toed feet, instead of catapulting the body, roll forward on a great elastic cushion and the straightened legs, with long humeri and femora, swing forward like massive beams. The ilium widens transversely into a huge fan.

Saltatorial or Leaping Types are usually developed from the scampering or cursorial types. In the jerboas and kangaroo rats, which have evolved from scampering rodents, the animals leap on their powerful hind-limbs, holding the body erect and using the fore-limbs chiefly in manipulating the food. The tail is used as a balancing organ in leaping. The kangaroos have doubtless been derived from arboreal phalangers, in which the fourth digit of the hind-foot was already enlarged, the first digit divergent and prehensile, the second and third small and closely appressed or syndactylous. The early hopping stage is illustrated by the tiny musk kangaroo (*Hypsiprymnodon*), in which the great toe is still present though reduced. In later stages the great toe disappears and the fourth digit becomes enormously enlarged, forming the lower joint of a catapult, the power for which is supplied by the massive muscles of the buttocks, thigh and shank. The tail acts as the third leg of a tripod. Bipedal leaping is convenient for hurdling obstacles in sudden alarms, but for heavy animals it is uneconomical for long distances.

Fossorial or *Digging* Types have been developed usually from scampering short-footed types with short powerful arms. In the mole, an extreme and unique fossorial type, the fore-limbs have been moved forward under the neck to enable the enormous, wide hands to reach in front of the nose. The humeri have acquired a secondary contact with the clavicles, which have become solid blocks that form the pivots of the forearm and rest on a keel-shaped forward extension of the sternum. The scapulae are elongate, to give long shoulder muscles and a long reach of the humeri; the enormous triceps is inserted into a great hooked olecranon process of the ulna, the lower surface of which supports the powerful flexors of the carpus. The hind limb is small and not much modified.

The Cape golden moles (Chrysochloridae) differ widely from the true moles. Their forefeet are very narrow and adapted for digging in hard soil, with one or two sickle-like claws. The armadillos and many rodents dig with their large claws and powerful fore-limbs.

Natatorial or Swimming Types have been developed in many orders, although the extreme form of aquatic adaptation is limited to the Cetacea and Sirenia (*q.v.*). The end-results of prolonged aquatic adaptation naturally depend partly on what type of terrestrial forms the given aquatic types took rise from. Thus among the marsupials the aquatic opossum or yapok is simply an opossum with webbed feet. Among the Mustelidae the ordinary otter, the African Aonyx and the sea otter *(Enhydra)* represent progressive adaptation to aquatic life, in which the feet become webbed and enlarged. The sea lions carry this line of adaptation much further, greatly enlarging the hands and feet into flippers, but retaining the power to support the body on all four limbs. Finally, the earless seals (Phocidae) have lost the power of bringing the hind limbs forward under the body and all four feet are specialized paddles. The body, enclosed in a thick layer of fat, has become streamlined and in the cetaceans becomes fish-like. These specializations were already under way in the oldest known whales, the Eocene Archaeoceti. Nevertheless, evidence from comparative anatomy and embryology proves that the Cetacea have been derived from terrestrial, quadrupedal placentals, perhaps allied with the stem of the insectivores and carnivores. The manatees and dugongs (Sirenia) approach the Cetacea in aquatic specialization, but the resemblance is due to convergence as the anatomical differences indicate that the Sirenia have been derived from herbivorous ancestors, possibly related to the ancestral elephants.

Scansorial or Climbing Types.—Many small mammals with well-developed claws and spreading hands and feet supplied with interdigital pads can climb tree-trunks. In the marsupials the opossums afford an example of a primitive stage of arboreal specialization. The phalangers illustrate a more advanced type of highly specialized hind feet; the great toe is strongly divergent and flattened, the second and third toes slender, closely appressed and enclosed in a common skin, the fourth and fifth enlarged and forming the outer fork of a clamp, the great toe forming the inner.

The tree shrews (Tupaidae), which are probably very primitive Primates, give the initial stages of arboreal adaptation in that order. The pen-tailed tree shrew (Ptilocercus) of Borneo has small spreading hands and feet and a generalized skeleton. The lemurs and their Eocene forerunners Adapidae and Notharctidae, have grasping hind-feet with a wide flat nail on the large great toe; the digits are elongate, slender with small nails, except the second digit, which bears a small claw. Lemurs are essentially arboreal quadrupeds, running along the tops of the branches, and the same is true of the typical monkeys. The Kew World monkeys, which have a prehensile tail, can also hang and swing from the branches. The monkeys, especially those of the Old World division, sit upright, or partly so, resting on the ischial callosities. The hands are used in manipulating the food.

Brachiating or Acrobatic Forms.—The gibbons do not run on all fours but hold the body erect, raising the long arms above the head. They make long leaps through the air, catching the branches. In their skeleton as well as in their internal anatomy they are closer to man than to the lower primates.

Of the larger anthropoids the orang-utan (*q.v.*) is extremely specialized for arboreal life, using the suspension grasp of the hands and feet. The arms are excessively long, with enfeebled thumbs, the legs very short. Progression on the ground is awkward, the long arms being used as crutches.

The chimpanzee (*q.v.*) is a moderately heavy-bodied brachiating form, iess specialized than the orang. In running on the ground a secondarily quadrupedal gait is employed, the weight of the heavy forepart of the body resting on the bent knuckles. Nevertheless tame chimpanzees, when carrying large objects in their arms, walk erect.

Old male gorillas are gigantic, extremely massive animals which run on the ground on all fours upon bent knuckles. Nevertheless the locomotor skeleton as a whole is surprisingly close to that of man, except in certain parts such as the ilium and the great toe, in which the brachiating features are conspicuous.

Biped Type.—This is exemplified by man and the adaptations are treated elsewhere (see MAN, EVOLUTION OF).

Volplaning Types.—Certain active climbing types with long limbs, leaping boldly from the trees skim downward easily by holding extended their patagium, a fold of skin stretching from the neck outward and from the arms to the legs and sometimes from the legs to the tail. Such an adaptation has been acquired independently among marsupials in the flying phalangers, among rodents in the flying squirrels and in the anomalures, and also in the colugos ("flying lemurs"), an isolated type remotely related perhaps to the tree-shrews and lemurs. No marked skeletal specializations except the lengthening of the limbs distinguish the volplaning types from their arboreal relatives.

Flying Types.—The Chiroptera or bats (*q.v.*) are the only mammals to achieve true flight. Their wings are enormously elongated hands and arms covered with thin skin. The hind legs are weak and mostly used for suspension. It is supposed that bats have been derived from skimming forms in which the web of skin extended between the long fingers.

The Backbone.—In the line of ascent to the mammals there was a tendency toward simplification of the complex eight-piece vertebrae (see AMPHIBIA), with progressive reduction of certain elements, until in the dorsal vertebrae of the mammal-like reptiles four of the original eight pieces were nearly or quite eliminated, and we have left a vertebra composed of two main parts: (a) the neurocentrum, an inverted Y-shaped piece, arising from the fusion of the opposite "basidorsals," which cover the spinal nerve cord and afford origin for the spinal muscles; (*b*) the centrum proper, a short cylinder somewhat constricted in the middle, consisting of the opposite pleurocentra, or interdorsals, of earlier vertebrates and serving for the insertion of the ribs and for the support of the body as a whole.

In the oldest Amphibia there was a gradual regional differentiation of the backbone as we pass from the neck to the tail; in the mammal-like reptiles, especially in the cynodonts, regional differentiation is pronounced though not sudden. The ribs of the cervical or neck region are short, but still have shafts, while at least in the higher mammals these shafts are lost. The cynodonts were progressing in the direction of the mammals in the fact that their lumbar ribs were suturally connected with the sides of the vertebrae as in some very young marsupials. In many more advanced mammals the lumbar ribs are completely replaced by transverse processes which grow out from the sides of the vertebrae. Similarly in the sacral region the cynodonts and less specialized mammals had free sacral ribs, whereas in more specialized mammals the rib elements of the sacrum are replaced by transverse processes.

In the older mammal-like reptiles the condyle was median and ball-like as in typical reptiles, but in the cynodonts the lateral parts grew outward while the median part retreated so that a double condyle almost of mammalian type was attained.

The mammalian atlas-axis complex is a contrivance of great functional and morphologic intricacy, the purpose of which is to provide a wide range of movement combined with automatic checks, to prevent sudden stresses from dislocating the joint and squeezing the spinal cord. One of the most essential morphological features of the atlas-axis complex of cynodonts and mammals is that the paired occipital protuberances are received into the upper or neural arches of the atlas or first vertebra and that the centrum or body of the atlas becomes a buffer which in the adult is closely united to the centrum of the second vertebra or axis, of which in adults it forms the odontoid process. Meanwhile the neural spine of the second vertebra becomes enlarged vertically to give origin to some of the powerful muscles that raise the head.

In the dorsal vertebrae the stout neural spines act as levers for the powerful spinal muscles in extending the back, while the transverse processes and centra serve as bases for the movable ribs enclosing the heart, lungs and diaphragm.

The contour of the vertebral column in the standing pose in the side view differs widely in accordance with the habits. In scampering types with short legs the column is usually strongly arched in the mid-dorsal region. This culminates in the short-footed carnivorous types such as weasels. In long-limbed running types, especially those with a long neck or a heavy head, the backbone may bear long stout spines on the neck and forepart of the back, to which are attached the heavy ligaments of the neck and the deeper muscles of the occiput.

A profound difference between a typical reptile and a typical mammal is that in the former the great muscles on the lower side of the tail act powerfully in pulling the hind limbs backward in running. In mammals, on the contrary, the tail muscles are greatly diminished and of slight importance in locomotion.

Skull.—The mammalian skull is here treated under the section locomotion because the vertebrate skull in the first place arose as a fulcrum or thrust-block to withstand the forward thrust of the locomotor muscles acting through the vertebral column in the rear and the resistance of the water in front. Hence even in the oldest known chordates, the ostracoderms, the skull consists of two parts: (1) a wedge-like sloping roof and sides, forming a bony *dermocranium* and (2) a cartilaginous or partly ossified inner skull or endocranium, comprising (a) the capsules surrounding the olfactory, optic and balancing organs and (b) the central brain-trough or trabecular region.

Modifications of the jaws and teeth in the mammals, in adaptation to different food habits, have a profound effect upon the form of the skull as a whole, since the jaws usually form the greater part of the bony face, while the jaw muscles cause the upgrowth of ridges on the top and sides of the braincase and condition in many ways the form of the base of the skull.

On the whole the mammalian braincase has advanced beyond that of primitive reptiles in the following features:

(1) The elimination of several dermal bones of the circum-orbital and occipito-temporal series, the tabulars, supratemporals, postorbital, postfrontal, prefrontals;

(2) The widening-out of the brain-trough through the widening of the brain; the change of the reptilian epipterygoid into the mammalian alisphenoid;

(3) The elaboration of the turbinate bones, scroll-like outgrowths from the median cartilaginous septum of the nasal chamber;

(4) The consolidation of the bony elements surrounding the inner ear into a single dense bone, the periotic, and the fusion of this with the squamosal;

(5) The shifting of the inner ear from the side to the base of the skull.

CONTROL SYSTEMS

The mammalian nervous system, which reaches unprecedented complexity in man, can scarcely be understood apart from other regulating devices or control systems, which greatly condition its activities. In all vertebrates the ductless or endocrine glands play an important part in the production and maintenance of the specific and individual patterns of growth and behaviour, since they pour into the blood-stream certain hormones which give the chemical impetus to particular changes in the direction of growth. (See ENDOCRINOLOGY.)

On the whole there is a marked contrast, however, between chemically and nervously determined functions. Chemical regulation (as from the ductless glands) tends to be rigid and determinate. Nervous regulation, on the other hand, has tended toward flexibility, modifiability, choice of several courses of action. Mammals, especially man, have achieved extraordinary adaptability to wide ranges of environmental changes largely through the greater flexibility and range of response of their nervous system.

The nervous system of mammals (more fully treated in the article BRAIN), like that of other vertebrates, comprises the following elements: (1) paired organs of smell, sight, balance, hearing; (2) numerous organs of touch and taste and "somesthetic" sense (organs which convey sensations of bodily posture and movement); (3) "motor nerves," which release the activities of glands and muscles; (4) innumerable connecting tracts, relay stations and control systems of amazing intricacy.

In general the mammalian brain differs from that of lower vertebrates in the fact that the upper part and sides of the endbrain have grown outward into sack-like expansions, which form the neopallium or cerebral cortex of mammals. In the lower mammals this new part of the brain is but moderately developed and the localization of functional areas is at best incipient but in the higher mammals, including man, the neopallium becomes enormously complex, dominating the entire organism and tending to differentiate the cortical "centres" described in the article BRAIN. Meanwhile the thalamus and the "brain stem" have likewise become extremely complex, developing a bewildering maze of connections with other parts of the brain. The result of these expansions and complications is that the old primary control systems pass under the dominance of the newer and higher centres.

REPRODUCTION

In all mammals except the aberrant monotremes the embryo develops within the mother's body, and special arrangements for nourishing the embryo and eliminating its wastes are necessary. Certain fetal membranes unite with the lining of the mother's uterus to form a complicated structure called the placenta. The placenta contains blood vessels from both the fetal and maternal circulations. Thus a metabolic interchange between the blood streams of mother and fetus is made possible (see VERTEBRATE EMBRYOLOGY). The fetus absorbs foods and oxygen from the maternal blood and eliminates carbon dioxide and nitrogenous wastes into the maternal blood. At birth the placenta is shed.

After birth the development of higher mammals is prolonged over the period corresponding in man to infancy, childhood and adolescence; the delayed maturity affording opportunity for long-continued growth and differentiation of the brain, with a correspondingly extended period of learning.

In wide contrast with this are the conditions found in the lowest existing mammals, the egg-laying mammals of Australia (see MONOTREMATA) While these lay eggs, like reptiles, the embryo nevertheless derives some of its nourishment from the uterine wall as well as from the yolk stored in the egg.

In typical placental mammals the right and left uteri are fused in the mid-line, making a single uterus. In the lowest mammals, the monotremes, the right and left uteri are entirely separate as in reptiles. Various intergrading conditions between these extremes occur in the marsupials, edentates and rodents.

The milk-glands of female mammals are highly characteristic of the whole class. They are arranged in pairs on the ventral surface of the body, varying in number from one pair in man and other primates to eleven pairs in the insectivore Centetes. They are usually surmounted by nipples, raised folds of skin with a central tunnel for the passage of the milk. In the placental mammals the milk is actively sucked or pumped by the young but in the monotremes the nipples are represented only by depressed glandular areas with raised borders and the milk is said to be licked by the young from the base of the hairs in the mammary field. This condition may well give the clue to the origin of the milking habit, which must have originated after the sebaceous glands of the skin had developed an albuminous secretion, which may have served originally either to attach the eggs to the under-surface of the brooding mother, or to anoint the eggs with a heat-retaining coating. At any rate, the habit of milking in its initial stages seems to require some voluntary action by the young, such as licking.

THE RISE OF THE MAMMALIAN ORDERS

During the Triassic, Jurassic and Cretaceous, the fossil record of the mammals is meagre; later it is relatively abundant; but even then there are blank intervals and imperfectly preserved records. As many existing orders of mammals began to diverge during the Age of Reptiles, when the record is most imperfect, it is difficult to reconstruct the earlier history of the mammalian orders from present data.

Probably by Upper Triassic times some of the smaller mammal-like reptiles, a group already almost mammals, had crossed the line by acquiring a hairy covering and a new contact between the dentary bones of the lower jaw and the squamosal bone of the skull. With the coming of Lower Jurassic times the mammalian stock had split into three distinct groups: (1) the Allotheria or Multituberculata (q v), rodent-like mammals with gnawing front teeth and many-cusped grinding teeth; (2) the Triconodonta, small carnivorous forms with triconodont molar teeth, each crown consisting typically of three cusps in a fore-and-aft line and (3) the Pantotheria, or Trituberculata, very small insectivorous mammals typically with sharp-cusped lower molars of the most primitive tuberculo-sectorial type The Allotheria were probably not closely related to any other order of mammals but were a peculiar, now wholly extinct group extending in time from the Upper Triassic to the summit of the basal Eocene. The Triconodonts also appear to be an isolated and extinct group, but certain of the Pantotherians, such as *Amphitherium*, appear sufficiently generalized to be the potential ancestors of all later mammals except the recent monotremes which at present show distant relationships with the marsupials, but are still without known fossil ancestors, the features they share with the Allotheria being offset by many others that indicate wide differences. The marsupials may well be the descendants of some of the Pantotheria but actual connecting links are wanting. The same is true of the Placentals, which are first known in abundance in the basal Eocene of North America Recently, however, the field parties of the American Museum of Natural History in Mongolia have discovered several incomplete skulls of small mammals which appear to represent some of the Cretaceous forerunners of the centetoid insectivores and perhaps also of the most primitive carnivores or creodonts.

From comparison of the osteology and anatomy of the recent monotremes, marsupials and placentals, however, we may infer with high probability that the ancestral mammal was an egg-laying vertebrate that retained a primitive reptilian type of shoulder-girdle with two complete coracoid plates on either side and with the beginnings of the neopallium in the brain From such primitive types the marsupials (see MARSUPIALIA) evolved by developing, among other characters: (1) a three-way, vaginal passage; (2) the true or allantoic placenta was early replaced by a false or yolk-sack placenta; (3) the corpus callosum or great cross-band between the opposite halves of the neopallium was not developed; (4) all the milk teeth were suppressed except the hindermost premolars and (5) the dental formula of the adult dentition was reduced from a higher number to $I\frac{5}{4}\,C\frac{1}{1}\,P\frac{3}{3}\,M\frac{4}{4}$. On the other hand, the primitive placentals apparently never developed either the three-way vagina, or the yolk-sack placenta, but their true placenta early became highly developed, as did the corpus callosum; the entire set of milk teeth was retained and the dental formula was early reduced to $I\frac{3}{3}\,C\frac{1}{1}\,P\frac{4}{4}\,M\frac{3}{3}$ The marsupial group may have been dominant in the Lower Cretaceous, when fossil records are practically blank. By the Lower Eocene the marsupials were already a defeated group which took to the trees and persisted in North America only in the form of the opossums, among the most primitive of all living animals; in South America, however, they gave rise to several extinct families (Borhyaenidae, Caenolestidae, Didelphidae) and in Australia they became the dominant mammalian forms and gave rise to a great series of families, including the dasyures, bandicoots, phalangers, kangaroos and others.

The placental group is first known from primitive insectivorous representatives from Mongolia, as already noted, apparently it originated somewhere in the north and by basal Eocene times its diversified descendants are found in western North America and western Europe but as yet nowhere else. These were small-brained forms, many belonging to families that became extinct before the close of the Eocene. Here belong most of the archaic carnivores or creodonts, amblypods, tillodonts and others. Besides the "archaic" placental families that became wholly extinct were others apparently related to later groups. Here belong (1) the Plesiadapidae (apparently related to the tree-shrews and thus representing an early phase in evolution of the primates); (2) early forerunners of the tarsioid primates; (3) the insectivore *Palaeoryctes,* representing a primitive phase of the modern centetoid insectivores; (4) the progressive creodont *Didymictis* (in or near to the ancestry of the modem carnivores); (5) the palaeanodonts, including primitive relatives of the armadillo group of edentates. The bats (*q.v.*; Chiroptera), too, appear to be an old group, possibly dating back to the Basal Eocene or even earlier. Conspicuously absent from the Basal Eocene are the modernized or caeneutherian placental orders, including especially the perissodactyls, the artiodactyls, the rodents, the Proboscidea.

The condylarths or primitive ungulates of the Basal and Lower Eocene are not regarded by modern authorities as ancestral either to the perissodactyls or artiodactyls; it is however probable that some of the condylarths gave rise to the peculiar South American orders of litopterns, toxodonts, etc. By the Lower and Middle Eocene we find in Europe and western North America, side by side with the later families of meseutherian placentals, the earliest known representatives of the more progressive modern families: *Eohippus,* representing the horses (Equidae); *Hyrachyus* and other genera, forerunners of the lophiodonts and rhinoceroses; *Trigonolestes,* a primitive representative of the artiodactyls; *Metachiromys,* a specialized armadillo-like edentate; *Viveravus,* close to the ancestors of the later carnivores; *Paramys,* a forerunner of the sciuroid rodents; *Pelycodus* and *Notharctus,* early lemuroids, and the numerous anaptomorphids, relatives of the primate *Tarsius.* Even the Cetacea were represented by the peculiar zeuglodont group. During the Lower Eocene, western Europe and North America had several fossil genera in common (including the earliest stages of the horse family) which may perhaps have spread from central Asia.

In many cases the molar teeth of the Eocene placental mammals, while variously specialized, still retained distinct traces of derivation from an earlier tritubercular type characteristic of the basal Eocene; the hands and feet were either five-toed or bore clear traces of derivation by reduction from the five-toed type; the humerus had an entepicondylar foramen and the femur a third trochanter. So that it seems reasonable to infer that all the varied placental orders of Eocene times were descendants of some group that lived perhaps in the Lower Cretaceous; but as to the more precise interrelationships of the mammalian orders, extended research on the anatomy and osteology of the recent forms and on the osteology and dentition of the fossil forms has so far rather revealed the complexity of the problem than solved it. From present evidence the tree-shrews, lemuroids and primates, with *Galeopithecus* and the bats, appear to form one great superordinal assemblage, probably derived from arboreal Cretaceous insectivores. On the other hand, the old order of ungulates, formerly supposed to be a natural group, seems to consist of a heterogeneous assemblage of orders (condylarths, taligrades, amblypods, perissodactyls, hyracoids, proboscideans, sirenians, artiodactyls, notoungulates, arsinoitheres, etc.), related chiefly by descent from various as yet unknown protoungulates.

The aardvarks, formerly classed with the edentates, may prove to be highly specialized descendants of the condylarths, while the edentates themselves are probably the descendants of the palaeanodonts, which in turn may be remotely related to the insectivore-creodont stock. The earliest known cetaceans, the zeuglodonts, were not directly ancestral to the true cetaceans; nevertheless they tie in that order with the insectivore-creodont division of the placentals. On the other hand, the Sirenia, although resembling the cetaceans in general body-form, are herbivores and their real affinities are with the ungulates.

CONTINENTAL DISPERSAL OF MAMMALIAN ORDERS

From the studies of palaeontologists and mammalogists emerge the following among other general results bearing on geographic dispersal of the mammalian orders:

(1) At various times during the Age of Mammals pathways were opened by which a given group of mammals, acquiring its special characters in regional isolation, could pass from central Asia westward to Europe or eastward to North America, or from either Europe or America to Asia. Among the orders and families of placental mammals that may have originated in the northern realm (including Europe, Asia, North America) may be mentioned the perissodactyls and artiodactyls, the insectivores, the fissipede carnivores, the rodents, the edentates, the lemuroids, catarrhine primates, anthropoids and probably man. The families of rhinoceroses, lophiodonts, titanotheres and camels afford examples of the more or less free intercontinental commerce at certain periods.

(2) South America was early in contact with North America; then the contact was broken and for millions of years the country was left to develop its own fauna of litopterns, toxodonts, ground-sloths and other strange beasts. In late Tertiary times the way was again opened and mastodons, camels, tapirs, deer and other animals streamed in from the north, while South America sent platyrrhine monkeys, ground-sloths and other animals northward.

(3) Africa, especially in the north, was frequently in contact with the northern land mass but in late Eocene and early Oligocene times the Fayum district in Egypt may have been an outlier of some central African region which seems to have produced the Proboscidea, arsinoitheres, hyracoids and sirenians. The most primitive known cetaceans (*Pappocetus, Protocetus, Prozeuglodon)* are also found there. Madagascar, possibly part of a broad archipelago formerly connected with India, was the centre of peculiar families of carnivores (viverrids) lemuroids, insectivores (centetoids). Broadly, Africa's mammalian fauna to-day represents Europe and Asia of Miocene and Pliocene times.

(4) Australia, receiving its original marsupials at some early date, was then cut off from Asia and developed one of the most interesting mammalian faunas of all time, in which the marsupial stock was fashioned into herbivorous, carnivorous and rodent-like mammals, strangely similar in habitus to their analogues of the placental world and yet always preserving their marsupial heritage in brain and reproductive system and in the deeper characters of the skull and skeleton. At times during this long period placental invaders from the north managed to get in; first a peculiar family of rats and much later the dingo or native dog, together with that most devastating of all placentals, man. Australia, on the other hand, succeeded in sending some marsupials into New Guinea and as far northwest as Celebes. Some hold also that from Australia by way of Antarctica came the extinct carnivorous marsupials and caenolestoids of South America. (*See* MARSUPIALIA.)

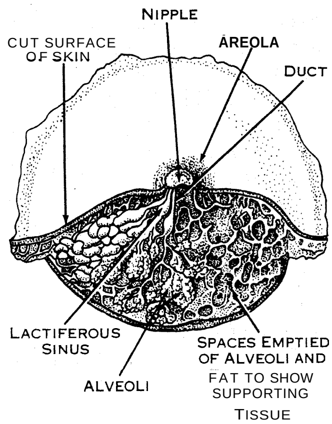
(W. K. G.)

MAMMARY GLAND, the milk-secreting organ that. together with hair. furnishes the prime distinguishing characteristics of mammals. Such glands are present in both sexes. but in the male the organ is incompletely developed.

Anatomy. — In the human female the breast extends vertically from the second to the sixth rib, and transversely from the edge of the breastbone into the territory of the armpit. A little below the centre of the glandular swelling is the somewhat cylindrical nipple, whose rounded top bears minute pores where the milk ducts open; deep within is involuntary muscle that causes the nipple to erect in response to stimulation. Surrounding the nipple is a pigmented, circular patch called the areola, which is studded with slight nodules produced by from 10 to 15 underlying rudimentary milk glands (areolar glands). During the second or third month of pregnancy the areola darkens, but after lactation ceases, this added pigmentation fades. The glandular mass proper is composed of from 15 to 20 lobes, and these subdivide into smaller lobules that contain the secretory endpieces and lesser, branching ducts. Each lobe is drained by a single excretory lactiferous duct, which swells into a reservoir (lactiferous sinus) and then dwindles again and finds an outlet on the nipple. The endpieces (alveoli) are scarcely recognizable as entities before pregnancy, and the entire gland has a blighted appearance Connective tissue and fat comprise by far the greatest bulk of the inactive organ. During pregnancy the duct system extends and alveoli appear as minute vesicles. expanding the lobules. During lactation the alveoli become relatively prominent sacs, which are packed closely together. The secretory cells of the sac wall are cuboidal in shape. and the milk secreted by them collects in the relatively capacious cavity of the sac itself. The ending of lactation is accompanied by regressive changes that return the gland to the previous inactive state.



ADAPTED FROM MORRIS, "HUMAN ANATOMY"

THE BREAST DURING LACTATION. DISSECTED TO SHOW ITS SECRETORY ALVEOLI AND DUCTS

The glands of both sexes remain equal until the approach of puberty. Then the female breast increases suddenly and continues to grow for some time. During pregnancy it augments further and after childbirth still more. Growth is largely (and possibly wholly) a response to the ovarian hormone. estrogen, whereas a pituitary hormone. prolactin. brings about actual secretion. When lactation ceases. the gland returns to approximately its former size. At the end of the childbearing period of life, the glandular tissue atrophies greatly. but compensatory deposition of fat may maintain the size of the breast. which often becomes pendulous. The two breasts are seldom equal in size, the left tending to be somewhat larger. Suppression of a nipple or of the breast itself occurs at times. Supernumerary nipples or even small glands are relatively common; they usually lie along a line that corresponds to the position of the embryonic mammary ridge and represent extra developments from that tissue. Occasionally the male breast will simulate the female breast on one or both sides (gynecomastia).

Embryology. — The mammary glands are highly modified sweat glands; transitional stages are seen in the glands of the areola and armpit. In the sixth week of human development a thickened epidermal band appears in the pectoral region, much less extensive than the axilla-to-groin mammary ridge of many lower mammals. Each future gland begins as a local thickening on this ridge. the remainder of the ridge vanishing. This lens-shaped thickening becomes a globular mass from which 15 to 20 cords grow into the deeper regions of the skin; these cords are the primary ducts and they continue to grow and branch throughout fetal life. The exposed. free surface of the original thickening hollows into a pit, and at about the time of birth this area elevates as a nipple, bordered by an areola. The further history, folloning birth, has been summarized in the preceding paragraphs. Since these glands evolved late in the history of vertebrate animals, it is remarkable that they arise so early in the mammalian embryo.

Comparative Anatomy. — Both the number of glands developed in the different mammalian groups and their locations vary widely. In general, the number corresponds to the number of young ordinarily produced at one birth. This agreement is not always exact, as in evidence are the extra glands of sheep and cattle; moreover, since the glands occur in pairs, the minimal number of two is in excess of single human births. Actually, the number of glands is not entirely constant in individuals of the same species. The position of the glands seems to bear a relation to convenience of suckling. Mammals that have many young at birth, as the sow, most carnivores, many rodents, etc.. have as many as 11 pairs of glands distributed along the wall of the underbody. In the pouched mammals (monotremes and marsupials) inguinal mammae are found, and the same is true in most ungulates as well as in the Cetacea. In sloths, elephants, Sirenia, Chiroptera and primates. on the other hand, they are confined to the pectoral region, and this is also the case in some rodents; *e g*, the jumping hare. The outcome depends on the development of glands along localized patches of the embryonic mammary ridges, while the intervening parts of the ridges disappear.

In the monotremes a pair of pits within the longitudinal, pouch-like skin fold receive 100 or more separate mammary tubules. Milk is conducted from these openings along hairs. whereupon it is licked off or sucked up by the nursing young. In all other mammals the glands open in relation to nipples. The primary type is a pseudo nipple, as illustrated by the teat of cattle and other ruminants. in which the skin around the openings of the glandular ducts grows upward so as to surround a very deep pit; in the bottom of this canal the glandular ducts open. In the true nipple the gland surface itself is elevated into a papilla. and the ducts then open at its apex. In monotremes the glands are equally developed in both sexes, and it has been thought that among bats the male often assists in suckling the young. These facts, together with the occasional occurrence of functional activity of the organ in the human male, make it probable that among ancestral mammals both sexes participated in lactation and nursing. (L. B. AY.)

Diseases. — The breast is the seat of various disturbances, all of which are worrisome and some of which are fraught with danger.

Mastodynia.—Mastodynia, or persistent pain in the breast. intensified before the menstrual period, is relatively common in mature women. The pain is often referred to a lump that is tender to the touch. These symptoms usually disappear spontaneously after months or years, but the possibility of infection or cancer must be considered.

Cysts of the *Breast.*—A galactocele is a tumour due to the locking up of milk in a greatly dilated duct. Other forms of cystic disease are usually special modifications of chronic mastitis. Such cysts are best treated by free incision, and by passing a gauze dressing into their depths. If the tissue is occupied by many cysts, it is well to remove the whole breast.

Acute ,Mastitis. — This is a temporary inflammatory condition of the breast. It is apt to occur in a woman who is suckling, and is due to the presence of septic microorganisms. which, as a rule, have found their way into the milk ducts, the lymphatics or the veins through a crack or other wound in a nipple that has been made sore by the infant's vigorous attempts to obtain food. Especially is this septic inflammation likely to occur if the nipple is depressed or so badly formed that the infant has difficulty in feeding from it. The inflamed breast is enlarged, tender and painful, and the skin over it is hot. and perhaps reddened. The woman feels ill and feverish, and she may shiver or have a definite rigour if the inflammation is passing on to the formation of an abscess. The abscess may be above or beneath the breast, but it is usually nithin the breast itself. In the early stages, cold packs and the cessation of nursing may abort the infection. The response to sulfa drugs and penicillin therapy is excellent. If pus collects. applications of heat are administered to localize the abscess, followed by incision and drainage.

Chronic Mastitis.—This condition is not uncommon in women who are past middle age. The symptoms may have been present for months to many years. The part of the breast involved is enlarged, hard and more or less tender and painful. It is sometimes impossible clinically to distinguish this disease from cancer. True, the tumour is not so definite or so hard as a cancer, nor is it attached to the skin, nor to the muscles of the chest wall, and if there are any glands secondarily enlarged in the armpit they are not so hard as they may be in cancer. But all these are questions of degree, and the indications given for a diagnosis of cancer indicate also that the disease is so advanced as to have reduced the chance of successful operation to a minimum. Moreover, it is highly inadvisable to leave it to time to clear up the diagnosis, for a chronic mastitis, innocent at first, may become cancerous, while cancer and chronic mastitis often coexist in the same breast. Hence the only safe course is removal of the breast.

Fibro-adenoma.—A simple fibro-glandular tumour may be found in the breasts of younger women, who may possibly give an account of some blow or other injury; there may, however, be no history of injury. The tumour is smooth, rounded or oval, and lies loose in the midst of the breast; as a rule it is not tender. It is not associated with enlarged glands in the armpit. The tumour, though innocent, should be removed promptly, for such growths may enlarge rapidly and become cancerous later.

Cancer.—This is the commonest disease of the breast. It occurs chiefly among women between 40 and 60 years of age, but men are not entirely immune and women older or younger than the ages mentioned may suffer. The early symptoms are given elsewhere (see CANCER), and the later symptoms are those of cancer in general; viz., local spread, destruction of normal tissue, ulceration, early extension to the nearest group of lymphatic glands (in this case, axillary) and from these to neighbouring groups of glands (in this case, supraclavicular) and formation of secondary growths in skin, liver, bones, muscle, indeed in any tissue of the body. With the exception of melanotic sarcoma the secondary growths in cancer of the breast are more widely spread than in cancer affecting any other primary site. Probably this is in part due to the fact that the natural duration (*i.e.,* duration apart from all treatment) of breast cancer is relatively long, viz., about three and a quarter years. The pain and distress are usually great, particularly in the later stages when probably ulceration will have occurred and pressure of the cancerous mass in the armpit on the veins and lymphatics may have led to great swelling of the arm. Death may be brought about in various ways, the immediate cause often being some intercurrent disorder which the patient, enfeebled by absorption of toxic material from the ulcerated surface, anemia and pain, cannot resist; or by extension of the growth to the pleura and lung, with coincident pleurisy and pneumonia.

Cancer of the breast is usually spheroidal cell carcinoma, but the columnar cell type also occurs, notably in so-called "duct carcinoma," which is a less malignant variety. Sarcoma is also met with. Carcinoma is either hard and fibrous (scirrhous) or highly cellular (encephaloid), but many intermediate forms occur even in different parts of the same breast. A scirrhous growth is relatively smaller and runs, locally, a less rapid and extensive course than encephaloid, but as regards extension from the primary focus and the occurrence of secondary growths there is little difference between them. Sarcoma of the breast locally forms a large growth and the secondary growths have a somewhat different distribution. Speaking generally, scirrhous is associated with an atrophied and shriveled breast and retraction of the nipple.

It is often said that cancer runs a more rapid course in the young; statistical evidence does not support this view, though many cases in the very aged progress slowly. On the other hand during pregnancy a cancer of the breast participates in the rapid growth of the organ. But there is no evidence that suckling conduces to cancer; on the contrary, abeyance of the natural function seems to be related to the occurrence of chronic mastitis and consequently to local cancer after a longer or shorter interval.

The treatment of cancer of the breast depends to an overwhelming extent upon the stage at which the disease comes under full and proper treatment. If cancer of the breast is dealt with by the modern complete operation while the growth has not extended beyond the limits of the organ, approximately 90% of the patients are alive and well ten years later and their expectation of life is not materially different from that of women of the same age who have not suffered from cancer. But if the cancer has extended beyond the limits of the gland, a matter of a few weeks from the time when it first becomes recognizable, the case is very different. In spite of the same operative treatment, 90% of the patients will be dead by the end of ten years. No better evidence could be given for the paramount value of early and adequate operation, but the surgeon is dependent upon the patient and there is evidence that about half the number of patients dying with cancer of the breast do not seek medical treatment at all till the last days of life; of the remainder who seek advice, an average period of six months or more has elapsed between their first noticing that something was wrong and consulting a surgeon. There may be many explanations of this delay, but the fact remains that with each hour they have been throwing away a good chance of healthy life.

In cancer of the breast early and complete operation easily holds the first place for success so far as present knowledge goes. Radium and X-ray treatment, though highly valuable in some other sites, are far inferior to surgery as curative agents in cancer of the breast with the present technique. Possibly it will remain so even with improved technique because of the special peculiarities appertaining to cancer of this organ. Upon this point no confident opinion can be given. When the disease is beyond operative treatment, radiation methods may afford palliative relief. (See CANCER; CANCER RESEARCH.)

Chronic Eczema.—Chronic eczema around the nipple of a woman late in life, with perhaps, localized ulceration, is known as Paget's disease and has a sinister significance, for it indicates that the superficial layers of the fibrous dermis are in all probability infiltrated uith cancer. Hence, when eczema about the nipple refuses to clear up in a few days under the influence of soothing treatment, the usual recommendation is the removal of the entire breast. The nipple is retracted in most of these cases, which, however, are not often met with.

MAMMEE APPLE, MAMEY or ST. DOMINGO APRICOT, the fruit of Mammea *americana,* a large tree of the garcinia family (Guttiferae), with opposite leathery gland-dotted leaves, white, sweet-scented, short-stalked, solitary or clustered axillary flowers and yellow or russet fruit 3 to 6 in. in diameter. The bitter rind encloses a sweet aromatic flesh, which is eaten raw or with sugar, and is also used for preserves. There are one to four large rough seeds, which are bitter and resinous, and used as anthelmintics. An aromatic liqueur distilled from the flowers is known as eau de *Créole* in the West Indies, and the acrid resinous gum is used extensively for destroying the chigoes which attack the naked feet of the natives.

MAMMOTH, an extinct elephant (*q.v.*) about the same size as the existing Indian form, characterized by possessing a short, high and pointed skull, which supported a pair of tusks unique in their spiral curvature, the roots diverging from one another, the middle part of the tusks turning upward and outward, and the tips being directed toward one another. Mammoth tusks (well known in fossil form), although they may be extremely long, possibly reaching a maximum length of 10 ft. 6 in. from the socket, are usually rather slender, and must from their shape have been incapable of being used as pickaxes, as are those of an Indian elephant. The tusks of the frozen mammoths of Siberia are so well preserved that they can still be used industrially, and fossil ivory has been exported from Siberia to China and Europe since medieval times.

The molar teeth of the mammoth are variable in character but the number of plates is always large. The teeth are deep and wide, so that in dentition the mammoth reached perhaps the highest point in the evolution of the elephants.

The mammoth is found only in deposits dating from Pleistocene times and is in Europe always associated with a fauna whose character indicates a cold or arctic climate. It was the only one of the elephants adapted to life in cold climates. When. as in England, warm interglacial periods intervened, the mammoth and its associates migrated to the north, following the retreating ice field.

The mammoth was hunted by late Paleolithic man, and drawings and statuettes representing the animal are found in French caves. From these drawings it is apparent that the creature was covered with hair so long that it almost reached the ground, and that the body mas shaped into a great hump at the back of the neck; the ears were small. The accuracy of these drawings has been confirmed by the evidence afforded by frozen mammoths discovered in the tundra of northeastern Siberia. These animals, because of their great weight, became bogged in marshy plains, sinking down into ice-cold mud, which subsequently became frozen and has so remained. The specimens show that the whole body was covered with an undercoat of yellowish-brown wooly hair through which projected long black thicker hairs which formed patches on the cheeks, flanks, abdomen, etc. The tail was short and, like that of a modern elephant, provided with a terminal tuft of long, stiff bristles. The small ears were covered with fur.

It is not known when the mammoth became extinct, but it survived in France to the extreme end of the glacial period, and may have lived on in Siberia to a much more recent period.

Closely related to the mammoth are several species of elephant found in warmer areas of Europe, India and North America. The American mammoths attained a gigantic size, being perhaps the largest of all elephants, attaining a height of 14 ft.

(D. M. S. W.; X.)

MAMMOTH CAVE, a cave in Edmonson county, central Kentucky, U.S.A.. 37° 14′ N. lat. and 86° 12′ W. longitude. It is a distinct part of an extensive system of caves in the soluble St. Louis limestone, overlain by the Chester (Mauch Chunk) sandstone both of the Mississippian or Lower Carboniferous series. The area of the cave-bearing formation is over 8,000 sq.m. in southern Indiana, through central Kentucky and into northern Tennessee. The cave is said to have been discovered in 1809, when a hunter named Hutchins is reported as having pursued a bear into its entrance; but it must have been known earlier, for its entrance was designated in the county records of 1797. Readily accessible to the majority of the Eastern States it is visited by many tourists. It is now a national park.

The St. Louis limestone throughout the cave-bearing area is massive and homogeneous, lying almost horizontal and showing few traces of tectonic or structural deformation. Owing to its relative purity and consequent solubility, it has been carved, chiefly since the Miocene period, by underground waters percolating and flowing along its joint and fracture planes, into a great series of caves. Where its cap of Chester sandstone has given way it has been perforated by hundreds of "sink-holes," more or less funnel-shaped depressions distinctive of the landscape of the region, and interrupted by scarp-rimmed valleys with little or no relation to surface erosion. The depth to which the cavern has been cut has been determined by the level of Green river, to which the Mammoth cave system is tributary by subterranean passages opening along its banks. As Green river graved itself deeper into its bed, the dissolving and eroding waters passing through the limestone were enabled to proceed with their carving deeper and deeper. The thickness of the St. Louis limestone approaches and in places exceeds a thickness of 300 ft. The sections of the cave ordinarily traversed have been surveyed by civil engineers and geologists; but owing to insurmountable difficulties, many avenues are still unexplored. The temperature of most of the cavern and its passages is fairly uniform at 54° F. Just within the entrance a noticeable draught sweeps, outward for most of the year when the exterior air is the warmer, inward occasionally in winter when the exterior air is the colder. The upper galleries are dry; the lower damp owing to streams and pools, and the air is pure and wholesome.

The entrance is 118 ft. below the summit of a limestone bluff and 194 ft. above the level of Green river, but a half mile distant. The arch at the entrance has a span of 70 feet. The vestibule within the entrance rapidly contracts 300 ft. within to a passage called the Narrows where a gateway has been built. A short distance beyond the Narrows the passage opens upon the Rotunda, the first notable chamber of the main cave. It was in the Rotunda where during the War of 1812 and at other times nitre was prepared for powder, from the guano, chiefly the excrement of myriad bats. By crude processes calcium nitrate worth $20,000 was obtained in 1914, when the industry reached its peak The main cave is from 40 to 300 ft. wide and from 35 to 125 ft. high. It extends through the Rotunda, thence by Star Chamber, Chief City and minor chambers connected by long passages or narrow defiles to its rather abrupt termination 4 m. from the entrance. Though the entire cave extends under an area but 10 m. in diameter, the main cave and the accessible tributary passages with their domes and chambers on its five different levels aggregate a length of at least 150 miles. The extent charted includes 225 avenues, 47 domes, 23 pits, eight cataracts, three rivers, two lakes and one sea. Streams and pools contribute to the majesty of the cave. They are navigable from May to October when Green river, with which they are connected, subsides. The Dead sea is a pool walled by cliffs 60 ft. high and in length 100 ft., along which a pathway runs to a stairway leading downward to the River Styx, a body of water 40 ft. long, crossed by a natural bridge. Lake Lethe, in a broad basin with mural cliffs 90 ft. high, becomes shallow and turbid at times. Many blind fish have been taken from it. A narrow path along Lake Lethe leads to a pontoon at the neck of the lake, and beyond it, a beach of fine yellow sand to Echo river, a stream or pool $\frac{3}{4}$ m. long, 20 to 200 ft. wide and 10 to 40 ft. deep, with a symmetrical arched roof, varying in height from 19 to 35 feet. It is famous for the resonance of the tones given out by its vibrant stone which reverberate for from 10 to 30 sec. along its vaulted gallery. Other streams and pools, some of them even miles in length, occupy some chambers and galleries. They are fed by surface waters, which in the rainy season percolate and cascade into the cave in great volume, and collect in River Hall. For about seven months of the year these streams are unnavigable. When Green river is in freshet the waters in the cave become connected, sometimes rising 60 ft. above low-water mark.

Four main routes through the cave are summarized below.

Route No. 1.—Echo River; Mammoth Dome with six majestic columns, royally fluted, 80 ft. high and 25 ft. in diameter; Gorin's Dome, 217 ft. high, the walls of which are draped with three immense calcic curtains of exquisite tint and texture; River Hall, by which the gardens of crystal roses are approached; Grand Crossing; and the Natural bridge.

Route No. 2.—Rotunda, with its ruins of the nitre works; Banquet Hall, equipped with tables, seats, lights and table service; Olive's Bower; Gothic Avenue, where the mummies of a race reputed to antedate the Indians were found; the Pillars of Hercules, gigantic columns; the Bridal Altar, a majestic shrine where many weddings have taken place; the Arm-chair; Elbow Crevice; Annetta's Dome; the Giant's Coffin 40 ft. long, 20 ft. wide, and 8 ft. deep, resembling a sarcophagus; Martha Washington's statue, a lighted silhouette in fancied resemblance of the first First Lady of the Land; and the resplendent Star Chamber, a hall of sable walls and ceiling thick set with immaculate patens of magnesium sulphate efflorescence gleaming by lantern light.

Route No. 3.—Violet City, the new section discovered and explored in 1908, comprising the resonant Chimes, the glorious Marble Temple. Albert's. Stairway, the Grand Portal, Elizabeth's Dome and Valhalla; Proctor's Arcade, a symmetrical chamber, near the Star Chamber and one of the sensations of the cave when lighted by blue flares; Indian Relics; Wright's Rotunda, 400 ft. in its shortest diameter; Chief City, two ac. of troglodytic grandeur where Indian chiefs gathered in council and by blazing flambeaux and faggot fires smoked the calumet and decided for peace or war: cataracts. of impressive beauty: Waldach's Dome; the Epsom Salts deposits, their drifts of snow-white crystals; Haines Dome; the Grand Portal and the Marble Temple.

Route No. 4.—Echo river; the Valley of Flowers; the Snowball Room; Cleveland Avenue; Florist's Garden; Donna's Garden; Diamond Grotto; the Rocky Mountains; Dismal Hollow; the Maelstrom; Ganter Avenue: and the Corkscrew.

The biota of the cave is distinctly subterranean in character. All the known forms of plant life are either fungi or allied to them, many but microscopic. (W. E. E.)

MAMORÉ, a river of Bolivia formed by affluents rising on the slopes of the Cordillera Real and flowing northward to join the Guaporé river and subsequently the Madeira river. The Mamoré is the central and most significant river in the system of waterways which drain the northern plains region of eastern Bolivia and ultimately converge into the Madeira in the northeastern section of the country. Its complex of affluents includes the Chaparé, originating to the north of the city of Cochabamba, the Isiboro, the Ichilo, the Yapacani and its tributary the Piray and the Río Grande. The latter, also known as the Guapay, rises in the cordilleras of Cochabamba and Sucre. Starting out directly east, the Río Grande then sweeps northward, northwest, and after executing a semicircle for a distance of about 600 mi. unites with Mamoré a few miles below the confluence of the latter with the Chaparé.

Most of the upper tributaries of the Mamoré are navigable by some type of craft, depending upon the season; consequently, the Mamoré is an important route from the north and east as it provides access to Cochabamba from both Trinidad and Santa Cruz. Fluvial travel from Cochabamba to the lowlands is accomplished by way of the Chaparé, Chimoré and Isiboro utilizing rafts as far as the confluence of these rivers with the Mamoré, where larger craft are operative. The Mamoré can be descended without difficulty as far as Guayaramerín, a point about 36 mi. from Villa Bella where the first rapids of the river are encountered. The Amazon river is reached by way of the Madeira and the Madeira-Mamoré railway via Pôrto Velho. The Guaporé river, or Iténez, the largest affluent of the Mamoré, is navigable along its course of 1,000 mi. at any season by vessels of light draft.

Starting from the edge of the mountains to its confluence with the Madeira, the Mamoré flows due north for about 1,000 mi. passing close by the town of Trinidad midway and absorbing several tributaries as it progresses. The downward slope to the north is so gradual in this section of the lowlands that the rivers are slow, shallow and irregular in their courses. This feature, together with the flatness of the land, results in the inundation of much of El Beni during the rainy season. The Mamoré is about 1,200 mi. long and in part constitutes the northeast boundary of Bolivia and Brazil. (J. L. Tr.)

MA'MUN (*c.* 786–833), originally 'Abdullah, surnamed AL-MA'MUN ("in whom men trust"), the seventh of the Abbasid caliphs of Baghdad, was the second son of Harun al-Rashid and successor-designate to his brother Amin. A five years' struggle between the two ended in the death of Amin and the proclamation of Ma'mun as caliph (Sept. 813). A serious rebellion, the result of his countenancing the heretical sect of 'Ali, soon after threatened his throne. In the succeeding period of tranquillity Ma'mun, who had already founded a college at Khurasan, did much to foster literature and science. The first Arabic translation of Euclid was dedicated to him in 813. He founded observatories at Baghdad and Kassium, determined the inclination of the ecliptic, caused a degree of the meridian to be measured on the plain of Shinar and constructed wonderfully accurate astronomical tables.

In 827 he adopted and gave state support to the heterodox tenets of the Mu'tazilites (*see* ISLAM). In his last years he took personal command of expeditions in Egypt and Asia Minor; and in 833, when marching against the Greeks, he died near Tarsus.

See CALIPHATE.

MAN, EVOLUTION OF. From the point of view of the biologist, the problem of the evolutionary origin of man is only one of the many problems of mammalian evolution; for, in his physical structure and physiological functions, man falls within the biologists' definition of a mammal, and thus may be presumed to be the product of an evolutionary process similar to that which is now known from the fossil record to have occurred with other groups of mammals. At the time of the publication of Charles Darwin's Origin of Species (1859) there was considerable opposition to the conception of evolution as a whole, mainly because the idea of the fixity and immutability of the different species of animals and plants was very prevalent at that time. In part, this opposition was no doubt due to the influence of the biblical story of the creation and to the fact that the teleological "argument from design" for the existence of a divine intelligence was superseded by the hypothesis of adaptation through natural selection, but it was also due to the purely scientific evidence adduced by taxonomists that species are clear-cut and sharply defined categories which are not linked by intergradations. As is well known, the cumulative evidence advanced by Darwin, reinforced by his exposition of the process of natural selection (a conception which had also occurred independently to the great naturalist Alfred Russel Wallace), eventually compelled acceptance of the main hypothesis of organic evolution. But general acceptance was certainly delayed by the circumstance that the hypothesis inevitably involved the consideration of man's relationship to lower animals, and the implied conclusion that man is also the product of an evolutionary process (and not a unique and special creation) dominated the minds of antievolutionists for a considerable time. It is possible that some of the more bitter controversies in the early days of evolutionary discussion might have been avoided if a clear distinction had been made between what may be termed "anatomical and physiological man" (*i.e.,* the biological species *Homo sapiens*) and the concept of Man in its wider philosophical context, for it is certain that misconceptions have arisen in the past, and even today still arise from time to time, from the use and misuse of the colloquial terms "man" and "human" in discussion of evolutionary origins.

The difficulties involved in achieving a precise definition of these terms are discussed in HUMAN NATURE—an article that includes also an outline of the Encyclopedia *Britannica's* treatment of the efforts of scientists and philosophers to explore the nature of human nature.

Not even anthropologists always employ the terms "man" and "human" consistently, but the main difficulty is that they are terms which in ordinary usage are commonly taken to imply very much more than the meaning attached to them by anatomists and biologists when they are considering man only in a strictly anatomical or biological sense. It is, in fact, almost impossible to give a satisfactory definition of man which will satisfy all schools of philosophy. The anatomist is not qualified as an anatontist to define man as *Man;* he is competent only within his own special field of study to define man in anatomical terms as one of the species of the animal world—Homo *sapiens.* For this reason, it is a matter of importance that in discussing the evolutionary origin of our own species we should so far as possible avoid the terms "man" and "human"—except only when there can be no possible misunderstanding as to what is meant by them. undoubtedly we can approach the whole problem with much greater objectivity if we confine ourselves rather strictly to the scientific terms of zoology, such as Homo (meaning the generic group of which H. *sapiens* is one of the species—in fact, the only surviving species) and the Hominidae (an inclusive term meaning the zoological family of which *Homo* is one of the genera). It has been suggested that, as a matter of convention, the terms "man" and "human" may reasonably be applied (and limited) to those representatives of the family Hominidae which acquired a level of intelligence enabling them to fabricate tools and implements.

As a broad generalization there is much in favour of such a definition. for the ability to design and manufacture tools for different purposes, even if they are of quite simple construction, involves mental powers of visualization and abstraction far beyond anything found in the rest of the animal world. But it is a definition which is not always applicable to extinct types of hominid, for the evidence of toolmaking capacities in such cases may not always be forthcoming.

GENERAL EVIDENCE FOR EVOLUTION

There is no need here to enter on a detailed discussion of the evidence for evolution as a whole, for this will be found in another article (see EVOLUTION, ORGANIC). But we may summarize briefly the different lines of evidence, in order to see how far they are applicable to the special problem of the evolutionary origin of the Hominidae. The evidence falls within the following main categories.

Comparative Anatomy of Living Types.—The unity of design shown in the anatomical structure of different animals (even when they appear superficially to be strongly contrasted) suggests a genetic relationship; *i.e.,* that the common structural pattern has been inherited from a common ancestry, and that the superimposed differences have been developed as the result of a gradual process of evolutionary diversification. On this hypothesis degrees of relationship are indicated by degrees of resemblance in anatomical structure. Thus, if two types very closely resemble each other in a complex pattern of anatomical details. it is inferred that their genetic relationship is correspondingly close. Considerations such as these provide the basis for modern classificatory systems in zoology. and taxonomists aim at a natural classification of animals which expresses real evolutionary relationships. The fact that it is often possible, in the study of modern types, to arrange the latter in a gradational series connecting those of simpler with those of more complex organization, or, in other words, to demonstrate what the older French naturalists called *l'échelle* des *êtres,* does indeed suggest that they are the products of an evolutionary process. For such a series demonstrates that there are links of an approximate kind in the animal kingdom even as it exists today, and such links may evidently represent the modified survivors of an actual evolutionary sequence in the past.

Geographical Distribution.—The geographical distribution of different types of living creatures is most easily explained on an evolutionary basis. This argument is particularly convincing in the study of animal and plant communities isolated by geographical or other factors. In an island population, for example, the degree to which local varieties, subspecies or species differ from each other and from those on the adjacent mainland appears to be directly related to the length of geological time during which they have been isolated and thus prevented from interbreeding with parent groups.

Vestigial Structures.—Detailed anatomical study of an animal often reveals degenerate and useless relics of some organ or structure which are explicable only on the supposition that it was fully developed and of functional importance in a past ancestry. The remnants of eyes in naturally blind animals, of wings in flightless birds and of the limb skeleton in functionally limbless creatures are examples of such vestiges.

Embryology.—The temporary appearance of certain structures during the development of the individual from a fertilized ovum (ontogeny) is difficult to explain unless it has reference to stages of evolutionary development in the past. For example, in embryos of those mammals in which, in the adult, certain elements of the skeleton or dentition have been lost, transitory traces of these elements may be found during embryonic development.

Genetics.—The study of the cytological basis of hereditary variations (mutations) demonstrates that the latter have their origin in definite changes involving the hereditary units (genes) which are located in the chromosomes of the cell nucleus. Such variations may lead either to large and abrupt or small and closely graded changes in the structure of an organism, and, in either case, they provide a theoretically adequate basis for structural modifications which may be stabilized by the cumulative effect of selective processes.

Potentialities of Selection.—The experience of animal breeders and plant cultivators makes it clear that a diversity of new varieties can be produced from common parent stocks by artificial selection, and field studies demonstrate by population surveys that the genetic make-up of a local group may undergo a gradual transformation under natural conditions of isolation and a changing environment; *i.e.,* that natural selection, as well as artificial selection, is an effective agent in altering the distribution of gene frequencies in a local population. Further, statistical studies have shown that with a known mutation rate exposed to selective influences of a given intensity, natural selection is in fact adequate for the production of structural changes such as those which have been postulated to have occurred in evolution in a known period of geological time.

Evidence of the Fossil Record (**Palaeontology**).—The fossil record provides in a number of cases a direct demonstration of a succession of closely graded intermediate types which form a temporal sequence and which thus provide concrete and objective evidence of the gradual transformations which have been postulated on the basis of indirect evidence to have led to the evolution of a whole series of types from a common ancestral stock.

EVIDENCE THAT MAN IS THE PRODUCT OF AN EVOLUTIONARY PROCESS

These different lines of evidence for evolution, which have been briefly listed above. are applicable to man as well as to other types of mammal, and some of them may now be considered in this particular context.

Comparative Anatomy.—Anatomically speaking, *Homo sapiens* belongs to the mammalian order of the Primates. This classification carries the implication that, in common with other representatives of the order, he belongs to a natural group whose members have become gradually diversified during the course of evolution from a common ancestral stock. The living Primates are characterized (and distinguished from other groups of mammals) by the fact that they have avoided structural specializations of an extreme type. Rather, they have preserved a somewhat generalized structure which confers on them a very considerable degree of functional plasticity. The order can be defined on the basis of the prevailing tendencies which have dominated its evolutionary development, and which include the following: the preservation of a generalized structure in the limbs associated nith a free mobility of the digits (especially the thumb and big toe) and the replacement of sharp compressed claws by flattened nails; the elaboration of the visual powers and a corresponding reduction in the apparatus of smell; and the progressive development of a large and complicated brain. In the Hominidae these same tendencies have manifested themselves and (particularly in the expansion of the brain and the reduction of the jaws) have advanced much further than in other Primates; this zoological family also shows a unique specialization in the "hind limbs." for the latter have become transformed into "lower limbs" for supporting the rest of the body in the erect position, while the mobility of the foot and toes (so characteristic of the Primates in general) has become secondarily lost. The justification for the inclusion of the Hominidae in the order Primates is not only based on these general considerations, it is still further emphasized by a detailed anatomical comparison with some of the other members of the order.

The Primates that exist today comprise a rather remarkable gradational series which serve to link Homo anatomically uith small mammals of a very primitive type. The most lowly representatives of the living Primates are the tree shrews, small squirrel-like creatures which have a wide distribution in southeast Asia. So primitive are the tree shrews that some authorities are reluctant to include them in the Primates. But even these authorities would also agree that they are at least very closely related to the ancestral stock from which the Primates in general have been derived in their evolutionary history. The fact is that in many of their anatomical characters the tree shrews show such a close resemblance to undoubted Primates (*e.g.,* some of the lemurs) as to amount in certain details to an identity of structure. The lemurs, again, show in their more advanced anatomical structure a mixture of characters which indicate an intermediate position between tree shrews and monkeys. The curious little tarsier (which inhabits Borneo and the Philippines) is in some respects even more monkeylike. The various types of tailed monkeys represent a still higher grade of organization and, through the small gibbon, are linked with the large, tailless anthropoid apes, the chimpanzee, orangutan and gorilla. As their colloquial name implies, these anthropoid apes are very "manlike" in their anatomical structure. Their brain, although much smaller than a modern human brain, is relatively well developed as compared with lower Primates. It also shows the same pattern of convolutions as a human brain (though in a simplified form), and the similarities in many details of its intrinsic structure (including the cerebral cortex) are astonishingly precise. These anatomical resemblances in the brain have been found by experimental observation to be correlated with physiological similarities. Thus, the sensory and motor mechanisms fulfil functions which so closely reproduce those of the human brain that for experimental studies anthropoid apes have been found to be far more reliable than any other mammal in their application to problems of cerebral function and dysfunction in man. Many features of the skull and skeleton of the large apes approximate very closely to those of the Hominidae, particularly if account is taken of certain primitive hominids which are now extinct. Some of the structural similarities in the skeleton of the trunk and limbs are in part related to posture, for the chimpanzee and gorilla are capable at times of balancing themselves on their hind limbs in a manner which suggests an approach (though a rather distant one) to the erect posture which is so characteristic of the Hominidae. In their dentition, particularly in the molar teeth, the anthropoid apes also show a close resemblance to the Hominidae. Indeed, it may sometimes be a matter of considerable difficulty to determine whether certain isolated fossil molar teeth belong to apes or hominids, for the distinctions which exist between the teeth of apes and man are in general far less obtrusive when fossil types are considered. Many of the muscles of the human body have the same disposition and attachments as those of the anthropoid apes.

For example, it is particularly noteworthy that in the sole of the human foot the same muscles are found which are used for the mobile functions of the ape foot, even though in man this mobility has been lost. The disposition of the thoracic and abdominal viscera in apes corresponds quite closely with that of man, and even in their microscopical details some of the organs of the body show a remarkable resemblance. These examples of anatomical and physiological similarities between the large anthropoid apes and the Hominidae could well be multiplied, and their implications for a real phylogenetic relationship are further supported by reference to similarities in the serum precipitin reaction of the blood. the similarity of some of the blood groups, similarities in parasitic infestation and in susceptibility to certain diseases and so forth.

So far as anatomical resemblances are concerned, it was stated many years ago by T. H. Huxley that "Whatever system of organs be studied, the comparison of their modifications in the Ape Series leads to one and the same result—that the structural differences which separate Man from the Gorilla and Chimpanzee are not so great as those which separate the Gorilla from the lower Apes" (by "loner Apes" Huxley was referring to the catarrhine monkeys). This proposition was subsequently labelled by E. H. Haeckel the "pithecometra thesis," an unfortunate term since it might have been taken to imply that the degrees of structural differences between man, anthropoid apes and lower Primates were capable of expression in strictly quantitative terms. But, though it is possible to express quantitatively individual measurements considered as isolated abstractions, or even combinations of measurements by the technique of multivariate analysis, it is not yet possible with present knowledge to give a quantitative value to different morphological characters according to their relative taxonomic importance for the assessment of degrees of phylogenetic relationship. Thus, while it is possible to state that in certain of its dimensions, or in the degree of complexity of some of the cerebral convolutions, the anthropoid ape brain is morphologically closer to the human brain than it is to the brain of catarrhine monkeys, it is not feasible to state in quantitative terms just how much more closely the ape brain *as a whole* resembles the human brain. Still less is it possible. of course, to state in quantitative terms how much more closely in his anatomical structure as a nhole man resembles the large anthropoid apes than the latter resemble the catarrhine monkeys. Another difficulty arises from the fact that, so far as concerns the soft structures of the body which are not preserved in fossils, it is of course possible to compare only *modern* apes with *modern* man (*i.e., Homo sapiens*); in other words, in respect of these components of their anatomy it is not possible to include extinct types and thus to compare the anthropoid ape family as a whole with the Hominidae as a whole. However, with the data of comparative anatomy of living types and those so far available of extinct types (known from fossil remains), it can be affirmed that, on purely morphological criteria, the Hominidae show closer affinities with the anthropoid apes than with any other group of mammals. and with increasing accessions to the fossil record the morphological boundary line bet een the two families is becoming more and more difficult to define.

Notwithstanding the numerous structural resemblances between the Hominidae and the large anthropoid apes, there are, of course, quite pronounced differences which (as already noted) are mainly related to the size of the brain and the adaptations to an erect posture and gait, as well as certain characteristic features of the dentition. These differences (and certain others) have from time to time been stressed by those who claim a certain uniqueness for *Homo sapiens* as a biological species and argue therefrom that the phylogenetic sequence of which he represents one of the terminal products must have had an extremely long history of evolutionary independence. Indeed, some have gone as far as to claim that most of the anatomical resemblances between man and apes are the result of evolutionary parallelism or convergence, and that the phylogenetic relationship between the two is far more remote than is commonly supposed. But there is little doubt that the significance of the morphological differences has been grossly exaggerated, for, in fact, they are no greater than equivalent differences ahich are to be found in many other groups of mammals known from the fossil record to be by no means very distantly related. Anatomically speaking, *Homo sapiens* is unique among mammals only in the sense that every mammalian species is in some features unique among mammals. The results of the study of comparative anatomy can be fairly summed up by the statement that, in morphological characters, the Hominidae are not sharply separated from other Primates by any major feature of either a quantitative or qualitative kind, and it is a reasonable assumption, therefore, that this zoological family like other zoological species is the product of an evolutionary process.

Embryology. — The evidence from comparative anatomy for the evolutionary origin of man receives further support from the study of ontogenetic development. As is well known, each individual begins his existence as a single (fertilized) cell, the ovum. This becomes converted into a mass of cells as the result of progressive division and multiplication, the mass of cells undergoes a gradual differentiation to form the various tissues, and the tissues become gradually moulded into all the definitive organs of the body. This whole process of ontogeny in some sense reflects the evolutionary history of the individual, but also, apart from such considerations, it is quite clear that it has a very direct bearing on the conception of human evolution as a whole. For it may well be argued that if man as an individual, with all his unique qualities of mind and spirit, can come into being as the result of the proliferation and differentiation of a single cell of microscopic dimensions, there can be no possible philosophical objection to the main thesis of evolution that mankind as a whole has come into existence as the result of a progressive evolutionary development initiated in the primary stage of a simple unicellular organism and passing through successive stages leading from simple multicellular organisms to organisms of an increasing complexity of organization. The suggestion that, in a modified form, ontogeny repeats phylogeny has been termed "recapitulation. But here it is necessary to avoid misconceptions by emphasizing that this does not mean (as it is sometimes popularly supposed to mean) that the successive stages of embryonic development in any way represent the mature forms of successive stages of the evolutionary history of the individual. It means only that, broadly speaking, in his ontogeny the developmental stages through which man passes reproduce the embryonic form of certain ancestral types. It is a fact, for example, that in the early human embryo a foundation of gill arches is laid down in the neck region, precisely similar to that which, in fishes, finally leads to the establishment of functional gills. But in the human embryo (as in the embryos of other mammals) the elements of these gill arches become completely reorganized so as to form not the gills for which it seems certain they were originally intended in past evolutionary history but quite different structures such as the skeleton of the larynx, muscles of the face and so forth. This transformation of the gill arches involves a most remarkable rearrangement of skeletal elements. muscles, nerves and blood vessels, and it seems impossible to explain such a profound modification unless it is supposed that the gill arches have been inherited from a remote ancestor of fishlike form. Some of the skeletal elements, for example, become displaced from their original position and rearranged to form the small ossicles of the middle ear through which sound vibrations are conducted to the cochlea, and it is particularly interesting to note that structural stages demonstrating this transformation have actually been followed in the fossil record of mammalian evolution. Examples of similar kinds of transformation in ontogenetic development are to be seen also in other systems of the human embryo. For example, the muscles of the trunk are at first laid down in a regular segmental arrangement as they are in the adult form of primitive vertebrates, and subsequently become rearranged to form the definitive pattern of musculature characteristic of the human adult. The early human embryo shows a distinct, projecting tail, but this becomes secondarily withdrawn into the pelvic cavity to be represented finally by degenerate vertebral elements which form the coccyx. The heart is not laid down de *novo* with the four chambers which are characteristic of the mammalian heart; the partitioning takes place secondarily, so that for a time in the human embryo the heart is constructed on the same plan as that of lowly vertebrates. The formation of the definitive kidney is preceded by the appearance of kidney tissue corresponding to that which becomes functionally mature in lower vertebrates; but in the human embryo this tissue only puts in a transitory appearance and in the course of development disappears again. The arteries of the limbs are at first disposed in a pattern similar to that of lower vertebrates, but this pattern subsequently becomes rearranged in a new pattern which is functionally more suitable for limbs of human structure. The fact that in the development of the human embryo the various tissues and organs do not proceed directly to the patterns of organization adapted to the functional requirements of the mature individual, but follow (as it were) a circuitous route which leads them through stages of development characteristic of lower forms of life and which involves the "scrapping" of many temporary structures so that the latter can be replaced by structures of a very different pattern—all this obviously provides very strong additional evidence in support of the thesis of man's evolutionary origin from lower forms of life.

Vestiges. — The functionless remnants of vestigial structures normally found in the human body, or relics which appear occasionally in individuals as abnormalities, are also explicable only on the assumption that Homo sapiens has an evolutionary past. Reference has already been made to the vestigial remains of a tail which are represented by the small nodules of bone which form the coccyx, and it is interesting to note that in relation to the latter even some of the caudal musculature has persisted in a rudimentary or modified form. The human ear has attached to it a number of muscles whose existence is very difficult to understand unless it is assumed that they are the relics of muscles which controlled the movements of a mobile ear in some ancestral stage of evolutionary development. The canine tooth is often sharply pointed and projects beyond the level of the adjacent teeth, and it is provided with an unusually strong root; this, again, is explicable only if we suppose that in some ancestral stock the canines were used for the special functions which they commonly have in lower mammals, for in modern man these teeth have no special functions to perform. In the routine examination of the human cadaver by dissection (in medical schools) it is by no means uncommon to find the remains of abnormal muscles which are not normally present in the human body; but they may be normally found in lower Primates in which they are required for particular activities such as those associated with arboreal life. An example of this is the dorsi-epitrochlearis muscle which extends down the inner side of the arm and which is normally present in the lower Primates. The occasional reappearance in the human body of an anatomical structure which was presumably present in an ancestral form is termed an atavistic variation. It is an example of the astonishing conservatism of morphological elements as the result of which the genetic basis of the latter may persist for millions of years after they have ceased to be of any real functional importance.

Human Genetics. — The study of hereditary traits by the analysis of pedigrees has demonstrated that the mechanism of hereditary transmission is the same in man as in other mammals and that the ultimate basis of mutational variations is similar in its genetic organization. In other words, there is no reason for doubting that these variations arise as the result of alterations in the gene complex of the chromosomes precisely as they do in other animals, and that in the same way they provide the raw material for evolutionary modifications under the influence of selection. Some of the characteristic differences which distinguish the various races of mankind, such as skin pigmentation and hair form, are apparently based on genetic differences which are by no means simple, for they depend on the interaction of a number of genes. It should be emphasized that the study of human genetics is a peculiarly difficult one, and the genetic analyses of racial traits are still very incomplete.

Geographical Distribution of Human Races and Adaptive Racial Characters — Homo *sapiens* is a polytypic species; that is to say, it comprises a number of different geographical varieties or subspecies which are commonly termed the races of mankind. As is well known, the major races have a fairly well-defined geographical distribution, the Caucasoid or White peoples in the European area, the Mediterranean type extending from southern Europe and northern Africa through southwestern Asia into India, the Australoid people in Australasia, the Negroids in central and southern Africa, the Mongoloids in eastern Asia and the American continent, and so forth. This type of geographical distribution is most easily explicable on the basis of an evolutionary diversification following the migration of representatives of a common ancestral stock to different parts of the world. Such migrations would lead to geographical segregation and genetic isolation which in the course of time have provided the opportunity for structural modifications in adaptation to different environments. For example, the Australian aboriginals have distinctive characters which presumably became stabilized during a long term of isolation in Australasia following a migration from southeastern Asia, where certain peoples are still found (*e.g.,* the Veddas of Ceylon) which show similar characters but in a less extreme form. Again, the highly characteristic features of the Negroids must have developed during a period of isolation — probably in central Africa. That natural selection has played an important part in the evolutionary development of racial characters may be inferred from the fact that some of these can be shown to be directly related to particular environments. Thus, the dark pigmentation of some of the tropical peoples provides a protection against exposure to strong sunlight; the width of the nose is closely related to the prevailing temperature and humidity and almost certainly has an important physiological significance in respiratory functions; and the type of bodily physique (*e.g.,* the contrast between races of long, lanky physique and those of short, stocky build) can also be correlated with environmental differences. Observations of this sort are consistent with the hypothesis that the different races of mankind, like the different varieties of animal species generally, are the product of a gradual process of evolutionary diversification.

RELATIONSHIPS OF THE HOMINIDAE

Even the antievolutionary biologists of past days classified man as one of the Mammalia, but they emphasized his apartness by placing him in a separate order, or even a separate subclass, of mammals. This distinction was influenced by the general view held at that time that man is the product of a special creation and unique in characters other than those of a purely anatomical or physiological kind. But while it may be readily conceded that modern man has such unique qualities. it has to be recognized that the problem of his zoological classification and phylogenetic relationships. as in the case of the Mammalia in general, is primarily a morphological problem and must be approached on a morphological basis. The intensive studies of comparative anatomy after the beginning of the 20th century, together with the evidence of the fossil record that accumulated later, made it clear that the Hominidae (*i.e.,* the zoological family which includes not only Homo *sapiens* but also his extinct precursors) are more closely related to the anthropoid ape family (Pongidae) than to any other group of Primates. This view was expressed in the now generally accepted scheme of classification which includes both the Hominidae and the Pongidae in a common superfamily, Hominoidea, and thus contrasts them both with the catarrhine monkeys which comprise the superfamily Cercopithecoidea. Some systematists would go even further in this taxonomic approximation of the two groups by including them in the same zoological family, but so far this view has found but few adherents.

If the taxonomic approximation of the Hominidae and the Pongidae in a common superfamily represents a natural classification, the assumption follows that these two families have ultimately been derived from a common ancestral stock by an evolutionary process of divergent modification. And, if this is so, it might be expected that, in tracing back the ancestry of the two groups in the fossil record, the morphological distinctions between the two would be found to become less and less obtrusive. This, indeed, is the case, for we now know from fossil material that the geologically earlier representatives of the Hominidae approximated much more closely to a simian level of development than modern man, while the earlier representatives of the anthropoid ape family. in so far as they had not at that time developed all the specializations characteristic of the modern apes, showed a lesser degree of morphological divergence from the Hominidae.

PALAEOANTHROPOLOGY

Palaeontology, or the study of fossils, provides the really crucial evidence for the evolution of the Hominidae in the past. For. however extensive and compelling it may be, the evidence for evolution based on the study of creatures living today can be only indirect evidence. Direct evidence, on the other hand: must depend on the actual demonstration from the fossil record of a succession of transitional stages representing the transformation in geological time of an ancestral into a descendant type. It may perhaps be put this way: The evidence from comparative anatomy of living forms, together with the geographical distribution of local species and varieties which exists today, suggests that evolution *might* have occurred. The evidence provided by a study of the process of natural selection, experimental genetics, population statistics and so forth establishes quite clearly that the machinery exists whereby evolution *could* have occurred. But that evolution did occur can be scientifically established only by the discovery of the fossilized remains of representative samples of those intermediate types which have been postulated on the basis of indirect evidence. The field of palaeontology which is related to the study of the origin of man is termed palaeoanthropology. It is concerned not only with the actual fossilized remains of early representatives of the Hominidae and of those groups of extinct Primates from which this family may have been derived, but also with the relics of the cultural activities of ancient man and the nature of the environment in which he lived. Here, however, attention will be confined almost entirely to the evidence of skeletal remains. Broadly speaking, the main features of the evolutionary succession of the Primates are now known from the fossil record. and they conform in a remarkable way with inferences already reached by a consideration of the scale of living Primates as they exist today (*see* above). At the beginning of the geological era called the Tertiary period—that is to say, about 70,000,000 years ago—there were in existence the most primitive of the Primates, small tree shrewlike creatures called the Plesiadapidae. So primitive are their anatomical characters that it might be impossible to determine that they actually were Primates but for the fact that they mark a gradation toward more highly organized creatures which definitely come within the category of Primates as these are ordinarily defined. Early in the Tertiary period, during the Palaeocene and Eocene, more advanced Primates appeared which belong to the same zoological groups as the modern lemurs and tarsiers. Somewhat later, in the Oligocene (probably about 45,000,000 years ago), there came into existence primitive monkeys and exceedingly primitive anthropoid apes. In the succeeding Miocene (30,000,000 years ago or so). anthropoid apes of a generalized type appeared in great diversity in different parts of the world, and their remains have been found in considerable quantity in East Africa, Europe and India. Some of these early types, so far as can be ascertained from teeth and jaws and fragmentary limb bones, might possibly have provided the basis for the evolutionary origin of the Hominidae, but the fossil evidence is still too meagre to make possible any positive conclusion on this question. The earliest hominids so far known date from near the beginning of the Pleistocene (about 1,000,000 years ago), but the fact that these ancient types were already well advanced along the direction of hominid evolution makes it certain that still earlier representatives of the Hominidae must have existed in the preceding Pliocene period. Here there is a conspicuous gap in the fossil record which still remains to be filled by future discoveries.

ESTIMATION OF GEOLOGICAL ANTIQUITY

Before the evolutionary history of man, so far as this may be determined by the examination of fossil remains. is traced back in further detail: it is desirable to say something about the geological changes which marked the passage of time in the Pleistocene period. As already noted, the Pleistocene period of geological time may be regarded as having started about 1,000,000 years ago. The date of the transition from the Pliocene to the Pleistocene period is no more than an arbitrary point of time, and geologists have not found it easy to agree on the definition of this arbitrary point. Broadly speaking! it was marked by the gradual onset of a cooler climate in many parts of the world; and the general lowering of the temperature finally led to the Great Ice Age during which, in the temperate zones, ice caps and glaciers, originating on high levels, spread out for considerable distances over lowlands. This process of glaciation was a recurrent phenomenon which extended throughout most of the Pleistocene period, and it is now generally agreed that there were four main glacial periods, of varying duration and different degrees of severity, separated by interglacial periods during which the climate became warmer and in some cases (even in Europe) almost subtropical. Evidence of the successive glaciations can be detected by study of the characteristic geological deposits left by melting ice and so forth, and also by reference to the fossil remains of the arctic or subarctic types of animals and plants which inhabited the neighbourhood of the glaciated regions. By the determination of the rhythmical succession of glacial and interglacial phases during the Pleistocene period, geologists have been able to provide a time scale by reference to which it is possible to infer the relative antiquity of the fossil remains of prehistoric hominids or of the stone implements which they left behind. For if the deposits laid down during the successive glacial and interglacial periods can be placed in a regular temporal sequence on purely geological evidence, any fossils found in these deposits can likewise be placed in their proper sequence. It may be noted, also, that even in those parts of the world (*e.g.,* equatorial regions) where there was no actual glaciation, climatic fluctuations of a different type occurred, for in those regions there was a succession of alternating rainy and dry periods. There is some evidence that these pluvial and interpluvial phases can be equated with the glacial and interglacial periods in the northern and southern hemispheres, a matter of importance for determining the time relationships of fossil hominids found in widely separated parts of the world.

The recurrent glaciations in Europe and elsewhere were accompanied by considerable falls in the sea level. and this had a profound effect on the formation of river valleys. With the fall in sea level the erosive power of the rivers was increased so that they cut their valleys deeper. On the other hand, with the rise in sea level during the interglacial periods the rivers flowed more sluggishly and laid down stratified deposits of gravel and sand, etc., over their alluvial plains. As the result of these alternating periods of erosion and deposition, series of terraces were formed along the river banks, and it is in these river terraces that some of the oldest remains of Palaeolithic man and his stone implements have been found. The time relationship of the terraces to the rhythmic succession of glaciations has been worked out in some detail by geologists. and it is largely on this basis that the relative antiquity of the fossils which they contain can be established.

The relative age of fossils may be determined by purely geological data — that is to say, it may be inferred from the stratigraphical level of the deposit in which the fossils are indigenous— and in the case of skeletal remains embedded in sedimentary formations which have been deposited layer by layer under the influence of agents such as running water or in stalagmitic formations in caves, the more ancient fossils are found in the deeper layers and vice versa. As has been noted, these deposits in some cases can be assigned to one of the several glacial or interglacial periods, and a relative dating can thus be obtained in relation to the rhythmical succession of climatic changes which characterized the greater part of the Pleistocene. Another method depends on the analysis of the fluorine content of fossil bones. The fluorine content increases with geological age, for by a process of ionic interchange this element is slowly taken up from the soil and becomes fixed in bony tissue in the form of a very stable compound, fluorapatite. The amount of fluorine in a fossil bone thus increases with time and gives an indication of the period over which it has lain in position in a particular deposit. However, the amount of fluorine taken up also depends on the amount of fluorine in the soil, and it does not therefore permit a comparison of the relative antiquity of fossilized bones derived from different deposits in which the fluorine content of the soil may vary widely. But in a case where in the same geological deposit a hominid skull is found in association with the remains of extinct mammals of known antiquity, the fluorine test may provide evidence of the utmost importance for determining whether they are all contemporaneous or whether the hominid remains may be the result of (say) an artificial interment at a much later time. A further method, the radiometric method, depends on the observation that fossil bones and teeth often show some degree of radioactivity, a result of the gradual absorption of uranium from percolating ground waters, and the degree of radioactivity of a fossil therefore depends partly on its geological age. But it also depends on the permeability of the deposit in which the fossil lies and on the uranium content of the percolating waters in past ages. Thus, like the fluorine test. the radiometric assay is of value only for determining the relative age of fossils found in the same or strictly equivalent geological formations.

The absolute antiquity of a fossil in terms of years can be determined only rarely with the methods at present available. One of these methods depends on the estimation in organic material of the relative quantities of radioactive carbon (C^{14}) and ordinary carbon (C^{12}), of which the former is an isotope. Radioactive carbon is assimilated into the substance of living organisms from the atmosphere (directly or indirectly), and at death it undergoes a gradual disintegration at a known rate. The proportion of radioactive carbon thus progressively diminishes in dead organic material in proportion to its antiquity, and it is estimated that after a period of 5,600 years the ratio of radioactive carbon will have dropped to half the value found in living material. With modern techniques, the accuracy of the method is limited to estimations of a period of not more than about 50,000 years. Lastly, reference should be made to the method of varve analysis — that is. a method which depends on counting the annual layers of deposits (varves) laid down seasonally by the melting of the glaciers as they gradually receded at the end of the Ice Age. But this method is applicable only for the determination of the rate of climatic change in the final stages of the Pleistocene period, and the estimations based on it are complicated by the fact that the varves may not always be strictly seasonal in their sequence.

ANTIQUITY OF HOMO SAPIENS

The biological species *Homo sapiens* (of which the modern human races comprise a number of different subspecies or geographical varieties) is defined in terms of the anatomical characters which all its members possess in common. So far as prehistoric representatives of the species are concerned, the definition must necessarily be limited to skeletal characters, for such individuals are to be identified only by their bony remains. The definition of H. *sapiens* (which will not be given in detail here) includes such features as a mean cranial capacity of about 1,350 c.c., an approximately vertical forehead, a rounded occipital region of the skull with a relatively small area for the attachment of the neck musculature, jaws and teeth of reduced size, small canine teeth of spatulate form, the presence of a chin eminence. limb bones adapted to the mechanical requirements of a fully erect posture and gait, and so forth. Any skeletal remains of ancient man which conform to this morphological pattern, or which do not deviate from it to an extent comparable with that which is accepted as adequate for specific distinctions in other groups of higher Primates, must be assumed to be those of some variety of *H. sapiens.* It is necessary to emphasize this rather obvious point, for in the past there was a most unfortunate tendency to create entirely new species of *Homo* on the basis of fragments of prehistoric human skeletons, even though it might not be possible objectively to demonstrate any significant difference from modern man. This tendency was no doubt partly the result of subjective impressions influenced simply by the supposed antiquity of the remains, or of a failure to realize how variable some features are even in modern *H. sapiens.* One of the best examples of this kind of fallacy is the famous Galley Hill skeleton. which was discovered in 1888 in the Thames valley and was supposed to be of very great antiquity. Some anatomists persuaded themselves that they could recognize very primitive features in this specimen. particularly in the shape of the lower jaw. Moreover, an apparently exhaustive study of the thighbone, involving an elaborate statistical comparison of a number of measurements and indices, even led to the conclusion that it was quite distinct from modern man. But in later years it was determined, largely as a result of the analysis of its fluorine content, that the Galley Hill skeleton was a burial of comparatively recent date — perhaps the remains of a Neolithic man or possibly even a later interment. How is this discrepancy of evidence from the statistical side to be explained? This is rather an important question, for statistical tables (particularly to anyone who is not a statistical expert) are apt to convey an impression that conclusions based on them are final and indisputable. But it has come to be realized that the application of statistical methods to the study of zoological relationships of fossil remains is open to rather serious fallacies, depending on the statistical methods used, on the actual number of measurements taken, on whether the measurements compared are really strictly equivalent in the morphological sense, on whether they are taxonomically relevant and so forth. It has also been demonstrated that if the individual characters and measurements of a bone or a tooth are compared independently one by one, as isolated abstractions. instead of in their totality as integral components of a total pattern (which can be done by the very complicated method of multivariate analysis), entirely different and sometimes very misleading conclusions may be reached. In the case of the Galley Hill thighbone, the answer is fairly simple, for in the statistical study of this bone comparison was made with only a very limited sample of modern thighbones, and it seems to have been assumed that these could be taken as representative of H. *sapiens* as a whole. But obviously the comparison must be made with adequate samples of all the main varieties of *H. sapiens* before it can be legitimately concluded that there is a distinction from "modern man."

If the history of mankind is traced back beyond the ages of metal into the Neolithic period, a period which began about 7,000 years ago, it is found from the numerous examples of the skeletal remains which have been excavated that these show no significant difference from modern man. Indeed, much of the Neolithic population in Europe was probably indistinguishable from the modern types of European which inhabit the Mediterranean area. Still further back in time. in the latter part of the Palaeolithic period, the human remains discovered are also those of H. *sapiens.* This is the case. for example, with the Magdalenian period, which lasted during the terminal stages of the last glaciation of the Ice Age and which is sometimes referred to as the "Reindeer period" for the reason that reindeer were characteristic of the local fauna at that time. The Magdalenian people were very skilful in the production of a great variety of beautifully made flint implements and also instruments of bone, ivory and reindeer antler. They are also noted for their mural art, represented in cave paintings of great artistic merit which have been found chiefly in the caves of southern France and northern Spain. In some of the most famous of these caves. those at Lascaux in the Dordogne region of France, pieces of charcoal were found which are believed to be contemporary with the paintings, and a sample tested by the radioactive carbon method gave a dating of about 15,000 years ago. The Magdalenian period was preceded still earlier in Europe by the Aurignacian period of Palaeolithic culture, and as is known from a number of skulls and skeletons of the Aurignacian people these were also of modern type. Moreover, although in many respects they were culturally inferior to the succeeding Magdalenian people, they had already developed a fairly complex civilization. Now, the geological evidence indicates that the Aurignacian period, at a conservative estimate, could hardly be less than about 20,000 years old. and if men of modern type had already developed well-organized communities with an elaborate culture in Europe at this early date the presumption is that. as a zoological species, H. *sapiens* must have been in existence considerably earlier. There is indeed palaeontological evidence for this inference. But before some of the evidence for the earlier existence of H. *sapiens* in Europe is considered, the fossil evidence of his wanderings in other parts of the world may be briefly referred to.

Several remains of early man, some unfortunately very fragmentary, have been discovered in Africa, which can with reasonable certainty be assigned to a cultural stage equivalent to the Upper Palaeolithic of Europe. In all cases these remains appear to be indistinguishable from H. *sapiens.* One skull, found at Florisbad in South Africa, is of particular interest, for it was embedded in deposits containing layers of peat, and a sample of the peat closely associated with the skull was used for dating by the radioactive carbon method. According to this estimate the peat was probably deposited at least 40,000 years ago, and it has therefore been inferred that the skull is of like antiquity. In the far east, Upper Palaeolithic remains of H. *sapiens* were reported from cave deposits near Peking, associated with a stone culture corresponding to the Aurignacian or Magdalenian in Europe. In America remains of the species also were described from deposits which were dated on geological evidence to the terminal part of the last glaciation, and the antiquity of this was estimated in a very general way at 10,000 years more or less. One well-preserved skull found at Tepexpan in Mexico was assigned to such an antiquity, and this may well prove to be justified, for the radioactive carbon dating of organic material from an overlying deposit (which must have been laid down long after the skull was in position) gave an antiquity of certainly more than 4,000 years. There are two other relevant carbon datings which indicate an antiquity for *H. sapzens* in America of at least 10,000 years; one of these was based on the analysis of charred bison bones associated with stone implements of the Folsom type (in Texas) and the other on the analysis of woven rope sandals found in Oregon buried beneath pumice deposited by a prehistoric eruption.

From this short account, it is evident that H. *sapiens* had spread over most parts of the world at a very remote time, carrying with him types of Palaeolithic culture which provide evidence of their common origin while at the same time showing local differentiations. It is unfortunate that the place of their origin is not yet certainly known, for this might give a useful clue to the geographical area of origin of the species. Various claims have been put forward on behalf of one area or another, mainly on the basis of fossilized skeletal remains which have been assigned to an antiquity far greater than is known in other regions of the world. But the evidence for this supposed greater antiquity has not in all cases been sufficiently convincing. So far as Europe is concerned, there is good evidence that primitive types of H. *sapiens* were already in existence before the last glaciation of the Ice Age—that is to say, during the last (or third) interglacial period —and this could hardly have been less than 50,000 years ago. Examples of such early representatives of the species have been found at a number of different Palaeolithic sites (*e.g.,* Fontéchevade, Ehringsdorf, Krapina, Saccopastore, etc.). Some of these skulls are very fragmentary, and although some show an accentuation of certain primitive features, such as strongly developed brow ridges, this is not the case in all the specimens. The significance of these features tends to be overemphasized if comparisons are made only with modern European skulls, but they appear far less obtrusive when compared with the other varieties of modern H. *sapiens* such as the Australian aboriginal. and they are not sufficiently marked to warrant a taxonomic distinction from this species. There are at least two fossil specimens identifiable as H. *sapiens* which date back to the second interglacial period—an almost complete skull from Steinheim. Ger.. and a very fragmentary skull from Swanscombe, Kent. Eng. Because of their importance for determining the antiquity of the species, further reference to these two fossils is desirable. The Steinheim skull was discovered in 1933 near Stuttgart in interglacial gravels containing remains of extinct mammals such as *Elephas antiquus* and *Dicerorhinus merckii.* There had been some doubt whether these gravels were laid down in the second or third interglacial period, but later studies make it reasonably certain that they belong to the older of these two phases. The skull has rather a low cranial capacity (1,100 c.c.), but the latter comes well within the range of modern man. The brow ridges are strongly developed, but it is doubtful whether they exceed in size those occasionally to be found in some of the modern races of mankind. The anatomical evidence of the skull as a whole, indeed. permits the inference that it may be attributed to a primitive type of H. *sapiens.* The Swanscombe skull consists of only two of the cranial bones. the left parietal and the occipital. both of which are exceptionally well preserved. They were discovered in 1935 and 1936, 24 ft. below the surface in well-stratified gravels forming part of the 100-ft. terrace of the Thames. These are definitely interglacial deposits, and the associated fauna includes *Elephas antiquus, Dicerorhinus megarhinus* and *Megaceros.* Also associated with the skull bones were found flint implements which can with certainty be assigned to the Middle Acheulean hand-axe industry. The geological, archaeological and faunal evidence is all consistent with the conclusion that the skull bones date back to the second interglacial period. Finally. this received confirmation from an analysis of the fluorine content of the bones and of their radioactivity. A most detailed anatomical and biometrical study of the bones (and of the endocranial cast) failed to show any feature in which they could be distinguished from the corresponding bones of modern human skulls. It was inferred, therefore, that they provide unusually convincing evidence of the existence of H. *sapiens* in the second interglacial period, a period to which conservative estimates based on geological considerations give an antiquity of not less than 100,000 years. While this inference regarding the antiquity of the Snanscombe skull bones may be provisionally accepted, it should be regarded as no more than a provisional inference pending the accession of further and more complete material. But, taken with the evidence of the Steinheim skull, it does at least indicate a high degree of probability that the species H. *sapiens* has an antiquity of this order.

NEANDERTHAL MAN AND NEANDERTHALOIDS

It is known from many fossilized remains discovered in different parts of Europe that there existed during the first phase of the last glaciation a rather peculiar type of the genus *Homo* commonly known as "Neanderthal man," and it is generally accepted that the type is referable to a distinct species. *H. neanderthalensis.* In the early days of palaeoanthropological discovery, H. *neander-*

thalensis was commonly assumed to represent the ancestral type from which *H. sapiens* was derived in late Pleistocene times. This assumption was based partly on morphological arguments; for in a number of features, such as the flat and retreating forehead, the low height of the cranium, the massive brow ridges, the robust and chinless jaws, the large teeth and so forth, the skull of Neanderthal man certainly presents a somewhat simian appearance. But the accumulation of further discoveries made it clear that these apparently primitive features are secondary—the result of a "retrogressive" evolution from still earlier types which (as seen above) do not appear to be specifically distinguishable from H. *sapiens.* The brain was, surprisingly, rather large, for the mean cranial capacity actually exceeded that of modern human races. Neanderthal man was contemporaneous with the latter part of the Mousterian period of Palaeolithic culture, and his remains have been found at various sites in Europe (*e.g.,* in France, Germany, Italy and the U.S.S.R.) as well as in North Africa and Palestine. The species evidently disappeared from Europe rather abruptly after the climax of the last glaciation, when he was replaced by an Upper Palaeolithic population of completely modern type. It is probable that, with the first recession of the ice following the last glaciation, Europe was invaded (probably from some region in the near east) by the more highly cultured Aurignacian people and that the latter displaced and exterminated H. *neandertlzalensis.*

Remains of early man have been found in Java, Rhodesia and South Africa which in the general appearance of the skull show a strong resemblance to H. *neanderthalensis,* and by many authorities they are regarded as geographical variants of this species. However, they show differences in certain morphological details, so that their taxonomic relationships are somewhat doubtful. For this reason they are commonly referred to by the rather informal term "Neanderthaloid." The remains from Java were found in terrace deposits related to the river Solo and are of Upper Pleistocene date (probably corresponding in time to the last glaciation). They consist of 11 skulls (all lacking the facial skeleton) and two shinbones. In the heavy brow ridges, the thick cranial walls and the flattened skull vault they approximate closely to H. *neanderthnlensis.* On the other hand, the cranial capacity was smaller, and the shinbones are similar to those of H. *sapiens.* The Rhodesian fossils were found in the course of open-cast mining of lead and zinc ores at Broken Hill in Northern Rhodesia and consist of a skull (almost complete except for the mandible), a maxillary fragment, a sacrum and portions of the pelvis and limb bones. The skull is of unusually massive appearance, with huge brow ridges, a strongly retreating forehead and a large palate. The sacrum. pelvis and limb bones. on the other hand. are not distinguishable from those of H. *sapiens* and show none of the features commonly regarded as characteristic of *H. neanderthalensis*. The artifacts found with these remains indicate an Upper Pleistocene date. A second skull of the Rhodesian type (almost identical in its cranial features) was later discovered at Hopefield, north of Cape Town. and from the geological evidence it probably somewhat antedates the Rhodesian skull. The significance of "Solo man" and "Rhodesian man" in the problem of human evolution is uncertain. If these types represent variants of Neanderthal man, it must be assumed that the latter wandered widely over the earth's surface. It has also been postulated that they represent local developments in the areas where their remains were found, and that they were either aberrant types which became extinct or they provided the ancestral stock from which the Australoid and Negroid races of modern mankind were derived. However, there is no convincing evidence for this last view, and in any case it would appear that they existed too late in time.

If we accept that, on the fossil evidence so far available. H. *sapiens* certainly extended back to the third and almost certainly to the second interglacial period, the question now arises—is there any evidence that he existed anywhere on the earth at a still earlier date? In spite of reported discoveries for which a greater antiquity has been claimed, the answer to this question in the later 1950s still remained entirely negative. If the term "man" is taken to connote toolmaking hominids, then it is correct to say that man has been in existence since at least the early part of the Pleistocene period—that is to say (on the basis of indirect geological evidence) 500,000 years ago or more—for his stone implements have been recovered in great numbers from deposits going back to this remote time. The advanced culture of Aurignacian times was preceded by more primitive cultures termed the Mousterian and Levalloisian, and these again were preceded by populations which were responsible for the Acheulean hand-axe industry. The latter persisted into the last interglacial period in Europe, but it extended back through the whole length of the prolonged second interglacial period, a matter of many thousands of years. Still earlier was the primitive Abbevillian industry, characterized mainly by large hand axes of a rough and unfinished type. Lastly, the very crude pebble-tool industry has left its traces in deposits dating from the earliest part of the Pleistocene and found in many different parts of the old world. The only certain evidence of fossil man antedating the second interglacial period bears witness to hominids which, on morphological criteria. were very different from *Homo sapiens,* and they have been referred to as a separate genus altogether, *Pithecantlzropus.*

PITHECANTHROPUS

The first discovery of the remains of the genus *Pithecanthropus,* made at Trinil in central Java in 1891, consisted of a skullcap and thighbone. These were found in alluvial deposits on the bank of the Solo river at a stratigraphic level which (it is now generally agreed) is of middle Pleistocene age, and they were probably laid down at a time corresponding to the second glaciation of the Ice Age in other parts of the world. The skullcap is astonishingly small and presents a remarkably simian appearance. So much so, indeed, that some anatomists at first refused to recognize it as a hominid skull at all and supposed it to be the remains of a giant gibbon. By contrast, the femur is entirely similar to that of *Homo sapiens,* and some doubt was expressed whether it really belonged to the same creature as the skull. However, portions of other thighbones of modern type have also been recovered from the same series of deposits, and that they are properly attributable to *Pithecanthropus* has been confirmed by fluorine tests and by the fact that thighbones of similar type have also been found in association with the remains of the same genus *Pithecanthropus* in China. That the skullcap belongs to a true hominid (and not to a large ape) is shown by the cranial capacity, which exceedsconsiderably that of any known ape, and by further discoveries in Java of other skulls and of jaws and teeth. These later discoveries include the remains of three adult skulls and the cranium of an infant. an upper jaw and the adjacent part of the facial skeleton, some fragments of lo er jaws and a number of teeth. One of the lower jaw fragments, distinguished for its great size, has been referred to a new genus of extinct hominid, *Meganthropus,* but there is no convincing evidence that it is other than an unusually large jaw of *Pithecanthropus.* It should also be noted that some of these remains were found in deposits underlying the Trinil horizon, and this makes it clear that *Pithecanthropus* was already in existence in Java during the early Pleistocene.

From all this fossil evidence it has been established that the Javanese type of *Pithecanthropus* shows very primitive characters in the skull and dentition. The mean cranial capacity was probably rather less than 1,000 c.c., the forehead region is flat and retreating, the brow ridges project forward as a shelf of bone overhanging the orbits, the cranium is extremely flattened and in its general contour very simian in appearance, the area on the back of the skull for the attachment of the neck musculature shows that the latter must have been po erfully developed, the nasal aperture is very broad, the palate and jaws are massive, there is no chin eminence, the molar teeth are exceptionally large. and (in some individuals) the upper canine tooth projects beyond the level of the adjacent teeth and interlocks to a slight degree with the lower canine tooth. The infant skull, found at Modjokerto in eastern Java, is of particular interest, for although it belonged to an individual of perhaps not more than two or three years old, already at that early age it shows the incipient development of some of the characteristic features of the adult *Pithecanthropus* skull; *e.g.*, the retreating forehead and the strong brow ridges. The cranial capacity of the skull is about 700 c.c., and from this it has been estimated that in the fully grown individual it would not have exceeded 1,000 c.c. The study of endocranial casts has further emphasized the primitive character of this extinct hominid. for in its proportions and dimensions the cerebrum shows an approximation to that of the apes, as also in the convolutional pattern of the frontal lobe of the brain. Apart from the size of the canine tooth in some individuals, the dentition is entirely hominid in its general characters. No stone artifacts have been found in the strata from which remains of *Pithecanthropus* were recovered in Java, but stone chopping tools and primitive hand axes occur in deposits of a slightly later age, and it is not improbable that such tools were actually made and used during the middle Pleistocene by hominids of the *Pithecanthropus* type in that region. The thighbones provide evidence of a height of about 5 ft. 8 in. and, since (as already noted) they are not distinguishable from the thighbones of *Homo sapiens,* it may be inferred that *Pithecanthropus* had already developed an erect posture and gait quite similar to those of modern man. It is for this reason that the Javanese type of the genus has been called by the specific name *P. erectus*. It may be noted that some authorities have interpreted the large mandibular fragments as evidence for the existence in Java during the Pleistocene of "giant" hominids. But this is a misapplication of the term "giant," which is commonly taken to refer to stature. A large jaw does not necessarily imply a giant individual; on the contrary, so far as the available palaeontological evidence goes, there is some reason for assuming a negative correlation between the size of the mandible and the total stature in primitive hominids. Certainly, as has been seen. the thighbones from the Trinil deposits provide no evidence of great height.

The Chinese representatives of *Pithecanthropus* (usually assigned the specific name *P. pekinensis)* are known from skeletal remains discovered at Choukoutien near Peking. The first find was made in 1927 and consisted of a lower molar tooth. Two years later, a well-preserved cranium of very primitive type was found at the same site. These remains were at first given a different generic name. *Sinanthropus,* but their close relationship to the Javanese *Pithecanthropus* soon became evident, and the term *Sinanthropus* has been discarded. *P. pekinensis* is now known from the remains of 14 skulls. as well as portions of the facial skeleton. several mandibles, many teeth and a few limb bones. The cranial capacity has a mean value of rather more than 1,000 c.c., but it seems to have been remarkably variable. for in four individuals it shows a range from 850 c.c. to 1,300 c.c. The latter figure comes well within the range of variation of H. *sapiens*. • the skulls show a marked flattening of the cranial vault, heavily constructed brow ridges and thick bony walls. The facial skeleton is strongly built, the jaws and teeth are large, and the mandible lacks a chin eminence. The forehead region is rather better developed than in *P. erectus,* and, with the somewhat larger cranial capacity, this has been taken to indicate that *P. pekinensis* was a slightly more advanced type. The teeth, in spite of their large size. conform in all essentials to the hominid pattern and the canines. though in some individuals large and conical, do not project to any marked degree beyond the level of the adjacent teeth. The limb bones found at Choukoutien comprise portions of seven thighbones, two upper arm bones, a collarbone and one of the small bones of the wrist. In no character has it been satisfactorily demonstrated that any of these limb bones are distinguishable from those of H. *sapiens.*

In the same deposits yielding remains of *P. pekinensis,* crude cores and trimmed flakes of quartz and silicified rocks were found, comprising a local Palaeolithic industry of an archaic but fairly uniform character. Some animal bones were also found which had evidently been broken and shaped for use as implements. Finally, the deposits contained the remains of hearths and quantities of charred animal bones, evidence that these ancient hominids were skilful hunters and had learned the use of fire for domestic purposes. From all this evidence, it seems clear that, in spite of their very primitive morphological characters, the Chinese representatives of *Pithecanthropus* had already developed a communal life of a very active kind.

The geological evidence makes it fairly certain that they lived during the middle Pleistocene, probably at a time corresponding to the second interglacial period.

The question arises whether the geographical range of *Pithecanthropus* extended outside the far east. There is no certain evidence of this. but reference may be made to the massive, chinless jaw found in 1907 in a sand pit at Mauer, near Heidelberg. Ger. The jaw is very simian in appearance, but the teeth. though large, are typically hominid. This specimen is usually referred to the species *Homo heidelbergensis,* but it may equally well belong to the genus *Pithecanthropus.*

The identification of the specimen is hardly possible in the absence of the skull. The fossil was found in association with *Elephas antiquus* and other extinct mammals characteristic of the early part of the Pleistocene; it probably dates from the commencement of the first interglacial period, which would give it an antiquity of several hundred thousand years. No stone implements were found at the site. Two lower jaws, quite similar to the Heidelberg fossil and possibly also belonging to a type of fossil hominid not taxonomically distinct from *Pithecanthropus,* were found in Algeria in 1954, in association with stone artifacts of an early hand-ax industry.

The geological and archaeological evidence suggests that these specimens date from a period of the Pleistocene slightly later than Heidelberg man.

The palaeontological evidence so far available indicates that *Pithecanthropus* lived long before *Homo sapiens* came into existence. He was therefore a precursor of *H. sapiens* and the conclusion naturally suggests itself that he was actually ancestral to this species. Here it is necessary to draw attention to a misunderstanding which frequently arises in discussions on probable ancestors.

When it is suggested that *Pithecanthropus* may have been ancestral to *H. sapiens* (and the evidence of palaeontology and comparative anatomy lends considerable support to this thesis), it is not of course meant to be implied that the actual individuals whose remains have been found in the far east were themselves the ancestors: nor even that the local groups or species which they represent were so. It only means that the genus as a whole may have provided the ancestral basis from which modern types of man were initially derived. Other representatives of *Pithecanthropus* than those already known, and perhaps a different specific group of the genus may have provided the actual ancestors. This problem will be settled only when much more palaeontological evidence has accrued.

The most that can be said at the present time is that. considered together, *Pithecanthropus,* primitive types of *H. sapiens* such as those known to have existed in pre-Mousterian times. and modern *H. sapiens* provide a gradational series which is also a temporal sequence, and this is highly suggestive of the conclusion that they represent an actual evolutionary lineage.

Perhaps the most striking feature of the archaic *Pithecanthropus* is shown in the combination of very primitive and almost simian characters of the skull, jaws and brain with a dentition which is fundamentally of the hominid type (contrasting very strongly with the dentition of all anthropoid apes, whether Recent or extinct) and with limb bones which, so far as they are known from rather fragmentary remains. are no different from those belonging to modern man.

It seems clear, therefore, that in evolutionary development of the Hominidae, the adaptation of the limbs for an erect posture and gait and the acquisition of the hominid type of dentition began earlier and proceeded more rapidly than the modification of the skull and jaws or the expansion of the brain to the form and proportions characteristic of *H. sapiens*. There is some reason to suppose that the expansion of the brain to modern proportions must have been a rather rapid process compared with evolutionary rates in general. Certainly there is no evidence at all that the brain had begun to approach modern dimensions before the Pleistocene, and it is a matter of some importance that this should be recognized. For the consensus among palaeoanthropologists was (at mid-20th century) that the Hominidac. as an evolutionary radiation distinct from the evolutionary radiation of the anthropoid apes, probably became segregated not later than the Miocene or the early Pliocene; that is to say, several million years before the commencement of the Pleistocene. If this mere so, it means that the earlier representatives of the Hominidae must have retained brains of simian proportions for a prolonged interval of geological time.

But during this interval they were presumably already differentiated from the ape family by progressive modifications of the limbs for the erect posture. which is one of the outstanding diagnostic characters of the Hominidae as a whole, and by the development of the hominid type of dentition (both of which features, as we have seen, were already well established in the early Pleistocene by the genus *Pithecanthropus*). By a consideration of the comparative anatomy of man and the modern apes, and by reference to the palaeontological evidence recounted above. it is clear that the initial differentiation of the Hominidae and the anthropoid ape family from a common ancestral stock was related to divergent trends of evolution which, in the limbs and dentition, were rather strongly contrasted. and there is some reason to suppose that, more than anything else, it was the divergent modification of the limbs for very different modes of life which determined the initial segregation.

If these general inferences regarding the early evolutionary development of the Hominidae are correct. it must be presumed that the *Pithecanthropus* phase of hominid evolution was preceded by a phase characterized by a still smaller brain but in 'nhich the limb structure and the dentition might be expected to shon at least some degree of modification in the direction of evolution which has characterized the Hominidae. The interesting question now arises —is there any fossil evidence that such a type ever existed? The answer to this question is to be found in the remarkable discoveries made in South Africa of the remains of creatures to which (as a group) the somewhat cumbrous name Australopithecinae has been given. Unfortunately it is difficult to give them a less pedantic name without misleading implications, though, because of the curious mixture of anatomical features nhich characterize these creatures, they are sometimes referred to as "man apes" or "near men."

. AUSTRALOPITHECINAE

The first fossil evidence of the existence of these creatures was obtained from the discovery at Taungs in Bechuanaland in 1924 of the skull and a natural endocranial cast of an immature individual. This specimen shows a number of features (particularly in the milk dentition) in which it approximates much more closely to the Hominidae than any of the known anthropoid apes do. But, because the distinguishing characters of the skulls of apes and of the Hominidae are not so conspicuous in immature as they are in adult individuals, considerable doubt was at the time expressed regarding the significance of the apparently hominid features of the Taungs skull.

Later. from the year 1937 onward, considerably more remains of the same type were discovered in the stalagmitic deposits of ancient caves and fissures formed in dolomitic limestone at various sites in the Transvaal. As the result of excavations extending over a number of years, a great quantity of important fossil material mas collected. consisting of a number of skulls of immature and adult individuals, many upper and lower jaws, numerous examples of the permanent and deciduous dentition. several specimens of the limb skeleton. three examples of the bony pelvis and the greater part of a vertebral column. which was found still in an articulated condition.

With this material, more information is available about the anatomy of the Australopithecinae than about that of almost any other extinct group of the higher Primates. Their outstanding characters are (1) a small cranial capacity equivalent to that of the modern large apes (but in some examples probably exceeding it, at any rate in relation to body size), (2) massive projecting jaws, (3) large molar and premolar (or bicuspid) teeth but remarkably small incisors and canines and (4) pelvis and limb bones constructed on the hominid plan (but showing significant differences from those of modern Homo sapiens). The combination of a small brain case nith large jaws gives to the skull a most "apelike" appearance, and largely for this reason some authorities at first took the view that the creatures were really "apes" in the taxonomic sense.

However. on the other hand, a critical analysis of the cranial and dental characters, and especially the evidence of the pelvis and limb skeleton, seemed to make it clear that the total morphological pattern nhich they present conforms to the pattern diagnostic of the hominid sequence of evolution and certainly not of the anthropoid ape sequence.

It is not surprising that this remarkable combination of characters provoked rather acute controversies regarding their precise taxonomic position. Unfortunately, the discussions were at first somewhat confused by exaggerated claims on both sides. Thus, claims that the Australopithecinae were capable of fabricating bone tools and that they had even learned the use of fire were based on evidence which proved to be quite inadequate. On the other side, it was claimed (mainly on the basis of the rather scanty earlier discoveries and partly from the application of inadequate statistical methods) that some of the skeletal and dental characters were no different from those of modern apes. The later accession of further and much more complete material showed that these latter claims had been put forward too hastily. For example, the dental morphology is now completely known, and it became evident that it conforms in all fundamentals to the hominid type of dentition.

The canine teeth are consistently small, of spatulate (instead of sharply conical) form and they became worn down flat from the tip so that (as in modern man) the biting surface at an early stage of attrition was brought level with the biting surface of all the other teeth. They never overlapped and interlocked in occlusion as they do in anthropoid apes. The front lower premolar tooth is consistently bicuspid in shape as in *Pithecanthropus*, and entirely different from the pointed. "sectorial" type of tooth which is consistently found in all known apes, Recent and extinct. The molar teeth are not easily distinguishable in their cusp pattern from those of *Pithecanthropus* and, though large, in many individuals their size comes within the range of this genus of hominids. Lastly, the teeth are consistently arranged in an even arcade of elliptical or parabolic form. nith no gap (or diastema) between the canines and adjacent teeth—a disposition which, once again. is hominid and in marked contrast with the ape type of dentition.

It may be noted, also. that application of careful statistical methods has demonstrated that the taxonomically relevant dimensions of the canine teeth lie far outside the range of variation of modern apes.

So far as the skull is concerned, it presents a number of features which, taken in combination, are never found in apes but which are characteristic of the hominid skull. These include the cranial height. the low position of the occipital protuberance (at the back of the skull). the detailed conformation of a number of features in the cranial base. the shape of the mandible and so forth. In a few of the largest australopithecine skulls the vertex of the skull is marked by a lon median crest which is related to the growth of the large temporal muscles that moved the massive jaws. In one of the earliest of these skulls to be discovered, the occipital region at the back of the skull was missing, and it was argued that the median crest must have extended back into a high transverse nuchal crest on the back of the skull just as it does in gorillas (implying an exceptionally ponerful development of the neck musculature).

However. other skulls with a median crest on top and with the occipital region preserved shon that there was no high nuchal crest of the gorilloid type—the muscular markings for the neck muscles are situated low down in the typical hominid fashion. This observation has an important bearing on the poise of the head, for the reduction of the neck musculature in the Hominidae is related to the fact that with the development of an erect posture the skull becomes more evenly balanced on the top of a vertical spine, and a powerful neck musculature is no longer required for holding up the head on the end of a forwardly sloping spine. The contour of the back of the australopithecine skull, combined with certain details of the articular condyles on the cranial base. led to the inference that the Australopithecinae must have been adapted to an erect posture and gait approximating that of *Homo*. This inference received remarkable corroboration from the discovery of portions of thighbones and of three pelvic bones. The latter are of particular importance, for the total morphological pattern of the bony pelvis of the Hominidae is perhaps the most characteristic skeletal feature of this family and, indeed, distinguishes it from all other Primates (including the anthropoid apes). This pattern, moreover, represents in its major components an adaptation to the mechanical requirements of an upright or erect posture.

These components include the great breadth of the iliac blade, lengthening of the iliac crest for the more extensive attachment of the powerful back muscles needed to support the trunk in the vertical position, the backward displacement of the area of attachment of certain of the buttock muscles so that they can be effectively used in upright walking, the rotation and downward shifting of the joint through which the weight of the body is transferred from the spinal column to the lower limbs. the development of a very distinctive bony eminence marking the attachment of a powerful ligament which is required to stabilize the hip joint in the erect position. and so forth. Not one of these features is found in combination — or, indeed, even singly — in the ape type of pelvis.

On the other hand, pelvic bones of the Australopithecinae all show every one of them consistently; in other words, the pelvis is constructed fundamentally on the hominid plan, and this makes it perfectly clear that it was adapted for an erect. bipedal posture and gait. It is interesting to note that the anatomical evidence of bipedalism is entirely consistent with the geological evidence of the environment in which the creatures lived, for this shows quite positively that they were not forest dwellers but lived in open country very similar to the veld of the Transvaal today—an environment quite unsuitable for anthropoid apes of the modern type.

The decision as to the taxonomic status of a previously unknown fossil — nhether it is a primitive type of small-brained hominid or a member of the anthropoid ape family — must depend on a recognition of the fundamentally different trends which have characterized the evolution of these two families and which are diagnostic of each of them as a natural taxonomic group. As noted above, the indirect evidence of comparative anatomy and (so far as it goes) the direct evidence of palaeontology lead to the conclusion that the anthropoid ape family and the Hominidae represent divergent lines of evolution deriving from a common ancestry. and that only toward the terminal stages of the hominid line did the brain expand to the large size characteristic of the terminal species *Homo sapiens.*

The anthropoid ape sequence of evolution became adapted for a quite specialized kind of arboreal life with accompanying specializations in the limbs, skull and dentition. The hominid sequence, by contrast, became adapted for terrestrial progression with profound modifications of the pelvic and limb skeleton (and also the skull) for erect bipedalism, and was also characterized by the replacement of sharp interlocking canines by blunt spatulate teeth and of pointed "sectorial" lower front premolars by bicuspid teeth, as well as rather numerous other associated structural changes.

So far as Australopithecinae are concerned, a careful appraisal of their anatomical structure makes it clear that, in spite of the primitive characters mhich they still retained in the size of the brain and jaws, they had already advanced a considerable way in the direction of the hominid sequence of evolution and quite opposite to the direction which was followed by the anthropoid ape sequence. For example, in those features in which the pelvic bone has undergone modification away from what must be presumed to have been the type of pelvis in the common ancestral stock, the modification has in every respect followed the direction of hominid evolution. Thus by definition the Australopithecinae must be classified zoologically in the family Hominidae. But it is important to note that this does not mean that the terms "man" and "human" can be appropriately applied to them, at any rate in the sense in which these terms are ordinarily used, for there is so far no evidence that they had any of the distinctively human attributes such as the faculty of speech or the ability to fabricate implements. They are to be regarded, rather, as representatives of the prehuman phase of hominid evolution.

The question arises whether the Australopithecinae could have been the evolutionary ancestors of later hominids, including *Pithecanthropus* and *Homo sapiens.* There appear to be no sound morphological arguments against such an inference; indeed, it is a perfectly valid interpretation of the morphological evidence, for the Australopithecinae conform very closely indeed to theoretical postulates for the phase of hominid evolution which. it must be presumed, preceded the *Pithecanthropus* phase. But the australopithecine individuals whose remains have so far been discovered in South Africa probably existed too late in time to be regarded as representatives of the ancestral stock, for the geological evidence indicates that they lived in the early Pleistocene more or less contemporaneously with *Pithecanthropus* in the far east. On the other hand, the Australopithecinae were already at that time differentiated into at least two varieties or species, and it is thus certain that the group as a whole must have been in existence at a still earlier date, at least at the end of the Pliocene. So far as the time factor is concerned, therefore. the group as a whole could certainly have provided the matrix from which more advanced types of hominid became differentiated by a process of evolutionary development.

In this brief survey of the fossil evidence for human evolution a rather remarkable gradational series has been traced, leading from modern H. *sapiens* to primitive types of apparently the same species living many thousands of years ago in the Ice Age, from the latter to the archaic *Pithecanthropus,* which still preserved a number of anatomical characters approximating to a simian level of development, and finally to the still more apelike Australopithecinae of South Africa. The simian characters to which reference is here made do not necessarily indicate a very close relationship to the modern anthropoid apes, for they are to be regarded rather as primitive characters which were derived in the distant past from a common ancestry and which have been ketained in the modern apes but became subsequently lost in the *later* stages of hominid evolution.

Therefore, although in a certain sense it might appear that the primitive characters of the Australopithecinae — such as the small brain and large jaws--emphasize the closeness of man to the apes in their evolutionary relationship, these extinct creatures were in fact already at that early time very different from apes in many fundamental hominid characters of the skull, teeth and limbs. And, from what we know of the rates of evolutionary change in general, this makes it certain that the line of hominid evolution must have become a separate and independent line at a much more remote time.

ORIGIN OF THE HOMINIDAE

At what point in geological time the Hominidae, as a separate and independent line of evolution, became segregated from the anthropoid ape family is still not certainly known. No fossil hominid remains have so far been discovered which antedate *Australopithecus* and *Pithecanthropus;* indeed, this is at present the most serious gap in the fossil record of the Hominidae. Remains of several types of fossil apes are known from Pliocene and Miocene deposits in Europe, Africa and Asia, but they consist almost entirely of teeth and fragments of jaws. Morphologically, these approximate quite closely to those of the modern apes, but at least some of the genera were more primitive in a number of features.

The very few remains of the skeleton which have been found also indicate that the limbs had not at that time developed the specialized modifications which are characteristic of the modern apes, for in many respects they were more like those of the cercopithecoid monkeys.

All these primitive characters of the Miocene and Pliocene apes are particularly relevant to the problem of the origin of the Hominidae. It has been seriously argued that the latter could hardly be derived from an anthropoid ape ancestry because anthropoid apes are too specialized in their limb structure and limb proportions. But there is a remarkable fallacy in such an argument—the assumption that extinct anthropoid apes of earlier times must necessarily have shown the same degree of structural specialization as do the end products of the pongid sequence of evolution which are represented today by the gorilla, chimpanzee and orangutan.

It later became known that (as of course might have been expected) this was certainly not so. Indeed, on the purely morphological evidence there is no improbability in the thesis that one of the known genera of Pliocene or Miocene apes may represent the common ancestral stock nhich gave rise by different and contrasting kinds of adaptive modifications to the two divergent evolutionary sequences of the Pongidae and Hominidae. It has indeed been proposed, and by some even taken for granted, that such features as the sharp overlapping canines, the moderately "sectorial" first lower premolars and certain quite minor features of the cusp pattern of the molars constitute "specializations" which, so to speak debar these early apes from any consideration as possible ancestors of the Hominidae. But this is to make assumptions on the "irreversibility of evolution" which are not only groundless but are demonstrably untrue.

In genetic studies it has been shown that single mutations can be reversible in direction, and in phylogenetic studies there are many examples of what may be termed '.negative reversals"; *i* e., the retrocession of characters previously well developed. So far as the canines and premolars are concerned, there are in fact strong morphological reasons for inferring that the hominid characters of these teeth have been secondarily derived from those of the pongid type.

It may be noted here that the palaeontologist has frequently to consider the question whether certain extinct types had already attained to such a degree of structural specialization that they must be regarded as a divergent or aberrant group having no ancestral relationship to modern types. The answer to this question must depend on the assessment of the total morphological pattern in terms of the probable complexity of its genetic constitution and the probable complexity of the selective influences mhich have determined its initial evolutionary development, and also on gauging the degree to which morphological changes have committed the group to a mode of life which has restricted too far the opportunities for selection in other evolutionary directions

We have referred above to the morphological gap which at present separates the most primitive of the known hominids (*Australopithecus*) from the known fossil apes of the Miocene and Pliocene. The temporal gap is also large—a matter of at least several million years. From what is known of rates of evolutionary development in other groups of mammals there is certainly no difficulty in postulating a transition from one to the other in this time period.

But such a transition, the approximate period in geological time during which it took place and the region where it actually occurred can of course be demonstrated only by the discovery of the relevant fossil material.

MAN, **ISLE** OF (Manx-Gaelic, ELLAN VANNIN), one of the British Isles situated in the Irish sea, roughly equidistant from England, Ireland, Scotland and Wales. It is a lozenge-shaped island about 30 mi. long and 10 mi. wide. its main axis being southwest to northeast. Area 221 sq.mi. The capital is Douglas (*q.v.*).

The island is not a part of the United Kingdom, nor is it a "foreign dominion" of the crown; it is a dependency, with a considerable degree of self-government, administered by the home office in a manner comparable with the Channel Islands. It is not exempt from the power of the English court to issue a habeas corpus.

PHYSICAL FEATURES

The island consists of a central mountain mass culminating in Snaefell (2,034 ft.) and extending north and south in low-lying agricultural land. There is fine cliff scenery along both sides of the central massif, whose slate peaks are smooth, rounded and grass covered, the result of ice action during the various glacial periods.

The landscape is treeless except in sheltered places; the many glens are not glacier formed. The island is almost bisected between Peel and Douglas by a narrow lowland tract which is in fact a double river valley, the rivers, all of which are small, running in opposite directions from the centre, The chief rivers are the Sulby, flowing north and east to enter the sea at Ramsey; the two-branched Douglas at Douglas; the Santan at Cas-ny-howin; the Silverburn at Castletown; and the combined Neb-Rhenass at Peel

There are no lakes, but the Douglas corporation constructed a large reservoir in the west Baldwin valley. To the southwest is a small islet, the Calf of Man, with precipitous cliffs, similar in structure to the main island, leased by the National trust of Great Britain to the Manx National trust, consisting of one farm and a strictly kept bird sanctuary.

Geology.—The central mass consists of Manx slates, flags, grits and conglomerates in which there is an almost complete absence of recognizable fossils. The slates, provisionally classed as Cambrian, have been much folded and crushed; they overlie the granite mass which has been denuded at Foxdale, the Dhoon and Oatlands (Kirk Santan).

Located in the south is a tract of about eight square miles of Carboniferous limestone which was formerly of great economic importance, providing building material for Rushen castle, the old houses of Castletown, King William's college and the quay walls of all the island ports. The quarries are no longer used for building stone, but there are extensive limekilns. Beneath the limestone is a basalt conglomerate, well exposed on Langness with some interesting "fault arches," and good examples of unconformable strata of conglomerate on the tilted slates. The Carboniferous limestone shows two main series, the lower, Castletown series, the upper, Poylvaish, both rich in fossil forms. Flags overlying the upper series were formerly polished and known as Castletown marble; they made good fireplace surrounds, but as tombstones they quickly weathered. At Peel an exposure of a dark red sandstone, attributed to the basement beds of the Carboniferous limestone series, provides picturesque building stone uhich gives the town, its cathedral and castle their rose-red coloration. The northern part of the island is a roughly triangular plain uith its apex pointing northeast. This plain is based upon the limestone on which lies a thin band of Permian sandstone covered by a much wider band of Triassic sandstone, all deeply covered by a mass of glacial and alluvial material forming a marshland (curragh) formation of great floral and faunal interest. Toward the apex of the triangle (Point of Ayre) are the Bride hills, a mass of glacial drift, and beyond, along the northwestern coast, is a region of bloun sand called the Ayre. The soil in the south is mainly of glacial gravel with local lacustrine and river deposits; from Derbyhaven to Port St. Mary there is blown sand upon which the aerodrome and golf links are situated. To the south of Cregneish are signs of heavy earth movements in the faulting of the slate cliffs, which are rent by chasms and fissures running the whole height of the zoo-it. cliffs. To the southwest of Castletown stands the Stack of Scarlett, possibly a basaltic volcanic side cone, and around it for a considerable area are lava overlays, with basalt sills, and volcanic ash. There is a long history of mining activities—lead, zinc, copper and haematite having been worked—but by the mid-1950s all the mines but two were derelict. They mere centred around Laxey and Foxdale, with a few isolated mines in the south.

Climate.—The prevailing winds are from the southwest and the climate is equable. The mean annual temperature is 46.6" F., the average mean temperature in February is 40.9° and in August 57.8°; the average annual mean daily sunshine is 4.31 hours; the average annual rainfall is 41.2 in. Fogs are common, snow and frosts are rare and of short duration. Thunderstorms are rare.

Flora and Fauna.—The flora of the island is small, and its main interests lie in its varied associations and a comparison of its species with those of the surrounding countries. With the end of the glacial periods the land link was soon destroyed so that comparatively few plants were re-established. Fewer than 700 species have been recorded as compared with about 1,200 in Cumberland and the southern counties of Scotland. There is a profusion of ferns. Subtropical shrubs. such as the fuchsia, hydrangea, myrtle, Escallonia and Clianthus, flourish out-of-doors, while a prominent feature of the coastal landscape is the abundance of dragon palm (Dracaena).

There are no snakes or toads, few frogs and two lizards (common and sand). There are no badgers, foxes, moles, voles or squirrels. The mountain hare grows more and more scarce; rabbits. formerly a pest, were very greatly reduced by myxomatosis. Hedgehogs, accidentally introduced from a wrecked ship at the beginning of the 19th century, are plentiful. The pygmy shrew (Sorex arenaeus) is abundant, as is the long-tailed field mouse (*Mus sylvaticus*); the black and the brown rat and the house mouse are too well established; the stoat (*Mustela* arminea) is not common. The gray seal (Phoca vitulina) breeds on the Calf. There are three bats, the pipistrelle (Vesperugo *pipistrellus*), Natterer's bat (Murina natteri) and the long-eared bat (Plecotus *auritus*). Across the land bridge following the retreating ice came the giant Irish stag (Cervus gigantaeus), of which many skeletons have been found. There is only one species of freshwater fish, the perch, much localized. The fish indifferent to salt and fresh water—salmon, brown trout, eel and stickleback—are present. The Manx cat, without a tail or with a greatly reduced tail, is common as a domestic pet in the island but is not indigenous. There is still one small flock of Manx loghtan sheep, a handsome four-horned breed. The main faunal interest is in the bird life, as the central position of the island makes it ideal for the study alike of sea and land birds and their migrations. Of the nonmigrants the magpie, introduced in the early 18th century, has attained the rank of an insular species. Birds not recorded are the jay and the woodpeckers. The chough is much less common than formerly; ravens are plentiful. The buzzard is a rare visitor, and the peregrine falcon is becoming rarer. Only two peculiar Lepidoptera have been recorded, Dianthaecia caesia and D. *capsophila.*

HISTORY

Prehistory.—A11 traces of Palaeolithic inhabitants were destroyed during the glacial periods. There are many and varied evidences of Mesolithic civilizations, including Tardenoisian and the Bann type of northern Ireland. The Neolithic also has two aspects, one culture being associated with the megalithic monuments (c. 2000–1500 B.C.); the other, the highly individual Ronaldsway culture (named after a domestic site excavated in 1943), is apparently a Manx equivalent of the late Neolithic of Orkney (Skara Brae). The three chief megalithic monuments are: Cashtal yn Ard, near Kirk Maughold, a gallery grave with a noble forecourt; King Orry's grave, near Laxey, a "double" long cairn cut in two by a road and further mutilated by 19th-century houses; and the Meayl (or Mull) circle, near Cregneish. a unique structure comprising six pairs of chambers disposed on the circumference of a circle.

The Bronze Age is represented mainly by graves containing food vessels, several of Irish type (only one Beaker burial is recorded), and the subsequent cinerary urns, and by surface finds of bronze tools and weapons. Groups of circular house foundations at Ronaldsway (excavated 1935–37, later destroyed) may belong to the late Bronze Age.

The early Iron Age is marked on the one hand by hilltop forts like some Celtic strongholds in Wales (South Barrule is the largest) and on the other by large, circular, wooden farmhouses, undefended and often sited in lowland meadows (notably Ballakeigan, excavated 1941–44 by G. Bersu), assigned to the 2nd century A.D.

History.—The island became the home of many Irish missionaries in the centuries succeeding the teaching of St. Patrick. This period was marked by the building of oratory chapels or *keills,* and by gravestones with incised crosses of varying artistic merit, many of which are to be seen in the parish churches and in the museum. The Scandinavian invasions began about A.D. 800 and the first phase lasted till after the Norman Conquest of England, during which time the vikings came mainly for plunder but slowly began to settle. Already settlements had been made in the Nordreys (Orkney and Shetland) and the Sudreys (the Western Isles of Scotland). Such history of the period as is known is recorded in the sagas of the period. The second viking period began with the arrival of Godred Crovan in 1079 and lasted till 1266. Its history is recorded in the Chronicon Manniae (British Museum), written by the monks of Rushen abbey (founded 1134). Fourteen kings and 15 bishops are recorded, and Godred Crovan appears to be the King Orry or Gorry of Manx legend. During this period the island was controlled by a Scandinavian system of government which has remained practically unchanged. Godred's son Olaf (1113–52) was the first king to style himself Rex Manniae et *insularum.* His son Godred II became the vassal of Henry II of England, and from that time the island became a pawn in the game of war between Scotland and England. Reginald I of Man paid homage to the king of England, 1187. Memorials of the Scandinavian age, apart from the ancient Tynwald parliament and many place names, are to be found in the remains of farm fortresses on the cliff edge, as well as in ship burial mounds at Balladoole (Arbory) and Knock-y-dooney (Andreas). In 1229 Bishop Simon was sent from Trondheim (Nidavos) to be bishop of the Sudreys, and under his episcopate the building of the cathedral was begun and the tower of Bishopscourt built. In 1266 the king of Norway sold his suzerainty of Man and the isles to Alexander III of Scotland. This suzerainty had long been repudiated by the kings of Man. Magnus, king of Man at the time, sent an army to assist an invasion of Scotland by the Norwegians. The battle of Largs found Alexander triumphant, and he demanded from Magnus the Sudreys, which were ceded, and from Magnus' son Godred he bought all Godred's claims as king of Man, thus becoming king of Man by purchase. With the rise of Edward I Man changed hands and became an appanage of England. Edward II lost it to Bruce, who came to the island in person and conquered it, capturing King Orry's tower on the site of the present Rushen castle. But Edward III, by beating Scotland, won back Man, after which time all its kings were English. Edward III gave the kingship to William de Montacute, 1st earl of Salisbury, and from him the title passed to his son, who sold it and his "crowne" to Sir William le Scrope. During the kingship of the Montacutes, Rushen castle, a typical castle of the period, was rebuilt round King Qrry's to er at Castletown (*q.v.*). It became the home of the Manx kings and the seat of government. Scrope built a small castle beside the cathedral on Peel (*q.v.*) Island, but he was attainted and executed by Henry IV, who in 1406 granted the island to Sir John Stanley, his heirs and assigns to be called "kings of Mann." The Stanleys refused to be called "kings" but adopted the title of "lord of Mann," which title still holds.

With the Stanley regime came a much more stable period of government. The lords rarely visited the island, but they appointed wise governors and sent strong garrisons from Lancashire. Thirteen members of the Stanley family were lords in succession, with two brief interludes. Queen Elizabeth I in 1594 took over the lordship when Fernando Stanley died leaving only daughters. It was retained by James I till 1607 when he gave it to the earls of Salisbury; but in 1609 it was returned again to the Stanleys. During the Commonwealth, James, the 7th earl, the "Great Stanley," left the island in charge of his countess, Charlotte de la Tremoille, whose military commandant, William Christian (Illiam Dhone), surrendered it to the Roundheads when the earl was executed after the battle of Worcester. Lord Fairfax was made lord of Man. but at the Restoration the young earl Charles resumed the lordship and undid a great amount of his father's good work, chiefly by disputing the permanent tenancies of the farmers, who held their lands under the Scandinavian system of permanent freehold upon payment of the lord's rent and not under the Norman feudal system as in England. As a result of a lasting quarrel with their lord, the farmers neglected the land and turned their attentions to fishing and the contraband trade. The island had no fiscal laws, and spirits, tobacco and silk could be legally imported into the island from which they were re-exported to Great Britain by a fleet of fast clippers with skilful crews. The land question was ultimately put right by the influence of Bishop Thomas Wilson in 1745 in an act of settlement, by which tenants receive their lands in perpetuity on payment of a fixed rent, and a fine on succession or alienation. With the death of the 10th earl the male line of the Stanleys came to an end, but the claim of the daughter Charlotte, Baroness Strange and duchess of Athol. to the sovereignty of Man was upheld, and in 1764 the Athols became lords of Man.

The chief feature of the Athol rule was the gigantic increase in the contraband trade, which became a serious menace to British revenue, and parliament resolved to suppress it. A Revesting act was passed in 1765 purchasing for the crown the sovereignty of Man for the sum of £70,000 together with an annuity to the duke and duchess of £2,000. The Athols still retained their manorial rights and the patronage of the see. These were bought by the British parliament from the family in 1828 for the very high sum of £417,144. The 4th duke of Athol, who built Castle Mona (now a hotel) at Douglas, as the official residence of the lords of Man, in 1804, remained as governor appointed by the crown. The Revesting act interfered to a considerable extent with the home rule of the island, but constant representations, specially in 1837. 1844 and 1853, produced alleviations, and in 1866 a good measure of home rule was restored to the island.

PEOPLE

The earliest inhabitants in historic times were Celtic in speech. both British (Brythonic) and Gaelic (Goidelic) being spoken in the 6th century A.D. Gaelic (Manx) became dominant and remained the everyday speech of the majority until the first half of the 19th century. Racially the population is mixed, the most important types being described as "Mediterranean" and "Nordic," respectively. In 1961 the population of the island was 48,150, that of Douglas 18,837.

The Church. — The first organized church was the Scandinavian church which was based on "treen" churches or *keills*, in which a priest had charge of a tiny church and burial ground, living himself in a small cell usually beside a holy well. Later. 17 parishes were organized, their *keill* churches being enlarged from age to age. But the church buildings maintained the constant type, a nave without transepts, side aisles or chancel, usually whitewashed and with a western bell turret and west door. In general they stand at some distance from the villages. The diocese was organized in Scandinavian times (see SODOR AND MAN). During the same age, too, were built the cathedral of St. German (now ruined and roofless); Rushen abbey (also in ruins), a branch of the abbey of Furness, which was the controlling factor of the religious life; and Bishopscourt, built as a fortress tower with a moat, and extended later. Of the nunnery near Douglas and the Franciscan friary at Bemaken, Kirk Arbory (founded in 1373 for 12 brethren), nothing remains except the chapels. Since the Reformation the church has retained its ancient organization and has formed a diocese of the northern province of the Church of England. In 1880, by act of Tynwald, four rural deaneries were formed and commissioners appointed to take charge of church endowments. In 1895 a cathedral chapter was authorized, consisting of the bishop (himself to be the dean of his cathedral), the archdeacon, four canons and the vicar-general.

The churchmanship of the island is traditionally evangelistic John Wesley, on his visits, won the affection of the Manx, and as a result the Wesleyan Church is very well established. There are Roman Catholic churches in all the larger towns.

Education. — Bishop Isaac Barrow in 1667 made education compulsory and founded a system of parish schools run by the clergy — the earliest scheme of compulsory education in the British Isles, In 1872, when the insular legislature passed the Elementary Education act establishing a board of education and local school committees, the state undertook direct responsibility for education. It became free in 1892 and a higher grade school was established in 1894. An act of 1907 established a system of secondary education. Parish boards were abolished in 1920 and one education authority took their place. The Education act of 1949 is based upon the English act of 1944. There are 31 primary schools (one Church of England, two Roman Catholic). Secondary school reorganization was completed in 1948, based on the bilateral system (combined grammar and modern sides), there being separate secondary schools for boys and girls in Douglas and mixed secondary schools in Ramsey and Castletown. There is a small public school for girls (the Buchan school) at Castletown. and a public school for boys, King William's college, founded from the funds of Bishop Barrow's charity in 1832. Among its famous alumni have been Dean Farrar, Field Marshal Sir George White. J. Ellerton the hymnologist, Sir W. H. Bragg and T. E. Brown the Manx poet.

For the language see MANX LANGUAGE AND LITERATURE.

GOVERNMENT

The government consists in a lieutenant governor, appointed by the monarch as lord of Man; a council or upper house; and a house of keys or lower house. The two houses sit separately as legislative bodies but come together to form a Tynwald court for certain business. The governor presides over the council and Tynwald; the house of keys elects a speaker. The Tynwald court and the house of keys constitute one of the most ancient legislative assemblies in the world. In the Tynwald court the two houses sit and vote separately but transact business and sign bills together. Tynwald controls revenue and appoints boards (education, agriculture and fisheries, local government, etc.). Customs duties are still controlled by parliament, but Tynwald can "impose, abolish or vary" customs duties. subject to parliamentary approval. The approval of the governor and the assent of the sovereign are necessary for every legislative enactment, and until lately such enactments were enforceable only after public proclamation from Tynwald hill in English and Manx. Acts of the imperial parliament are enforceable in the island only if the island is directly named in them. The lieutenant governor is the supreme legislative authority, chancellor of the exchequer and commandant of military forces and police. An executive committee (constituted in 1946) acts as an advisory council on all matters of government and consists of the chairmen of spending boards and other members of Tynwald up to a total of seven members. The governor presides, and the government secretary, attorney general and clerk of Tynwald are in attendance. There is little trace of party government and no party "whips," and the majority of members are independent. The house of keys is elected for five years but may be dissolved by the governor; there is universal suffrage for men and women above the age of 21. The island is divided into six sheadings (administrative subdivisions); four of these elect three members each and the other two elect two. The towns of Castletown, Peel and Ramsey each elect one member, and Douglas has five members.

The annual reading of the laws passed during the year is carried out on old midsummer day, July 5, on the Tynwald hill at St. Johns in the centre of the island. The day is a holiday and all inhabitants are bidden to attend. The Tynwald court assembles in the church of St. John for a short service after uhich it proceeds to the "hill," a mound of earth distant about zoo yd., preceded by the coroners, captains of parishes, clergy and other dignitaries. Only the titles of the acts are now read, first in English, then in Manx.

Law. — Until 1920 the governor was president of the high (supreme) court of justice, but after that date he had no judiciary powers. There are now two judges of the high court, called "deemsters," and they have complete jurisdiction covered by the general jail delivery. queen's bench, chancery, admiralty, probate and divorce divisions. There is no regular assize; deemsters' courts are held every week of the legal term in one of the court towns of the island. The senior deemster is also clerk of the rolls; both deemsters can be called upon to act as judges of appeal in cases in which they have not been concerned, and another judge of appeal is appointed from the English bar. Magistrates (justices of the peace) sit in the four court towns, uhere also the high bailiff (stipendiary magistrate) holds courts; he also acts as coroner in the matter of inquests, etc. The Manx coroner, one in each sheading, holds a less exalted position; he is a court officer, empanels juries, serves summonses, collects fines and acts as a bailiff in cases of unpaid debt. The Manx bar differs from the English in that its members (advocates) act as solicitors and barristers.

There are peculiarities in the laws of real property, but otherwise the laws are practically identical with those in England.

Arms. — The arms of the island are "Gules, three legs armed, conjoined in fesse at the upper part of the thighs, flexed in triangle, proper booted and spurred, or." The earliest appearances of the "three legs of Man" are on the hilt of the Manx sword of state (A.D. 1300), on the market cross of Kirk Maughold (*c.* 1350) and of more definite date on the shield of Henry de Bello Monte (1310) and the earl of Moray (1313). The origin is Sicilian.

The motto, *Quocunque* jeceris *stabit* ("It will stand wherever you throw it"), first appears on the coinage of 1668, jeceris being misspelled as gesseris.

ECONOMICS

Fishing. — The local fishing industry is almost dead, but a Scottish fleet lands herring in the summer at Peel, Port St. Mary and Douglas, where large quantities are kippered. The Manx kipper is famous and is the most valuable export. There is a profitable scallop fishing (Manx tanrogan) off Bradda head. Sizable salmon run up the larger rivers and there is a government salmon and trout hatchery at Kirk Michael. Liverpool university maintains a biological station at Port Erin which does scientific work in all phases of marine life.

Agriculture. — The central massif is not cultivated but is used as grazing ground for sheep. The northern and southern plain lands and the central valley have mixed and dairy farms. Of the chief crops (1955) about 17,000 ac. are occupied by cereals (mainly oats, a valuable export), 2,000 by potatoes and 12,000 by hay. There are extensive market gardens but not enough to supply the demands during the holiday season. The aim of the island is to be self-supporting in agricultural produce and a great deal is exported.

Industries. — By far the most important industry is the "holiday" trade; 500.000 persons, on an average, visit the island yearly from all parts of the British Isles. There are flourishing woollen mills producing Manx tweeds, and there are modern flour mills.

Communications. — There is a civil airport (with modern buildings, 1953) at Ronaldsway, near Castletown, which handles many planes daily from all parts of the British Isles. Packet boats maintain a daily service to and from Liverpool all the year round. The railway has two narrow-gauge single-track lines running, one from Douglas to Port Erin via Castletown, the other to Peel and Ramsey via St. Johns. The electric railway has a wide-gauge double-track line from Douglas to Ramsey via Laxey, with a branch to the top of Snaefell. There is a motorbus service from Douglas to all parts of the island.

The Isle of Man has taken a great part in the development of the gasoline engine by passing an act in Tynwald every year since 1904 closing the roads to ordinary traffic in order to allow the running of Tourist Trophy races for motorcycles and cars over a 37-mi. course from Douglas to Ramsey and back over the mountain road. These races test the engines, frames and accessories under very severe conditions. The car race began in 1904, the motorcycle in 1907. The motorcycle Tourist Trophy race has been continuous except for the war years, but the car race is intermittent.

Finance. — The finance of the island is based on a "common purse" agreement with Great Britain, by which duties imposed in Great Britain are also imposed in the island and amounts of duty paid for dutiable goods purchased in the island are credited to the insular exchequer from London on a basis calculated as the amount of consumption per head in Great Britain. There are no death duties, and income tax is lower than in the rest of Great Britain,

(E. H. S.)

MANA is a word meaning "occult power" and occurs in many languages of Oceania. It is of uncertain origin, though probably introduced by immigrants from the west. While having also a wider and vaguer application, it stands for the "divine right" of the aristocratic class to wield authority and to enforce religious prohibitions. The sanction behind the taboo is the mana of the governing class, while conversely that taboo serves to keep the tribal mana intact; that is, ensures the good luck for all that waits on sound government. As a term of general anthropology mana may be treated as the positive while taboo is the negative aspect of the occult. In other words, the occult as such is taboo, or "not to be lightly approached," because it is mana, or charged with wonder-working power.

Noa Contrasted. — In the Pacific region the word "noa" is used to signify the opposite kind of object or situation which is "common"; that is, ordinary. The man who wields mana with impunity must abstain from all that is sordid. There are two worlds, a low-level and a high-level condition of spiritual activity, and a man cannot dwell in both at once. Thus by the very virtue of his profession the medicine man or the divine king must hold himself apart from those who by status or by choice are noa, laymen. The latter may live in brutish contentment; but to the end they lack enlightenment, participating in the highest mysteries at best from without. Every member of a primitive society is in some degree versed in experience of the occult, though for the most part some better-qualified person is present to help him through it.

The Crises of Life. — The initiation of youths, puberty, marriage, a battle, a hunt may all lead to privations whereby one may acquire mana, "a strong heart," "uplift." Tradition has devised very efficient means of coping with crises, whether of organic or circumstantial origin, by laying down a prescribed discipline which as it were enables the sick soul to go into retreat, so as by concentration on its inner resources to obtain an access of strength and comfort. (See PASSAGE RITES.)

Mana and Ritual.--Old-world religion is inarticulate, and mana stands for the power set in motion by ritual (q v.), almost regardless of the intention behind the ritual, which among savages is always apprehended rather than comprehended. Thus when the ritual is of a public nature and guaranteed by custom and tradition. the mana therefrom resulting is felt by all to be a good mana. Such and such is known to be the ceremony proper to the occasion, and everyone is sure that the society will be the better for it. If, on the other hand, a private individual in overt and sinister fashion trafficks with the occult, everyone is equally sure that a bad mana liable to afflict all and sundry will be unloosed. Sometimes, too. it is rather difficult to know which way a professional wonder-worker will use his power; for if he can heal he can also hurt, and it might occur to him to hurt if one did not make it worth his while to play the healer. Or, again, a man in authority will certainly use his mana to blast the public enemy, or even to suppress the unruly within his own society, and so far he will be acting legitimately.

Ambivalence.—Mana, then, is an "ambivalent" notion; it cuts both ways, implying alike divine and diabolic effects as possible manifestations of the awful power lurking in the occult. It is thus equally the root idea of religion and of black magic, since both equally use rites that, duly performed by the expert, bring mana into play; and the procedure will electrify or electrocute according to the will of the operator. In a dim way the primitive mind perceives, if it hardly conceives, that intention or will has to be incorporated in the notion of mana before its moral value can be expressed. Thus not only from the Pacific but from many other parts of the norld. Australia, for example, and North America, evidence is forthcoming of a tendency to split the notion into two, and distinguish a good and a bad kind of mana; as, for instance, orenda and *otgon* in the Huron dialect. For the Huron everything had its modicum of orenda — the deer, for instance, that might be clever enough to escape the hunter and thus outmatch his luck by greater luck of its own; but in this world of relative powers there were some that transcended man's so completely that in regard to them he must "lay down his orenda," which simply meant that he must "pray." Moreover. in such a warfare of competing agencies many might be expected to display otgon, the bad kind of orenda. If the primitive mind were clearer about the direction in which to turn for help in what is a pandaemonic rather than a pantheistic universe, the moralization of religion would correspondingly be brought about. As it is, the notion of the divine power would seem to be historically prior to that of the divine goodness, whether displayed as justice or as love.

Pervasiveness. — In particular. the very fluidity of mana makes it hard for religion to identify it with the good will of a personal god. It is all-pervasive. manifesting itself here. there and everywhere in the most momentary experiences of the occult. Or, even when, as in the case of the living medicine man or king, it can be referred to a definite owner, it is apt to discharge itself through anything that has been in contact with him; so that, with so many transmitters in the shape of his bones or other belongings, secondary storage cells of divine energy are distributed in all directions. Mana thus implies a religious experience that is primarily of the perceptual order, a frame of mind in which the sacred is simply "sensed." A conceptual attitude is not likely to come into being until the manifestation is individualized by being invested with a proper name. A god or even the merest demon who can be propitiated by name, has a chance of acquiring a personality and a moral character

The "Numinous." — It may be, however, that little more than the binding force of the bare name is involved in the ritual invocation, as when the Roman ejaculated a number of preposterous vocables corresponding to the parts of the door that he wished to construct "rite," "according to form." When *nomina* are thus *numina* and no more, the stage of mana has not been left behind; and indeed the word "numinous" has been suggested to cover the sacred in its more impersonal forms. It only remains to add that the mana-taboo formula, together with animatism, preanimism, dynamism. numinism or any other terms — the now discarded word "fetishism" is one of them — that have been used by theorists in the same connection, may or may not apply closely to the beliefs and institutions of some particular people, and may or may not be represented by appropriate words in a given language. Their value consists entirely in such help as they may afford in describing generally a phase of the religious life in which the need of coming to terms with the mysteries that beset life at once from within and without is satisfied mainly by ritual action, running ahead of articulate and reasoned doctrine, but none the less powerfully moving.

MANAAR, GULF OF, a portion of the Indian ocean lying between the coast of Madras and Ceylon. Its northern limit is the line of rocks and islands called Adam's Bridge. Its extreme width from Cape Comorin to Point de Galle is about zoo mi.

MANABÍ, a province in the coastal lowland and hilly belt of Ecuador. bounded west by the Pacific ocean, north by Esmeraldas, east by Pichincha and Guayas and south by Guayas. Area 7,306 sq.mi.; pop. (1950) 401.378 Its capital is Portoviejo, pop. (1950) 16.300. The province is occupied chiefly by lowland Indians, who have successfully withstood the advance of the Negroes from the north. The chief products are cotton, coffee, sugar cane, rice, beef cattle and goats. From the fibre of the toquilla palm. a plant that grows wild in the semiarid scrub woodland. the Indian women weave Panama hats. The forests also yield balsa wood, tagua nuts and fine cabinet moods.

Connections are by sea through Manta and Bahia de Caráquez or in dry weather by road from Quevado. (P. E. J.)

MANACOR, a town of Spain in the island of Majorca. Pop. (1950) 18,702 (mun.). Nearby are the caves of Drach. with underground lakes, Els Hams and Arta, one of the largest and finest groups of stalactite caverns in western Europe.

MANADO, formerly a residency of the island of Celebes (*q.v.*), Netherlands Indies, comprising the northeast peninsula and the coast of the Gulf of Tomini; area 34,203 sq.mi.; pop. (1930) 1,138,65j.

MANAGEMENT SCIENCES is a phrase intended to represent a common and mutually accepted concern on the part of a number of scientific disciplines with the study and solution of the problems of management. World War II and the period after saw a great increase of interest on the part of the applied scientist in the management problems of the military and of industrial firms. Recognition of this common interest led to the formation of new societies in the Gnited Kingdom, the United States, and throughout Europe. Asia and Australia: such as the Operational Research society (U.K.). the Operations Research Society of America, The Institute of Management Sciences and Société Française de Recherche Opkrationelle. The phrase "operations research" which appears in some of these titles, was originally used by the military agencies in the U.K. and the U.S. to designate teams of scientists who studied military operations. but has since come to designate the application of science to any operations initiated and controlled by managers. Hence the phrases management science and operations research are often used interchangeably, although the latter sometimes refers to applied research conducted under contract. Similarly. because of a mutual interest in the process of decision making, decision theory and organization theory frequently have the same connotation as the management sciences. The scientists. in the typical fashion of such cases where the object under investigation is not easily susceptible to recognized methods of science, are groping for names that will adequately portray their interests.

Definition. — The management sciences are bound together by more than a common intellectual interest; they also share a common philosophy of method: namely. the need ior more rigorous analysis of the complicated problems of management. This need can often be satisfied by the use oi mathematics or of carefully controlled observation and experiment. Opinions about the importance of mathematics vary among those who recognize themselves to be management scientists, but most if not all would admit that science connotes among other things the attempt to become as precise as possible and that mathematics is one of the chief resources of the mind in this endeavour. Differences of opinion usually reflect different judgments about the possibility of reaching refinement oi language in specific projects, and the relative importance of research problems. Sometimes the management scientists try to characterize their aims in terms of quantification of managerial activities, because they feel that this term connotes the refinement and rigour they aspire to, and not because they feel any importance attaches to numbers as such.

In order better to understand the goals that hold this community of scientists together and motivates them to form associations, one has to examine the concept of management with some care. Any such scrutiny reveals the confusion that attaches to the word in the English language. Often management has a very special connotation; for example, the class of rulers in a society as opposed, say. to labour. Often the phrase is used in a very general way to connote rational behaviour. as when we say that a man manages his affairs very well. Neither connotation represents what the management scientist has in mind. For him, examples of managers are to be found among those who act as administrators or executives in firms, unions, city, state or federal governments, military agencies, churches and educational institutions.

Thus it is not too difficult to point to specific examples of managers. But it is clear that persons who are called managers do not always manage, and it is almost as obvious that many persons who are not called managers are really a part of the management process. Hence, there is a need to define management as a certain kind of activity, rather than a certain kind of person. Most management scientists would agree that this activity must take place within human organizations. Even this minimal agreement is at variance with some common usage; it precludes talking about the management of a beehive. for example, or the management of one man's affairs. But when scientists band together under a common name, this kind of opposition to common meanings is quite usual.

Next, the community of management scientists would also recognize that the activity or management in organizations includes at least the following: (a) discovering, developing. defining and evaluating the goals of the organization and the alternative policies that will lead toward the goals, (b) getting the organization to adopt the policies, (c) scrutinizing the effectiveness of the policies that are adopted, (d) initiating steps to change policies when they are judged to be less effective than they ought to be. Activity (a) is often called planning and is essentially a cognitive activity carried on by individuals or by committees, who use iniormation collected for them by their staffs. It has become convenient to characterize planning as short range and long range. Long-range planning emphasizes the fact that management may be obliged to consider the survival and growth of the organization over many years, and hence may have to consider many social and intangible goals not usually relevant in short-range plans. Activity (b), the adoption of plans. is an extremely difficult one in large organizations. A paper-and-pencil plan, no matter how attractive to the manager, often cannot be put into action by a simple order. Elaborate communication systems may have to be designed to get a large body of persons moving in the planned direction, and the many subleties of persuasion and motivation are involved as well. Activity (c), the "on-going" scrutiny of the effectiveness of adopted plans, is often called control, and is a function that in some instances is the responsibility of accounting staffs. Activity (d), the process of changing plans once they are deemed ineffective, requires not only a designed data processing system, but it also entails the search for the mean between the extremes of changing too oiten and not changing often enough.

If management is characterized in this manner, it is a term which is applicable to any organized, goal-seeking group of persons. Hence the phenomenon of management may occur in national governments. civic governments, labour unions, schools, universities, business firms and even in scientific research establishments. One should recognize that management does not connote rigid control; an organization may be managed best by permitting maximum freedom of decision among its members.

Further, it should be noted that management as defined above will oiten include the activities of staff as well as line personnel in an organization, and may in many cases include some aspect of the activities of every member of the organization. Indeed, as in the case of any teleologically defined activity, it is usually not possible to separate management behaviour from nonmanagement behaviour or managers from nonmanagers. A foreman of a shop may in the same act be serving the function of management and the iunction of production. On the other hand, it oiten happens that the owners of a firm, members of a union or the citizens of a country do not manage the organizations that supposedly serve their interests. The management of these organizations seeks to determine the goals of the interested parties and tries to make these goals a part or whole of the evaluation basis of their plans, but the interested parties themselves may contribute very little to the management of the enterprise.

The definition of management does not imply that all forms of management are good, but the community of management scientists does have a strong interest in establishing criteria of good and bad management. In this sense, the management sciences are not primarily descriptive, although detailed descriptions of management processes may be quite important. Instead, they are predictive. But interest lies not only in predicting what a given management will do in a certain circumstance, but more fundamentally in predicting what would occur if certain activities mere adopted. The outcomes of these predictions are then evaluated, and an attempt is made to rank management activities in terms of better and worse, and if possible to discern the best. Evidently, this evaluation is based on a decision as to whose interests are to be served by management or, more precisely, how various competing interests are to be weighted.

The community of management scientists is largely made up of persons from various disciplines; very few claim this field as their sole area of expertise. Interest in and conceptualization of management problems depends on the background of the scientist, so that the management sciences inevitably display radically different emphases. In true academic style, the more vocal management scientists are apt to argue that their own approach and emphasis is fundamental, thus giving rise to the healthy disputes that constitute intellectual growth.

One description of the composition of the community of management scientists follows a traditional classification of the sciences that leads from logic and mathematics through the physical and engineering sciences to biology. psychology and the social sciences, culminating in ethics. But it may be noted that this classification is at best arbitrary, reflecting as it does but one structure of the sciences. Indeed. the adequacy of a classification of the sciences is itself a problem oi the management of science, so that members of the community might well be expected to differ on this score as well.

Logic. — Logicians find in the study of management a fertile field for axiomatic theory. The post-World War II trend in the management sciences emphasized both mathematical models and the development of precise measurements. In either case, there was a clear need ior a rigorous iormulation of the underlying language. This need was especially true in the case of measurement. a term nith many historical meanings. The tradition in the management of firms has been that some aspects of the activity are measurable (*e.g.,* a cash balance) and some, called intangibles, are not (*e.g.,* good will). On the other hand, pure scientists observing the vagueness of discourse that surrounds business research often have been inclined to say that in this area nothing is ever really measured. The logicians' task has been to state in as unambiguous a manner as possible what measurement is, what kinds of measurement there are and what can be said in terms of each kind. Of particular importance to the management sciences has been the axiomatic treatment of utility and subjective probability. In the case of utility, an attempt has been made to state in unambiguous terms a theory of preferential choice in decision-making situations. Formal studies of subjective probability try to define precisely a decision maker's beliefs in the likelihood that a certain outcome will follow upon a choice; these studies are based on the observation that even the most carefully educated man does not behave in accordance with the principles of objective probabilities. For example, it has been found that in relatively simple gambling situations involving the toss of a coin, persons typically believe heads (or tails) will be more likely to occur. No doubt this bias in favour of certain kinds of events is also displayed in the attitudes of many managers as well. The scientific task is to measure the attitude in order to better understand the subtle ways in which subjective probabilities influence decisions.

Mathematics — Interest in the mathematics of management increased tremendously after World War II, although a number of notable treatises had appeared before. This interest resulted in new fields of mathematical research, fields whose titles reflect the potential application to management problems: inventory theory, waiting line (queuing) theory, linear and nonlinear programing, dynamic programing, game theory. Many of the traditional fields of mathematics have been the bases of these developments, but maximization theory and probability theory are extremely important in this connection, because almost all criteria of evaluation are expressed in terms of maximizing some variable, and because almost all management decisions are based on probabilistic forecasts. The nature and diversity of the mathematics of management can be suggested by brief characterizations of some of the more important examples.

Inventory Theory. — This provides a language for describing the status of a system that is subject to a pattern of demand and has available resources for building up supplies. The demands may be probabilistic and may vary in kind. The replenishment may be subject to delays and uncertainties. The reservoir may be depleted by obsolescence and deterioration. Management costs include cost of shortages, cost of replenishment, cost of holding the supplies. Many studies have been made of inventory problems; it has been found possible to predict the demands on inventory within statistical limits and to estimate the net costs of adopting various inventory policies, even when there are many kinds of inventory, seasonal fluctuations and unpredictable demands. Mathematical language is not restricted to the original intent of its designer. Thus inventory theory may be applied to many problems where the term inventory would not normally be used, such as planning of personnel assignments, parking facilities and cash flows.

Waiting Line Theory. — The language of a system of service units, this describes how customers arrive for service. how service meets their requirements in terms of average service time and variation in service time, how long the customer may have to nait, how long the service unit may be idle.

Linear *Programing*.—A language of activities which describes how these activities utilize their resources in order to accomplish certain prescribed tasks; linear programing also describes how these activities operate within the limitations of time and space. The term linear reflects the fact that the basic descriptions must take the form of linear algebraic equations (or inequations). Nonlinear programing permits a relaxation of this requirement. The language of Iinear programing is astonishingly versatile. In addition to its obvious use in the planning of production schedules, it has been employed in such areas as military logistics, transportation and traffic, personnel assignments and salary levels.

Dynamic Programing. — This maximization theory, among other uses, permits one to maximize over a whole series of states where each state depends on decisions that have been made in earlier states. This language allows one to state in rigorous terms the period-by-period consequences of decisions and to calculate the desirability of incurring temporary losses, say, for the sake of long-run gains.

Game Theory.—A language for describing competitive strategies when the opponents can influence the probability of success of the other "players" under prescribed rules, and can form coalitions to thwart the activities of others. This language therefore is well adapted to the study of competition, but its application has not been extensive because in many realistic problems it is difficult to ascertain what the players really want and the rules that govern their plays. (See GAMES, THEORY OF.)

In addition to these languages, the following can also be mentioned: theories of search, replacement, communication, information and decision making.

All these languages enable the scientist to state in rigorous terms the nature of the problem as he sees it, and the consequences of alternative decisions even when the situation is extremely complicated. Many management problems continue to defy the best efforts of mathematicians to describe them, so that the management sciences devote a great deal of effort in searching for even richer languages than those developed thus far. The complexity and subtlety of many management problems have quite naturally led the unwary to force the problem to fit an existing mathematical model, a procedure that is certainly not unique to this field of science.

Mathematical Statistics. — From the 1920s and 1930s, this discipline has attempted to formulate its foundations in terms of the utilization of information for decision making under uncertainty; it therefore shares a common concern with the management sciences, despite differences in terminology. In a sense, the manager of an organization is a statistician, since he gathers data and attempts to test hypotheses, while taking cognizance of the risks and losses associated with wrong decisions. Mathematical statisticians have tried to give a precise formulation of this process, and to determine optimal solutions in cases where the data can be assumed to come from some random source. Of course, in most management problems it is difficult to ascertain the random characteristics of the data, and it is not generally possible to set up experimental designs to test for randomness. But there can be little doubt about the usefulness of a number of statistical models in management studies, and especially models of control and stability.

The physical sciences would normally be expected to have only an indirect interest in management problems, although in the postwar period a number of physicists and chemists applied their research abilities in this area.

Engineering Sciences. — On the other hand, engineering shares many problems with management sciences. For example, the engineer is often concerned with systems in which human beings are links. These systems are goal directed and must include devises that enable one to adjust the activity when it deviates from the goals significantly. It is clear, therefore, that the manipulation and control of an engineered system (*e.g.,* a chemical plant or a guided missile) has many characteristics in common with the management of a human organization. The chief difference seems to be one of degree: the importance of motivation, status, persuasion may be less in the engineered system. But some engineers have quite naturally wanted to apply their knowledge to the area of management. This interest goes back at least as far as the "scientific management" movement, which, in its earlier development, seems to have been chiefly concerned with the control of procedures, especially those of the shop. This movement showed little inclination to develop mathematical models of these procedures, but rather tried to use careful observation and physical measurement to discern how improvements could be made. In this regard, the scientific management movement differs radically in its philosophy from the management science movement. Perhaps this difference can be clarified by saying that scientific management was not interested in trying to develop a model that would reveal all alternatives and provide a criterion for the selections of the optimal choice. Those who, like some "systems-and-procedures" or "time-and-motion" engineers, followed the scientific management movement have been somewhat apart from the community of management sciences, a segregation that may very well be a phase in the maturation of each group.

However, systems engineers who design electronic systems must construct models of the system and it is natural to associate themselves with the management sciences movement. Many industrial engineers have also approached the problems of the scientific management movement from a mathematical point of view.

One output of the systems engineer has been of great importance to all the management sciences: the development of high-speed computers. Evidently the problems of management may involve many variables. and the solutions thus require quite elaborate computations. Such has been especially the case with linear programing models. where several algarithms have been developed which can most economically be solved by computers. Furthermore, the management sciences have found the simulation of a system to be enormously helpful in understanding its complexities, and computers frequently provide the means for simulating. Finally, in the early 1960s there was considerable interest in "business games" and "military games." These games partially simulate an organization in a specially constructed competitive environment. The computer enables the researcher to structure the environment in rather complicated ways, and yet to derive the consequences of the managerial decisions of the teams in a short time. These simulations differ from simulations of a model in that they include human inputs which the experimenter does not control, whereas in model simulation every input is a decision of the experimenter. The games provide the management scientist with an opportunity of performing controlled experiments with more and more complicated structures.

Biology. — One might expect some coalition of biologists and management scientists, because (1) the analysis of the concepts of organism and organization clearly share a common ground and (2) the central nervous system seems to display a managerial activity. In the early 1960s, however, there were only a few instances of this mutual sharing of intellectual ideas.

Psychology. — Psychologists have studied management from several points of view. Some have concentrated on intense experimental studies of decision making, where the choices are relatively simple and the relevant variables can be controlled. These studies are intended to investigate the utilities of the decision maker and to relate these utilities to other personality variables or to his material or social environment. Some experimental studies have observed the effect of communication patterns, psychological variables and the social environment on the performance of groups who have been given specified tasks to perform. According to one viewpoint, these small group studies are a logical prelude to controlled observation of larger organizations.

Learning and problem solving are psychological concepts that are extremely important for management and hence for the management scientist. It would be unrealistic to picture the manager as a person who knows all the alternatives and merely tries to select the best from the available. Instead, the manager searches for new alternatives and for new goals. He is presumably engaged in a gigantic learning process by which he hopes to make his activities better. Thus the management scientist may try to understand not only what is optimal. but also how one may move most adequately in an optimal direction. Many management problems entail a fantastic number of discrete alternatives. In some of these situations the important problem may be the learning process and not the direct selection of the optimal choice. Hence management scientists share with some psychologists an interest in developing more rigorous models of learning.

Many psychologists have been willing to sacrifice precision in order to gain a broader view of management: *e.g.,* to study conscious and unconscious motivations, status or the "actual" way in which decisions are made. It must be admitted that the management scientists have not been in agreement about the importance of these studies, primarily because although their general value may be apparent, the manner in which they fit into more rigorous models of management is not clear. Similar remarks apply to social psychology and sociology. No doubt here too both the management sciences and the social sciences are in a period of transition; the one may tend to relinquish its rigid and often naïve insistence on precision, while the other will come to recognize the great research power provided by the mathematical languages.

Economics. — During the 20th century, economists have shown a divided opinion on the importance of rigour in economic studies. Some have felt that emphasis on rigour may sacrifice significance. But the econometrician and mathematical economist are clearly allied with the management scientist. Indeed, many such economists view the work of the management sciences in business firms as a logical development of micro-economics. It is true that much of the mathematics of management has come from economics; queuing, search and replacement theory being important exceptions. Although systems engineering and human motivation other than that expressible by utility functions have not been the concern of the traditional economists, some economists think that both these areas are of dubious importance at best to the development of the management sciences. In any case, in the years following World War II, the mathematical economist came to play a central role in the management sciences. Some economists have called themselves managerial economists, to emphasize the fact that the studies of management problems belong in a subclass of economic studies.

Business Administration. — Tending to regard itself as a profession prior to World War II, business administration's chief method of research and instruction depended on detailed descriptions of cases. As would be expected, the management scientist does not look upon the case method as a scientific method. partly because the language of the case studies is not precise, but mainly because there appears to be no basis for relating the case to the population of which it is presumably a sample. After World War II, a number of business administration faculty joined the management sciences. In some instances, these researchers found it possible to develop mathematical models of marketing behaviour or financial policy making or production planning, that satisfied the criteria of the scientific community and were at the same time useful to managers. In other instances (especially in accounting), the management sciences have presented new problems to an old profession. Although managerial accountants sometimes speak as though certain types of accounting data could be used for planning, a careful scrutiny often reveals that the data must be presented in an entirely different way, and that additional data have to be obtained, before an optimal decision be estimated. Many accountants point out that accounting has other functions to perform besides that of aiding the manager in his decisions. But it is natural to expect that the growth of the management sciences will attract the interest of research minded accountants. The term administration has raised semantic problems for the management scientist. Many would prefer to use it instead of management because it is less apt to reflect the unintended connotations of rigid control or of management v. labour. Others feel that administration should be restricted to the execution of plans and not to their origination.

Organization Theory. — This sometimes refers to a set of principles that are intended to predict how effectively a social group will behave when given an organized structure of lines of authority, responsibility, control, etc. In the 1960s, many students of organization theory tried to develop rigorous models and to incorporate the findings of the behavioral sciences. Thus the intellectual objectives of the management sciences and organization theory are quite similar, especially because organization theorists emphasize the role of management in organization designs.

Other Disciplines. — Law, political science, anthropology, city planning, education and history have a research interest in the study of management, but few of their representatives believe strongly in the feasibility of developing rigorous models of and applying precise measurements to the phenomena they study. This condition seems to be true of ethics and epistemology as well. One would expect that a community of scientists whose chief interest lies in the study of optimal plans and procedures would inevitably find itself deeply concerned with ultimate values. But management scientists tend not to translate this concern into research activity, but rather to accept the value of an enterprise as "givens," no doubt because they are skeptical of the possibility of precise methodology in the area of ethics. Similarly, epistemology could be interpreted rather easily as the study of the management of groups whose aim is to acquire knowledge; *i.e.,* epistemology could be understood as the theory of the management of science. though the use of such terminology might be undesirable in view of the connotations of rigid control that are often associated with the concept of management. But if one keeps in mind the much more general characterization given above, then a plausible case can be made for the position that pragmatism is the philosophy of management (or more generally perhaps, of decision theory). But most pragmatists have not shonn a strong interest in the management sciences.

As would be expected, it is not at all clear when a study should be regarded as belonging within the purview of management science. Perhaps the only operational criterion is whether or not the study would have been accepted in any of the existing journals that clearly publish in this field. But such a criterion would ignore the rather rapid changes that are taking place in the management sciences: changes which will bring about a recognition that many studies of the so-called less exact disciplines are really instances of management science.

Importance. — From this account of the sciences one can readily understand that the phenomena of management is pervasive both in the engineering and the social sciences. Furthermore, few can deny the importance of management for the human race, especially in an age when almost all major social problems are studied and resolved within an administrative framework. But until the post-World War II period there was no strongly discernible trend to bring this common interest under one discipline. Thus management is sometimes viewed as the control of a system or as a set of interacting psychological forces or as an economically directed activity or as an activity directed toward the public welfare or as an ethical activity. Each discipline has looked at the phenomena through its own spectacles. The management scientists have tried to bring about a coalition which may eventually lead to an established discipline. They have often done this under the banner of a methodological adherence to the value of rigour and therefore at some risk to their entire efforts. for those who prefer not to march under this banner are bound to declare that one's choice in this area is to be precisely insignificant or vaguely significant. And those who prefer the foundations of their own disciplines are bound to find any proposed coalition both dangerous and needless, no matter how much they sympathize with the attempt to become precise. Like all movements, this one will have to develop with due regard to its dilemmas.

Nothing has been said so far about those who are called managers. The management sciences are unique in this respect: the subjects whom they investigate (1) are very vocal and critical, (2) maintain persistent pressure on the scientists to produce something "useful" and "intelligible" and (3) often support the research. These facts sometimes make it difficult for the management scientist to be "pure," even if he is so inclined. Furthermore, the dilemma of precision *v.* communication is especially acute when the scientist must talk to the manager. Also, the manager may try his best to influence the direction the field will take. All of which leads one to conclude that the management sciences in all likelihood will have to develop their own peculiar methodology, and will not be able in time to rely on the traditional successful means of other disciplines.

MANAGUA, a small department in Nicaragua, bordering three sides of Lake Managua. Area 1,332 sq.mi.; pop. (1950) 161,513. The population is 71% urban and is concentrated in the volcanic zone southwest of Lake Managua. With fertile volcanic soils. the department is important in producing coffee. dairy products. vegetables and fruits. Managua city, the departmental capital. is located on the southeast shore of Lake Managua, in view of smoldering Mt. Masaya and the extinct volcanoes of Momotombo and Momotombito. (C. F. J.)

MANAGUA, capital of Nicaragua and of the department of Managua. is the largest city in the Central American republic. Pop. (1950) 109,352. The city lies on the southeast shore of Lake Managua (Xolotlán), which is 38 mi. long and 16 mi. wide, the lesser of the two great lakes which are one of the chief physical characteristics of the country. It is on the Pacific railroad, 87 mi. from the port of Corinto, and on the Pan American highnay. It is connected with the important cities of the world by airlines and has tno airports. Las Mercedes (International) and Xolatlán (local). Managua is the industrial and commercial centre of Nicaragua; its factories produce cotton fabrics, beer, cigarettes and matches. It is also the centre of an important agricultural region which produces cotton. rice and coffee; cattle are also raised and exported.

The city is located in beautiful surroundings between Lake Managua and the tiny lakes of Xsososca. Nejapa and Tiscapa. Its climate is rather hot and humid during most of the year but many residents have built homes on the hills around the city, where the temperature is cooler. There are many new buildings of modern architecture, among them the communications palace and the social security building. The presidential palace and the U.S. embassy are on the southern outskirts of the city.

Managua's importance began in the late 1840s when it was used as a compromise capital in order to avoid the rivalry between Granada and Leon; it was established as the final site of the capital in 1855 after the war against William Walker (*q.v.*). The city was occupied almost continually between 1912 and 1933 by U.S. marines. In 1931, it was almost completely destroyed by earthquake and fire.

In addition to being the political capital of the country, Managua has been the religious capital since the beginning of the 20th century. when it was made the site of an archbishopric of the Roman Catholic Church. (M. F.-G.)

MANAKIN, applied to the small birds which form the family Pipridae, a passerine family allied to the Tyrannidae. They are peculiar to the neotropical region, living in deep forests. associating in small bands, and keeping continually in motion, but feeding almost wholly on the large soft berries of the different kinds of *Melastoma.* The manakins are nearly all birds of gay appearance, generally exhibiting rich tints of blue, crimson, scarlet, orange or yellow, in combination with chestnut, deep black. black and white or olive green; among their most obvious characteristics are their short bills and feeble feet, with the outer and middle toes united for a good part of their length. P. *leucilla,* one of the best known, has a wide distribution from the Isthmus of Panama to Guiana and the valley of the Amazon; but it is one of the most plainly coloured of the family, being black nith a white head. They are often kept in captivity.

MANASSAS, a town and seat of Prince William county, Va., U.S., 25 mi. S W. of Washington, D.C. The town, first known as Manassas Junction, came into being in 1853 when the Manassas

Gap and the Alexandria. Orange and Midland railroads were joined. During the American Civil War this strategic junction afforded a direct connection between the Shenandoah valley and the railroad from Washington to Richmond. Confederate forces won the battles of First and Second Manassas (Bull Run, *q.v.*) nearby; the battlefields are preserved by the national park service. Manassas was incorporated as a town in 1873 and in 1892 it became the county seat, Prince William's fifth. It adopted a city-manager form of city government in 1927 and was rechartered in 1938.

Manassas with a population of about 3,500 is a trading centre for a general farming. dairying and stock raising area. Brushless generators are manufactured there. Many residents are government workers and skilled craftsmen who commute to Washington. the marine base at Quantico and other government installations. (G. M. BE.)

MANASSEH (in the Douai version of the Bible, MANASSES), king of Judah, succeeded his father, Hezekiah (*q.v.*), and reigned about 692–638 B.C. That he maintained his position so long is a tribute to his statesmanship, and probably his kingdom prospered materially. Very little is heard about him, however, because his recognition of alien cults was a grave offense in the eyes of those who edited the historical writings. He is, indeed, held responsible for the ultimate ruin of the kingdom. He was very much under the influence of Assyria, and documents from his reign unearthed at Gezer disclose the presence of Assyrians in his realm, the use of their language and method of dating. No doubt his introduction of the worship of the host of heaven and other Assyrian cults was dictated by political rather than religious motives. He may well have been involved in the conspiracies of Shamash-shum-ukin, the rebellious brother of Ashurbanipal. If so, the account of his deportation to Babylon, and subsequent return (II Chronicles xxxiii, 11–13) may be historical. Manasseh appears in inscriptions of Esarhaddon and Ashurbanipal as an Assyrian vassal. (W. L. W.)

MANASSEH, a tribe of Israel, was descended, according to the traditions. from Manasseh, the elder of the two sons born to Joseph by his Egyptian wife Asenath, the younger being Ephraim. Numbers xxxii states that half the tribe received an allotment of territory in the conquered land of Gilead, east of Jordan. In Joshua iv, 12 it is stated that this part of Manasseh joined with Reuben and Gad in support of the tribes who mere fighting for a foothold on the west of the river. But other traditions tell of a Manasseh tribe settled west of the Jordan. In Joshua xvi–xviii Manasseh, regarded as forming with Ephraim a single tribe, is settled in the hill country south of the fertile Plain of Esdraelon and cut off from it by a strong chain of fortified Canaanite towns. Its western border is the Mediterranean; but the territory occupied by it cannot be defined with precision. Machir, the "son" of Manasseh, seems to represent sometimes that part of Manasseh dwelling in central Palestine, sometimes an element of that part of the tribe dwelling east of the Jordan. and sometimes the whole tribe. Machir appears in the ancient poem Judges v as taking part in the struggle against Sisera, and seems to have Zebulon on the one side, Ephraim and Benjamin on the other. as neighbours. From I Chronicles vii, 14 it may be deduced that the tribe contained some Aramean elements. The various traditions are so confused that certainty in detail seems unattainable. To Manasseh belonged the deliverers Gideon and Jephthah. (W. L. W.)

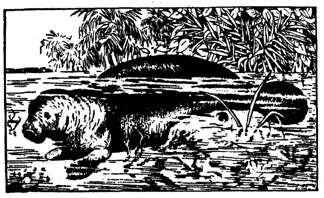
MANASSES, CONSTANTINE (d. 1187), metropolitan of Naupactus, was an author of Byzantine "political" (*i.e*, 15-syllable) verse and of prose works. At the request of Manuel I's sister-in-law, he wrote a verse chronicle *(Synopsis historike)* from the creation to 1081. His verse romance on Aristander and Callithea survives in fragments only. He wrote a variety of other poems, as nell as descriptive pieces in prose (some on works of art), and a number of orations, including an address to Manuel I and a funeral eulogy of Nicephorus Comnenus. Much of his work is unedited.

Herchcr, in *Scriptores erotici Graeci,* vol. 2 (1859); orations named above ed. by E. Kurtz in *Vizantiski Vremennik,* vol. 12, pp. 88–98 (1905) and vol. 17, pp. 302–322 (1915). Some of his other minor works are edited in various publications. *See* also K. Krumbacher, *Geschichte der byzantinicchen Litteratur,* pp. 376–380, 2nd ed. (1897); G. Moravcsik, *Byzantinoturcica,* vol. 1, pp. 353–356, 2nd ed. (1958). (J. M. HY.)

MANASSES, PRAYER OF, a short apocryphal book of the Old Testament. It purports to be the prayer of the Judaean king Manasseh (*q.v.*) referred to in II Kings xxi, 1–18 and in II Chron. xxxiii, 1–20. This fine penitential prayer seems to have been modeled after the penitential psalms. It exhibits considerable unity of thought, and the style is, in the main, dignified and simple. The date of its writing is unknown. Some scholars assign it to the Maccabaean period (2nd century B.C.), but its eschatology and doctrine of "divine forgiveness" may point to an earlier date; on the other hand, there are some indications of a doctrinal character which point to post-Maccabaean times. The book was used in the early Christian Church, but was never included in the Vulgate Bible.

For the text, *see* H. B. Swete, *The Old Testament in Greek,* vol. iii (1894). *See* also H. E. Ryle in R. H. Charles (ed.), *The Apocrypha and Pseudepigrapha* of *the Old Testament,* vol. i (1913).

MANATEE or MANATI, the name of the American representative of a small group of herbivorous aquatic mammals, constituting the order Sirenia (*q.v.*). Manatees are somewhat whalelike in shape, with a similar horizontally expanded tail fin; but here the resemblance to the Cetacea ceases. The American manatee, *Trichechus manatus,* inhabits the rivers of Florida, Mexico, Central America and the West Indies and measures from 9 to 13 ft. in length. The body is somewhat fishlike, but depressed and ending posteriorly in a broad, shovellike, horizontal tail, with rounded edges. The head is of moderate size, oblong, with a blunt muzzle, and divided from the body by a slight constriction. The forelimbs are flattened oval paddles, placed rather low, with no external signs of division into fingers, save three diminutive flat nails near their extremities. No traces of hind limbs are discernible either externally or internally. The mouth is peculiar, the snollen upper lip being cleft in the middle line into two lobes, each of which is separately movable. The nostrils are two valvelike slits at the tip of the muzzle. The eyes are minute and nearly circular with wrinkled margins; external ears are wanting. The skin is dark grayish and finely wrinkled. There is a scanty covering of delicate hairs, and both lips are supplied with short, stiff bristles. Manatees have a number — as many as 20 pairs in each jaw—of two-ridged teeth, of which, however, comparatively few are in use at once. They lack the large tusks of the male dugong (q v.). In life the palate has a horny plate, with a similar one in the lower jaw.



FROM VOGT AND SPECHT, "NATURAL HISTORY OF ANIMALS" (BLACKIE)

THE MANATEE (TRICHECHUS INUNGUIS) OF THE AMAZON

Manatees inhabit bays, lagoons, estuaries and large rivers but not the open sea. As a rule they prefer shallow water, in which, when not feeding, they lie near the bottom. In deeper water they often float, with the body much arched, the rounded back close to the surface and the head, limbs and tail hanging downward. They feed below water on aquatic plants. They are slow of movement and perfectly harmless but are persecuted for the sake of their oil, skin and flesh. From the shoulder joint the flippers can be moved in all directions, and the elbow and wrist permit of free extension and flexion.

In feeding, manatees push the food toward their mouths by means of the hands and introduce it without the assistance of the lower lip, the action of the upper lip recalling that of the mandibles of caterpillars.

The Amazonian manatee (T. *inunguis)* is smaller, not exceeding 8 ft. in length, nith less well-developed lip pads and without nails to the flippers. It ascends most of the tributaries of the Amazon until stopped by rapids. The West African T. *senegalensis* extends about 10° S. and 16° N. of the equator and ranges into the continent as far as Lake Chad. From 8 to 10 ft. appears to be the normal length; the weight of one specimen was 590 lb. The colour is bluish black, with a tinge of olive green above and yellow below.

The manatee is said to be the origin of many legends of mermaids, while the Amazonian species is the object of superstitious reverence by the Indians.

MANATÍ, a town of Puerto Rico, situated in the northern part of the island, about 3 mi. from the Atlantic ocean. Pop. (1960) 9,682 (mun. 29,354). Manati is located in a beautiful valley drained by the Manati river. The name is of Indian origin and refers to a sea mammal called manatee in English. The soil of the rural area around the town is very fertile. Sugar cane and pineapple are extensively cultivated; coffee, grapefruit, oranges and bananas are also produced. Several important industries, including a shoe factory, have been established in the town.

(T. G. Ms.)

MANAUS (MANÁOS), a city and port of Brazil and capital of the state of Amazonas, is on the left bank of the Rio Negro, 12 mi. above its junction with the Amazon (Solimões) and 900 mi. above the mouth of the Amazon in the heart of the Amazonian rain forest. Pop. (1956 est.) 164,799 (mun.). Manaus stands on a Tertiary terrace overlooking the river, 106 ft. above sea level, traversed by several *igarapés* (canoe paths) or side channels that are spanned by bridges and divide the city into separate compartments. The climate is less oppressive than is commonly believed—the annual average temperature is 81° F., relative humidity 82% and average rainfall 75 in.

hlanaus has a famous botanical garden, a zoological garden. a museum and a tropical research institute. Its majestic public buildings and homes, including the ornate opera house, where Caruso sang on opening night, date from the period 1890–1920 when the rubber boom brought wealth and luxury to hlanaus. The port, which is the commercial hub of the entire upper Amazon region, was nothing but a river anchorage before 1902. In that year, an English corporation began improvements which included a stone river wall or quay, storehouses for merchandise and floating wharves or landing stages connected with the quay by floating bridges. The floating wharves and bridges are made necessary by the rise and fall of the river, the range between high and low waters reaching jo ft. under extreme conditions. The principal exports are rubber, Brazil nuts, rosewood oil and jute; a host of minor forest products also move through the port. Cordage and coffee sacks are made in Manaus from locally grown jute. The city receives its beef from the savannas of the upper Rio Branco and from that region also come hides and horns for export.

Manaus is a regular stop on the shortest north-south air route between Miami, Fla., and eastern Brazil. It also serves as the hub of the well-developed air service of the Amazon valley. The port has direct steamship connections with New York and Great Britain and with all ports of the Amazon river system. A 5,000-bbl. refinery, built on a bluff below the city in 1956, refines crude oil barged down the Amazon from Peru. In 1955, oil was discovered at Nova Olinda, which is on the lower Madeira, about 110 mi. S.E. of hlanaus.

The first European settlement on the site of Manaus was made in 1660, when a small fort was built there by Francisco da Motta Falcão and named São José do Rio Negro. The mission and village which followed were called Villa da Barra or Barra do Kio Negro ("barra" referring to the bar or mouth of the Negro). Manaus succeeded Barcellos as the capital of the old *capitania* of Rio Negro in 1809 and became the capital of Amazonas when that province was created in 1850, its name being then changed to Manaus after the principal tribe of Indians living on the Rio Negro at the time of its discovery.

In 1892, Manaus became the see of the new bishopric of Xmazonas. (Js. J. P.)

MANBHUM, a former district of the Chota Nagpur division of Bihar state, India. Area, 4,129 sq.mi.; pop. (1951) 1,547,559. In 1956 Manbhum district was transferred to West Bengal; Bihar state retained the Chas and Chandil thanas and Patamda police station.

Manbhum district forms the first step of a gradual descent from the tableland of Chota Nagpur to the delta of lower Bengal. In the northern and eastern portions the country is open and consists of a series of rolling donns dotted here and there with isolated conical hills. In the western and southern tracts the country is more broken and the scenery much more picturesque. The principal hills are Dalma (3,038 ft.), the crowning peak of a range of the same name; Gangabari (Gajburu or Gorgaburu) (2,220 ft.), the highest peak of the Baghmundi range; and Pachet (2,110 ft.), on which stands the old fort of the rajahs of Pachet. The hills are covered with dense jungle. The chief river is the Kasai, which flows through the district from northwest to southeast into Midnapore. A large proportion of the population is of aboriginal descent, the chief tribes being the Santals, the Bhumij and Bauris; the latter two have adopted Hindu customs and are fast becoming Hindus in religion.

Containing the Jharia coal field and part of the Raniganj coal field, Manbhum is the chief colliery district in West Bengal. The growth of the industry is comparatively recent. In 1894 the railaay was opened from Barakar to Dhanbad, and in the 20th century coal mining developed rapidly, especially after the Bengal-Nagpur railway was extended to the Jharia coal field in 1904. The public health of the coal fields, and indeed of the whole Dhanbad subdivision and of a small area to the south, with a total area of 790 sq mi. and a population of 731,700, is in the charge of the mines board of health, which has done admirable aork.

Besides the administrative headquarters, Purulia (pop., 1951, 41,461), which is at the junction of the narrow-gauge line to Ranchi, the only town is Dhanbad (pop. [1951] 34,077), the headquarters of a subdivision and a railway settlement.

MANCE, SIR HENRY CHRISTOPHER (1840–1926), British scientist and engineer who invented the heliograph. was born in London in 1840. He joined the Persian gulf telegraph department of the government of India in 1863 and was employed on laying the first submarine telegraph cables in the Persian gulf. He was the originator of the Mance method for detecting and localizing faults on submarine cables and wrote several papers dealing with this subject. He also invented the modern heliograph, which was used successfully during the Second Afghan War and subsequently adopted for general use in the British army. Mance was made a companion of the order of the Indian empire in 1883 and was knighted on his retirement in 1885.

A member of professional and scientific bodies, Mance was president of the Institution of Electrical Engineers in 1897. He died at Oxford on April 21, 1926. (G. R. M. G.)

MANCHA, LA (Arabic, AL MANSHA, "the dry land" or "milderness"). in its nidest sense denotes the bare and monotonous elevated plateau of central Spain that stretches betneen the mountains of Toledo and the western spurs of the hills of Cuenca, being bounded on the south by the Sierra Morena and on the north by the Alcarria region. Altitude about 2,000 ft. It thus comprises portions of the modern provinces of Toledo, Albacete and Cuenca, and the greater part of Ciudad Real. Down to the 16th century the eastern portion was known as La Mancha de Montearagon or de Aragon, and the western simply as La Mancha; afterward the northeastern and southwestern sections respectively were distinguished by the epithets *Alta* and *Baja* (upper and lower). La Mancha remains almost exactly as Cervantes described it. Many villages. such as El Toboso and Argamasilla de Alba, both near Alcázar de San Juan, are connected by tradition with episodes in *Don Quixote.*

MANCHE, a *département* of northwestern France, made up chiefly of the Cotentin and the Avranchin districts of Normandy, and bounded nest, north and northeast by the English channel (Fr. La *Manche*), from nhich it derives its name, east by the department of Calvados, southeast by Orne, south by Mayenne and Ille-et-Vilaine. Pop. (1954) 446,860. Area 2.476 sq.mi. The department south of Coutances and St. Lô is composed of folded Palaeozoic rocks of the Armorican system, with east and west zones of granite. rising in the southeast to 1.200 ft. There are younger and softer deposits on the east. The west coast is an ancient structural line from north to south and is marked by cliffs up to 420 ft. alternating with bays, at the south end the great bay of Mont St. Michel, with its famed abbey surmounting a rock 400 ft. high. Reefs off the coast make navigation perilous, the chief forming Les Iles Chausey. The north coast also seems to be a structural line and is marked by the great roadstead of Cherbourg. The greater part of the department may be described as a dissected plateau with deeply cut valleys. The chief streams are the Vire, running northward past St. Lô, and the Sienne, running northwestward just south of Coutances. The climate of Manche is mild and humid; myrtles flourish in the open air. The characteristic industry of the department is horse and cattle rearing, carried on especially in eastern Cotentin; sheep are raised in the west. Wheat, buckwheat, barley and oats are cultivated. Manche is a foremost department for the production of cider apples and pears; plums and figs are also largely grown. Butter, poultry and eggs are important sources of profit. Flourishing market gardens are in the west. The department contains valuable granite quarries in the Cherbourg *arrondissement* and the Chausey Islands; building and other stone is quarried. There are metal industries, and the weaving of osiers is a local feature. Oyster beds are on the coast (St. Vaast, etc.); and the maritime population, besides fishing in home and distant waters, collects seaweed for manure. Coutances is the seat of a bishopric of the province of Rouen. The north of the department forms part of the region of the 3rd (Rouen) and the south of the 10th (Rennes) army corps and of the circumscriptions of the *académie* (educational division) and appeal court of Caen. Cherbourg (*q.v.*), with its important port, arsenal and shipbuilding yards, is the chief centre of population. St. Lô (*q.v.*) is the capital; there are four *arrondissements* (St. Lô, Avranches, Cherbourg and Coutances), comprising 48 cantons and 648 communes. Valognes, Mortain, Coutances, Granville and Mont St. Michel are also important. At Lessay and St. Sauveur-le-Vicomte there are the remains of ancient Benedictine abbeys, and Torigni-sur-Vire and Tourlaville (close to Cherbourg) have interesting châteaux of the 16th century. Valognes. which in the 17th and 18th centuries was a provincial centre of culture, has a church remarkable for its dome, the only one of Gothic architecture in France.

MANCHESTER, EARLS AND DUKES OF. The Manchester title. in the English peerage, belongs to a branch of the family of Montagu (*q.v.*). The first earl was SIR HENRY MONTAGU (c. 1563–1642), grandson of Sir Edward Montagu, chief justice of the king's bench 1539–45. He was born at Boughton, Northamptonshire, was educated at Christ's college, Cambridge, and, having been called to the bar, was elected recorder of London in 1603, and in 1616 was made chief justice of the king's bench, in which office he passed sentence on Sir Walter Raleigh in 1618. In 1620 he was appointed lord high treasurer, being raised to the peerage as Baron Kimbolton of Kimbolton, Huntingdonshire, and Viscount Mandeville. He became president of the council in 1621, and Charles I created him earl of Manchester in 1626. In 1628 he became lord privy seal, and in 1635 a commissioner of the treasury. He was a judge of the Star Chamber, and one of the most trusted councillors of Charles I. In conjunction with Coventry, the lord keeper, he pronounced in favour of the legality of ship money in 1634. He died on Nov. 7, 1642.

EDWARD MONTAGU, 2nd earl of Manchester (1602–71), eldest son of the 1st earl by his first wife, was educated at Sidney Sussex college, Cambridge. He was member of parliament for Huntingdonshire 1624–26, and in the latter year was raised to the peerage as Baron Kimbolton of Kimbolton, but was known generally by his courtesy title of Viscount Mandeville. At the beginning of the Long parliament he was one of the recognized leaders of the popular party in the upper house, his name being joined with those of the five members of the house of commons impeached by the king in 1642. At the outbreak of the Civil War, having succeeded his father in the earldom in Nov. 1642, Manchester commanded a regiment in the army of the earl of Essex, and in August 1643 he was appointed major general of the parliamentary forces in the eastern counties, with Cromwell as his second in command. He became a member of the "committee of both kingdoms" in 1644, and was in supreme command at Marston Moor (July 2, 1644); but subsequently he disagreed with Cromwell, and in November 1644 he strongly expressed his disapproval of continuing the war. Cromwell brought his shortcomings before parliament in 1644; and early in the following year Manchester resigned his command. He took a leading part in the frequent negotiations for an arrangement with Charles and was custodian with William Lenthall of the great seal, 1647–48. He opposed the trial of the king, and retired from public life during the Commonwealth; but after the Restoration, which he actively assisted, he was honoured by Charles II. In 1667 he was made a general. He died on May 7, 1671. Manchester was made a K.G. in 1661, and became F.R.S. in 1665.

CHARLES MONTAGU, 1st duke of Manchester (c. 1662–1722), son of Robert, 3rd earl of Manchester, was educated at St. Paul's school and Trinity college, Cambridge, and succeeded to his father's earldom in 1683. He fought under William at the Boyne, became a privy councillor in 1698, and held various important diplomatic posts between that date and 1714, when he received an appointment in the household of George I, by whom in 1719 he was created duke of Manchester. He died on Jan. 20. 1722.

GEORGE MONTAGU, 4th duke of Manchester (1737–88), was the son of Robert, the 3rd duke. He was a supporter of Lord Rockingham, and an active opponent in the house of lords of Lord North's American policy. In the Rockingham ministry of 1782 he became lord chamberlain. He died in Sept. 1788.

WILLIAM MONTAGU, 5th duke of Manchester (1771–1843), third son of the preceding, was educated at Harrow, and entered the army. He became a colonel in 1794 and was appointed governor of Jamaica in 1808. Here he remained, except for a visit to England (1811–13), until 1827, doing much to prepare the way for emancipation of the slaves. From 1827 to 1830 he was postmaster general in the cabinet of the duke of Wellington.

See G. E. C[okayne], *Complete Peerage,* vol. viii, rev. ed. (London, 1932).

MANCHESTER, a cathedral city and county borough in Lancashire, Eng. Pop. (1961) 661,041. Area 42.6 sq.mi. The city of Manchester stands at the junction of the rivers Irwell, Irk and Medlock, 189 mi. N.W. of London and 31 mi. E. of Liverpool by road. Before the last Ice Age, a range of high mountains closed the approaches to Manchester's site on the north and east. Glacial action ground down and flattened them to a height of 1,000–2,000 ft. and glacial streams carved deep clefts and valleys whose streams converge on the area that is now the Manchester district. Here. where nature had laid down its own lines of communication, and where the high land gave way to estuarine marshes, making a natural defensive position, the settlement of Manchester first arose. The city varies from 100 ft. above sea level in the south to 400 ft. in the north, the height at the centre being 133 ft. Bordering the south of the city is the fertile Cheshire plain; to the east, north and west is the remainder of the huge east Lancashire industrial area.

Manchester is built on Triassic. Permian and Carboniferous rocks, which often reach the surface, but which are usually overlaid with thick deposits of glacial drift-sands, gravel and boulder clay. The heavily faulted rocks, particularly the Pendleton fault, give rise to occasional earth tremors. Industrial water is obtained in part from wells in the Triassic rock, but the bulk is piped from lakes in Cumberland and Westmorland, and the Longdendale valley in the Pennines. The whole region is seamed with coal and one of England's largest coal mines lies within the city boundary. The city enjoys a temperate climate varying from 2j° F. to 72" F. It is damp rather than wet, with an average rainfall of less than 30 in. each year, but with sunshine somewhat reduced by the industrial smoke pall and by the prevalent cloudy conditions.

History.—An early name for Manchester—Mancenion—is believed to have been taken from that of a Celtic settlement on the site. known as "the place of tents." One of the principal Roman roads from Chester northward passed through Manchester—a portion of it is still known as Watling street—and the Romans established in A.D. 79 a fort, small portions of which still remain, to safeguard military and trading traffic through the area.

The Romans gave to Mancenion their own version of the name —Mancunium. They were in occupation for about 350 years, and from then onward there was little of note to relate until 870, when the Danes destroyed the town, except for the fact that the place was brought under the dominion of the Saxons early in the 7th century and named, in various forms "Mamecaster" or "Memcestre." In addition. mention is made of the district in the Domesday and other surveys. Edward the Elder rebuilt Manchester in 920 and the right to coin money was granted to Manchester's citizens by King Canute. In the Domesday survey of 1086, Manchester is mentioned as an area poor and sparsely populated.

It was not until the 13th century that the first signs were visible of the Manchester of today. In 1229. the town was granted an annual fair by Henry III, and immigrant Flemish manufacturers chose the area for the establishment of their textile industry in 1330, thus giving the first evidence of the suitability of the area for textile production. The introduction about 1500 of vegetable cotton. known as cotton wool, must have been a stimulus to trade, for the antiquary. John Leland, reported to Henry VIII that Manchester was "the fairest. best builded, quikkest and most populous towne in all Lancashire." It is quite evident that Manchester's industry at the time was confined entirely to textiles, for a publication dated 16jo lists the town's manufactured products as "woolens, frizes, fustians, sack-cloths: mingled stuffs, inkles, topes and prints," and in 1690 the art of calico printing was introduced from France.

Present-day blanchester is one of the results of the Industrial Revolution which transformed the place, in a generation, from a market town to a thriving industrial centre. The discovery and exploitation in the late 1700s of steam power, and the opening up of road, river and, later. rail communications went hand in hand with the invention of devices for the mechanical manufacture of textiles. In 1761 the first English "navigation" or canal was opened to bring coal into Manchester from the duke of Bridgewater's estate at Worsley. In 178j the culminating invention of the power loom for weaving was made and in 1789 the first steam engine for spinning cotton was erected in Manchester. The *Manchester Guardian* newspaper which began publication in 1821 became, under the editorship of C. P. Scott (*q.v.*), one of the leading journals of the day. of Liberal views. hlanchester is a centre for journalism second only to London and also is the headquarters of the north regional branch of the British Broadcasting corporation.

Manchester's rise to municipal borough status in 1838 was probably due more to the efforts of one single man, Richard Cobden, than to anything else. Although of Sussex birth, Cobden had established himself in business in Manchester as a calico printer by 1829. when he was only 25 years of age. It was in 1837 that he emerged as a public figure, both when he stood unsuccessfully as a parliamentary candidate for Stockport, and when he led the struggle for bfanchester's incorporation as a borough. His being summoned as a juror to the manorial court leet led to his becoming aware of the hopeless inadequacy of manorial rule in an industrial town. Two days later he had drawn up a declaration, later signed by his fellow jurors, which criticized the existing system of local rule and was followed by his celebrated pamphlet "Incorporate Your Borough." This movement for incorporation resulted, at the beginning of 1838, in a public meeting at which Cobden was the principal speaker, to discuss the advisability of petitioning the queen for a charter of incorporation. Despite much opposition and the forgery of signatures to an anti-incorporation petition, the charter was eventually granted in Oct. 1838; Richard Cobden was elected as councillor for the St. Michael's nard, and elevated to the aldermanic bench after one day's service as councillor. He remained on the borough council until 1844. After the incorporation of the borough. Cobden became closely associated with John Bright? the son of a Lancashire cotton spinner, in the formation of the National Anti-Corn-Law league. While Bright was famous as a national figure, his local connection with Manchester was confined to representing the borough in parliament in the 1847 and 1852 elections. A statue of Richard Cobden stands in St. Ann's square, and one of John Bright is in Albert square; busts of both are in the town hall.

Other notable occasions in Manchester's history are the opening in 1851 of what is now the University of Manchester, the rise to city status in 1853, the completion of the Manchester Ship canal in 1894, the commencement of the city's new town at Wythenshawe in 1929 and the opening in 1938 of Manchester airport at Ringway.

In World War II the oldest part of the city — that around the original market place — together uith the warehouse quarter near Piccadilly, the assize courts, the royal exchange and the Free Trade hall, were bombed in air raids nhich damaged 30,000 houses and killed more than 600 citizens, but by 1954 few signs remained in Manchester of the scars of war.

Until the Reformation Manchester lay in the diocese of Lichfield, but in 1541 Henry VIII founded the diocese of Chester which included the whole of Lancashire. Owing to the increase in population caused by the Industrial Revolution. a new see of Manchester was formed in 1847. This diocese covered the greater part of Lancashire and the collegiate church became the cathedral. The northerly part was transferred in 1926 to the new diocese of Blackburn. Hulme and Middleton are bishoprics suffragan.

From 1921–29 William Temple (*q* v.), who was translated to York and later to Canterbury, was bishop of Manchester.

Architectural Features. — Of mediaeval Manchester, few traces remain. Chetham's hospital and library occupy stone-built mediaeval buildings which were the ancestral home of the Grelle (Gresley, Grelley) and de la Warr (Warre) families, and were presented to the church of Manchester when it became collegiate in 1421; they were purchased by the Chetham trustees in 1653.

Manchester's cathedral is not externally imposing, but its history as parish church, college of priests and cathedral is long and interesting. An important church is thought to have stood here in the 10th century, and Domesday Book records that "the church of St. Mary and the church of St. Michael hold in Mameceaster one ploughland, free from all burdens save Danegeld." There are no relics of Norman work, but there is evidence of a large Early English church. In 1421, chiefly through the efforts of Thomas de la Warr, who was rector and lord of the manor, a royal licence and charter was obtained. making the church collegiate, with a warden, eight fellows, four clerks and six singing boys, and endowing it with extensive lands. U'arden James Stanley, afterward bishop of Ely, built the present choir in 1485. During the 15th and 16th centuries nine chapels were built. During air raids of Dec. 1940 one corner of the cathedral. containing the Regimental chapel, Ely chapel, Lady chapel and Jesus chapel, was totally destroyed and serious damage was done to the roof, fabric and organ. Repairs were complete with the exception of the Lady chapel by the end of 1954. The cathedral is the widest in Great Britain.

The Wellington inn in the market place, the Rovers Return in Withy grove and Wythenshawe hall at the southern edge of the city are the only remaining half-timbered buildings. Of the Georgian period, though only St. John street and Ardwick green retain their period character, there are a number of notable buildings: Heaton hall, in Heaton park, is a splendid example of the work of James Wyatt and is furnished in the character of the time. Platt hall. Rusholme, was the home of the Carrill-Worsley family. St. Thomas' Church, Ardwick, and the Church of the Holy Family are fine Georgian; St. Ann's church is thought to be the design of Sir Christopher Wren or a pupil. The City Art gallery and the adjoining Manchester Athenaeum building are to the design of Sir Charles Barry, and the Portico library, the Friends' Meeting house, the District bank and the Bank of England also belong to Georgian days. On the whole, however, Manchester is a Victorian and modern city: visitors from the United States comment that it has much of the character of the larger American towns. Notable Victorian buildings include the town hall, in ornate neo-Gothic style built in 1877 to the design of Alfred Waterhouse. In the fine great hall are frescoes by Ford Madox Brown of incidents in the history of, or connected with, Manchester. The university main buildings are by the same architect. The John Rylands library, designed by Basil Champneys, is in severe Gothic revival style. The Manchester Royal ex:hange, built in 1874 and extended in 1914–21, is in Italianate classical style; the floor of the great hall accommodates more than 1,000 members at "high 'Change." It was severely damaged in U'orld War II but has since been rebuilt internally and was reopened in 1953.

Of Manchester's 20th-century buildings, among the finest are the town hall extension and Central Library; the latter, in Early English Renaissance style, was opened in 1934. The Midland bank building. to the design of Sir Edwin Lutyens in a severe modern adaptation of the classical style, stands at the upper end of King street and with the adjoining Ship Canal house forms a fitting climax to a street described as "worthy of Stockholm in its architectural excellence and variety." The modern concert hall, rebuilt in 1951 within the walls of the bombed Free Trade hall of 1856, was designed by Leonard C. Howitt in a style to harmonize with the classical exterior; the acoustics are particularly satisfactory.

Administration.— In 1301 the lord of the manor, Baron Thomas, Lord Grelle, yielded to the pressure of the burgesses a charter appointing town's officers, making rules for the management of the town and defining the functions of the courts. Even so, the courts remained under the thumb of the Grelle family and it was not until the late 18th century that centrally appointed town's commissioners took over the local government of the place. They failed to govern the town satisfactorily and when the Municipal Corporations act of 1835 offered opportunity, a movement led by Richard Cobden and other notable reformers secured the incorporation of Manchester as a municipal borough.

The city council is no composed of 38 aldermen and 114 councillors with jurisdiction over 43 sq.mi. and more than 700,000 people. The municipal markets at Smithfield and elsewhere distribute foodstuffs throughout the northwest of Britain. The southerly suburb of Wythenshawe, transferred from Cheshire to Manchester in 1930, was planned as a "new town" whose population would total nearly 100,000 when complete, with its own industrial areas and civic centre; as opportunity afforded, the central areas would be rebuilt to modern ideas of planning. The city's parks have an acreage of 2,290 in which are included Heaton park of 638 ac. and Wythenshawe park of 251 ac. Manchester was the first city to put into effective operation a smokeless zone, 412 ac. in 1955. As capital city of northwest England, Manchester houses the regional offices of 16 government ministries and the local offices of 41 other government departments; there is a court of assize and a district registry of the high court of justice, and seven other courts of law. Twenty countries have consular representation in Manchester.

With the exception of the parliament of 1654, Manchester had no representation until the Reform bill of 1832 when it sent two representatives. In 1868 this was increased to three. In 1885 the city was divided into six divisions and in 1918 into ten divisions, each returning one member. By the Representation of the People act, 1948, the number was reduced to nine: Blackley. Clayton, Gorton, Ardwick, Withington, Moss Side, Exchange, Cheetham and Wythenshawe. In 1955 Openshaw replaced Clayton.

Cultural **Life.**—Manchester is famous for its many private, public and specialized libraries. The municipal libraries, with 32 branches, have as their focus the building in St. Peter's square opened in 1934. This central building is the home of a reference library which includes the Greenwood library for librarians, a commercial library and a technical library to serve the industrial and commercial interests of the region, a lending library, and the music library presented to the city by Henry Watson in 1902. The music library, which includes the Chapman collection of musical instruments, contains a comprehensive selection of rare and early music. The total number of volumes in the municipal libraries is more than 1,080,000.

The John Rylands library in Deansgate was built by Mrs. Rylands in memory of her husband, a Manchester merchant. Opened to readers on Jan. 1, 1900, the library is a place of pilgrimage for scholars and bibliophiles the world over. Its basis is the Althorp library collected by the 2nd Earl Spencer, and the earl of Crawford collection of manuscripts, together with incunabula, bibles from the Gutenberg Bible onward, works of the 16th-century scholar-printers and the de luxe printers of the 17th and 18th centuries and of modern times. It also contains historical' pamphlets of the 17th and 18th centuries; records on clay, bark, bamboo, papyrus, parchment and other materials in 50 languages from the 3rd millenium B.C. onward; legal documents and family muniments from the 11th to the 20th centuries; mediaeval jewelled bindings; and extensive collections of historical, political and literary papers including 3,000 letters of the Johnsonian circle and of Charles Dickens, John Ruskin and other well-known figures.

The University of Manchester has its own library with a special one for the education of the deaf. Chetham's library, at Chetham's hospital. Fennel1 street, founded in 1653 under the will of Humphrey Chetham, a Manchester merchant, was the first free public library in England, if not in Europe, and is substantially in its original setting. At first the books were chained and the stools used by readers in those days are still preserved. Its great strength lies in the collections of printed books of the 16th, 17th and 18th centuries, and in both old and modern books on local history and related subjects. The Portico library in Mosley street was opened in 1806; the first secretary was Peter Mark Roget. the author of the *Thesaurus of English Words and Phrases.* Among the members down the years were John Dalton the physicist, and the Rev. William Gaskell, whose wife wrote *Cranford* and other novels of Victorian life. The library contains'an unusual collection of rare historical treatises, ancient medical tracts and curiosities of many kinds.

The City Art gallery, formerly the Royal Manchester institution, was opened to the public in 1829 and presented to the corporation in 1882, together with the nucleus of the present art collection. Subsequent purchases have been supplemented by numerous gifts and bequests, notably that of contemporary works presented by the late Charles L. Rutherston in 1925 for use as a lending library from which pictures and sculpture could be borrowed by schools, colleges of art and galleries in the north of England. There are a number of branch galleries. The gallery of English costume at Platt hall, opened in 1947, is the first institution in Britain to be solely concerned with that art and is based on the fine collection of Englishwomen's costume formed by C. Willett Cunnington. Heaton hall contains a display of Georgian painting, furniture, pottery, silver, porcelain and glass, as well as a fine Georgian two-manual organ. At Queens Park gallery a display of pictures, maps, models and other objects illustrates the past history of Manchester. The Manchester Whitworth institute, now the Whitworth Art gallery, Rusholme, was founded in Oct. 1889 under the will of Sir Joseph Whitworth, the industrial magnate, inventor and standardizer of screw-thread measurements. It contains early textiles and embroideries, and a collection of English water colour drawings illustrating the history of the art of water colour.

Upon the choral singing and brass bands of south Lancashire, which amount almost to a folk tradition, was superimposed, in the middle of the 19th century, a foreign musical culture arising from the immigration of German and central European merchants. From this period survives the Hallé Concerts society, formed in 1898 to keep in being the orchestra inaugurated in 1858 by Sir Charles Hallé. The Hallé orchestra, under its conductor Sir John Barbirolli, has become an international orchestra. The Tuesday Mid-Day Concerts society has given weekly concerts since 1916 at which many artists, later to become world-famous, have been introduced to the public. The Manchester Royal College of Music is the only body outside London whose diplomas are recognized as qualifying the holder for a professional career in music.

There is a wealth of private bodies for the furtherance of literature, art and kindred subjects, notable among which are the Ancient Monuments society, the Chetham (Printing) society, the Classical association, the Academy of Fine Arts and the Literary and Philosophical society (which has a long and notable history and among whose past members mere John Dalton who died in Manchester and Thomas De Quincey who was born there).

Manchester has two theatres, two variety palaces, two resident repertory companies, the first of which was instituted in 1907 by Miss Annie Horniman, and a municipal "little theatre" at the central library. At the racecourse at Castle Irwell the principal meeting is the November handicap. The Manchester Athletic club at Fallowfield promotes athletic events of every kind: there are two first-division Association football clubs and one Rugby league football club, and at the ground of the Lancashire County Cricket club, Old Trafford, a test match is played against overseas cricket teams visiting Britain. At Belle Vue, West Gorton, is a large zoological gardens and amusement park.

Education and Religion. — The oldest educational institution in Manchester is the grammar school, founded in 1515 by Hugh Oldham, bishop of Exeter. Moved to new buildings at Rusholme in 1931, it now accommodates more than 1,200 boys. Another ancient educational foundation is that of Humphrey Chetham whose Bluecoat school, founded in 1653, is housed in the building formerly occupied by the college of clergy. The boys, who number about 100, dress in a 17th-century style on ceremonial occasions. The educational charity of William Hulme (1631–91) is administered under a scheme drawn up in 1881 and supports a grammar school. The College of Technology was founded as a mechanics' institute in 1824; the College of Art has been redesignated the Regional College of Art. Schools for the deaf and dumb are situated at Old Trafford next to the blind asylum, to which Thomas Henshaw left a bequest of £20,000. There is also an adult deaf and dumb institution and a branch of the National Library for the Blind.

The Victoria University of Manchester has developed from the college founded by John Owens, who in 1846 bequeathed nearly £100,000 to trustees for an institution in which should be taught "such branches of learning and science as are usually taught in the English universities." It was opened in 1851 in a former residence of Richard Cobden (now the Manchester county court) in Quay street, but such was the expansion of the college that a new building was erected in Oxford road and opened in 1873. In 1880 a university charter was granted and the Owens college was constituted a college of the university. In 1884 University college, Liverpool, was admitted and in 1887 the Yorkshire college, Leeds. The federal institute thus created lasted until 1903, when a separate university was established in Liverpool. In 1904, when the Yorkshire college was raised to university rank, the Owens college was incorporated with the Victoria University of Manchester by act of parliament. Though the Victoria University in its curriculum tends to serve the scientific, industrial and commercial interests of the area of which Manchester is the focal point, this statement is true quantitatively only; qualitatively, Manchester is as strong as ever in the humanities. The chairs instituted since 1945, which include psychiatry, astronomy, social anthropology, Arabic and town and country planning, indicate the vitality of the university. There are in Manchester a number of denominational colleges and many of the students preparing for the ministry receive their arts training at the university.

Manchester is a notable centre of research. The Shirley institute at Didsbury deals with the problems of the cotton industry, the Cotton Board Colour, Style and Design centre in York street co-ordinates the many facets of the design of fabric patterns and of the styling of cotton materials into women's wear and household materials; the university and the College of Technology join in industrial research with the chamber of commerce and the Lancashire and Merseyside Industrial Development association, a body representing local government and trade interests in south Lancashire. The United Manchester hospitals, a group separate from the national scheme and centred round the Manchester Royal infirmary, join with the university in medical research; at the Christie cancer hospital and Holt radium institute, Didsbury, is the largest centre of cancer research in the British Commonwealth; a research fellowship in poliomyelitis was set up by the university in 1954. At Jodrell Bank, Cheshire, the department of astrophysics of Manchester university has established a pioneer radio-astronomy observatory and in 1954 it was building the world's biggest radio-telescope, about 260 ft. across and on a movable track.

Manchester is the seat of an Anglican bishopric: the Roman Catholic community is large, but their cathedral is in the neighbouring city of Salford and the principal Roman Catholic church is the Holy Name church. The city has long been a stronghold of nonconformity, and the Baptist, Christian Science, Congregationalist, Jewish, Methodist, Presbyterian, Unitarian and Free Christian congregations are considerable.

Industry, Commerce and Transport. — Manchester's importance arises primarily from the textile industry. In the 12th century locally produced wool was made up into cloth and garments until the introduction of cotton as a wool substitute, when the wool industry gradually moved into Yorkshire. The spinning, weaving, bleaching, dyeing, printing and finishing of the cloths is now carried out in the towns of south Lancashire, after which it comes to Manchester for warehousing, packing and shipping.

Manchester is, therefore, not only the office and warehouse of Lancashire's textile industry, but also provides banking, insurance, marketing and shipping facilities for the whole of south Lancashire's industry. On its own account it has extensive businesses of heavy and light engineering, factories for clothes, chemicals and dyestuffs, oil refining and food processing, which now make it less vulnerable to fluctuations in the prosperity of the cotton trade.

The total population within a 10-mile radius of Manchester centre was 2,220,944, and within 25 mi. 4,614,500, in 1951.

The development of local industry was paralleled by the establishment of a network of road, rail and canal transport to bring in the raw materials and to take away the finished products. The first railway, the Manchester-Liverpool line of 1830 (of which the Liverpool road station still remains as the oldest railway station in the world), was followed by lines to Birmingham, London, Yorkshire and the north; Manchester now has four major main-line stations. The canal system began in 1761 with the Bridgewater canal, designed by James Brindley, and was followed in 1767 by a second length dug from Stretford to Runcorn. A third section joined the canal with the Leeds-Liverpool canal early in the 19th century. Since the opening of the Manchester Ship canal (*q.v.*) in 1894, the barge canals have fallen into disuse, but the access to Manchester, via the Ship canal, of ocean-going vessels of up to 15,000 tons dead weight has made the inland town of Manchester the third port of the United Kingdom, and laid the foundation of the region's continued prosperity.

The port of Manchester should be regarded as an elongated harbour, including as it does the whole of the 36-mile Manchester Ship canal from the entrance locks at Eastham on the Mersey estuary to the terminal docks in Manchester. It is now the nearest port (54 mi. from the open sea) for an area containing the main mass of British industry and extending as far as Birmingham to the south, and Wakefield in Yorkshire to the east. In that first year of 1894, the cargo entering the port amounted to 925,000 tons; in 1954 it totalled nearly 16,500,000 tons and, with the other Merseyside port of Liverpool, handled one-third of the imports and exports of Great Britain. With the coming of the oil industries to Stanlow early in the 20th century, Manchester has become Britain's second oil port. In 1896, Trafford park, a country estate adjoining the Manchester docks, was purchased to become the first and greatest planned industrial estate in Britain.

The first municipal airport in the world was established at Wythenshawe in Manchester in 1929. The present Manchester airport at Ringway dealt with 238,102 terminal passengers and more than 14,000,000 lb. of freight in 1954. It became a transatlantic airport in 1953. By the end of 1954 Manchester airport had five direct transatlantic services to North America.

MANCHESTER, largest city in New Hampshire, U.S., and one of the seats of Hillsboro county, is located in the centre of the state at Amoskeag falls on the Merrimack river, midway between Nashua and Concord, and 54 mi. N. of Boston. The Amoskeag falls, originally Namoskeag, Indian for "place of much fish," drop from a ledge 85 ft. high across the Merrimack river providing water power for industrial developments.

The first white settlers (Scotch-Irish) came in 1722–23. Through its early years the settlement was known for its fisheries. First called Old Harry'stown, it became Tyngstown after 1735 when it mas granted to Capt. William Tyng's men by the Massachusetts .Bay colony. In 1751 the settlement was incorporated as Derryfield. It was apparently renamed Manchester in 1810 at the suggestion of Samuel Blodget, who had seen the barge canals at Manchester, Eng., and who after 16 years of effort and aided by lotteries planned and constructed (1794–1807) the first canal around the falls, which together with the Middlesex canal in Massachusetts made navigation possible all the way to Boston.

It was chartered as a city in 1846. The Scotch-Irish community of potato and flax-raising farms emerged into a rapidly growing metropolis with riverside factories whose principal industry, the Amoskeag Manufacturing company with 18 mi. of water rights and numerous mills, employed 15.000 persons and reached a peak production of 360 mi. of cotton cloth a day, a prosperity augmented by the manufacture of shoes, cigars, locomotives and fire engines.

The downfall of Manchester's textile industry in 1935 caused by shrinking markets, foreign competition and the advent of silk and rayon, together with the disastrous floods of 1936 and the hurricane of 1938 awakened the city to the need for rehabilitation. In 20 years as a result of energetic action by civic leaders who bought the Amoskeag mills and leased many of them to small business enterprises, metropolitan Manchester was planned and rebuilt, and became an industrial and shopping centre for more than 106,000, with about 25% of the state's population residing within a radius of 20 mi. By the early 1960s Manchester had more than 200 industrial establishments manufacturing textiles, leather goods, rubber, automobile accessories, electrical instruments, confectionery, beverages and dairy products.

The city has 479 ac. of public parks, including Stark park, the burial place of Gen. John Stark (*q.v.*), and within its limits is Massabesic lake, the source of its water supply. It is the home of the Manchester Institute of Arts and Sciences, the State Industrial school, Currier Gallery of Arts, Manchester Historic association, St. Anselm's college (Roman Catholic; 1889) and the John Stark Homestead.

The Manchester city population, mainly of English, Irish, Scotch, French-Canadian, German, Greek and Polish ancestry, was 88,282 in 1960; the standard metropolitan statistical area which includes Goffstown had a population of 95,512. (E. M. Hu.)

MANCHESTER SHIP CANAL, an important artificial waterway affording passage for ocean-going vessels between the Mersey estuary (opening into the Irish sea) and the inland city of Manchester, Eng.

By the second half of the 19th century it had become essential that Manchester should be made into a port. This situation arose from the development of the city's cotton industry, from the high cost of carriage on existing routes to the coast and from the ruinous dock dues at Liverpool. The promoters of the ship canal, led by Daniel Adamson, had to meet stiff opposition from the barge-navigation proprietors, the railway, the Liverpool dock board and other hostile interests; and it was only after two bills had been thrown out (1883, 1884) that the project received parliamentary assent in 1885. The canal was begun on Nov. 11. 1887, with Edward Leader Williams (later knighted) as engineer in charge. Despite financial difficulties, floods and freeze-ups, the canal was opened to traffic on Jan. 1, 1894. Its completion was encouraged by immense popular interest, and 90% of the original shareholders were middle- and working-class persons. Queen Victoria formally inaugurated the canal on May 21, 1894. One of the most striking features of Williams' design was his method of getting the old Bridgewater canal across the ship canal at Barton, by the first navigable swing aqueduct in the country.

The canal is $35\frac{1}{2}$ mi. long. It begins on the south bank of the Mersey estuary 25 mi. from the sea at Eastham, where locks keep the canal at mean tidal high-water level. Thence it runs in a southward curve near the estuary waters to a point east of Runcorn ($13\frac{3}{4}$ mi.); thence inland; straight and almost due eastward, at the same water level to Latchford ($8\frac{1}{4}$ mi.), where locks stop all tidal action; thence, fed by the fresh water of the hlersey and Irwell, into Manchester ($14\frac{1}{2}$ mi.). The minimum depth is 28 ft.. the minimum bottom width 120 ft. except (in 1955) for a $\frac{3}{4}$-mi. section east of Latchford (90 ft.). There are extensive docks, dry docks, uharfs and warehouses at Manchester; and other important installations owned or operated by the Manchester Ship Canal company are the Stanlow oil docks, Ellesmere Port and Queen Elizabeth II dock at Eastham (opened in Jan. 1954), connected to the Stanlow refinery by a 6-mi. pipeline.

The ship canal company bought out the Bridgewater Navigation company before the ship canal was begun, and now operates the Bridgeaater canal (Manchester-Stretford-Runcorn and Stretford-Leigh; 4 ft. 3 in. minimum draft) through a separate department.

MANCHOUKUO, a former state, created as nominally independent in 1932 by the Japanese out of old Manchuria and Jehol. Dissolved after World War II and subsequently divided by the Peking government into the provinces of Heilungkiang, Kirin, Liaoning and Jehol and the Inner Mongolian Autonomous region. In 1955, Jehol was abolished and absorbed into Inner Mongolia, Liaoning and Hopeh.

See MANCHURIA and articles on the political divisions.

MANCHU LANGUAGE. Manchu belongs to the southern group of the Tungusic languages (*see* URAL-ALTAIC LANGUAGES). Tungusic peoples probably inhabited the present Manchuria by the 3rd century B.C. The predecessors of the Manchus were the Nü-chên (Džürčen, Ju-Čen), who usurped the empire of the Liao dynasty in 1115 and ruled as the Chin dynasty until 1234, being overthrown in turn by the Mongols. The real founder of Manchu power was Nurhachi, who proclaimed himself emperor in 1616 and established his capital at Mukden in 1625. Under his reign the Manchus adopted for their own use the Mongolian alphabet which they inherited from the Uighurs. In the course of time changes were made in order to adapt this writing to the Manchu language, and in its final form it became far more elaborate and serviceable than its Mongolian prototype. Books had been printed in Manchu by 1647. The two emperors K'ang Hsi and Ch'ien Lung did most to establish and stereotype this somewhat artificial language by causing translations to be made of Chinese and Mongolian works and by the publication of numerous polyglot dictionaries. All officials had to pass an examination in Manchu. All imperial decrees and most official documents were issued in this language in addition to Chinese.

With the abdication of the young emperor P'u Yi and the proclamation of the republic in 1912, Manchu may be said to have disappeared from China proper. It is. however, still spoken in parts of northern China, Manchuria and elsewhere. Regarded as a dead language, Manchu has received a considerable amount of attention from European scholars because the literal translations made into that language from the Chinese classics have simplified the interpretation of the latter.

The vocalic harmony is not so strictly observed in Manchu as in Mongolian. and in the case of grammatical suffixes there are in some instances no alternative hard or soft forms. The suffixes are as follows: accusative *be;* genitive instrumental *i* or *ni;* dative locative *de;* ablative ti. The Manchu verb, like the Chinese, does not distinguish either person or number, the tenses are imperfectly expressed and general notions are conveyed by adverbial and participial forms. Manchu has no relative pronoun and expresses a relative preposition as any other subordinate clause by means of participles.

Manchu, like the other Altaic languages, adds suffixes to the verbal theme to form derived verbs or gerunds expressing some extended meaning; thus the syllable *bu* added to *ara* ("to write") gives *arabu* ("to cause to write") and the syllable *na* added to *wa* ("to kill") gives *wana* ("to go to kill"), etc. A peculiarity of Manchu is the indication of masculine and feminine, or strong and weak, by the alternation of the vowels *a/e:* thus, *ama* ("father") and *eme* ("mother"). Even foreign words undergo this change: the Turkish *arsalan* ("lion") is modified into *erselen* ("lioness") Sanskrit *garudai* ("male phoenix") becomes *gerzcdei* for the female phoenix; *ganggan* ("strong") becomes *genggen* ("weak") and *wasime* ("to descend") becomes *wesime* ("to climb").

MANCHURIA, the western name for northwestern China (Tungpei). This term applies to the provinces of Liaoning (*q.v.*), Kirin, and Heilungkiang (*q.v.*) including the eastern section of Jehol (*q.v.*), which was abolished as a province in 1956 and parts of the reorganized Inner Mongolian Autonomous Region. In the 1960s this area had a population of more than 50,000,000, about 8% of the national total.

On the north and the east Manchuria borders on the Soviet Union (along the Amur and Ussuri rivers) and Korea (along the Tumen and Yalu rivers) ; on the south it ends in the Po Hai and the Yellow sea; on the southnest and the west it is bounded by Hopeh province and the Inner Mongolian Autonomous region.

Manchuria, with an area of more than 300,000 sq.mi., represents the most important single geographical region of China today and is the most advanced industrially, producing about half of the country's steel. It has rich potential in hydraulic power, forestry and mineral resources. Manchuria is also one of the ranking grain-surplus areas. It has been since the 19th century one of the key geopolitical areas in the world, essential to the safeguard of northern China where the capital Peking is located.

GEOGRAPHY

Geographical Regions. — The entire area of Manchuria may be divided into four subregions : the Manchurian plain, the southern Liaoning hills, the Ch'ang-pai mountains and the Khingan mountains.

Manchurian (Sungari-Liao) Plain. — This is a vast, flat basin formed mainly by erosion and alluvial deposit by the rivers. It is bounded by the east Manchurian uplands in the east, the Lesser Khingan range in the north. the Greater Khingan range (now largely in Inner Mongolia) in the west, and ends in the Liaotung peninsula in the south. Its average elevation ranges between 150 and 600 ft., with the Ch'ang-ch'un area in the central part higher than the rest (750 to 1,000 ft.). The eastern section of the plain is the meeting ground of the rivers Sungari, Ussuri and Hei-lung Chiang (see AMUR). The Sungari follows a northwesterly course to meet the Nonni river, then turns sharply to the northeast. After being joined by the Mutan Chiang, it flows northward to meet the Hei-lung Chiang. In the southern sector of the plain the Liao Ho flows east and then southward into the Gulf of Liaotung. This fertile plain region is a major granary of China.

Southern *Liaoning* Hills. — These may be divided into two general regions: the hills in the Liaotung peninsula, and those in southwest Liaoning province. Most of the Liaotung peninsula is characterized by eroded mountains which take the form of two hilly areas, 600 to 1,500 ft. above sea level. Along the seacoast and rivers are narrow stretches of plains. Dairen and Port Arthur (*qq.v.*) are located at the tip of the peninsula. Coal. iron, magnesium and oil shale are among the major mineral resources of this region.

Ch'ang-pai ("Long *White*") *Mountains.*—Also called the east Manchurian uplands, these mountains extend in a series of ranges north of the Liaotung peninsula and south of the Sungari plain. Elevations are generally between 1,500 and 3,000 ft. The culminating volcanic peak Pai-t'ou Shan ("white head") of the Ch'ang-pai Shan rises to 9,003 ft., the highest in the northeast. There, also, is the famous crater lake, T'ien Ch'ih ("heavenly pond"). Another lake, Ching-po Hu, was formed when the valley on the upper Mutan Chiang was blocked by lava. The spectacular waterfall Tiaoshuilou cascades from the Ching-po Hu. The Yalu and Tumen rivers border Korea and the Sungari. This area has vast timber reserves and hydroelectric potential. There are rich mineral deposits, notably of coal and oil shale at Fu-sung.

Khingan Mountains. — These mountains consist of three ranges : Greater Khingan, Lesser Khingan and Ilkhuri (I-li-hu-li Shan). The Greater Khingan are almost entirely within the Inner Mongolian Autonomous region. The Ilkhuri extend to the north and the Lesser Khingan to the east; they form the watershed between the Hei-lung Chiang and Sungari systems. See also KHINGAN MOUNTAINS.

Climate. — Climatically Manchuria, lying between lat. 40° and 50° N., reflects its northerly location on the eastern margins of the Eurasian continent with short, hot summers and long, cold winters. Average January temperature is 21° F.; in the Khingan mountains, −14° F. Such low winter temperatures are not found elsewhere in the world in these latitudes. Consequently, even in south Manchuria the rivers are frozen for about six months. Only the harbours at Dairen, Port Arthur and Hu-lu-tao remain ice-free. Summer months last about three months in the south and are practically nonexistent in the extreme north. As a result the growing period for plants is confined generally to five or six months a year, and the one annual crop is sown in late spring or early summer and harvested in autumn.

Precipitation. — Annual precipitation is very unevenly distributed, ranging from 40 in. in the southeast to 15 in. in the northwest. Precipitation is heaviest in the mountain areas; in the plains the rainfall is relatively light but most of it occurs during the growing seasons. Half of the annual rainfall occurs in the months of July and August. However, these natural handicaps to farmers have been partially counteracted by the extensive irrigation projects constructed by the Peking government.

Vegetation. — The natural vegetation cover of most of Manchuria is grassland or mixed grassland and forest, although variation in climate and terrain results in marked regional differences in soil and vegetation. In the Ch'ang-pai and Khingan mountain areas the soil is generally turfy and podsolic, conducive to forest growth. Brown forest soil prevails only in the southeastern district of the Ch'ang-pai mountains and in low slopes and gullies. The forests of Manchuria. mostly conifers, constitute about 30% of total timber reserves of China. Korean pine is the chief commercial tree and is found, together with spruce, larch, fir and other evergreens, at higher elevations. Hardwood forests of deciduous species — oak, elm. poplar and birch — occupy the lower elevations. Exploitation over a long period of time resulted in the decimation of the most accessible forests, leaving large stands of virgin timber only in remote areas. In the 1950s a huge afforestation project was initiated. The projected forest belt measures about 620 mi. from north to south — from the eastern foot of the Greater Khingan mountains to the southern part of Liaoning. Its widest point from east to west is 186 mi. In the northeast region of Manchuria marshes and ill-drained meadowlands follow the course of the lower Sungari. The southern section of the plain consists chiefly of dark brown soil, good for farming. In western Manchuria lies an open steppe which blends into the rolling steppes of Mongolia. Soils of the western plain range from dark chestnut-coloured to lighter saline varieties characteristic of semiarid and desert regions. Soils in the northern and higher eastern uplands are podsolic, formed under forest vegetation. (KN. C.)

POPULATION AND SETTLEMENT

Manchuria ceased long ago to be the land of the Manchus (*q.v.*). They were largely absorbed into the now overwhelmingly Chinese population who speak a Northern (Peking) Mandarin dialect. Ethnic compositions of other minorities represented are Korean, Japanese, Russian and Mongol (including Tungusic). Population in the early 1960s totaled more than 50,000,000.

There were Chinese in Manchuria from ancient times, possibly from as early as 1000 B.C., but until well into the 19th century their area of occupance was localized almost entirely in a triangular region in southern Manchuria, centring about the alluvial basin of the lower Liao Ho and the uplands of the Kwantung peninsula. Immigration apparently mas primarily by sea, and communication with China was by means of coastal shipping services with what later became Shantung and Hopeh provinces. This so-called Chinese Pale was bounded on three sides by a wall known as the

Willow Palisade. An extension of this frontier, the so-called Outer Willow Palisade, ran northeastward from a point north of Mukden to the Sungari river north of Ch'ang-ch'un. The southeastern portion of the Willow Palisade formed a frontier between Chinese and Koreans; the Outer Willow Palisade separated what was predominantly Manchu territory in the east from the Mongol-occupied steppe lands of west-central and western Manchuria. Within the Pale were duplicated as nearly as possible the patterns of occupance that characterized the north China plain; *i.e.,* a relatively dense agricultural population living in compact villages and oriented around rectangular walled cities.

Much of Manchuria was held until modern times by non-Chinese, Tungusic peoples. *(See* TUNGUSES.) On at least three occasions these peoples gained control of southern Manchuria and moved into north China as barbarian conquerors, recruiting manpower from their "reservoir" outside the Willow Palisade and from the Chinese whom they had conquered within the Pale. According to S. M. Shirokogoroff, Tunguses originally dwelt in northeastern China and retreated into Manchuria in the 2nd millennium B.C. before the Chinese advancing from the loesslands of northwestern China. The tide of Chinese colonization then swung south into the Yangtze valley and, while northern branches of the Tunguses spread into the northern forest, the southern remained in Manchuria. Tunguses of the forest retained their old hunting, nomadic life but those of the central and southern plains in time acquired the arts of cultivation from their Chinese neighbours and, according to Chinese annals, were already dependent by the 1st millennium A.D. on the "five kinds of cereal." Although excellent horsemen as befitted dwellers on the steppe, the Tunguses of the plain—as evidenced by the Manchus—were ignorant of the art of milking and were essentially not pastoral nomads. On the other hand, the Mongols were true steppe nomads. They came to occupy most of western Manchuria after the upsurge of Mongol power which culminated in the Yüan dynasty's rule over China; they continued well into the 19th century to control the grasslands of the central lowland eastward to Ch'ang-ch'un and nearly as far as Mukden itself.

Immigration of Chinese was long forbidden; but after 1776 this prohibition was relaxed in the case of Liaoning (Feng-t'ien), the southern province, and in the third quarter of the 19th century the Manchus had to recognize colonization in Kirin. The dense agricultural population of north China was beginning to spill over in considerable numbers into vacant lands whose settlements, always sparse, had been further depleted by recruitment for the Manchu garrisons in China. By the end of the 19th century the population of Manchuria, exclusive of Jehol, was estimated at 14,000,000, of which 80% were Chinese. In comparison with what was to follow, however, this movement was no more than an infiltration and consisted mainly of males who intermixed with the Manchus and in time absorbed them. Pure Manchu groups remain only in northern Manchuria, chiefly in the Ai-hun district. These are descendants of soldier-colonists planted by the early Manchu emperors in the Hei-lung Chiang valley. The rapid economic development of south Manchuria under Japanese auspices after 1905 set in motion a mass migration, coming mainly from Hopeh and Shantung, the most densely peopled provinces of north China. This for years involved from 300,000 to 400,000 annually, but of these more than half used to return to China after the Manchurian harvest. In the 1920s the seasonal migration of labourers was accompanied by a permanent migration of families. These Chinese peasant farmers penetrated inland along the railways and settled along the Chinese Eastern as well as the South Manchuria railways. In the 1960s they constituted about 90% of the total population. The Japanese restricted Chinese immigration but in peak year 1939 a net inflow of 595,000 was recorded. At that time the Japanese, exclusive of troops, numbered 850,000, almost entirely in cities despite Japanese attempts to encourage agricultural settlement. Only 68,347 Japanese agrarian colonists mere recorded in 1940. By 1944 these totals had changed to about 1,000,000 and 220.000 respectively. Almost all Japanese were repatriated by the end of 1946, however. Mongols numbered about 2,000,000, although Japanese statistics listed only 1,000,000. Koreans numbered an estimated 2,000,000, most of them concentrated in the Chien-tao region just northwest of the Tumen river, a region in which Korean settlement—long a fact—was encouraged officially by the Japanese after 1932. Many of these Koreans became supporters of the Chinese Communists and later formed the trained core of the North Korean armies.

Liaoning (58,301 sq.mi.) is the most densely settled province, with about 47% of the region's population; Kirin (72,201 sq.mi.) has 26%; and Heilungkiang (178,996 sq.mi.), 27%. Many expanding industrial centres, such as An-shan, Dairen, Fusin (Fouhsin), Fu-sung and Pen-ch'i, are located in Liaoning province; and Heilungkiang receives a steady stream of migrant farm labour.

Urban population in Manchuria rose sharply after 1949, when the Peking government undertook an accelerated program of industrialization. In the 1950s urban dwellers comprised 30% of the population, as compared with 70% rural. Over 50% of the former was concentrated in seven cities, each with 500,000 or more. Although the region has only 74% of China's total population, it has about 17% of the national urban total. Since urbanization and industrialization are related, this percentage reflects that Manchuria was more industrialized than other regions of the country.

Illiteracy among the Manchurian population was very high in the period of Japanese domination; and in the mid-1950s it was still estimated at 78%. However, by the 1960s it was claimed that over 90% of school-age children in the three northeastern provinces were receiving primary education and that illiteracy had been basically removed among adults, except the aged. Special attention was assigned to technical education.

HISTORY

Until 1900 Manchuria was not integrated with China proper. From earliest times Manchuria, except for the lower alluvial basin of the Liao Ho, had been sparsely populated, by non-Chinese Mongoloid peoples. To the Chinese it was. historically, the easternmost part of the vast territory beyond the Great Wall of China, peopled by nomadic barbarians who left their predominantly grassland "reservoir" region from time to time to invade China itself. Manchuria was an especially important part of the great reservoir. From it the Liao (Khitan or K'itan) dynasty extended its control over the northern China plain in the 10th century. In the 12th century the Nu-chen (Chin) also extended their advance to south of the Yangtze river from Manchuria. Later the Mongols spread over the region and descended upon China in the 13th century to found the Yuan dynasty. Finally the Manchus, a Tungusic tribal group originally from eastern Manchuria, crossed the Great Wall and established the Ch'ing dynasty (1644). Between these periods Chinese control extended over much of the outlands, but for centuries most of Manchuria remained a preserve of the Manchus and their Mongol tribal allies. It was not until the latter half of the 19th century, when Chinese immigration into Manchuria began to increase rapidly, that Manchuria became "Chinese."

In the closing decades of the 19th century foreign powers began to eye the region as a fruitful field for imperialist expansion. For Russia, Manchuria was to be an eastern outpost and terminus of the Trans-Siberian railway, intended to bind the tsarist empire together Japan, nith an overfloaing population and only limited resources, had a more vital interest than Russia in Manchuria; as a relatively undeveloped but potentially productive country, Manchuria promised an exportable surplus of foodstuffs and industrial raw materials, and a field for Japanese colonization.

Russo-Japanese Conflict.—-The conflict between Russia and Japan for control of Manchuria first raged over possession of the Liaotung peninsula, which not only represents the southern gateway into Manchuria but commands the seaward approaches to Peking. The first move aas made by Japan. As the prize of victory in the Chinese-Japanese War (*q.v.*) of 1894–95, Japan demanded the cession of the Liaotung peninsula from the mouth of the Yalu to the mouth of the Liao Ho. But Russia, backed by France and Germany. forced Japan to abandon this claim. Then, by means of intrigue and a show of force, Russia acquired (1898) the lease for 25 years of the territory of Kwantung (*q.v.*) at the tip of the peninsula—a territory containing the future naval base of Port Arthur (*q.v.*) and what later became the great commercial entrepbt of Dairen (*q.v.*). Japan returned to the attack and. by the treaty of Portsmouth (1905) which registered its victory over Russia in the Russo-Japanese War (*q.v.*) of 1904–05, obtained transfer of the Kwantung lease. Meanwhile Russia had been pushing forward its scheme of railway construction. It had already built the Chinese Eastern railway (C.E.R.) across northern Manchuria to Vladivostok, and completed construction of a branch through southern Manchuria to Port Arthur. Russia also had established an ethnically Russian centre of settlement Harbin (q v) on the Sungari river banks in northern Manchuria. By the treaty of Portsmouth Japan became heir not only to the lease of Kwantung but also to the Russian-built railway from Ch'ang-ch'un to Port Arthur. In 1906 the rights pertaining to it nere vested in the semigovernmental South Manchuria Railway company (S.M.R.). Russian interests were thus pushed back into Manchuria north of Ch'ang-ch'un and into the provinces of Kirin and Heilungkiang. The properties of the C.E.R. and S M.R. were held on leases of 99 years and 80 years respectively. China had the option of purchasing the latter after 36 years. Investment in the S.M.R. was limited to Chinese and Japanese subjects, in the C E.R to Chinese and Russian; in effect the paramount interests were Japanese and Russian.

1915–1930.—Through possession of the arterial railway through southern Manchuria and of its seaward terminus in the entrepbt of Dairen, Japan held the chief key to economic penetration of southern Manchuria. The famous Twenty-one demands presented to China in 191; affirmed "the predominant position of Japan in South Manchuria and Eastern (Inner) Mongolia." During the Chinese civil nar Japan continued to exercise a controlling influence in southern Manchuria with support of its Kwantung army, organized in 1919 and destined to become Japan's most powerful military force on the Asian continent. As a result there had come to exist an unstable condominium among Japanese. Russian and Chinese interests. Only tno possible changes could take place: either Manchuria could be divided among the three powers—an unlikely prospect at best because of the spread of Chinese colonists across the Manchurian lowland—or one or more of the powers would be eliminated from the scene.

For a few years it appeared that the first power to be eliminated would be Russia. The Russian Revolution of 1917 was followed by the breakdown of orderly Russian administration in the far east. The situation was complicated by dispatch of troops to invade eastern Siberia by Great Britain, France. Japan, the United States and China. Japanese troops outnumbered the others and for a time it appeared that Japan might supplant Russia in that region. Partly to prevent this development the C.E.R. was placed under control of an inter-Allied commission with an American at its head. In 1919 after the Communists had gained control in Russia they announced their renunciation of all special privileges acquired by the tsarist government in China. By an agreement signed May 31, 1924, after negotiations with China, Soviet Russia retained a share in the administration of the C E.R.. while surrendering extraterritoriality and former Russian concessions and agreeing in principle to eventual repurchase by China of the railroad. A somewhat similar agreement regarding the C.E.R. was signed between Russia and Chang Tso-lin (*q.v.*), the ruler of Manchuria, Sept. 20, 1924. Friction followed, accentuated by anti-communist and anti-Russian reaction in China after 1927. In 1929 under Chang Hsüeh-liang, youthful successor of Chang Tso-lin, the Chinese—impelled by the rising tide of nationalism—attempted to oust the Russians from their participation in the C.E.R. The Russians struck back, and in a sharp, brief, undeclared war the status quo was restored.

Japanese Domination.— Not Russia, but China was the first of the three powers to be eliminated from Manchuria as mounting Chinese nationalism clashed with Japanese militarism. The Chinese nere attempting to restrict the Japanese in various ways. Friction developed, too, between Koreans and Chinese in Manchuria, the former being Japanese subjects, On the night of Sept. 18–19, 1931, the Japanese military forces struck, giving as the reason an allegedly Chinese bomb explosion on the South Manchuria railway near Mukden. In the following few weeks they occupied a number of strategic centres. At the time Chang Hsüeh-liang had most of his forces south of the Great Wall, and his rule in Manchuria quickly collapsed before the Japanese army. China appealed to the League of Nations. That body appointed a commission, headed by Lord Lytton, which, after investigation, issued a report generally unfavourable to the Japanese in the autumn of 1932. The League proved unable to implement its decision but its action led to Japan's withdrawal from League membership.

Manchoukuo.—In the meantime the Japanese were erecting a puppet administration. Local and provincial provisional governments were set up, mostly by resident Chinese (and, in some areas, Mongols) with Japanese "advisers." Early in 1932 a Manchuria-wide government mas organized and on Feb. 18 of that year it declared the independence of the three eastern provinces under the name of Manchoukuo ("the state of Manchu"). To provide an air of legitimacy, P'u Yi—who, with the title of Hsüan T'ung, had been the emperor of the Manchu dynasty when it abdicated its control of China in 1912 and who had since been living in retirement in Peking and Tientsin—became "chief executive." A further step was taken when, on March 1, 1934, P'u Yi formally announced his ascent to the throne of newly-named Manchoutikuo ("the empire of Manchu") under the title of K'ang Te. His residence was established at Ch'ang-ch'un, renamed Hsin-ching, or Hsinking ("the new capital"). No attempt was made by the Japanese, however, to restore the Ch'ing dynasty for all of China by linking the new state with another puppet regime of Wang Ching-wei in northern China. Nevertheless, the government of Manchoutikuo throughout its life was Japanese-controlled. The most important agency in the government was the so-called general affairs board, a kind of executive secretariat with a Japanese director-general. Practical military control was exercised by the Kwantung army. Internationally, the new country was recognized only by Japan, Germany and Italy (its Axis partners) and El Salvador. Soviet official interests were practically eliminated by the sale of the C.E.R. to the Manchoutikuo government in 1935. However, Russia's continuing concern with the region was indicated by a series of border skirmishes between Soviet troops and military units (including Japanese) of the new government, in 1937, 1938 and 1939, the last at Nomonhan (No-men-k'an).

After World War 11.—On Aug. 9, 1945, after the Soviet Union's declaration of war against Japan, Soviet and Outer Mongolian troops invaded Manchuria from the southwest, the northwest: the northeast and the east. Fighting was sharp and short. The Japanese capitulated on Aug. 14, and within two weeks thereafter Soviet troops had occupied all the chief cities. Under the Yalta agreement the U.S.S.R. was granted use (with China) and practical control of the naval base at Port Arthur; Dairen was internationalized, although the harbour master was to be a Soviet national; and the C.E.R. and S.M.R. main lines, under the name of the Chinese Ch'ang-ch'un railway, were to be placed under joint Chinese-Soviet control for a period of 30 years. These conditions were confirmed in the treaty between China and the U.S.S.R. of Aug. 14, 1945. As a result the U.S.S.R. regained essentially the same rights and privileges, other than extraterritoriality, which tsarist Russia had held in 1904. By the end of April 1946 the Soviet Union had evacuated its troops from almost all of Manchuria, but not before a large-scale removal of Manchurian industrial equipment as war booty had taken place.

Meanwhile Chinese Communist troops had begun to enter Manchuria in large numbers as "civilians" under orders from Communist leader Chu Teh. with the tacit consent of the Russians. After the evacuation of the Soviet troops Chinese Communists—aided by anti-Japanese Chinese and Korean guerrillas and later by the Mongols of Manchuria—gained control and organized politically all of northern Manchuria and much of the countryside in the south. They armed themselves with captured Japanese military equipment. again with tacit Soviet consent. Nationalist troops landed at Ch'in-huang-tao in Nov. 1945, since Dairen was closed to them by the Russians and other ports were in Chinese Communist hands; they marched north along the Peking-Mukden railway and by May 1946 had gained control of Ch'ang-ch'un, the former capital. Nationalist and Communist armies fought over central Manchuria until Mukden fell to the Communists Oct. 30, 1948; the entire region passed shortly thereafter into their hands. Manchuria thus became the first major region of China to come wholly under Communist domination, and it was largely the Manchurian troops of Gen. Lin Piao who occupied Peking atter its surrender on Jan. 22, 1949. Manchuria became one of the seven major administrative regions of China and on Xug. 27, 1949, the Northeast People's government was established at Mukden under Kao Kang, it nas the first such government to be established among the seven administrative regions. On June 21, 1954, the major administrative regions were abolished in China because of tendencies toward regional independence from Peking; Kao Kang was purged and the powers of the Northeast People's government reverted to Peking, to the reconstituted truncated provinces of Heilungkiang, Kirin and Liaoning and to Inner Mongolian Autonomous region, respectively. Russian influence remained strong in the region, although on Dec. 31, 1952, the Soviet Union transferred its rights in the Chinese Ch'ang-ch'un railway to the Chinese. On Oct. 12, 1954, the U.S.S.R. agreed to withdraw from Port Arthur and transfer installations to China without compensation by May 31, 19jj. *See* also CHINA: *History;* JAPAN: *Hzstory;* RUSSIA: *History.* (N. S. G.; KN. C.)

ADMINISTRATION

After the reorganization of Jan. 1956, when all but 10,000 sq.mi. of Jehol was taken out of the administrative jurisdiction of the northeast, Manchuria consisted administratively of the three provinces of Liaoning, Kirin and Heilungkiang. This was almost a reversion to the old division at the beginning of the 20th century when the three provinces covered a larger area. The 1956 redivision transferred some parts of Manchuria into the Inner Mongolian Autonomous Region and a small part to Hopeh province.

When the Chinese Communist forces gained control of the northeast in 1948 the entire area consisted of nine provinces: Liaoning, Antung, Kirin, Sungkiang, Liaopeh, Hokiang, Nunkiang, Hsingan and Heilungkiang. In 1949 the number of provinces was reduced to six: Liaotung, Liaohsi. Jehol, Kirin, Sungkiang and Heilungkiang. The provinces of Hsingan and Liaopeh and a large part of Nunkiang were transferred to the Inner Mongolian Autonomous region, while some other provinces were consolidated. (See MONGOLIA.) In 1954 the number was further reduced to four (Liaoning, Kirin, Heilungkiang and Jehol) without any change in the total area. In 1956 the province of Jehol (created in 1928) was abolished, with about 34,000 sq.mi. going to the Inner Mongolian Autonomous region and Hopeh, while the remaining 10,000 sq.mi. were added to Liaoning province.

Between 1949 and 1953 Manchuria was under the semi-autonomous administration of an elaborately constructed regional government (the Northeast People's government). In 1954 the northeast regional government, together with five other Chinese regional governments, was abolished. The provinces came under direct control of the state council of the Central People's government. Some municipalities also lost their autonomous status and became subordinate administrative units under various provinces.

Each of the three provinces of Manchuria and the other provinces of China is governed by a provincial government which is elected by a provincial people's congress. Congressional delegates are elected by the county people's congress, which, in turn. is elected by the *hsiang* (or administrative village) people's congress. The members of the *hsiang* people's congress are chosen directly by the voters at the villages, now the people's communes.

Liaoning (1 chairman and 10 deputy chairmen) controls 10 municipalities with jurisdiction over 37 counties and 1 banner or *ch'i* (area populated by Mongols, comparable to *hsien* or district). Kirin (1 chairman and 8 deputy chairmen) controls 6 municipalities, 6 counties. 3 special districts and 1 autonomous *chou* (Yenpien Korean Autonomous district). Heilungkiang (1 chairman and 8 deputy chairmen) controls 7 municipalities. 8 counties. 1 autonomous county and 5 special districts which have 51 counties under their jurisdiction.

ECONOMY

After 1900 Manchuria made progress in many fields of economic activity — industry, agriculture, mining, trade, transportation and population expansion.

Transportation. — The framework for Manchuria's economic development was the railway system, virtually nonexistent in 1900. (See *Hzstory* above, for development) In the early 1960s the total length of railways in Manchuria mas more than 8,000 mi., or some 40% of the nation's total. From such trunk routes as Man-chou-li to Tung-ning (Suifenho), Harbin-Dairen, Mukden to Shan-hai-kuan, Mukden-Kirin, Ssu-p'ing to Tsitsihar and T'u-men to Chia-mu-ssu a netnork of railroads fans out in all directions. During the period of Japanese domination the Southern Manchurian Railway company not only controlled transportation but also participated in all the important economic activities. Roads are also extensive but unsurfaced, except for those connecting large cities. Inland navigation is generally restricted to the Sungari and its lower tributaries. The rivers of southern Manchuria are shallow and little used above their lowest courses, except by small native boats. There are a number of fine harbours in southern Manchuria. including Dairen, Port Arthur and Hu-lu-tao. Some ports need the help of icebreakers in winter but Antung and Ying-k'ou are frozen about four months a year.

Mining. — Although the northeast became the most important industrial region of China because of an intensive effort at industrialization, the mineral resources of Manchuria are not particularly superior to those of the rest of China. As development and prospecting increased elsenhere the relative weight of mineral resources of Manchuria decreased accordingly. In the 1930s it was estimated that Manchuria had about 8% of China's coal reserves (then estimated at 265,000,000,000 tons). By the 1960s the revised estimate of China s coal deposits came to 1,000,000,000,000 tons, with most of the reserves outside Manchuria. The chief deposits of coal in Manchuria are found in a belt along the line of demarcation between the eastern highlands and the plain, particularly at Fu-sung. Most of the Manchurian coals are non-coking and bituminous but good coking coals are found at Pen-ch'i, Pel-p iao, Hao-li and Tung-pien-tao. These deposits are associated uith vast beds of oil shale containing 3% to 7% petroleum. Little liquid petroleum has been found so far but there are favourable geological formations near Hu-lun Ch'ih (Lake Dalai Nor).

Iron ore represents a major resource of Manchuria. with an estimated half of China's ore reserves and a little less than half of the nation's iron output coming from the region The major mining centres are An-shan and Miao-erh-kou south of Pen-ch'i, and Talitze (Ta-li-tzu) in the Tung-pien-tao district on the Korean border. In the first two cases the ores are mostly low-grade mag-

POWER [illegible] FU-SUNG, MANCHURIA, LARGE [illegible] ERS' HOUSES ARE IN THE FOREGROUND netites and hematites with small deposits of higher-grade ores; in the last area the ores are hematites averaging 60% iron.

Gold is found both in placers and in lode deposits. The mining is done particularly in the eastern and northern highlands, along the Hei-lung Chiang and lower Sungari rivers. Lode deposits are mined near Hua-tien and \-en-chi bordering Korea.

Other important minerals mined in Manchuria include molybdenum, copper, zinc, lead, magnesite, alumina shales, limestone, talc, clays, mica, the last four being nonmetallic.

Industry. — For generations Manchuria has been known as the "Ruhr of China." About 90% of the steel produced on the Chinese mainland during the 1930s and early 1940s came from Manchuria. In the late 1950s, out of a total annual production of about 11,000,000 tons, 2,000,000 to 5,000,000 tons were produced in Manchuria, with An-shan accounting for some 80% of the steel manufactured in the northeast. More than 40,000,000 tons of coal (against the previous peak figure of 26,000,000 tons in 1943) were mined annually in the northeast. It was claimed that the capacity of electric power in Liaoning province alone had reached 10,000,000 kw.hr. in the early 1960s.

Although no detailed information is available, many major industrial projects scheduled to be completed during the first five-year plan are probably located in Manchuria. The first automobile plant at Ch'ang-ch'un was built with Soviet assistance. China's first precision instruments factory is now in production at Harbin. The shipyards at Dairen are reported to be building 20,000-ton ocean-going vessels and Mukden has become the nation's centre of machine-tool manufacturing. Primarily because of the development in Manchuria, China can manufacture about 80% of all the machine equipment she needs. According to official statistics the value of industrial production in the northeast increased by 144% during the first five-year plan period (1953–57) and 150 big industrial projects were completed.

Agriculture. — In agriculture Manchuria has always played an important role as supplier of both food grains and commercial crops, particularly soybeans. During the Japanese domination large quantities of food grains were shipped to Korea. which had to surrender most of her rice to feed Japan. Before World War II, 60% of the value of Manchuria's exports was derived from agricultural products, consisting largely of soybeans and soybean products. By the 1960s the picture had changed drastically, with industrial goods constituting the bulk of export values.

Under the Communists the rate of progress in Manchuria's agricultural development was not as rapid as industrial gronth. Not until 1952 did food-grain production reach its pre-1949 peak figure (20,800,000 tons, including soybeans, achieved in 1943). During the first five-year plan period there was no appreciable rate of increase in agricultural production. However, in the "big leap forward" of the entire nation in 1958 Manchuria also achieved impressive advances in food-grain production (kaoliang. millet. corn [maize], rice. wheat), claiming 30,000,000 tons, exclusive of the most important crop, soybeans, which was taken out of the category of food grains in 1956. Industrial crops include fibres (cotton, flax, hemp), sugar beets, tobacco and peanuts. Livestock raising (pigs, sheep, horses, cattle, goats) is important along the western margins of the Manchurian plain.

Programs to enhance agricultural production in hlanchuria, as those in other parts of Communist China, may be grouped into four general categories. (1) Those which contribute to the expansion of crop acreage — conservation, reclamation (especially in Heilungkiang) and encouragement of multiple-cropping practices. (2) Those which aid the increase of yield per acre—irrigation, afforestation, water and soil conservation, use of better seeds, application of more fertilizers. new farm implements and agrotechnical training; the promotion of higher-yielding crops, such as corn and potatoes. and the expansion of rice cultivation also help to increase the yield per unit of land. (3) Those which help reduce crop losses and waste. including control of plant or animal pests, better storage facilities and a host of other methods of practising greater economy in the use of agricultural produce. (4) Those organizational measures, such as establishment of co-operative and collective farming, which aim to raise labour efficiency and to achieve a more rational use of resources, as well as reform of marketing systems and improvement of other socio-economic institutional factors in rural areas.

In the propagation of various forms of organized farming, such as the mutual-aid teams, the co-operatives, the collective farms and the people's communes, the northeast played a major role in all except the last stage. As Manchuria was the first area to be consolidated under the Chinese Communists after World War II, major reforms and experiments in social engineering often were first tried out there. When mutual-aid teams were introduced in areas south of the Yangtze in 1950 they had already been extensively introduced in Manchuria. The region also led in co-operative farming. By the late 1950s all farms in the northeast were practically collectivized and about 10,000,000 peasant households in Manchuria participated in the communes.

Numerous advantages have been attributed to the commune system; among them, pooling of resources (land, labour, capital, farming skill), more rational utilization of such resources, release of village women from household chores by establishment of common dining halls, sewing services and nurseries; and the ability of communes to sponsor cultural-recreational programs for members.

Although several other regions, particularly in the northwest and the southwest, are currently developing their economies at a relatively quicker pace, Manchuria, with its solid foundation and rich resources, is likely to remain the major industrial base of China for some time to come.

Trade. — Manchuria's importance in domestic and foreign trade is obvious, given its position as the major geographical link between China and the G.S.S.R., which takes about 75% of China's exports. As the most industrially advanced base of China, Manchuria supplies a variety of capital goods to many areas in China proper, while receiving certain consumers' goods in return from light industrial centres such as Shanghai. Tientsin and Wuhan.

MANCHUS. "Manchu" is the name given to a people who lived for many centuries in Manchuria and adjacent areas and who in the 17th century conquered China and ruled that country for more than 250 years. The term "Manchu" is comparatively modern, having been first used in the 16th century, but it is certain that the Manchus are the direct descendants of a people who under other names had lived in northeastern Manchuria from a time long prior to the Christian era. In the early Chinese records they are known as the Tung-i or Eastern Barbarians. In the 3rd century B.C. they were given the name of Sushen or Ilu. In the 10th century A.D. the Chinese historians speak of them as Nu-chi or Ju-chi, an attempt to transliterate the native word "Jurchen." The Jurchen managed to establish a kingdom of some extent and importance in Manchuria and in 1115 A.D. were able to secure control over northeastern China. In Chinese records the rulers of this kingdom were known as the Chin or Golden dynasty. This kingdom was annihilated by the Mongols in 1234 and the surviving Jurchen were driven back into northeastern Manchuria. In the 16th century the descendants of these Jurchen again came into prominence. but before long they dropped the name Jurchen and adopted the name Manchu. The Manchus rapidly rose to power under the leadership of a tribal leader named Nurhachi, who established military and political control over the whole of Manchuria. In 1616 he proclaimed himself emperor. Nurhachi fought several successful battles against the Chinese, but he died before he could carry out his life-long ambition of invading China. In 1644 the long-expected attack took place. Peking, the Chinese capital, soon fell, and by 1680 the Manchus had complete control over all sections of the Chinese empire. The Manchus managed to maintain a brilliant and powerful government until about 1800, after which they rapidly decayed in energy and ability. It was not, however, until 1912 that the Manchu dynasty was overthrown.

In order to understand the origin and cultural development of the Jurchen-Manchus it is important to bear in mind that Manchuria is divided into two sections: one, to the south and west, is an open, rolling and almost treeless plain, ideally suited for pasturage; the other. to the north and east, is essentially mountainous and is covered with natural forestation. In early times the south and west section was inhabited by the Tunghu tribes, the ancestors of the Mongols, who soon developed a nomadic horse culture. while the north and east section served as the breeding ground for the Ilu and their descendants, the Jurchens and Manchus. Because of the difference in terrain the Manchus never adopted the Mongol culture pattern. even after they secured control over the whole of Manchuria.

Modern research showed that Jurchen-Manchus are members of a widespread ethnic group known as the Tungus. At one time various Tungus tribes occupied most of Siberia between the Yenisei river and the Pacific ocean. Many of these tribes disappeared with the advance of Russian settlements, but others remained. Other Tungus tribes are to be found on Sakhalin Island. Basically the Manchus, like all the other Tungus peoples, are members of the Mongoloid race, but it is obvious that they have interbred widely with other peoples as there is wide variation in body type between different Manchu groups. It is almost certain that they have absorbed some of the Caucasoid races (Alpine and Proto-Nordic) which inhabited parts of Siberia in prehistoric times. From inscriptions in the two languages it is clear that the old Jurchen language and modern Manchu are practically identical. Manchu is also closely related to the other Tungus languages. There is some doubt as to the relationship of Tungus to other languages. but because of similarity of structure, most scholars place Tungus along with Mongolian, Turkish. Hungarian and Finnish in a language group known as Ural-Altaic. In any case it is certain that Tungus is in no way related to Chinese. In writing the Manchus never adopted the Chinese ideographs but employed a phonetic alphabet developed by the Jurchen on the basis of the Mongolian alphabet. The ultimate source of this alphabet is to be found in Syria.

From the Chinese records it is evident that the Ilu, the ancestors of the Manchus. were on a rather low cultural level. They, like many modern Tungus tribes in Siberia, were essentially hunters, fishers and food gatherers, though in later times they and their descendants the Jurchens and Manchus developed a rather primitive form of agriculture. Unlike the Mongols and Turks, the Jurchen-Manchus were noted breeders and eaters of swine. Swine also played an important role in their religious myths and rites. It is probable that the word "Tungus" is derived from an early Turkish word for pig. From very early times the Jurchen-Manchus were accustomed to braid their hair into a queue or "pigtail." When the Manchus conquered China they forced the Chinese to adopt this custom as a sign of loyalty to the new dynasty. Apart from this the Manchus made no attempt to impose their manners and customs upon the Chinese. They even permitted foot binding to go on among the Chinese women, though the Manchu women never adopted this custom.

After the conquest of China, the greater part of the Manchus migrated to the latter country, using their ancestral estates only as hunting lodges for occasional vacations. Eventually these estates were broken up and sold to or occupied by Chinese immigrant farmers. By 1900 even in Manchuria the Chinese enormously outnumbered the Manchus. Many Manchus in the years following 1644 settled in and around Peking, where they obtained official positions. No effort was made to destroy or even seriously to modify the traditional Chinese governmental structure. but in most cases the Manchus were given a good share of the higher administrative posts. Thus the grand council. the highest governmental organ, was usually half Chinese and half Manchu. A large number of Manchus were also incorporated in the mandarinate or administrative hierarchy scattered throughout the country. A great many Manchu males became hereditary soldiers, being incorporated in eight special "banners" or army divisions which were stationed at various strategic posts in order to maintain law and order and to prevent revolution.

Prior to their conquests of China the Manchus were distinctly backward as regards cultural development, but they were quick to learn once they had secured military and political power. Several of the early rulers of the Manchu or Ch'ing dynasty (especially the emperors K'ang Hsi and Ch'ien Lung. who between them ruled for 120 years) were not only men of high intelligence, they were also among the most able and munificent patrons of literature and art which China had ever known. Under their stimulus a Manchu literature was created. Many of these Manchu works were subsequently translated into Chinese. In like manner, many important Chinese works were translated into Manchu and published at imperial expense. The emperor K'ang Hsi gathered together from all parts of the empire the best scholars and set them to work on literary and historical research. As the result of these efforts there appeared the *K'ang Hsi* Dictionary, still the standard dictionary of the Chinese language, and the authoritative "(imperial edition" of the Chinese classics. A little later the Manchu court fostered the publication of a gigantic encyclopaedia comprising more than 1.joo volumes. The Manchu rulers were also noted patrons of ceramic art, and the types of porcelain known as K'ang Hsi and Ch'ien Lung ware are still prized museum pieces.

The Manchu emperors, in spite of their patronage of Chinese culture, made strenuous efforts to prevent the Manchus from being absorbed by the Chinese. The Manchus were urged to retain their own language and to give their children a Manchu education. Attempts were made to prevent the intermarriage of Manchus and Chinese, so as to keep the Manchu strain racially pure. Too much social intercourse between the two peoples was frowned upon. All these efforts proved fruitless. During the 19th century, as the dynasty decayed, the efforts to preserve cultural and racial segregation gradually broke down. The Manchus began to adopt Chinese customs, to speak the Chinese language and to interbreed with the Chinese. When the dynasty was overthrown, and it became politically inexpedient to be known as a Manchu, the Manchus quietly disappeared into the main mass of the Chinese populace. (W. M. McG.)

MANCINI, PASQUALE STANISLAO (1817–1888), Italian jurist and statesman, was born at Castel Baronia. Avellino province. March 17, 1817. In 1848 he helped to persuade Ferdinand II of Naples to participate in the war against Austria. Upon the triumph of the reactionary party he undertook the defense of the liberal political prisoners. Threatened with imprisonment in turn, he fled to Piedmont, where he obtained a professorship and became preceptor of the crown prince Humbert. After the fall of the Bourbons, he went to Naples as administrator of justice. in which capacity he suppressed the religious orders, revoked the concordat, proclaimed the right of the state to church property and unified civil and commercial jurisprudence. In 1862 he became minister of public instruction in the Rattazzi cabinet, and induced the chamber to abolish capital punishment. For the next 14 years he devoted himself chiefly to international law and arbitration. but in 1876, upon the advent of the left to power, became minister of justice in the Depretis cabinet. Mancini's liberalism found expression in the extension of press freedom, the repeal of imprisonment for debt and the abolition of ecclesiastical tithes. During the conclave of 1878 he succeeded, by negotiations with Cardinal Pecci (afterward Leo XIII), in inducing the Sacred College to remain in Rome, and, after the election of the new pope, arranged for his temporary absence from the Vatican for the purpose of settling private business. Resigning office in March 1878, he resumed the practice of law. and secured the annulment of Garibaldi's marriage. The fall of Cairoli led to Mancini's appointment (1881) to the ministry of foreign affairs. An indiscreet announcement of the limitations of the Triple Alliance contributed to his fall in June 1885; he was succeeded by Count di Robilant. He died in Rome, Dec. 26, 1888.

MANCUNIUM, the name often (though probably incorrectly) given as the Romano-British name of Manchester. Here, close to the Medlock, in the district still called Castlefield near Knott Mill, stood in Roman days a fort of 5 acres garrisoned by a cohort of Roman auxiliary soldiers. The site is now obscured by houses, railways and the Rochdale canal, but vestiges of Roman ramparts can still be seen, and other remains were found in 1907 and previous years. Traces of Romano-British inhabitation have been noted elsewhere in Manchester, especially near the cathedral. But there was no town here; we can trace nothing more than a fort guarding the roads running north through Lancashire and east into Yorkshire, and the dwellings of women-folk and traders which would naturally spring up outside such a fort. The ancient name is unknown. Our Roman authorities give both Mancunium and Mamucium, but it is not clear that either form is correct.

MANDAEANS, also known as Subba (Sabians), Naṣoraeans, or St. John's Christians, are an ancient sect akin to the Gnostic Christians of the 2nd and 3rd centuries, which still exists in lower Mesopotamia, in such places as Basra and Kut and Sūḳ-esh-Shuyūkh. They number now not more than about 2,000, and are said to be diminishing. Subba (sing. ṣubbi) is the modern Arabic name, referring to their frequent baptisms (in Mandaean mas*buta*); Naṣoraeans, like the Arabic *Naṣāra,* is ultimately connected with Ναζωραῖοι (*comp.* Acts 24, 5 and נוצרי), and is used by Mandaeans in the sense of "true believers"; St. John's Christians is the inappropriate name given to the Mandaeans by Christian missionaries from the 17th century onwards, who mistook their frequent immersions and the reverence paid by them to John the Baptist for signs that they were derived from the Baptist's disciples. This is not so, and their interest in the Baptist is grounded in their hostility to the Church as it was under the Sassanian empire, *i.e.,* the Nestorians. Mandaeans means γνωστικοί (מאנדאייא, from מאנדא, Syriac *mad'ā*): the Gnosis of which they profess themselves adherents is a personification, the aeon and mediator "knowledge of life" (Manda d'hayye).

The present condition and practices of the Mandaeans may be gathered from Siouffi's book, published in 1880. A later account, including a detailed description of a Mandaean baptism, is to be found in the Quest for Oct. 1924 and Jan. 1925. (See **Bibliog**raphy.) The sacred books of the Mandaeans are: (1) the Ginza ("Treasure"), known also as Sidra rabba ("the Great Book"); (2) the John-Book, a later collection; (3) Qolasta, a sort of hymnbook, cf. the Syriac *ḳullāsā* ("praise") and some minor works, partly astrological. The editions of the Ginza (1925) and the John-Book (1905–IS), both by Mark Lidzbarski, have now made the chief Mandaean writings generally accessible to scholars.

Mandaean mss. are written in a peculiar Aramaic. As in the Babylonian (cuneiform) documents the characteristic Semitic gutturals have disappeared; on the other hand the vowels are represented, a by *, e by ײ, while' is used both for *i* and y, ו for w and *u* and o. Initial *u* (or o) is represented by עו, initial *i* by עי. No ms. older than the 16th century seems to have survived, but the texts show few variations of importance.

The Ginza is the oldest document. It begins at both ends, like many ms. note-books. The longer part is called the Right-hand Ginza (GR), the shorter (about a quarter of the whole) is the Left-hand Ginza (GL). It is usually cited by the pages of Peterman's facsimile, given in the margin of Lidzbarski's edition. The last chapter of 'GR presents a kind of world-history, and as the dominion of the Arabs is placed at only 71 years it is evident that it must have been compiled very shortly before A.D. 700.

GR contains general cosmological, hortatory and doctrinal pieces. GL consists chiefly of hymns and doctrinal pieces about the fate of the soul after death. This part (GL) shows most clearly the essence of the Mandaean religion; this is the σῶμα-σῆμα ("the body, a tomb") philosophy, which Mandaism shares with almost all the religions which flourished in the early days of Christianity, except Judaism and Catholic Christianity itself. For the world in itself, both visible heavens and this earth, together with the bodies of all men, there is no redemption, and the final end of everything on the earth, except for the souls of the righteous, is to be swallowed by Leviathan and so annihilated (GR 393). Our world had been a kind of mistake from the beginning. There was a light-world, and a world of darkness in which the evil woman-demon lived, whom the Mandaeans call Ruha. That world seems to consist of the dark (or black) waters and things thereto allied, and in GR v. 134–172 we read the fantastic tale of how Hibil the Bright (Hibil-Ziwa, lit. "Abel-Splendouro": Hibil is the Mandaean form, *Hābēl* the Syriac form of Abel), son not of Adam but of Manda d'Hayye, traversed all these dark lower regions, despoiling the principalities and powers and enchaining them. But somehow—the account itself is not clear (GR 150ff.)—Ruha, as the result of this visit, bore a monstrous son called *Ur* (possibly a corruption of ὕλη), and from Ur and his mother Ruha came broods of Seven and of Twelve, which are the planets and the zodiacal constellations. Meanwhile a lower being of the light-world called Abathur had looked below into the dark waters and seen his image, which thereupon took independent shape and was called *Ptahil.* This Ptahil had in him therefore some of the substance or quality of the dark waters: he was told to form a solid world out of the dark waters, but failed to do so till he was helped by Hibil, who put some of his brightness into the mixture. Ruha also took some part, for she saw that this new world was partly formed out of her waters. This is our world, formed out of the dark substance, yet with a little of the light mingled with it.

Hibil set the sons of Ruha as sun and moon and planets in the sky. When man was made these constructed the body of Adam, while Hibil brought out a soul from the treasury of life and put it into Adam's body (GR 172).

No satisfactory derivation for the names Abatur and Ptahil has yet been found. (See Pallis: Mandaean Studies, pp. 111–114.) Abathur has become the judge and "weigher" of Mandaean souls (see esp. JB 70–72), but this does not seem to have been his original function.

Manda corresponds exactly to the Syriac mad'd, which Bardaisan used for the Divine element in man (Mitchell ii. 158), distinct from knowledge, and corresponding to something between "reason" and "revelation." The actual phrase *mad'ā d'ḥayyē* occurs in the Syriac Bible in Luke i. 77 (=γνῶσιν σωτηρίας).

The Mandaean hostility to Eshu *mshiha* (Syr. *Ishō' mshīḥā,* Jesus Christ) is hostility to the fully developed post-Niccne Church. In several places "Christ" is actually called "the Byzantine" (Rumaya), and we read that the disciples of this Christ become "Christians," and turn into monks and nuns who have no children and who keep fasts and never wear white clothes like the Mandaeans (GR 55). The Holy Spirit of Catholic theology is identified by the Mandaeans with the evil Ruha. The peculiar hfandaean terminology sometimes makes the ordinary use of familiar terms impossible and other words have to be substituted. Thus Ruha to the Mandaeans means exclusively the evil spirit, so that they never use it, as all other Aramaic dialects do, for "wind," but use zika (lit. "storm") instead. Similarly *Alaha* means to them "false god," so for "true God" they speak of "the Great Mana" or other titles. Now we have seen that "Jesus Christ" was to the Mandaeans only the Pseudo-messiah worshipped by the official Christians: the Mandaean name for the true Jesus was *Anush* (or *Enush*). In GR 29 and 53 we read that Anush-Utra comes into the world in the days of Piliaṭus (or Palṭus, *i.e.,* Pilate) the king of the world; he heals the sick, makes the blind to see, cleanses the lepers, etc. (*cf.* Luke vii. 22). (*Utra* [Syr. uthra, lit. "wealth," "treasure"] is the Mnndaean term for a good spirit, so that Anush-Utra might almost be rendered "St. Enosh.") With the power of the high King of Light he raises the dead. Those who believe in him among the Jews he teaches that there is truth and error, life and death, light and darkness and burning fire. At his word 360 (or 365) prophets go out of Jerusalem and preach: then Anush ascends to the Mandaean paradise (Mshune-Kushṭa, "the abode of Truth") and will not be seen again by mankind till the end comes. *Kushṭa,* lit. "truth," is much used by Mandaeans for "true religion" generally; "to give Kushṭa" means to shake hands (always the right hand), a ceremony which takes the place of the laying on of hands in Catholic ritual. (Note that this word is spelt by Mandaeans with k not k.) Before he ascended, however, he will have unmasked the Deceiver, the Byzantine Christ, who will confess that he is only Hermes-Mercury (Nbo), one of the deceiving Seven Planets; he will be seized by the Jews and crucified (GR 58).

What more or less orthodox Christians thought of the Mandaeans we learn from the Scholion of Theodore bar Ronai (?Kēwāni = Saturninus) who compiled a sort of catalogue of heretics in A.D. 792. He treats them as a comparatively recent sect, founded by one Ado, a beggar (*i.e.*, a wandering fakir) from Adiabene, and says that their doctrine is borrowed from the Marcionites, from the Manichees and from the Kantaeans (or Knathaeans). Of these last, who are only known from Theodore himself, the one significant fact handed down is that they professed to derive their teaching from Abel, as in part the Mandaeans do.

In polemic against Catholic Christianity some Mandaean writers must have studied the Bible. In all cases it is the Syriac Bible (the Peshiṭta) of which they show knowledge. Their general grasp of Bible history and geography is extremely slight and they do not clearly distinguish the Jews from the Church Christians. (See esp. Pallis: Mandaean Studies, p. 141.) The evidence which has from time to time been brought forward to show independent Mandaean knowledge of Jewish traditions or literature breaks down on closer investigation.

Especially is this the case with regard to Mandaean tales about John the Baptist. Mandaeans use for Baptism a different word from that used by Catholic Christians, so that their conception of baptism may be more or less independent of Catholic Christianity, but the fact that they call all running water in which baptism may be performed "Jordan" must ultimately be based on the biblical stories about John.

John plays very little part in the Ginza. Manda d'Hayye goes down to the place where he baptizes, but the Jordan draws back before him, and he takes John (*Yuhana*) away to heavenly regions. In the *John-Book,* on the other hand, a long section is devoted to John, in which he is also called Yahia. the Arabic form of the name John. The tale, at least in its present form, is therefore later than the Arab conquests. In this, and also in GR 57, we read of John's aged parents, the priest Zacharia and his wife Enishbai (*i.e.*, the Syriac name Elishba' corrupted): it is difficult to believe that this is not derived from Luke i. Presently *Eshu* meshiha goes down and asks baptism from John, who is at first unwilling but finally complies on hearing a voice from heaven. It was, of course, a trump card for the Mandaean controversialist to be able to point out that the Jesus of the Catholics had had to be baptized by John, while the Mandaean Anush-Utra had not needed baptism. (Note that in GR v. 189–196 we have what Lidzbarski calls "the baptism of Manda d'Hayye by John." But in this tale Manda d'Hayye is not baptized: Manda d'Hayye asks baptism from John, but at His approach Jordan is driven back, and when Manda d'Hayye at length "gives truth"; *i.e.*, holds John by the right hand, John's soul is drawn out of his body and goes to Paradise.) But from the point of view of the modern investigator of Christian origins, the Mandaean accounts of the Baptist are both too fantastic and too near in some details to the Christian tale preserved in Luke to be regarded as in any sense independent tradition.

Baptism is called by Mandaeans *maṣbuta,* the corresponding form of which in Syriac would be masbo'ithd. The common Syriac term for baptism is *ma'modīthā,* only used by Mandaeans in speaking of Catholic baptism, which they regard with contempt as being administered in "cut off," *i.e.,* not running water. It should be noted that the Christian Palestinian dialect uses the term *maṣbo'īthā.* The Jewish term is *ṭibbūlā.* But the main difference between the Mandaean and the Christian rite is that the Mandaean masbuta is continually being repeated; it is a purification. not an initiation Everything defiles. but running water makes all things clean: that is the Mandaean idea.

The Mandaeans have a clergy: the assistant or deacon (*shkanda*), the priest (*tarmida,* lit. "disciple") and the bishop (*ganzibra,* lit. "treasurer"). The priestly garment is called rasta. A sort of eucharist is given, consisting of a dough-cake (pehta,? Syr. *pitthā* "bit of bread") and a draught of water (Mambuha, lit. "fountain"): there is some reason to think that the original rite consisted of the *mambuha* alone. Their temples (*mashkana*) are small, being merely receptacles for objects used in the services, which are conducted in the courtyard outside. The congregations assemble on Sundays.

History. — No Arab accounts of "Ṣābians" or "Mughtasila" are detailed or accurate enough to be useful. Portuguese missionaries came to lower Babylonia as a result of the Portuguese occupation of Basra at the end of the 16th century, and found the Mandaeans there, a flourishing community estimated at over 14,000 souls. They were regarded as Christians of John the Baptist, and as such amenable to the Inquisition. The first account of them in Europe was in a letter from the Jesuit Pietro della Valle, dated June 1622, in which year the Portuguese lost their ascendancy in the Persian gulf. From about 1622–1651 the Jesuits were replaced by Carmelites under Ignatius a Jesu, who published in 1658 at Rome an account of the Mandaeans. A few years later some Mandaean mss. were bought for Robert Huntington, then in Aleppo, who left them to the Bodleian Library at Oxford. In 1854 the German orientalist, H. Petermann, spent three months at Suk esh-Shuyūkh and learnt the language from the local priest Yahya; in 1875 the grandson of this Yahya, having become a Christian, expounded the Mandaean religion to N. Siouffi, then French Consul at Baghdad, who published a full account of the modern Mandaeans at Paris in 1880.

Incantation Documents. — Quite distinct from the religious literature of the Mandaeans are two series of magical formulae described respectively by H. Pognon and M. Lidzbarski. (See Bibliography.) The former are written on earthenware saucers found at Khouabir, on the Euphrates between Baghdad and Kerbela. They are all formulae designed to protect so-and-so from hostile incantations.

Lidzbarski's documents consist of leaden tablets of similar content: in these the names of deities, etc., are of a more definitely Mandaean caste.

MANDALAY, formerly capital of independent Burma, now headquarters of the Mandalay division and district, as well as the chief town in Upper Burma, stands on the Irrawaddy, in 21° 59' N. and 96° 8' E. Built in 1856–57 by King Mindōn, it is now a municipality.

The area inside the old walls of the palace and environs was called Fort Dufferin after the annexation, though no longer used as a fort. In the centre the palace, a group of wooden buildings, many of them highly carved and gilt, resting on a brick platform 900 ft. by 500 ft., and 6 ft. high, stood until its destruction during World War II. Pop. (1941) 163,537. The population is mixed, but Burmese Buddhists number over 77% of the whole. Mandalay is thus far more Burmese than Rangoon and is a great Buddhist religious centre and the abode of very large numbers of monks (*Hpongyis*). Besides Burmese there are Zerbadis (the offspring of a Mohammedan with a Burman wife), Mohammedans, Hindus, Jews, Chinese, Shans and Manipuris (called Kathe). Trains run from Mandalay to Rangoon, to Myit-kyina, and to Lashio, the beginning of the Burma road to Kunming. Steamers also ply in all directions. There are 20 bazaars.

The MANDALAY DISTRICT has an area of 2,115 sq.mi. and a pop. (1941) of 408.926. About 600 sq.mi. along the Irrawaddy are flat land, nearly all cultivated. In the north and east there are 1,500 sq.mi. of hills and tablelands, forming geographically a portion of the Shan tableland. This part of the district is well wooded and watered. The Maymyo subdivision has plateaux of 3,000 to 3.600 ft. The highest peaks are between 4.000 and 5,000 ft. The Irrawaddy, the Myit-ngè and the Madaya are the chief rivers. The last two come from the Shan states. and are navigable for between 20 and 30 mi. The Sagyin hills near Madaya are noted for their alabaster.

On the plains the climate is dry and healthful, the rainfall averaging about 30 in. Considerable areas are irrigated. The hilly eastern tracts have a heavier rainfall — about 60 in. — and are forested. The extremes of temperature on the plains are considerable, the thermometer in December going down to 55° and in July up to 110".

The DIVISION in 1941 included the districts of Mandalay, Kyaukse, Meiktila, Myingyan and Yamethin, with an area of 12,504 sq.mi. and a pop, of 1,907,703.

MANDAMUS, WRIT OF, originally a formal order of high prerogative issued by the crown commanding an official to perform a specific act within the duty of his office (Lat. *mandamus,* "we command"). It later became a judicial writ issuing from the court of king's bench in the name of the king at the request of individual suitors whose interests were alleged to be adversely affected by the failure of an official to act as his duty required.

It is not awarded as a matter of right but rather at the discretion of the court, and, although classified as a legal remedy, it is largely controlled by equitable principles. It is pot ordinarily granted where an alternative remedy is available and, it is said, never where the official to whom it mould be directed has legal discretion to perform the act demanded or to abstain from doing so.

In both England and the United States mandamus is used by courts of superior jurisdiction to compel the performance of a specific act refused by a lower court, such as the hearing of a case falling within the latter's authority. See PRACTICE AND PROCEDURE; APPEAL. (P. B. K.)

MANDAN. This Siouan tribe formed, with the Hidatsa and Arikara (*q.v.*), the so-called village Indians among the bison-hunting nomads of the plains in central United States. Their speech allies them rather with the Winnebago than with the Hidatsa, who in turn are close to the Crow. They lived in dome-shaped, earth-covered lodges clustered in stockaded villages; planted maize, beans, pumpkins and sunflowers; hunted buffalo seasonally; and made pottery. They had an origin myth of emergence from the lower world by a vine; treasured a sacred palladium in an ark; and performed ceremonies which, while containing Plains elements, were rather distinctive. The culture thus had eastern or southeastern affiliations; their drift in the historic period was upward along the Missouri river. Numbering 1,250 in 1804. they were reduced to a fraction a few decades later by disease, especially smallpox. The recent population has been variously given, owing to virtual loss of tribal identity among the Hidatsa. Theories deriving them from the mound builders of Ohio are unwarranted, and from the Welsh, fantastic. They were known as "tattooed people" in the sign language.

MANDARIN, the common name for all public officials in imperial China, the Chinese name for whom is kuan. The word comes through the Portuguese from Malay mantri, a counselor or minister of state. With the passing of the old order in China the term, as applied to officials, went out of use.

The words "mandarin language" remained in use, though inappropriately so. Originally the term was used to describe the language as spoken in the capital city of Peking and, with local variations, in most parts of China away from the coast. The proper name is the national language, or *kuo-yü,* taught all over the country.

The mandarin duck (yuan-yang) is so described because of its bright, variegated plumage like the dress of the mandarins in imperial China.

The mandarin orange (*kan*) is so called because of its resemblance in colour, shape and size to the large button perched on the hat of those high officials, or very likely because of the similarity in colour to the brilliant yellow of their silk robes. (L. M. L.)

MANDASAUR or MANDSAUR, a municipal town, tehsil and district in Madhya Pradesh state, India. The town (pop., 1951, 34,541), formerly in the state of Gwalior, gave its name to the treaty with Holkar, which concluded the Mahratta-Pindari war in 1818. An inscription discovered near the town is of considerable archaeological interest. It indicates the erection of a temple of the sun in A.D. 437. The fort dates from the 14th and 15th centuries. Mandsaur tehsil (pop., 1951, 119,340) covers an area of 511 sq.mi. MANDSAUR DISTRICT (area 3.961 sq.mi.) had a population in 1951 of 606,601.

MANDATE refers generally to an authorization to act, but the connotation is different according as the term is used in a political, administrative or legal context. Politically, a mandate is an instruction from a constituency to its elected representative in a legislative body or to a policy enjoined upon the legislature as a whole by the results of an election (see REPRESENTATION; ELECTORAL SYSTEMS). Administratively, a mandate is an authoritative command or order, especially an order from a superior to an inferior court, a papal ordinance dealing with an individual case, or an order from the Roman emperor to a provincial officer. In private law and, by analogy, in international law the term refers to an authorization by a person to act for another. In Roman law it is a contract constituted by one person (the mandatarius) promising to do something gratuitously at the request of another (the mandator), who undertakes to indemnify him against loss. (See ROMAN LAW.) The essentials and the terminology of the contract are preserved in most modern systems; but in English law, mandate, under that name, can hardly be said to exist as a separate form of contract. To some extent the law of *mandatum* corresponds to the law of principal and agent. "Mandate" is retained to signify the contract more generally known as gratuitous bailment. It is restricted to personal property, and it implies the delivery of something to the bailee, both of which conditions are unknown in the *mandatum* of the civil law (see BAILMENT).

Mandate System of the League of Nations. — The treaty of Versailles set up various conditions for the administration of the former overseas possessions of Germany and Turkey, under which mandatory powers were selected by the supreme council of the Allies to administer the territories under mandate. This system was a novel experiment in the relations between a sovereign state and a country under its control, involving new departures in international law. It was created by art. 22 of the covenant of the League of Nations. which formed part of the treaty of Versailles, and thus gained the recognition of all states that were members of the League. Upon formation of the United Nations in 1945, the mandate system was superseded by the trusteeship system, and most of the mandated territories became trust territories. (See TRUSTEESHIP SYSTEM.)

In its origin the mandate system was in the nature of a compromise. After World War I the victorious Allies naturally wished to retain the German and Turkish colonies, in the conquest of which they had in most cases made great sacrifices. Pledges had been made to the native inhabitants, some of whom had taken part with the victors in the fighting. that they should not be handed over to the vengeance of their former masters; and finally, a misgiving existed lest. in case of rendition, Germany might use them as recruiting grounds for native armies. and their ports as bases for submarines in a future war. On the other hand, the Allies had declared (more particularly in the pre-Armistice statement of Nov. 5, 1918) that annexation of territory was not their aim in the war.

International control of some kind was the only alternative. Joint administration was believed to be impracticable and opposed to the interests of the people. Even as a condominium between two powers only, it had given rise to friction in Egypt. Samoa and the New Hebrides. The only other course lay in the appointment of an individual power in uhom could be vested responsibility for the administration of each separate territory as an agent or mandatory of the League. For this course there were analogies in the delegation of quasi-sovereign powers to British and Dutch chartered companies and in the control of the Ionian Isles on behalf of the powers by Great Britain in 1815, and of Morocco by France under the Algeciras treaty of 1906. Individuals also had been appointed as mandatories of the powers. as when King Leopold II of Belgium undertook control of the International Free State of the Congo, and when Prince George of Greece was made governor of Crete in 1898.

The main defect of these delegatioris of sovereignty was that they provided no machinery to ensure the due execution of the trust. and it mas the distinctive feature of the mandate system that it attempted to remedy this defect. The League of Nations afforded just such a supervisory authority as was needed, and its supervision was exercised through the medium of a standing committee knonn as the Permanent Mandates commission. The League did not assign the mandates or define their terms or the extent and boundaries of the territories. These were determined by the supreme council and confirmed by the League council. which had authority under the covenant to define "the degree of authority, control or administration to be exercised by the mandatory if not previously agreed on by the members of the League." The United States. not being a member of the League, was no party to this arrangement, but it insisted that as an associated power its consent was necessary. The mandates therefore nere submitted to the United States and approved on condition that "free and equal treatment in law and in fact was secured to the commerce of all nations." The United States negotiated separate treaties with most of the mandatories securing its interests.

Terms **of** the Mandates. — The mandates were framed to give expression in detail to the principles embodied in art. 22 of the covenant; and since that article prescribed that their character must vary with the varying conditions of each territory, they were divided into three classes to correspond with the three paragraphs of that article.

Class A included the former Turkish vilayets of Iraq, Palestine and Syria. whose independence was to be provisionally recognized until they were able to stand alone. The two former were assigned to Great Britain, the latter to France. These mandates came to an end through recognition of the independence of Iraq in 1932, of Syria and Lebanon in 1941, of Transjordan in 1946, and of Israel in 1948. The last two included the territory of the original mandate of Palestine.

Class B comprised the former German central African colonies —Togoland, Cameroons, Tanganyika and Ruanda-Urundi—in which the mandatory was responsible for the administration and undertook to promote the moral and material welfare of the people. Tanganyika and a small part of the Cameroons and Togo fell to Great Britain. the major portions of the latter tno being assigned to France, while Belgium became responsible for Ruanda-Urundi. These territories all became trusteeships under the United Nations, with the same administering powers. In 1956 British Togoland was, with approval of the United Nations following a plebiscite, joined to the Gold Coast, which soon became a member of the United Nations as the state of Ghana. France reorganized the independence of French Togoland in 1958.

Class C territories included those which could "best be administered under the lams of the mandatory as integral portions of its territories. subject to the safeguards in the interests of the indigenous population" which were laid donn for class B. The territories mere South-West Africa, Samoa. New Guinea, the islands north of the equator in the west Pacific and the tiny island of Nauru. For these. respectively. the Union of South Africa. New Zealand. Australia, Japan and the British empire accepted mandates.

In the case of Nauru, in July 1919 (before the issue of the mandate) Great Britain. Australia and New Zealand had by agreement jointly acquired control of the phosphate deposits, which constituted the sole value of the island, and they jointly undertook the execution of the mandate. Since. however, the British empire had no single code of laws, the administration was assigned by the tuo others to Australia.

These territories all became trusteeships under the United Nations except South-West Africa. The International Court of Justice held in 1950 that the latter continue under the mandate of South Africa, with supervisory authority vested in the United Nations general assembly. The United States became trustee of the former Japanese mandated islands. The others retained the same administering authorities.

The "safeguards in the interests of the indigenous population" were: (1) freedom of conscience and religion. subject only to the maintenance of public order and morals; (2) prohibition of abuses, such as the arms and liquor traffic and the slave trade; and (3) prevention of fortifications, naval and military bases and the military training of natives except for police and the defense of the territory.

After acceptance by each mandatory, the mandates were confirmed by the League council, which was charged with seeing that their terms were in accord with the covenant and whose consent was required for any alteration. The A class could not be issued until the treaty of Lausanne came into force (Aug. 1924). The mandate was to be a "sacred trust of civilization" assumed by nations who (inter *ulia)* "by reason of their resources can best undertake this responsibility and are milling to accept it." The altruistic nature of this pledge was confirmed in a reply to a German protest. "The Mandatory Powers." said the Allies. "in so far as they may be appointed trustees by the League of Nations. will derive no benefit from such trusteeship." A mandated territory differed from a protectorate in that the protecting power obtained rights over the population and against other powers, whereas a mandatory in its capacity as guardian assumed obligations both toward the population and the League.

League Supervision. — The system differed from such partial precedents as have been cited in that it set up machinery by which the proper execution of the mandate might be assured. This consisted in the unqualified right of supervision vested in the League, which imposed upon each mandatory the obligation to submit an annual report on its administration.

These reports were examined by a permanent mandates commission in the presence of an accredited representative of the mandatory concerned. The commission originally consisted of nine members of the following nationalities: Belgian, British, Dutch, French, Italian, Japanese. Portuguese. Spanish and Swedish. To these a Swiss and a German were later added, and a Norwegian superseded the Swede. The majority were nationals of nonmandatory states. The members were selected "for personal merit and competence" as private individuals, and not as representatives of their respective nations. They were nominated by their governments, but approved and appointed by the League council, and could not hold any office under their government. A representative of the International Labour office attended the sessions and took part in any discussions relative to labour. This international composition negatived any suspicion of bias and gave to the commission the aspect of an impartial tribunal of practical men, whose object it was to promote co-operation while fearlessly exposing any breach of the covenant. Its functions were purely advisory to the council.

In addition to the annual review of the reports of the mandatories. the commission received any petitions and memorials from inhabitants of the territories and others interested, and these, unless trivial or irrelevant, were forwarded to the mandatory concerned for comments before examination by the commission. The proceedings were conducted in French and English and were generally held in private to facilitate freedom of discussion. Full minutes were printed and given publicity. A permanent secretariat, under a director. collected and circulated all documents of interest concerning mandates and conducted the routine business. The conlmission met at least twice a year at Geneva; its procedure was governed by rules approved by the council.

The weak point in the system lay in the impossibility of independent verification of statements contained in the reports, which varied in completeness and accuracy. The League council refused to permit the permanent mandates commission to visit the mandated territories or to hear oral petitioners, but the International Court of Justice in 1956 authorized the general assembly committee on South-West Africa to hear petitioners from that territory. After Japan's withdrawal from the League in 1933, the reports on its mandate were inadequate. For information not contained in the report. the commission had to rely on those public bodies or individuals who interested themselves in the welfare of native races and on such memorials and petitions as were presented to it. In order to obtain more accurate information, the actual administrators generally appeared as the mandatory's representatives. The only practical means at the disposal of the League for compelling the proper execution of the mandate was the force of public opinion. although in theory the League could transfer a mandate if the mandatory grossly violated its obligations.

The French mandates in west Africa—unlike the British mandates for portions of the same territories (Cameroons and Togo)—contained a clause to the effect that "troops thus raised" (*i.e.*, for purposes of local defense and police) "may in the event of general war be utilized to repel an attack, or for defense of the territory outside that subject to the mandate." It was difficult to reconcile this clause with the words of the covenant. At the instance of the Mandates commission the British government was willing to go even further than the covenant prescribed, and agree to pledge itself not to enlist the natives of a mandated territory, even though they offered themselves for enlistment outside its frontiers, thus limiting its sovereign rights in adjacent territories not under mandate. The French government declared its willingness to accept the same restriction.

Prevention of Abuses.—The covenant enjoined the "prohibition of abuses such as the slave-trade, the arms traffic and the liquor traffic." Some urged that these words meant the enforcement of total prohibition alike for natives and nonnatives. The mandates, however, only prescribed a "strict *control* over the sale of spirituous liquors." The rights of the natives and the prevention of material advantages to the mandatory were major concerns of the League. To this end financial accounts were carefully scrutinized, as were administrative or customs unions of mandated territories with adjacent colonies of the mandatory.

In the matter of equal commercial opportunity for all nations, the covenant itself failed to fulfill the expectations raised by the pre-Armistice declarations of the Allies. No obligation in this regard was imposed in the C mandates, while in the B class it was restricted to states which were members of the League.

Boundaries.—Another cause of practical difficulty was presented by the fact that in some cases the boundaries of the territories assigned under mandate were not defined. In the case of Iraq this led to an acute dispute with Turkey in regard to the northern boundary. It was eventually settled by the council of the League. advised by a special commission sent to the area. The southern frontiers were the subject of an agreement with the sultan of Nejd, and an Anglo-French agreement determined the frontiers with Syria. The French in northern Syria had similar difficulties with Turkey. to whom they ceded Cilicia and later Alexandretta. In the Cameroons a joint commission was set up to determine the precise boundaries: while with regard to Ruanda, the mandatory (Belgium) complained that the agreed boundary involved the loss to King Musinga of a considerable part of his territory. The British at once agreed that this area should be restored to him, and the consequent changes in the mandates were approved by the council. In South-West Africa a neutral zone had long existed betneen the German and Portuguese colonies. This was replaced by a precise demarcation embodied in a treaty between the Union of South Africa and Portugal.

Sovereignty.—Wider issues were raised by such questions as the nature and extent of sovereignty exercised by a mandatory and the international status of the inhabitants of a mandated territory. The mandatory was authorized to make and enforce laws, to raise troops, to set up tribunals, to appoint officials and to raise and spend revenues. Sovereignty was not ceded by the treaty of Versailles to the League, but to the "principal allied and associated powers" who were obliged to place the territories under "mandatories on behalf of the League." The highest court in South Africa recorded the opinion that the territories were not ceded at all, but placed by Germany at the disposal of the Allies. to be administered under mandate—a status new to international law. (Rex v. *Christian,* S.Af. L.R. [1924], App. Div. 101.)

The mandatory's powers were exercised "in its capacity as such." Any action on the part of the mandatory which had for its object (or would ultimately involve) annexation—as for instance the acquisition of large monopolistic rights, or of essential public services—was held to be contrary to the covenant and the mandate.

Juristic opinion differed as to the location of sovereignty in the sense of capacity to change the status of the territories. Arguments were made for the mandatory, the principal allied and associated powers, the mandated communities, the League of Nations and various combinations of these. Opinion tended, however, to accept the theory of ultimate League sovereignty; and practice gave support to this theory, particularly if the United Nations was to be regarded as the successor of the League. Art. 80 of the UN charter recognized that mandated territories remained in *status quo* until changed by appropriate action in accord with that instrument.

Status of Natives.—The status of the indigenous inhabitants of a class B or C mandate territory was the subject of special definition. Since the country was not annexed, its inhabitants did not become the subjects of the mandatory. The formula was therefore adopted by the council that "they should be designated by some form of descriptive title which would identify them as such," viz., as "persons administered or protected under mandate." Art. 327 of the treaty of Versailles stipulated that they should be entitled to the diplomatic protection of the mandatory when outside the mandated territory; individuals could, if they so desired, become naturalized subjects of the mandatory.

The application to mandated territories of special conventions, entered into by a mandatory power, was the subject of investigation and recommendation by the Mandates commission, in older to ensure that 'persons protected under mandate" should not be in a less favourable position in regard to their persons and property and their economic interests than the inhabitants of a protectorate or colony. The terms of the covenant contemplated self-government as the natural fruition of the mandate and all of the A class territories achieved that status.

The mandate system for the first time in history accorded international sanction to the principles of "trusteeship," of "tutelage" and of "mandate" The annual report forined an effective means of inviting a popular verdict on the fulfillment of the trust and supervision by the League, constituted a fundamental distinction from annexation, whatever the degree of assimilation to other possessions of the mandatory.

The standards of the covenant came to be regarded as principles of general application and contributed both to the welfare and self-determination of dependent peoples. The mandate system was an acknonledgment of the international responsibility of powers that exercise control of "peoples not yet able to stand by themselves" and a contribution to the peaceful liquidation of "colonialism."

BIBLIOGRAPHY.—The mandates section of the League secretariat issued a *List of Books and Pamphlets Relating to the Mandates System and to Territories Under Mandate;* a bibliography was also prepared by the Royal Colonial Institute. *See* D. P. W. Van Rees, *Les Mandats internationaux* (1927); L. M. Palacios, *Los Mandatos internacionales de la Sociedad de naciones* (1927); Benjamin Gerig, *The Open Door and the Mandates System* (1930); Quincy Wright, *Mandates Under the League of Nations* (1930); *H.* D. Hall, *Mandates, Dependencies and Trusteeship* (1948). (Lu.; Q. W.)

MANDAYA, a tribe of Mindanao Island in the Philippines, which lives in tree dwellings, several families in one house; cultivates scanty plots of rice and other crops; practises slavery and ceremonial cannibalism, eating part of the liver of a slain enemy, but not genuine head-hunting (*q.v.*). As offensive weapons, spears, daos, daggers and poisoned arrows are used; as defensive, light wooden shields, cloth-protective armour and bamboo caltrops. The turtledove is regarded as sacred, and spirits are worshipped by mediums (ballyan), generally female, and are associated with wooden figures representing ancestors. Groups are governed by warrior leaders (bagani) whose rank is acquired by the killing of many enemies, as insignia for which a red costume is worn. Half a red costume (trousers only) is awarded for exploits not worthy of the whole. They do not tattoo, but file and blacken the teeth. They have been erroneously reported to be white in complexion.

See Cole, *Wild Tribes of Davao District* (1913).

MANDELIC ACID, discovered by F. L. Winckler (1832) in an emulsion of bitter almonds. (See Glycosides, Natural.) It is most conveniently obtained in colourless rhombic prisms, melting at 118° C., with sp.gr. 1.364, and soluble in water, alcohol or ether, from commercial benzaldehyde (*q.v.*) by adding concentrated aqueous sodium hydrogen sulphite to a mixture of benzaldehyde and aqueous sodium cyanide; oily mandelonitrile, $C_6H_5.CH(OH).CN$, separates and is hydrolyzed to mandelic acid (phenylglycollic acid, phenyl-α-hydroxyacetic acid), $C_6H_5.CH$-$(OH)\cdot CO_2H$, at the ordinary temperature with concentrated hydrochloric acid. The acid may be extracted with benzene or ether (see H. Gilman and others, Organic Syntheses, vol. vi., 1926). Mandelic acid contains an asymmetric carbon atom and is accordingly resolvable into two optically active isomerides (see Stereochemistry). This resolution has been accomplished, (1) through the agency of the alkaloid cinchonine, which furnishes a less soluble salt with dextro-mandelic acid, and (2) by means of living organisms. The yeast *Saccharomyces ellipsoideus* removes the d-modification and leaves the laevo-mandelic acid, whereas the mould, *Penicillium glaucum,* destroys the I-form in a solution of ammonium mandelate, leaving the *dextro*-mandelic acid. The two optically active forms, which melt at 132·8° C., are less fusible and more sparingly soluble in water than the inactive or racemoid variety, which has been termed paramandelic acid. A mixture of equal weights of the two active forms produces the inactive acid, which is also obtained on heating either active form at 160° C.

MANDER, KAREL VAN (1548–1606), Dutch painter, poet and biographer of painters, was born of a noble family at Meulebeke. He studied under Lucas de Heere, at Ghent, and in 1568–69 under Pieter Vlerick, at Courtrai and Tournai. The next five years he devoted to writing religious plays, for which he painted the scenery. From 1574–77 he studied in Rome, where he made the acquaintance of Bartholomaeus Spranger. On his return journey he passed through Vienna, where he collaborated with Spranger and the sculptor Hans Mont on the triumphal arch for the entry of the emperor Rudolf II. After much wandering he settled at Haarlem, where, with H. Goltzius and C. Cornelisz, he founded a successful academy of painting. His fame is principally based upon a biographical work on the painters of various epochs — a book that has become for the northern countries what G. Vasari's Lives of *the* Painters became for Italy. It was completed in 1603 and published in 1604, in which year Van Mander went to Amsterdam, where he died on Sept. 2, 1606. He translated Virgil's Bucolics and Georgics.

His *Het Schilderboeck* (1604) was translated into French by H. Hymans (1884) and into German by H. Floerke (1906). The poem in 14 chapters dealing with the technique of painting, which forms the introduction, was used as a source of information by Charles Eastlake in Materials for a History of Oil *Painting* (1847). (R. E. W. J.)

MANDEVILLE, BERNARD DE (1670?–1733), English philosopher and satirist, was born at Dordrecht, the Netherlands, where his father practised as a physician. On leaving the Erasmus school at Rotterdam he gave proof of his ability by an *Oratio scholastica* de medicina (1685), and at Leyden university in 1689 he maintained a thesis De brutorum operationibus, in which he advocated the Cartesian theory of automatism among animals. In 1691 he took his medical degree, pronouncing an "inaugural disputation," *De chylosi vitiata.* Afterward he came to England "to learn the language" and succeeded so remarkably that many refused to believe he was a foreigner. He died Jan. 21, 1733, at Hackney.

The work by which he is known is the Fable of the Bees or *Private* Vices made Public Benefits, published first in 1705 under the title of The Grumbling *Hive,* or *Knaves Turn'd* Honest (200 doggerel couplets) and often reprinted, with additions. The book was primarily written as a political satire on the state of England in 1705, when the Tories were accusing Marlborough and the ministry of advocating the French War for personal reasons. The edition of 1723 was presented as a nuisance by the grand jury of Middlesex, was denounced in the London Journal by "Theophilus Philo-Britannus," and attacked by many writers, notably by Archibald Campbell (1691–1756) in his Aretelogia (published as his own by Alexander Innes in 1728; afterward by Campbell, under his own name, in 1733, as Enquiry into the Original of Moral *Virtue*). George Berkeley attacked it in the second dialogue of the *Alciphron* (1732), and John Brown criticized him in his Essay *upon* Shaftesbury's Characteristics (1751).

Mandeville's main thesis is that the actions of men cannot be divided into lower and higher. The higher life of man is merely a fiction introduced by philosophers and rulers to simplify government and the relations of society. It is the vices (*i.e.,* the self-regarding actions of men) which alone, by means of inventions and the circulation of capital in connection with luxurious living, stimulate society into action and progress. Mandeville's ironical paradoxes are interesting mainly as a criticism of the "amiable" idealism of Shaftesbury, and in comparison with the serious egoistic systems of T. Hobbes and C. A. Helvetius. He may be said to have cleared the ground for the coming utilitarianism.

Works.—*Typhon: a Burlesque Poem* (1704); *Aesop Dress'd, or a Collection of Fables writ in Familiar Verse* (1704); *The Planter's Charity* (1704); *The Virgin Unmasked* (1709, 1724, 1731, 1742), a work in which the coarser side of his nature is prominent; *Treatise of the Hypochondriack and Hysterick Passions* (1711, 1715, 1730) admired by Johnson (Mandeville here protests against merely speculative therapeutics, and advances fanciful theories of his own about animal spirits in connection with "stomachic ferment": he shows a knowledge of Locke's methods, and an admiration for Sydenham); *Free Thoughts on Religion* (1720); *A Conference about Whoring* (1725); *An Enquiry into the Causes of the Frequent Executions at Tyburn* (1725); *The Origin of Honour and the Usefulness of Christianity in War* (1732); *A letter to Dion occasioned by his book called Alciphron* (1732). Other works attributed, probably wrongly, to him are *A Modest Defence of Public Stews* (1724); *The World Unmasked* (1736); and *Zoologia medicinalis hibernica* (1744).

See Hill's *Boswell,* iii, 291–293; L. Stephen's *English Thought in the Eighteenth Century;* A. Bain's *Moral Science* (593–598); Windelband's *History of Ethics* (Eng. tr. by Tufts); J. M. Robertson, *Pioneer Humanists* (1907); *P.* Sakmann, *Bernard de Mandeville und die Bienenfabel-Controverse* (Freiburg i/Br., 1897); and articles Ethics; Shaftesbury, Anthony Ashley Cooper; Hobbes, Thomas.

MANDEVILLE, GEOFFREY DE (d. 1144), earl of Essex, succeeded his father, William, as constable of the Tower of London in or shortly before 1130. Though a great Essex landowner, he played no conspicuous part in history till 1140, when Stephen created him earl of Essex in reward for his services against the empress Matilda. After the defeat and capture of Stephen at Lincoln (1141), the earl deserted to Matilda, but before the end of the year, learning that Stephen's release was imminent, returned to his original allegiance. In 1142 he was again intriguing with the empress; but before he could openly join her cause, he was detected and deprived of his castles by the king. In 1143–44 Geoffrey maintained himself as a rebel and a bandit in the fen country, using the Isle of Ely and Ramsey abbey as his headquarters. He was besieged by Stephen in the fens and met his death in Sept. 1144 in consequence of a wound received in a skirmish. His career is interesting for two reasons. The charters which he extorted from Stephen and Matilda illustrate the peculiar form taken by the ambitions of English feudatories. The most important concessions are grants of offices and jurisdictions which had the effect of making Mandeville a viceroy with full powers in Essex, Middlesex and London, and Hertfordshire. His career as an outlaw exemplifies the worst excesses of the anarchy which prevailed in some parts of England during the civil wars of 1140–47, and it is probable that Mandeville inspired the rhetorical description, in the Peterborough Chronicle of this period, when "men said openly that Christ and his saints were asleep."

See J. H. Round, *Geoffrey de Mandeville, a Study of the Anarchy* (1892). (H. W. C. D.)

MANDEVILLE, JEHAN DE ("Sir John Mandeville"), the name claimed by the compiler of a singular book of travels, written in French, and published between 1357 and 1371. By aid of translations into many other languages it acquired extraordinary popularity, while a few interpolated words in a particular edition of an English version gained for Mandeville in modern times the certainly spurious credit of being "the father of English prose."

In his preface the compiler calls himself a knight, and states that he was born and bred in England, of the town of St. Albans; had crossed the sea on Michaelmas Day 1322; had travelled by way of Turkey (Asia Minor), Armenia the little (Cilicia) and the great, Tartary, Persia, Syria, Arabia, Egypt upper and lower, Libya, great part of Ethiopia, Chaldaea, Amazonia, India the less, the greater and the middle, and many countries about India; had often been to Jerusalem, and had written in Romance as more generally understood than Latin. In the body of the work we hear that he had been at Paris and Constantinople; had served the sultan of Egypt a long time in his wars against the Bedawin, had been vainly offered by him a princely marriage and a great estate on condition of renouncing Christianity, and had left Egypt under sultan Melech Madabron, *i.e.,* Muzaffar or Mudhaffar[1] (who reigned in 1346–1347); had been at Mount Sinai, and had visited the Holy Land with letters under the great seal of the sultan, which gave him extraordinary facilities; had been in Russia, Livonia, Cracow, Lithuania, "en roialme daresten" (? of Daresten or Silistria), and many other parts near Tartary, but not in Tartary itself; had drunk of the well of youth at Polombe (Quilon on the Malabar coast), and still seemed to feel the better; had taken astronomical observations on the way to Lamory (Sumatra), as well as in Brabant, Germany, Bohemia and still farther north; had been at an isle called Pathen in the Indian Ocean; had been at Cansay (Hangchow-fu) in China, and had served the emperor of China fifteen months against the king of Manzi; had been among rocks of adamant in the Indian Ocean; had been through a haunted valley, which he places near "Milstorak" (*i.e.,* Malasgird in Armenia); had been driven home against his will in 1357 by arthritic gout; and had written his book as a consolation for his "wretched rest."

This personal history of Mandeville is mere invention. There is no reasonable doubt that the travels were in large part compiled by a Liége physician, known as Johains à la Barbe or Jehan à la Barbe, otherwise Jehan de Bourgogne, who drew his information not from his own travels, but from the works of Odoric, Carpini, Vincent de Beauvais, and others. Jehan à la Barbe is himself a man of mystery.

A modernized extract quoted by the Liége herald, Louis Abry (1643–1720), at third or fourth hand from the lost fourth book of the *Myreur des Hystors* of Johans des Preis, styled d'Outremeuse, states that "Jean de Bourgogne, dit à la Barbe," revealed himself on his deathbed to d'Outremeuse, whom he made his executor. and described himself in his will as "messire Jean de Mandeville, chevalier, comte de Montfort en Angleterre et seigneur de l'isle de Campdi et du château Pérouse." Having had the misfortune to kill an unnamed count in his own country, he engaged himself to travel through the three parts of the world, arrived at Liége in 1343, was a great naturalist, profound philosopher and astrologer, and had a remarkable knowledge of physic. In the now destroyed church of the Guillclmins was a tombstone of Mandeville, with a Latin inscription stating that he was otherwise named "ad Barbam," was a professor of medicine, and died at Liége on Nov. 17, 1372; this inscription is quoted as far back as 1462.

Whether after the appearance of the *Travels* either de Bourgogne or "Mangevilayn" visited England is very doubtful. St. Albans Abbey had a sapphire ring, and Canterbury a crystal orb, said to have been given by Mandeville; but these might have been sent from Liége, and it will appear later that the Liége physician possessed and wrote about precious stones. St. Albans also had a legend that a ruined marble tomb of Mandeville (represented cross-legged and in armour, with sword and shield) once stood in the abbey.

It is a little curious that the name preceding Mangevilayn in the list of persons pardoned is "Johan le Barber." But Dr. G. F. Warner has ingeniously suggested that de Bourgogne may be a certain Johan de Bourgogne, who was pardoned on Aug. 20, 1321. Did this suggest to de Bourgogne the *alias* "à le Barbe," or was that only a Liége nickname? Note also that the arms on Mandeville's tomb were borne by the Tyrrells of Hertfordshire (the county in which St. Albans lies); for of course the crescent on the lion's breast is only the "difference" indicating a second son.

The Sources.—Leaving aside the stories which have grown up around the Liége physician, there remains the question whether the book contains any facts and knowledge acquired by actual travels and residence in the East. Possibly it may, but only in a small portion of the section which treats of the Holy Land and the ways of getting thither, of Egypt, and in general of the Levant. Even this section seems to be based on the travels of William of Boldensele (1336). The prologue, indeed, points almost exclusively to the Holy Land as the subject of the work. The mention of more distant regions comes in only towards the end of this prologue, and (in a manner) as an afterthought.

By far the greater part of these more distant travels, extending in fact from Trebizond to Hormuz, India, the Malay Archipelago, and China, and back again to western Asia, has been appropriated from the narrative of Friar Odoric (written in 1330). These passages, as served up by Mandeville, are almost always, indeed, swollen with interpolated particulars, usually of an extravagant kind, whilst in some cases the writer has failed to understand the passages which he adopts from Odoric and professes to give as his own experiences. Thus where Odoric has given a most curious and veracious account of the Chinese custom of employing tame cormorants to catch fish, the cormorants are converted by Mandeville into "little beasts called *loyres* (*layre,* B), which are taught to go into the water" (the word *loyre* being apparently used here for "otter," *lutra,* for which the Provençal is *luria* or *loiria*). Much, again, of Mandeville's matter, particularly in Asiatic geography and history, is taken from the *Historiae Orientis* of Hetoum, an Armenian of princely family, who became a monk of the Praemonstrant order, and in 1307 dictated this work on the East, in the French tongue at Poitiers. A good deal about the manners and customs'of the Tatars is demonstrably derived from the famous work of the Franciscan Joannes de Plano Carpini (*q.v.*), but Dr. Warner considers that much was taken at second hand and that Mandeville's immediate source was the *Speculum historiale* of Vincent de Beauvais.

The account of Prester John (*q.v.*) is taken from the famous *Epistle,* which was so widely diffused in the 13th century, and created that renown which made it incumbent on every traveller in Asia to find some new tale to tell of him. Many fabulous stories, again, of monsters, such as Pliny has collected, are introduced here and there, derived no doubt from him, Solinus, the bestiaries, or the *Speculum naturale.* And interspersed. especially in the chapters about the Levant, are the stories and legends that were retailed to every pilgrim, such as the legend of Seth and the grains of paradise from which grew the wood of the cross, that of the shooting of old Cain by Lamech, that of the castle of the sparrow-hawk (which appears in the tale of Melusina), those of the origin of the balsam plants at Maṭarīya, of the dragon of Cos, of the river Sabbation, etc.

[1]The *on* in Madabron apparently represents the Arabic form, though, as a matter of fact, its use in such a case is very odd.

While recording Mandeville's borrowings it is only fair to recognize his imaginative powers; a notorious passage, filched, with additions, from Boldensele, seems likely to have inspired the Valley of the Shadow of Death in *Pilgrim's Progress*. Nor does it follow that the whole work is borrowed or fictitious. In such works as those of Jan van Hees and Arnold von Harff we have examples of pilgrims to the Holy Land whose narratives begin apparently in sober truth, and gradually pass into flourishes of fiction and extravagance.

So in Mandeville also we find particulars not yet traced to other writers, and which may therefore be provisionally assigned either to the writer's own experience or to knowledge acquired by colloquial intercourse in the east.

BIBLIOGRAPHY.—The oldest known manuscript of the original—once Barrois's, afterward the earl of Ashburnham's, now Nouv. Acq. Franç. 4515 in the Bibliothèque Nationale, Paris—is dated 1371, but is nevertheless very inaccurate in proper names. The first English translation direct from the French was made (at least as early as the beginning of the 15th century) from a manuscript of which many pages were lost.

For Mandeville's sources *see* A. Bovenschen, *Die Quellen für die Reisebeschreibung des Johann von Mandeville, Inaugural-Dissertation . . . Leipzig* (Berlin, 1888), revised and enlarged as "Untersuchungen über Johann von Mandeville und die Quellen seiner Reisebeschreibung," in the *Zeitschrift der Gesellschaft für Erdkunde zu Berlin,* Bd. 23, Heft 3 u. 4 (no. 135, 136), and G. F. Warner, in the edition prepared for the Roxburghe club.

All English printed texts before 1725, and Ashton's 1887 edition, follow these defective copies.

The Egerton text (Brit. Mus. manuscript Egerton 1982) edited by G. F. Warner, has been printed by the Roxburghe club, while the Cotton text (Brit. Mus. manuscript Cotton Titus c xvi), first printed in 1725 and 1727, is in modern reprints the current English version.

That none of the forms of the English version can be from the same hand which wrote the original is made patent by their glaring errors of translation, but the Cotton text asserts in the preface that it was made by Mandeville himself. Mätzner (*Altenglische Sprachproben,* I, ii, 154–155) seems to have been the first to show that the current English text cannot possibly have been made by Mandeville himself. Other works bearing the name of Mandeville or de Bourgogne are a short French life of St. Alban of *Germany,* the author of which calls himself Johan Mandivill[e], knight, formerly of the town of St. Alban, contained in manuscript Add. C. 280 of the Bodleian; a *Lapidaire* printed in L. Pannier, *Les Lapidaires français;* and there are medical and alchemical receipts in the Ashmolean manuscripts in the Bodleian by John de Villa Magna. Finally, de Bourgogne wrote under his own name a treatise on the plague, *see* David Murray, *The Black Book of Paisley,* etc. (1885), and *John de Burdeus,* etc. (1891), extant in Latin, French and English texts, and in Latin and English abridgments. Herein he describes himself as Johannes de Burgundia, otherwise called *cum Barba,* citizen of Liège and professor of the art of medicine; says that he had practised 40 years and had been in Liège in the plague of 1365; and adds that he had previously written a treatise on the cause of the plague, according to the indications of astrology (beginning *Deus deorum*), and another on distinguishing pestilential diseases (beginning *Cum nimium propter instans tempus epidimiale*). "Burgundia" is sometimes corrupted into "Burdegalia," and in English translations of the abridgment almost always appears as "Burdews" (Bordeaux) or the like. Manuscript Rawlinson D. 251 (15th century) in the Bodleian also contains a large number of English medical receipts, headed "Practica phisicalia Magistri Johannis de Burgundia."

See further G. F. Warner's article in the *Dictionary of National Biography* for a comprehensive account, and for bibliographical references; Ulysse Chevalier's *Répertoire des sources historiques du moyen âge* for references generally; and the *Zeitschr. f. celt. Philologie* II, i, 126, for an edition and translation, by Whitley Stokes, of Fingin O'Mahony's Irish version of the *Travels*. (E. W. B. N.; H. Y.)

MANDHATA, a famous place of Hindu pilgrimage in the Nimar district of Madhya Pradesh, India, partly on the south bank of the Nerbudda river and partly on an island in the river. One of the temples is famous for containing one of the 12 great lingas of Siva.

Mandhata's annual fair was formerly the scene of the self-immolation of devotees who threw themselves from the high cliffs into the river. The last sacrifice, which was witnessed by a British officer, occurred in 1824.

MANDI, town and district of Himachal Pradesh, India. The town is 2,991 ft. above sea level on the Beas, a mountain torrent crossed by a fine iron bridge, and is a centre for transfrontier trade with Tibet and Yarkand. Pop. (1951) 8,909. It is linked by road to Simla.

The DISTRICT OF MANDI, area 1,527 sq.mi. (before 1948 a princely state), is intersected by two great parallel ranges, with an average height of 5,000 to 7,000 ft. above sea level.

The valleys are fertile and produce all ordinary grains, besides more valuable crops of rice, maize, sugar cane and tobacco. Rock salt is found (annual production about 4,000 tons). Pop. (1951) 310,626. (S. GL.)

MANDINGO (MANDINGA, MANDINKA, MANDE), one of the most important groups of tribes in western Africa, covering much of the western Sudan and the Guinea coast. Although primarily a linguistic classification, the Mandingo group still exhibits some degree of cultural unity (*e.g.,* in leatherwork). In the late middle ages the principal Mandingo-speaking peoples were politically much more closely knit than in recent times, and maintained one of the major empires of the western Sudan. The western group of Mandingo-speaking tribes includes the Mandingo of the Gambia valley and, on the middle Senegal, the Khassonke, Soninke and Marka; the eastern group includes the Bambara (Banmana), the Malinke, the Diula, the Bozo and the Sorko, mostly near the upper reaches of the Niger, and it is to this group rather than to the Mandingo-speakers as a whole that the term "Mandingue" is commonly applied in French ethnological literature. The southern group includes the Dan and Guro of the Ivory Coast, the Mende and Kono of Sierra Leone and the Kissi (who, however, have adopted a language of the Senegal-Guinea group), Kpelle, Susu, Toma and Vai of French Guinea and Liberia. These tribes are still predominantly pagan, though some groups are partly Islamized; all are mainly agriculturalists, and the men are normally organized by age groups in secret societies (such as the Poro among the Dan and Mende, and the N'tomo among the Bambara), one of whose main functions is to promote increase and well-being by ritual dances (though the political function of the societies is uppermost in some tribes). With these societies (notably among the Bambara, Dan, Guro, Toma and Mende) are often associated some of the finest African sculpture in the form of wooden figures and dance masks or dance headdresses, often of highly abstract design. An elaborate system of symbolism is said to play an important part in the life of some tribes, especially the Bambara, and certain symbols are found to be shared with the Dogon of the Niger bend on the one hand and the Ashanti of the southern Gold Coast.

See H. Labouret, "Westsudan und Guineaküste" in *Afrika,* ed. by H. A. Bernatzik, vol. 1 (Innsbruck, 1947), and *Les Manding et leur Langue* (Paris, 1934); D. Zahan, "Pictographic Writing in the Western Sudan," *Man,* vol. 50, no. 219 (London, 1950). (W. B. FG.)

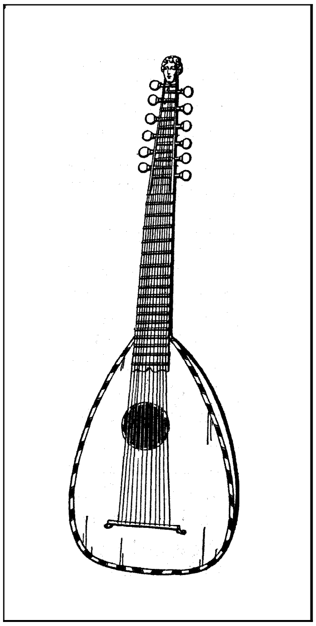
MANDLA, a town and district of Madhya Pradesh, India, on the Nerbudda river, notable for the manufacture of bell-metal vessels. A large part of the town was submerged by the flood of 1926. Pop. (1951), 14,243.

The DISTRICT OF MANDLA (area 5,122 sq.mi.) is in the Satpura hills. It is a wild highland region broken up by the valleys of numerous rivers and streams. The Nerbudda flows through the centre of the district, receiving several tributaries which take their rise in the Maikal hills, a range thickly clothed with sal forests and forming part of the great watershed between eastern and western India.

Except for one small fertile area producing wheat, it is a district of jungle, rice and millets, with a large aboriginal population. The forest area is large, including some sal forests and fine grazing areas on the plateau lands. The forests abound with big game and tigers are numerous. A few main roads opened up the district to some extent and the Eastern railway (Satpura section) touches the district at Mandla town. The population of the district in 1951 was 547,620 (60% aboriginal tribes, principally Gonds).

There is some export of food grains and oilseeds, and a larger export of timber and forest produce. It is a favourite shooting district, but very malarious.

MANDOLINE, the treble member of the lute (*q.v.*) family, and therefore a stringed instrument of great antiquity. There are two varieties and both Italian: (1) the *Neapolitan,* 2 ft. long, the best known, which has for strings four courses of pairs of unisons, tuned like the violin in fifths; (2) the *Milanese,* which is slightly larger and has five or six courses of pairs of unisons. The strings, of wire-spun gut, steel and brass, are twanged by means of a plectrum or pick. The Neapolitan mandoline was scored for by Mozart as an accompaniment to the celebrated serenade in *Don Giovanni.* Beethoven wrote for it a "Sonatina per il mandolino" and an Adagio for mandoline and harpsichord. Grétry and Paisiello also introduced it into their operas as an accompaniment to serenades.



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART

THE MANDOLINE, THE DESCENDANT AND ONLY SURVIVOR OF THE LUTE

MANDRAKE (*Mandragora officinarum*), a plant of the potato family, Solanaceae, and a native of the Mediterranean region. It has a short stem bearing a tuft of ovate flowers. with a thick fleshy and often forked root. The flowers are solitary, with a purple bell-shaped corolla; the fruit is a fleshy orange-coloured berry. The mandrake has been long known for its poisonous properties and supposed virtues. It acts as an emetic, purgative and narcotic. and mas much esteemed in old times; but. except in Africa and the East, where it is used as a narcotic and antispasmodic, it has fallen into disrepute. In ancient times it was used as a narcotic to diminish sensibility under surgical operations. Shakespeare more than once alludes to this plant, as in *Antony and Cleopatva:* "Give me to drink mandragora." The notion that the plant shrieked when touched is alluded to in *Romeo and Juliet:* "And shrieks like mandrakes torn out of the earth, that living mortals, hearing them. run mad." The mandrake was supposed to have other virtues. and was much used for love philtres. while the fruit was supposed, and in the East is still supposed, to facilitate pregnancy. The North American May apple (*q.v.*) is known also as mandrake.

MANDRILL, the most hideous and most brilliantly coloured of the baboons (*Papio*). The mandrill (*P. sphinx*) inhabits West Africa and is characterized by the shortness of its tail, heavy body, prominent brow ridges, small, deeply sunk eyes placed close together, and by the vivid colouring of the bare skin on the face and buttocks. In the latter region it is crimson, shading into blue at the sides and varying in intensity according to the condition of the animals. The cheek prominences are intense blue. while the central line and termination of the nose are scarlet. The fur is light olive above and silvery-gray beneath, with a small pointed yellow beard. The female is much smaller and less brightly coloured. Young males have black faces. Mandrills feed on fruit, roots, reptiles, insects, scorpions, etc., and inhabit rocky country in large troops. The old males are very ferocious, but, when young. the animals can be easily tamed.

MANDU (Mandogarh), a ruined city in Dhar district, Madhya Pradesh. India. the ancient capital of the Mohammedan kingdom of Malwa. The city is 38 mi. S.W. of Indore city, at an elevation of 2,079 ft., and extends for 8 mi. along the crest of the Vindhyan mountains. It reached its greatest splendour in the 15th century under Hoshang Shah (1405–34). The circuit of the battlemented wall is nearly 23 mi., enclosing a large number of palaces, mosques and other buildings. The oldest mosque dates from 1405; the finest is the Jama Masjid or Great mosque, a notable example of Pathan architecture. founded by Hoshang Shah. The marble-domed tomb of this ruler is also magnificent.

MANES, the inhabitants of the underworld, especially the ghosts of the dead. (Lat. "good people," an obvious euphemism.) In pure Roman cult we hear nothing of the worship of individual dead persons. and fear of ghosts does not seem to have been prevalent. But the collectivity of the inhabitants of the underworld was regarded as divine (*di manes*). Properly, the ancestral ghosts of a family are called *di parentes* or *parentum*, the *di manes* being the same as the *di inferi;* but this distinction tends to disappear about the beginning of our era, hence the common formula on tombstones, *dis manibus* followed by a name in the genitive or dative. *i.e.,* "to the glorified spirit of so-and-so" or "to so-and-so, a glorified spirit." The formula is clumsy at best.

Of public cult of the *manes* we hear little. They are mentioned in a few prayers (*see* Ancestor Worship); such things as burial grounds are sacred to them; certain persons guilty of very serious offenses were devoted (*sacri*) to them (*see* Consecration). It was supposed, at least in later times. that they came forth when the *mundus,* or ritual pit dug at the foundation of a city and opened three times a year (Aug. 24, Oct. 5, Nov. 8) was uncovered. Their dwelling place was the bowels of the earth, to which any deep chasm might lead (*see* Livy, vii.. 6, 4).

In private cult, they, or properly the *di parentes,* were propitiated with offerings of food. wine, garlands, etc., left on potsherds in the middle of the road, during the *dies parentales,* Feb. 13–21. On Feb. 22 followed a family reunion, the Caristia. At the Lemuria (May 9, 11, 13) each householder rose in the night, dropped beans from his mouth, saying "with these beans I ransom me and mine," and then bade the *manes paterni, i.e.,* the *di parenturn,* be gone (Ovid, *Fasti,* ii., 531, *et seq.;* v. 419 *et seq.*). Hence, perhaps, is derived the name *lemures* for ghosts. The *larvae* were malignant phantoms, supposed to possess and madden people (Plautus, *Capt.,* 598, *Menaech.,* 890); they had no part in cult.

See G. Wissowa, *Religion u. Kultus* (2nd ed.) p. 232, *et seq.,* and in Pauly-Wissowa, *Realencyklopädie, s.v.* Lemuria; W. Warde Fowler, *Roman Essays,* p. 24 *et seq.*

MANET, ÉDOUARD (1832–1883), one of the greatest French painters and engravers, and precursor of the Impressionists, was born in Paris. the son of a magistrate, on Jan. 23, 1832. He studied at the Collège Rollin (1844–48), where he met his future biographer, A. Proust. He is alleged to have already preferred to make drawings from nature than from casts and to have subscribed to the realist doctrine, *il faut être de son temps* ("one must be of one's own day and age"). After seeking entrance to the naval college, he joined the training ship "Guadeloupe," bound for Rio de Janeiro, returning to Le Havre in June 1849. From 1850 to 1856 Manet was a pupil in the studio of T. Couture, where he seems to have been only an intermittent visitor since he made several visits, during these years, to Fontainebleau in France, and to Italy, Austria, Germany, Belgium and Holland. It was in 1859 that he made his first submission to the Salon, a painting. "Buveur d'absinthe" (Absinthe drinker), in which. according to Proust, concessions had been made to the formulae of Couture. It was rejected but in 1861 his entries ("Portrait of the artist's parents," related to the style of Gustave Courbet, and "Guitarrero") mere accepted, earned an honourable mention and were well received by the critics. In 1862 Manet became a member of the Société des Aquafortistes and in the same year was praised by Charles Baudelaire. In 1863 Manet exhibited at the Galerie Martinet 14 pictures including his latest and most personal work "La Musique aux Tuileries" (Music in the Tuileries), (1862); in the same year the Salon des Refusés was opened to all artists who had been rejected at the official Salon, and included three pictures by him, chief among them being "Le déjeuner sur l'herbe" (Picnic on the grass). Both of these exhibitions aroused considerable hostile criticism, but also succeeded in making of Manet a rallying point for the younger painters who were to form the nucleus of the Impressionists. Despite the obvious allusions to traditional themes in the latter painting, it was the realism (the painting of the events and appearances of contemporary life!, together with the rejection of customary relationships of colour and tone, that inspired both the hostile criticism and the enthusiasm of the younger painters.

In 1865 Manet exhibited at the Salon "Christ mocked by soldiers" and "Olympia," painted in 1863, the latter evoking another storm of abuse. This key work in his development is one in which.

having assimilated the lessons to be gleaned from Japanese woodcuts, his preoccupation with the formal qualities of painting is perhaps for the first time clearly evident. In August of the same year he visited Spain primarily to study Velazquez, and one of the earliest pictures executed on his return, "Le Fifre" (The Fife-Player, rejected at the Salon 1866), represents a combination of the renewed influence of Velazquez (the open atmospheric background), and the lessons of Japanese art (the simplification and intensification of colour and tone and the ornamental character of the silhouette).

On the occasion of the international exhibition in 1867, Manet organized his own exhibition, showing some 50 paintings, but these were hardly received any more favourably than before. During the later 1860s his work was varied in character, but in general it seems to represent a greater concern with close relations of tone, with complexities of illumination and atmosphere, and sometimes exhibits a freedom of handling comparable with that in "La Musique aux Tuileries." "The Execution of Maximilian," of 1867, and "The Folkestone boat," of 1869, are representative of his work at this time.

During the Franco-German War of 1870 Manet served in the national guard under J. Meissonier, witnessing the siege of Paris and the Commune. In 1872, on a visit to Holland, he was impressed by the work of Frans Hals, and was much influenced by this artist when painting his "Bon Bock," which achieved considerable success when exhibited at the Salon of 1873.

At this time Manet was in intimate contact with all the members of the Impressionist group and during the course of 1874 spent some time at Argenteuil (near Paris) in the company of Monet and Renoir painting directly from the motif, a practice which he seems to have begun a few years earlier. An example of his work done at this time is "The Monet family in their garden at Argenteuil." Despite his intimacy with the Impressionists, and their influence upon his work at this time, he refused to participate in their independent exhibitions and continued to send to the Salon. "The Railway" (Salon, 1874) and one Argenteuil picture (Salon, 1875) were both badly received while two were rejected in 1876. At this time critics readily underlined the connection between Manet and the Impressionists even though the character of the works shown did not really justify it. Manet continued to submit to the Salon with very little success until 1880 when his portrait of Proust was fairly well received, but it was not until the following year that he obtained a second-class medal and became thereby free to exhibit as he liked. In 1882 the important "Bar at the Folies-Bergère" was exhibited with some success and in the same year, partly through the machinations of Proust, Manet was nominated *chevalier* of the Legion of Honour. By this time, however, he was seriously ill and he died at Paris on April 30, 1883. In 1884 a large retrospective exhibition was organized at the École des Beaux Arts and it was after this memorial show and after the Manet sale of the same year that the price of his pictures began to rise.

Manet's importance is due first to his insistence upon drawing his subjects from the events and appearances of his own time and upon representing them in attitudes, shapes and relationships of tone and colour which he had seen and considered to be "natural." and secondly, to the importance given to the appearance of the picture as an arrangement of paint areas on a canvas over and above its function as representation.

MANETHO (Μανέθων in an inscription of Carthage; Μανεθὼς in a papyrus), Egyptian priest and annalist, was a native of Sebennytus in the Delta. The evidence of Plutarch and other indications connect him with the reigns of Ptolemy I. and II. His most important work was an Egyptian history in Greek, for which he translated the native records. It is now only known by some fragments of narrative in Josephus's treatise *Against Apion*, and by tables of dynasties and kings with lengths of reigns, divided into three books, in the works of Christian chronographers. The earliest and best of the latter is Julius Africanus, besides whom Eusebius and some falsifying apologists offer the same materials; the chief text is that preserved in the *Chronographia* of Georgius Syncellus. Notwithstanding all their defects, the fragments of Manetho have been of great service to scholars ever since Champollion's first decipherments.

MANFRED (*c.* 1232–1266), king of Sicily, was a natural son of the emperor Frederick II by Bianca Lancia, or Lanzia. Frederick appears to have regarded Manfred as legitimate and by his will named him as prince of Tarentum and representative in Italy of his half brother, the German king Conrad IV. Manfred acted loyally and with vigour in the execution of his trust. and when Conrad appeared in southern Italy in 1252, his authority was quickly and generally acknowledged. When Conrad died (1254), Manfred, after refusing to surrender Sicily to Pope Innocent IV, accepted the regency on behalf of the infant Conradin.

On a rumour (1258) that Conradin was dead, Manfred was crowned king of Sicily at Palermo on Aug. 10 in that year. The report was false, but the new king declined to abdicate and pointed out the necessity for a strong native ruler. The pope declared Manfred's coronation void and pronounced sentence of excommunication. In conjunction with the Ghibellines, Manfred's forces defeated the Guelphs at Monte Aperto on Sept. 4, 1260. He was eventually defeated and killed near Benevento, Feb. 26, 1266.

MANFREDONIA, town and archiepiscopal see (with Vieste), Puglia, Italy, province of Foggia. $22\frac{1}{2}$ mi. X.E. of Foggia by rail, on the coast, 13 ft. above sea level, to the south of Monte Gargano, and giving its name to the gulf to the east of it. Pop. (1951) 27.634. Founded by Manfred (1263), the Turks destroyed it in 1620, but the castle of the Angevins and parts of the walls are preserved. In the church of S. Domenico. the chapel of the Maddalena contains 14th-century paintings. Two miles southwest is the cathedral of Sta. Maria Maggiore di Siponto, built in 1117 in the Romanesque style, with a dome and crypt. This marks the site of the ancient Sipontum, the harbour of Arpi, which became a Roman colony in 194 B.C. and was not deserted in favour of Manfredonia until the 13th century, having become unhealthy owing to the stagnant lagoons.

MANGABEY, a name applied to slender west African monkeys of the genus *Cercocebus*, characterized by their bare, whitish upper eyelids, large cheek pouches and the uniformly coloured hairs of the fur. *See* PRIMATES.

MANGALORE, a seaport and administrative headquarters of the South Kanara district, Mysore state, India. It is the terminus of the west coast line of the Southern railway. Pop. (1951) 117,083. The harbour is formed by the backwater of two small rivers, and large vessels lie 3 mi. offshore. The chief exports are coffee, pepper, sandalwood, fish and fish manure. There is a small shipbuilding industry, and fishing, coffee curing and manure making are carried on. The town has a large Roman Catholic population, with a European bishop, several churches and a convent, and is an industrial and educational centre. It is the headquarters of the Basel Lutheran mission, which successfully introduced the industries of printing, carpentry and the manufacture of tiles. There are three colleges, all affiliated to the University of Madras: the Government college, St. Agnes' college and St. Aloysius' college.

Mangalore was gallantly defended by Col. John Campbell in 1784, with a garrison of 1,850 men, of whom 412 were English, against Tipu sahib's whole army.

MANGAN. JAMES CLARENCE (1803–1849), Irish poet, was born'in Dublin on May 1, 1803. His baptismal name was James, the "Clarence" being his own addition. His father, a grocer, who boasted of the terror with which he inspired his children, had ruined himself by imprudent speculation and extravagant hospitality. The burden of supporting the family fell on James, who entered a scrivener's office at the age of 15 and drudged as a copying clerk for ten years. He was employed for some time in the library of Trinity college, and in 1833 he found a place in the Irish ordnance survey. He suffered a disappointment in love, and continued ill heaith drove him to the use of opium. He mas habitually the victim of hallucinations, which at times threatened his reason. For Charles Maturin, the eccentric author of *Melmoth,* he cherished a deep admiration, the results of which are evident in his prose stories. He belonged to the Comet club, a group of youthful enthusiasts who carried on war in their paper, the *Comet,* against the levying of tithes on behalf of the Protestant clergy. Contributions to the *Dublin Penny Journal* followed, and to the *Dublin University Magazine* he sent translations from the German poets. The mystical tendency of German poetry had a special appeal for him. He also wrote versions of old Irish poems, though his knowledge of the language, at any rate at the beginning of his career, was but slight. Some of his best-knoun Irish poems. however, *O'Hussey's Ode to the Maguire,* for instance, follow the originals very closely. Besides these were "translations" from Arabic, Turkish and Persian. How much of these languages he knew is uncertain, but he had read widely in oriental subjects, and some of the poems are exquisite though the original authors whom he cites are frequently mythical. He took a mischievous pleasure in mystifying his readers and in practising extraordinary metres. For the *Nation* he wrote from the beginning (1842) of its career, and much of his best work appeared in it. He afterward contributed to the *United Irishman.* On June 20, 1849, he died at Meath hospital, Dublin, of cholera. It is not true that starvation was the real cause, but there is no doubt that his wretched poverty made him ill able to withstand disease.

Mangan's fame was deferred by the inequality and mass of his work, much of which lay buried in inaccessible newspaper files under his many pseudonyms, "Vacuus," "Terrae Filius," "Clarence," e t ~ .Of his genius, morbid though it sometimes is, as in his tragic autobiographical ballad *The Nameless One,* there can he no question. He expressed with rare sincerity the tragedy of Irish hopes and aspirations, and he furnished abundant proof of his versatility in his excellent nonsense verses, which are in strange contrast with the general trend of his work.

The Poems of *James Clarence Mangan* (1903) and the *Prose Writings* (1904) mere both edited by D. J. O'Donoghue, who wrote in 1897 a complete account of the life and writings of the poet.

MANGANESE, symbol Mn, a hard, brittle metal melting at 1,245° C. (2,273° F.), was first recognized as an element by the great Swedish chemist C. W. Scheele in 1774 while working with pyrolusite, the manganese dioxide ore, and was isolated by his associate, J. G. Gahn, in the same year. Frequently found in conjunction with iron ores, the element was named for the magnetic properties exhibited by pyrolusite from the Latin, *magnes,* or magnet.

The addition of manganese in the Bessemer steelmaking process, initiated in 18j6 by Robert Mushet, made that process a practical success *(see* MANGANESE STEEL). In 1882 Robert Hadfield discovered the high-manganese steels which bear his name. The use of manganese is essential in steel manufacture for deoxidation and the control of sulfur content, and this application accounts for over 90% of the manganese consumed in all forms in the United States. Somewhat less than 13 Ib. of manganese, chiefly in the form of ferromanganese, is used for each ton of steel produced, and no substitute exists for it.

Manganese is vital to plant and animal life and is essential to reproduction in animals. While it has been known and commonly used in both alloy and compound form for a long time, it was only introduced to industry in pure form with the development of the electrolytic process for its recovery in the late 1930s. Relatively impure metal, made by aluminothermic *(see* THERMIT) or silicothermic reduction of the oxides, had previously been available, but only with the advent of the very pure electrolytic product was precise and extensive work on the potentialities of manganese made possible.

OCCURRENCE

Manganese is widely distributed in the combined state, ranking 12th in abundance among the elements in the earth's crust. It is commonly found associated with iron ores in concentrations too low in most cases, however, to make its commercial recovery attractive.

The United States is a have-not nation insofar as deposits of high-grade manganese ore are concerned. The known manganese deposits in this country have been estimated to total 3,500,000,000 long tons (2,240 Ib.) of ore and 75,000,000 tons of contained manganese. More than 98% of this manganese is contained in 12 large low-grade deposits, of which the most important are those of Chamberlain, S.D.; the Cuyuna range, Minnesota; Aroostook county, Maine; and Artillery peak, Arizona.

The Aroostook ore averages 6.5% to 9% manganese content. The Artillery mountains (Mohave county, Arizona) deposits are comprised of 200,000,000 tons of 3% to 4% manganese. 20,000,000 tons of 5% or more, 2,000,000 to 3,000,000 tons of 10% or more, and 500,000 tons of 15% or more. The South Dakota ore is estimated to comprise 2,000,000,000 tons, of which about 78,000,000 tons average 15% manganese.

The U.S. reserves of high-grade ore (48% or more manganese) amount to less than 200,000 tons. About 20,000,000 tons of ore average over 15% manganese, and when the grade is decreased to include ores containing 10% or more manganese, the reserves amount to about 100,000,000 tons.

Over 90% of the country's consumption of manganese ore is imported. and most of the domestic ore is derived from the Butte, Mont., district as the carbonate mineral rhodochrosite *(q.v.).* After 1950 annual manganese imports amounted to over 2,000,000 tons of ore containing under 50% manganese, the domestic consumption was almost the same and domestic production was about 300,000 tons of ore. India and Brazil supplied the largest amounts of imports, followed by Ghana, Union of South Africa, Cuba, Mexico and Brazil. Ghana provides the bulk of the battery and chemical grade ore. Before the deterioration of trade between the two countries. Russia was a major supplier of manganese to the United States, and its production is about one-third of the world production. *(See* also NATURAL RESOURCES: *Minerals: Iron and the Ferroalloys.)*

A large portion of the steel industry's manganese requirement could be obtained on a current basis from the basic open-hearth slag that contains from 10% to 15% manganese. This concentration is equal to or better than much of the low-grade ore available and is located at the steel mills. Further, millions of tons of previously produced slag might be treated to supply all needs for a period of many years.

The strategic import of the lack of this vital raw material has been long recognized and has impelled the development of feasible methods of utilizing the low-grade deposits and basic open-hearth slag for the production of manganese oxides suitable for ferromanganese manufacture. These programs have been conducted by the U.S. bureau of mines, the American Iron and Steel institute and many private companies. While the processes developed cannot compete economically with prices of foreign ores, they assure a supply of manganese should imports be cut off.

The most common minerals of manganese are pyrolusite and psilomelane *(qq.v.)*; characteristics of these and other manganese minerals are:

Pyrolusite, MnO_2, black, 60%–63% Mn
Psilomelane, $BaMnMn_8O_{16}(OH)_4$, black, 45%–60% Mn
Hausmannite, Mn_3O_4, brown, black, 72% Mn
Rhodochrosite, $MnCO_3$, light rose, 47% Mn, most common carbonate mineral, constituent of the Butte deposits
Rhodonite, $MnSiO_3$, reddish brown, 42% Mn
Braunite, $3Mn_2O_3.MnSiO_3$, black, 63% Mn

USES

Ferroalloys.—Over 95% of the manganese consumed is used in the form of ferroalloys by the metal industries, chiefly for steel manufacture. The predominant type, ferromanganese (74%–82% manganese, 12%–16% iron, 6%–8% carbon, 1% silicon), is made in blast furnaces and, to a lesser extent, in electric furnaces, by reduction of high-grade ores (48% or more manganese) with carbon. About 1,000,000 tons are produced annually. Low-carbon grades containing 0.07%–0.75% carbon are made by reduction of ores with ferrosilicon. Other types include spiegelcisen (16%–28% manganese, 6.5% carbon, 1%–3% silicon, balance iron) and siiicomanganese (65%–70% manganese, 17%–20% silicon, 1.5% carbon, balance iron). These are used in steelmaking to a lesser extent than standard ferromanganese. In addition to their use in deoxidizing and desulfurizing steel, the ferroalloys are used in the preparation of manganese-containing alloy steels.

Pure Manganese. — The only source of pure manganese is the electrolytic process, and while the tonnage of metal produced is small compared with that used in the form of ferromanganese, it has grown steadily. Following the pioneering work done by S. M. Shelton and co-workers at the U.S. bureau of mines, production on a commercial scale was begun in the United States in 1941 by the Electro Manganese Corp. in Knoxville, Tenn. Electrolytic manganese contains 99.9% manganese, and the greater portion, 60%–75%, goes into steel production as an alloying element and purifying agent, where it competes in cost with low-carbon ferromanganese. The balance is consumed in the preparation of nonferrous alloys of copper, aluminum, magnesium and the nickel-base alloys and of chemicals of high purity.

While methods in various plants differ in details, the electrolytic process uses a two-compartment diaphragm cell whose anolyte contains manganous sulfate, ammonium sulfate and sulfuric acid to give a pH of about 1, and whose catholyte is maintained at a pH of 7.2 to 7.6 in the presence of sulfur dioxide. The raw material is high-grade ore or high-manganese slag whose manganese content has been converted to manganous oxide, MnO, by roasting. This material is then leached with the anolyte from the cell, and the solution carefully purified to remove such impurities as iron, arsenic, antimony, tin, lead, nickel, cobalt, molybdenum, silica, aluminum, calcium and magnesium. The leach solution is returned to the cells as catholyte.

The compartmented cell operates with lead-base alloy anodes and stainless steel or Hastelloy C (trade name of Haynes Stellite Co. for alloy containing 14%–19% molybdenum, 4%–8% iron, 12%–16% chromium, 3%–5.5% tungsten, balance nickel', cathodes in the form of thin sheets. Manganese cathode deposits are removed periodically from these sheets by flexing and hammering and are recovered in the form of chips from & to $\frac{1}{8}$ in. thick. An impure form of manganese metal, containing 95%–98% of the element, is made by the reduction of manganese oxide with aluminum or ferrosilicon.

Alloys. — Several alloys containing manganese are of commercial importance. One of the ferrous alloys is the iron-chromium-manganese stainless type, where manganese is substituted for nickel (*see* STAINLESS STEEL: *Austenitic Stainless Steels*). These contain 17%–19% chromium, 8%–10% manganese and about 0.1% carbon and have good structural strength and corrosion resistance. Practically all commercial alloys of aluminum and magnesium contain manganese to improve corrosion resistance and mechanical properties. The presence of manganese in titanium improves the strength and workability of this light metal. An extremely high ability to damp vibrations is possessed by binary copper-manganese alloys. The development of alloys of manganese has expanded with the increasing availability of electrolytic manganese (*see* also ALLOYS).

Chemical Applications. — About 50,000 tons per year of high-grade natural manganese dioxide are used in the preparation of dry cells, or primary batteries, where the MnO_2 acts as a depolarizer to react with the hydrogen liberated by the cell reaction. A special crystal structure in addition to chemical purity is required for this purpose. A satisfactory grade is made by electrolysis of manganous sulfate in a sulfuric acid solution. This battery use is the most important nonmetallurgical application of manganese

Manganese compounds are used in glassmaking to counteract the green colour from iron and for pink and black colouring. Organic compounds, such as the naphthenate, as well as oxides and salts of manganese, are used in paints and varnishes as driers to promote the absorption of oxygen, which causes paints to set. Manganous sulfate, $MnSO_4$, is used alone and admixed with fertilizers to supply trace quantities of this element in agriculture, especially for citrus crops, to stimulate growth and to combat chlorosis in crops grown in certain calcareous and highly organic soils. Manganous chloride, $MnCl_2$, is added in some cases directly to the electrolytic cells producing magnesium in order to add the desired quantity of manganese for the alloying of the magnesium. The powerful oxidizing properties of potassium permanganate are utilized for disinfecting, deodorizing and decolorizing, and this compound is an important analytical reagent.

CHEMICAL AND PHYSICAL PROPERTIES

Chemical Properties. — Manganese, whose atomic number is 25 and atomic weight 54.93, is located in group VIIa of the periodic table, horizontally between chromium and iron. Although somewhat similar to iron in general chemical activity, it can exist in its compounds in the valence states of 1, 2, 3, 4, 6 and 7, the most stable salts being those of the divalent form, and the most stable oxide, the dioxide MnO_2. The lower oxides, MnO and Mn_2O_3, are basic; the higher oxides, acidic. The most stable compounds are those of valence 2, 6 and 7, exemplified, respectively, by the manganous salts, such as $MnCl_2$, $MnSO_4$ and $MnNO_3$; the manganates, such as K_2MnO_4; and the permanganates, such as $KMnO_4$. Divalent manganese is a reducing agent, tetravalent manganese is a good oxidizing agent and heptavalent manganese is a powerful oxidizing agent. The trivalent and hexavalent forms undergo auto-oxidation and reduction in acid solutions:

$$2Mn^{+3} + 2H_2O \longrightarrow MnO_2 + Mn^{+2} + 4H+$$
$$3MnO_4^{-2} + 4H^+ \longrightarrow MnO_2 + 2MnO_4^- + 2H_2O$$

These factors make manganese compounds useful for analytical procedures and for a variety of industrial applications.

Manganese metal oxidizes superficially in air and rusts in moist air. It burns in air or oxygen at elevated temperatures, like iron; decomposes water slowly when cold and rapidly on heating, forming manganous hydroxide, $Mn(OH)_2$, with hydrogen evolution; and dissolves readily in dilute mineral acids, with hydrogen evolution and the formation of the corresponding divalent salts.

Fluorine, chlorine and bromine react with manganese when heated. At 1200° C. or over, nitrogen attacks the metal to form the nitride Mn_5N_2, and when heated with ammonia, manganese forms the nitride Mn_3N_2. Manganese reacts with sulfur.

Fused manganese dissolves carbon, as does iron, ultimately forming a carbide, and it reacts with carbon monoxide at temperatures above 330° C. and with carbon dioxide when strongly heated.

Because of its position in the electromotive series, the metal will displace arsenic, antimony, bismuth, tin, lead, copper, iron, nickel, cobalt, cadmium and zinc from solutions of salts of these elements. This property can be used to substitute manganese for zinc as a sacrificial electrode for cathodic protection and corrosion pre-

vention in steel equipment. Roiling, concentrated solutions of potassium or sodium hydroxide have no action on manganese.

Physical Properties.— Manganese exists in three: and possibiy four, allotropic modifications, the alpha being the one stable at ordinary temperatures. Alpha and beta manganese are hard, brittle metals that will scratch glass. Tine pure metal cannot be fabricated. Gamma manganese, which changes to alpha at ordinary temperatures, is reported to be flexible and soft and can be bent and easily cut. The alpha form can be transformed to a ductile alloy by the addition of 2% copper and 1% nickel. The physical properties of manganese are listed in the accompanying table.

See Index references under "Manganese" in the Index volume.

MANGANESE STEEL. In the middle of the 19th century. when Sir Henry Bessemer (*q.v.*) was developing his pneumatic process for converting pig iron into steel, his experiments almost failed. He found that when he used Swedish pig iron, made from high-purity ore and reduced with charcoal, he could produce a usable steel; however, when he tried English pig irons, with higher contents of sulfur and phosphorus, the steel he produced could not be hot-rolled or forged without breaking up. It was hot-short. Fortunately, contemporary experiments by Robert Mushet showed that manganese, added to steel containing sulfur, would prevent this hot-shortness, and steelmaking on a large scale thus became successful. Since that time, manganese has been the one most essential additive to steels (iron-carbon alloys). In the absence of manganese, the iron sulfide in the steel melts at about 985° C., or 1,805° F., forming an intergranular liquid at hot-rolling temperatures. Manganese converts the sulfur to manganese sulfide, which has a much higher melting point and which remains a plastic solid during hot-rolling or forging and thus cures hot-shortness. When not added for alloying effects the normal manganese content of steel is 0.3% to 0.7%. In resulfurized steels, where sulfur is added to improve machinability, manganese may be increased to 1.5% with a sulfur content of 0.35%.

The term manganese steel often connotes Hadfield's austenitic manganese steel, which contains about 1.25% carbon and from 12% to 14% manganese. The carbon and manganese contents are high enough to cause the transformation from the high-temperature form of iron, austenite, to the low-temperature form, ferrite, to be very sluggish. As a consequence, when this steel is water quenched from a temperature of 1,000° C. (1,800° F.), it remains wholly austenitic at room temperature and is soft and ductile. The austenite is metastable, however, and when the steel is plastically deformed, as by cold working, it transforms rapidly to very hard martensite. (See STEELS, ALLOY.) Thus, for very rugged service, as in the rock crushers or railway frogs, it presents a hard, wear-resistant and self-renewing surface over a tough unbreakable core.

Manganese is fully the equivalent of nickel, chromium and molybdenum in promoting hardenability in steel, and it is cheaper. In low-alloy steels that are to be used in the normalized or hot-rolled condition. an increase in carbon will raise the strength, with a sacrifice in ductility, but an increase of manganese strengthens the steel, with no loss of ductility. Popular compositions contain 0.20% to 0.30% carbon and 1.25% to 1.75% manganese. Manganese is seldom used alone, however, because such steels tend to be coarse grained and notch sensitive. If not to be hardened, the grain size is usually refined with small additions of vanadium, titanium or aluminum. Whey they are to be hardened by water quenching, they often contain 0.2% molybdenum.

The so-called silicomanganese spring steel, containing 0.45% to 0.60% carbon, 1.8% to 2.2% silicon and 0.6% to 0.9% manganese, is really a silicon steel. Nondeforming steels for gauges, master tools, dies, etc., contain 0.80% to 0.90% carbon and 1.5% to 3% manganese and are characterized by their ability to maintain their shape and dimensions through a heat-treating cycle.

The high price and great scarcity of nickel and the production of carbon-free electrolytic manganese spurred the substitution of manganese for part of the nickel in austenitic stainless steels of the 18% chromium, 8% nickel type. Successful steels range from 16% chromium, 16% manganese, 1% nickel with 0.15% nitrogen to 18% chromium, 10% manganese, 4% nickel and 0.15% nitrogen, the latter being almost identical in properties with the 18% chromium, 8% nickel.

See also MANGANESE: Uses; IRON AND STEEL INDUSTRY: Some Ferro-Alloys. (C. E. Ss.)

MANGANITE, a basic manganese oxide mineral, MnO(OH), is an ore of manganese. ranking after pyrolusite and psilomelane (*qq* v.), to which it readily alters. The colour of manganite is dark steel gray to iron black. and the lustre brilliant and submetallic. The streak is dark reddish-brown. the hardness 4, and the specific gravity 4.33. It is a low-temperature hydrothermal vein mineral, and is chemically similar to lepidocrocite FeO(OH) and boehmite AlO(OH), but has a different structure. Manganite crystallizes in the monoclinic system, but nith an angle β of 90°, and hence appears as orthorhombic. The crystals are prismatic and deeply striated parallel to their length; they are often grouped in bundles and in columnar or fibrous masses. There is a perfect cleavage parallel to the side pinacoid. Manganite contains So 6% MnO; it dissolves in hydrochloric acid with evolution of chlorine Fine crystals are found at Ilfeld, Harz mountains. Ger., with calcite and barite. It also occurs in England, in Nova Scotia and in the United States, in the Lake Superior iron district. (L S. RL.)

MANGBETU (*Monbuttu*), a Negroid, Sudanic-speaking people of central Africa living to the south of the Azande in the Welle district of the Belgian Congo, where they cultivate chiefly bananas and manioc. The name Mangbetu refers strictly only to the aristocracy. which in the 19th century established a number of powerful kingdoms, though in looser usage it denotes the whole amalgam of peoples whom they rule. They impressed early travelers with their political institutions and their arts, especially with their remarkable skill as builders. potters and sculptors. They became renowned also for their cannibalism and for their practice of deforming the heads of babies by binding them tightly so that they retained through life a curiously elongated form. (E. E. E.-P.)

MANGEL, mangel-wurzel or mangold is a large type of beet belonging to the species Beta *vulgaris* which also includes vegetable and sugar beets arid Swiss chard. These types interbreed freely. The species probably originated from the wild beet Beta *maritima* and had its principal developmental centre in the eastern Mediterranean region. Mangold, the original name, is German and it has been somewhat modified in use. In France mangels are known as disettes. The mangel root is a store of food-stuffs in the forms of sugar and other carbohydrates. The sugar percentage is approximately 7%-8%, being about half that of sugar beets. The principal use of the crop is to provide a high tonnage of a succulent. nutritious feed for use in livestock, including poultry feeding. As feed for cattle and sheep. mangel roots are highly regarded and being very palatable they are often utilized as a relish for stimulating milk production. They are also considered valuable in conditioning animals for show purposes. Pound for pound the dry matter of mangels is equivalent in feed value to grain. The crop is usually grown in regions too cool or seasons too short for corn and where other conditions, such as soil fertility. soil type and moisture supply: are particularly favourable. Corn as compared with mangels will produce nearly double the yields of dry matter in the regions of its adaptation. Mangels are grown chiefly in northern and coastal western Europe and on the Pacific coast of the United States and Canada.

The plant is a biennial. During the first year of growth the stem of the mangel remains short and a rosette of large, crisp. prominent-veined leaves arises from it. The upper portion of the primary root becomes large during midsummer and autumn, attaining a diameter of from 4–10 in. and a length of from 6–30 in. The shape of the root is a varietal characteristic. If it remains in place and survives the winter, or if it is properly stored, and transplanted the following spring, tall, angular, branching stems grow to heights of three feet or more and produce inconspicuous flowers and seeds. The flowers are perfect and arranged in dense, sessile clusters, each subtended by a small bract, along an axis. The seeds are embedded in the flower parts and usually several flowers clustered together give rise to the seed ball, from which several seedlings may develop. Five groups of varieties are recognized based upon root shape and colour and leaf colour. Shapes recognized are globular, flattened, cylindrical and fusiform while colours may be white, yellow, orange or red. Zonal colouration may also occur within the root.

Culture. — Like other root plants the mangel is a row crop. The seed is drilled about $1\frac{1}{2}$ in. deep in rows 24–36 in. apart at a rate of 10–15 lb. per acre. After emergence of the seedlings cultivation is begun and continued until late summer. When the plants reach the iour-leaved stage they are spaced about 10–14 in. apart in the rows by thinning. Hand hoeing is then begun and the crop is weeded as required. Harvesting is done by mechanically liiting the roots previous to heavy frosts in the fall and removing the tops by cutting. The roots may be stored in large heaps or in covered pits or root cellars. Successful storage is dependent upon careful handling to avoid severe bruising, and also upon good ventilation. The roots may be pulled and ied directly as needed without topping.

Best soils for mangels are those rich, well drained and in good tilth. On more shallow land varieties with shorter roots may he grown. The crop responds markedly to heavy applications of barnyard manure and to potash, phosphate and nitrogen fertilizers. Although mangels are sometimes grown for several years on the same land they more commonly occupy a place in rotation with grain and forage crops. Requiring careful cultivation and weed control, they leave the soil in excellent condition for succeeding crops.

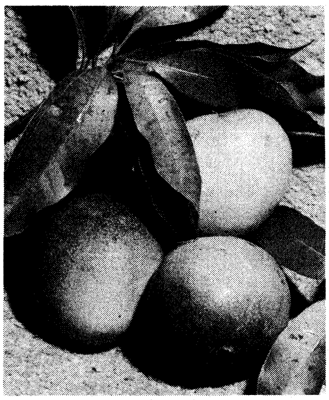
The principal values of the mangel are its productiveness, yields usually being 20–45 tons per acre, and its succulence. Very few crops will produce as much succulent feed per area. Mangels require much hand labour in thinning, cultivating, harvesting and storage. In corn regions cost of producing corn ensilage for succulent feed is much less than with mangels or other root crops. Mangels are more drought and heat-tolerant but more sensitive to frost than turnips or rutabagas, often grown for similar uses. Also, they are less affected by root maggots and aphis than the latter crops. Important objectives sought in better varieties are high yield of sugar and dry matter, freedom from disease and premature seed-stalk formation (bolting) and smooth, well-shaped roots of good keeping quality. (D. C. SH.)

MANGO, one of the most important and widely cultivated fruits of the tropical world. Its origin is lost in antiquity: according to some authorities, horticultural forms are derived from *Mangifera indica* (family Anacardiaceae), considered indigenous to the region of the eastern Indian subcontinent. Burma and Assam; but other species. such as *M. laurina* may have entered into the composition of some, particularly those of the Malayan region.

History.—Few fruits are so inextricably connected with the folklore and religious ceremonies of India as the mango. Buddha himself was presented with a mango grove, that he might find repose in its grateful shade. The economic importance of the mango in ancient times is attested by one of the Sanskrit names, ***am***, which has an alternative meaning of provisions or victuals. The Chinese traveler Hwen T'sang, who visited Hindustan between A.D. 632 and 645, was the first person, so far as known. to bring the mango to the attention of the outside world. Friar Jordanus wrote of it in 1328. and John de Marignolli in 1349. Akbar. the Mogul emperor who reigned at Delhi from 1jj6 to 1605, planted near Darbhanga the Lakh Bagh. an orchard of 100,000 mango trees. Nothing better attests the esteem in which the fruit has long been held than this immense planting. made at a time when large orchards of fruit trees were almost unknown.

The name mango, by which the fruit is known in English- and Spanish-speaking countries, is derived from the Tamil *man-kay* or *man-gay,* which the Portuguese adopted as *manga* when they settled in western India. Probably because of the difficulty in transporting seeds (they retain their viability a short time only). introduction of the tree into the western hemisphere did not take place until about 1700, when it was planted in Brazil; thence it reached the West Indies about 1740. It has taken on the appearance of a wild species in many parts of tropical America, trees springing up everywhere from seeds scattered by the roadside. During the ripening season, mangos are a major foodstuff wherever grown.

Description. — The tree is evergreen, often reaching large size (50–60 ft.) and attaining great age. It is one of the favourite shade trees of the tropics. The leaves are lanceolate, up to 12 in. long; the flowers, which are small. pinkish and fragrant, are borne in large terminal panicles. They are polygamous, *i.e.,* some have both stamens and pistil, others stamens only. The fruit varies greatly in size and character, as would be expected of a species (or combination of species) which has been in cultivation for a long time. The smallest mangos are no larger than plums. while others may weigh four or even five pounds. The form is oval, round, heart-shaped. kidney-shaped or long and slender. Some varieties are beautifully coloured with shades of red and yellow, while others are dull green. The single large seed is flattened. the flesh which surrounds it yellow to orange in colour, juicy and of delicious spicy flavour. Fryer, writing of mangos in 1673. said "for Taste, the Nectarine. Peach and Apricot fall short." Hamilton. who wrote in 1727, went even further. "The Goa mango," he declared. "is reckoned the largest and most delicious to the taste of any in the world. and I may add, the wholesomest and best tasted of any Fruit in the World." There are ample grounds for considering the mango—as has been done by many writers—the "king of tropical fruits."



BY COURTESY OF FLORIDA STATE NEWS BUREAU

FLORIDA MANGOS

Most of the seedlings so abundant throughout the tropics do not represent this fruit at its best. While of good flavour, they are commonly characterized by coarse fibres throughout the flesh which makes eating an annoying process. In contrast, the fine grafted varieties which have originated in India and a few other regions, as well as seedlings of the race cultivated in the Philippines and other countries (known as Mangos de Manila in Mexico and Filipinos in Cuba), are almost devoid of fibre and are of excellent quality.

Distribution and Cultivation. — In 1889 the U.S. department of agriculture introduced into Florida the first of the grafted Indian varieties known in the United States — the variety Mulgoba, of superb quality but not highly productive. In subsequent years, mainly through the efforts of Reasoner brothers and David Fairchild (*q.v.*), more than jo other choice varieties mere taken to the Gnited States, whence the cultivation of several gradually spread to many parts of the American tropics. The British and French also introduced a number into the West Indies. Some of the best imported varieties are Pairi (known in Jamaica as Bombay). Borsha and Amini. In addition to these such varieties as Carabao from the Philippines and Saigon from Cambodia should be mentioned. as well as Julie which first received horticultural attention in the French West Indies and later became popular in Jamaica.

Because of the failure of many varieties to produce regular and heavy crops of fruit, they have been replaced in commercial orchards by Haden (a seedling of Mulgoba which originated in Florida) and others which have been developed in that state.

Mango trees are injured by a few degrees of frost. They are grown commercially in southern Florida. but were not wholly successful in California. though numerous trees have fruited in that state. The mango is not particular as to soil, but the finer varieties only yield good crops where there is a well-marked dry season to stimulate fruit production rather than vegetative growth. There is another serious problem in rainy areas: a fungous disease known as anthracnose (*Colletotrichum*) which destroys the flowers and young fruits and is expensive to control.

Propagation is by means of grafting or budding. Inarching is widely practised in tropical Asia. but is tedious and relatively expensive. In Florida better methods have been developed and are used commercially. Chief among these are veneer grafting and chip budding. However. seedling trees of the Philippine race usually produce fruit like that of the parent and for this reason are extensively grown in Mexico. This race is polyembryonic. which means that trees usually do not develop from fertilized ovules, but from what are known as nucellar buds arising from the vegetative tissues surrounding the egg cell, hence they are in most respects similar to grafted plants. On the other hand, most of the Indian varieties are monoembryonic, which means that young plants develop only from fertilized ovules and thzrefore are subject to the variation which is characteristic of cultivated fruit trees in general.

Except with occasional dwarf varieties such as Julie, mangos in commercial plantings are spaced 35 to 45 ft. apart. The tree has a number of enemies, chief among which are the anthracnose disease mentioned above and certain scale insects (family Coccidae). In numerous tropical regions the fruits may be infested by the larvae of fruit flies, which render them unfit for human consumption and are difficult to combat. (W. Po.)

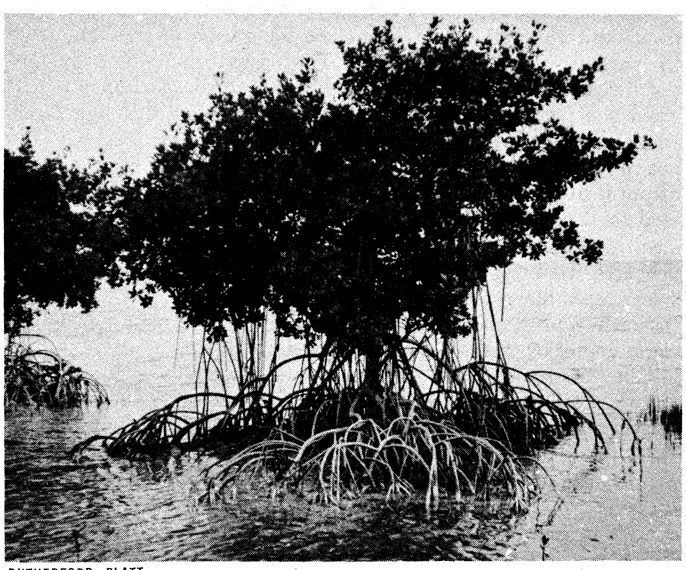
MANGOLD: *see* MANGEL.

MANGOSTEEN. A beautiful, delicious fruit of tropical southeast Asia. produced by a handsome tree *(Garcinia mangostana)* of the family Guttiferae which under favourable conditions reaches a height of about 35 ft. It has thick, dark-green, glossy leaves six to ten inches long; the flowers are large, polygamous; the fruits are about three inches in diameter, round to oblate in form, and dark purple in colour. They have thick hard rinds surrounding a large cavity in which lie several segments of snow-white flesh, resembling a mandarin orange; it is juicy, delicate in texture, and of delightful acidulous flavour.

In spite of the fact that the mangosteen is so highly valued, and that its cultivation in such regions as Java, Sumatra, Indochina and the southern Philippines dates from very early times, the tree has nowhere been planted on an extensive scale, for mangosteens are difficult to ship very long distances. It was introduced into the western hemisphere in the 19th century, where it became established in several of the West Indian islands; it was later established on the mainland; *e.g.,* in Guatemala, Honduras, Panama and Ecuador. It did not prove well adapted to the climates of California and Florida. but has been grown successfully in Hawaii.

For best results the mangosteen needs a rich deep soil and a moist tropical climate, but it will grow under less ideal conditions. though not where temperatures often go below about 40° F. Propagation is by seeds, which do not long retain their viability. Grafting has been unsuccessful and not required, since the embryos develop from tissues surrounding the ovary; hence, being of vegetative origin they produce trees which are as much alike as grafted ones. Occasional trees may yield as many as 500 to 600 fruits; there is a tendency to produce good crops only in alternate years. (W. Po.)

MANGROVE. The mangrove forests along tidal estuaries, in salt marshes, and on muddy coasts in the tropics of both old and new worlds, are composed of trees and shrubs belonging mainly to the genus *Rhizophora* of the family Rhizophoraceae, but including. especially in the eastern mangrove formations of further India and the Malay archipelago, members of other families, such as Lythraceae (*Sonneratia*), Verbenaceae (*Avicennia*), and the acaulescent Nipa-palm. Their trunks and branches constantly produce adventitious roots. which, descending in arched fashion, strike at some distance from the parent stem, and send up new trunks, the forest thus spreading like a banyan (*q.v.*) grove. An advantage in dispersal, very characteristic of the order, is afforded by the seeds, which have a striking peculiarity of germination While the fruit is still attached to the parent branch the long radicle emerges from the seed and grows rapidly downward. When the seed falls the young root is in the right position to be driven into the mud; the plant being thus rooted the plumule makes its appearance. The young root may grow to such a length that it becomes fixed in the mud before the fruit separates from the parent tree. An interesting feature of the mangrove is the air roots, erect or kneed branches of the roots, which project above the mud, and are provided with minute openings (lenticels), into which the air diffuses and then passes by means of passages in the soft spongy tissue to the roots which spread beneath the mud. The wood of some species is hard and durable; the astringent bark is used in tanning, yielding cutch. The fruit of the common mangrove. *Rhizophora mangle,* is sweet and wholesome.



RUTHERFORD PLATT

COMMON MANGROVE (RHIZOPHORA MANGLE) SHOWING THE TANGLED ROOT FORMATION

MANHATTAN, a city of northeastern Kansas, U.S., the seat of Riley county, is located on the north fringe of the rolling Flint Hills, at the confluence of the Big Blue and Kansas (Kaw) rivers, 55 mi. W. of Topeka, and 10 mi. E. of Fort Riley, one of the state's beauty spots. The village was founded in 1854 when the settlements of Poleska and Canton were consolidated as Boston. It was renamed Manhattan in 1855 by mutual agreement between the Boston association and a party of colonists from Cincinnati. The city was incorporated in 1857 and adopted the commission-manager form of government in 1951. Manhattan, chiefly an educational centre, is the home of Kansas State University of Agriculture and Applied Science (formerly Bluemont Central college, chartered 1858), one of the first land-grant colleges in the U.S. The city supports a municipal airport, a zoo, several large parks and a recreational program. It is 5 mi. from Tuttle Creek dam. Commercial and industrial activities include insurance, wholesaling, food processing, farm machinery, cut stone and truck farming. For comparative population figures see table in KANSAS: *Population.* (A. B. SR.)

MANHATTAN, an island 14 mi. long and 2.3 mi. wide lying between the Hudson and East rivers in the southernmost part of New York state, U.S., is one of the five boroughs comprising New York city and also forms New York county. The borough of Manhattan includes, in addition to the island, a small area on the mainland known as Marble Hill and a number of small islands in the East river — Welfare, Governors, Randalis and Wards. Manhattan is the centre of much of the city's activities and is often mistaken as being synonymous with New York city.

The Dutch West India company founded Manhattan as a trading post and from the beginning finance was among its chief interests. In 1626 Peter Minuit, the first director-general of New Netherland province, is said to have purchased the island from the Brooklyn Indians (Canarsees) with trinkets and cloth valued at 60 guilders (then about $24). The island became the possession of the English in 1664, having already been incorporated as the city of New Amsterdam in 1653. Renamed New York city, it played a prominent role in the early history of the republic, both militarily and politically. It served as the meeting place for congress from 1785 to 1790 and George Washington was inaugurated there in 1789 as the country's first president. In the 19th century, particularly following the opening' of the Erie canal in 1825, Manhattan developed rapidly and became the heart of a prosperous and expanding metropolis. In 1898 greater New York was formed when Manhattan was joined with the newly created boroughs of Brooklyn, Queens, Richmond and the Bronx (*qq.v.*).

Manhattan is renowned for its many attractions and points of interest. Among these are Broadway, one of the best-known streets in the world; Wall street, focal point of the financial district; the skyscrapers, such as the Empire State building; Greenwich Village; Central park, extending from 59th to 110th street; the United Nations Headquarters building; and cultural and educational institutions, including the Metropolitan Museum of Art; Metropolitan Opera house; American Museum of Natural History; Hayden planetarium; Columbia university, including Barnard college; Hunter college and City College, both operated by the College of the City of New York; and New York university. See also NEW YORK (CITY). (D. L. D.)

MANI (MANES or MANICHAEUS) (215/6–274?), the Iranian founder of the Manichaean religion, was born in 215/6 in southern Babylonia, where his father, Patek, a native of Hamadan, had joined a religious community practising baptism and abstinence. Through his mother Mani was related to the Parthian royal family (overthrown in 224). Information about his life appears to derive from his own writings and the traditions of his church. He grew up at his birthplace, speaking a form of eastern Aramaic. Twice, as a boy and young man, he saw in vision an angel, the "Twin," who, the second time, called him to preach a new religion. He traveled to India (probably Sind and Turan) and made converts. Favourably received on his return by the newly crowned Persian king, Shapur I, he was permitted to preach his religion in the Persian empire during that long reign. There is little information about Mani's life in those years. He probably traveled widely in the western parts of the empire, but later traditions that he visited the northeast seem unsound. Under the reign of Bahram I he was attacked by Zoroastrian priests and imprisoned by the king at Gundeshapur (Belapet), where he died after 26 days in captivity in 274 or 277. See also MANICHAEISM.

BIBLIOGRAPHY.—H. C. Puech, *Le Manichéisme* (1949), an account of Mani's life, with full references; for the disputed dates of Mani's life, see W. B. Henning with G. Haloun, "The Compendium of the Doctrines and Styles of the Teaching of Mani," in *Asia Major*, n.s., III/ii (1952), and with S. H. Taqizadeh, "The Dates of Mani's Life," *Asia Major*, VI/i (1957). (MA. B.)

MANICHAEISM, the religion of Mani (*q.v.*), which spread from Babylonia and during the 4th century was widely influential in the empire.

Manichaean System.—The Manichaean system is one of consistent, uncompromising dualism, in the form of a fantastic philosophy of nature. The distinction between the physical and the ethical, the natural and the spiritual, did not exist for Mani. When he co-ordinates good with light, and evil with darkness, this is no mere figure of speech, but light is actually good and darkness evil. Religious knowledge involves the knowledge of nature and her elements, and redemption consists in freeing light from darkness. Thus ethics becomes a doctrine of abstinence in regard to all elements originating within the sphere of darkness.

The self-contradictory character of the present world forms the point of departure for Mani's speculations. From the contradictory character of the world he concludes the existence of two beings, originally quite separate from each other—light and darkness. Each is to be thought of according to the analogy of a kingdom. Light presents itself to us as the good primal spirit (God, radiant with the virtues of love, faith, fidelity, high-mindedness, wisdom, meekness, knowledge, understanding, mystery and insight), and then further as the heavens of light and the earth of light, with their guardians the glorious aeons or angels. Darkness is likewise a spiritual kingdom (more correctly, it also is conceived of as a spiritual and feminine personification), but it has no "God" at its head. It embraces an "earth of darkness." As the earth of light has five tokens (the mild zephyr, cooling wind, bright light, quickening fire and clear water), so has the earth of darkness also five (mist, heat, the sirocco, darkness and vapour). Satan with his demons was born from the kingdom of darkness. These two kingdoms stood opposed to each other from all eternity, touching each other on one side, but remaining unmingled. Then Satan made an incursion into the kingdom of light, into the earth of light. The God of light, with his syzygy, "the spirit of his right hand," now begot the primal man, and sent him, equipped with the five pure elements, to fight against Satan. But the latter proved himself the stronger, and the primal man was for a moment vanquished. And although the God of light himself now took to the field and with the help of new aeons (the spirit of life, etc.) inflicted total defeat upon Satan and set the primal man free, the latter had already been robbed of part of his light by the darkness, and the five dark elements had mingled themselves with the generations of light.

Creation of Man.—It is significant of the pessimistic character of the system that, while the formation of the world is considered as a work of the good spirits, the creation of man is referred to the princes of darkness. The first man, Adam, was engendered by Satan in conjunction with "sin," "cupidity," "desire." But the spirit of darkness drove into him all the portions of light he had stolen, in order to be able to dominate them the more securely. Thus Adam is a discordant being, created in the image of Satan. but carrying within him the stronger spark of light. Eve is given him by Satan as his companion. She is seductive sensuousness, though also having in her a small spark of light. But if the first human beings thus stood entirely under the dominion of the devil, the glorious spirits took them under their care from the very outset, sending aeons down to them (including Jesus), who instructed them regarding their nature, and in particular warned Adam against sensuality. But this first man fell under the temptation of sexual desire. Cain and Abel indeed are not sons of Adam, but of Satan and Eve; Seth, however, who is full of light, is the offspring of Adam by Eve. Thus did mankind come into existence, its various members possessing very different shares of light, but the men having uniformly a larger measure of it than the women. In the course of history the demons sought to bind men to themselves by means of sensuality, error and false religions (among which is to be reckoned above all the religion of Moses and the prophets), while the spirits of light carried on their process of distillation with the view of gaining the pure light which exists in the world. But these good spirits can save men only by imparting to them the true gnosis concerning nature and her forces and by calling them away from the service of darkness and sensuality. To this end prophets, preachers of true knowledge, have been sent into the world. Mani, following the example of the gnostic Jewish Christians, appears to have held Adam, Noah, Abraham (perhaps Zoroaster and Buddha) to be such prophets. Probably Jesus was also accounted a prophet—not, however, the historical Jesus, but a contemporaneous phantom Jesus, who neither suffered nor died (Jesus *impatibilis*). According to the teaching of some Manichaeans, it was the primal man who disseminated the true gnosis in the character of Christ.

Mani, the "Ambassador of Light."—But at all events Mani himself, on his own claim, is to be reckoned the last and greatest prophet, who took up the work of Jesus impatibilis and first brought full knowledge. It is only through his agency and that of his imitators, "the elect," that the separation of the light from the darkness can be completed. The system contains very fantastic descriptions of the processes by which the portions of light when once set free finally ascend even to the God of light. He who during his lifetime did not become one of the elect, who did not completely redeem himself, has to go through a severe process of purification on the other side of the grave, till he too is gathered to the blessedness of the light. When the imprisoned elements of light have at last been completely, or as far as possible, delivered from the world, the end of all things comes. All glorious spirits assemble, the God of light himself appears, accompanied by the aeons and the perfected just ones. The angels supporting the world withdraw themselves from their burden, and everything falls in ruins. A tremendous conflagration consumes the world; the perfect separation of the two powers takes place once more.

Ethics of the **Manichaeans.**—On the basis of such a cosmical philosophy, ethics can have only a dualistic ascetic character, Manichaean ethics is not merely negative, however, since it is necessary to cherish, strengthen and purify the elements of light, as well as free oneself from the elements of darkness. The aim is not self-destruction, but self-preservation; and yet the ethics of Manichaeism appears in point of fact as ascetic, to an extent that could be practised only by few; hence the religion must have abandoned all attempts at an extensive propaganda had it not conceded the principle of a twofold morality. A distinction was made in the community between the electi (*perfecti*), the perfect Manichaeans, and the *catechumeni* (auditores), the secular Manichaeans. Only the former submitted themselves to all the demands made by their religion; for the latter the stringency of the precepts was relaxed. They had to avoid idolatry, sorcery, avarice. falsehood, fornication, etc.; above all, they were not allowed to kill any living being (the ten commandments of Mani). They had also to free themselves as much as possible from the world: but in truth they lived very much as their non-Manichaean fellow citizens. We have here essentially the same condition of things as in the Catholic Church, where a twofold morality is also in force. that of the religious orders and that of secular Christians—only that the position of the electi was more distinguished than that of the monks. For, after all, the Christian monks never quite forgot that salvation is given by God through Christ, whereas the Manichaean electi mere themselves redeemers.

It is evident that the religion of Mani borrowed various elements from older oriental faiths especially from Babylonian and Zoroastrian sources. It arose "in a country where several religions were competing with one another. and where, in consequence of this, various hybrid sects had been formed" The relations of Manichaeism to other religions have been investigated in detail; but mention must be made of its relation to Christianity.

Manichaeism and Christianity.— It is very difficult to determine the extent of Mani's knowledge of Christianity. how much he himself borrowed from it, and through what channels it reached him. It is certain that Manichaeism, in those districts nhere it was brought much into contact with Christianity, became influenced by it. The western Manichaeans of the 4th and 5th centuries are much more like Christians than their eastern brethren As regards Mani himself. it is safest to assume that he held both Judaism and Catholic Christianity to be false religions.

Finally, the Manichaean doctrines exhibit points of similarity to those of the Christian Elkessites. The historical relation of Mani to Christianity is then as follows From Catholicism. of which he very probably had no detailed knonledge he borrowed nothing. On the other hand, he looked upon what he considered to be Christianity proper—that is, Christianity as it had been developed among the sects of Basilidians, Marcionites and perhaps Bardesanites—as a comparatively valuable and sound religion. He took from it the moral teaching of the Sermon on the Mount and a criticism of the Old Testament and of Judaism so far as he required it Indications of the influence of Marcionitism are found in the high estimation in which Mani held the apostle Paul and in the fact that he explicitly rejects the Book of Acts.

The Secret of **Manichaeism.**—What gave Manichaeism strength was that it united an ancient mythology and a thoroughgoing materialistic dualism uith an exceedingly simple spiritual uorship and a strict morality. On comparing it with the Semitic religions of nature we perceive that it was free from their sensuous cultus substituting instead a spiritual uorship as well as a strict morality. Manichaeism nas thus able to satisfy the new wants of an old world. It offered revelation. redemption moral virtue and immortality, spiritual benefits on the , of the religion of nature. A further source of strength lay in the simple yet firm social organization which was given by Mani to his new institution. The wise man and the ignorant, the enthusiast and the man of the world could all find acceptance here, and there was laid on no one more than he was able and willing to bear.

Originally furnished from fragments of various religions, Manichaeism could increase or diminish this possession nithout rupturing its own elastic framework. And. after all, great adaptability is just as necessary for a universal religion as a divine founder. Manichaeism indeed, though it applies the title "redeemer" to Mani, has really no knowledge of a redeemer, but only of a physical and gnostic process of redempticn; on the other hand, it possesses in Mani the supreme prophet of God. If we consider in conclusion that Manichaeism gave a simple, apparently profound, and yet convenient solution of the problem of good and evil, a problem that had become peculiarly oppressive to the human race in the 2nd and 3rd centuries, we shall have named the main factors which account for the rapid spread of the system.

History of **Manichaeism.**—Manichaeism first gained a firm footing in the east, *i.e.,* in Persia, Mesopotamia and Transoxiana. The persecutions it had to endure did not hinder its extension. Even after the conquests of Islam the Manichaean Church continued to maintain itself, indeed it seems to have become still more nidely diffused by the victorious campaigns of the Moslems, and frequently it gained secret adherents among the latter themselves Its doctrine and discipline underwent little change in the east; in particular. it drew no nearer to the Christian religion. It first penetrated the Greek-Roman empire about the year 280, in the time of the emperor Probus (see the Chronicon of Eusebius).

It was only subsequent to about 330 that Manichaeism spread rapidly in the Roman empire. Its adherents were recruited on the one hand from the old gnostic sects (especially from the Marcionites—Manichaeism exerted besides this a strong influence on the development of the Marcionite churches of the 4th century) on the other hand from the large number of the "cultured," who were striving after a "rational" and yet in some manner Christian religion. Its polemics and its criticism of the Catholic Church now became the strong side of Manichaeism, especially in the west. It admitted the stumbling blocks which the Old Testament offers to every intelligent reader and gave itself out as a Christianity nithout the Old Testament. Instead of the subtle Catholic theories it offered an exceedingly simple conception of sin and goodness.

The farther Manichaeism advanced into the west the more Christian and philosophic did it become. In Syria it maintained itself in comparative purity. In north Africa it found its most numerous adherents, gaining secret support even among the clergy.

Opposition of Roman **Emperors.**—The Christian Byzantine and Roman emperors, from Valens onwards. enacted strict laws against the Manichaeans. But at first these bore little fruit. The *auditores* were difficult to trace out, and besides they really gave little occasion for persecution. In Rome itself between 370 and 440 Manichaeism gained a large amount of support. especially among the scholars and public teachers. It also made its way into the life of the people by means of a popular literature in which the apostles were made to play a prominent part (Apocryphal Acts of the Apostles). In Rome Leo the Great was the first who took energetic measures, along with the state authorities, against the system. Valentinian III decreed banishment against its adherents. Justinian the punishment of death. In north Africa hlanichaeism appears to have been extinguished by the persecution of the Vandals. But it still continued to exist elsewhere, both in the Byzantine empire and in the west, and in the earlier part of the middle ages it gave an impulse to the formation of new sects, which remained related to it. It is at least undoubted that the Paulicians and Bogomils, as well as the Catharists and the Albigenses, are to be traced back to Manichaeism (and Marcionitism). Thus the system. not indeed of Mani the Persian, but of Manichaeism as modified by Christian influences, accompanied Catholicism until the 13th century.

Sources.—(a) Oriental. Among the sources for a history of Manichaeism the most important are the Oriental. Of these the Moslem sources, though of comparatively late date, are distinguished by the excellent manner in which they have been transmitted to us, as well as by their impartiality. They must be named first, because ancient Manichaean writings have been used in their construction. At the head of all stands En-Nedim, author of the *Fihrist* or "Catalogue" (c. 980) containing an account of hlanichaeism which has been published separately with translstion and notes by G. Flügel, Mani, seine *Lehre* u. seine *Schriften* (1862).

Of the Christian Orientals those that afford most information are Ephraem Syrus (d. 373), in various writings; the Armenian Esnik (German translation by J. M. Schmid. 1900 see also *Zeitsch. f. hist.* Theol., 1840, ii.; Langlois, Collection, ii. 375 seq.), who wrote in the 5th century against Marcion and Mani; and the Alexandrian patriarch Eutychius (d. 916), Annales, ed. Pococke (1628). There are, besides, scattered pieces of information in Aphraates (4th cent.), Bar-Hebraeus (13th cent.) and others. The newly found Syriac *Book of Scholia* of Theodor bar Khouni (*see* Pognon, *Les Coupes de Kouabir*, Paris, 1898) gives many details about Mani's teaching (also ed. without translation by Dr. M. Lewin, Berlin, 1905).

(b) Greek and Latin. The earliest mention of the Manichaeans in the Graeco-Roman Empire is to be found in an edict of Diocletian (*see* Hanel, *Cod. Gregor.*, tit. xv.), which is held by some to be spurious, while others assign it to one or other of the years 287, *290*, *296*, 308 (so Mason, *The Persec. of Diocl.*, pp. 275 *seq.*). Eusebius gives a short account of the sect (H. E., vii. 31). It was the *Acta Archelai*, however, that became the principal source on the subject of Manichaeism for Greek and Roman writers. In the form in which we now possess them, they are a compilation after the pattern of the *Clementine Homilies*, and have been subjected to manifold redactions, and give an account of Manichaeism which is largely legendary. These *Acta* were used by Cyril of Jerusalem (*Catech.* 6), Epiphanius (*Haer.* 66), and a great number of other writers. Important matter is to be found in the resolutions of the councils from the 4th century onwards (*see* Mansi, *Acta concil.*, and Hefele, *Conciliengeschichte*, vols. i.–iii.), and also in the controversial writings of Titus of Bostra (6th century), Πρὸς Μανιχαίους (ed. Lagarde, 1859), and of Alexander of Lycopolis Λόγος πρὸς τὰς Μανιχαίου δόξας (ed. Combefis; transl. in *Ante-Nic. Lib.*, vol. xiv.). Of the Byzantines, the most worthy of mention are John of Damascus (De *haeres.* and *Dialog.*) and Photius (*cod.* 179 *Biblioth.*).

BIBLIOGRAPHY.—The most important works on Manichaeism are Beausobre, *Hist. critique de Manichée et du Manichéisme* (2 vols., 1734 *seq.*; the Christian elements in Manichaeism are here strongly, indeed too strongly, emphasized); Baur, *Das manich. Religionssystem* (1831; in this work Manichaean speculation is exhibited from a speculative standpoint); Flügel, *Mani* (1862; a very careful investigation on the basis of the *Fihrist*); Kessler, *Untersuchung zur Genesis des manich. Religionssystems* (1876); and the article "Mani, Manichaer," by the same writer in Herzog-Hauck's *R.E.*, xii. 193–228; Kessler, *Mani* (2 vols., Berlin, 1889, 1903); *Recherches sur le manichéisme: I. La cosmogonie manichéenne d'après Théodore Bar Khôui*, by Franz Cumont (Brussels, 1908); *II. Fragments syriaques d'ouvrages manichéens*, by Kugener and F. Cumont. *III. Les Formules grecques d'abjuration imposées aux manichéens*, by F. Cumont. *See* also A. A. Bevan, art. "Manichaeism" in Hastings' *Encyclopaedia of Religion and Ethics* (*vol.* viii. 1915).

MANICURING is the art of treating the nails of the hands to protect and improve their health and to beautify them according to the current standards of fashion. In the days of Salome and Cleopatra, women stained their nails with henna, and this vogue persists among some primitive peoples to-day. Under the social régime of the Chinese Empire, finger nails worn several inches long, and covered with gold cases, were a symbol of the aristocracy who did not have to work with their hands. The present mode is to shape the nails like the finger-ends and pink them to emphasize or suggest their healthy colour.

These rules, almost the same as those for a professional manicure, should be followed in the home manicure:

The nails should be thoroughly cleaned with a nail brush and warm soap suds. They should then be filed and shaped. Extreme points or blunt nails are not natural or in good taste. The tip of the nail should conform to the curved shape of the cuticle at the base of the nail, when this is normal.

When the filing is completed, immerse the fingers in soapy water for about three minutes to soften the cuticle. Then use a cuticle solvent with an orangewood stick (the end of which has been wrapped in a bit of cotton) around the base of the nail, under the edge of the cuticle surrounding the base of the nail, and under the free edge of the nail at the tip of the finger. Gently remove the accumulated loosened cuticle with a blunt pointed cuticle knife, holding the blade of the knife flat against the cuticle at the side of the nail, and wipe off with the end of a small towel.

A little bleach may be applied under the nails to whiten them. Then rub in a little nail cream around the cuticle to nourish the nail and keep the cuticle from becoming dry and cracking or forming hang-nails. Remove any loose bits of cuticle with a nipper or manicure scissors.

If a powder polish is used, first apply a bit of nail burnish cream to the nails and then the powder. Polish each nail with a chamois-covered buffer, using long strokes from left to right until the desired gloss is secured. (D. Co.)

MANIFEST, in commercial law, a document delivered to the officer of customs by the captain of a ship before leaving port, giving a description of the shipped goods of every kind, and setting forth the marks, numbers and descriptions of the packages and the names of the consignors thereof. In England, by the Revenue Act 1884, s. 3, where goods are exported for which no bond is required, a manifest must be delivered to the officer of Customs by the master or owner of the ship within six days after the final clearance, or a declaration in lieu thereof, the penalty in default being a sum not exceeding five pounds.

The U.S. Rev. Stat., § 2807, specifically sets forth the requirements of a manifest. It should list, among other items, the ports of lading and destination, names of consignees, passengers and owners of the vessel.

MANIFOLDS. Two geometrical figures are said to be *homeomorphic* if it is possible to set them into point for point continuous correspondence with one another. To illustrate: a closed curve (of the simple sort which passes through no point more than once) is homeomorphic with the circumference of a circle; the surface of a sphere is homeomorphic with the surface of an ellipsoid or of a cube, but not with a ring shaped surface such as a torus (fig. 1). The *topological* properties of a figure F are those which are shared by all figures homeomorphic with F. For instance, one of the topological properties of a line segment is its separability into two pieces by the removal of just one of its points; a non-topological property of the segment is its length. *Analysis Situs* (*q.v.*), or *Topology*, is the theory of the topological properties of figures. Theorems of analysis situs are very general in character and often synthesize results originally obtained in widely separated fields of mathematics.

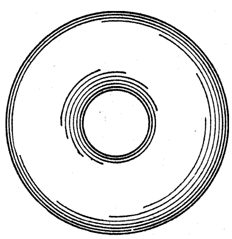


FIG. 1

n-Dimensional Manifolds.—The theory of functions of several variables leads directly to the study of a special class of figures called n-dimensional manifolds. These figures are hard to define with precision in non technical terms. We may say that a *one-dimensional manifold* is *a* simple, closed curve, a *two-dimensional manifold* a closed surface without singularities and, broadly speaking, an *n-dimensional manifold* the generalization to n dimensions of a closed curve or surface without singularities. One of the important outstanding problems of analysis situs is to classify higher dimensional manifolds into *types* such that two manifolds are of the same type if, and only if, they are homeomorphic. Up to the present, a complete classification has been carried out only for manifolds of dimensions one and two. The case $n=1$ is trivial: all one-dimensional manifolds are of the same type since every simple, closed curve is homeomorphic with the circumference of **a** circle. We shall outline below the results of the classification for the case $n=2$.

Mobius Strip.—First, it will be necessary to call attention to a rather curiously shaped surface known as a *Möbius* strip. This surface may be obtained by taking a plane rectangular region $ABCD$, where A and C denote diagonally opposite points, and deforming the region in three dimensional space so as to bring the point A into contact with the point C and the edge AB into contact with the edge CD. The resulting strip will be a belt-shaped surface with a twist in it (fig. 2). It obviously differs in type from an ordinary belt-shaped surface without the twist, since its boundary consists of a single curve, whereas the boundary of the untwisted surface consists of a pair of curves.

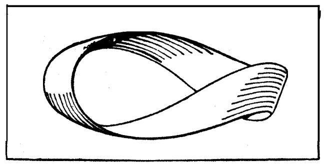

FIG. 2

A two dimensional manifold is said to be *orientable* if no **por-**

tion of it is homeomorphic with a Mobius strip; otherwise, it is said to be non orientable. The manifold is said to have the *connectivity* k if the maximum number of simple, closed curves that may be traced upon it without separating it into two or more pieces is k—1. The type of a two dimensional manifold is completely fixed when we know the connectivity of the manifold and whether or not the manifold is orientable.

A model of the most general orientable, two dimensional manifold M may be obtained by making a target out of a spherical block and shooting a suitable number of bullet holes completely through the block. The surface of the pierced block will then be homeomorphic with the manifold M. The connectivity of the manifold M is $k=2p+1$, where p is the number of bullet holes in the target; consequently. the connectivity of M is always odd in this case. The number p is called the genus of the manifold M. The sphere is of genus zero, the torus of genus one.

Genus of a Manifold.—The notion of the genus of a manifold plays an important rôle in the theory of algebraic equations of the form

$$F(x, y) = 0 \tag{1}$$

The solutions (x,y) of an irreducible algebraic equation (1) may always be represented by the points of an orientable two dimensional manifold of suitable genus p, where p is a function of the expression $F(x,y)$. Many of the properties of equation (1) depend upon the value of the number p. In Riemann's classical theory of the integrals of rational functions,

$$\int\Phi(x, y)dx, \tag{2}$$

where x and y are connected by a relation of the form (1) the genus of the manifold determined by (1) again comes into evidence. When p is zero the integral (2) is elementary, in the sense that it may be expressed in terms of rational functions and logarithms; when p is unity, the evaluation of (2) leads to the theory of elliptic functions, and so on.

A non orientable two dimensional manifold M cannot be immersed in a Euclidean space of less than four dimensions. It may, however, be represented schematically by a plane region R bounded by a suitable finite number q of non intersecting circles, where pairs of opposite points on the various bounding circles are each to be thought of as representing a single point of the manifold In four dimensional space it would be possible to reconstruct a model of the manifold M by deforming the region R in such a manner as to bring into coincidence opposite points on the bounding circles. The connectivity of the manifold M is $k=q+1$, so that, in this case, k may be any integer greater than unity. The plane of real, projective geometry (with a line of points at infinity) is a non orientable manifold of the simplest type, with k equal to two.

Combinatorial Method.—A very effective way of studying manifolds is the so-called *combinatorial* one. Consider a convex polyhedral surface in ordinary space. Regarded as a set of points, the surface is an ordinary manifold of genus zero of the same type as the sphere. But the surface may also be regarded as a collection of vertices, edges and faces. Let the number of these vertices, edges and faces be α_0, α_1, and α_2 respectively. We then find that a relation of the form

$$\alpha_0-\alpha_1+\alpha_2 = 2 \tag{3}$$

is always satisfied, irrespective of the polyhedron chosen. Now, in reality, relation (3) has an underlying topological significance. Let us use the terms *o-cell*, *1-cell* and *2-cell* to denote figures homeomorphic with the vertices, edges and faces respectively of a convex polyhedron. Then if we take any two dimensional manifold and subdivide it in a perfectly arbitrary manner into a finite number of cells we always obtain the relation

$$\alpha_0-\alpha_1+\alpha_2 = 3-k \tag{4}$$

where, this time, α_0, α_1 and α_2 denote the number of 0-, 1- and 2-cells of the subdivision respectively. Relation (3) is a special case of relation (4); where we have $k=1$, and where the cells are all straight. The number $\alpha_0-\alpha_1+\alpha_2$ is called the *Euler number* of the manifold M. In view of relation (4), a knowledge of the Euler number of a manifold is equivalent to a knowledge of the connectivity number k.

Manifolds of more than two dimensions were considered by Riemann and Betti, but Poincaré was the real founder of the higher dimensional theory. Poincaré extended to n dimensions the combinatorial method of cellular subdivision described above and discovered a number of new topological invariants. Of these last, the most important ones are his "Betti numbers" $P_1, P_2, \ldots, P_{n-1}$ which are generalizations of the connectivity number k. The Betti numbers satisfy a duality relation

$$P_i = P_{n-i}, \quad (i = 1, 2, \ldots, n-1)$$

and a generalized Euler

$$\sum_{i=0}^{n}(-1)^i\alpha_i = 1+\sum_{i=1}^{n-1}(-1)^iP_i+(-1)^n$$

which reduces to (4) in the two dimensional case. Alexander has shown that the invariants of Poincaré are insufficient to fix the type of a higher dimensional manifold, and has found further invariants which appear, also, to be insufficient. Heegaard has studied the theory of three dimensional manifolds by a somewhat different method which would, no doubt, bear further exploitation.

An important class of problems has to do with the possible types of continuous transformations of a manifold into itself. and with the existence of points left invariant by these transformations. Brouwer has studied the transformations of a sphere of n dimensions and has shown, in particular, that a one-to-one sense preserving transformation of a two dimensional sphere always leaves at least one point invariant. Lefschetz has obtained a very general theorem about the fixed points of an arbitrary transformation of an arbitrary n-dimensional manifold. Morse, Nielsen and others have made noteworthy contributions to the theory. Numerous applications are to be found for this branch of analysis situs. For example, to take a very simple case, the so-called fundamental theorem of algebra to the effect that every algebraic equation

$$F(x) = 0$$

has a root obviously reduces to the theorem that the transformation

$$y = x+F(x)$$

has a fixed point. Birkhoff and Kellogg have proved that extremely general systems of differential and integral equations admit solutions by studying the transformations of a sphere of infinitely many dimensions. (*See* also KNOTS; TOPOLOGY.)

(J. W. A.)

MANIHIKI (MANAHIKI), a scattered part of the Cook islands in the central Pacific ocean, between 4° and 11° S., and 150° and 162° W. It includes Caroline island, Vostok and Flint to the east; Suvorov, Manihiki or Humphrey. and Tongareva or Penrhyn to the west; and Starbuck and Malden to the north. Nearly all are coral atolls of small land area. There are pearl and pearl-shell fisheries at Tongareva and Suvorov; other products are copra and guano. The inhabitants are Polynesians The islands were mostly discovered early in the 19th century and were annexed by Great Britain mainly in 1888–89. They are administered by New Zealand.

MANIHOT: *see* CASSAVA.

MANILA, the premier city of the Philippines in almost all respects. It is the chief port, the major trade centre. the leading manufacturing area and the focus of political and intellectual activity of the islands. Its northeastern suburb, Quezon City, is the official national capital but Manila handles many functions of government.

Manila has grown rapidly to a 1960 population of 1,145,723 (1948 census 983,906). About 80,000 Chinese, 4,000 U.S. citizens, 2,000 Spanish and a few hundred nationals from each of several other countries give the city an international aspect.

Geography and Topography. — Manila is about 1,500 mi. from Singapore and 1,400 mi. from Nagasaki. The city lies on the eastern shore of Manila bay (*q.v.*). To the north Mt. Arayat, a sacred mountain to the early Malays, is visible from the bay; to the west are the Mariveles mountains, and to the east the terrain rises to Laguna de Bay, a large lake from which the Pasig river issues to bisect the city. Various tidewater creeks find their way through Manila, connecting with the river or directly with the bav.

The modern Manila metropolitan area includes the chartered cities of Manila, Pasay City, Quezon City and 13 separate municipalities. Urban subdivisions reach out into Rizal province, overlapping a number of rural towns, villages and barrios in which truck gardening, poultry raising and a few rice fields still are found. Northeast of Manila is the suburb and national capital of Quezon City (*q.v.*) to which the University of the Philippines was moved. On the south is the smaller area of Pasay City.

Each of the 13 municipalities that serve as administrative centres for the political districts around Manila forms an older core of urban settlement around which new subdivisions in modern style were built. On the north, along the bay, lie Navotas and Malabon, with Caloocan inland. On the northeast, just beyond Quezon City. is San Mateo. To the east, south of Quezon City, are Marikina, San Juan del Monte and Mandaluyong. On the southeast lie San Pedro Makati, Pasig, Pateros and Tagig, and on the south, beyond Pasay City, are Paranaque and Las Pinas. Outward from the city core run main highways to the north, east and south; and thousands of persons who work daily in the urban area commute distances up to 20 mi.

Local names are applied to districts that are not formal political units, such as Diliman district, where the University of the Philippines is located, Wack Wack, where a country club was established, and Santa Mesa. Grace Park, Rosario Heights and Balintawak, chiefly residential subdivisions.

As there are three Romes so there are three Manilas. There is the native Malay element indicated by pile-built houses of nipa palm thatch and bamboo thickly packed together along narrow streets and tidal creeks. There are the bits and pieces of Spanish medieval, reduced to remnants during World War II. Finally there is the Americanized modern element in the city (sometimes clearly of U.S. origin and sometimes a subtle blend of American, Malay and Spanish) indicated by public buildings, docks and warehouses, bridges, wide streets crammed with automobiles, the newer hotels, apartment houses, private houses built in contemporary U.S. styles, the country clubs and the airports.

The city of Manila proper is divided into 14 districts of unequal size, population and appearance. The most populous district is Tondo; north of the Pasig river and fronting the bay, it is still largely a native Malay zone. San Nicolas, Binondo, Santa Cruz, San Miguel and Quiapo, just north of the Pasig, are the heart of old Manila and of the business district, with Chinese stores, embroidery shops, banks, shipping offices, theatres and the Escolta— the famous business street — plus a tightly jammed residential zone.

Just out of the retail district, along the Pasig in San Miguel, is the Malacaiian palace, formerly the residence of Spanish and U.S. governors and later the home of the Philippine president. To the east Sampaloc, the largest district and formerly a native residential area, gradually became largely a business section.

Four bridges cross the Pasig river within the main part of the city, offering access to the seven southern districts'. On the bay front is the Port Area, a result of U.S. dredging of the harbour and construction of docks and warehouses. Although it was later dwarfed by a larger port district north of the Pasig, between San Nicolas, Tondo and the bay, most of the companies and government offices dealing in shipping services remained in the Port Area.

Just inland from this is the old walled city of Spanish times, the Intramuros, with its 20-ft. walls stretching for two and one-half miles. About 1905 the old moat was filled and much of the space outside the wall was converted into gardens, playgrounds and a golf course. By the end of World War II only the church of St. Augustine was left intact within the Intramuros. South of the Port Area and the Intramuros lie Burnham Green, the Luneta and Wallace field, Manila's "common." Southward along the bay, Dewey boulevard and Taft avenue lead through the older residential zones, where many government bureaus, the general hospital and other institutions were established.

Ermita and Malate, the two districts involved, remained choice residential area;, and large houses and apartment houses were rebuilt there after World War II. Inland lie the chiefly middle-class

SAINT AUGUSTINE CHURCH. BUILT IN THE **16TH** CENTURY. WAS THE ONLY CHURCH INSIDE **INTRAMUROS** NOT DESTROYED DURING WORLD WAR II

residential areas of Paco, Pandacan and Santa Ana.

Climate. — The climate of Manila is similar to that of lowlands along the Philippine west coasts, having two pronounced seasons in rainfall but only mild seasonality in temperature. Weather is normally dry during January through April and rainy the rest of the year, particularly from June through October. July, normally the rainiest month, has high humidity and frequent thundershowers —24 rainy days as opposed to 3 rainy days in February. The annual total of 159 rainy days produces an average of 81.52 in., but annual variation is marked, ranging from 35.69 in. in 1885 to 154.35 in. in 1919. In temperature March through June is the warmest period, with May having a monthly mean of 83.4"; November through February is the cooler period, January having a monthly mean of 76.8°.

History. — The first European settlement at Manila was established by Miguel López de Legazpi in 1571. At that time a Mohammedan rajah (Lakandola) reigned in Tondo. Manila became the capital and Lagazpi the first governor of the Philippines. The islands were placed under the viceroy of New Spain in Mexico City, and official communication between the two widely separated areas was maintained by a galleon which plied annually between Acapulco and Manila. Trade of considerable proportions was developed.

Accompanying Legazpi to the islands was an Augustinian friar, Urdaneta, with others of that order, some of whom went on to Manila. In 1577 arrived Franciscans, who were followed by Dominicans, Jesuits and Augustinian Recollectos. These orders founded convents, churches and schools and became very powerful in the government. In 1580 the first and only Roman Catholic bishop of Manila arrived in the person of Domingo de Salazar, a Dominican; but in 1595 the diocese was raised to a metropolitan see. and Ignacio Santibañez became the first of a long line of Spanish archbishops which ended with Nozaleda about 1900. In 1583 an *audiencia* (supreme court) was established. Abolished later, it was re-established in 1558 and continued as a Spanish institution for three centuries. The Spanish law was applied in those portions of the archipelago actually ruled by Spain; but the Spanish civil code came into force there only in 1889.

In the 17th century Spain warred with the Dutch and Moros, and Manila was menaced repeatedly. In 1762. the city was captured by British forces under Gen. William Draper and Adm. Samuel Cornish, who held it until 1764, the treaty of Paris (1763) having restored it to Spain. The 19th century was marked by some signs of progress. In 1825 Russell and Sturgis of Boston opened a branch of their Canton mercantile house—the first U.S. enterprise in the Philippines—and in 1837 the city was opened generally to foreign trade.

On the completion of the Suez canal a generation later, direct means of communication with Europe were provided and commerce accordingly was stimulated. The first Masonic lodge was founded at Cavite, near Manila, in 1856, and the Katipunan, a revolutionary society, borrowing some of its features from Masonry but never sanctioned by the Filipino nationalist leader José Rizal y Mercado, acquired a large following. The execution of Rizal on Dec. 30, 1896, was the signal for the outbreak of revolution, and the Spanish-American War brought Commodore George Dewey and his U.S. fleet, which destroyed the Spanish fleet at Cavite on May 1, 1898. Manila surrendered to the United States forces on Aug. 13, and for nearly 44 years the U.S. flag floated continuously over the city. The Japanese invasion on Dec. 8, 1941 (Philippine time), and Japanese occupation of the city on Jan. 2, 1942, was its fourth capture by a foreign power.

Liberation of greater Manila from Japanese control was accomplished by the end of Feb. 1945, and reconstruction began throughout the city, which had suffered greatly from war devastation. A significant change in the appearance of the city was brought about by its rapid industrialization; from 1950 to 1956 industrial capacity of the area increased 50%. In order to accommodate the expanding population many private houses and older two-story constructions were replaced with apartment buildings. The historic Intramuros area was cleared of debris and a reconstruction scheme was proposed in the early 1960s. The rehabilitation program in Manila, as throughout the Philippines, was assisted by war damage payments by the U.S.; see PHILIPPINES, REPUBLIC OF THE.

(C. S. L.; J. E. SR.; R. E. HE.)

Educational and Religious Institutions.— Most of the early schools and churches in the islands were founded in Manila by religious orders. The Dominican order founded the University of Santo Tomas in 1619 and the Collegio de San Juan de Letran in 1640. As early as 1601 the Jesuit order founded the Collegio de San José, and in 1859, after the order returned to the islands, it established the Escuela Municipal, which later became the Ateneo de Manila. The Augustinians (the original order and the Augustinian Recollectos) also have churches and convents.

The Protestant churches generally supported the public schools; a union theological school—Ellinwood seminary—was established for the training of Protestant ministers. The imposing Episcopal cathedral of St. Mary and St. John is located in Ermita, as is the Union (formerly Presbyterian) church.

There are a number of private technical schools, colleges and universities in greater Manila. Of these, the Far Eastern university was the largest in the second half of the 20th century. At the apex of the public school system are three national institutions, the Philippine Normal college, the Philippine College of Commerce and the University of the Philippines, in the Diliman district of Quezon City.

Administration.— Under Spain the city formed part of a province of the same name, which was abolished by the U S. government after about three years of military rule. On July 31, 1901, by an act of the Philippine commission, Manila became the first of the Philippine chartered cities; other municipalities of the old province became part of the new province of Rizal. The so-called administrative code of 1917, amended in 1921, provided for a mayor appointed by the governor general (later by the commonwealth president) and confirmed by the senate, and a municipal board of ten members elected at large and serving for three years. Administrative departments were: engineering and public works, police, law, fire, finance. assessment, health and welfare.

On gaining independence in 1946, the Philippine government made the officeof mayor in all chartered cities and municipalities elective, though the Philippine president exercised executive authority thereafter with regard to various of the chartered cities. There also are elective councils for each of the chartered cities. Because the national government's seat is in Manila and Quezon City, none of the cities and municipalities in greater Manila operates with complete autonomy; all are peculiarly subject to controls and influence from congress and the executive department.

Trade and Industry.— Greater Manila is by far the most important manufacturing center in the islands, having about one-half of the assets, one-quarter of the value of production and one-third of the persons engaged in manufacturing in the country. Growth in and around Manila continued to be rapid after World War II. The circumferential highway around the city was a particular focus of development during the late 1950s. Manufacturing in the city includes textiles and clothing, food and beverage processing, fish canning, vegetable oil pressing, lumber veneer and plywood manufacture, production of chemicals and drugs, leather tanning and manufacturing, light metal fabrication and shipbuilding. Manila is the heart of most service facilities in the islands, the nerve centre of financial and political activity, and the centre of educational and medical facilities. About one-half of all professional persons in the country live in greater Manila. See also Index references under "Manila" in the Index volume. (J. E SR.; R. E. HE.)

MANILA BAY, an almost completely landlocked bay extending into the Philippine island of Luzon from the South China sea. Its widest diameter from northwest to southeast measures 36 mi. and from Corregidor Island to the piers in Manila harbour is 30 mi. The bay has two entrances, one on either side of Corregidor (*q.v.*); the seldom used South channel is 6 mi. wide while the busy and safer North channel between Corregidor and Bataan peninsula is only 2 mi. wide. The north and northeast shore of Manila bay adjoins the central plain of Luzon. In this section the bay is shallow and lined by mud flats and mangrove; here are located the most extensive commercial fish ponds in the Philippines. The major part of the bay is between 30 and 120 ft. in depth; it has only a moderate tidal range and provides good to excellent anchorage. Manila harbour at the easternmost part of the bay is divided into two sections, North harbour for interisland ships and South harbour for international shipping; both have excellent docking facilities. Sangley Point, a U.S. naval reservation near Cavite city on the southeast shore, provides servicing for naval vessels. Bolanga on the western shore is home base for a small fishing fleet. In 1574 the Chinese pirate Lim-Ah-Hong sailed into Manila bay but was repulsed by Spanish forces. The bay was the western terminus of the Manila-Acapulco "galleon trade" between 1593 and 1815. The Spanish fleet was destroyed in the bay by a U.S. squadron under the command of Commodore George Dewey on May 1, 1898. During World War II many Philippine, American and Japanese ships were sunk at Manila, Cavite, Corregidor and several other locations by aerial bombardment. *See* WORLD WAR II: *The War in the Pacific.* (R. E. HE.)

MANILA HEMP: *see* ABACÁ FIBRE.

MANILIUS, MARCUS (fl. early 1st century A D.), Roman didactic poet, was the author of *Astronomica,* an unfinished poem on astronomy and astrology, of which five books remain. The poem consists of over 4.000 hexameters and was composed in the reigns of Augustus and Tiberius. To the reader unversed in astrological calculations the interest chiefly resides in the attractive prefaces to each book and the mythological or moralizing digressions Manilius, writing as a Stoic, stresses the providential government of the world and the operation of divine reason. His style shows indebtedness to Lucretius, Virgil and Ovid. He abuses his unparalleled facility for versifying astronomical computations and habitually substitutes the complex for the simple. Rarely read *in tòto* even by Latinists, he has been given unexpected publicity by the five brilliant volumes of A E. Housman.

Housman, *M Manilii Astronomicon, j* vol, 2nd ed. (1937) *See* also G *P* Goold, "De fonte codicum Manilianorum," *Rheinisches Museum,* vol xcvii (1954). (H. H HY.)

MANIN, DANIELE (1804–57), Venetian patriot and statesman, was born in Venice, on May 13, 1804. He was the son of a converted Jew, who took the name of Manin because that patrician family stood sponsors to him, as the custom then was. He studied law at Padua, and then practised at the bar of his native city. A man of great learning and a profound jurist, he was inspired from an early age with a deep hatred for Austria. The heroic but foolhardy attempt of the brothers Bandiera. Venetians who had served in the Austrian navy against the Neapolitan Bourbons in 1844, was the first event to cause an awakening of Venetian patriotism, and in 1847 Manin presented a petition to the Venetian congregation, a shadowy consultative assembly tolerated by Austria but without any power, informing the emperor of the wants of the nation. He was arrested on a charge of high treason (Jan. 18, 1848), but this only served to increase the agitation of the Venetians, who were beginning to know and love Manin. Two months later, when all Italy and half the rest of Europe were in the throes of revolution, the people forced Count Palffy, the Austrian governor, to release him (March 17). The Austrians soon lost all control of the city, and under the direction of Manin a civic guard and a provisional government were instituted.

The Austrians evacuated Venice on March 26, and Manin became president of the Venetian republic. He was already in favour of Italian unity, and though not anxious for annexation to Piedmont (he would have preferred to invoke French aid) he gave way to the majority, and resigned his powers to the Piedmontese commissioners on Aug. 7. But after the Piedrnontese defeats in Lombardy, and the armistice by which King Charles Albert abandoned Lombardy and Venetia to Austria, the Venetians attempted to lynch the royal commissioners, whose lives Manin saved with difficulty; an assembly was summoned, and a triumvirate formed with Manin at its head. Toward the end of 1848 the Austrians, having been heavily reinforced, reoccupied all the Venetian mainland. Early in 1349 Manin was again chosen president of the republic and conducted the defense of the city.

After the defeat of Charles Albert's forlorn hope at Novara in March the Venetian assembly voted "Resistance at all costs!" and granted Manin unlimited powers. Meanwhile the Austrian forces closed round the city; but Manin, assisted by G. Pepe, showed an astonishing power of organization. On May 26, however, the Venetians were forced to abandon Ft. Malghera, halfway between the city and the mainland; food was becoming scarce, on June 19 the powder magazine blew up and in July cholera broke out. Then the Austrian batteries began to bombard Venice itself, and when the Sardinian fleet withdrew from the Adriatic the city was also attacked by sea, while certain demagogues caused internal trouble. At last, on Aug. 24, 1849, Manin, who had courted death in vain, negotiated an honourable capitulation, on terms of amnesty to all save Manin himself, Pepe and some others, who were to go into exile.

On the 27th Manin left Venice forever on board a French ship. His wife died at Marseilles, and he himself reached Paris broken in health and almost destitute, having spent all his fortune for Venice. In Paris he became a leader among the Italian exiles. There he became a convert to monarchism, being convinced that only under the auspices of King Victor Emmanuel could Italy be freed, and together with Giorgio Pallavicini and Giuseppe La Farina he founded the *Società Nazionale Italiana* with the object of propagating the idea of unity under the Piedrnontese monarchy.

His last years were embittered by the terrible sufferings of his daughter, who died in 1854; and he himself died on Sept. 22, 1857, and was buried in Ary Scheffer's family tomb. In 1868, two years after the Austrians finally departed from Venice, his remains were brought to his native city and honoured with a public funeral.

Manin was a man of the greatest honesty and possessed genuinely statesmanlike qualities. He believed in Italian unity when most men, even Cavour, regarded it as a vain thing, and his work of propaganda by means of the National society greatly contributed to the success of the cause.

MANING, FREDERICK EDWARD (1812–1883), New Zealand judge and author, son of Frederick Maning, of Johnville, county Dublin, was born July 5, 1812. His father emigrated to Tasmania in the ship "Ardent" in 1824 and took up a grant of land there. Young Maning served in the fatuous expedition which attempted to drive in the Tasmanian blacks by sueeping with an unbroken line of armed men across the island. Soon afterward he decided to try the life of a trader among the wild tribes of New Zealand and, landing in the inlet of Hokianga in 1833, took up his abode among the Ngapuhi. With them the tall Irish lad—he stood *6* ft. 3 in.—full of daring and good humour and as fond of fun as of fighting, quickly became a prime favourite, was adopted into the tribe, married a chief's daughter and became a "Pakeha-Maori" (foreigner turned Maori). With the profits of his trading he bought a farm of 200 ac. on the Hokianga, for which, unlike most white adventurers of the time, he paid full value. When New Zealand was peacefully annexed in 1840, Maning's advice to the Maori was against the arrangement, but from the moment of annexation he became a loyal friend to the government, and in the wars of 1845–46 his influence was exerted with effect in the settlers' favour. Again, in 1860, he persuaded the Ngapuhi to volunteer to put down the insurrection in Taranaki. From 1865 to 1881 he was a judge of the native lands court, where his unequalled knowledge of the Maori language, customs, traditions and prejudices was of solid value. He died in London on July 25, 1883. At his wish, his body was taken back to New Zealand and buried there. Maning wrote *Old New Zealand* and *History of the War in the North of New Zealand against the Chief Heké,* reprinted in London in 1876 and 1884.

MANIPLE, a liturgical vestment of the Catholic Church, proper to all orders from the subdeacon upward. It is a narrow strip of material, silk or half-silk, about a yard long, worn on the left fore-arm in such a way that the ends hang down to an equal length on either side. In order to secure it, it is sometimes tied on with strings attached underneath, sometimes provided with a hole in the lining through which the arm is passed. It is ornamented with three crosses, one in the centre and one at each end, that in the centre being obligatory, and is often elaborately embroidered. It is the special ensign of the office of subdeacon and at the ordination is placed on the arm of the new subdeacon by the bishop with the words: "Take the maniple, the symbol of the fruit of good works." It is strictly a "mass vestment," being worn, with certain exceptions (*e.g.,* by a deacon singing the Gospel at the service of blessing the palms), only at mass, by the celebrant and the ministers assisting.

The earliest extant specimen of the bandlike maniple is that found in the grave of St. Cuthbert (early 10th century); by the 11th century (except in the case of subdeacons, whose maniples would seem to have continued for a while to be cloths in practical use) the maniple had universally assumed its present general form and purely ceremonial character.

The maniple mas originally carried in the left hand. In pictures of the 9th, 10th and 11th centuries it is represented either as so carried or as hung over the left fore-arm. By the 12th century the rule according to which it is worn over the left arm had been universally accepted. According to present usage the maniple is put on by priests after the alb and girdle; by deacons and subdeacons after the dalmatic or tunicle; by bishops at the altar after the *Confiteor*, except at masses for the dead, when it is assumed before the stole.

In the east the maniple in its western form is known only to the Armenians, where it is peculiar to subdeacons. This vestment is not derived from the Roman rite but is properly a stole, which the subdeacons used to carry in the left hand. It is now laid over the subdeacon's left arm at ordination. The true equivalent of the maniple (in the Greek and Armenian rites only) is not. as has been assumed, the *epimanikion,* a sort of loose, embroidered cuff *(see* VESTMENTS), but the *epigonation.*

See J. Braun, S. J., *Die liturgische Gewandung* (1907), pp. 515–561, and the bibliography to VESTMENTS.

MANIPUR, a territory of the Republic of India, against that country's frontier with Upper Burma. Area 8,629 sq.mi. Pop. (1951) 577,635. Its western districts project into Assam state and are bounded on the north by the Naea country and the hills overlooking the Assam valley, on the west by Cachar district and on the south by the Lushai hills. The capital is Imphal (pop., 1951, 2,862). The state consists of the wide valley of the Manipur river. a tributary of the Chindwin, with an area of about 650 sq mi.. and a large surrounding tract of mountainous country. The hill ranges generally run north and south. with occasional connecting spurs and ridges of lower elevation between. Their greatest altitude is in the north. where they reach to more than 8,000 ft. above sea level. The principal geographical feature in the valley is the Loktak lake. over 25 sq.mi. in area, but said to be gradually growing smaller. The state is watered by numerous other rivers, the Barak in the west being the most important. The hills are densely covered with tree jungle and large forest timber. Rice and forest produce are the principal exports. The road from Imphal northward to the North-Eastern railway at Dimapur, Assam. and southeast to Tamu on the Burmese border, is the principal trade route.

Although their general facial characteristics are Mongolian, there is a great diversity of feature among the Manipuris, some of them showing a regularity approaching the Aryan type. In the valley the people are chiefly Hindus, that religion being of recent introduction. Their own name for themselves is Meithei, and their language is a branch of the Kuki-Chin family. One of their peculiarities is the high position enjoyed by women, who conduct most of the trade of the valley. The aboriginal hillmen belong to one of the two great divisions of Nagas and Kukis, and are subdivided into innumerable clans and sections. The state is noted for the excellence of its breed of ponies.

The first relations of the British with Manipur date from 1762, when the rajah solicited British aid to repel a Burmese invasion and a treaty was concluded. Little further communication took place until 1824, on the outbreak of the first Burmese War. British assistance was again invoked by the rajah, and the Burmese were finally expelled from both the Assam and the Manipur valleys. Disputed successions became a continuous cause of trouble. In 1890 a brother of the rajah. the *senapati* or commander in chief, dethroned the rajah and installed the *jubraj* or heir apparent as rajah. In 1891 the chief commissioner of Assam (James Wallace Quinton) marched to Manipur with 400 Gurkhas, in order to recognize the new ruler and remove the *senapati.* An attempt was made to arrest the *senapati,* but after some sharp fighting he escaped. The Nanipuris then attacked the British residency with an overwhelming force. An armistice having been declared, Quinton with the political resident (Frank St. Clair Grimwood) and three other officers went to the fort, under promise of safe conduct, to negotiate. They were all treacherously murdered. The attack on the residency was resumed and the defenders, thinking it untenable, retreated to Cachar, taking Mrs. Grimwood and the wounded with them. A month later a military expedition occupied Manipur. The *senapati* was captured, tried and hanged and the new rajah transported for life. It was decided to preserve the existence of the state, and a five year old child of the ruling family, named Chura Chand, was nominated rajah.

During his minority the administration was conducted under British supervision. The opportunity was seized to abolish slavery and unpaid forced labour, to open up the state by roads and to introduce other reforms. In 1907 the government of the state was handed over to the rajah and durbar, or council, with a member of the Indian civil service as vice-president. Subsequently the administration of the state was transferred to the rajah from the durbar, of which the vice-president became president.

During World War I a corps of 2,000 labourers was raised in Manipur and sent to France. When an attempt was made to raise a second corps in 1917, the Kukis broke out in rebellion, which was not suppressed until the cold weather of 1918–19 by a large force of Assam Rifles and Burma military police.

A new system of administration was adopted after this, three subdivisions being established, each under an officer lent by the Assam government. After the accession of the state to India (Aug. 15, 1947) the political agency exercised by Assam was abolished; on Oct. 1j, 1949, the administration was taken over by the Indian government and effected through a chief commissioner.

MANISA (anc. *Magnesia* **ad** *Sipylum*), the chief town of the Manisa *vilayet* (province) in Turkey, situated in the valley of the Gediz Chai (Hermus). at the foot of Mt. Sipylus, and connected by railway with Smyrna and Afium Kara-Hissar. Population (1955) 45,484. Manisa is an important commercial centre, and contains interesting buildings dating from the times of the Seljuk and early Osmanli sultans, including mosques built by Murad II and III and a Mevlevi *Tekke* second only to that at Konia.

In 1204 Manisa mas occupied by John Ducas, who when he became emperor made it the Byzantine seat of government. In 1305, Roger de Flor besieged it unsuccessfully. In 1313 the town was taken by Saru Khan and became the capital of the Turcoman emirate of that name. In 1398 it submitted to the Osmanli sultan Bayezid I, and in 1402 was made a treasure city by Timur. In 1419 it was the scene of the insurrection of Bedr ed-Din, which was crushed by Prince Murad, residing in the town as Murad II. In the 17th century Manisa became the residence of the greatest of the Dere Bey families, Kara Osman Oglu, Turcoman in origin, and possibly connected with the former emirs of Sarukhan, which seems to have risen to power by farming the taxes of a province which princes of the house of Othman had often governed and regarded with especial affection. The *liva* of Sarukhan was one of the 22 in the Ottoman empire leased on a life tenure up to the time of Mahmud II.

In the 18th century the family of Kara Osman Oglu (or Karasman) ruled *de facto* all west central Anatolia, one member being lord of Bergama and another of Aidin, while the head of the house held Manisa with all the Hermus valley and had greater power in Smyrna than the representative of the capitan pasha in whose province that city nominally lay. Outside their own fiefs the family had so much property that it was commonly said they could sleep in a house of their own at any stage from Smyrna to Baghdad. The last of its great beys was Haji Hussein Zade, who was frequently called in to Smyrna on the petition of his friends, the European merchants, to assure tranquillity in the troublous times consequent on Napoleon's invasion of Egypt and the British and Russian attacks on the Porte early in the 19th century. He always acquitted himself well; but, since he refused to bring his contingent to the grand vizier when on the march to Egypt in 1798 and awakened the jealousy of the capitan pasha, he was in continual danger. Exiled in 1812, he was subsequently restored to Manisa. and died there in 1821. His son succeeded after sanguinary tumults; but Mahmud II. who had long marked the family for destruction, was so hostile toward it, after he had disposed of the janissaries, that it had lost al! but the shadow of power by 1830. Descendants survived in Manisa who retained a special right of granting title deeds within the district, independent of the local administration.

MANISTIQUE, city and seat of Schoolcraft county in the Upper Peninsula of Michigan, U.S., lies at the mouth of the Manistique river on the north shore of Lake Michigan about 40 mi. N.E. of Escanaba. It was incorporated as a village in 1885, chartered as a city in 1901, and adopted a city-manager form of local government in 1926. Manistique originated as a lumbering centre, and much of its pine went to help build many midnestern cities, including Chicago. Its natural harbour. kept relatively ice free by the swift current of the Manistique river, makes it an important commercial fishing port Wood and paper products are among its principal manufactures. The area is rich in Indian folk-lore, and sites include the allegedly haunted Big Spring or Kitchitikipi in the woods adjoining Indian lake (5 mi. W.), said to have been worshipped by the Chippewa tribe. (B. L. F.)

MANITO (MANITOU or MANITU), a term for supernatural power used by the Algonkian-speaking Indians of eastern North America. Generally it was attributed to various deities and nature spirits, who might become protectors or guardians as well as causing ill-fortune. In some tribes the manito was personified as the supreme deity, perhaps as a result of Christian teachings. (F. R. E.)

MANITOBA, a province of Canada, situated midway across the North American continent. Area 251,000 sq.mi., of which 39,225 sq.mi. are fresh water. Although known as one of the three "prairie" provinces (with Saskatchewan and Alberta), Manitoba possesses great diversity and only a small portion is treeless prairie. The remainder consists of parkland, forest interspersed with lakes, and subarctic tundra, and the province has 400 mi. of coast on Hudson bay. It is bounded by the U.S. on the south, Saskatchewan on the west, Mackenzie District on the north, and Ontario on the east. The whole of the province falls within the central time zone, which is six hours behind Greenwich time.

Geology and Physiography. — The Pre-Cambrian shield (see map), covering three-fifths of the province, is made up of ancient rocks (gneisses, granites, etc.); it forms hilly broken ice-worn country with numerous lakes, and is drained noriheast to Hudson bay by the Seal, Churchill and Nelson rivers. The Hudson bay lowland, the land sloping down from the shield to the sea, is built of horizontal Palaeozoic limestones. The Manitoba lowland, southwest of the shield, is a basin that once held the great glacial lake known as Lake Agassiz. The several large lakes found in this lowland today are its remains and include some of the largest lakes in Canada: Lake Winnipeg (9,094 sq.mi.), Lake Winnipegosis (2,086 sq.mi.), Lake Manitoba (*qq.v.*) (1,817 sq.mi.), Cedar lake (537 sq.mi.) and Moose lake (525 sq.mi.). The Red river valley forms the southern part of the lowland and its fertile soils derive from the lacustrine clays deposited there by Lake Agassiz. The Manitoba escarpment (or cuesta) terminates the lowland on its southwest side; this feature has been broken up by rivers (of which the Assiniboine is the chief) into hilly areas known as the Porcupine, Duck and Riding mountains. The Saskatchewan plain, composed of Cretaceous shales with a covering of glacial boulder clays and lacustrine clays, extends westward from the escarpment into Saskatchewan.

Climate. — The climate is extreme or continental, with very cold winters and warm summers. In winter the temperature may fall to $-40°$ F. and below in all parts of the province. The average minimum January temperature is $-13°$ at Winnipeg and $-27°$ at Churchill. The average maximum January temperature is $7°$ at Winnipeg and $-11°$ at Churchill. Sudden changes of temperature of up to $40°$ may occur within 24 hours in winter. Spring is a brief season in which temperatures rise rapidly in May after the April thaw. June, on the average, is about $25°$ warmer than April.

Summer temperatures often exceed $90°$ F. and occasionally reach $100°$ in the south, but nights are relatively cool. The average minimum July temperature at Winnipeg is $55°$, at Churchill $43°$; the average maximum July temperature is $79°$ at Winnipeg and $64°$ at Churchill. Violent electrical storms accompanied by heavy rain and often hail occur in summer. Autumn often has prolonged periods of dry sunny weather with mild days and frosty nights. Annual precipitation, occurring mostly in the suinmer months, ranges from 15 in. in the north and west to 20 in. in the south and east. Most of the province receives over 2,000 hours of sunshine a year.

Vegetation and Animal Life. — Except for a belt cf barren tundra along the Hudson bay shore and a small area of prairie along the U.S. border in the south, the natural vegetation of Manitoba is forest. North of the prairie comes an open parkland with such trees as the aspen, Manitoba maple, elm and bur oak. This gives way to a mixed forest, where coniferous species are found along with deciduous trees. Next, beginning at the southern edge of the Canadian shield, comes the full development of northern coniferous forest with spruce, larch, pine and fir. This degenerates northward into subarctic forest where the trees become smaller and fewer until open tundra is reached.

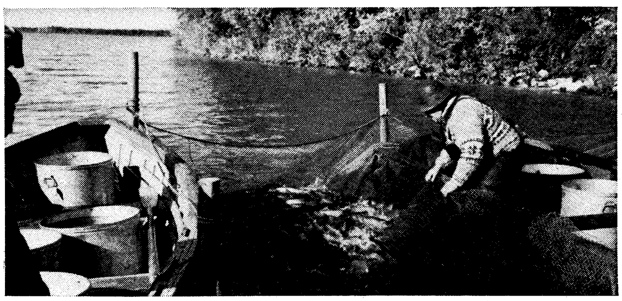
The bison, antelope and elk, which flourished on the prairie before the white man came, have vanished. The principal prairie animals are gophers, badgers, coyotes and jack rabbits, and among the birds are prairie chicken, grouse, gull, and mallard and black duck. In the forests, the black bear, moose, timber wolf, fox, otter, skunk, marten, mink and weasel may be found. along with such rodents as the squirrel and beaver. A variety of fish inhabit the lakes (see ***Fishing,*** below).

History. — Southern Manitoba was inhabited by Blackfoot. Sarcee, Assiniboine and Ojibwa (Chippewa) Indians, with Eskimos farther north along the shores of Hudson bay. The first white man to enter the territory was probably Sir Thomas Button, who entered the Nelson river in 1612; seven years later two Danish ships wintered at the mouth of the Churchill. After its foundation in 1670, the Hudson's Bay company began to build forts in the area, the chief of which was York Factory at the mouth of the Nelson. From here, in 1691–92 Henry Kelsey explored parts of the province in the direction of the Saskatchewan river. In 1717 a wooden fort, Fort Prince of Wales, was built at the mouth of the Churchill; this was rebuilt in stone (1731–76).

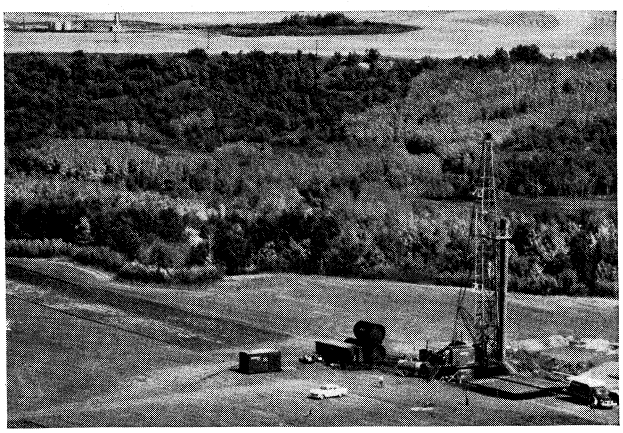
Throughout the 18th century the area was affected by the Anglo-French feud. The Hudson bay region was recognized as British by the treaty of Utrecht in 1713, but the French entered Manitoba' from the east. In 1731 La Vérendrye crossed southern Manitoba and in 1738 the French built Fort Rouge at the future site of Winnipeg. After the British conquest of Canada this rivalry was continued by the Hudson's Bay company, operating southward from York Factory, and the Northwest company of Montreal, the successor of the French fur traders. The routes from the north and the east met at "the Forks" or junction of the Red and Assiniboine rivers (Winnipeg). There the Northwest company built Fort Gibraltar (1804). It was in this disputed area that Lord Selkirk, in 1812, began the first agricultural settlement on the Red river (see RED RIVER SETTLEMENT). A struggle ensued in which the Northwest company destroyed the colony and the Hudson's Bay company destroyed Fort Gibraltar. Yet colonists still arrived, despite the harsh journey by way of Hudson bay. Numerous half-breeds (métis) swarmed around the colony and trading post. In 1821 the rival companies amalgamated and a new fort, Fort Garry, was built, first of wood, but later, in 1836–39, of stone. The whole territory was then under the jurisdiction of the Hudson's Bay company.

In 1867 the Red river colonies became linked by steam navigation with the westward development of settlement and railways in the United States. and settlers began to pour into the region from the south; they came from eastern Canada, the British Isles and continental Europe. In 1869 the newly formed Dominion of Canada acquired the territory from the Hudson's Bay company, and in the unsuccessful Riel rebellion of that year the métis took up arms against the new order. In 1870 the province of Manitoba was

Harvesting wheat near Portage la Prairie. Grown chiefly in the southern part of the province, wheat is Manitoba's most important field crop



Commercial fishermen netting a catch from one of Manitoba's many lakes. Only Alberta outranks Manitoba in the development and value of its inland fisheries



Oil derrick in the plains region of southwestern Manitoba. Although not commercially produced until after World War II, petroleum became the most valuable mineral industry of the province

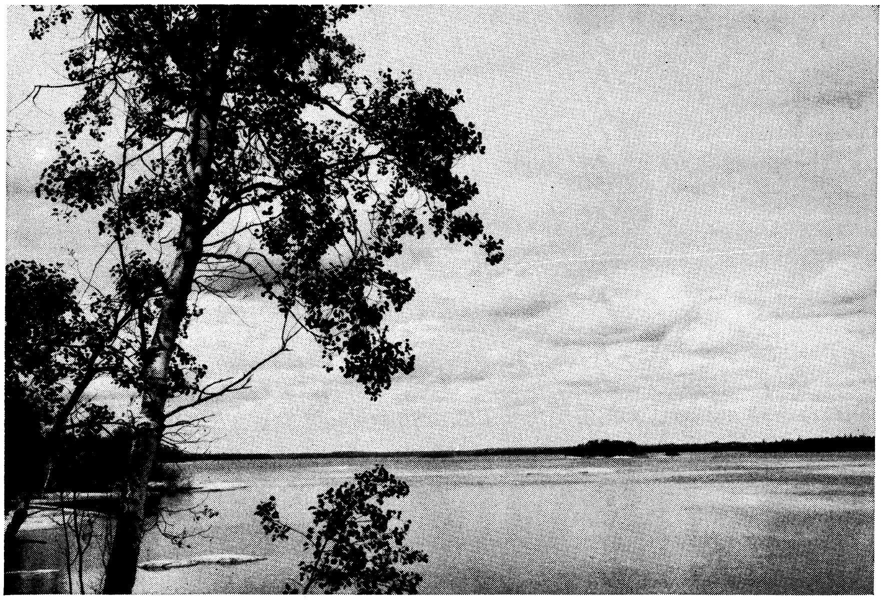
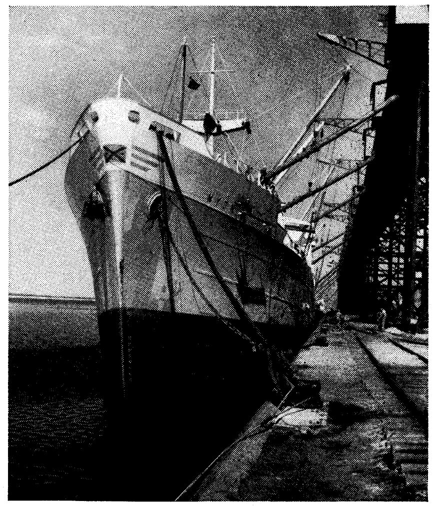
MANITOBA



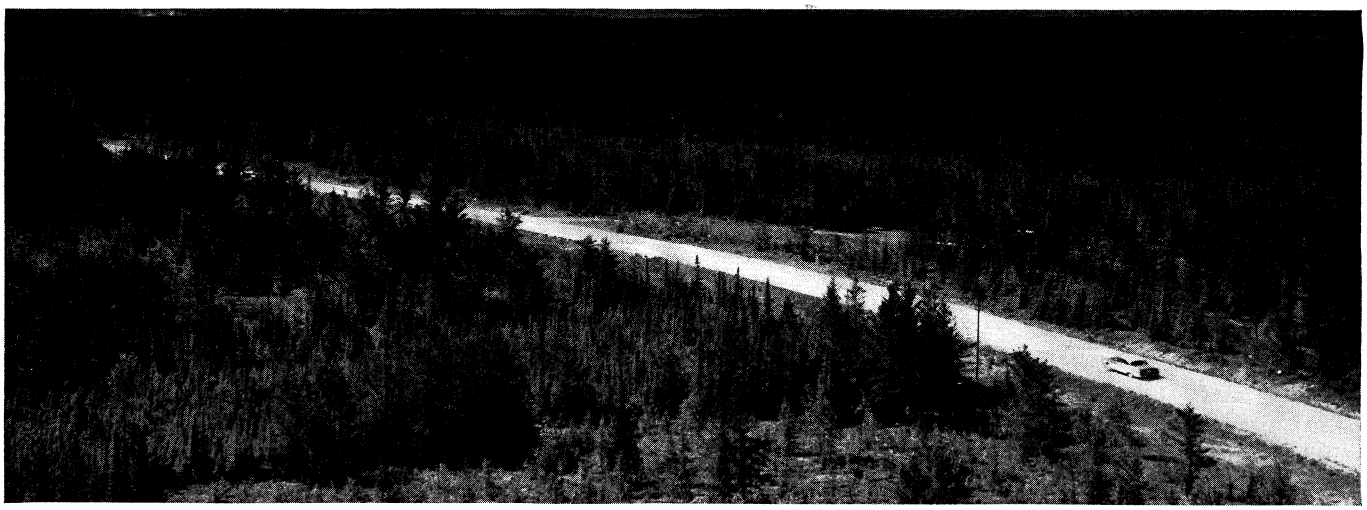
View along the Winnipeg river in the Whiteshell forest and game reserve near the Ontario border. Once a route used by explorers and trappers, the river now supplies most of the hydroelectric power of Manitoba



Ocean-going freighter tied up at Churchill, chief seaport of Manitoba, on Hudson bay. Wheat is the major item of export

Freight yards at Winnipeg, among the largest in the world. Its central location made Winnipeg the principal rail and air centre of western Canada

Miners preparing to drill into ore face in one of the pits at Flin Flon, the chief mining and smelting centre of Manitoba



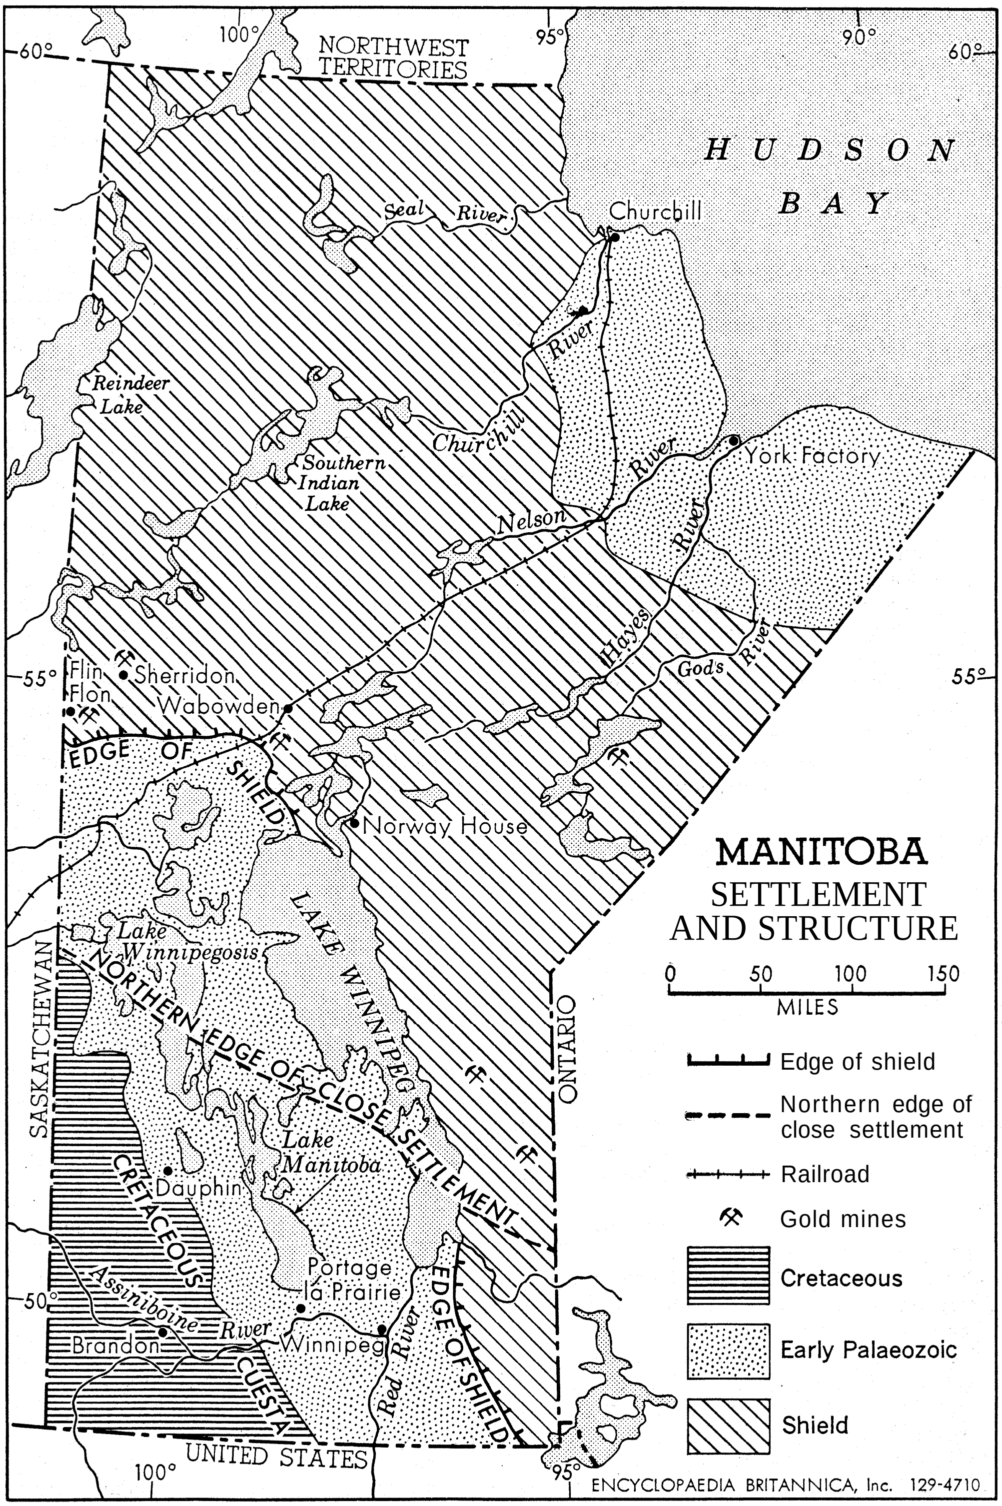
Highway through the forest region of northern Manitoba. Only small sections in the east have been cut over for paper and pulp. The remainder is virgin timber, and the area is largely unpopulated

TRANSPORTATION AND INDUSTRY

BY COURTESY OF (TOP LEFT) MANITOBA TRAVEL AND PUBLICITY BUREAU, (TOP RIGHT, BOTTOM) PROVINCE OF MANITOBA, DEPARTMENT OF INDUSTRY AND COMMERCE, (CENTRE RIGHT) CANADIAN CONSULATE GENERAL, CHICAGO: PHOTOGRAPH, (CENTRE LEFT) KARSH OF OTTAWA FROM PUBLIX set up and entered the federation. The town of Winnipeg grew rapidly around Fort Garry after 1870 and was linked by rail with the U.S. in 1878 and with eastern Canada in 1881. Immigrants came in still larger numbers by rail to Winnipeg and spread over the province to the west, breaking up the virgin land; wheat flowed eastward in increasing quantities. To provide an additional outlet for this growing agricultural production, a railway to Hudson bay was begun in 1910, but work had to be abandoned with the outbreak of World War I; it was resumed again in 1926 and completed to the port of Churchill in 1929. The population of Manitoba, which was 25.000 in 1871, had passed 250,000 by 1901 and reached 700.000 in 1931. The boundaries of the province were extended in 1881 and again in 1912.

The 1930s were years of depression and drought. After World War II there was a greater diversification of agriculture, increased industrial expansion and mining activity.

Population.—With a population of 850,040 in 1956, and 921,-686 in 1961, Manitoba was sixth among the Canadian provinces. The rate of growth was very slow during the economically difficult period from 1931 to 1946, when immigration almost ceased and there was much migration from the province. After 1946 the increase was marked; it amounted to 123.117 in the intercensal period 1946–56, compared with 26.784 in the preceding 15 years. Urban population increased rapidly while rural inhabitants became less numerous; between 1941 and 1951 the urban population increased from 49% to 56%, and in 1961 almost one-half the population lived in greater Winnipeg. The chief towns of the province with their populations (1961 census) are: Winnipeg (*q.v.*) 260,391; St. Boniface (*q.v.*) 37,247; St. James 33,644; Brandon (*q.v.*) 27,787; East Kildonan 27,174; Portage la Prairie 12,223; Transcona 14,171; Flin Flon 10,992. All except Brandon and Portage form part of greater Winnipeg (469.055).



SETTLEMENT IS CONCENTRATED IN THE SOUTHERN PART AWAY FROM THE INFERTILE SHIELD. THE CHURCHILL RAILWAY TO CHURCHILL ON HUDSON BAY IS SHOWN

An excess of males over females has always been a feature of Manitoba's population, but this excess steadily declined and by 1961 had almost disappeared. The population is mixed by national origin; in 1951 less than 50% were of British origin. There are large minorities of French. Ukrainian. German. Dutch, Polish, Scandinavian and Jewish origin: many other nationalities are represented by smaller groups. Several European languages are spoken in different parts of the province. The United Church of Canada is the largest religious denomination (1951 census. 224,554 adherents), followed by the Roman Catholic (156,283) and Anglican (120,690) Churches: there are also considerable numbers of Lutherans. Mennonites. Presbyterians. Greek Orthodox and Jews.

Government and **Public Finance.**- he constitution of the province is derived from the British North America acts of the imperial parliament (1867 and 1871) ; the hlanitoba act of the Canadian parliament (1870); such laws and institutions of the Northwest Territory as have not been abolished or amended; and British common law and constitutional conventions. Power is divided between the federal government at Ottawa and the provincial government seated in Winnipeg, the capital. The crown is represented in the province by the lieutenant governor. The provincial premier and his ministers are normally selected from the largest party in the single-chamber legislature, which consists of 57 members and is elected for a maximum period of five years. Local government is under provincial control, and in 1958 there were 6 incorporated cities, 35 incorporated towns, 37 incorporated villages and 112 rural municipalities which vary greatly in size and which are divided into land units called townships (each 6 miles square). There are 14 unincorporated local government districts in newly developed areas which before 1945 had no organization. There are no counties but 16 census divisions. Manitoba is represented in the federal parliament at Ottawa by 6 senators and 14 members of the house of commons. Revenue for 1958–59 was estimated at $81,000,000, derived from taxes (44%), gasoline tax (17%), liquor control (13%), licences (8%) and mining (5%). Expenditure was estimated at $105,000,000, mostly for highways (34%), education (22%), health and public welfare (18%).

Education. — Public-school education (primary, secondary and technical) is administered by locally elected school boards under the general supervision of the provincial department of education, and financed by government grants and local rates. Many rural schools are one-room schools. There are two stages of secondary education: the junior high school offers a general program with options for special interests; the senior high school has five courses: general, agricultural, industrial. commercial and home economics. Teachers are trained at the University of Manitoba, the Manitoba Teachers' college. and at Brandon college. The University of Manitoba, situated at Fort Garry near Winnipeg, has over 6,000 students.

Production. — Agriculture. — Although Manitoba is traditionally thought of as an agricultural province, the relative importance of farm produce declined steadily after 1937, and in 1957 the value of manufacturing was almost three times as great. Agriculture became more diversrfied with less dependence on grain crops. Out of a total production valued at $251,000,000 in 1957, field crops contributed a little over one-half while most of the remainder was made up of livestock and derived products. Among the field crops, the importance of wheat declined while that of oats, barley, pasture land, canning crops and grass and fodder crops increased. Wheat still led in value of production (45,000,000 bu. from 2,114,-000 ac., valued at $50,000,000), but more oats were grown (58,-000,000 bu. from 1,800,000 ac., valued at $27,000,000); barley was third in importance (33,000,000 bu. from 1,704,000 ac., valued at $25,000,000), followed by flaxseed, potatoes, mixed grains and rye. Sunflowers, grown for their oil seeds. occupied 25,000 ac. in the Red river valley. The production of sugar beets, though small and limited to lands close to the Winnipeg refinery, increased from 80,000 tons in 1948 to 219,000 tons in 1957.

The principal variety of wheat grown was Selkirk (94% in 1957); the protein content was about 13%. Wheat seeding normally takes place in May and the harvest in August. Frost in the ground stops plowing in November. The province has over 700 grain elevators with a total storage capacity of 60,000,000 bu.

The principal animal livestock is cattle (885,000 in 1957), followed by swine (316,000) and sheep (71,000); there is a large demand from the U.S. for Manitoba cattle. Because of mechanization there are very few horses left. There are also over 6,000,000 chickens and hens, 780,000 turkeys, 40,000 ducks and 4,000 geese. More than 30,000,000 eggs are produced annually. Beekeeping and honey production (5,000,000 lb.) are noteworthy.

Agricultural land is concentrated in the southern part of the province, where about 7,000,000 ac. are cultivated (4,000,000 tilled, 3,000,000 summer fallow). Another estimated 2,500,000 ac. could be developed elsewhere in the province and in the second half of the 20th century land reclamation projects were under way in northern Manitoba. The federal government has worked an experimental farm at Brandon since 1888, with substations at Melita (soil reclamation), Portage la Prairie (special crops) and Waborden (crop testing in the northern clay belt). There is a horticultural experimental farm at Morden. In 1956 the province had 49,201 farms; their average size was about 300 ac., which is relatively small for the prairie. About 43,000 farms, or 83%, were served with electricity.

Forestry. — Forest production in the form of pulpwood (70%) and lumber was valued at over $26,000,000 in 1957. A survey made in 1956 showed that about 120,000 sq.mi. or about one-half the total area of the province was forested and that timber reserves amounted to 27,400,000 cords. The forested lands are almost all crown land and administered by the provincial forest service. Fire is a great hazard; there are annually nearly 300 fires burning over 200,000 ac.

Fishing. — The fresh-water fishery of Manitoba is one of the most valuable in the world and produces about 30,000,000 lb. of fish a year valued at over $5,000,000. Lake Winnipeg provides about half the catch. The principal fish caught in order of poundage are pickerel, whitefish, pike. sauger, tullibee, suckers, perch, bass, trout and carp. More than 5,000 commercial fishermen take part, using motorboats in summer and fishing through the ice from snow-tractors in winter. Aircraft and refrigerated boats, trucks and rail cars are used to transport the fish, 90% of which is sold in the U.S. Sports fishing is a major tourist attraction, with about 82,000 licensed anglers taking part in the summer season and about 3,000 in the winter season.

Mining. — The value of mineral production rose sharply after 1945; in 1957 it was more than $61,000,000. A little more than half of this total was made up of metals, principally nickel (20,-000,000 lb. valued at more than $14,000,000), copper (37,000,000 lb.. more than $10,000,000), gold (120,000 fine oz., $4,000,000) and zinc (27,000,000 lb., more than $3,000,000). Petroleum was the most important single mineral; more than 6,000,000 bbl., valued at $15,000,000, were produced from 846 wells. Industrial minerals accounted for $14,000,000.

The Hudson Bay Mining and Smelting company produces copper, zinc, gold, silver, cadmium, selenium and tellurium at Flin Flon, which has been the principal mining and smelting centre in the province since 1930. Sherritt Gordon Mines have been producing copper and nickel at Lynn Lake since 1951, and San Antonio Gold Mines operate at Bissett. The Britannia Mining and Smelting Company has been mining gold around Herb and Snow lakes since 1946. In Dec. 1956, the International Nickel Company decided to begin mining nickel in the Mystery-Moak lake area. The company and the province are investing $180,000,000 in the construction of mines, concentrator, smelter, refinery, railways, a hydroelectric power station and a townsite (Thompson).

Petroleum is produced in the southwestern part of the province near Virden. where commercial production began in 1951. The oil is of good quality, though sometimes affected by excess sulfur.

Electricity. — A remarkably rapid growth in the supply and consumption of hydroelectricity between 1947 and 1958 made Manitoba the most completely electrified province in western Canada. In 1958 there were nine power stations. Six were on the Winnipeg river 70 mi. northeast of Winnipeg and supplied the towns and rural areas of southern Manitoba; the others were in northern Manitoba on the Laurie river and on Island lake. The total output from all stations in 1957 was 3,374,000,000 k.w.h. Average annual consumption in 1958 was 7,600 k.w.h. per consumer in the Winnipeg area and 4,704 k.w.h. in rural areas. An estimated 5,000,000 h.p. remained to be developed in the province.

Manufacturing. — In 1957 the gross value of manufactured goods was $705,000,000, or more than double the combined value of agricultural, mining, forest and 'fishery output. This represented an increase of 84% since 1947. The growth was based upon increased population, advantageous position with respect to communications, greater diversification of agriculture, and expanding mineral, forest and water-power exploitation. The industries of the province, which are mostly located in the Winnipeg area, serve a regional market extending from the Rockies to the Great Lakes and containing about 20% of Canada's population and national income.

Over 50,000 workers were employed in industry in 1957 and the payroll reached almost $140,000,000. The food and beverages industry. with output valued at $2 50,000,000 and employing 10.000 workers, was most important; its major subdivisions were meat packing and slaughtering. Iron and steel products (value $100,-000,000, 5,250 employed) came next, followed by petroleum and coal products (value $60,000,000, 926 employed); this industry rose from 12th to 3rd place in ten years. Fourth in value of output ($50,000,000), but second in numbers employed (6.600) was the transportation equipment industry, producing railway rolling stock, buses, automotive and aircraft parts. The clothing industry, including fur processing, employed 5,605 workers, mostly female, and produced goods valued at $48.000.000. Chemicals, electrical goods, textile and leather products were also important.

Communications. — Southern Manitoba enjoys unusually good transport facilities because the approach of the northern wilderness toward the U.S. frontier compels east-west traffic to concentrate in the Winnipeg area. Westward from Winnipeg, rail, road and air routes fan out over the prairies.

Canadian National railways and Canadian Pacific railways operate nearly 5.000 mi. of railway in the province; these are centred on Winnipeg, the major rail town of western Canada, possessing some of the largest freight yards in the world. A 510-mi, railway, opened in 1929, connects The Pas with the northern port of Churchill on Hudson bay. Churchill is only about 450 mi. farther from Liverpool, Eng., than Halifax on the Atlantic coast, but this advantage is offset by the short navigable season (July–October) and the distance from Winnipeg. Nevertheless. nearly 17,000,000 bu. of grain were exported from Churchill in 1957. The nearby military base greatly increased the use and importance of the port. It possesses a modern 5,000,000 bu. elevator.

In 1958 there were 92,000 mi. of road but only a small proportion of these were surfaced. The most important main roads are the Trans-Canada highway running from east to west, and two highways into the U.S. Roads also serve the beach resorts on the lakes north of Winnipeg. About 180,000 passenger cars were licensed in the province in 1957. There are bus services from Winnipeg, Brandon and other towns to most of the inhabited parts of the province. Winnipeg is a stopping place on all Canadian transcontinental air services, some of which also serve Brandon. The northern resort, mining and fur-trapping centres are accessible by regular or chartered aircraft.

The telephone system is owned and operated by the province; it has nearly 250,000 subscribers, over half of whom are in Winnipeg. The principal radio station is CBW with transmitter at Carman (50,000 watts, 990 kc.); it serves the whole province. There are several local privately owned stations. CKSB at St. Boniface is a French-language station. In 1958 there were two television stations, CBWT in Winnipeg and CKX-TV at Brandon.

MANITOBA, LAKE, a narrow, irregularly shaped lake in the Red river lowlands of Manitoba, Can. Discovered by Pierre de la Vérendrye in 1738, the lake is 124 mi. long and lies 813 ft. above sea level. Its southern end is 80 mi. N.W. of Winnipeg and 25 mi. N. of Portage la Prairie. Separated from Lake Winnipegosis by a narrow isthmus, it is a remnant of Lake Agassiz which covered the area in glacial times. It has a valuable commercial fishery and there are small settlements and summer resorts located around its low and often swampy shores. Many of the settlers are Icelandic in origin. (W. H. PR.)

MANITOWOC, seat of Manitowoc county, Wis., U.S., is an industrial city and port on Lake Michigan at the mouth of the Manitowoc river, 83 mi. N. of Milwaukee. A French Canadian established a post there in 1795 and permanent settlement by Americans began in 1836. The city was incorporated in 1870. Manitowoc was early renowned for its shipbuilding; hence its nickname of "Clipper city." It built a sailing ship of 62 tons in 1847 and a steamboat of 434 tons in 1861. The harbour, which is kept open throughout the year, handles more than 2,400,000 tons of freight annually. Railway car and auto ferries connecting nith Michigan ports account for about 60% of this total. The city has a diversified industry with a labour force of more than 6,000. One-third of that number is engaged in shipbuilding and maintenance, and as many more in aluminum work. Other important industries are food packing, lumber, wood products and furniture, paper, metal products including toys, and electrical and other machinery. The name Manitomoc means "spirit land." For comparative population figures *see* table in WISCONSIN: *Population.* (W. F. RY.)

MANIU, IULIU (1873–1953), Rumanian statesman who was the first after the country's unification to win a free election, was born a Roman Catholic on Jan. 8, 1873, at Simleul-Silvaniei, Transylvania. Elected deputy in 1906, he sat in the Budapest parliament until 1910. When the Habsburg monarchy collapsed he was elected head of the regional government at Alba Iulia. In 1926 the National party of Transylvania and the Peasant party of old Rumania merged under Maniu's leadership. On Nov. 10, 1928, he formed the government and the National Peasant party won 349 seats out of 387. In June 1930 Maniu aided Carol II's return from exile but was forced to resign in October. He returned to power in Oct. 1932 to resign again in Jan. 1933. Maniu opposed Carol's dictatorship and from 1940 that of Gen. Ion Antonescu. As a democrat Maniu opposed the Communist dictatorship. Arrested on July 14. 1947, he was sentenced on Nov. 11 to hard labour for life. He died in the Sighet prison in 1953.

MANIZALES, a city of Colombia on the western flank of the volcanic Central Cordillera, 75 mi. S. of Medellín. Pop. (1951) 88,893. It is situated on a commanding ridge-top (elevation 6,988 ft.) its huge, gray cathedral visible for miles in all directions. Manizales was founded in 1848 by colonists from Antioquia. In 1905 it was made capital of the newly created department of Caldas. The airport is located 20 mi. away, near the Cauca river. An unusual means of transportation, an aerial cableway across the crest of the Central Cordillera. connects Manizales with Mariquita and the Magdalena river. Manizales is the halfway point on the principal highway between Bogotá and Medellín and is also connected by highway and railroad with the Quindio region and Cali. It is the centre of Colombia's most important coffee-growing district; nearby, at Chinchiná, is an important coffee experiment station. (Js. J. P.)

MANKATO, a city in south central Minnesota, U.S, the seat of Blue Earth county, about 85 mi. S W. of Minneapolis. The site was settled at the head of navigation on the Minnesota river in the early 1850s by Henry Jackson, Parsons K. Johnson and Daniel Williams of St. Paul. It was incorporated as a village in 1865, was chartered as a city in 1868, and adopted the city-manager form of municipal government in 1953. Mankato is the Sioux name for the blue earth of the region, once thought to be copper-bearing. In its early years as a frontier settlement it was menaced by hostile Indians. The Sioux uprising of 1862 culminated there in the multiple hanging of 38 Indians out of more than 400 who were tried for massacring white settlers. It is the centre of a prosperous farming region, and has an important hog market and many agricultural processing plants, two of which process a large part of Minnesota's soybean crop. Other industries include the manufacturing of cans, electrical equipment, brake assemblies, insulation and cement and the quarrying of limestone. The city is a large wholesale and retail trade centre.

Mankato State college (1868) and Bethany Lutheran college (1911), a junior college, are located there. For comparative population figures *see* table in MINNESOTA: *Population.* (H. T. H.)

MAN LANGUAGES. The term "Man" (in Chinese, "southern barbarian) is applied to languages also known as "Yao" which together nith the Miao languages constitute a group (Miao-Yao) spoken by hill peoples in southern China. North Vietnam, Laos and northern Burma. The Miao-Yao languages are Imperfectly knonn but appear to be an independent group remotely related to the Mon-Khmer languages (Mon and Cambodian). They have no writing system of their onn and no published literature.

Maspero in Meillet and Cohen, *Les langues du monde,* pp. 563–566 (1952); 4 G Haudricourt, "Introduction à la phonologie *historique des langues miao-yao," Bulletin de l'école française d'extreme-orient,* 44 555–576 11954). (W S. CN.)

MANLEY, MARY DE LA RIVIÈRE (c. 1663–1724), English writer, daughter of Sir Roger Manley, governor of the Channel Islands. was born on April 7. 1663, in Jersey. She wrote her own biography under the title of *The* Adventures of *Rivella,* *or the History of the Author of the Atalantis* by "Sir Charles Lovemore" (1714). In 1709 she achieved her principal triumph as a writer by her *Secret Memoirs . . . of Several Persons of Quality,* a scandalous chronicle "from the New Atalantis, an island in the Mediterranean." She was arrested in the autumn of 1709 as the author of a libellous publication, but was discharged by the court of queen's bench on Feb. 13, 1710. Mrs. Manley sought in this scandalous narrative to expose the private vices of the ministers whom Jonathan Swift, Lord Bolingbroke and Robert Harley, earl of Oxford, combined to drive from office. Later were published her tragedy *Lucius* (1717), *The Power of Love, in Seven Novels* (1720) and *A Stage Coach Journey to Exeter* (1725).

MANLIUS, the name of a Roman gens, chiefly patrician, but containing plebeian families also.

1. MARCUS MANLIUS CAPITOLINUS, a patrician, consul (392 B.C.). According to tradition, when in 390 B.C. the besieging Gauls were attempting to scale the Capitol, he was roused by the cackling of the sacred geese, rushed to the spot and threw down the foremost assailants (Livy v, 47; Plutarch, *Camillus*, 27). Several years after, seeing a centurion led to prison for debt, he freed him with his own money, and sold his estate to relieve other debtors. He was charged with aspiring to kingly power, and condemned by the comitia when the assembly had adjourned to a place whence they could no longer see the Capitol which he had saved. His house on the Capitol (the origin of his surname) was razed, and the Manlii resolved that henceforth no patrician Manlius should bear the name of Marcus.

See Livy vi, 14–20; Plutarch, *Camillus,* 36, and Cicero, *De Domo,* 38.

2. TITUS MANLIUS IMPERIOSUS TORQUATUS, twice dictator (353, 349 B.C.) and three times consul (347, 344, 340). When his father was brought to trial by the tribune M. Pomponius for abusing his office of dictator, he forced Pomponius to drop the accusation by threatening his life (Livy vii, 3–5). In 360, during a war with the Gauls, he slew one of the enemy, a man of gigantic stature, in single combat, and took from him a *torques* (neck ornament), whence his surname. When the Latins demanded an equal share in the government of the confederacy, Manlius vowed to kill with his own hand the first Latin he saw in the senate house. The Latins and Campanians revolted, and Manlius, consul for the third time, gained two great victories in Campania. In this campaign Manlius executed his own son, who had killed an enemy in single combat, and thus disobeyed the express command of the consuls.

See Livy vii. 4, 10, 27, and viii, 3; Cicero, *De Officiis,* iii, 31.

MANN, HEINRICH (1871–1950), German novelist, elder brother of Thomas Mann (*q.v.*), was born at Lubeck on March 27, 1871. Educated in Liibeck and Berlin, he travelled in Italy and Germany and produced a series of novels which displayed a deep feeling for beauty and much satiric power. *Im Schlaraffenland* (1900) was a mordant account of high finance in Berlin. *Dte Göttinnen* (3 vol., 1903) was a romantic and often very beautiful, but fantastic, account of a Dalmatian duchess with political, artistic and erotic aspirations. Later works described and satirized German society. They include *Die Jagd nach der Liebe, Professor Unrat* (1905), *Die kleine Stadt* and the trilogy, *Das Kaiserreich* (1914–2j). After leaving Germany in 1933, he wrote two historical novels about Henry of Navarre, and the autobiography *Ein zeitalter wird besichtigt* (1945–46).

Mann died March 12,1950.

MANN, HORACE (1796–1859), U.S. educator, "the father of American public education." was born in Franklin, Mass., on May 4. 1796 He grew up in an environment governed by poverty, hardship and self-denial. His early schooling came in brief and erratic periods of eight to ten weeks a year, and from comparatively poor teachers. But he managed to educate himself in the Franklin tonn library, and with the help of some tutoring by an itinerant schoolmaster he gained admission at the age of 20 to the sophomore class at Brown university. He did brilliant work at Brown, manifesting great interest in problems of politics, education and social reform; his valedictory address, on the progressive character of the human race, was a model of humanitarian optimism: portraying the way in which education, philanthropy and republicanism can combine to allay the wants and shortcomings that have traditionally beset mankind.

Cpon graduation in 1819 Mann chose law as a career. There was a brief period of reading law with a Wrentham, Mass., lawyer, followed by an interlude of teaching at Brown. Then came a time of more concentrated study at Litchfield (Conn.) Law school, and finally admission to the bar in 1823. Meanwhile, he had decided to settle in Dedham, and there his legal acumen and oratorical skill soon won him a seat in the state legislature. From 1827 to 1833 he served in the Massachusetts house of representatives, where he led in the establishment of a state hospital for the in. sane at Worcester, the first of its kind in the United States. In 1833 he moved to Boston and was elected to the Massachusetts senate. where he served four years, the last two as president of that body.

Of the many causes Mann espoused, none was dearer to him than the education of the people. Nineteenth-century Massachusetts could boast a public school system going back to 1647. Yet during Mann's own lifetime, the quality of education had steadily deteriorated as school control had gradually slipped into the hands of economy-minded local districts. A vigorous reform movement arose, committed to halting this decline by reasserting the state's influence over the schools. The result was the establishment in 1837 of a state board of education, charged with collecting and publicizing school information throughout the state. Much against the advice of friends. who thought he was tossing aside a promising political career, Mann accepted the first secretaryship of this board.

Endowed with little direct power, the new office demanded moral leadership of the highest order and this Mann supplied for 12 years. He started a biweekly *Common School Journal* for teachers, and lectured widely to interested groups of citizens. His 12 annual reports to the board ranged far and wide through the field of pedagogy, stating the case for the public school and discussing its problems. Essentially his message centred in six fundamental propositions: (1) that a republic cannot long remain ignorant and free, hence the necessity of universal popular education; (2) that such education must be paid for, controlled and sustained by an interested public; (3) that such education is best provided in schools embracing children of all religious, social and ethnic backgrounds; (4) that such education, while profoundly moral in character, must be free of sectarian religious influence; (5) that such education must be permeated throughout by the spirit, methods and discipline of a free society, hence harsh pedagogy in the classroom is undesirable; and (6) that such education can be provided only by well-trained, professional teachers who have mastered their subject matter and the pedagogical arts as well. Mann encountered strong resistance to these ideas—from clergymen who deplored nonsectarian schools, from educators who condemned his pedagogy as subversive of classroom authority and from politicians who opposed the board as an improper trespass on local educational authority—but in the end his views prevailed.

Mann resigned the secretaryship in 1848 to take the seat of former Pres. John Quincy Adams in the United States congress. There followed a stormy period during which he took an uncompromising stand against slavery. In 1853, having run unsuccessfully for the Massachusetts governorship a year before: he assumed the presidency of Antioch college in Ohio, a new institution committed to coeducation, nonsectarianism and equal opportunity for Negroes. There, amidst the usual crises attendant upon the running of an infant college, Mann finished out his years. He died on Aug. 2, 1859. Two months before, he had given his own valedictory in a final address to the graduating class: "I beseech you to treasure up in your hearts these my parting words: Be ashamed to die until you have won some victory for humanity."

MANN, THOMAS (1875–1955), German novelist and recipient of the 1929 Nobel prize for literature. He was born at Lubeck on June 6, 1875, the son of a merchant and senator. At 19 he moved to Munich, where, while working in an insurance office. he devoted himself to literature. Later he studied at the university, lived in Italy and worked on the satirical journal *Simplicissimus.* In 1897 he began Buddenbrooks (pub. 1900), his first important work, a chronicle of a Lubeck family, nhich introduced his favourite themes of a civilization in decay and the conflict between art and life. It was followed by *Tristan* (1903), a collection including the powerful "Tonio Kroger"; Konigliche Hoheit (1909; Royal Highness); and Der Tod in *Venedig* (1912; Death in Venice).

In 1912 Mann began Der Zauberberg (1924; The Magic Mountain), a study in microcosm of the forces which disrupted European society. In it and Betrachtungen *eines Unpolitischen* (1918) he sought to clarify his ideas about Germany's national ideal. His growing liberalism led to his leaving Germany in 1933; in 1936 he was deprived of his citizenship and in 1944 became a U S. citizen. In 1954 he settled in Zurich, where he died on Aug. 12, 1955.

The novels of Mann's exile—ever more diffuse and idiosyncratic in style—included the biblical tetralogy. Joseph und seine *Brüder* (1933–43); *Lotte* in *Weimar* (1939); Dr. *Faustus* (1947); Die Betrogene (1953); and Bekenntnisse des *Hochstaplers* Felix *Krull,* (1954), a comic novel expanded from an early short story.

MANNA. Although the word manna is familiar and widely quoted, it has no exact meaning; it may refer to plants or even birds However it popularly connotes a miraculously supplied food—"the bread of heaven." Not all the references to manna (in at least ten books of the Bible) signify the same species of plant; that falling from heaven. in the wilderness (Ex. xvi) was presumably wind-borne lichens, while the "honeydew" manna of many later references signifies gummy exudations or resins from several desert trees and shrubs. Exodus xvi:13–15 states ". . . Behold it will rain bread from Heaven . . . the children of Israel saw it, they said one to another, it is manna: . . . taste of wafers made with honey . . . and the children of Israel did eat manna forty years . . . ."

Lichens.—The Biblical manna is believed to be the lichen *Lecanora* esculenta—perhaps also L. *affinis, L. fruticulosa* and L. tartarea. Lecanora is a relative of reindeer moss (Cladonia *rangiferina*), famed in the arctic tundra as sustenance for sizable herds.

A lichen (*q.v.*) is a "synthetic" plant, consisting of a partnership (see SYMBIOSIS) of a green alga and a fungus The alga manufactures food for the combination and the fungus provides the protective housing.

Bedouin herdsmen collect lichen manna and consume it mixed with one-third meal. In many parts of the near east, lichen breads are baked and a manna jelly is prepared.

Lecanora manna ranges from southern U.S.S.R. to Syria and Iran; it is absent from the Sinai desert and eastern north Africa, but is found in Algeria and the Atlas mountains During drought, it curls into lightweight flakes or balls. which break loose easily. Strong winds carry it great distances and windrows often accumulate in the desert, wafted from the mountains. In 1854 a manna shower fell upon Persia during drought and famine. In 1891 an abundant fall was reported in Turkey. It is supposed that manna was, in this way, provided Moses while en route to the Promised Land, or that a migration of quail may have coincided with the blowing in of lichen, providing additional food.

Resins.—*Alhagi maurorum* (camel's thorn) is a spiny-branched shrub up to 3 ft. tall. with simple leaves. It occurs in the uastes of Syria. Lebanon. Palestine and Arabia. Heat or insect activity causes it to exude a resin. which hardens and may be collected by shaking the bushes over a cloth, spread on the ground.

A tamarisk. Tamarix *gallica,* a shrub up to 15 ft. in height. with scalelike leaves and clusters of tiny pink flowers, occurs in the deserts of the same area as the *Alhagi* and is common in the Sinai. A scale insect either punctures the stem, triggering the exudation which hardens in drops; or secretes the manna itself. Bedouins collect this honeylike material, considering it a great delicacy.

The flowering ash, Fraxinus ornus, is a tree, up to 50 ft. in height, with pinnate leaves. It ranges from southern Europe into Syria and Lebanon and is cultivated on some Mediterranean islands. In summer the branches are slashed and the juices exude and harden as manna (the source of commercial manna).

Ash manna is a saeetish exudate, finding limited commerce as flakes (flake manna) or fragments (common manna) or viscid droplets (fat manna). Chemically it consists of mannin, which is a laxative, demulcent and expectorant.

One of these purchasable "sweet mannas" was likely referred to in the book of Baruch i:10, ". . . and prepare ye manna, and offer upon the altar of the Lord. . . ." Authorities have also suggested a dozen other arid land species which might be the source of gum-resin mannas, including legumes, willows, oaks, pears, cedars and members of the genus Eucalyptus and the composite family.

(R W. SY.)

MANNERHEIM, CARL GUSTAF EMIL, BARON (1867–1951), Russian and later Finnish army officer, called the George Washington of modern Finland, was born at Villnäs, near Turku, Fin., on June 4, 1867. He began his military career as a lieutenant of cavalry in the Russian army in 1889, and served in the Russo-Japanese War and in World War I. By 1917 he was a corps commander with the rank of lieutenant general. In Dec. 1917, following the Russian Revolution, he returned to his native Finland, which had declared its independence. In Jan. 1918 he assumed command of the "White" forces opposing the Bolsheviks. leading them to victory in four months. He became regent of Finland in Dec. 1918, holding this position for seven months until a republic was declared.

In 1931 Mannerheim returned from retirement to become chairman of the defense council. During his eight years in this post there was built a line of fortifications across the Karelian isthmus, popularly called the Mannerheim line in his honour. At the age of 72, Mannerheim served as commander in chief in the defensive "winter war" against the Soviet Union (Nov. 1939 to March 1940). The brilliance and remarkable skill of this campaign against a great power led to a relatively favourable peace settlement. Following a new Soviet attack in June 1941, Mannerheim continued to serve as commander in chief until peace was negotiated in Aug. 1944. He was named the only marshal of Finland in June 1942. Mannerheim became president of the republic in 1944, retiring because of ill health in 1946.

He died at Lausanne, Switz., on Jan. 27, 1951. He wrote Across Asia From West to East in *1906–1908* (1940); the Memoirs of Marshal Mannerheim was published in English in New York in 1954.

(R. L. GF.)

MANNERISM is the name now given to the style which prevailed in the arts in Italy from about 1520 until about 1590. The word derives from the phrase di maniera, meaning "by rote," frequently used by G. Vasari and others to describe the creation of a work of art without reference to nature but by dependence on an inner idea, formed originally in the artist's mind from nature, but modified by aesthetic considerations and by the study of other works of art.

Early in the 20th century it was realized that the art of the period between the death of Raphael and the rise of the Carracci and Caravaggio (*qq.v.*) is not simply a decadent version of the high Renaissance but a fundamentally different style. The reasons for this change are manifold, although a school of Marxist historians in the 1920s sought to explain the phenomenon in terms of the economic and social crises precipitated by the rise of Lutheranism and, still more, by the catastrophe of the sack of Rome in 1527. The sack of Rome came as a numbing shock to contemporaries; and it led to the complete collapse of the serene and apparently stable world of humanist values which had given birth to the Renaissance and to a marked increase in religious emotion in the arts, but the external causes do not explain Mannerism as an artistic phenomenon: it is also necessary to refer to artistic reasons. A desire for a new style, expressed in what would now be called Mannerist terms, can be traced well before 1527 and even in Raphael's own last works, most notably in the "Transfiguration" (Vatican gallery) begun in 1517. This uas the result of two main factors: the general feeling that the Stanze (in the Vatican palace) of Raphael, or the architecture of D. Bramante, represented a norm of classical perfection and that no further progress was possible on that road; and the opening of new vistas in the use of the nude as a means of emotional expression by Michelangelo's "Battle of Cascina" and Sistine chapel ceiling, whereby many artists fell into the trap of regarding "clever" poses, much foreshortening and anatomical knowledge as ends in themselves. Others, perhaps more sensitive to approaching disaster, began to impart a tension into their works directly at variance with the serenity of the Renaissance style. In architecture the deliberate flouting of Bramante's ideas in favour of a new style, both exciting and deliberately allusive, can best be seen in the Palazzo del Tè at Mantua, begun in 1525 by Raphael's pupil Giulio Romano (*q.v.*).

The neurosis implicit in much early Mannerist art was partly caused by its exponents, for Rosso. Jacopo da Pontormo and Parmigianino uere all somewhat unbalanced; but they created a religious art of direct and personal expressiveness which was later continued outside central Italy by Tintoretto and El Greco, who, with the aged Michelangelo, were the greatest artists of the style.

Mannerism is a negative style based on rejections and unresolved conflicts. The imitation of nature is modified in favour of the "idea" in the artist's mind (see G. P. Lomazzo, Trattato dell Arte . . . , 1584), compositions are deliberately asymmetrical and too little picture space is allotted to the figures, thus crowding them together and emphasizing the twisted and elaborate poses imitated from Michelangelo. Figures are much elongated to gain in grace and also for the sophisticated pleasure of breaking the classical rules of proportion. It is essentially a learned art, for the spectator is supposed to be both shocked and thrilled by this rule-breaking, as where Michelangelo, in his Laurenziana library in Florence, recessed columns into the wall thus contradicting their strengthening function.

In the second half of the century Mannerism itself became codified into a set of elaborate rules, but many fine portraits of cold elegance were painted (by Bronzino in Florence and N. Hilliard in England, for example), and much of what began as an Italian movement was copied, though rarely understood, by the Romanists in the Low Countries, France and elsewhere. According to some critics, Mannerist influences are discernible in certain trends of modern art and literature, such as Surrealism (see G. R. Hocke, Die *Welt Als* Labyrinth, 1957).

MANNERS, CHARLES (1857–193j), English musician, whose real name was Southcote Mansergh, was born in London, son of Col. John Mansergh, an Irishman. He had a fine bass voice, and studied at the Royal Academy of Music in London. He began singing in opera in 1881, and in 1882 had great success as the sentry in *Iolanthe* at the Savoy, following this with numerous engagements in opera both in England and America. He married the singer Fanny Moody. already a leading soprano on the operatic stage, in 1890; and in 1897 they formed the bloody-Manners opera company, which had a great success in the provinces and undertook seasons in London in 1902, 1903 and 1904.

Manners died at Dundrum, Ire., May 3, 1935.

MANNERS-SUTTON, CHARLES (1755–1828), archbishop of Canterbury, was educated at Charterhouse and Cambridge, where he graduated in 1777. He became dean of Peterborough (1791), bishop of Norwich (1792), dean of Windsor (1794), and archbishop of Canterbury (1805).

During his primacy the old archiepiscopal palace at Croydon was sold, and the country palace of Addington bought with the proceeds.

For his son Charles see CANTERBURY, CHARLES MANNERS-SUTTON.

MANNHEIM, a town in the Land of Baden-Württemberg, Germany, lies at the confluence of the Neckar with the Rhine and is joined by a railway and road bridge with Ludwigshafen on the left bank of the Rhine. The old tonn, which is surrounded by the Ring, is built like a chessboard in 136 rectangular blocks of houses, known as the Quadraten. Pop. (1950) 245,634.

First mentioned in 766 as a village, Mannheim was fortified in 1606 and received its privileges and municipal law in 1607. It was destroyed in 1622 during the Thirty Years' War and again in 1689 in the struggle for succession which led to the War of the Grand Alliance. In 1720, however, when Charles Philip of the Palatinate moved his residence from Heidelberg to Mannheim, it was rebuilt. The castle, the Jesuit church, the old town hall in the market place with the Unteren Pfarrkirche, the Kaufhaus and the Zeughaus or arsenal are among the baroque buildings of this period. Learning and the arts were cultivated and the Mannheim school of conductors, violinists and composers, the art gallery and the academy of sciences had a European reputation. In 1778 the court moved to Munich. In the same year the National theatre was opened and in 1782 it gave the first performance of Schiller's Die *Räuber*. In 179j Mannheim was destroyed for the third time, during the French mars, and in 1802 it was transferred to Baden. In 1848–49 it was at the centre of the revolutionary movement.

Mannheim's economic rise in the 19th century was due to its position at the highest navigable point on the Rhine for large ships. By the end of the century it had developed from a commercial into an industrial city. In World War II more than half the town was destroyed in air raids but the castle, the Jesuit church, the old town hall and the arsenal were later rebuilt.

Mannheim's chief manufactures are chemicals, cellulose, soap, machinery, steel, electrical and railway equipment, foodstuffs and tobacco. Of special importance is the import trade and trade in coal and iron. With more than 1,000 yd. of quays, numerous docks and a dock railway, Mannheim has the second largest inland harbour in Europe. Mannheim has remained a cultural centre with the National theatre (rebuilt 1954–57, with two stages), colleges for music and drama, engineering and industry, and art collections in the Reiss museum and the Kunsthalle. (G. JB.)

MANNING, HENRY EDWARD (1808–1892), English Roman Catholic cardinal, was born at Totteridge, Hertfordshire, on July 1j, 1808[1], being the third and youngest son of William Manning, a West India merchant, who was a director of the Bank of England and governor, 1812–1813, and who sat in parliament for some 30 years. Manning's boyhood was mainly spent at Coombe Bank, Sundridge, Kent, where he had for companions Charles and Christopher U'ordsworth, afterward bishops of St. Andrews and of Lincoln. He was educated at Harrow, and at Balliol college, Oxford. He made his mark in the Union, where Gladstone succeeded him as president in 1830. He graduated with first-class honours in 1830, and obtained, in 1831, through Viscount Goderich, a post as supernumerary clerk in the colonial office. But he returned to Oxford in 1832, was elected a fellow of Merton college, and was ordained; and in 1833 he was presented to the rectory of Lavington-with-Graffham in Sussex by Mrs. Sargent, whose granddaughter Caroline he married on Nov. 7, 1833. Manning's married life was of brief duration. His young wife died childless (July 24, 1837). This bereavement tended to facilitate his acceptance of the austere teaching of the Oxford Tracts; and though he was never an acknowledged disciple of Newman, it was due to the latter's influence that from this date his theology assumed an increasingly High Church character, and his printed sermon on the "Rule of Faith" was taken as a public profession of his alliance aith the Tractarians.

In 1838 Manning took a leading part in the Church education movement, by which diocesan boards were established throughout the country; and he wrote an open letter to his bishop in criticism of the recent appointment of the ecclesiastical commission. In December of that year he paid his first visit to Rome, and called on Dr. Wiseman in company with W. E. Gladstone. In Jan. 1841 Shuttleworth, bishop of Chichester, appointed him archdeacon. In 1842 he published a treatise on The Unity of *the* Church, arid in that year he was appointed select

[1]Purcell's assertion that the year of his birth was 1807 rests on no trustworthy evidence.

preacher by his university. Four volumes of his sermons appeared between the years 1842 and 1850, and these had reached the 7th, 4th, 3rd and 2nd editions respectively in 1850, but were not afterwards reprinted.

Newman's secession from the Church of England in 1845 placed Manning in a position of greater responsibility, as one of the High Church leaders, along with Pusey and Keble and Marriott; but it was with Gladstone and James Hope (afterwards Hope-Scott) that he was at this time most closely associated. In the spring of 1847 he was seriously ill, and that autumn and the following winter he spent abroad, chiefly in Rome, where he saw Newman "wearing the Oratorian habit and dead to the world." He had public and private audiences with the pope on April g and May 11, 1848, but recorded next to nothing in his diary concerning them, though numerous other entries show an eager interest in everything connected with the Roman Catholic Church, and private papers also indicate that he recognized at this time grave defects in the Church of England and an attraction in Roman Catholicism. Returning to England, he protested, but with moderation, against the appointment of Hampden as bishop of Hereford, and continued to take an active part in the religious education controversy. Through the influence of Samuel Wilberforce he was offered the post of sub-almoner to Queen Victoria, always recognized as a stepping-stone to the episcopal bench, and his refusal of it was honourably consonant with all else in his career as an Anglican dignitary, in which he united pastoral diligence with an asceticism that was then quite exceptional.

In 1850 the decision of the privy council, that the bishop of Exeter was bound to institute the Rev. G. C. Gorham to the benefice of Brampford Speke in spite of the latter's acknowledged disbelief in the doctrine of baptismal regeneration, brought to a crisis the position within the Church of England of those who believed in that Church as a legitimate part of the infallible *Ecclesia docens.* Manning made it clear that he regarded the matter as vital, though he did not act on this conviction until no hope remained of the decision being set aside or practically annulled by joint action of the bishops. In July he addressed to his bishop an open letter on "The Appellate Jurisdiction of the Crown in Matters Spiritual," and he also took part in a meeting in London which protested against the decision. In the autumn of this year (1850) was the great popular outcry against the "Papal aggression" *(see* WISEMAN, NICHOLAS PATRICK STEPHEN), and Manning, feeling himself unable to take part in this protest, resigned, early in December his benefice and his archdeaconry; and writing to Hope-Scott, who a little later became a Roman Catholic with him. stated his conviction that the alternative was "either Rome or licence of thought and will."

He was received into the Roman Catholic Church by Father Brownbill, S.J., at the church in Farm Street, on Passion Sunday, April 6, 1851. On the following Sunday he was confirmed and received to communion by Cardinal Wiseman, who also, within ten weeks of his reception, ordained him priest. Manning thereupon proceeded to Rome to pursue his theological studies, residing at the college known as the ('Academy for Noble Ecclesiastics," and attending lectures by Perrone and Passaglia among others. The pope frequently received him in private audience, and in 1854 conferred on him the degree of D.D. In 1857 the pope, *proprio motu,* appointed him provost (or head of the chapter) of Westminster, and the same year he took up his residence in Bayswater as superior of a community known as the "Oblates of St. Charles," an association of secular priests on the same lines as the institute of the Oratory, but with this difference, that they are by their constitution at the beck and call of the bishop in whose diocese they live.

The community was thus of the greatest service to Cardinal Wiseman, whose right-hand man Manning thenceforward became. During the eight years of his life at Bayswater he was most active in all the duties of the priesthood, preaching, hearing confessions, and receiving converts; and he was notably zealous to promote in England all that was specially Roman and papal, thus giving offence to old-fashioned Catholics, both clerical and lay, many of whom were largely influenced by Gallican ideas, and had with difficulty accepted the restoration of the hierarchy in 1850. In 1860 he delivered a course of lectures on the pope's temporal power, at that date seriously threatened, and shortly afterwards he was appointed a papal domestic prelate.

He was now generally recognized as the able and effective leader of the Ultramontane party among English Roman Catholics, acting always, however, in subordination to Cardinal Wiseman; and on the latter's death (Feb. 15, 1865) it was felt that, if Manning should succeed to the vacant archbishopric, the triumph of Ultramontanism would be secured. Such a consummation not being desired by the Westminster chapter, they submitted to the pope three names, and Manning's was not one of them. Pius IX. ignored the nominations, and appointed Manning to the archi-episcopal see. Consecrated at the pro-cathedral at Moorfields (since destroyed) by Dr. Ullathorne, bishop of Birmingham (June 8, 1865), and enthroned there (Nov. 6), after receiving the *pallium* in Rome, Manning began his work as archbishop by devoting himself especially to the religious education of the poor and to the establishment of Catholic industrial and reformatory schools. He steadily opposed whatever might encourage the admission of Catholics to the national universities, and so put his foot down on Newman's project to open a branch house of the Oratory at Oxford with himself as superior. He made an unsuccessful and costly effort to establish a Catholic university at Kensington, and he also made provision for a diocesan seminary of strictly ecclesiastical type. He procured a further condemnation at Rome of the "Association for the Promotion of the Unity of Christendom," which advocated prayers for the accomplishment of a kind of federal union between the Roman, Greek and Anglican Churches, and in a pastoral letter he insisted on the heretical assumption implied in such an undertaking. He also worked for the due recognition of the dignity of the secular or pastoral clergy, whose position seemed to be threatened by the growing ascendancy of the regulars, and especially of the Jesuits, whom, as a practically distinct organization within the Church, he steadily opposed.

In addition to his diocesan synods, he presided in 1873 over the fourth provincial synod of Westminster, which legislated on "acatholic" universities, church music, mixed marriages, and the order of a priest's household, having previously taken part, as theologian, in the provincial synods of 1853 and 1855. with a hand in the preparation of their decrees. But it was chiefly through his strenuous advocacy of the policy of defining papal infallibility at the Vatican council (1869–1870) that Manning's name obtained world-wide renown. In this he was instant in season and out of season. He brought to Rome a petition in its favour from his chapter at Westminster. and during the progress of the council he laboured incessantly to overcome the opposition of the "inopportunists." And he never ceased to regard it as one of the chief privileges of his life that he had been able to take an active part in securing the definition, and in having heard with his own ears that doctrine proclaimed as a part of divine revelation In 187j he published a reply to Gladstone's attack on the Vatican decrees; and on March 1; in that year he was created cardinal, with the title of SS. Andrew and Gregory on the Coelian. He was present at the death of Pius IX. (Feb. 7, 1878): and in the subsequent conclave, while some Italian cardinals were prepared to vote for his election to fill the vacant chair, he himself supported Cardinal Pecci, afterwards known as Leo XIII.

With Leo XIII. Manning found less sympathy than with his predecessor, though Manning's advocacy of the claims of labour attracted Leo's attention, and influenced the encyclical which he issued on the subject. After the Vatican council, and more especially after the death of Pius IX., Manning devoted his attention mainly to social questions, and with these his name was popularly associated during the last fifteen years of his life. From 1872 onwards he was a strict teetotaller, not touching alcohol even as a medicine. His example and his zeal profoundly influenced for good the Irish poor forming the majority of his flock; and the "League of the Cross" which he founded, and which held annual demonstrations at the Crystal Palace, numbered nearly

30,000 members in London alone in 1874. He sat on two royal commissions, the one on the housing of the working classes (1884), and the other on primary education (1886); and in each case the report showed evident marks of his influence, which his fellow-commissioners recognized as that of a wise and competent social reformer. In the cause of labour he was active for many years, and in 1872 he set an example to the clergy of all the churches by taking a prominent part in a meeting held in Exeter Hall on behalf of the newly established Agricultural Labourers' Union, Joseph Arch and Charles Bradlaugh being among those who sat with him on the platform.

In later years Manning's strenuous advocacy of the claims of the working classes, and his declaration that "every man has a right to work or to bread" led to his being denounced as a Socialist. That he was such he denied more than once (Lemire, *Le Cardinal Manning et son action sociale,* Paris, 1893, p. 210), nor was he ever a Socialist in principle; but he favoured some of the methods of Socialism, because they alone seemed to him practically to meet the case of that pressing poverty which appealed to his heart. He took a leading part in the settlement of the dockers' strike in the autumn of 1889, and his patient and effectual action on this and on similar occasions secured for him the esteem and affection of great numbers of working men, so that his death on Jan. 14, 1892, and his funeral a week later, were the occasion for a remarkable demonstration. The Cathedral at Westminster is his joint memorial with his predecessor, Cardinal Wiseman.

Preeminently Manning was a devout ecclesiastic, a "great priest"; and his sermons, both Anglican and Catholic, are marked by fervour and dignity, by a conviction of his own authoritative mission as preacher, and by an eloquent insistence on considerations such as warm the heart and bend the will rather than on such as force the intellect to assent. But many of his instincts were those of a statesman, a diplomatist, a man of the world, even of a business man; and herein lay, at least in part, the secret of his influence and success. In the later years of his life especially he showed that he loved righteousness and hated iniquity, and that he realized as clearly as any one that the service of God was incomplete without the service of man.

The publication in 1896 of Manning's *Life,* by Edward Purcell, with its very frank revelation of character was the occasion for some controversy on the ethics of biography. Edward Purcell was a Roman Catholic journalist, to whom Manning, late in life, had entrusted, rather by way of charitable bequest, his private diaries and other confidential papers. It thus came to pass that in Purcell's voluminous biography much that was obviously never intended for the public eye was, perhaps inadvertently, printed, together with a good deal of ungenerous comment. The facts disclosed which mainly attracted attention were: (1) that Manning, while yet formally an Anglican, and while publicly and privately dissuading others from joining the Roman Catholic Church, was yet within a little convinced that it was his own duty and destiny to take that step himself; (2) that he was continually intriguing at the back-stairs of the Vatican for the furtherance of his own views as to what was desirable in matters ecclesiastical; (3) that his relations with Newman were very unfriendly; and (4) that, while for the most part he exhibited towards his own clergy a frigid and masterful demeanour, he held privately very cordial relations with men of diverse religions or of no theological beliefs at all. And certainly Manning does betray in these autobiographical fragments an unheroic sensitiveness to the verdict of posterity on his career. But independent critics (among whom may specially be named François de Pressensé) held that Manning came well through the ordeal, and that Purcell's *Life* had great value as an unintentionally frank revelation of character. *See* also sketches by J. E. C. Bodley, *Cardinal Manning* (and other essays) (1912); Lytton Strachey's *Eminent Victorians* (1918); Shane Leslie's *Henry Edward Manning, His Life and Labours* (1921), in which Purcell is supplemented by correspondence not before used, and the Cardinal's letters are sympathetically interpreted.

(A. W. Hu.; X.)

MANNING, WILLIAM THOMAS (1866–1949), U.S. Protestant Episcopal divine, was born in Northampton, England, on May 12, 1866. He entered the ministry from the diocese of California, being ordained deacon 1889 and priest 1891. He became rector of Trinity church, Redlands, Calif., 1892, and in 1893 was appointed professor of theology in the University of the South, Sewanee, Tenn., where in the same year he received the degree of bachelor of divinity. He became successively rector of St. John's, Lansdowne, Pa., 1896; rector of Christ church, Nashville, Tenn., 1898; Vicar of St. Agnes's chapel, Trinity parish, New York city 1903. In 1904 he was appointed assistant rector of Trinity church, New York city, becoming rector in 1908. He was consecrated bishop of New York, May 11, 1921. In 1925 he inaugurated the public movement for the completion of the cathedral of St. John the Divine, New York city. He resigned as bishop 25 years later, in 1946, and on Nov. 18, 1949, he died in New York city.

MANNY, SIR WALTER DE MANNY, Baron de (d. 1372), soldier of fortune and founder of the Charterhouse (*q.v.*), was a native of Hainaut, from whose counts he claimed descent. He was a patron and friend of Froissart. He appears to have come to England as an esquire of Queen Philippa in 1327, and he took a distinguished part in the Scottish wars of Edward III. In 1337 he was placed in command of an English fleet, and in the following years proved himself an able military commander. He was summoned to parliament as a baron by writ from Nov. 1347 to Jan. 1371. In 1359 he was made a knight of the Garter, and at various times received extensive lands both in England and in France. He was frequently employed by King Edward in the conduct of diplomatic negotiations as well as in military commands. He was one of those charged with the safe custody of the French king John when a prisoner at Calais in 1360; in 1369 he was second in command under John of Gaunt.

Manny is remembered for his share in the foundation of the Charterhouse in London. In 1349 he bought some land near Smithfield and built a chapel, afterwards sold to the bishop of London, Michael de Northburgh, who died in 1361 and bequeathed a large sum of money to found there a Carthusian convent. It is not clear whether this direction was carried out; for in 1371 Manny obtained letters patent from Edward III. permitting him to found, apparently on the same site, a Carthusian monastery called "La Salutation Mère Dieu," where the monks were to pray for the soul of Northburgh as well as for the soul of Manny himself. The bishop's bequest may have contributed to the building and endowment of the house; or possibly, as seems to be implied by a bull granted by Urban VI., in 1378, there were originally two kindred establishments owing their foundation to Northburgh and Manny respectively. At all events, Manny who died early in 1372 left instructions that he was to be buried in the church of the Carthusian monastery founded by himself. About 1335 he married Margaret, daughter and heiress of Thomas Plantagenet, earl of Norfolk, son of King Edward I.

Beltz, *Memorials of the Most Noble Order of the Garter* (1841); *Chronicon Angliae 1323–1388,* ed. by E. Maunde Thompson (Rolls series 64, 1874); P. Bearcroft, *An Historical Account of Thomas Sutton and of his Foundation in Charterhouse* (1737).

MANNYNG (of Brunne), **ROBERT** (*fl.* 1283–1338), early English poet and author of *Handlyng Synne,* a poem of popular morality, and of the chronicle *Story of England.* He is probably to be identified with a Sir Robert de Brunne, chaplain, named as executor in a Lincoln will of 1327; apart from this mention his biography can only be reconstructed from his writings. He was born at Brunne (Bourne), Lincolnshire, in 1283 or somewhat earlier, and in *c.* 1300 was at the University of Cambridge, where he met Alexander, brother of the future King Robert the Bruce of Scotland. For 15 years (*c.* 1302–*c.* 1317) Mannyng was a Gilbertine canon at Sempringham priory, Lincolnshire, the original foundation of the order. There in 1303 he began *Handlyng Synne* and was still working at it after 1307. For many years before 1338 he was engaged on the *Story of England,* which he wrote at the request of the prior of the Gilbertine house at Sixhills near Market Rasen, Lincolnshire. The *Story of England,* the author relates, was finished between three and four o'clock, on Friday, May 15, 1338.

Handlyng Synne is an adaptation in about 13,000 lines, in short couplets poorly versified, of the *Manuel des Péchés,* which is usually ascribed to William of Waddington (or Widdington), an Englishman, probably a Yorkshireman, writing in Anglo-Norman between 1250 and 1270. The text of the *Manuel* remains amorphous; there are more than a score of manuscripts, which present the work in many degrees of completeness and expansion—evidently it was highly popular and influential. Like Waddington, Mannyng aimed to provide a handbook which should serve to stimulate careful self-examination as preparation for auricular confession. *Handlyng Synne* is thus an exact title, and the English work and its source represent extensions into the terms of popular thought and into vernacular languages of the copious clerical literature on confession which had developed in western Europe from the end of the 12th century.

Mannyng follows his original closely. He sometimes omits, but more often amplifies to elucidate doctrine, does not hesitate to soften the rigour of injunctions and in general shows a superior power in organization. He deals in turn with the Ten Commandments. the Seven Deadly Sins and the sin of sacrilege, the Seven Sacraments, the 12 requisites of confession and the 12 graces of confession. There is much direct instruction, exhortation and didactic comment, but each of the topics is illustrated by one or more tales. These *exempla* have sometimes been considered to provide the particular interest of the work. Most of them are drawn from the *Manuel*, but Mannyng sometimes provides a local setting and sometimes goes back to Waddington's sources for further detail He also adds 13 fresh stories, some from the Bible and several of local provenance. The whole work is designed for oral delivery. Mannyng's merit as a storyteller lies in his apt management of material and in his lucid, direct narration. Otherwise the literary merits of *Handlyng Synne* are negligible, although its documentary value for social history is great. It illustrates clearly the attitudes and values of the English minor clergy and peasantry in the early 14th century; throughout there is much comment on the social, domestic, parochial and commercial scene. The poem was popular in the 14th and 15th centuries; passages from it were worked into other compositions. Its modern appeal will be found in its moralized realism.

Of similar literary quality is Mannyng's later work, the *Story of England;* but, as Mannyng's editor, F. J. Furnivall, observes, whereas the matter of *Handlyng Synne* is fact, the basis of the *Story of England* is fiction. As history it is almost worthless, The work falls into two parts. The first, in something less than 9,000 lines written in short couplets, tells the story from Noah to the death of Cædwalla in 689. In form and substance Mannyng follows *Le Roman de Brut* by the Anglo-Norman poet Wace, but he draws also on Bede, on Geoffrey of Monmouth (Wace's source) directly and on the Anglo-Norman *Chronicle* of Peter Langtoft (*q.v.*). In the 9,000 lines of the second part, taking the story to the death of Edward I (1307), Mannyng relies primarily on Langtoft's *Chronicle* and again adopts the metrical form of his original, in this case the alexandrine couplet, which he manages clumsily.

He continues to incorporate material from other sources—from Bede again! from lives of English saints and from later historians —and he adds scraps of his own. Of particular interest is his use of popular romance. into his account of Aethelstan he inserts the story of Guy of Warwick's encounter with the giant Colbrand, he affects surprise that no reputable historian has dealt with Arthur or with Havelock and he draws heavily on the extravagant 14th-century romance of Richard the Lion-Hearted. Following Langtoft, but with some variations from Langtoft's text, he works into his narrative several topical songs, mainly on the Scottish wars of Edward I's time.

Handlyng Synne and the *Story* are preserved independentiy in several manuscripts, none contemporary with Mannyng and none of certain provenance; but insofar as the original east midland dialect of composition can be discerned, Mannyng's language is of importance in tracing the development of the spoken and literary standard of English. *Meditations of the Supper of Our Lord,* a verse rendering of part of the *Meditationes vitae Christi* of St. Bonaventure, has been ascribed to Mannyng on no better ground than that in two manuscripts it is transcribed immediately after *Handlyng Synne.*

BIBLIOGRAPHY.—Mannyng's *Handlyng Synne* was ed. by F. J. Furnivall, with text of the *Manuel* in parallel, for the Roxburghe club (1862) and with extracts from the *Manuel* for the Early English Text society, original series 119, 123, 2 vol. (1901–03); there is no satisfactory edition of the *Manuel des Péchés*. The 1st pt. of *The Story of England* was ed by F. J. Furnivall, "Rolls Series," 2 vol. (1887); for the 2nd pt. see *Peter Langtoft's Chronicle, T.* Hearne (ed.), 2 vol. (1725). *See* also Ruth Crosby, "R. M. of B.: *A* New Biography," *Publications of the Modern Languagr Association of America,* vol. lvii (1942); E. J. F. Arnould, *Le Manuel des Péchés, Étude de littérature religieuse anglo-normande* (1940); and, for full bibliography, J E. Wells, *A Manual of the Writings in Middle English, 1050–1400* (1916) and *Supplements* (1919–51). (G. SD.)

MANOAH, or MANUE (Douay version), in biblical history the father of Samson (*q.v.*).

The story, according to chapter 13 of the Book of Judges, is that a messenger appeared first before Manoah's wife, who had been childless, and announced that she was to bear a son, who would begin to deliver Israel from the Philistines. He admonished her to abstain from drinking wine or strong drink and from eating "any unclean thing"

After learning of this visit, Manoah prayed to have the messenger return to give him more instructions concerning the child. When he appeared before Manoah, the angel answered his questions by repeating his instructions to the woman. When Manoah made a burnt offering of a kid, the angel ascended with the flames toward heaven.

The child which was later born to them was named Samson. Samson was buried, according to chapter 16 of the same book. in his father's burying place between Zorah and Eshtaol (Saraa and Esthaol in Douay version).

MANOEL II, former king of Portugal (1889–1932), was born at Lisbon on Nov. 15, 1889, the younger son of Carlos I by his wife Marie Amélie of Orleans. On the assassination of King Carlos and of the crown prince, Luis, duke of Braganza, on Feb. 1, 1908, Dom Manoel succeeded to the throne of Portugal, but he retained it for only a short time, since the revolution of Oct. 3, 1910, forced him to flee the country (*see* PORTUGAL). He took refuge with his mother in England, and finally settled at Fulwell Park, Twickenham. He became a familiar and popular figure in English society. On Sept. 4, 1913, he married, at Sigmaringen, Princess Augusta Victoria of Hohenzollern, daughter of Prince Wilhelm of Hohenzollern. Dom Manoel died July 2, 1932.

MANOEUVRE, in military and naval tactics, a planned or regulated strategic movement, evolution or change of position of troops, vessels, etc. Used in the plural, the term usually refers to a series of extended field tactical movements or exercises carried out in imitation of war conditions by troops, ships, coastal defenses, etc.

In 1758 the term was discussed in *The Annual Register: "Coup de main*, and *Manoeuvre*, might be excusable in Marshal Saxe, as he was in the service of France . . . ; but we cannot see what apology can be made for our officers lugging them in . . . , as a sudden stroke might have done for one, and a proper motion for the other." The following use of the term is attributed to Manasseh Cutler in 1778 in *Life, Journal,* and *Correspondence, by his Grandchildren* (1881): "The army was ordered . . . to embark and re-embark in the boats, that they might the better understand such a maneuvre."

In general, the term means skilful or artful operation or management. It is used figuratively to mean an adroit move, expedient or proceeding in politics, finance, etc. According to John Adams's *Familiar Letters* (1876), Adams in 1774 said, "These A: ts of Parliament and ministerial manoeuvres will injure me." In Adams's *Works* (1854), he is quoted in 1790: "If the time should ever come when corruption shall be added to intrigue and manoeuvre in elections . . . chance will be better than choice."

MANOLY, LUDWIG EMANUEL (1855–1932), Hungarian double-bass player and teacher, was born in Teresia-Opel, Hungary, on Feb. 18, 1855. Manoly attended the Vienna conservatory and studied under Anton Bruckner. In 1876 he went to the United States, where he played with the Theodore Thomas orchestra and later played with the Mendelssohn Quintet in Boston, Mass. He was a member of the New York Symphony orchestra and later of the New York Philharmonic orchestra for many years. In 1927 he retired.

Manoly was a teacher at the New York Institute of Musical Art.

He died in New York on March 16, 1932.

MANOMETER: *see* VACUUM.

MANOR. Any definition of a manor, in land tenure, must take note of two elements — economic and political. The manor has an estate for its basis, although it need not coincide with an estate, but may be wider. It is also a political unit, a district formed for purposes of government, although the political functions made over to it may greatly vary. As a lordship based on land tenure, the manor necessarily comprises a ruler and a population dependent on him, and the characteristic trait of such dependence consists in various forms and degrees of subjection, chiefly regulated by custom. In the sense mentioned the manor is by no means a peculiarly English institution; it occurs in every country where feudalism got a hold. Under other names we find it not only in France, Germany, Italy, Spain, but also, to a certain extent, in the Byzantine empire, Russia, Japan, etc. It is especially representative of an aristocratic stage in the development of European nations. When tribal notions and arrangements ceased to be sufficient for upholding their commonwealths, when social and political life had to be built up on the basis of land-tenure, the type of manorial organization came forward in natural course.

Origin and Development.—One problem common to the entire European world has to be considered from the very beginning. Does the manor date from the Roman empire, or not? Can its chief features be traced in Roman institutions? There can be no doubt that at the end of the Roman period certain traits are noticeable which might, under favourable conditions, develop into a manorial combination. Great estates with political functions, populations subjected to the political lordship of landowners, appear in the closing centuries of the empire, and have to be reckoned with as precursors of mediaeval manorial life. During the last centuries of its existence the Western empire became more and more a conglomerate of barbaric and half-civilized populations. The central power, after claiming an absolute sway over its subjects, is obliged more and more to lean on private forces in order to maintain itself. One of its favourite resources in the 4th and 5th centuries consists in making great landowners responsible for the good behaviour of their tenants and even of their less important neighbours. The *saltus,* the great domain, is occasionally recognized as a separate district exempt from the ordinary administration of the city, subordinated to its owner in respect of taxes and police. Even in ordinary estates (*fundi*) there is a tendency to make the landowner responsible for military conscription, for the presentation of criminals to justice. On the other hand the incumbents of ecclesiastical offices are nominated in accordance with the wishes of patrons among the landowners; in the administration of justice the influence of this same class makes itself felt more and more. Nor are signs of a convergent evolution wanting on the economic side. Slaves are used more and more as small householders provided with rural tenements and burdened with rents and services. Free peasant farmers holding by free agreement get more and more reduced to a status of half-free settlers occupying their tenancies on the strength of custom and traditional ascription to the glebe. Eventually this status is recognized as a distinct class by imperial legislation. Yet there could be no talk of a manorial system as long as the empire and the commercial intercourse protected by it continued to exist.

The fall of the empire hastened the course of evolution. It brought into prominence barbaric tribes who were unable to uphold either the political power or the economic system of the Romans. The Germans had from of old certain manorial features in the constitution of their government and husbandry. The owner of a house had always been possessed of a certain political power within its precincts, as well as within the fenced area surrounding it: the peace of the dwelling and the peace of the hedged-in yard were recognized by the legal customs of all the German tribes. The aristocratic superiority of warriors over all classes engaged in base peaceful work was also deeply engraved in the minds of the fighting and conquering tribes. On the other hand the downfall of complicated forms of civilization and civil intercourse rendered necessary a kind of subjection in which tributary labourers were left to a certain extent to manage their own affairs. The Germanic conqueror was unable to move slaves about like draughts: he had no scope for a complicated administration of capital and work. The natural outcome was to have recourse to serfdom with its convenient system of tribute and services.

But, as in the case of the Roman empire, the formation of regular manors was held back for a time in the early Germanic monarchies by the lingering influence of tribal organization. In the second period of mediaeval development in continental Europe, in the Carolingian epoch, the features of the estate as a political unit are more sharply marked. Notwithstanding the immense efforts of Charles Martel, Pippin and Charlemagne to strengthen the tottering edifice of the Frankish empire, public authority had to compromise with aristocratic forces in order to ensure regular government. As regards military organization this is expressed in the recognition of the power of *seniores,* called upon to lead their vassals in the host; as regards jurisdiction, in the increase of the numbers of commended freemen who seek to interpose the powerful patronage of lay and secular magnates between themselves and the Crown. Great estates arose not only on the lands belonging to the king, but on that of churches and of lay potentates, and the constitution of these estates reminds us forcibly of that of later feudal estates.

The struggle against Northmen, Magyars and Slavs gave a crowning touch to the process of localization of political life and of the aristocratic constitution of society.

France. — In order to describe the full-grown continental manor of the 11th century it is better to take French examples than German, Italian or Spanish. Feudalism in France attained the greatest extension and utmost regularity, while in other European countries it was hampered and intermixed with other institutional features. The expression best corresponding to the English "manor," in the sense of an organized district, was *seigneurie. Manoir* is in use but meant strictly "mansion" or chief homestead in France.

The *seigneurie* may be considered from three points of view—as a unit of administration, as an economic unit, and as a union of social classes.

(*a*) In principle the disruption of political life brought about by feudalism ought to have resulted in the complete administrative independence of the manor. *Chaque baron est souverain dans sa baronie* is a proverb meant to express this radical view of manorial separatism. As a matter of fact this separatism was never completely realized, and even at the time of the greatest prevalence of feudalism the little sovereigns of France were combined into a loose federation of independent fiefs. The institutional expression of this aspect of feudalism in the life of the *seigneurie* was the jurisdiction combined with the latter. The principal origin of this jurisdiction was the dismemberment of royal justice, the acquisition by certain landowners of the right of holding royal pleas. The assumption of authority over public tribunals of any kind was naturally considered as equivalent to such a transmission of royal right. But other sources may be noticed also. It was assumed by French feudal law that in all cases when land was granted by a *seigneur* in subinfeudation the recipients would be bound to appear as members of a court of tenants for the settlement of conflicts in regard to land. A third source may be traced in the extension of the patrimonial justice of a person over his serfs and personal dependents to the classes of free and half-free population connected with the *seigneurie* in one way or another. There arose in consequence of these assumptions of jurisdiction a most bewildering confusion of tribunals and judicial rights. A certain order was brought into this feudal chaos by the classification of judiciary functions according to the four categories of high, middle, low and tenurial justice. The scope of the first three subdivisions is sufficiently explained by their names; the fourth concerned cases arising from subinfeudation. As a rule the baron or *seigneur* sat in justice with a court of assessors or peers, but the constitution of such courts varied a great deal.

(*b*) The economic fabric of the French *seigneurie* varied greatly, according to localities. In the north of France it was not unlike that of the English manor. The capital messuage, or castle, and the home-farm of the lord, were surrounded by dependent holdings, *censives,* paying rent, and villein tenements burdened with services. Between these tenancies there were various ties of neighbourhood and economic solidarity recalling the open-field cultivation in England and Germany. When the harvest was removed from the open strips they returned to a state of undivided pasture in which the householders of the village exercised rights of common with their cattle. Wild pasture and woods were used more or less in the same fashion as in England *(droit de pacage de vaine pâture).* The inhabitants often formed courts and held meetings in order to settle the by-laws, and to adjudicate as to trespasses and encroachments *(courts colongdres).*

(c) The social relations between the manorial lord and his subjects are marked by various forms of the exploitation of the latter by the former. Apart from jurisdictional profits, rents and agricultural services, dues of all kinds are exacted from the rural population. Some of these dues have to be traced to servile origins, although they were evidently gradually extended to groups of people who were not descended from downright serfs but had lapsed into a state of considerable subjection. The *main morte* of rustic tenants meant that they had no goods of their own, but held movable property on sufferance without the right of passing it on to their successors, although after payment of a heavy fine, succession might be permitted. The *formariage* corresponded to the English *merchetum,* and was exacted from rustics on the marriage of their daughters; this payment was considered a badge of serfdom. *Chevage (capitagium)* might be exacted as a poll-tax from all the unfree inhabitants of a *seigneurie,* or, more especially, from those who left it to look for sustenance abroad. The power of the lord as a landowner was more particularly expressed in his right of pre-emption *(retrait seigneurial),* and in taxes on alienation *(lods et ventes).* As a person wielding political authority, a kind of sovereignty, the lord enjoyed divers rights which are commonly attributed to the State—the right of coining money, of levying direct taxes and toll *(tallagium, tolneta)* and of instituting monopolies, such as the use of the lord's mill *(moulin banal),* or of his oven *(four banal)* or of his bull *(taureazc banal).*

THE MANOR IN ENGLAND

The typical English Manor, if there be a recognized or definite type, is known to us through the records of the 13th century. There is much valuable material in the somewhat cryptic descriptions in the Domesday survey; there are admirable pictures of the custom and working of a manor in the 12th century extents, surveys, custumals and cartularies, but in the 13th century we find in addition to these, systematic information as to the economic progress of the manor, in the Ministers' accounts, and as to the judicial proceedings of the manorial courts, in the court rolls. By the 14th century we are confronted with a picture of change and decay, emancipation and development.

Topography.—Topographically, a manor is a complex estate, consisting of *(a)* the lord's demesne, scattered in strips in the open fields, or in consolidated blocks of fields; *(b)* the land of the free tenants, who owe the lord small rents in money or in kind, and certain fixed labour-services; *(c)* the land of the villeins, lying for the most part in the open fields, and owing more onerous and uncertain services, as well as rents in money and in kind. The land of the manor is partly arable, partly meadow (very highly valued), partly rough pasture, waste or wood. In central and southern England the arable land was divided into three great fields, arranged for a three year rotation of crops and fallow; the fields were divided into acre or ½-acre strips, grouped in "shots" or furlongs. The lord, the free tenants and the villeins all held more or less defined rights to a share in the meadow and the waste. Much of the communal administrative action of the manorial courts is connected with these rights. In the north and west, and again in Kent and East Anglia the three-field division is hardly to be found, and the whole agrarian system varies sharply from the "normal"; this fact is important in local investigations.

Inhabitants of the Manor.—The inhabitants of the manor have all their separate rights, asserted and defended by the manorial court. The lord at the head of the society, in his hall or manor-house, enjoys his own demesne, holds a certain "superiority" over the lands of the villeins (which, the later lawyers describe as ownership of the freehold of all villein or copyhold land) and possesses rights over the waste paramount to those enjoyed by the other inhabitants. These rights were to some extent limited by the Statute of Merton (1236) and the second Statute of Westminster (1285). The lord's rights of jurisdiction will be better treated in connection with the courts. The free tenant is not yet a modern free-holder; economically he is often hardly distinguishable from a villein, but his status is clearly marked by his power to appeal to the royal courts of justice, even against his lord. Below the free-tenants came the villeins *(nativi, rustici,* bondmen, virgaters, customers, etc.)—customary tenants holding a house, a virgate or half-virgate in acre strips, and a share in the meadows and waste. A virgate was normally about 30 acres—the fourth part of a hide; but it might vary from 10–15 acres up to 60 or 80, while the acre itself varies in different districts. The villein was in certain respects unfree; in the eye of the law he had no rights against his lord, who "was protected from all suits by the *exceptio villenagii";* he might not leave the manor without permission. and he could be reclaimed if he did, by the writ *"de nativo habendo";* he could not, in theory, own any property, and he was subject to certain "base" incidents, such as the payment of *merchet,* and the need to ask permission to put his son to school or to allow him to seek ordination. But in practice the villein bought and sold like other men, after payment of a small fee; he leased, exchanged or sold his land, through the very efficient machinery of the manorial cburt; he made wills, and at times appears even to have disposed of his villein lands by will—proved in the lord's court. He could, no doubt, be ejected by the lord, but such ejection was very rare, and seemed to require a complete cessation of services, by physical or mental incapacity, before it could be accomplished "according to the custom of the manor." The villein was never exposed to the arbitrary will of the lord, but was always protected by the court, which interpreted the "custom" by the spoken witness of the *villata* (or the *curia,* the *homagizcm,* the *jurati*) or the written testimony of court roll or custumal. The inevitable confusion which arose between unfree status, and unfree tenure usually reacted to the advantage of the villein by blood, but on some estates (notably monastic lands) there was a determined attempt to impose the whole burden of unfree status upon free men holding villein tenements. Individual villeins, with their *sequela,* or villein brood, were sometimes bought and sold, but they could not be separated from their tenements, and all that is implied by sale is transfer from one lord to another as regards services and jurisdiction. The hardship or prosperity of a villein's lot depended mainly upon his economic position, which would seem to have steadily improved in the 14th century. His rents in money, in kind, and in services were for the most part fixed. The rents of assize (probably a commutation of earlier rents in kind rather than of services) varied considerably on different manors, but as they remained fixed for centuries, the advantage of any fall in the value of money remained with the villein. The dues in kind were gradually almost all commuted, or dropped.

Labour Services.—Although it happened that the villein paid small rents in moneys and in kind, labour dues were the most serious part of a villein's obligations. Two or three days week-work throughout the year might be combined with two or three extra days per week in harvest to make an apparently insupportable burden It should be noted, however, that a day's work sometimes means, by definition, half a day's work, or a fixed measure of reaping or mowing. Moreover, the labour was due from the virgate, and not from each man; hence a father might send his son to fulfill his obligation. Generally the harvest works (boon-days) survived longest as they were available for emergencies.

One of the most important problems in connection with the manor is the local distribution of labour services, and the varying reasons for their commutation. The history of the manor in the 14th century is the story of the change from typical mediaeval methods to an elementary form of the modern farm worked by hired labour. By the end of the 14th century the class of villeins included men of varied economic status; cottiers or bordars holding a plot of 4 or 5 acres and a cottage at one end of the scale were legally in the same position as men who had laid field to field, virgates and enclosures, until they might hold 100 to 200 acres of land, and require the services of wage-paid men, even while they themselves owed "base" services.

Administration of the Manor.—A very important factor in the development of the manor was the administrative system, the history of which has as yet been imperfectly explored. This aspect of manorial history is, however, useful in correcting over-sweeping generalizations. The lord of a manor might be the king, the duke of Lancaster, a wealthy bishop or monastic house, or, on the other hand the humblest of knights or freemen. Upon his status and the number of his manors depended the character of the administration. The minimum staff would be the lord's bailiff, working with the provost or reeve, who was usually elected by the "homage," and who had under him certain regular servants of the manor—a hay-ward, a reap-reeve, a shepherd, swineherd, bee-keeper, etc. Whenever it happened that the lord held a number of manors, he required a seneschal, or steward, whose office is variously described as agricultural supervision, or as judicial and legal (cf. Walter of Henley, etc.). The seneschal was usually assisted by a group of clerks and auditors, and other officials, who were responsible for the final presentation of the manorial accounts. The seneschal and his subordinates were admitted to office by an oath, closely parallel to that of a royal councillor; the whole group of officials tended to develop into a private council, which often contained professional lawyers, described as *utrius jurisperiti.* Rudimentary forms of these private councils may be found in the 12th century, and they were evidently well established by the end of the 13th century (*e.g.,* for the abbey of St. Albans, or the bishoprics of Durham, Worcester and Ely, and the archbishopric of Canterbury).

Manor Court.—The manor court is a complicated structure, though the division court leet, court baron and court customary does not belong to its early history. It originally exercised its criminal, civil, or manorial jurisdiction as one court; its names may differ, the parties before it may be free or unfree, but the court is the same. Its president was the lord's steward; the bailiff was the lord's representative and the public prosecutor; and the tenants of the manor, both free and unfree, attended at the court and gave judgment in the cases brought before it To modern ears the constitution sounds unfamiliar. The president of the court settled the procedure of the court, carried it out, and gave the final sentence, but over the law of the court he had no power. All that is comprised in the word "judgment" was settled by the body of tenants present at the court. The business of the court may be divided into criminal, manorial and civil. The powers under the first head depended on the franchises enjoyed by the lord in the particular manor; for the most part only petty offences were triable, such as small thefts, breaches of the assize of bread and ale, assaults, and the like; except under special conditions, the justice of great offenses remaining in the king. But offences against the custom of the manor, such as bad ploughing, improper taking of wood from the lord's woods, and the like, were of course the staple business of the court. Under the bead of manorial business the court dealt with the choice of manorial officers, and had some power of making regulations for the management of the manor; but its chief function was the recording of the surrenders and admittances of the villein tenants.

It is in this function that we find the origin of copyhold tenure. The manorial court acted as a registry of an active land market, and, provided the fees on transfer were paid, lords evidently made no effort to maintain static conditions. On some estates we find an almost complete replica of the system of royal writs for possessory and even proprietary actions. Litigation became so common that the written record takes the place of the testimony of the old men or of the court. Court rolls were constantly produced in court, as evidence, and from the first half of the 14th century, we find tenants in possession of a copy of court roll. By 1400 the possession of a copy is often enforced, and the existence of the copyholder is thus acknowledged. Besides land questions, the manorial court dealt with any other civil suits that might arise, such as questions of debt, detinue, damages, or contract. In semi-urban manorial courts, which might have to deal with fairs or with industry, these civil cases became of considerable importance. Occasionally, the manor court would appear to encroach upon the province of the courts christian—*e.g.,* in dealing with wills of villeins and copyholders, and in proceedings against usurers.

During the 15th century, the villein slowly developed into a copyholder, and the importance of the manorial court was correspondingly diminished. After ten well-known decisions of Danby, C.J., and Bryan, C.J., in 7 Ed. IV. and 21 Ed. IV., it was established that the courts of law could entertain an action of trespass brought against his lord by a customary tenant. From this time onward, the courts, both of law and of equity, began to intervene, and the records of the courts of Chancery, Star Chamber, and Requests show that in the Tudor period equitable suits brought by tenants against their lords were not infrequent The few remaining "bondsmen" of the 16th century were constrained to pay heavily for their manumission. Gradually the manor ceased to have any social or economic importance, and its few remaining privileges and peculiarities of tenure were swept away by the Law of Property Acts 1922.

It is clear that the manor court as here described consisted of conflicting elements of very different origin and history. Founded partly on express grants of franchises, partly on the inherent right of a feudal lord to hold a court for his free tenants, partly on the obscure community traceable among the unfree inhabitants of the manor, it is incapable of strict legal definition. All these elements, moreover, contain in themselves reasons for the decay which gradually came over the system In some cases of urban development, the manorial court was strengthened. But for the most part only a shadow of its former powers survived to control the few remaining copyholders, until the passing of the Law of Property Acts 1922.

Later Legal Theory.—A few words must be given to the legal theories of the 17th century on the manor court. It would seem to have become the law that to the existence of the manor two courts were necessary—a court customary for customary tenants, and a court baron for free tenants. If the freeholders in the manor diminish to less than two, the court baron cannot be held, and the manor perishes. This distinction seems to be without historical justification, as the court of the 13th century was not differentiated in this way; the terms were also very loosely applied, and it is not unusual in the 16th century to find a so-called court baron exercising all the functions of a customary court.

Apart from the change in the court of the manor, the most important thread in its later history is the process, mentioned above, which converted the villein into the copyholder. Although it seems hardly accurate to describe the villein of the 13th century as holding at the will of the lord, yet he could claim no protection from the king's courts. If, however, the villein were a tenant on the king's Ancient Demesne, his condition was distinctly more secure. He was protected by the writs of *monstraverunt* and the little writ of right close from the improper exactions of services and from ejection by the lord. But in ordinary manors there was no such immunity. That ejection was legally possible has already been shown, and it was not until the well-known decision of

Danby. C. J. and Bryan, C. J. in 7 Edw. IV, and 21 Edw. IV, that the courts of law would entertain an action of trespass brought against his lord by a customary tenant. There was nothing. however. to prevent a customary tenant from proceeding by way of petition to the king, and there are cases of such petitions as early as the end of the 14th century.

Moreover, in 1381 royal justice had come to the aid of the lords against their villeins, and it was not unknown that a lord should call in the private aid of a distinguished justice or counsel. In time the process is reversed: and the royal courts begin to help the villein or copyholder against his lord. From the decision of Bryan and Danby onwards, the courts, both of law and of equity, begin to intervene and the records of the courts of Chancery, Star Chamber. and Requests show that in the Tudor period equitable suits brought by tenants against their lords are not infrequent. The 16th century also saw the manumission of the few remaining "bondsmen." who were constrained to pay heavily' for their personal freedom. From that period onwards the manor ceased to have any social importance, and survived merely as the nucleus of a peculiar form of land tenure.

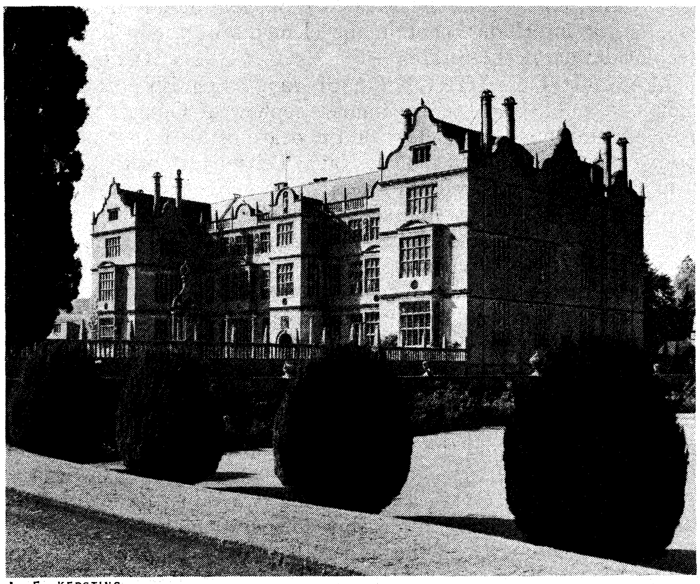
MANOR **MOUSE,** the dwelling of the lord of the manor or his residential bailiff, and the administrative centre of the feudal estate. Development in the middle ages is related to that of the castle (*q.v.*), which is however distinguished by Its primarily defensive character and greater political significance as a military strong point. Early manors were generally fortified, licence to crenelate being required from the king. and the evolution of domestic planning at the expense of more military considerations is in proportion to the degree of peaceful settlement of any country or region. With the church, the medieval manor house was the centre of village life. its hall the scene of the manorial court and the place of assembly of the tenantry. Usually the work of local craftsmen. the house mas more subject than the castle to local influences. physical and political. giving rise to distinctive regional forms of building. The particular character of the manor house is most clearly represented in England and France. but under different names the dwellings of feudal overlords are to be found in all countries wherein the manorial system developed. fulfilling similar functions within the national expression of style and period.

In England in the 11th century, the early manor house was an informal group of related buildings in timber or stone comprising the hall. chapel, kitchen and farm buildings contained within a defensive wall and ditch. The manor house of Boothby Pagnell, Lincolnshire, is of late 12th-century date and comprises a hall and private chamber placed defensively at first-floor level over a storage undercroft, and contained n-ithin a moated enclosure. In large houses at this time the hall (*q.v.*), which throughout the medieval period was the major element of domestic architecture, was more conveniently planned at ground level, as in Oakham castle. Rutland. n-ithin a more strongly deiended enclosure. and subsequently this hall arrangement was generally adopted. Stokesay castle, Shropshire. is the finest surviving example of a fortified manor house of the 13th century, the ground-floor hall being flanked by toners and further defended by a moated enclosure. By the 14th century the manor house plan was clearly defined, with private living apartments and service rooms planned at opposite ends of the great hall. the parts being more closely integrated, in many major instances enclosing an irregular courtyard, while battlements, gatehouse and moat continued to be provided as at Ightam Mote. Kent. Cothay manor, Somerset, is a characteristic house of the 15th century showing little advance in planning but having more domestic character than earlier instances, while Ockwells manor. Berkshire. also built in the 1 jth century, is the regional timber framed expression of the same hall plan, without defensive pretensions.

Comparable development in France was delayed by internal conflict. and until the ending of the Hundred Years War. in 1453, considerations of defense dominated manorial building. Such early manor houses as that at Saint Medard en Jalle. near Bordeaux, built in the 13th century, and the 14th-century Manoir de Camarsac (Gironde) comprise a rectangular fortified tower in which the principal rooms are at first-floor level above cellars, standing nith subsidiary buildings in a walled and moated enclosure. In Normandy, the Manoir d'Ango, near Dieppe. reveals some advance in domestic planning in the 1 jth century, the house standing at one end of a courtyard, flanked by farm buildings and defended by a gatehouse.



A. F. KERSTING

MONTACUTE HOUSE. SOMERSET. EARLY ENGLISH RENAISSANCE STYLE, 1580–1601

With the decline of manorial significance coinciding with increased prosperity and the call for more commodious dwellings, development of the manor house in the 16th century emerges into that of the Renaissance country house. In England. increased formality combined nith the new use of bricks and terra cotta produced more elaborate buildings, frequently of regular quadrangular plan, the hall declining in size and importance. Sutton place, Surrey (c. 1525), illustrates this phase. which leads to the more complex block plans of the Renaissance as at Ramsbury manor. Wiltshire (c. 1680). where the hall is reduced to the status of an entrance. The defended tower-house tradition persists in France throughout the 16th century in such instances as the Manoir des Tourelles, at Rumilly, near Troyes. generally retaining corner turrets and other defensive archaisms. while revealing classical influence in the symmetry of the *appartement* plan, which was later to become a feature of the Renaissance château. In later years the title of manor house in England lost particular significance. being adopted by large country mansions which had no manorial foundation.

Wood. *Thirteenth Century Domestic Architecture in England* (1950); Ernest de Ganay, *Châteaux et Manoirs de France* (1938); Pierre Lavedan, *French Architecture* (1944). (K. B. W.-J.)

MANRESA, a rown of Spain, in the province of Barcelona, on the Cardoner river and the Barcelona-Lérida railway. Pop. (1950) 40,021 (mun.). It is probably the *Munorisa* of the Romans, the capital of the Jacetani or Jaccetani. A large part of the town was burned by the French in 1811. Manresa is the chief town of the highlands watered by the Cardoner and upper Llobregat, which meet below the town, and are also connected by a canal 18 mi. long. The principal buildings are the collegiate church of Santa Maria de la Seo, the Dominican monastery, and the church of San Ignacio, built over the cavern where Ignatius de Loyola spent most of the year *1522* in penitentiary exercises and the composition of his *Exercitia spiritualia.* Manresa has iron-foundries and manufactures of woolen, cotton and linen goods, ribbons, hats, paper, soap, chemicals, spirits and flour. Building stone is quarried nearby.

MANRIQUE, GÓMEZ (1415?–1490?), Spanish poet, chiefly remembered as the earliest Spanish dramatist whose name is known, was born at Amusco, Tierra de Campos, and probably died at Toledo. He took a prominent part in the rebellions of the reigns of John II and Henry IV, as soldier, politician and diplomat and won fame as an orator during his governorship of Toledo. His *Cancionero* contains 108 poems, written in the manner of the time. His nativity play, *Representacidn del nacimiento de Nuestro Señor,* his *Lamentaciones fechas para Semana Santa,* and his two *momos,* or interludes, contain the elements of the religious and secular drama of the future. (C. C. SH.)

MANRIQUE, JORGE (1440?–1479), Spanish poet and soldier, of a noble and literary family, nephew of Gómez Manrique (*q.v.*), is famous for his elegy on the death of his father. He was born probably at Paredes de la Nava, Palencia, *c.* 1440, and died near Garci-Muñoz on March 27, 1479. His love songs, satires and acrostic verses are little more than ingenious compositions in the manner of his age; he owes his imperishable renown to the *Coplas por la muerte de su padre* (1476), an elegy in the haunting *pie quebrado* metre, in which each 12-line stanza has 4 triplets, the triplets having lines of 8, 8 and 4 syllables. Although this is based in part on a similar lament by his uncle, and contains numerous echoes of the Bible and Boethius, its derived thoughts and commonplaces on death are transformed by grief into something intensely personal and (for the 15th century) unusually lyrical. The perfect technique and the sublimity of expression help to explain the poem's lasting fame. (C. C. SH.)

MANSARD ROOF, a roof having two slopes on every side, the lower slope being considerably steeper than the upper. Although used as early as the mid-16th century by Pierre Lescot at the Louvre, it was named after François Mansart (*q.v.*), who employed it for Paris *hôtels* and the châteaux of Balleroy. Blois and Maisons. It was probably first used because its predominantly horizontal profile was more in harmony with the classical orders than high-pitched roofs. The mansard, when pierced with dormers, also provides a more spacious and economical attic story. During the mid-19th century it was particularly popular, especially in France and the United States. *See* also **ROOF.** (Js. S. P.)

MANSART (MANSARD), **(NICHOLAS) FRANÇOIS** (1598–1666), French architect, who expressed more than any contemporary architect the classical spirit of the 17th century in France, was born in Paris on Jan. 23, 1598. He was the son of a Parisian master carpenter, probably worked under Salomon de Brosse and was certainly strongly influenced by him. By 1635 he was undertaking important commissions for the crown, but the masterpiece of his early period is the château of Balleroy (begun *c.* 1626) for Choisy. chancellor to Gaston d'Orleans, in which he combines the classicism of de Brosse with the Henri IV brick-and-stone style of building. Soon afterward Mansart reconstructed Blois for Louis XIV's brother. This work, although never completed, shows Mansart's classicism at its most subtle; it was there that he first used the high-pitched type of roof which bears his name (mansard), though. in fact, de Brosse had already used it at Rennes. In 1645 Mansart was commissioned by Anne of Austria to build the church of the Val-de-Grbce in Paris. Though he was replaced by J. Lemercier in 1646, the plan and much of the construction of the walls is Mansart's work. The design derives from Palladio's church of the Redentore at Venice, one of the purest examples of High Renaissance classicism, and a scheme adopted again by Mansart for the chapel at Fresnes. Between 1635 and 1655 he built a number of important private houses in Paris in which his subtle and ingenious mind is revealed in skillful planning on sites often awkwardly shaped. The château de Maisons (now Maisons-Laffitte) is the most complete work by the architect to survive. It was completed save for the severely rich decoration by 1646.

Mansart's work is marked by extraordinary clarity and restraint. He was able to combine a flexible use of the classical with great richness of decoration.

See A. F. Blunt, *François Mansart* (1941) and *Art and Architecture in France 1500 to 1700* (1953). (F. J. B. W.)

MANSART (MANSARD), **JULES HARDOUIN** (1646?–1708), French architect, who designed Versailles under Louis XIV, was born in Paris probably on April 16, 1646, son of the painter Raphael Hardouin. He was a grandnephew by marriage of the architect François Mansart, whose surname he adopted in 1668. In 1674 Mansart was commissioned by Louis XIV to build a château for Madame de Montespan. He was by this time launched upon a brilliant career under the king's patronage. Among his earlier additions to St. Germain were a number of private houses, including the Hôtel de Lorges (later Hôtel de Conti), his own residence. As official architect to the king he was entrusted with the redesigning and additions to the palace of Versailles and its environs; there he built the new Galerie des Glaces and Orangerie, the Trianon and the north and south wings in a harmonious, classical style. In addition to this enormous project. which occupied much of his life, Mansart built many other public buildings, churches and sumptuous houses. After making additions to the Palais Royal and building part of Orleans cathedral, he completed the famous chapel of St. Louis des Invalides (Dôme des Invalides), Paris, in a blend of Greek classical and baroque styles. He was responsible for the Place Vendôme, the Place des Victoires and the Maison de St. Cyr, all in Paris. His country mansions included the Château de Luneville and the Chbteau de Sagonne. The royal residence at Marly was his creation. One of the most successful architects of his day, Mansart had his own atelier where he worked with collaborators and trained his protégés. He was working on the chapel at Versailles when he died on May 11, 1708.

MANSEL, HENRY LONGUEVILLE (1820–1871), English philosopher and churchman, born at Cosgrove, Northamptonshire on Oct. 6. 1820, was educated at Merchant Taylor's school and St. John's college, Oxford. He was elected Waynflete professor of moral and metaphysical philosophy at Oxford in 1859 and regius professor of ecclesiastical history in 1867, in which year he also became canon of Christ Church. He was appointed dean of St. Paul's in 1868. Mansel died at Cosgrove on July 30, 1871.

In philosophy, Mansel was a follower of Sir William Hamilton (*q.v.*), developing Hamilton's ideas in an article on metaphysics written for the eighth edition of the *Encyclopœdia Britannica* (1857) and defending them, in *The Philosophy of the Conditioned* (1866), against the attacks of John Stuart Mill. In his Bampton lectures, *The Limits of Religious Thought* (1858), Mansel developed Hamilton's doctrine that human knowledge was strictly limited to the finite and "conditioned." The resulting contention that the human mind could not attain to any positive conception of the nature of God provoked much controversy in which Mansel was accused of agnosticism, though he had meant to attack deism, not theism. Mansel's other published works include *Prolegomena logica: an Inquiry Into the Psychological Character of Logical Processes* (1851) and *The Gnostic Heresies of the First and Second Centuries* (ed. by J. B. Lightfoot, 1875). He edited Henry Aldrich's *Artis logicae rudimenta* (1849) and, with J. Veitch, Sir W. Hamilton's *Lectures on Metaphysics and Logic,* 4 vol. (1859–60).

See J W. Burgon, *Lives of Twelve Good Men* (1888).

MANSFELD, a German family which took its name from Mansfeld in Saxony, where it was seated from the 11th to the 18th century. One of its earliest members was Hoyer von Mansfeld (d. 1115), a partisan of the emperor Henry V during his struggles with the Saxons; he fought for Henry at Warnstadt and was killed in his service at Welfesholz. Albert, count of Mansfeld (1480–1560), nas an intimate friend of Luther and one of the earliest and staunchest supporters of the Reformation

With Albert was associated his brother Gebhard, and another member of the family was Johann Gebhard, elector of Cologne from 1558 to 1562. A scion of another branch of the Mansfelds was Peter Ernst, Fürst von Mansfeld (1517–1604), governor of Luxemburg, nho was loyal to Charles V. He went with the emperor to Tunis and fought for him in France He served Philip II at St. Quentin and in the Netherlands, and led a body of troops against the Huguenots. In this capacity he was present in 1569 at the battle of Moncontour, nhere Count Wolrad of Mansfeld (d 1578) was among the Huguenot leaders.

MANSFELD, ERNST, GRAF VON (*c* 1580–1626), German soldier, was an illegitimate son of Peter Ernst, Fürst von Mansfeld. He allied himself with the Protestant princes, and was dispatched by Charles Emmanuel duke of Savoy, at the head of about 2 000 men to aid the revolting Bohemians at the outbreak of the Thirty Years' War in 1618. He took Pilsen, but in the summer of 1619 he was defeated at Zablat. After this he remained inactive while the titular king of Bohemia, Frederick V elector palatine of the Rhine, was driven from Prague. Mansfeld was appointed by Frederick to command his army in Bohemia, and in 1621 he established himself in the Upper Palatinate, successfully resisting the efforts made by Tilly to dislodge him. From the Upper he passed into the Rhenish Palatinate. There he relieved Frankenthal and took Hagenau; then, joined by his master, the elector Frederick, he defeated Tilly at Wiesloch in April 1622 and plundered Alsace and Hesse. Mansfeld's ravages were so ruinous to the districts he was commissioned to defend that Frederick was obliged to dismiss Mansfeld's troops from his service Joining Christian of Brunswick, the count then led his army through Lorraine, devastating the country, and in Aug. 1622 defeating the Spaniards at Fleurus. He next entered the service of the Gnited Provinces About 1624 he paid three visits to London, where he was hailed as a hero. James I furnished him with men and money for the recovery of the Palatinate, and in Jan. 1625 Mansfeld and his army sailed from Dover to the Netherlands. On the renewal of operations in Germany in the autumn Mansfeld was again engaged. Defeated by Wallenstein at Dessau (1626), he raised another army, and pursued by Wallenstein, he pressed toward Hungary, where he hoped for aid from Bethlen Gabor, prince of Transylvania. But Gabor made peace with the emperor, and Mansfeld was compelled to disband his troops. He died at Rakowitza Nov. 20, 1626.

MANSFIELD, KATHERINE (1888–1923), British writer, was born at Wellington, N.Z. She published *In a German Pension* (1911), and in 1918 married John Middleton Murry, the critic, with whom she had been associated in the publication of a literary review, *Rhythm*. Her brilliant talent for the short story form was displayed in a collection issued as *Bliss* (1920), and her acute critical powers in frequent contributions to *The Athenaeum*, then edited by her husband. This was followed by *The Garden Party* (1922), but a career of great promise was cut short by death on Jan. 9, 1923. Further stories, *The Doves' Nest*, appeared later in that year, also a volume of *Poems*. In 1924 was published *Something Childish*, tales and fragments of minor interest, and in 1927 the *Journal of Katherine Mansfield* (1914-22). Her *Letters* in two volumes were published in 1928.

MANSFIELD, RICHARD (1854 or 1857–1907), U.S. actor, intense, somewhat eccentric, but unquestionably brilliant and one of the last of the great romantic stars, was born on May 24 in Berlin, where his mother Erminia Rudersdorff was engaged in a concert tour. His father Maurice Mansfield died when Richard was two, and Madame Rudersdorff and Richard spent the subsequent years in concert tours of England and the continent. In 1872 they arrived for the first time in New York city, where young Richard alternately turned to singing, painting and acting. Dissatisfied with his lack of accomplishment, he returned to England in 18;7 and during the next six years achieved moderate success as a singer of light opera, principally of Gilbert and Sullivan. In the United States again in 1882, he turned to the spoken drama, attracting considerable attention as Baron Chevrial in *A Parisian Romance*. Through the next 20 years he continued to build his reputation in both England and the United States as an exciting, though frequently unpredictable, star. His chief roles were Jekyll and Hyde (1887), Richard III (1889), Beau Brummell (1890), Shylock (1893) and Cyrano (1898). In 1894 Mansfield produced *Arms and the Man* in New York, the first production of Shaw in America. In 1906 his *Peer Gynt* was a success in its Chicago opening, but, after moving it to New York and playing Peer and Baron Chevrial on the same day, Mansfield collapsed, physically and nervously exhausted. After a year's struggle to regain his health, he died in New London, Conn., Aug. 30, 1907.

See Paul Wilstach, *Richard Mansfield, the Man and the Actor* (1908); William Winter, *Life and Art of Richard Mansfield*, 2 vol. (1910).

(S. W. H.)

MANSFIELD, WILLIAM MURRAY, 1ST EARL OF (1705–1793), English judge, for 34 years chief justice of the king's bench, was born at Scone, in Perthshire, Scot., on March 2, 1705, the son of the 5th viscount Stormont. Only Sir Edward Coke and Sir Matthew Hale rivaled him as chief justice, parts of his work being published and becoming authoritative almost before he was off the bench. Subsequently, he three times procured position as a member of the cabinet, simultaneously getting the Great Seal (the chancellor's office) entrusted to a committee. Thus he retained the chief justiceship regardless of changes in administration but still exerted political power, a practice which later happily became unconstitutional. Educated at Perth grammar school, Westminster school and Christ Church college, Oxford, Mansfield was called to the bar at Lincoln's Inn in 1730. In Scotland he became famous by his appearance for the city of Edinburgh when it was threatened with disfranchisement for the affair of the Porteous mob, but his English practice remained scanty until in 1737 a single speech in one jury trial placed him at the head of the bar. In 1742 he was appointed solicitor general. In 1754 he became attorney general and acted as leader of the house of commons under the duke of Newcastle. In 1756 he claimed the chief justiceship of the king's bench and was made Baron Mansfield. In 1776 he was created earl of Mansfield. In 1783, during the coalition ministry, he declined cabinet office, but served as speaker of the house of lords. He resigned as chief justice in 1788 and died on March 20, 1793.

As must be the case with any court in central position, politics followed Mansfield to the bench. Three matters particularly reveal the man. After the burning of his house and precious library in 1780 in those "No Popery" riots, which involved mobs of 50,000 and invasion of parliament itself, Mansfield so fairly conducted the treason trial of the leader Lord George Gordon, that an acquittal resulted. In the Wilkes case (1768) he rose above both popular clamour and royal pressure by careful technical work on the precedents. This work developed legal flaws in the crown's case unknown to the defendant himself. Thus the Tory judge discharged an agitator because the Tory's own type of due process so required. The nidespread viem that Mansfield abolished slavery with one judicial decision, while it took a civil war in the United States, is, however, superstition. Mansfield sought, with all of his high tactical powers, to avoid any slavery issue: he was a property-minded man of commerce. Even the famous judgment in Somersett's case (1772) decided only that an escaping slave could not be forcibly removed from England to vengeance in a colony. This, as Benjamin Franklin rightly protested, meant no abolition of "a detestable commerce" or of slavery in the colonies—both encouraged by the British laws until statutory changes in 1807 and 1833. Indeed, no vital emotional issue can be settled—though it may be helped toward solution—by judicial decision. The Dred Scott case and the segregation cases make this clear.

Mansfield's permanent stamp upon Anglo-American law lies in commercial law. When he mounted the bench, two years before the start of that Seven Years War that riveted Britain's grasp upon America, India and international trade, the English law was land-centred and landbound in outlook and intrenched professional tradition. Reform was imperative. Mansfield's vision and ambition reached beyond following the continental model of a special body of rules for commerce and banking. He sought to make the international law of commerce not a separate branch but an integral part of the general law of England, both common law and equity, using the leverage thus gained to pry loose from feudalism whole blocks of other rules which had few or no direct commercial bearing. An important part of this brilliant venture succeeded.

In the area of bills of exchange (drafts), promissory notes and the then novel check. Mansfield, modeling on standard international practice. shaped the law in sweeping judgments, each typically canvassing the whole relevant situation and its reasons. *Heylyn* v. *Adamson* (1758) 2 Burrow 669 is an example. No judge has ever surpassed him here. A second area involved fresh creation. Marine insurance. then a new industry. was centred in London and was a weapon of competition and cold war. Mansfield did not build here on models; he created the entire discipline.

He was not always so successful. In *Pillans* v. *Van Mierop* (1765) 3 Burrow 1663. he made enforceable without consideration, *i.e.*, roughly. without any bargained-for return, a merchant's (banker's) "confirmed credit" or promise to accept drafts drawn from abroad. This decision was viewed, though without good ground, as a flat attack on the whole doctrine of consideration. and that doctrine was reaffirmed in its entirety by the house of lords in *Rann* v. *Hughes* (1778) 7 T.R. 350, n. A second defeat was in his effort to make a document transferring land receive an interpretation according to plain intention, rather than have such intention frustrated by some technical rule giving unmeant effect to words. His decision on this, in *Perrin* v. *Blake*, was reversed in 1772 (one of six reversals during 32 years of active service). But he triumphed in his expansion of the idea that a man should turn back or turn over any value received by mistake or wrongdoing or otherwise under circumstances making it inequitable for him to retain it. The remedy was by a fictitious "promise" to pay over ("quasi-contract"; modernly, the fiction being discontinued: "restitution"). This decision involved not only a wide new range for remedy but, as in the case when the sum received on resale of another's goods was substituted for their arguable value, an important simplification and easing of the plaintiff's proof.

Despite his long tenure, the "father of commercial law" had almost no cases on the heart of modern commercial law: mercantile contracts for the sale of wares. But he had chosen to make commercial law and general law a single whole. When commercial sales cases did arise, they came, ironically, before judges who thought in terms of haystacks and of horses, and the central area of commercial law was for more than a century given a flavour of land and manure rather than of commerce.

MANSFIELD, a municipal borough in the Mansfield parliamentary division of Nottinghamshire, Eng., on the river Maun, 14 mi. N.N.W. of Nottingham. Pop. (1951) 51,352. It lies on the western outskirts of Sherwood forest and the dukeries. Mansfield was occasionally the residence of Mercian kings and afterward the resort of Norman sovereigns. During the reign of Edward the Confessor it was a royal manor and was finally held by the duke of Portland. A market charter was granted in 1227, a fair charter in 1377. In 1891 it was incorporated. Rock houses (hewn out of the solid rock) are a reminder of the town's antiquity. The parish church of SS. Peter and Paul is early Norman and Perpendicular. The Old Meeting house was built in 1701. The Moot hall was built in 1752. The Bentinck memorial, in the market place, was erected in 1849. Newstead abbey, ancestral home of the poet Lord Byron, lies 4 mi. S.

Mansfield is situated in the heart of the north Nottinghamshire coal field. Manufactures include boots and shoes, hosiery, artificial silk. woolens, plastics, radio and aircraft components, leather and bricks.

MANSFIELD, a city in north-central Ohio, U.S., the seat of Richland county., is almost equidistant between Cleveland and Columbus, about 75 mi. from each city. Situated on rolling land at the very edge of the Allegheny plateau, it was first surveyed by Gen. James Hedges in 1808, three years after Indian titles were removed by the treaty of Fort Industry. Named after Jared Mansfield. surveyor general of the United States, the town grew slowly until the advent of the Mansfield and Sandusky railroad (later part of the Baltimore and Ohio system) in 1846; the Pittsburgh, Fort Wayne and Chicago railway (ultimately part of the Pennsylvania system) in 1849; and the Atlantic and Great Western railway (later included in the Erie system) in 1863. Thereafter its growth was more rapid; the city became an important manufacturing centre in the post-Civil War period. By the 1960s Mansfield's diversified industry embraced electric and gas appliances, tires and inner tubes, auto bodies, sheet steel, electric distribution equipment, plumbing fixtures, vitreous china and thermostats.

Distinctive features of the community include the Kingwood Center; a 47-ac. horticultural and botanical garden; a War of 1812 log blockhouse; and a monument to John Chapman (Johnny Appleseed), who for nearly 20 years considered Richland county his home.

The Malabar farm, established by novelist Louis Bromfield, is not far from the city. For comparative population figures ***see*** table in OHIO: *Population*. (P. R. S.)

MANSHIP, PAUL (1885–), U.S. sculptor, creator of the large bronze figure of Prometheus overlooking the Rockefeller Center plaza, in New York city, was born in St. Paul, Minn., on Dec. 25. 1885. After studying in St. Paul, Philadelphia and New York city, he won a scholarship in 1909 to the American academy in Rome. After three years abroad he settled in New York. Starting in 1913 with a prize from the National Academy of Design, his works continued to win awards. In their subjects and generalized style his statues are inspired by classical art. To a lesser degree he was influenced by the east, especially India. Renowned for excellent craftsmanship, he developed a distinctive style remarkable for its simplified modeling and rhythmical patterns. Among his large decorative works, mostly in bronze, are: "Dancer and Gazelles" (1916), of which there are versions in several museums; the Prometheus fountain (1934) in Rockefeller plaza; "Celestial Sphere" (1939); and Woodrow Wilson memorial at the Palais des Nations, Geneva.

Manship executed many portraits in marble; most striking are: "Pauline Frances — Three Weeks Old" (1914), Metropolitan Museum of Art, New York city and "John D. Rockefeller" (1918), collection of John D. Rockefeller, Jr. His bronze "The Young Lincoln'! is in Fort Wayne, Ind. Manship's delightful depictions of animals are much admired; particularly famous is the Paul J. Rainey memorial gateway at the Bronx zoo, New York city (1934).

See E. Murtha, *Paul Manship* (1957). (M. I. B.)

MANSLAUGHTER, in Anglo-American criminal law, the unlawful killing of another human being, without malice, either express or implied. In the U.S., several states define by statute two kinds of manslaughter: voluntary, in which there is intent to produce the injury; and involuntary, in which there is no such intent. Other states recognize several distinct degrees of the crime. All these distinctions are purely statutory and do not enter into the common law definition. For the distinction between manslaughter, murder and other forms of homicide, see HOMICIDE. (A. DM.)

MANSON, SIR PATRICK (1844–1922), British parasitologist, the first outstanding modern practitioner, teacher and research worker in the field of tropical medicine, was born in Scotland on Oct. 3, 1844 He practised medicine in Takao, Amoy and Hong Kong (1866–89), and thereafter in London until his death. He was elected fellow of the Royal society in 1900, knighted in 1903, created Knight Grand Cross of St. Michael and St. George in 1912, became first president of the Society of Tropical Medicine and Hygiene (1907–08) and was recipient of many medals and honorary degrees. He published several hundred scientific papers. He died on April 9. 1922.

Manson was first to discover (1877–79) that an insect (mosquito) can be host to a developing parasite (the worm *Filaria bancrofti)* of a human disease (filariasis). In 1894 he published his mosquito-malaria hypothesis, which led to the discovery by Ronald Ross (*q.v.*) that malaria, like filariasis, is a mosquito-transmitted disease.

In 1898 Manson published a textbook on tropical diseases that, frequently revised, has been a standard ever since. In 1899 he organized the London School of Tropical Medicine.

See P. H. Manson-Bahr and A. Alcock, *The Life and Work of Sir Patrick Manson (1927).* (P. F. R.)

MANSUR, AL-, throne name or honorific title assumed by several Muslim rulers, meaning "aided," or "rendered victorious [by God]." It is also used as an ordinary name. The best-known are discussed below.

ABU JA'FAR ABDULLAH AL-MANSUR (714–775), second Abbasid caliph (see CALIPHATE). who reigned from 754 to 775. Born in Xug. 714, the son of a Berber slave girl. he followed his brother Abu'l-Abbas al-Saffah on the throne. His main task mas to secure the rule of the dynasty, which had come to power only in 750. So successful mas he in this that he must be regarded as the real founder of the dynasty. First. with the help of Abu Muslim. he defeated his uncle Abdullah, governor of Syria. who disputed his succession. Then he had Xbu Muslim treacherously murdered, since his power in Khurasan seemed to threaten the caliph's. Later, in 762–763. a Shi'ite rising in Mecca and Medina was ruthlessly crushed. Khurasan was pacified by the appointment in 759 of al-Mansur's son. known as al-Mahdi, as governor. The completion of the new capital at Baghdad in 766 was an outward mark of al-Mansur's success in pacifying the caliphate (apart from Spain) and firmly establishing Xbbasid rule. The new capital also shows the shift of power eastward, since the Abbasids depended on the armies of Iraq and Khurasan. At the same time Persian traditions of government mere followed more closely. and Persian Muslims had a greater share in the state. The Persian office of vizier was introduced. with a number of separate offices or ministries (diwans) subordinate to it, Al-Mansur died in Bir Maimun in Oct. 775 while on a pilgrimage to Mecca.

ABU TAHIR ISMA'IL IBN AL-QA'IM, third Fatimid caliph in north Africa who reigned from 946 to 953.

ABU YUSUF YAQUB AL-MANSUR. often called Jacob Almanzor, nho ruled from 1184 to 1189 as prince of the Moorish dynasty of the Xlmohads (*q.v.*) in north Africa and Spain. He was the son of a Christian slave girl. The Giralda at Seville is a notable architectural monument of his reign. His defeat of Alfonso VIII of Castile at Xlarcos (1196) is the culminating event of Almohad rule in Spain. Subsequently it rapidly declined.

IBN ABI-'AMIR AL-MANSUR. known to European writers as Almanzor, chief minister and virtual ruler of the Omayyad caliphate of Córdoba from 978 to his death in 1002. (See CÓRDOBA, CALIPHATE OF.) Descended from an Arab nho took part in the conquest of Spain, he rose by his own skill. tact and efficiency. He had the support of Subh, the Basque mother of the young caliph Hisham II, and she nas said to be his mistress. With his father-in-law. the general Ghalib, he overthrew the previous chief minister in 978. A rupture with Ghalib led to the latter's defeat and death in battle in 981. By giving the African territories local independence under Omayyad suzerainty. he stopped a drain on his resources. This and the replacement of the Slavs in the army by Berber and Christian mercenaries enabled him to conduct a series of successful campaigns against the Christian states of northern Spain. including one against Santiago in 997. From 981, when he assumed the honorific name of *al-Mansur bi'llah* ("the one made victorious by God"), he had supreme power and gradually adopted various outward marks of it. Though in 994 he took the title of "Noble King" (*al-Malik al-Karim*). the caliph continued as nominal head of state. He died at Medinaceli on Aug. 10, 1002. on the way back from a campaign. His rise to power is comparable to that of the Buyids and Seljuks in the east. A son succeeded him. but the family. known as the Amirids. retained poner for only a few years. (W. M. WT)

MANSURAH, AL (MANSURA), a tonn of lower Egypt on the eastern side of the Damietta branch of the Nile. It is the capital of Ad Daqahliyah governorate and is 90 mi. N. of Cairo and 34 mi. S.W. of Damietta. Pop. (1957) 136 057. It has rail connections with Az Zaqaziq (Zagazig) and Cairo and is an important market centre for the cotton, flax and rice of the northeast delta. Its principal industries include cotton ginning. cottonseed oil extraction. rice milling and textile manufactures.

Al Mansurah was founded in A.D. 1221. The only event of importance in its history is the battle of the same name, when King Louis IX, who was leading a crusade to attack Islamic power in Egypt. was outmaneuvered and his forces decimated on Feb. 8, 1250. It was this battle that largely contributed to the ultimate defeat of the French expedition (*see* CRUSADES).

The fort, called St. Louis after the French king, is still standing. (A. B. M.; M. V. S.-W.)

MANTEGNA, ANDREA (1431–1506), greatest north Italian fresco painter of the 15th century. was born at Isola di Cartura near Piazzola. Italy, in 1431 and was apprenticed by his father, a carpenter. to the Paduan painter Francesco Squarcione. In 1441 he is mentioned as Squarcione's adopted son. He seems to have remained in this painter's studio for six years. moving mith Squarcione to Venice in 1446. By 1448. when at the age of 17 he signed a lost altarpiece for Sta. Sofia in Padua, he was an independent artist. Padua was the seat of the most prominent university in north Italy, and from a very early date Mantegna must have been indoctrinated with the humanist culture that formed the mainstay of his art. In addition. he would have become familiar with the work of the Florentine artists nho had been employed in the church of S. Antonio, notably Fra Filippo Lippi and Donatello. The latter was resident in Padua after 1443 and exercised a profound influence on Mantegna's work. In Venice the frescoes of Andrea del Castagno in S Zaccaria. the mosaics of Paolo Uccello and the personality of Jacopo Bellini must also have left their impression on his mind. These experiences are summed up in Mantegna's first major work, the frescoes in the Ovetari chapel of the church of the Eremitani in Padua.

Before this chapel was destroyed by bombing in 1944, it contained a cycle of frescoes covering the lateral walls and vault, the altar wall and the upper part of the apse behind. The commission owed its origin to the will of Antonio Ovetari and seems to have been allotted in the first instance to Squarcione, by whom the work was subcontracted to Antonio Vivarini and Giovanni d'Allemagna, on the one hand, and to Mantegna and Niccolo Pizzolo, on the other Of the sections executed by Mantegna, the "Martyrdom and Removal of the Body of St. Christopher" (begun by Pizzolo) and an Assumption of the Virgin survive in part. The poles of Mantegna's development in the Ovetari chapel are the still tentative full-length saints painted in the apse and the masterly scenes on the base of the left wall, which belong to the last phase of work in the chapel, and were probably painted in 1456. Viewed solely from the standpoint of space projection. Mantegna's frescoes are the most progressive paintings of their time. Throughout the scenes the architecture is authentically classical and incorporates the rich archaeological detail that is a feature of Mantegna's mature work.

In Aug. 1453 Mantegna received the commission for a polyptych for the chapel of St. Luke in Sta. Giustina at Padua. This altarpiece, now in the Brera gallery in Milan, was completed in November of the following year and corresponds in style with the intermediate frescoes in the Ovetari chapel. The style of the latest of the frescoes is translated to the field of panel painting in an altarpiece commissioned for S. Zeno at Verona by Gregorio Correr. probably in 1456 (completed 1459). Inspired by Donatello's high altar in the Santo at Padua, the main panels represent, between four massive wooden columns, the Virgin and Child enthroned with four saints in an open hall. One of the richest and most brilliant of all north Italian altarpieces, the S. Zeno triptych now lacks its predella which is distributed between the Louvre ("Crucifixion") and the museum at Tours ("Agony in the Garden" and "Resurrection").

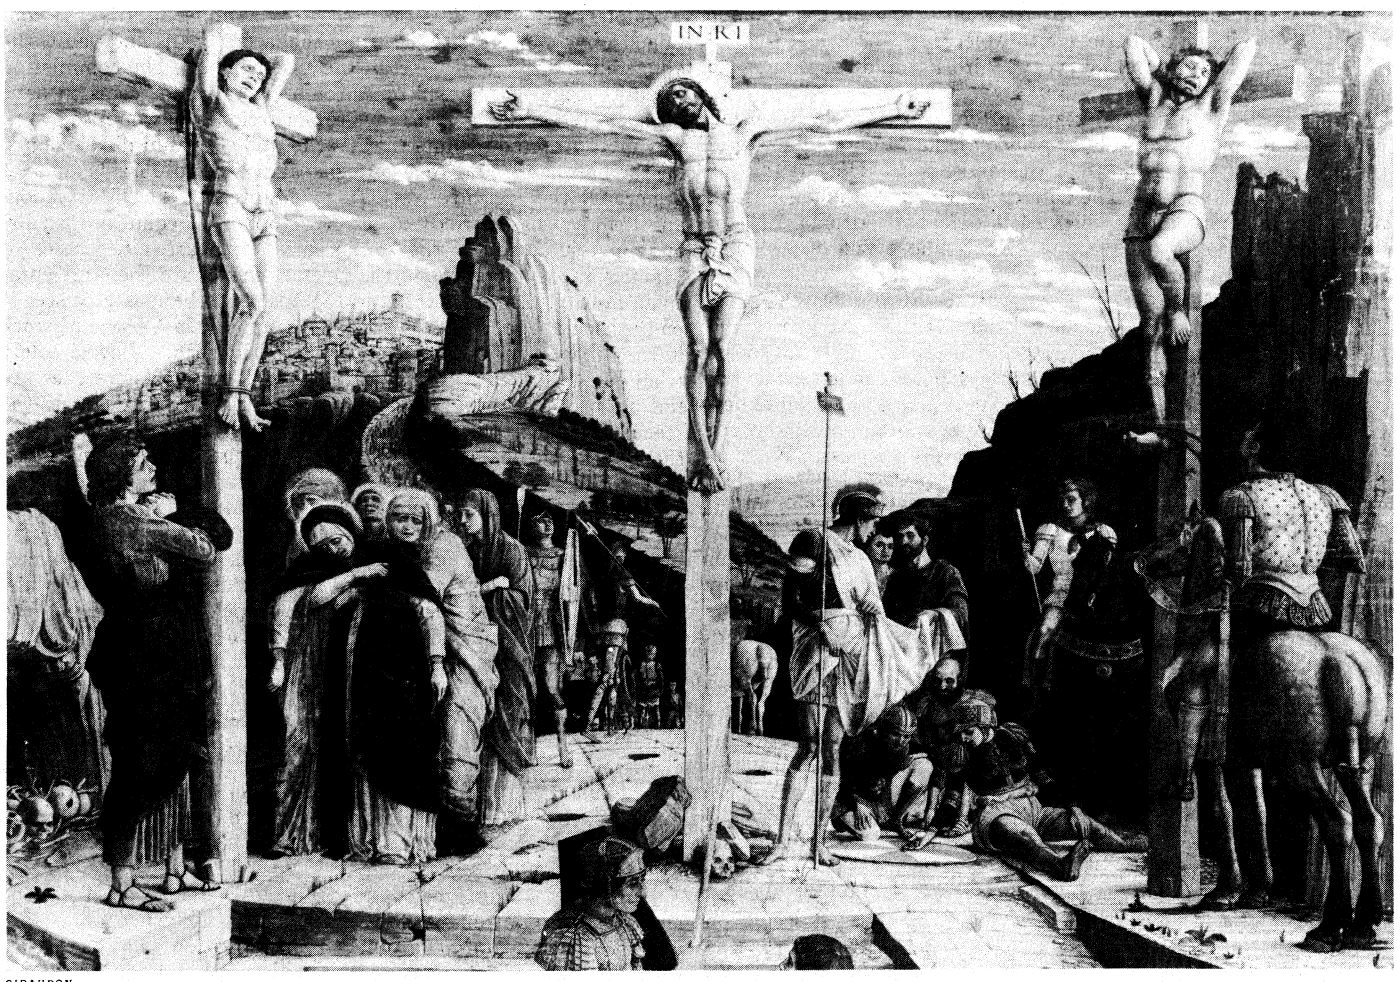
Before 1453 Mantegna married Nicolosia, daughter of Iacopo and sister of Giovanni Bellini. Mantegna's influence on Bellini is evident in a painting of the "Transfiguration" in the Museo Correr in Venice and certain other early works. A point of comparison betneen the tno artists is afforded by two paintings of the "Agony in the Garden" in the National gallery. London. both of which derive from a drawing by Iacopo Bellini. Mantegna's classicizing figures are set in the same arid landscape as the Ovetari "Martyrdom of St. James," whereas in Bellini's panel this academic classicism is replaced by a warm romantic apprehension of nature and natural forms.

On Jan 30, 1459, Mantegna was appointed court painter to Lodovico Gonzaga, marquess of Mantua, and he moved to Mantua later in the year. No dated work by him survives between this year and the completion of the frescoes in the Camera degli Sposi of the ducal palace at Mantua in 1474, though it is known that he executed paintings (lost) in the chapel of the ducal palace (still unfinished in 1464), in the castle of Goito and at Cavriana. In 1466–67 he visited Pisa and Florence. The commission for the Camera degli Sposi has been credibly assigned to the year 1472. The ceiling of the room is decorated with fictive reliefs of emperor heads and nith triangular grisaille paintings of mythological scenes, also in imitation of the antique. In the centre is a circular aperture in which a number of figures are represented looking down over a balustrade. This detail forms a landmark in the history of illusionistic painting and was of fundamental importance for the illusionistic frescoes of Correggio. On the wall above the fireplace is a much damaged scene representing the court of Lodovico Gonzaga. There, too, the wall surface is treated illusionistically with consummate constructional resource. On the second of the two painted walls is a fresco of Lodovico Gonzaga and his son Cardinal Francesco (possibly in commemoration of the latter's visit to Mantua in 1472), a fragmentary fresco of two huntsmen and hounds and. above the doorway between them. a number of putti supporting a tablet recording the date of completion of the work. The frescoes reveal Mantegna as a portrait painter of the first rank. Other examples of this aspect of his work are portraits of Cardinal Mezzarota (Raiser Friedrich museum, Berlin). Cardinal Carlo de' Medici (Uffizi, Florence) and an unidentified man (National Gallery of Art, Washington, D.C.).

At this time Mantegna enjoyed a high reputation not only as an artist but as a connoisseur of the antique. His archaeological and epigraphic studies provide a context for the second of his great Mantuan commissions. that for nine canvases of the "Triumph of Caesar" (Hampton court, Middlesex). These were in course of execution in 1486 and were still unfinished in 1492. Gravely damaged as they are, they form one of the most significant monuments of 15th-century humanist art.

In 1488 Mantegna visited Rome to decorate a small chapel in the Vatican (destroyed) on the commission of Pope Innocent VIII and to execute *trompe-l'oeil* (illusionistic) paintings in the adjacent sacristy. Work in the Vatican interrupted the progress of the "Triumph of Caesar." In 1495, after the completion of the latter work. Mantegna began work on the "Madonna of the Victory" (Louvre, Paris), which was commissioned by Giovanni Francesco Gonzaga to commemorate his victory over the French at Fornovo and was installed in the Cappella della Vittoria (also designed by Mantegna) in 1496. The course of Mantegna's development in the last years of his life may be judged from two paintings of St. Sebastian, one in the Louvre (probably 1481) and the other in the Ca d'Oro in Venice (before 1506). His last important commission was for three allegorical paintings for the studio of Isabella d'Este in the ducal palace. Two of these are now in the Louvre. A third painting (later completed by Lorenzo Costa) was unfinished when Mantegna died on Sept. 13, 1506. He was buried in the church of S. Andrea, Mantua, in a funerary chapel of his own design.

In addition to these major works Mantegna was responsible for executing many smaller paintings. Among these is a notable series



GIRAUDON

"THE CRUCIFIXION," CENTRE PREDELLA PANEL OF S. ZENO ALTARPIECE, BY ANDREA MANTEGNA. IN THE LOUVRE, PARIS of Madonnas (Kaiser Friedrich museum, Berlin; Accademia Carrara, Bergamo; Museo Poldi-Pezzoli, Milan; Brera gallery, Milan), the form of which was clearly influenced by the Madonna reliefs of Donatello. Other paintings are a well-known panel of "St. George" in the Accademia in Venice, a triptych of the "Adoration of the Magi." "Presentation in the Temple" and "Ascension" in the Uffizi gallery, Florence, and a strongly foreshortened figure, the "Dead Christ," in the Brera gallery, Milan. After 1491 (and perhaps as early as 1475) Mantegna was active as an engraver. Seven engravings (four of them of classical subjects) are usually accepted as his work. Though Mantegna's work is less immediately appealing, because colder and more detached, than that of his contemporary and brother-in-law Giovanni Bellini, we are conscious in his paintings of the working of a powerful intelligence and of the presence of an inventive faculty richer than that of any other north Italian artist of his time. His late work, like Bellini's, bridges the transition to the 16th century and opens the way to a world of experience which was explored, in the decades following his death, by his disciple Correggio.

BIBLIOGRAPHY.—P. Kristeller, Andrea *Mantegna* (1901); G. Fiocco, Mantegna (1937); E. Tietze-Conrat, Mantegna (1955).

(J. W. P.-H.)

MANTELL, GIDEON ALGERNON (1790–1852), pioneer English geologist and paleontologist, noted as a discoverer and collector, was born at Lewes, Sussex. Educated for the medical profession, he practised at Lewes, Brighton and Clapham. He studied the paleontology of the Secondary rocks, particularly in Sussex—a region which he made classical in the history of discovery. His most remarkable discoveries were made in the Wealden formations. He demonstrated the fresh-water origin of the strata, and from them he brought to light and described the remarkable Dinosaurian reptiles known as Iguanodon, Hylaeosaurus, *Pelorosaurus* and Regnosaurus. He also described the Triassic reptile Telerpeton elginense.

Mantell was elected a fellow of the Royal society in 1825 and died in London on Nov. 10, 1852.

MANTEUFFEL, EDWIN, FREIHERR VON (1809–1885), Prussian general field marshal, was born at Dresden on Feb. 24, 1809, and entered the guard cavalry at Berlin in 1827.

In 1848 Manteuffel became aide-de-camp to Frederick William IV, whose confidence he had gained during the revolutionary movement in Berlin. Promoted to lieutenant colonel in 1852, and colonel to command the jth Uhlans in 1853, he was sent on important diplomatic missions to Vienna and St. Petersburg. In 1857 he became major general and chief of the military cabinet. He supported the prince regent's plans for the reorganization of the army. He served in the Danish war of 1864, and at its conclusion was appointed civil and military governor of Schleswig. In the Austrian War of 1866 he occupied Holstein and afterward commanded a division under Vogel von Falkenstein in the Hanoverian campaign, and succeeded him, in July. in command of the army of the Main (see SEVEN WEEKS' WAR). His successful operations ended with the occupation of Wurzburg, and he received the order *pour le mérite*. He then went on a diplomatic mission to St. Petersburg, where he was persona grata, and succeeded in gaining Russia's assent to the new position in north Germany. In the war of 1870–71 he led the I corps under Steinmetz, distinguishing himself in the battle of Colombey-Neuilly, and in the repulse of Bazaine at Noisseville (see FRANCO-GERMAN WAR; and METZ). He succeeded Steinmetz in October in the command of the I army, won the battle of Amiens against General Farre, and occupied Rouen, but was less fortunate against Faidherbe at Pont Noyelles and Bapaume. In Jan. 1871 he commanded the newly formed army of the South, which he led, in spite of hard frost. through the Côte d'Or and over the plateau of Langres, cut off Bourbaki's army of the east (80,000 men), and. after the action of Pontarlier, compelled it to cross the Swiss frontier. where it was disarmed. When the southern army was disbanded Manteuffel commanded first the II army, and. from June 1871 until 1873. the army of occupation left in France, showing great tact in a difficult position. He nas rewarded by promotion to the rank of general field marshal and a large grant in money. He was employed on several diplomatic missions, was for a time governor of Berlin, and in 1879 was appointed governor general of Alsace-Lorraine; and this office he filled until his death at Carlsbad, Bohemia, on June 17, 1885.

MANTINEA (MANTINEIA), an ancient city of Arcadia, in Greece, about 8 mi. N. of modern Tripolis in a long narrow marshy plain bounded on the west by Mt. Mainalon, on the east by Mt. Artemision, and without opening to the coast, the water percolating through underground passages (*katavothra*) to the sea. The supremacy of the district was disputed with Tegea (*q.v.*).

Mantinea is mentioned in the catalogue of ships in Homer's *Iliad*, but in early Greek times it was only a cluster of villages, insignificant compared with Tegea and submissive to Sparta. But soon after the Persian wars its five constituent villages, at the suggestion of Argos, were merged into one city, whose policy was henceforth guided by three main considerations: its democratic constitution of small freeholders; its ambition to control the watershed of the Alpheus (Alfios) river and Arcadian roads to the Isthmus of Corinth; and its chronic disputes with Tegea. In 468 B.C. the Mantineans alone of Arcadian townships refused to join the combination of Tegea and Argos against Sparta, and they assisted Sparta during the revolt of the Messenian helots of 464. Though formally on the same side in the Peloponnesian War. they employed the truce of 423 in fierce but indecisive war with Tegea. After the peace of Nicias (421) Mantinea allied mith Elis, Argos and Athens, but this alliance was defeated by the Spartans at the battle of Mantinea (418) and dissolved. During the 4th century and Hellenistic period Mantinea was of less importance, and in the later Roman empire the city dwindled into a mere village (which from the 6th century bore the Slavonic name Goritza) and as a result of malaria and Turkish rule has disappeared. The site was excavated by the French school at Athens, in 1888. The agora and adjacent buildings and the walls have been investigated. When the city was rebuilt in 370 B.C., the Ophis river, which formerly ran through the town, was divided so as to encircle the malls.

Battles of Mantinea.—Battles were fought in the years 418, 362 and 207 B.C. at Mantinea.

1. The first battle, in the Peloponnesian War (*q.v.*), is of some interest in the evolution of tactics. On the one side were the Spartans under the Spartan king Agis, while the other was composed of Argives. Mantineans and a small Athenian force. As the Spartan line advanced, a drift to the right occurred—a common occurrence in ancient battles, due to the natural instinct of each man to hug closely to his neighbour's shield as a protection to his own unguarded (*i.e.*, nonshield-bearing) side. Agis. seeing that this drift would cause his left flank to be overlapped by the enemy. sought to prolong his left. This stretching caused a gap in the centre, and the Spartan left wing was broken up by their adversaries who poured into the gap. This, however, was offset by the success of the Spartan right.

2. The second and more justly famous battle took place in 362 B.C. Epaminondas had followed up the sensational Theban victory at Leuctra (*q.v.*) by invading the Peloponnese in 370 and 369. A surprise attack on Sparta had narrowly failed. but strong opposition against it had been built up. Messenia had been re-established as an independent state with a new capital, Messene. on Mt. Ithome, and a new federal capital had been designed at Megalopolis for the Arcadian league. The position of Epaminondas, however, was not secure and Theban policy lacked consistency. A serious division also broke out in the Arcadian league reviving the old hostility between Tegea and Mantinea.

In 362 Thebes was driven to choose between reasserting its authority and sacrificing its prestige. Its move against Arcadia caused Greece to divide afresh into two hostile coalitions. Once more Epaminondas made a surprise spring at Sparta. but he was deprived of the fruits of his night march through a deserter, who warned the Spartan main army in time for it to hurry back and safeguard the capital. Epaminondas then stood on guard at Tegea while the enemy forces concentrated at Mantinea. The valley in which these places lay is shaped like an hourglass by the surrounding mountain ranges, and at the mile-wide waist the Spartans and their allies took up a strong position. Epaminondas determined to seek a decision by battle, and as in his strategy so in his grand tactics showed his art by an indirect approach.

At first he marched directly toward the Spartan camp, causing the enemy to form up in battle order facing his line of approach. But when still several miles distant. he suddenly changed direction to the left, turning in beneath a projecting spur. This surprise maneuver threatened to take in enfilade the Spartan right. and to dislocate still further the Spartans' battle dispositions he halted his troops and made them ground arms as if to encamp. The deception succeeded; the enemy were induced to relax their battle order, allowing men to fall out and the horses to be unbridled. Meanwhile Epaminondas was actually completing his battle dispositions behind a screen of light troops.

Then, on a signal, the Theban army took up its arms and swept forward. Caught by surprise the enemy made haste to reform, but their cavalry were driven back by the Theban cavalry covering the left flank of the massed column, and this striking the Spartan line pierced it in two. But in the moment of decision Epaminondas himself was mortally wounded, and with his fall the advance came to a stop and failed to complete the victory.

3. The third battle for which Mantinea is notable mas that of 207 B.C., in which Philopoemen, the commander of the forces of the Achaean league, routed Machanidas, tyrant of Sparta.

MANTIQUEIRA, SERRA DA. a range of mountains in southeastern Brazil, running for about 200 mi. in a southwest-northeast direction along the southern border of the state of Minac Gerais. The range comes to a distinct ending west of Juiz de Fora and does not connect with the Serra do Espinhaço as was formerly thought. It rises abruptly from the northwest side of the Paraiba valley. reaching a height of 9,144 ft. in Mt. Itatiaia, or Agulhas Negras.

The mountains were originally forest-covered except for the tops which stand above the tree line. They provide charcoal and pasture for cattle; on the lower slopes there are several health resorts, such as Campos do Jordão. (P. E. J)

MANTIS, an insect belonging to the family Manteidae of the order Orthoptera (*q.v.*). Probably no other insect has been the subject of so many and widespread legends and superstitions as the common praying mantis, *Mantis* religiosa, L. of southern Europe. The ancient Greeks endowed it with supernatural powers (*μάντις*, "a diviner"); the Turks and Arabs hold that it prays constantly with its face turned toward Mecca, and the Provençals call it Prega-Diou (Prie-Dieu). Notwithstanding these attributes, mantids are creatures of voracious habits. The front pair of limbs are very peculiarly modified—the coxae being greatly elongated, while the strong third joint or femur bears on its curved underside a channel armed on each edge by strong movable spines. Into this groove the stout tibia is capable of closing like the blade of a penknife, its sharp, serrated edge being adapted to cut and hold. Thus armed, with head raised upon the much-elongated and semierect prothorax, and with the half-opened fore-limbs held outward in the characteristic devotional attitude, it rests mutionless upon the four posterior limbs waiting for prey or occasionally stalks it with slow and silent movements. finally seizing it with its knife blades and devouring it. These insects destroy many flies, grasshoppers and caterpillars, and the larger South American species attack small frogs. lizards and birds. They are pugnacious, fencing with their swordlike limbs, the larger often devouring the smaller, and the females the males.

Mantis *religiosa* fixes its somewhat nutlike egg capsules on the stems of plants in September. The young are hatched in early summer. and resemble the adults, but are without nings. The green coloration and shape of the typical mantis are procryptic, serving to conceal the insect alike from its enemies and prey. The passage from leaf to flower simulation has been perfected in certain tropical species of Manteidae by the development on the prothorax and raptorial limbs of laminate expansions so coloured on the underside as to resemble papillionaceous or other blossoms, to which the likeness is enhanced by a gentle swaying kept up by the insect in imitation of the effect of a lightly blowing breeze. As instances of this may be cited *Idolum* diabolicurn, an African insect, and *Gongylus* gongyloides, which comes from India. Examples of another species (*Empusa* egena) when standing upon the ground deceptively imitate in shape and hue a greenish white anemone tinted at the edges with rose; and Bates records what appears to be a true case of aggressive mimicry practised by a Brazilian species which exactly resembles the white ants it preys upon. More than 800 species of mantids are known and about 20 of these occur in Europe, and a similar number in the United States, but none are found in the British Isles.

MANTIS FLY, insects of the family Mantispidae, order Neuroptera, related to the ant lions, lacewing flies, etc., and named from their superficial resemblance to a mantis (*q.v.*) because of the length of the prothorax and the shape and prehensorial nature of the anterior legs.

The larva, at first very active and having well-developed legs (campodeiform), makes its way into the egg case of a spider or the nest of a wasp to feed on the eggs or young. Subsequently it changes into a fat grub with short legs. When full grown it spins a silken cocoon in which it transforms into the pupa. Mantis flies are widely distributed in both the old and new worlds, but occur chiefly in warm countries.

MANTRAP, a mechanical device for catching or injuring a trespasser. Such traps include concealed pits, traps with jaws that close on the victim's leg, and spring guns, triggered when one steps on a concealed wire. Since 1827 their use in England has been a misdemeanor, except to protect dwellings between sunset and sunrise.

In the United States, a number of states have banned the use of such devices. In jurisdictions that have not outlawed them, the law is far from settled, but it appears that the trap setter may be both criminally and civilly liable for resulting death or injury and that liability may depend on whether the victim was bent on committing a felony, a circumstance which is hardly predictable in advance.

Thus it appears that one who sets such a trap may be imposing as grave a risk on himself as on the potential intruder.

(H. L. Pr.)

MANTUA (Ital. Mantova), fortified city, Lombardia, Italy, capital of the province of Mantova, see of a bishop and centre of a military district, 25 mi. S.S.W. of Verona and 100 mi E.S.E of Milan by rail. Pop. (1957 est.) 57,656 (commune). It is 88 ft. above the level of the Adriatic on an almost insular site among swampy lagoons of the Mincio. On the west lies Lago Superiore, on the east Lago Inferiore—the boundary between the two being marked by the Argine del Mulino, a long mole stretching northward from the northwest angle of the city to the citadel, along which run the road and the railway.

On the highest ground in the city rises the cathedral, the interior of which was built after his death according to the plans of Giulio Romano. The church of St. Andrea after plans by Leon Battista Alberti, has a single, barrel-vaulted nave 338 ft. long by 62 ft. wide (1472–1494 and later); the dome was added in 1732–82. It has a noble facade with a deeply recessed portico, and a brick campanile of 1414. Mantegna is buried there. The immense ducal palace was begun in 1302 for Guido Bonaccolsi, but many of the fine apartments are of much later date, and the internal decorations are largely by Giulio Romano and his pupils. In one of the rooms is a set of tapestries after Raphael's cartoons now at South Kensington museum. Castello di Corte, the castle of the Gonzagas (1395–1406), erected by Bartolino da Novara, the architect of the castle of Ferrara, now contains the archives, and has some fine frescoes by Mantegna nith scenes from the life of Ludovico Gonzaga. Close by are the Piazza dell' Erbe and the Piazza Sordello, with Gothic palaces. Outside the city stands the Palazzo del Te, Giulio's architectural masterpiece, erected for

Frederick Gonzaga in 1523–1535, with numerous fresco-covered rooms. At the villa of Marmiruolo are other works by him. The architecture of Giulio's own house in the town is also good.

Mantua has an academy of arts and sciences (*Accademia Vergiliana*), occupying a fine building erected by Piermarini, containing a theatre designed by Antonio Bibiena (1769), and a museum of antiquities.

Mantua had still a strong Etruscan element in its population during the Roman period. Its main interest is as the birthplace of Virgil (*q.v.*). In 568 the Lombards took Mantua with difficulty; recovered in 590 by the exarch of Ravenna, it was recaptured by Agilulf in 601. The 9th century was the period of episcopal supremacy, and in the 11th the city belonged to Bonifacio, marquis of Canossa. It passed to Geoffrey, duke of Lorraine, and afterwards to the countess Matilda, but was taken by the emperor Henry IV. in 1090. Reduced to obedience by Matilda in 1113, the city on her death instituted a communal government of its own. It afterwards joined the Lombard League. But after internal discords Ludovico Gonzaga attained to power (1328), and was recognized as imperial vicar (1329); and until 1708 the Gonzagas were masters of Mantua (*see* GONZAGA). Under Gian Francesco II., the first marquis, Ludovico III., Gian Francesco III. (whose wife was Isabella d'Este), and Federico II., the first duke of Mantua, the city rose rapidly into importance. It was stormed and sacked by the Austrians in 1630. It was claimed in 1708 as a fief of the empire by Joseph I. Besieged by Napoleon in June 1796, it held out till February 1797. In 1799 it fell to the Austrians; restored to the French by the peace of Lunéville (1801), it became Austrian again (1814–66).

MANU, the Hindu Noah. In post-Vedic myth he is warned by a huge fish to build an ark, and after the deluge his sacrifices bear him a daughter, by whom he becomes the ancestor of mankind. More historically he is the author of the Code of Manu, a compilation of laws reflecting Hindu thought in the Buddhist period, but only preserved in a metrical recension made probably about A.D. 100.

MANUCODE, the common name given to the more somber coloured birds of paradise (*q.v.*) comprising the genus *Manucodia* and found in northern Queensland and New Guinea. The males resemble the females and help them with nesting duties; for these and other reasons manucodes are often regarded as an early group in the family Paradiseidae.

MANUEL I. COMNENUS (*c.* 1120–1180), Byzantine emperor (1143–1180), the fourth son of John II, was born about 1120. Having distinguished himself as a soldier, he was nominated emperor in preference to his elder surviving brother. He endeavoured to restore by force of arms the predominance of the Byzantine empire in the Mediterranean countries. In 1144 he brought back Raymund of Antioch to his allegiance, and in the following year drove the Turks out of Isauria. In 1147 he granted a passage through his dominions to two armies of crusaders under Conrad III. of Germany and Louis VII. of France; but the numerous outbreaks of hostility between the Franks and the Greeks on their line of march, nearly precipitated a conflict between Manuel and his guests. In the same year the emperor made war upon Roger of Sicily, whose fleet captured Corfu and plundered the Greek towns, but in 1148 was defeated with the help of the Venetians. In 1149 Manuel recovered Corfu and prepared to take the offensive against the Normans. With an army mainly composed of mercenary Italians he invaded Sicily and Apulia, and although defeated both on land and sea, Manuel maintained a foothold in southern Italy, which was secured to him by a peace in 1155.

Manuel made treaties with Pisa and Genoa, and supported the free Italian cities with his gold and negotiated with pope Alexander III. In spite of his friendliness towards the Roman church Manuel was refused the title of "Augustus" and he nowhere succeeded in attaching the Italians permanently to his interests. None the less in a war with the Venetians (1172–74), he actually drove his enemies out of the Aegean Sea. On his northern frontier Manuel defeated the rebellious Serbs (1150–52) and made repeated attacks upon the Hungarians. In the wars of 1151–53 and 1163–68 he led his troops into Hungary but failed to maintain himself there; in 1168, however, a decisive victory near Semlin enabled him to conclude a peace by which Dalmatia and other frontier strips were ceded to him. In 1169 he sent a joint expedition with King Amalric of Jerusalem to Egypt, which retired after an ineffectual attempt to capture Damietta. In 1158–59 he fought with success against Raymund of Antioch and the Turks of Iconium. In 1176 he was decisively beaten by them in the pass of Myriocephalum. This disaster, though partly retrieved in the campaign of the following year, had a serious effect upon his vitality; henceforth he declined in health and in 1180 succumbed to a slow fever.

In spite of his military prowess Manuel achieved but in a slight degree his object of restoring the East Roman empire. His victories were counterbalanced by numerous defeats, and his lack of statesmanlike talent prevented his securing the loyalty of his subjects. The expense of keeping up his mercenary establishment put a severe strain upon the financial resources of the state. The subsequent rapid collapse of the Byzantine empire was largely due to his brilliant but unproductive reign. Manuel married, firstly, a sister-in-law of Conrad III of Germany; and secondly, a daughter of Raymund of Antioch. His successor, Alexis II, was a son of the latter. (M. C.)

MANUEL II, PALAEOLOGUS (1350–1425), Byzantine emperor from 1391 to 1425, was born in 1350. At the time of his father's death he was a hostage at the court of Bayezid at Brusa, but succeeded in making his escape; he was forthwith besieged in Constantinople, but with some loss, beat off the attack. Manuel subsequently set out in person to seek help from the west, and for this purpose visited Italy, France, Germany and England, but without material success. The defeat of Bayazet at the hands of Timur (1402) gave him a genuine respite from the Ottomans. He stood on friendly terms with the Mahammed I, but was again besieged in his capital by Murad II in 1422. Shortly before his death he was forced to pay tribute to the sultan. Manuel was the author of numerous works of varied character—theological, rhetorical, poetical and letters. Most of these are printed in Migne, *Patrologia graeca,* clvi; the letters were edited by E. Legrand (1893).

See Krumbacher, *Geschichte der byzantinischen Litteratur* (1897).

MANUEL, LOUIS PIERRE (1751–1793), French writer and revolutionary was born at Montargis (Loiret), and became a tutor in Paris. In 1783 he was imprisoned for three months in the Bastille for publishing his *Essais historiques, critiques, littéraires, et philosophiques.* He was one of the leaders of the *émeutes* of June 20 and Aug. 10, 1792, and was made *procureur* of the commune. On Sept. 7, 1792 he was elected one of the deputies from Paris to the convention and on Nov. 5 made an eloquent speech at the Jacobins club in defense of Robespierre. His missions to the king, however, reconciled him to Louis, and he had to resign from the convention. He retired to Montargis, where he was arrested. He was guillotined in Paris on Nov. 17, 1793. His works include *Coup d'oeil philosophique sur le règne de St. Louis* (1786); *L'Année francaise* (1788); *La Bastille dévoilée* (1789); *La Police de Paris dévoilée* (1791); and *Lettres sur la Révolution* (1792).

MANUEL DE MELLO, DOM FRANCISCO: *see* MELO, FRANCISCO MANUEL DE.

MANUFACTURING PRODUCTION: *see* ECONOMIC PRODUCTIVITY.

MANUL (*Felis manul*), often called Pallas's cat, a small desert and rock-dwelling wild cat, ranging from Tibet to Siberia. The coat is long and soft, of pale silvery gray or light buff, marked with black.

It has been suggested that the high-set eyes and low-set ears are adaptations for peering over rocky ledges; the supposition is that the manul thus exposes the smallest portion of himself to his prey, small mammals and birds.

MANURES: *see* FERTILIZERS AND MANURES.

MANUTIUS, the Latin name of an Italian family (Mannucci, Manuzio), famous in the history of printing as organizers of the Aldine press.

1. ALDUS MANUTIUS (1450–1515). Teobaldo Mannucci, better known as Aldo Manuzio, the founder of the Aldine press, was born at Sermoneta in the Papal states. After studying at Rome and at Ferrara, in 1482 he went to reside at Mirandola with his old friend, the illustrious Giovanni Pico, whose nephew Alberto Pio, prince of Carpi, supplied him with funds for starting his printing press, and gave him lands at Carpi. Settling in Venice in 1490, he gathered Greek scholars and compositors around him, and Greek was the language of his household. He soon published undated editions of the *Hero and Leander* of Musaeus, the *Galeomyomachia,* and the Greek Psalter. During 1495–98 he issued five volumes of Aristotle; in 1498 nine comedies of Aristophanes; Thucydides, Sophocles and Herodotus followed in 1502; Xenophon's *Hellenics* and Euripides in 1503; Demosthenes in 1504; an edition of the minor Greek orators in 1508; and in 1509 the lesser works of Plutarch. During the struggle of Venice with the allied powers of Europe, Aldo's labours were suspended until 1513 when he published his Plato. Pindar, Hesychius, and Athenaeus followed in 1514. Besides these Greek texts, Aldo published the *Asolani* of Bembo, the collected writings of Poliziano, the *Hypnerotomachia Poliphili,* Dante's *Divine Comedy,* Petrarch's poems, a collection of early Latin poets of the Christian era, the letters of the younger Pliny, the poems of Pontanus, Sannazzaro's *Arcadia,* Quintilian, Valerius Maximus, the *Adagia* of Erasmus and many reprints To promote Greek studies, Aldo founded an academy of Hellenists in 1500 under the title of the New Academy. Its rules were written in Greek; its members were obliged to speak Greek, and their names were Hellenized. The biographies of those enrolled in this academy, including Erasmus and Linacre, are given in Didot's *Alde Manuce.*

2. PAULUS MANUTIUS (1512–1574). After the death of Aldo, his brothers-in-law, the Asolani, carried on the Aldine press, until his youngest son, Paolo, took it over in 1533. The Asolani attempted the duties of editing. and to reserve the honours for themselves, dispensed nith the service of competent collaborators. The result was that some of their editions, especially their Aeschylus of 1518, are singularly bad. Paolo determined to restore the glories of the house, and in 1540 separated from his uncles. The field of Greek literature having been well-nigh exhausted. he devoted himself principally to the Latin classics. He was a passionate Ciceronian, and perhaps his chief contributions to scholarship are the corrected editions of Cicero's letters and orations. his own epistles in a Ciceronian style. his Latin version of Demosthenes, and his four treatises on Roman antiquities Because of Paolo's financial difficulties, Pius IV in 1561 invited him to Rome, offering him a yearly stipend of 500 ducats, and undertaking to maintain his press there. The profits on publications aere to be divided between Paolo and the Apostolic camera. Paolo accepted the invitation, and spent the larger portion of his life in Rome under three papacies.

3. ALDUS MANUTIUS, JUNIOR (1547–1597), eldest son of Paolo, produced at the age of 14 a work upon Latin spelling, called *Ovthographiae ratio.* Remaining in Venice to superintend the Aldine press after his father's move to Rome, he published in 1575 his *Epitome orthographiae.* In the same year, in concert with his father-in-law, Giunta. he edited an extensive collection of Italian letters, and in 1576 published his commentary upon the *Ars poetzca* of Horace. About the same time, he was appointed professor of literature to the Cancelleria at Venice. In 1585 Aldo moved to Bologna, but after two years went to Pisa where he made the curious mistake of printing Alberti's comedy *Philodoxius* as a work of the classic Lepidus. Sixtus V called him in 1588 to Rome. In 1597 he died, leaving children, but none who carried on the Aldine press. Aldo himself, though a precocious student, a scholar of no mean ability, and a publisher of some distinction, was the least remarkable of the three publishers.

MANWARING, ROBERT (fl. 1760), English 18th-century furniture designer and cabinetmaker. The dates of his birth and death are unknonn. He was a contemporary, imitator and rival of Thomas Chippendale (q v). His work shows the same surprising variations of quality characteristic of that of nearly all the English cabinetmakers of the second half of the 18th century. His best had an undeniable elegance. his uorst was squat and ill-proportioned. He introduced the small bracket between the front rail of the seat and the top of the chair leg. or at all events made such constant use of it that it has come to be regarded as characteristic of his work. Among Manwaring's writings were *The Cabinet and Chair Makers' Real Friend and Companion, or the Whole System of Chairmaking Made Plain and Easy* (1765, reissued, 1937); *The Carpenters' Compleat Guide to Gothic Railing* (1765); and *The Chair-makers' Guide* (1766)

MANX LANGUAGE AND LITERATURE. Manx is the Celtic speech of the Isle of Man (*q.v.*). The earliest vernacular material is contained in the version of the Book of Common Prayer made in 1610 by Bishop Phillips. The mode of spelling used was not that used in Ireland, but was as phonetic as a language system based on Anglo-Scottish orthography could be. It is, therefore, very difficult to discover the real sound values attached to the various symbols. Manx is more closely related to Scottish Gaelic than the Irish: both Manx and Scottish Gaelic may be reckoned as modern dialects of the original Irish Gaelic language. A dialectical difference between north and south shows in the treatment of short accented vowels before *ll, nn,* and *m*, and vocalic *s* or *sh* tends to become voiced to *d*. For further discussion of the Manx language and for bibliography on it, *see* IRISH LANGCAGE.

Literature. — The literary remains written in the Manx language are considerably slighter than those of any other Celtic dialect. With one small exception nothing pertaining to the saga literature of Ireland has been preserved. The little we possess falls under tno heads — original compositions and translations. With regard to the first we must give the place of honour to an Ossianic poem contained in a manuscript in the British museum (written in 1789), which relates how Orree, Finn's enemy, was tormented by the women of Finn's household when the latter was away hunting, how he in revenge set fire to the house, and how Finn had him torn in pieces by wild horses. Most of the literature of native origin consists of ballads and carols, locally called carvels. These used to be sung on Christmas eve in the churches, the members of the congregation each bringing a candle. Any one who pleased could get up and sing one. These carvels deal largely with the end of the world, the judgment day and the horrors of hell. About 80 of them were published under the title of *Carvalyn Gailckagh* (1891). An attempt has been made in the 20th century by *Yn Cheshaght Gailckagh* to revive the *Oiel Voirrey* (=Irish *Oidhche Fhéile Mhuire*), "Feast of Mary." as the festival used to be called, and gatherings in the old style have been held in Peel. Apart from the carvels there are other ballads in existence. The earliest is an 18th-century song of Manannan Mac y Lheir, traditionally supposed to have been written in the 16th century, which tells of the conversion of the island by St. Patrick. Then comes *Baase Illiam Dhône* (Death of Brown William), dealing with the death of William Christian. who was shot as a traitor in 1662. The best-known Manx song is *Mylecharaine* (=Irish *Maolchiarán*). It is directed against a man of this name who was the first to give a dowry to his daughter, the custom having previously been for the bridegroom to pay money to the father of the bride. Others are *Ny Kirree* fo *Sniaghtey* (The Sheep Under the Snow), a song about the loss of the Douglas herring fleet in 1787 (reprinted 1872) and *O Vannin Veg Veen* (Dear Little Mona). In 1760 Joseph Bridson wrote a "Short Account of the Isle of Man" in Manx (*Coontey Ghiare jeh Ellan Vannin ayns Gailck).*

The translated literature is almost entirely of a religious character. There is the translation of the English Prayer-Book by Bishop Phillips, 1610 (published 1895). The *Sermons* of Bishop Wilson (1783), intended to be in three volumes, of which only one was ever printed, is a very rare work, highly important for our knowledge of Manx prose. A later translation of the Church of England Prayer-Book was printed in 1765, but by far the most important of all is the translation of the Bible. The energetic Bishop Wilson managed to get parts of the Scriptures translated and the Gospel of St. Matthew was printed in 1748. Wilson's successor, Bishop Hildesley, completed the work, and in 1775 the whole Bible appeared. As a curiosity it may be mentioned that

Aesop's Fables were translated into the vernacular (1901).

MANYCH, a river and depression in the southern U.S.S.R., stretching between the lower Don river and the Caspian sea, through the north Caucasian region and the Kalmy autonomous oblast. During the greater part of the year the Manych is either dry or occupied in part by a string of saline lakes (limans or *ilmens*); but in spring when the streams swell which empty into it, the water flows in two opposite directions from the highest point (near Shara-Khulusun). One stream flows westward with an inclination northward, until it reaches the Don, though when the latter river is running high, its water penetrates about 60 mi. up the Manych.

The eastern stream dies away in the sandy steppe about 25 mi. from the Caspian, though it is said sometimes to reach the Kuma through the Huiduk, a tributary of the Kuma. Total length of the depression is 330 mi. For its significance as a former (geologic) connection between the Sea of Azov and the Caspian sea, see CASPIAN SEA.

MANZANILLO, a city in Oriente province, Cuba, about 85 mi. to the west and slightly north of Santiago de Cuba. Pop. (1953) 42,252. It is an important export-import centre, located at the head of the shallow Gulf of Guacanayabo. It is the centre of a rich sugar, tobacco and rice zone and serves as the outlet for the extensive Cauto plain.

The town was founded in 1784 as Puerto Real and was sacked by the French in 1792. Its development proceeded rapidly after it was opened to foreign ships in 1827. The name was changed to Manzanillo in 1837. (D. R. D.)

MANZANITA, the name given to numerous shrubs of the botanical genus *Arctostaphylos* belonging to the heath family (Ericaceae), comprising about 40 species, confined chiefly to western North America, 25 species being found in California. They are evergreen shrubs, mostly from 3 to 12 ft. high, with dark red or chocolate-coloured, smooth and polished bark; very crooked, usually stiff branches; small, mostly toothless, often vertical leaves, and handsome white or pink flowers borne in terminal, usually nodding, globose clusters. The fruit, which becomes brownish and berrylike at maturity, is suggestive when young of a tiny apple, from whence comes the Spanish name manzanita, "little apple."

MANZIKERT, BATTLE OF. In the spring of 1071 Romanus IV Diogenes, the Byzantine emperor, having collected an army of about 60,000 mon, marched into Armenia to recover the fortresses of Akhlat and Manzikert, captured by Alp Arslan and his Seljuk Turks. His forces were composite, consisting of Byzantine cavalry and infantry, German mercenaries and Franks. At Akhlat he divided his army, leaving a division to besiege the fortress. With the main body he marched on to Manzikert and reduced that place. Hardly had he done so when he fell in with Alp Arslan's advanced guard. The sultan's army was 100,000 strong and mainly consisted of horse archers. The tactics which the emperor should have employed were those laid down by Leo the Wise, namely: to maintain an unbroken front, to beware of surprise and never to fight with uncovered flanks or rear.

Romanus was a brave soldier, but impetuous. In the advanced guard encounter one of his generals, Basilaces, fell into an ambush, losing all his men. The emperor then drew up his army in front of his camp. The right wing was composed of Asiatic cavalry, the left of European and the centre of Byzantine horse. In rear he drew up a strong second line of Germans and Normans under Andronicus Ducas. As he advanced on his enemy, the Turks refused to close, hovering round the two lines and plying them with arrows. According to the Greek narratives the emperor, fearing that his camp was in danger, ordered a retirement. This order was misinterpreted, and confusion resulted, whereupon the Turks, closing in, compelled the emperor to face about. Andronicus refused to halt and retired to the camp, leaving the front line open to attack from the rear. According to the oriental sources, the Greek troops fell into an ambush, prepared by the Turks. In either event Romanus was decisively defeated and made a prisoner. The result of this defeat was disastrous: Asia Minor was overrun! and by 1080 the old Byzantine army had all but ceased to exist.

(J. F. C. F.; X.)

MANZONI, ALESSANDRO (1785–1873), Italian poet and the author of a novel that has been ranked with the chief masterpieces of European literature, was born at Milan on March 7, 1785. His mother was the daughter of Cesare Beccaria. Manzoni was brought up as a Catholic, but moved with his mother to Paris in 1805 and there began to consort with liberal and empiricist *"idéologues"* and to familiarize himself with Voltairian scepticism. In 1808, however, he married Henriette Blondel, a Calvinist from Geneva who became a fervent Catholic; and he then reverted to his former faith. Settling in his villa at Brusuglio in Lombardy, he led for many pears a retired life, devoted partly to literature and partly to farming. His wife died in 1833, and in 1837 he married again. His writing won him the esteem of Goethe, his religious thought made him a friend of Rosmini and he came eventually to be recognized as one of the leading spirits of his age. In 1860 he was made a senator of Italy. The Christian serenity of his life, however, was unaffected by his fame and unshaken by many blows (not only both his wives but also eight of their ten children predeceased him). He died in Milan on May 22, 1873. Verdi's *Requiem* was written to honour his memory.

Manzoni's early poems "Il trionfo della liberta" (written in 1801), "Adda" (1803), the series of "Sermoni" (1803–04) and "Urania" (1805; published 1809) show the influence of Vincenzo Monti and Giuseppe Parini; his elegy in blank verse In morte *di Carlo Imbonati* (1806), on the death of his mother's lifelong friend, reveals his individual gift. Then followed Inni *sacri* (1812; printed 1815; augmented ed. 1822), a series of sacred lyrics, one of which, "La Pentecoste," in the edition of 1822, is a masterpiece; *Osservazioni* sulla morale cattolica (1819), a treatise; and *Il* conte di Carmagnola (1820), a tragedy which, with its bold violation of all classical conventions and its passionate political inspiration, clearly showed that Manzoni had been conquered by the romantic movement. The Piedmontese revolution of 1821 inspired Manzoni's beautiful ode "Marzo 1821," and on the death of Napoleon in the same year he wrote another ode, "Il cinque maggio," which Goethe declared to be the greatest of the many written to celebrate that event. His second tragedy, *Adelchi* (1822), dealing with Charlemagne's overthrow of the Lombard kingdom and conquest of Italy, if it lacks dramatic power, is nevertheless rich in passages of deeply moving poetry, especially in the choruses depicting the arrival of the Franks and the death of Ermengarda.

Manzoni's greatest work, however, is his novel I promessi *sposi*. Having first published this work in 1827 (3 vol. with imprint 1825–26), Manzoni then revised it, carefully removing anything that was not pure Tuscan idiom from the language, and finally republished it in 1842 (with imprint 1840). It is the story of two peasant lovers! Renzo and Lucia, in 17th-century Lombardy under Spanish rule: a wicked local tyrant, Don Rodrigo, forbids their marriage, and the parish priest, Don Abbondio, bows to his will; but a courageous friar: Cristoforo, takes up the lovers' cause and helps them through many adventures to safety and marriage. The description of great historical events, for instance the Milanese insurrection, the Thirty Years' War and an outbreak of the plague, is cleverly woven into the narrative. But I promessi sposi is much more than a historical novel: it is one of the great literary works of modern times: comparable for richness of beauty and depth of meaning with Goethe's Faust and Cervantes' Don Quixote. Manzoni's Christian attitude of resignation to the evils of life combined with firm belief in the final triumph of a good cause and with the concept of religion as the ultimate comfort of mankind give his novel its moral import! while his poetical inspiration, the charm of his style and a pleasant vein of humour contribute to its excellence as a work of art.

His complete works were edited by G. Lesca, 9 vol. (1923).

MAORI. This Polynesian people, composing about 10% of the population of New Zealand, came of a seafaring stock. Members of the great Polynesian linguistic and ethnic group which inhabits the far-scattered island groups of the eastern Pacific, they are the result of an intermixture of several distinct waves of canoe voyagers, the last of which, in the mid-14th century, came from Tahiti, with Rarotonga — about 1,800 mi. N.E. of New Zealand — as the port of call. Evidence of this is provided by comparison of the traditions and genealogies scrupulously preserved by the learned men in each tribe. The most important cultural influence in the Maori population was provided by the "great fleet" that arrived in 1350, and on this the traditional social organization largely depended. Prior to that time the islands were inhabited by the tangata whenua, "the people of the land," some of whom were descended from Toi-kai-rakau, a Polynesian immigrant of about 1150, and others probably from drift voyagers. With these folk the later arrivals intermarried and fought, ultimately gaining the ascendancy. The visit of Toi was in the nature of a search party for his lost grandson. The later migration, however, was a premeditated colonization; the kumara ("sweet potato"), taro, yam and other cultivated plants were introduced, as was also the native dog.

This article will discuss traditional Maori customs and ways of life; for history and modern conditions, see NEW ZEALAND.

Social Grouping. — The Maori people are divided into a score or more tribes, *iwi,* each with its own well-defined lands, and tracing kinship to a common ancestor. Thus all members of Ngati Maru, a tribe around Hauraki, claims descent from Marutuahu. the famous 14th-century chief whose name they bear. The principal canoes associated with the fleet are Tainui, Arawa, Matatua, Takitimu, Tokomaru and Aotea, and, generally speaking, the particular group of tribes descended from the captain and crew of each vessel occupy contiguous territory and form a separate unit of a loose political nature, known as a waka. Thus Ngati Maru, together with Waikato and the tribes of the King country make up the Tainui waka, a human canoe which extends from Hauraki to Mokau. A tribe is made up of several principal hapu or clans, each of which might in olden days include about 1,000 fighting men. The hapu was not a unilateral group, *i.e.,* a person could belong to it through either his father or his mother, nor was it exogamous, marriage within the group being favoured provided that the parties were not first cousins.

Within these major social units were lesser hapu, tracing descent to more immediate ancestors, and these in turn were composed of whanau, family groups of near relatives who together often occupied a dwelling hut. The individual family of parents and children existed, but, not forming a separate household, did nor play a large part in public life. Through all Maori social structure ran this principle of kinship by common descent, a bond which linked men together and welded whanau to form hapu, and hapu to form tribe. One hapu might fight another but on the approach of a tribal enemy their quarrel was laid aside and their arms were turned against the common foe.

The system of primogeniture played a leading part in the social organization. The highest chief was the ariki, eldest son in a line of first-born men of rank. His mana was very great; his word was law. The people of his tribe were his relatives, their rank being broadly represented by the closeness of their kinship to him. Next to him came the chiefs of his own family, then the rangatira, and finally the commonalty (ware). But every ordinary man, however undistinguished, could claim some sort of distant connection with his chief and with a noble family. Slaves (taurekareka) were mainly recruited from prisoners of war, and performed much of the menial labour.

Traditional Economy. — The Maori lived in villages (kainga), usually with a fort or defended position (pa) close at hand. The economic life of the different tribes varied according to the resources at their command. In the north, fertile soil and a warm climate allowed the cultivation of the *kumara* but in less-favoured districts forest products and the edible rhizome of the bracken (*aruhe,* Pteris esculenta) formed the staple food supply. Birds and the frugivorous native rat were snared and preserved by inland tribes, eels were taken by weirs on the Whanganui river, while around Rotorua and the adjacent lakes crayfish and the fresh-water mussel were obtained, while fish was the main food of the dwellers on the seacoast. In these economic pursuits the Maori were industrious.

Advantage was taken of the communal mode of life to secure co-operation in various tasks, and such labour was lightened by work songs. Division of labour was practised, though in somewhat rudimentary form. The men did harder work such as tree climbing, carving, fishing and fowling and tilling the ground for crops. The women weeded the crops, collected shellfish, plaited mats and wove garments from the useful harakeke and attended to the cooking of the t o daily meals. In each industry were specialists (tohunga) who had received training, including knowledge of the magic of the craft.

Warfare was frequent and each man was trained in the use of weapons. Hand-to-hand fighting was preferred, and ambuscade and stratagem were frequent. In later warfare against Europeans the Maori proved extraordinarily proficient in the military art. In time of peace the social side of life was developed, visits were made, and neighbouring tribes were invited to feasts at which dart throwing, wrestling, top spinning and posture dancing held the interest of the people. Such receptions were held on the marae, the temple enclosure in the centre of the village. Feasts also took place at tangi, the ceremonial wailing for the dead, at which many relatives assembled from long distances.

Religion. — The traditional religion of the Maori was closely bound up with social and economic life. The common people recognized a number of gods, as Tane-mahuta, guardian deity of the forest, trees and birds, or Tangaroa, the Polynesian Neptune, lord of the sea and fish. The higher priests and chiefs also held belief in Io, a supreme god of rather negative attributes, to whom appeals were made in birth, baptism and marriage ceremonies for people of rank. This knowledge was jealously kept from the common people, and from foreign anthropologists for many years. All Maori believed in a host of minor atua, rather malignant beings who provided omens, gave force to black magic, and punished breaches of tapu. The tapu was one of the strongest forces of law in the Maori community. With a sacred or unclean significance according to circumstances, it conveyed essentially the idea of a prohibition. For instance, the person of a chief, his goods, his place by the fire and the remnants of his meal; all things connected with the gods; a corpse and the surroundings of death were all tapu, as mere also a cultivated field or a new house or canoe. Thus things of social importance were protected from improper interference.

According to Maori belief, man was endowed with several spiritual potentiae, the wairua, the spirit which wanders abroad in dreams, the mauri and the hau, allied metaphysical concepts representing the vitality of a person, his essential life principle. At death the latter are dissolved, but the wairua, the soul, wends its way to Te Reinga, or Te Po, the underworld beneath the sea, a peaceful abode where men pursue their ordinary avocations as in life See NEW ZEALAND; PACIFIC ISLANDS; POLYNESIA; see also Index references under "Maori" in the Index volume.

MAO TSE-TUNG (1893–), Chinese revolutionist and statesman, Communist party leader and founder of the Chinese Communist state. was born into a moderately prosperous peasant family in the central Chinese province of Hunan, on Nov. 19, 1893. He early betrayed a restless, rebellious temper and left the paternal farm; for ten years he attended school after school, and clutched at creed after creed, while China lapsed into chaos. An avid reader, he felt briefly attracted to constitutional monarchism and English idealism, utopian socialism and anarchism. He finished normal school in 1918 and went to Peking, where he took a humble post in the library of Peking university. There he met two professors whose social criticism drew him into their orbit; these were Li Ta-chao and Ch'en Tu-hsiu, eventually the principal founders of the Chinese Communist party.

Mao returned to Hunan in 1919 and briefly taught school before Marxism finally became his faith and revolution his career (1920). He helped to found the Chinese Communist party (1921), and as its leader in Hunan devoted his principal energies to launching a trade-union movement. His local successes earned him a place in the party's national leadership (1923); he went to Shanghai, then to Canton, to serve in its two biggest headquarters (1923–26). But his old restlessness reappeared in the headquarters atmosphere; he often changed posts and seized any pretext to return to Hunan. One such return, in 1925, became a historic turning point: Mao discovered the latent strength of the peasants and organized them for action. Other party leaders had done so before him and might have risen as high from their own rural bases if they had not met early deaths in subsequent wars with the Kuomintang (*see* CHIANG KAI-SHEK; KUOMINTANG).

So far, the Kuomintang remained an ally, and Mao received various posts in it, even that of chief propagandist (1925–26); but rather than wait for the certain split he returned once again to Hunan (summer 1926). While the alliance fell slowly apart, he staged his first peasant rebellions, each quickly suppressed by Kuomintang troops, until he had to flee to the mountains (1927). He turned his few hundred followers into a band of guerrillas; other fugitive bands joined his, until he had a small army (1928–30). Roaming the mountainous southeast, he found some tenable bases; he expanded these into Red enclaves and proclaimed them a "soviet republic" (1931). He became chairman but shared actual power with a Russian trained group of leaders, who considered his knowledge of Marxism weak and his policies opportunistic. Like other good Marxists, they thought that he showed an inborn peasant mentality, seeming content that backward peasants should fill a communist party. They also grew more and more distrustful of his guerrilla tactics and finally made the Red command switch to positional warfare. But the defenses that they ordered built broke under the next assault by superior Kuomintang numbers; and the defenders found themselves forced to abandon the "soviet republic" (1934). Mao, vindicated as a strategist, led his remaining forces across China to the northwest, where they settled on new bases (1935–36). During this trek, the so-called Long March, he gained full control of the party; henceforth he determined its policies and proclaimed them dogma.

War with Japan forced Mao and the Kuomintang into an uneasy armistice; it also made Mao adopt moderate policies that won him much liberal sympathy. But civil war quickly resumed after Japan surrendered; the Communists won, sooner than they had hoped, by superior morale and leadership. Once they controlled continental China they proclaimed a people's republic (1949); Mao became chairman (*i.e.*, chief of state), a post that he kept through the following decade. He visited Moscow (his first trip abroad) to conclude an alliance with Russia and to secure all possible aid for China's economic development (winter 1949–50).

After Stalin's death (1953), Mao's influence grew throughout the Communist orbit, and he became freer to assert claims to ideological leadership. These rested on his contributions to Marxist-Leninist doctrine: actually new adaptations of it, not additions of substance. As China's ruler, Mao soon abandoned his moderate wartime policies for radical programs to transform the country ever more quickly and thoroughly. He drove the bulk of the Chinese people into a collective existence and into a race to catch up with the west in industrial production. With a fixed vision and determination to translate it into reality, he built in ten years the most tightly controlled and most taut-nerved of modern societies. By the time he resigned his government though not his party chairmanship (1959), Mao had gone far toward making China more Communist than Soviet Russia.

MAP (MAPES), **WALTER** (d. c. 1208/9), medieval ecclesiastic, author and wit, to whose authority the main body of prose Arthurian literature has, at one time or another, been assigned, flourished in the latter part of the 12th and early years of the 13th centuries. He studied at Paris under Girard la Pucelle, who began to teach in or about 1160, but as he states in his book *De nugis curialium* that he was at the court of Henry II before 1162, his residence at Paris must have been practically comprised in the decade 1150–1160.

Map was clerk of the royal household and justice itinerant; in 1179 he was present at the Lateran council at Rome, on his way there being entertained by the count of Champagne; at this time he apparently held a plurality of ecclesiastical benefices, being a prebend of St. Paul's, canon and precentor of Lincoln and parson of Westbury, Gloucestershire. There seems to be no record of his ordination, but as he was a candidate for the see of Hereford in 1199 it is most probable that he was in priest's orders. The last reference to him, as living, is in 1208, when an order for payment to him is on record, but Giraldus Cambrensis, in the second edition of his *Hibernica*, redacted in 1210, utters a prayer for his soul, "cujus animae propitietur Deus," a proof that he was no longer alive.

The special interest of Map lies in the perplexing question of his relation to the Arthurian legend (*q.v.*) and literature. To him have been attributed the *Lancelot* proper, the *Mort Artus* and the *Queste*. He is constantly referred to as an authority. It seems unlikely that a busy court official could have written the long prose romances that are attributed to him. But he seems to have been the man who linked up the Arthur legend proper to the cycle of the Holy Grail. His undoubted work is the *De nugis curialium*, and he is reputed to be the author of various witty goliardic verses.

Taking all the evidence into consideration it seems more probable that Map had, at a comparatively early date, before he became so important an official, composed a poem on the subject of Lancelot, which was the direct source of the German version, and which Chrétien de Troyes also knew and followed. (J. L. W.)

MAP, a systematic representation on a surface of the nature and distribution of phenomena in space. For example, terrestrial and celestial globes are maps of the earth and of the heavens, respectively, on a spherical surface. In a more restricted sense, a map depicts on a flat surface (plane) the relationships between selected items on or about the nearly spherical surface of the earth. Most maps are of this kind. A map projection is a system whereby horizontal positional relationships on the earth's curved surface are shown on a plane. There are innumerable projections, though only a few are in common use. Vertical relationships, essentially elevations above sea level, can be indicated on a flat map both quantitatively and qualitatively by various methods, which come under the general heading of relief representation.

Cartography is the art and science of map making. The development of the map is a part of the story of discovery, exploration and accumulation of detailed geographical knowledge; thus, in this article the history of cartography will be dealt with in its broadest sense. The article is outlined as follows:

I. ELEMENTS OF MAPS

A. Maps in the Modern World

1. Uses of **Maps.**—Maps provide an efficient and unique means for communicating certain types of information. Though a listing of all the countries in the world and their areas may be prepared, only a map can show the arrangements of these countries with respect to one another and the configuration of their boundaries. A map, unlike a photograph, does not reveal all the detail that can be seen in a landscape, but it provides a more comprehensive and selective picture. By a suitable choice of projection it is possible to prepare a map on which an observer can see at a glance a representation of the whole surface of the earth. This is not possible in the case of a terrestrial globe.

Maps are useful in many activities: in the appraisal, conservation and development of natural resources; in analyzing and forecasting weather conditions; in agriculture, fisheries and general commerce; in regional planning; in the building and development of communications; in the location of industry; in property surveys and the demarcation of boundaries. Governments need maps for aid in settling boundary disputes and in controlling floods and droughts, in taking censuses, levying taxes, organizing franchises, law enforcement and promotion of justice and health. Without maps the regulation of transportation and traffic control, on land and sea or in the air, cannot be undertaken efficiently. Maps aid in navigation by sea and air (*see* CHART). Planning and execution of military operations, defensive and offensive, tactical and strategical, would be impossible without maps. In fact, considerable mapping in the past was done for military purposes, and mapping activities were greatly stimulated and advanced during World Wars I and II.

One of the most significant uses of maps is that made by scientists concerned with the causes and effects of the distributions of phenomena, in such disciplines as geology, oceanography, meteorology, climatology! animal and plant ecology, agronomy, economics and the social sciences, as well as geography itself. In all these fields maps are indispensable tools. They record observations in succinct form; they aid in analysis; they stimulate ideas and aid in the formulation of working hypotheses; they make it possible to communicate findings.

Maps promote accessibility and freedom of movement by showing where places are and how they may be reached. They aid people to understand their own and others' environments, and they frequently accompany articles on important world events in newspapers and other periodicals. On occasion maps have been designed for propaganda — to promote local or national interests or to mislead for political purposes — in much the same way as statistics are sometimes abused. Fortunately such maps are rare; nevertheless all are not necessarily equally reliable in their content, and in the past cartographic sins of omission and commission frequently have been masked. wittingly or unwittingly, by excellent draftsmanship and reproduction. Thus an intelligent use of maps requires an appreciation of the factors that contribute to making maps reliable and an awareness of both the advantages and limitations of maps as mediums for the communication of factual information.

2. Concepts **of** Scale. — Scale means the size of the representation of an object in respect to its actual size. If a ship model's scale were to be given as 1 in. to 12 ft., few would fail to understand what is implied. On maps, more generally convenient methods of expressing scales are by means of the representative fraction or proportion as, for example. $\frac{1}{144}$ or 1:144, because these are independent of the unit of measurement employed. Thus $\frac{1}{144}$ is equivalent in meaning to 1 in. to 144 in. or 1 ft. to 144 ft. or 1 m. to 144 m. The scale of a map is smaller than the scale of another map if its scale denominator is larger: $\frac{1}{10,000}$ is a smaller scale than $\frac{1}{1,000}$.

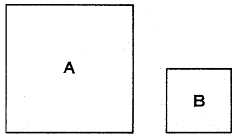

FIG. 1 — THE LINEAR SCALE OF SQUARE B IS ½ OR 1:2 IN RESPECT TO SQUARE A; ITS AREAL SCALE IS ¼ OR 1:4

On maps it is necessary to distinguish betneen linear and areal scale. In the fractional notation the areal scale denominator is equal to the square of the linear scale denominator (*see* fig. 1). Areal scale can be made constant by using a particular type of map projection (see *Map Projections,* below). On the other hand, it is impossible to maintain a precisely constant linear scale. Expressed in another way, the measured distance between two points will bear a definite scale relationship to the true curved distance on the earth, but this relationship will vary from one pair of points to another. When two points are extremely close a finite linear scale relationship still exists. A useful mathematical abstraction, therefore; is the concept of the scale at a point; *i.e.,* scale when the distance mapped is infinitely small. Such a concept gives meaning to such statements as "the scale is constant along a line on a map," or "the scale varies on a map as a function of distance and direction from a point."

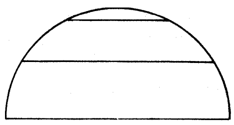

FIG. 2. — CHORD AND SURFACE ROUTES BETWEEN PAIRS OF POINTS ON A SPHERE

Because linear scale may vary from point to point, it is convenient to refer to the "nominal scale" of a map. This may mean the scale at a central point, or the constant scale along a particular line or set of lines on the map. It also may refer to the scale of a hypothetical globe from which the flat map has been projected. The term map scale without a qualifying statement usually refers to the nominal linear scale.

Scale ratio is a convenient term for the scale at a point divided by the nominal scale. For example, if the nominal scale is $\frac{1}{100,000}$ and the scale at the point is $\frac{1}{200,000}$, the scale ratio is 0.5, and if the scale at the point is $\frac{1}{50,000}$ the scale ratio is 2. The scale ratio at every point would be approximately equal to 1 only on a globe.

The difference between the chord distance and the surface distance between two points on the earth increases: of course, rapidly with distance. For example, the differences for 100 mi. and 1,000 mi. are 1 part in 39,458 and 378 respectively. These figures suggest that short distances can be scaled from a map with a fair degree of accuracy, even though in the mapping process the earth were to be considered flat. Consequently on large-scale maps of small areas it is customary to give a graphical scale as in fig. 3; on a very small-scale map, showing the whole world or large parts of it, a graphical scale of this sort may be misleading.

3. Classification **of** Maps. — Maps may be classified according to the method of their construction or according to their content and scale. In classifications of the first kind the major divisions

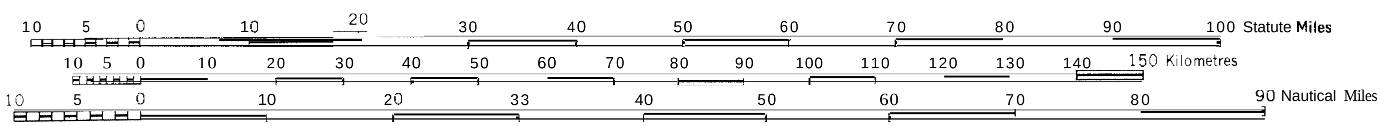

FIG. 3. — GRAPHICAL LINEAR SCALES

are usually between (1) surveyed maps made directly from precisely controlled surveys on the ground or from the air, and (2) maps compiled from a selection of the information contained in the surveyed maps. Surveyed maps are rarely on scales smaller than $\frac{1}{250,000}$ (roughly 1 in. to 4 mi.), usually on considerably larger scales and frequently on much larger scales. For example, the whole of Great Britain and Ireland with the exception of waste or mountainous areas has been mapped on the scale of $\frac{1}{2,500}$ or about 25 in. to 1 mi.

Though there is no hard and fast division between the scales of surveyed and compiled maps, the latter are usually on smaller scales and may be on very small scales indeed. A map of the world appearing in a book may show the equator as a straight line six inches in length; since the equatorial circumference of the earth is approximately 24,900 mi., the scale on the equator would be 1 in. to 4,150 mi., or approximately $\frac{1}{263,000,000}$.

Surveyed maps which show physical features such as rivers, lakes, forested areas and swamps, together with man-made features such as roads and towns, but with no representation of relief. are called planimetric (United States usage). When relief representation is added they are called topographic. Cadastral maps show property and political boundaries, roads and the shapes of buildings, etc., in sufficient detail so that dimensions may be recovered from them within the limits of accuracy controlled by the scale. Compiled maps may also be planimetric or topographical, but these terms usually are limited to map scales greater than $\frac{1}{1,000,000}$. On smaller scales, a general-purpose map is perhaps a preferable term.

An outline map, usually on a small scale and covering a large region, shows in simplified form coast lines, principal rivers and lakes and sometimes political divisions. Base maps may be simple outline maps or somewhat more complicated; as their name implies, their purpose is to present a base upon which specialized data can be plotted.

4. Modern Map Makers and the Status of Mapping. — Most of the topographical and cadastral mapping in the world is undertaken by national governments, though in the second half of the 20th century private corporations such as oil companies were still undertaking large mapping operations in underdeveloped regions.

Governments also produce maps compiled from their original source maps on smaller scales and from statistical and other data either as general-reference maps or for special purposes. The most important results of international co-operation in the production of compiled maps are the International Map of the World and the World Aeronautical Charts, both on the scale of $\frac{1}{1,000,000}$. The first consists of series of topographical or general-purpose maps prepared by the various participating countries according to internationally accepted standards. The second is a series containing for the most part less general information but a wealth of detail needed for air navigation. Total world coverage for neither of these series of maps was available in the decade following World War II.

Various geographical societies compile and publish maps showing the results of exploration and geographical discovery. Some of these societies — notably the National Geographic society (Washington, D.C.), the British Royal Geographical society (London) and the American Geographical society (New York)—undertake large cartographical projects. The National Geographic society produces many general reference maps for popular use, and the Royal Geographical society and the American Geographical society, among their numerous cartographical activities, have done much to promote the International Map of the World. For example, the American Geographical society, over a period of 25 years ending in 1947, compiled from thousands of original sources a series of 107 sheets covering the whole of Latin America on the scale of $\frac{1}{1,000,000}$ and conforming in essentials to the international scheme.

While most of the maps produced by commercial map publishers are based on surveys and compilations made by governments and private nonprofit organizations, this is by no means always the case. For example. the widely used road maps require special compilation and considerable research and revision to keep them up-to-date.

Maps appearing as illustrations in newspapers, other periodicals and books are often prepared by free-lance cartographers. These maps must often be prepared in a hurry, and to make them effective, special skills and artistry are required.

Not all national governments are willing to reveal the extent to which their countries have been mapped; hence it is not possible to give exact figures as to the status of mapping throughout the world. At the end of the first half of the 20th century, however, probably less than 25% of the world's land surface had been mapped adequately on topographical scales and far less than that on cadastral scales. Because of man's activities in changing the face of the earth, mapping is a continuous process, and map revision is almost as serious a problem as the initial surveying. A map satisfactory at one time may become quite unreliable within a very few years. The general use of aerial photography from World War I and especially from about 1930 has helped solve this problem; the mapping process has been greatly accelerated and mapping revision has become easier. Nevertheless, it cannot be positively stated that mapping as such has kept pace with the mapping needs of a rapidly expanding world population.

B. Techniques of Map Making

1. Compilation. — There are two principal steps in map compilation: (1) appraisal and selection of original source maps; and (2) selection of features to be shown and of the manner of their depiction, so that the compiled map, usually on a smaller scale than the original source material, will contain only essential information and will be legible and uncluttered. The first step poses no problem when the source material consists of accurately controlled survey maps, but difficulties occur when the area is poorly mapped or is mapped unevenly in patches by small local surveys or by reconnaissance surveys, the latter consisting largely of explorers' traverses and descriptions. For example, on a single sheet of the International Map of the World, hundreds of different sources, all varying in quality, may have been used. In such cases a small index map may be included in the margin to show the relative reliability of the source material. This procedure, now standard for sheets of the International Map, was first employed on the American Geographical society's maps of Latin America.

2. Drafting and Reproduction. — A completed map compilation is comparable with an author's typewritten manuscript. Before a finished map can be published, it must be redrawn in finished style and printing plates must be made. A draftsman must be able to draw smooth straight lines and curved lines varying both in their curvature and their width. He must be adept in the positioning of place names, so that important details are not masked. Up until about 1930, lettering was done mostly by hand; now, though there are still expert hand letterers, and hand lettering allows flexibility in size and spacing, large map-making establishments for the most part employ "stick up" lettering, in which names are printed. cut out, placed in position on the map drawing and stuck or burnished on. It is still an open question whether this process materially speeds up lettering; its main advantage is that it can be accomplished by relatively unskilled workmen. A similar procedure is frequently followed in laying down background patterns of fine lines or dots to differentiate among different types of areas. Patterns of many different kinds are printed for this purpose. When a map is to be printed in only one colour, the printing process may follow any one of a number of methods. Coloured maps are generally printed by photolithography rather than by letterpress, on rotary offset presses.

When colour is to be used, the finished map drawing is rarely hand coloured and reproduced by the kind of colour processing used in the reproduction of paintings. Instead, line copies of the compilation generally are made in nonphotographic blue. On these copies the draftsman makes separate finished dra ings in black for each solid printing colour to be used, using the blue lines as guides. When background tints are required, a colour guide is provided for the printer, who can produce in addition to the solid colours a wide variety of tints by means of half-tone screens, etc., used in conjunction with platemaking photography. In some cases, as many as a dozen printing plates have been used to produce a re-

w

quired colour effect on a single map sheet.

The chief technical problem to be surmounted by colour separation in the drafting stage is to insure that on the composite reproduction of the separate drawings there will be no interference between the different-coloured symbols and place names and that there is precise register, or fit, among the different colours. To accomplish this, it is necessary before the printing plates are made to proofread and edit the composite. This can be done by superimposing the various drawings over a "light table," which has a translucent surface illuminated from below. This, however, is an exacting and time-consuming procedure, and after World War II, several proofing processes were developed to facilitate the final checks. Contact prints of each colour separation drawing are made onto a single base by using a new emulsion for each successive exposure; separate drawings thus can be reproduced in different colours on the same sheet, and necessary adjustments will be indicated before the printing plates are made.

This proofing process does not by itself solve the technical problem of obtaining good register. For this, the separate finished drawings must be made on material that will not expand or contract significantly because of use or of changes in temperature and humidity. Printing plates must be made with great precision, and temperature and humidity control are essential during the actual printing.

Before World War I, first-class coloured maps were published for the most part in small editions. After that time, and especially after World War II, technological developments made possible the economical production of highly precise maps in editions that may run into millions of copies. Register was brought under better control, for instance, by the development of synthetic plastic materials, which keep their shape better than paper does, on which to make the colour separation drawings. Again, most map printing is done on multiple-colour presses, reducing the danger of paper distortion that might occur when there is considerable time lapse between the printing of one colour and the next on single-colour presses.

After plastics were introduced, the trend in most of the big mapping organizations was to eliminate as far as possible pen and ink drafting. In addition to "stick-up" lettering, "scribing" is widely used. In this work, a transparent glass plate or plastic sheet is coated with a thin opaque film. A light-sensitive emulsion is then spread over the surface, an exposure of a negative of the original compilation is made onto it and a line image developed. The finished line drawing is prepared by means of a scribing tool that scrapes or cuts the opaque coating away as desired, leaving a sharp transparent line against the opaque background. The main advantage of scribing over pen and ink work lies in the fact that fine sharp lines can be produced by persons with comparatively little training.

3. Detailed Design. — The minimum width of line that can be reproduced by offset lithography is about 0.002 in. A single black line of this width against a white background can be perceived by the normal human eye at the usual reading distance of between 10 and 20 in. As the viewing distance is increased, the eye soon fails to resolve the line, and if the distance is decreased there is difficulty in focusing. If a series of parallel straight lines 0.002 in. in width spaced 0.004 in. from centre to centre is viewed at normal reading distance, the average eye will see this pattern only as a smooth tint against the background.

These limits of printing and visual acuity have great significance in the rendering of detail and in the over-all design of a map. On scales of $\frac{1}{100,000}$ and $\frac{1}{1,000,000}$, respectively, 0.002 in. represents 16 ft. 8 in. and 166 ft. 8 in., and it is evident that many line features on the ground, such as roads and minor streams, cannot be shown distinctly except on the largest scales without an exaggeration of their widths. This, however, immediately suggests that variations in the width of printed lines on a map can be used to distinguish between line features of greater and lesser importance. Two effects occur when the width of a line feature is exaggerated: details in the neighbourhood of the line are masked, and the true shape of the line is smoothed out or generalized.

As the scale of a map becomes smaller, more and more detail must be eliminated and there must be greater generalization of what is left. In many cases, the outlines of important features (for example, towns or airport runways) must be eliminated and purely artificial symbols substituted.

Thus, except on very large scales, the representation of pertinent information on maps is not a true simulation to scale of features of the landscape but rather a symbolization or codification of information which requires learning. A well-established convention is to orient maps so that in general the north direction is toward the top of the map sheet. Convention is also important in the use of colour to differentiate between different types of lines or different types of areas. There is often an association of ideas, such as blue for water and green for forested areas, but colour is used principally for distinctiveness rather than to portray the landscape.

Names, essential items on most maps, also are symbols, whose selection and positioning constitute a specially difficult problem in composition. They tend to mask essential details of the landscape and otherwise to cause clutter. Without the exercise of thought and skill, they either may be hard to read or else may dominate the map at the expense of all other features. If properly composed, they not only name and locate places but may also, by means of different styles of type, aid in differentiating among different classes of features; *e.g.,* size of lettering may give a general indication of the size of a town or city.

The foregoing considerations indicate that the functional elegance of a reliable map is dependent largely on a critical selection of detail and place names, and on the portrayal of these legibly, with the proper emphasis and with the right degree of generalization or symbolization. This is the cartographer's art.

Because the interpretation of symbols, or as they are sometimes called conventional signs, is not immediately obvious, it is customary to provide an explanation in the margins of a map. This, together with details such as the title of the map and its nominal scale, combine to form what is called the map legend. When a number of sheets cover a region on a uniform nominal scale and with the same system of symbolization, a separate conventional sign sheet is often printed.

4. Relief Representation. — Relief, the variation of the earth's continuous surface in slope and in elevation either above or below sea level, influences many of man's activities—transportation, agriculture, housing, flood control and military tactics, to name but a few. It is therefore important that relief be shown clearly. This, however, involves representing a third dimension on a two-dimensional surface, a representation that can be achieved only symbolically.

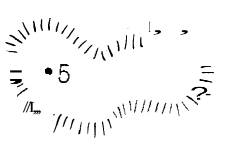

FIG. 4. — SPOT ELEVATION AND ROUGH OUTLINE OF HILL, PRIMITIVE METHODS OF SHOWING RELIEF (*see* TEXT)

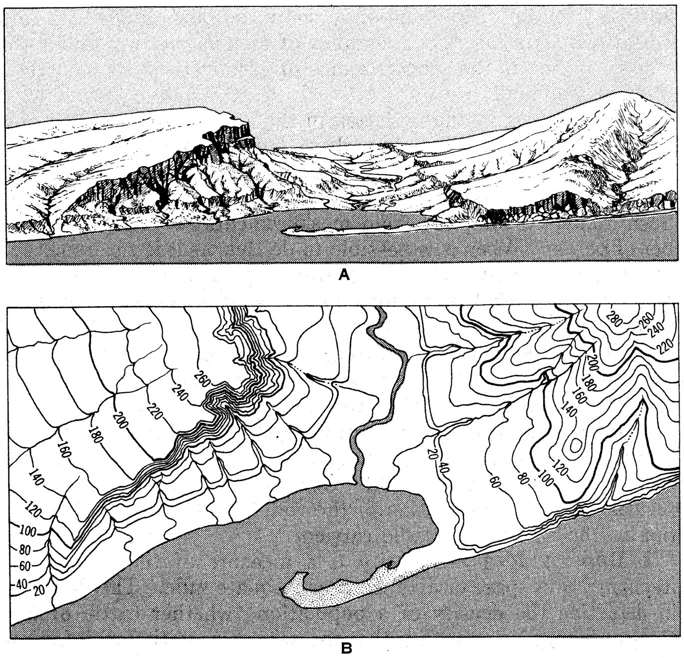
In fig. 4, two primitive methods are shown. The number and dot show the elevation and position of a single spot, usually a hilltop or mountain whose general shape and location are indicated by the "caterpillar" type outline. On a map covered with a composite of such crude symbols, the character of the relief cannot be properly interpreted; there is no quantitative representation of slope. On most maps that show relief, such selected spot elevations do appear: usually they are supplemented with contouring, layer or hypsometric tinting, hill shading, hachuring or other symbolic representations, singly or in combination.

Contouring.—Contouring, which depicts relief both quantitatively and qualitatively, is by far the most important method. A contour line (q v.) on a map is the representation of an imaginary line on the earth's surface having a constant elevation above sea level. The nearest approach to a contour line in reality is the outline of a lake. The pattern produced by contour lines at uniform vertical intervals makes it possible to determine the elevations of points by interpolation. Slopes can be estimated from the horizontal spacing between adjacent contours, since the closer the contour lines the steeper the slope represented, and it is this feature of the contour method, together with the general arrangement of



ADAPTED FROM U.S. GEOLOGICAL SURVEY TOPOGRAPHICAL SHEET

FIG. 5.— LANDSCAPE SHOWN IN PERSPECTIVE (A) IS REPRESENTED WITH THE AID OF CONTOUR LINES ON MAP (B)

the contour lines, which gives expression to the relief character of the ground. The method has its limitations, however.

A uniform vertical contour interval on a particular scale may be adequate for representing major land forms but may fail to catch small but significant details. If the vertical contour interval is small enough to catch such details, the contour lines may have a tendency to merge on steep slopes; this occurs because it is necessary to show contours, theoretically of no width, as printed lines of finite width. For example, on the scale of $\frac{1}{63,360}$ (one inch to the mile) if the width of the printed contour lines is 0.004 in. 20-ft. contours will be hard to see separately (if at all) on slopes greater than about 26°, yet in otherwise flat country they will not portray steep rises of less than 20 ft., though these may be important features in the landscape.

In areas of moderate but complex relief, the visual picture given by contour lines is often hard to interpret. This difficulty can be partly obviated by emphasizing certain contour intervals as, for example, every 100-ft. contour when the regular contour interval is 20 ft. Finally, from a graphical standpoint, contours must be printed boldly. If they are subdued or overprinted by a multitude of names or other features, they lose their visual effectiveness.

Hypsometric Tinting.—With layer or hypsometric tinting! successive zones of elevation are coloured differently. This aids in the visualization of relative elevations and can be quickly understood even by schoolchildren. If the area mapped is of moderate relief, only a few tints may be sufficient and these may be in one hue, usually darkening as higher land is covered. More often, in order to obtain sufficient distinction between a large number of zones, variation in hue is introduced. Established convention generally demands that the hues follow the spectrum, starting with green for low land and proceeding through the buffs and oranges to dark red or brown or even purple for higher elevations. Even so, however, not enough colour differentiations are available to make the method altogether effective. For example, for the sheets of the International Map on the scale of $\frac{1}{1,000,000}$, it is specified that the elevation range of the colour zones increase with elevation and that above 3,000 m. (9,842 ft.) all land be shown in the same tint; thus, relief detail diminishes as elevation increases, and hills and valleys in high upland regions may have no representation at all.

Hill Shading.—Hill shading, a qualitative method of presenting relief features, gives a three-dimensional or plastic effect somewhat similar to that provided by an actual model of a landscape. It is based on the optical theory that the brightness of any small area on a perfectly diffusing undulating surface varies as the cosine of the angle of incidence of parallel light falling on it. The method thus has nothing to do with shadows cast by hill features. Oblique hill shading is customary. It usually assumes that the incident light is inclined at 45° to the vertical, and, for a reason not clear, the convention has arisen that the light is assumed-to come generally from a northwesterly direction. This convention is so strongly intrenched that if an oblique hill shaded map is turned around so that south is at the top of the map, many people have difficulty in retaining the plastic impression. In practice, the optical theory is not always strictly followed. Oblique hill shading is a specialized art, brought to a high degree of effectiveness notably in Switzerland and, during the 20th century, increasingly used on topographical maps in combination with contouring. The method loses its effectiveness as scale becomes smaller, though it can always be made to give a generalized plastic effect to the major mountain masses. In inexpert hands. the method can be misleading; for example, the artist may overemphasize the relief in gently undulating country so that it looks as rugged as more mountainous country.

Hachuring.—Hachuring consists in laying down a pattern, of short lines to indicate the directions of slopes. By varying the width of the lines, some indication of steepness of slope is also obtained. Well-executed hachuring reveals the character of the relief and when used as a supplement to contouring can be effective. Though this method should allow for a more precise interpretation than hill shading does, and was used extensively on topographical maps in the 19th century, it is more difficult to execute properly and in the 20th century has largely been abandoned as a technique.

Other Methods.—There are other methods of relief representation, many of which are ingenious and some of which are statistical or diagrammatic, but only two will be mentioned here. One is a technique that characterizes land form features on small scales by perspective or semiperspective symbols, a qualitative method requiring skill and considerable knowledge of geomorphology. The second is the depiction of zones of slope by succession of tints. This method, though not in common use, gives on very small scales a revealing characteristic pattern of landscape when combined with the representation of drainage features; it may be useful, for example, in assessing the suitability of regions for development projects such as housing.

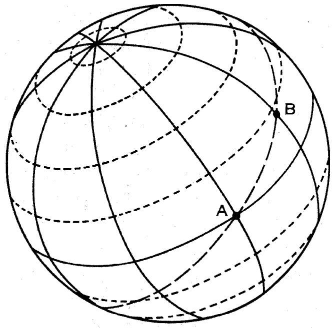
5. **Terrain** Models.—These are three-dimensional maps, which not only supply the user with a real plastic effect rather than the simulated effect obtained by hill shading, but also make possible the adequate representation of steep slopes and vertical precipices. The earth is, however, a remarkably smooth surface in respect to its radius. The elevation of Mt. Everest is only about $\frac{1}{7}$ of 1% of the earth's radius, and on a scale of $\frac{1}{1,000,000}$ its elevation is represented by about 0.35 in. In order, therefore, to give emphasis to the relief on models, the vertical scale on any but extremely large-scale models is usually made larger than the horizontal scale. This "vertical exaggeration" usually is increased as the horizontal scale becomes smaller. One effect of vertical exaggeration, not often noted, is that gentle slopes are given more exaggeration than are steep slopes. Obviously a vertical slope cannot be exaggerated by increasing vertical scale over horizontal scale.

Though vertical exaggeration actually distorts the representation of slope, the proponents of terrain models do not consider this to be a defect. In fact, in some cases, the vertical exaggeration is purposely varied with slope to emphasize the gentle slopes still further.

The principal difficulty in constructing a terrain model lies in the making of the master base model itself. Though this process is comparable to sculpturing, modern technology has reduced it to the point where it is nearly automatic. Modern methods for reproducing printed terrain models quickly and in quantity, which began to develop about the time of World War I and were greatly improved during and after World War II, involve printing the maps on flat sheets of opaque plastic. The sheets are vacuum pressed onto the master model or a facsimile and heat is applied so that the plastic nearly melts and molds itself to the model.

When it is cooled and removed, a lightweight printed model is produced.

6. Geographical Names.—Names of places are established, for the most part, from a multitude of complex considerations. Only an indication of the intricacies of toponymy (the study of place names) can be attempted here. If all nations used the same alphabet and spoke and wrote in one language, the rendering of geographical names on maps would be a comparatively simple matter. though this is not the only difficulty in place names: the same name is often given to different places (for example, Boston, Columbus, Washington and Lincoln); sometimes local usage varies from official usage (a mountain may be called by different names by the peoples living on opposite sides of it); the same place name has various spellings or is entirely different in different languages ("Wien" in German is "Vienne" in French, "Vienna" in English and "Becs" in Hungarian, and the English channel and the Straits of Dover in English become respectively La Manche and Pas de Calais in French).



MODIFIED FROM JOHN Q. STEWART & NEWTON L. PIERCE "MARINE AND AIR NAVIGATION" (1944)

FIG. 6.—SOLID AND LONG-DASH LINES INDICATE GREAT CIRCLES, SHORT-DASH LINES ARE SMALL CIRCLES. AND THE PORTION BETWEEN A AND B IS A GREAT CIRCLE ARC

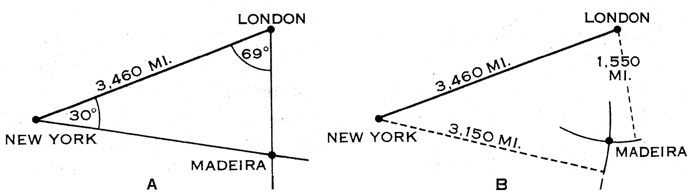
The greatest difficulties in the rendering of geographical names, however, occur because there are numerous different scripts and because sounds in one language may have no adequate representation in the alphabets used for another language. Sometimes names are translated; the Cabo da Boa Esperanca in Portuguese, for instance, has become the Cape of Good Hope in English. More often, the transcription of alphabets or the transliteration of syllabic symbols is attempted.

In passing, it may be noted that explorers not sufficiently versed in local languages to fully comprehend answers to questions have been known to place on their maps absurdities with meanings such as "I don't know."

In the English-speaking world since the beginning of the 19th century, the Royal Geographical society has pioneered in establishing order in the rendering of geographical names, and in 1919 it established the Permanent Committee on Geographical Names. In the United States. the Board on Geographic Names was established under a slightly different name in 1890. These two organizations deal specifically and exclusively with the subject, and considerable co-operation and co-ordination have been effected between them.

C. Special-Purpose Maps

1. Categories.—Special-purpose maps fall into several distinct categories. Air navigation charts and road maps, for instance, comprise one. Another divides the land up into areas or regions according to a system of classification. For example, a geological map may show the areas occupied by different kinds of outcropping rock. Land-cover maps may show forests, grasslands, swamps, tundra or deserts. The soil map is another important type. Such maps as these are compiled from intensive observations in the field. Other types within this category may have been derived from a combination of field observations and statistical analysis; for instance, maps may show the land divided up into climatic regions based on a complex of criteria, or may divide the land according to the predominance of certain crops or of certain races of mankind.



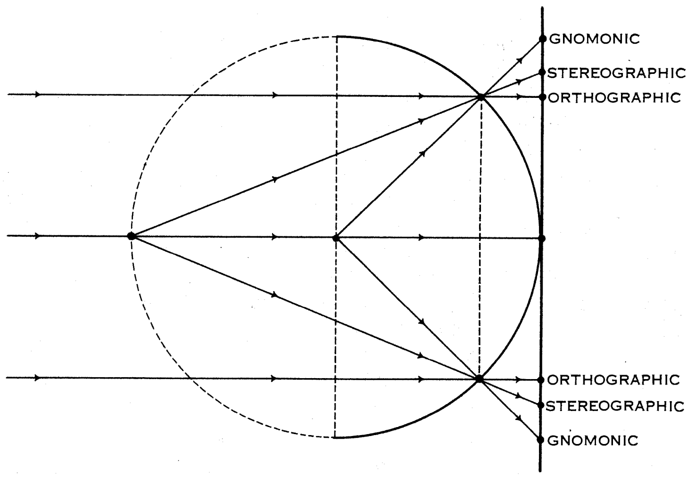
MODIFIED FROM IRVING FISHER & O M MILLER WORLD MAPS AND GLOBES

FIG. 7.—(A) MADEIRA PLOTTED SO THAT ITS AZIMUTHS FROM LONDON AND NEW YORK ARE CORRECTLY SHOWN; (B) MADEIRA SHOWN AT ITS CORRECT SCALE DISTANCE FROM BOTH POINTS

A map may show the variation in the amount of intensity of a single phenomenon. This is perhaps best exemplified in climatic maps that show the distribution of such items as temperature, barometric pressure or rainfall averaged over periods of time. Such maps are compiled from measurements at a discrete number of points. When it is possible to do this, as it is for numerous kinds of phenomena, it is also permissible to interpolate isolines, or lines of equal intensity, in the same way as contour lines may be interpolated from spot elevations.

Another category of special-purpose maps comprises those that show flow lines, such as sea currents or winds. The rate or amount of flow can be indicated. For example, a useful type of map for analyzing road traffic problems is one that differentiates between the number of cars passing over different sections of a road system in a given period. One way of depicting this is by regulating the representation of the width of the roads in proportion to the amount of traffic carried.

2. Density Maps.—Density is a measure of the number of items in a unit space or area, such as a square mile. The difficulty in depicting the density of a population (whether cattle or oak trees or human) on a map is that the necessary statistical information is summated over areas varying in size and shape; *e.g.,* minor civil divisions. If the population densities in counties are given as so many items to a square mile, there is no assurance that these items are regularly distributed over each area. In fact, quite a different picture generally will be obtained if it is possible to obtain statistics for areas considerably smaller than counties.

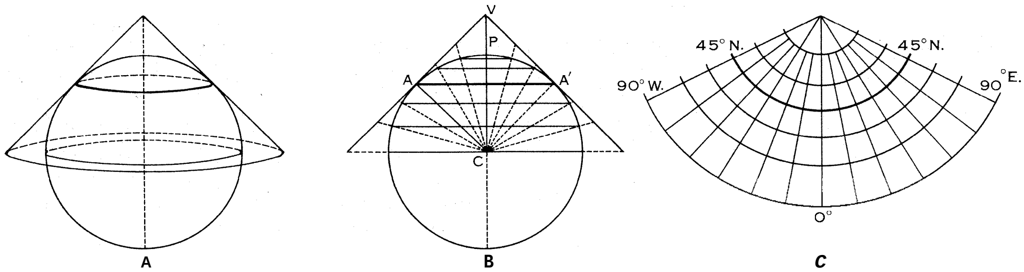


MODIFIED FROM IRVING FISHER & O. M. MILLER "WORLD MAPS AND GLOBES"

FIG. 8.—ORTHOGRAPHIC, STEREOGRAPHIC AND GNOMONIC PROJECTIONS OF A SPHERICAL SURFACE ONTO A TANGENT PLANE BY PERSPECTIVE RAYS

Because density is associated with area, the most valid method of indicating it on a map is to show by colour or pattern differentiation the density variation among the statistical areas; but this method may fail to give a revealing over-all picture graphically. If, on the other hand, the centres of the statistical areas are adopted as points of average density and isolines are then interpolated, the pattern of the isolines will depend to a large extent on the size and shape of the areas and on the compiler's judgment. Isoline patterns of density, therefore, must be viewed with suspicion except insofar as they show very general relationships.

The dot method in its simplest form would show each individual item in its correct position, and a map thus compiled would give a revealing over-all picture of density. However, because of considerations such as scale and the impossibility of collecting the necessary information, individuals are usually grouped, and each dot may represent hundreds or even thousands of individual items not necessarily at the mean position of the group. This method thus requires skill and judgment to be successful.



MODIFIED FROM IRVING FISHER & O. M. MILLER "WORLD MAPS AND GLOBES"

FIG. 9.—THE DEVELOPMENT OF A PERSPECTIVE CONIC PROJECTION (*see* TEXT)

D. Map Projections

1. Basic Concepts.—It is impracticable to record detailed surveys on topographic and cadastral scales and. in general, to compile maps from these surveys on anything but a plane surface. Nevertheless, these surveys and compilations must be tied to geodetic control points, whose positions have been determined with reference to the surface of an oblate spheroid which is a close approximation to the form of the earth. In practice, this problem is solved by expressing the positions of the control points in terms of their projected positions on a plane.

Though the subject of map projections is a highly specialized branch of applied mathematics, the principles involved and the properties of most map projections can be described quite simply in terms of elementary geometry and trigonometry by assuming the earth to be a sphere. (See SPHERE; SURFACE.) The following concepts and definitions are valid on the basis of this assumption.

The geographical poles (north and south) lie on the surface of the terrestrial sphere on its axis of rotation. The plane of the equator is perpendicular to this axis. The equator is only one of an infinite number of circles, called great circles, which divide the surface of the sphere into two equal parts. All other circles on the surface of the sphere are called small circles. Two points on the surface of the sphere can always be connected by a great circle, and the shortest surface distance between them lies along it. The portion of a great circle between two points is called a great circle arc. Because an arc subtends an angle at the centre of the sphere, it is convenient to express it either in arc measure (degrees, minutes and seconds) or in circular measure (radians). (See TRIGONOMETRY: Spherical Trigonometry.)

At all points on the surface of the terrestrial sphere, the vertical direction is assumed to be perpendicular to the surface. **A** horizontal line or area, therefore, lies on or parallel to this surface. Horizontal position on the terrestrial sphere is stated in terms of the geographical co-ordinates latitude and longitude (see LATITUDE and LONGITUDE). Lines of equal latitude are small circles parallel to the plane of the equator and are thus frequently referred to as parallels of latitude. Latitude as shown on maps varies between 0° on the equator to 90° N. and 90° S. at the poles.

Meridians are arcs of great circles connecting the two geographical poles. The angular difference between two meridians at the poles is called a difference of longitude. By international agreement in 1884, the meridian passing through the Greenwich observatory near London, Eng., long used by the British as a zero or prime meridian, was accepted as standard, and by 1950 the system was in universal use on the maps of practically all nations.

Longitude on maps is given almost invariably in arc measure up to 180° E. or 180° W. of the prime meridian.

The azimuth or direction at one point A of a second point B on the terrestrial sphere (see fig. 6) is the angle usually measured clockwise from the north direction of the meridian passing through A and the great circle arc passing through both **A** and B. Because of the convergence of the meridians toward the poles the reverse azimuth of A from B is in general not equal to the azimuth of B from **A** plus 180°.

The sides of a spherical triangle consist of great circle arcs. It is shown in spherical trigonometry that the sum of the angles of any spherical triangle exceeds 180°, and this excess is in direct proportion to the area of the spherical triangle. Thus, it is impossible to represent any spherical triangle on a plane without distorting some of the angles and sides. The two-point equidistant and two-point azimuthal projections are simple kinds of map projection that demonstrate this clearly. In both projections two points on the sphere are chosen and shown on a map at their correct scale distances apart. In the first projection, the position of any other point is mapped so that it is shown at its correct scale distance from both points. In the second projection, it is mapped so that its azimuths from the two points of origin are correct.

2. Properties of Projections.—A representation of meridians and parallels of latitude at regular intervals is often referred to as the map projection itself; more correctly, it is called a map graticule. **A** primary classification of map projections separates them into three groups: (1) equal-area, sometimes called equivalent or authalic; (2) conformal, frequently called orthomorphic; and (3) any other types. On equal-area projections the areal scale is constant from point to point; linear scale at a point, however, will in general vary with direction, and differences of direction will be distorted. On a conformal projection, the linear scale at a point is constant in all directions and angles around a point are shown correctly; in general, however, the scale varies from point to point. It is obvious that no map projection can be both equal-area and conformal.

The properties of map projections can be precisely described mathematically with the aid of the infinitesimal calculus. A. Tissot in his *Mémoire sur* la reprksentation des *surfaces* et *les* projections *cartographiques* (1881) demonstrated that when projecting a surface onto a plane in a continuous fashion so that there is a one-to-one point correspondence, an elementary (infinitesimally small) circle becomes an ellipse. Such an ellipse has consequently been called a Tissot indicatrix. It is possible, once a map projection has been defined. to calculate the relative dimensions of the elliptical indicatrix and the orientation of its major and minor axes for any point mapped. On an equal-area projection, the area enclosed by the ellipse will be the same as that within the elementary circle, but the shape of the ellipse and its orientation will vary from point to point. On a conformal projection the ellipse degenerates into a circle, but its relative size will vary

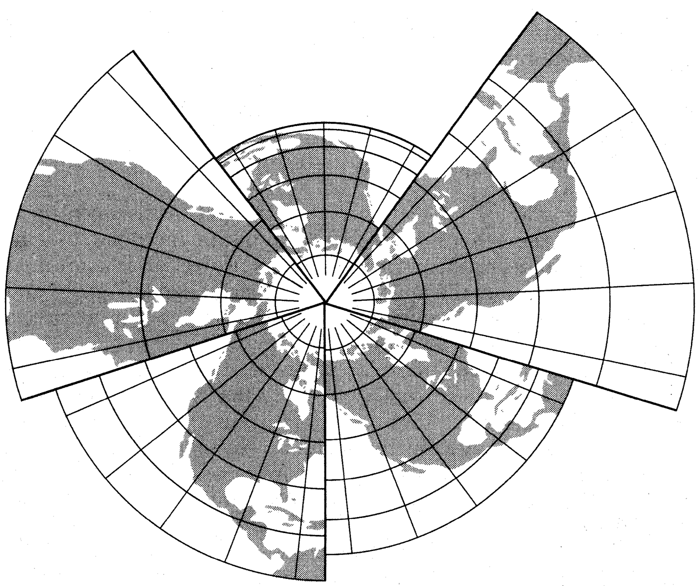


FIG. 10.—FIVE AZIMUTHAL PROJECTIONS FROM THE POLAR ASPECT. CLOCKWISE FROM TOP RIGHT THEY ARE STEREOGRAPHIC, EQUAL-AREA. EQUIDISTANT, GNOMONIC, ORTHOGRAPHIC

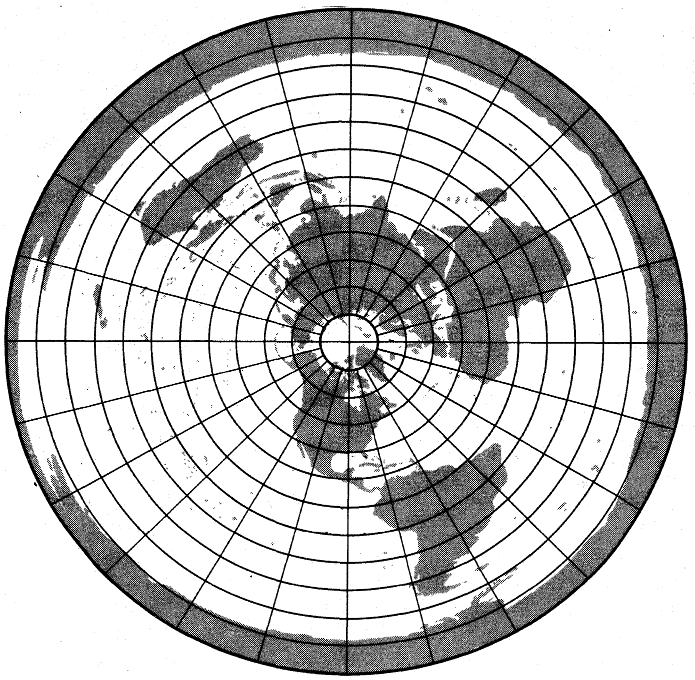


MODIFIED FROM IRVING FISHER & O. M. MILLER "WORLD MAPS AND GLOBES"

FIG. 11.—A POLAR AZIMUTHAL EQUIDISTANT PROJECTION OF THE WORLD. WITH THE SOUTH POLE REPRESENTED AS THE BOUNDARY LINE OF THE PROJECTION

from point to point. On all other projections the ellipse does not degenerate into a circle, nor is it equal-area at all points.

It is a necessary. but not a sufficient, condition for conformality that the meridians and parallels on a map projection intersect at right angles as they do on a sphere. However. conformal map projections are no exception to the general rule that shapes of areas of considerable extent will be distorted.

Any properly conceived map projection can be defined by means of a pair of mathematical formulas nhich enable the positions of the intersections betneen meridians and parallels of latitude to be calculated in terms of plane co-ordinates on the map projection. When these calculated positions have been plotted, the graticule is obtained by drawing smooth. continuous curves through all the points plotted for each meridian and for each parallel of latitude.

3. Perspective Projections.—Certain projections can be constructed by using the principles of perspective (*q.v.*). Points on a sphere of nominal scale are projected onto a plane tangent to it by perspective rays from a perspective centre.

The orthographic projection puts the perspective centre at infinity. Thus, the projecting rays are parallel to each other and perpendicular to the plane of projection. A map plotted on this projection gives the impression of the world as seen at a great distance away.

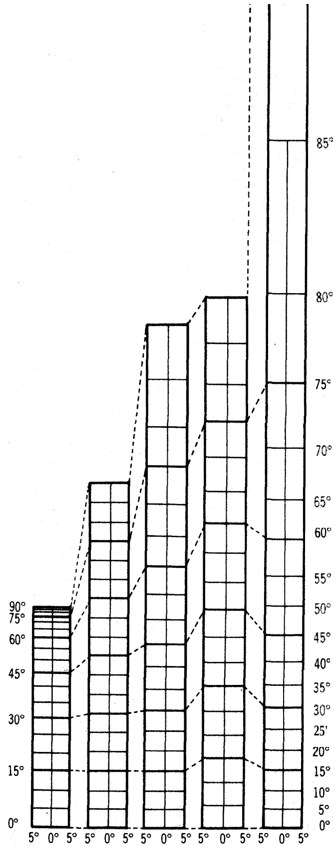
The stereographic projection places the perspective centre at the point on the sphere diametrically opposite the point of tangency of the plane of the projection. This projection is conformal and has in addition the remarkable property that all great and small circle arcs on the sphere are shown as either arcs of circles or as straight lines on the projection.

The gnomonic projection places the perspective centre at the centre of the sphere. It has the property that all great circle arcs are shown as straight lines, and this is useful for laying out the shortest route between two points. An innumerable variety of projections that will show great circles as straight lines can be derived from the gnomonic by making other perspectives of the plane of the gnomonic onto other planes inclined to it. This is because any projection of one plane onto another transforms straight lines into straight lines. Two-point azimuthal projections result from this procedure, and any particular case can be derived easily by orthogonal projection.

With the perspective centre at the centre of the sphere, a projection can be constructed onto a conical surface tangent to the sphere along any small circle. By cutting the conical surface along any straight line from the vertex, it can be developed into a plane by unrolling it. In such a projection, the scale ratio along the circle of tangency is equal to one. This circle is sometimes called the standard small circle or standard parallel when the centre of the projection is at one of the geographical poles. In fig. 9(B) AA' is the diameter of a circle of tangency and V is the vertex of the cone. The projected distance V is equal to the tangent of the angle VCA. When the cone is unwrapped as in fig. 9(C) all circles parallel to AA' will be shown as concentric arcs of circles centred on V. All great circles passing through P on the sphere will be straight lines passing through V. Their angles of intersection at V will be smaller than on the sphere. It can be shown that this angular compression, called the constant of the cone, is equal to the cosine of the angle VCA. Thus this constant, usually denoted by n, varies between the limits one and zero. When n is 1, the vertex V coincides with the point P and the gnomonic projection results. When n is zero the vertex V can be considered as being at infinity so that the cone becomes a cylinder and the resulting projection is called a perspective cylindrical projection. The great circles passing through P and the small circles concentric around P are shown in this cylindrical version as sets of parallel straight lines, one set cutting the other at right angles.

Except for the limiting case of the gnomonic projection, these perspective conical projections have no practical value. They are, however, the genesis of a much larger category of projections that fall under the general heading of conic.

4. Conic and Related Projections.—Conic projections include equal-area, conformal, so-called equidistant and other variants. All have the common characteristics that great circles radiating out from the origin, corresponding to V in fig. 9(B) in the perspective variant, are shown as straight lines and that concentric circles around the origin are shown as arcs of concentric circles. Geometrically, they vary one from another only in the manner in which the concentric circular arcs are spaced and in the value adopted for the constant n.



MODIFIED FROM "NOTES ON CYLINDRICAL WORLD MAP PROJECTIONS," "GEOGRAPHICAL REVIEW," VOL. 32 (1942)

FIG. 12.—SPACING OF PARALLELS FOR FIVE NORMAL CYLINDRICAL PROJECTIONS

From left to right: cylindrical equal-area, simple, Miller's modified Mercator, Gail's stereographic and Mercator

When n equals one the various projections are called azimuthal (azimuths of all points are correct at the centre) or zenithal (British usage). The group includes the orthographic, stereographic and gnomonic described above, the important azimuthal equal-area projection devised by Johann Heinrich Lambert and the azimuthal equidistant projection which represents all points at their correct distances to scale from the centre. When the centre of an azimuthal projection is at one of the geographical poles, it is called a polar azimuthal projection; when on the equator it is called a normal or equatorial azimuthal projection. With any other centre it is called an oblique or horizon azimuthal projection.

Mercator and Other Cylindrical Projections.—When n is zero the various projections are called cylindrical; and normal, transverse and oblique when the equator, a meridian and any other great circle is represented by the central straight line. The normal

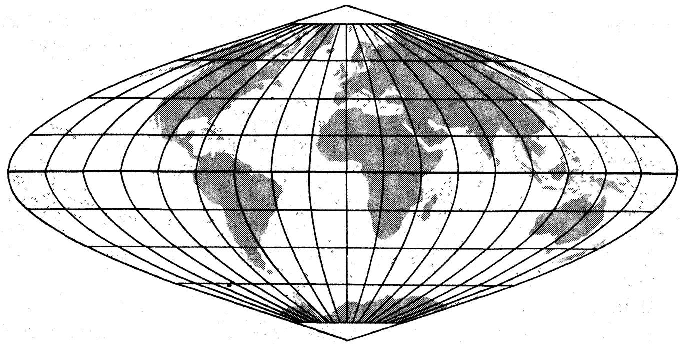


FIG. 13.—SINUSOIDAL OR SANSON-FLAMSTEED EQUAL-AREA PROJECTION OF THE EARTH

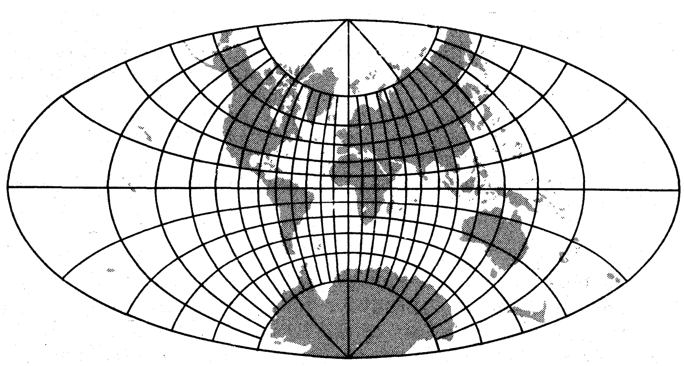
cylindrical projections in common use are the Mercator, the simple or equidistant (parallels of latitude are spaced correctly to scale), Gall's stereographic and Miller's modified Mercator. The equal-area variant is little used for world maps because the spacing of the parallels of latitude must of necessity become extremely compressed in high latitudes. Gerardus Mercator's (*q.v.*) famous projection, besides being conformal, shows all lines of constant azimuth (rhumb lines or loxodromesj as straight lines. These properties combine to make this projection more useful for navigation than the gnomonic even though the rhumb line route between two points is longer than the great circle route.

When n is greater than zero and less than one it is always possible to select two small circles less than go° from and concentric about a centre as standard. Thus, these may be chosen best to suit a given region. In the normal cases when one of the geographical poies is the centre, the important variants of the conic projections with two standard parallels are Alber's equal-area, Lambert's conformal and the "simple," which last has the property that the meridians as well as the two standard parallels have constant scale ratios equal to one.

Closely related to the conic family of projections are Bonne's equal-area projection and the polyconic projections. In Bonne's a standard parallel is developed as in the case of the perspective conic. All other parallels are concentric arcs of circles of constant scale ratio equal to one and spaced along a central straight line meridian at their correct scale distances apart. ,411 other meridians are curved lines which do not cut the parallels of latitude at right angles. One limiting case of this projection is nhen the equator is taken as the standard parallel. The resulting projection is called the sinsusoidal or Sanson-Flamsteed. In this case! the equator, the parallels of latitude and the central meridian are straight lines true to scale and the remaining meridians are sinusoidal curves.

One form of the polyconic projection is developed by constructing the parallels of latitude as if they were standard parallels on a perspective conic and then spacing them at their correct scale distances apart on a central straight-line meridian. The other meridians are curves and the projection is neither conformal nor equal-area.



MODIFIED FROM IRVING FISHER & O. M. MILLER "WORLD MAPS AND GLOBES"

FIG. 14.— ADAM'S CONFORMAL PROJECTION OF THE EARTH WITHIN AN ELLIPSE

5. Shape of World Maps.—Many other types of map projections have been conceived, but only a few can be mentioned here. Many world map projections are characterized by the shape of the area on the map which portrays the whole sphere. It is possible, for example, to obtain conformal maps of the world within the confines of a square, a rectangle, a circle and an ellipse. Two types of equal-area projection which represent the whole earth within an ellipse are the Mollweide and the Hammer (often wrongly called the Hammer-Aitoff or even the Aitoff). The Mollweide in its normal form represents the equator and parallels of latitude as parallel lines. The Hammer projection encloses the whole world within an ellipse of the same dimensions but, in this case, the parallels are curved. Both these projections have been used in their oblique forms with centres at latitude 45° N., and when the central meridian is the Greenwich meridian or one somewhat west of it, the general relationships between the land masses on the earth are shown well.

6. Discontinuities.— A spherical surface is continuous. When it is projected onto a plane, this continuity must be interrupted at least one point: more often at two points, and frequently along the whole or part of one or more small or great circles. Azimuthal equidistant and equal-area projections interrupt the sphere at only one point, which is diametrically opposite the centre of projection. This point becomes the boundary of the projection. The cylindrical projections are interrupted at two points diametrically opposite one another. These become straight lines on the map unless, as in the case of the Mercator projection, the points

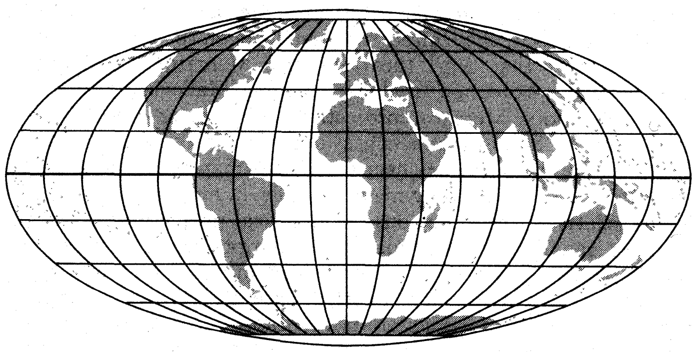


FIG. 15.— HOMOLOGRAPHIC OR MOLLWEIDE'S EQUAL-AREA PROJECTION OF THE EARTH WITHIN AN ELLIPSE

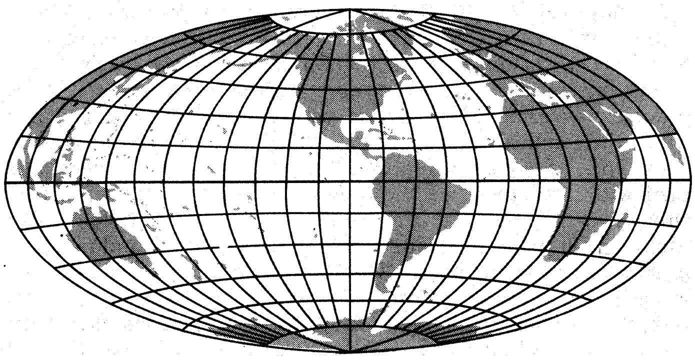
project at infinity. The cylindrical projections, however, have the useful property of being periodic or continuous in the direction of their central lines. The world shown enclosed in an ellipse is interrupted along the half of one great circle. Sometimes interruption is purposely introduced in order to reduce over-all shape distortion. This is done usually in the ocean areas in order to show the principal land areas with good shape characteristics. It is an open question whether much is to be gained by sacrificing continuity when these interruptions are asymmetrical.

When the nominal scale of a map is so large that the whole world or the region to be mapped cannot be shown on one sheet, another problem of continuity occurs. A single projection can be used so that all sheets can be assembled together. If. however, a separate projection is used for each sheet so that scale anomalies and shape distortion are limited to the single sheets, then, though it is possible to maintain fit along the edges of adjacent sheets, over-all continuity will be lost. Such a system is adopted, for example, for the sheets of the International Nap of the World on the scale of $\frac{1}{1,000,000}$. Compromises between the two systems are to be found in the use of the polyconic projection for the topographical sheets of the United States geological survey. In this system, sheets falling into one zone of longitude are on the same projection. The World Aeronautical Charts are on a system of conformal conic projections with two standard parallels. Here sheets falling into one zone of latitude are on the same projection.

7. Modern **Uses.**—Map projections in actual use to any great extent are limited in number! especially in the case of large-scale maps. On topographic and cadastral maps, the fact that the shape



MODIFIED FROM IRVING FISHER & O. M. MILLER "WORLD MAPS AND GLOBES"

FIG. 16.— HAMMER'S EQUAL-AREA PROJECTION OF THE EARTH WITHIN AN ELLIPSE

of the earth more nearly corresponds to an oblate spheriod than to a sphere is invariably taken into account. Equal-area projections such as Bonne's and nonconformal projections such as the transverse simple cylindrical (Cassini) were sometimes adopted for the maps of small countries. From the turn of the 20th century, however, the trend has been to base large-scale maps on conformal projections such as the transverse Mercator for regions having their greatest extent north and south; on the Lambert conformal conic with two standard parallels for regions having their greatest extent east and west, and the oblique stereographic for regions roughly circular. For example, until 1935 the topographical sheets of the United Kingdom were on the Cassini projection but after that time, the transverse Mercator was adopted. The Laborde projection used for mapping Madagascar is essentially an oblique Mercator projection. The latter type also has been used for strip maps along established air routes.

For world maps on one sheet equal-area map projections are in great demand because they make possible an over-all visualization of the relative sizes of regions. Cylindrical projections often are used for general reference maps over the populated areas of the world, because parallels of latitude and meridians are shown in the form of a rectangular network. Except for special purposes, conformal map projections are not suitable for world maps. On the other hand, they have certain technical advantages over other types for compiled maps on intermediate scales such as $\frac{1}{5,000,000}$. Principally, they permit compilation from sources on large-scale maps having little significant shape distortion to be accomplished quickly and accurately, since small areas on the large-scale maps, when suitably reduced in size, can be made to fit into the conformal small-scale projection with little adjustment.

A rectangular, usually square grid often is superimposed or indicated on a map in addition to the map graticule. Grids are useful for determining the relative positions of points in terms of map rectangular co-ordinates on large-scale maps of limited areas when the map projection distortion is relatively insignificant. They are also useful for locating place names on maps from an alphabetical index, in which a reference is given to the grid areas.

The mathematical aspects of projection are discussed further in ANALYTIC GEOMETRY; DESCRIPTIVE GEOMETRY; DIFFERENTIAL GEOMETRY; GEODESY; TRIGONOMETRY: *Spherical Trigonometry.*

FIG. 17.— OBLIQUE MOLLWEIDE PROJECTION WITH CENTRE AT 45° N.

E. GLOBES AND GAZETTEERS.

Terrestrial globes are maps of the earth on spherical surfaces, and because they show shapes without distortion, they are ideal objects wherewith to learn and visualize geographical relationships. However, they are difficult to construct precisely, and few have been made with a diameter of more than six feet. The schoolroom or office globe is generally not more than 18 in. in diameter and often less.

It must be appreciated that a map on a globe cannot be constructed until geographical features have been depicted on flat maps. When printed information is on a globe, this usually means that flat maps of narrow sections of the earth, usually gores, have been cut out and stuck on.

Gazetteers are the antitheses of globes. They list place and physical names alphabetically and also supply in varying degrees written information concerning the places or features referred to. The minimum information given in any gazetteer is the location of named places. Additional information may include the size and population of towns, cities, states and countries, their industries and histories, and descriptions of physical features such as rivers and mountain ranges. The more detailed gazetteers are usually national.

Maps are the practical compromise between globes and gazetteers. They are not limited in scale as are globes and they show spatial relationships which gazetteers cannot.

BIBLIOGRAPHY.—Few books in English deal comprehensively with modern techniques of map compilation, drafting and reproduction or with map design. The authoritative literature on the subject is mostly scattered in the technical publications issued by various government mapping agencies and in periodicals such as the *Geographical Journal* (Royal Geographical society, London), the *Geographical Review* (American Geographical society, New York), *Surveying and Mapping* (American Congress on Surveying and Mapping, Washington, D.C.), *Cartography* (the Australian Institute of Cartographers, Melbourne, Austr.). Most of the following books include extensive or specialized bibliographies and references: Arthur R. Hinks, *Map Projections,* (1912; 2nd ed., 1921), *Maps and Survey,* 4th ed. (1942); H. S. L. Winterbotham, *A Key to Maps* (1936); Irving Fisher and O. M. Miller, *World Maps and Globes* (1944); Charles H. Deitz and Oscar S. Adams, *Elements of Map Projections,* jth ed., Special Publication No. 68, U.S. Coast and Geodetic Survey (1945); W. Chamberlin, *The Round Earth on Flat Paper* (1947); Erwin Raisz, *General Cartography* (1938); T. W. Birch, *Maps, Topographical and Statistical* (1949); Arthur N. Strahler, *Physical Geography* (1951); Arthur H. Robinson, *The Look of Maps* (1952), *Elements of Cartography* (1953); J. A. Steers, *An Introduction to the Study of Map Projections,* 8th ed. (1950); M. Aurousseau, *The Rendering of Geographical Names* (1957); Eduard Imhof, *Gelande und Karte* (1950); François Reignier, *Les Systèmes de projection,* 2 vol. (1957). (O. M. M.)

FIG. 18.— SIMPLE CYLINDRICAL EQUAL-SPACE PROJECTION OF THE EARTH

II. HISTORY

Human existence would be impossible without knowledge of the sort that maps convey. Primitive folk carry such knowledge in their minds—mental "maps" of the areas where they live or hunt, fish or fight. As culture develops, such mental maps no longer suffice. and real maps are made to meet countless practical needs, to satisfy scientific curiosity and to give aesthetic pleasure. The history of maps and of all that the; have meant to mankind is

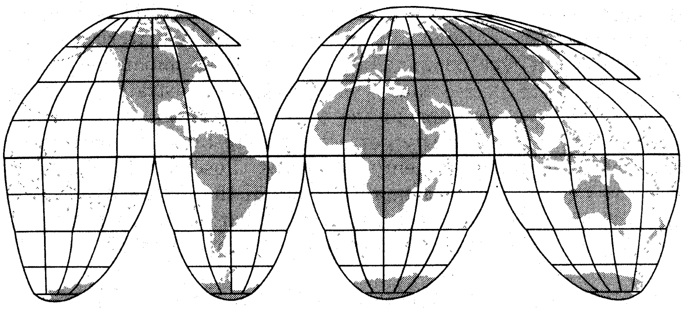

FIG. 19.— GOODE'S HOMOLOSINE EQUAL-AREA PROJECTION

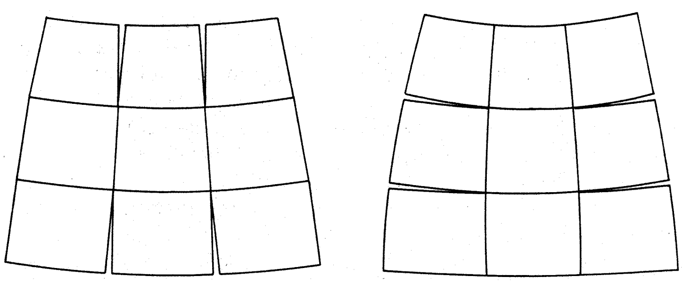
therefore an immense field, potentially as vast, perhaps, as the history of art or of literature.

Like modern science and technology, modem cartography throughout the world is essentially of western origin. It represents a phase in the development of a cartographic tradition that stems from ancient Greek times and that may have been stimulated in its beginnings by borrowings from the earlier cultures of southeastern Asia and Egypt. Four distinctive periods may be roughly blocked out (with highly arbitrary dividing dates): (1) the Greco-Roman (600 B C. to A.D. 400); (2) the medieval (400 to 1500); (3) the early modern (1500 to 1700); and (4) the modern (after 1700).

No maps, at least in their original form. have come down to us from the Greco-Roman period. Hence the nature of Greco-Roman cartography can only be inferred from what ancient authors wrote about geography and maps and from examination of a few extant medieval versions of ancient maps. There is enough evidence, however, to show that, until about the mid-2nd century of the Christian era, cartography made substantial if often halting progress and that many of its basic mathematical problems were recognized and understood, if not fully solved. Thereafter several centuries of retrogression and stagnation ensued.

Of the many late medieval and early modern maps that have been preserved, a goodly proportion have been reproduced and studied in detail from the beginning of the 19th century. Indeed, of the entire field of cartographic history, this part has been cultivated in by far the most systematic and intensive manner, and for two chief reasons: (1) medieval and early modern maps have, to our eyes, a quaintness. a naïveté and an artistic quality that make them exceedingly attractive; and (2) perhaps more significantly, early modern maps, in a way and to a degree achieved by the maps of no other age, record and illumine events of supreme historical importance — the voyages and travels of the great age of geographical discovery and the widening of man's geographical horizons that they brought about.

During the modern period maps have increasingly come to be based on accurate measuring. counting and computing, rather than mainly on speculation and guesswork. Modern cartography has stressed the scientific and the practical functions of maps at the expense, if not to the total neglect, of their aesthetic functions. The development of scientific instruments and statistical techniques and the accumulation of scientific data have enormously enlarged the variety and quantity of mappable facts and consequently of maps and their uses. So many and so diverse are these uses today that maps have become indispensable.



FROM IRVING FISHER & O M. MILLER WORLD MAPS AND GLOBES'

FIG. 20.— TWO METHODS OF ASSEMBLING SHEETS OF THE INTERNATIONAL MAP OF THE WORLD. BOTH INVOLVING DISCONTINUITY

A. Primitive Peoples

Travelers have described the remarkable ability of certain primitive folk — particularly those who, like the Eskimos or Bedouins or Polynesians, wander far and wide—to draw sketch maps of their territories, and a goodly number of crude maps that such people have carved on wood or bone or put together with sticks and shells or made in other ways may be seen in ethnographical museums. Better maps were produced by early civilized peoples — Egyptians, Babylonians, Chinese, Aztecs and Peruvians of the Inca empire. Their cartography was practical: they made cadastral plans, real-estate plots, specifications for the construction of temples, palaces, canals, roads — the equivalent of the blueprints of modern engineers. None of these peoples except the Babylonians gave much heed to speculative mapping of the world as a whole. A diagrammatic world map on a late Babylonian tablet (6th century B.c.), suggests that the Ionian Greeks may have borrowed from, or shared with, the Babylonians the long-lived belief in a flat, disk-shaped earth surrounded by an ocean stream and bordered on the north by a great range of mountains.

(J. K. W.)

B. Greece and Rome

The Greeks, more than any other people in the ancient world, were fitted to pursue and develop geographical knowledge. Shortage of arable land and adverse economic or political conditions at home induced impoverished or adventurous men to seek a livelihood overseas. Travel tales of Jason and his Argonauts and of Odysseus indicate that the Greeks were attracted to sailing from early times. During the great age of colonization (8th to 6th centuries B C) they established maritime settlements from the east coast of Spain to the far reaches of the Black sea. Miletus, the leading colonizing city, alone founded more than 40 city-states. Daughter colonies usually maintained close relations with the mother city, and these opportunities to exchange information about distant regions greatlv stimulated the Greeks to speculate about the shape of the world and the causes of physical phenomena.

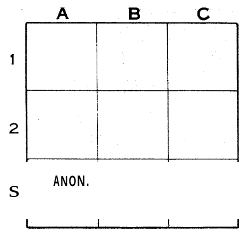


FIG. 21.—SIMPLE GRID REFERENCING SYSTEM
ANON followed by A3 in an alphabetical index indicates the approximate location of the place on the map (see text)

By 600 B.C. Miletus had become the leading centre of cosmographical speculation and geographical knowledge. Thales of Miletus (*q.v.*) was the founder of natural philosophy. His pupil Anaximander (*q.v.*), also of Miletus, was reputed to have been the first to publish a geographical map. Hecataeus of Miletus (*q.v.*) may have produced the first book on geography (c. 500 B.c.). surviving fragments of which make it possible to reconstruct the author's conception of the earth (fig. 23) as a circular plane, surrounded by a continuous belt of ocean. He located Greece at the centre. A generation after Hecataeus, the celebrated historian Herodotus (*q.v.*) traveled uidely and had more precise and extensive knowledge of geography than did his predecessors. He expressed contempt for the map makers of his day who supposed Europe and Asia to be of equal size and represented the earth as circular, surrounded by an assumed ocean. He himself presumed to know the size and actual shape of each region. Herodotus' *History* includes accounts of the Phoenician circumnavigation of Africa (c. 600 B.C.) and of the voyage of Scylax down the Indus river, concrete evidence of the broadening effect that reports of early explorations were having upon Greek geographical horizons. Herodotus found no evidence for a northern ocean but concluded from the report of the Phoenician voyage that the southern ocean extended from India to Spain. He regarded the Caspian as an inland sea, opposing the prevailing view that it was a gulf of the northern ocean (fig. 24).

Numerous other military and sailing expeditions, conducted by Greeks or reported by Greek writers, served to enlarge geographical conceptions. Early in the 6th century B.C. tno Carthaginian navigators cruised along the Atlantic coast, Hanno along west Africa to Cape Palmas and Himilco along the Spanish and Gaulish coasts to Brittany. Xenophon's account of the campaign of 10,000 Greek mercenaries (401 B.C.) against the Persian king, deep into Persia, and of their subsequent retreat across Armenia to the eastern shores of the Black sea, provided much geographical information. Far more important to geographers than these expeditions was the campaign of Alexander the Great, who in the 4th century penetrated to the shores of the Caspian sea and into northern India, sailing down the Indus, and dispatched his admiral Nearchus with a fleet along the coast of southern Asia and the Persian gulf while he was returning with his army through Gedrosia and Persia. A few decades later, Megasthenes, a Greek ambassador sent by Seleucus I to King Chandragupta, resided at his court on the Ganges river and wrote a book on India. About this time the Greek navigator Pytheas of Massilia rounded Spain and circumnavigated Britain; his precise recording of the sun's declination in northern latitudes served as the basis for Eratosthenes' research in mathematical geography.

Meanwhile a city was being built at Alexandria which was to serve as the Greek administrative capital of Egypt and to become the focal point of the highest developments of Greek science. Alexandria quickly became the new centre of geographical knowledge and research. Eratosthenes (*q.v.*), head of its famed library, a mathematician as well as scholar, succeeded in measuring the earth's circumference within an error of a few hundred miles,

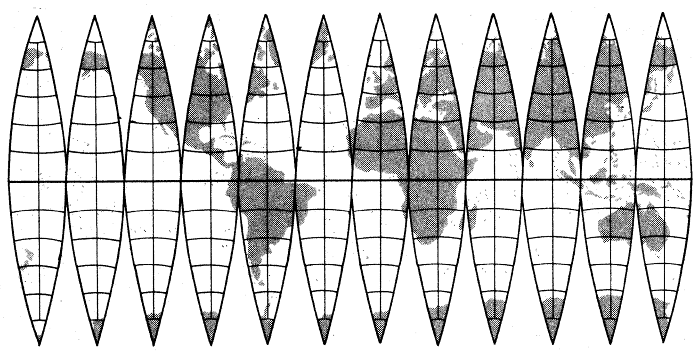

FIG. 22.— THEWORLD DIVIDED INTO 12 GORES SUITABLE FOR MOUNTING ON A GLOBE

and employing the recorded observations of Pytheas and others who had ascertained the latitudes of various places on the globe by measuring the sun's angle, he was able to produce a map based upon astronomical principles (c. 225 B.C.). Hipparchus, greatest of Greek astronomers and a leading mathematician, criticized this work (c. 130 B.c.), rebuking Eratosthenes for basing his map upon previously determined positions of latitude of a small number of places. He proposed instead a grid scheme of 360° of latitude and longitude for a map based solely upon astronomical observations, devising a method of determining longitudes by timing observations of eclipses. But precise determinations of geodetic positions depend upon precise instruments of timing and observation, and consequently Hipparchus' scheme could not be successfully applied until modern times. Nevertheless he laid the foundations for scientific cartography.

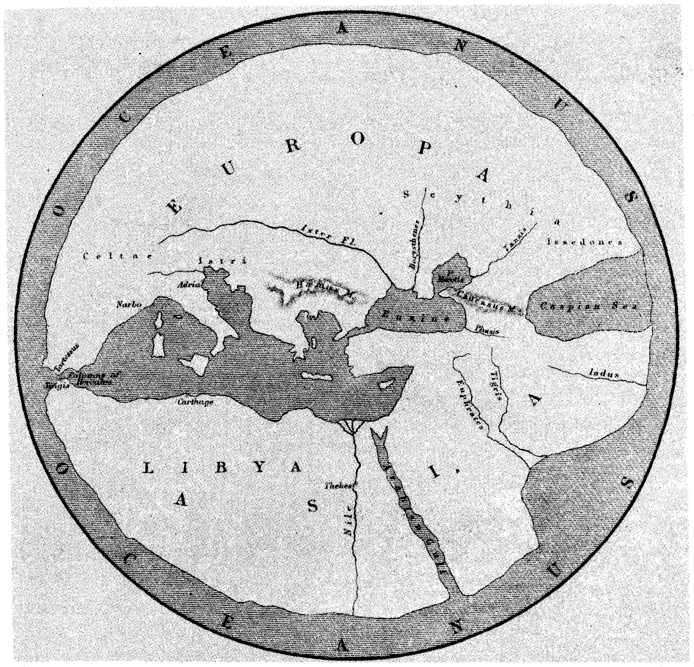
Poseidonius (*q.v.*) not himself an important original thinker, indirectly exerted-an extraordinary influence upon the science of western Europe until the Renaissance. The intellectual age to which Poseidonius belonged was lacking in creative genius. Many of the best minds were engaged in synthesizing and reconciling the more plausible views of earlier Greek philosophers and scientists. Of these compilers Poseidonius proved to be the most apt at assimilating the work of his predecessors and embodying their 'findings in readable compendiums of knowledge in many fields. The Greek compilations of this period provided the bulk of the scientific material of leading Roman intellectuals — Varro, Lucretius, Cicero, Seneca and Pliny the Elder — who in turn transmitted this body of handbook information to the Latin middle ages. And so, whereas Greek science went on to reach new heights at Alexandria in the 2nd century A.D. and to flourish at a high level at Byzantium and among the Arabs during the middle ages, scientific studies in the Latin west stagnated for 1,000 years in the hands of bookish laymen who were satisfied to copy or revise stock material largely originating in Greek compendiums of the Poseidonian age. The sort of influence Poseidonius wielded was demonstrated when he made a revised calculation of the circumference of the earth, reducing Eratosthenes' nearly correct estimate by over one-fourth; two centuries later, Ptolemy preferred Poseidonius' estimate. Ptolemy's acceptance of a smaller figure of the earth's dimensions and his enormous reputation as a geographer in the 15th century afforded Columbus encouragement to attempt a westward sailing to the Indies.

Strabo's *Geography,* in 17 books, is one of the two major works on the subject to survive from antiquity. He presents conventional handbook information on mathematical geography, sometimes without understanding it, yet has the temerity to criticize Pytheas, Eratosthenes and Poseidonius. Strabo traveled widely in Mediterranean regions and his extensive geographical treatment of the countries of the knoan world contains much valuable information. His book is the chief source on the history of earlier geography.

The Romans were not interested in the theoretical aspects of geography. While the Greeks were attempting to fix locations on the earth's surface and to ascertain the dimensions of the known world and of the entire globe, the Romans were producing crude but practical maps of battlefields and itineraries. As the empire expanded, the realization grew that maps were essential not only for military operations but for provincial administration as well. The emperor Augustus put his general Marcus Agrippa in charge of a mapping project of the entire empire, an undertaking that teams of surveyors required almost 20 years to complete. A survey of over 50,000 mi. of paved highways, recording mileages marked on milestones, served as a framework for the map, and other vital information, such as junctions of rivers and highways, provincial boundaries and facilities available to travelers in towns and cities along the highways, was compiled in the survey. At the conclusion a large master map, engraved in marble, was erected on a wall near the Roman forum. Countless copies were made on papyrus rolls and distributed among military and administrative bfficers.

A late copy of this map, known as the Peutinger Table (fig. 25), has survived, presumably belonging to the 3rd century A.D., although the present copy was reproduced in the 13th century. Because the map is in the form of a parchment roll, 21 ft. long and 1 ft. wide, designed to be folded in a portfolio, it grossly distorts the shape of the known world. Roman officials, interested only in the data recorded on the map, were not disturbed by its elongated form, which made rivers like the Nile take an east-west direction and made the Mediterranean and Black seas resemble canals. The 11 sheets of the map include the territory from the eastern tip of England and the Pyrenees to China and the supposed shores of the eastern ocean. A missing segment included the British Isles and Iberian peninsula. The segment in fig. 25 shows the southeastern tip of Britain, the northeastern part of Spain, and Gaul. The entire map contains 534 illustrations: 311 in Europe, 62 in Africa and 161 in Asia. The vignettes may have indicated the kinds of facilities available in towns; *e.g.,* 33 temples and 38 bathing establishments appear on this map. Distances between towns along the highways are fairly accurately recorded in Roman miles.

Meanwhile, scientific studies continued to flourish among the Greeks, particularly at Alexandria. Geographical and astronomical research reached its apex in antiquity in the work of Ptolemy (*q.v.*), whose *Geography* (c. A.D. 150), in eight books, culminated the researches of his predecessors. Ptolemy appeared to the ancient world to have fulfilled Hipparchus' scheme of constructing a map of the known world from geodetic positions located precisely upon a network of 360° of latitude and longitude. Book I of his *Geography* discusses the principles of mathematical cartography and the methods of representing a spherical surface on a plane. The remaining seven books are little more than a list of some 8,000 place names — cities, islands, mountains, river mouths, etc.,—whose locations were presumably determined even to min-



BY COURTESY OF THE LIBRARY OF CONGRESS

FIG. 23.—HECATAEUS' MAP OF THE WORLD

utes and seconds. Ptolemy's theory was excellent but his practice shoddy. Actually he had almost no scientific cartographic data—a few latitudes determined astronomically and a token attempt to ascertain longitudes by timing of eclipses. Instead he depended mainly on dead reckoning from reports of travelers. His book was accompanied by an atlas of sectional maps, 10 for Europe, 4 for Africa, 12 for Asia and a map of the known world. A modern reconstruction of his world map, based upon his 8,000 co-ordinates, reveals its most glaring defects (fig. 26). The Eurasian land mass covers 180° (instead of 130°), Scotland is at a right angle to England, lower Italy askew, the Sea of Azov exaggerated and too far north, the Caspian sea in a prone instead of upright position, the triangular shape of India not realized, Ceylon grossly exaggerated and the China coast. beyond the Malay peninsula, verging into Terra Australia and enclosing the Indian ocean. Despite its defects Ptolemy's work had canonical authority for 1,500 years, Maps in the "Ptolemaic style" continued to appear in atlases more than a century after Columbus and Magellan had disproved Ptolemy's conceptions, and some of his errors persisted on maps even in the 18th and 19th centuries.

Solinus early in the 3rd century wrote a geographical book largely copied from Pliny and Mela. In order to make his book entertaining. he culled the more incredible statements from Pliny's *Natural* History and inserted them in his geographical account. The result was a fascinating book of wonders that did much to popularize in later ages the tales of monstrous creatures in Africa and India. (W. H. S.)

C. Medieval Europe and Orient

Three main sources were used by the makers of medieval maps: the classics, Scripture and its interpretation by the fathers of church, and the information provided by the world of Islam. To the writers of the classical schools of geography the medieval map maker was indebted for names of places, for staristical and historical information; to the Christian sources, for authority to support the framework of the map and for references to religious matters; to the Arabs, for topographic detail, and possibly for the knowledge of the magnetic compass. A fourth source was first-hand observation, the results of which are evident in many maps.

Little survives of the maps of the late Roman empire. Besides some fragments of surveyors' sketches, part of ong unusual map escaped destruction, the mosaic map of Madeba (Ma'daba), which formed the floor of a Christian church in modern Jordan, southeast of the Dead sea. The fragments, found in the 1890s, show that it was a large map of the Holy Land, made during the first half of the 6th century. Its outstanding feature is a plan, in the form of a bird's-eye view, of Jerusalem before the Arab conquest.

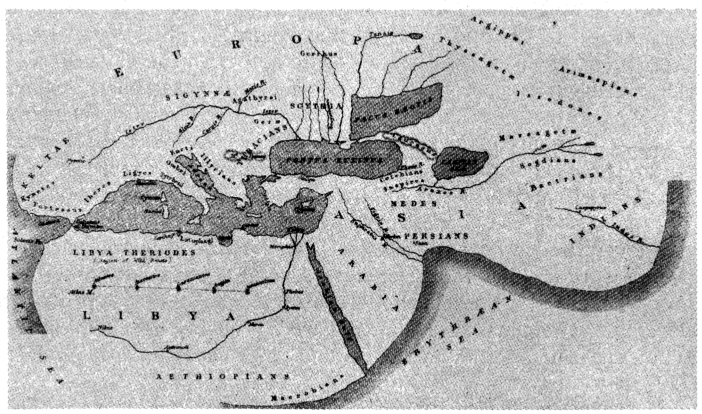
Pilgrims' guidebooks, some undoubtedly illustrated with crude maps, were popular as early as the 4th century A.D. The concern of theologians with an accurate interpretation of the world also led to the preparing of maps, the most famous and earliest of these being the world map of Cosmas (*q.v.*), a merchant of Alexandria turned Christian monk, who wrote his *Christian Topography* during the 6th century. Although only later copies of his world map survive, the book itself described the map in detail. It was a rectangular one, showing the world surrounded by the ocean sea, and surmounted by the heavens, the whole in the image of the tabernacle as described in the Bible. A later but equally primitive world map accompanied the commentaries written by Beatus, a Spanish monk, on the Revelation of St. John, during the 8th century. There are many variants of the Beatus world map, the earliest dating from the 10th century, all of them presenting a distorted, inaccurate view of the world.

1. "T" and "O" Maps.—The notion of the earth being round, though at times condemned by the church, never completely disappeared. Yet medieval maps, practically without exception, appear to show the earth as a flat disk. On this type of map, which often accompanied such church-approved encyclopaedias as that of Isidore of Seville (*q.v.*), the world is shown consisting of the three continents of Europe, Asia and Africa, with the top of the map being east, and the centre of the earth, in accordance with Scripture, at Jerusalem.

The threefold division of the world was best shown in the maps called "T and O" maps. These, popular throughout the medieval period, showed the world surrounded by a circular ocean, the "O"; the three continents of Europe, Asia and Africa were divided by a perpendicular line, the stem of the "T," representing the Mediterranean, and a horizontal line, the top bar of the "T," consisting of the Nile, separating Africa and Asia, and the Dnieper, separating Asia and Europe.

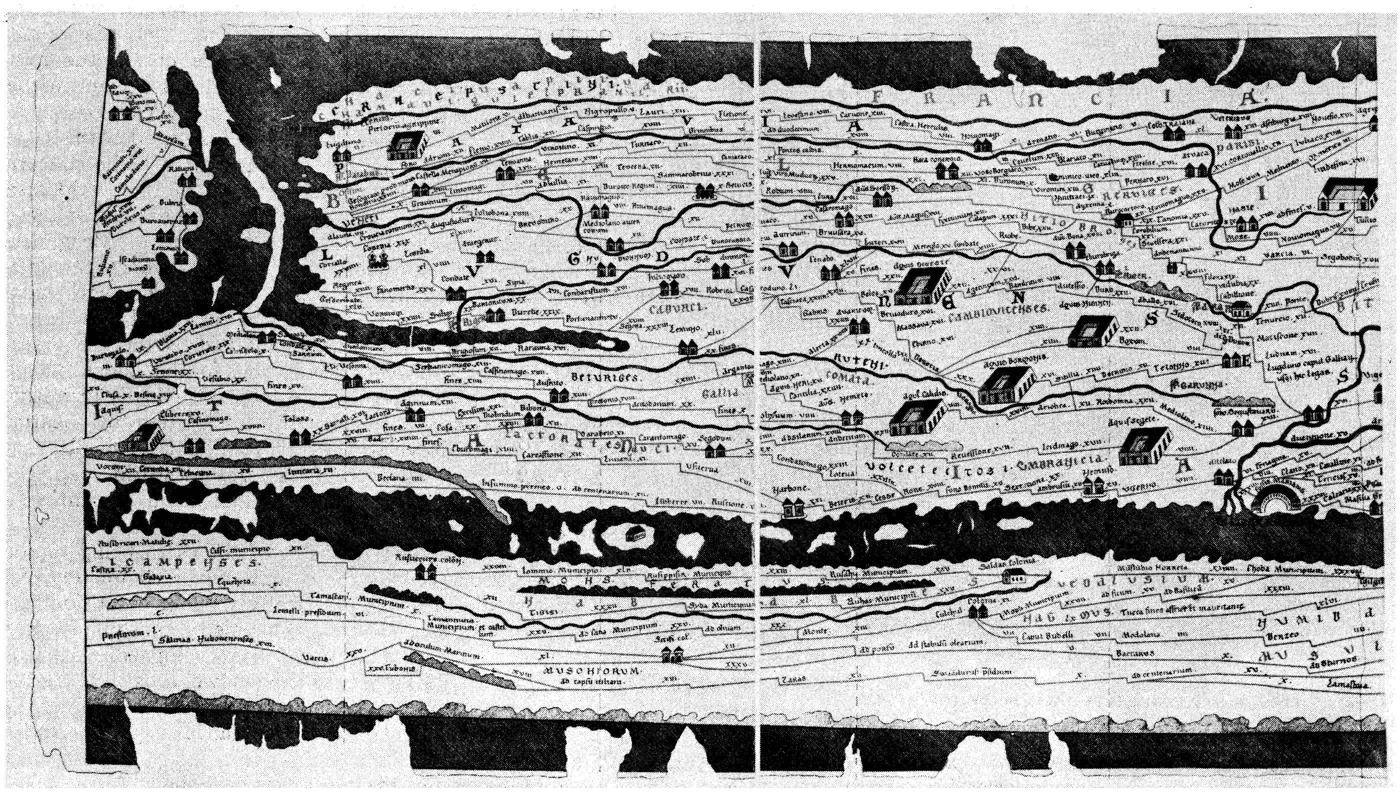
The simple frame ork of the "T and O" map eventually came to be embellished by a wealth of detail, some real, some imaginary, taken from Pliny, from Iater Roman and from early medieval writers. While some of the originals of this type barely measured an inch across and fitted into the top of the letter "P," as an illuminated initial, others were as much as 60 in. wide. The two most famous of this latter type, both made during the 13th century, are the Hereford map, in England, and the Ebstorf map, in northwest Germany. There existed also simple map sketches which, in defiance of the denial that life could exist beyond the torrid zone around the equator, showed the world divided into five climates, following closely the classical Greek scheme.

2. Portolan Charts.—The maps of Britain by Matthew Paris, an English chronicler of the 13th century, are among the very few medieval maps that show a definite attempt to present an accurate image of a single country. It was not until the latter part of



BY COURTESY OF THE LIBRARY OF CONGRESS

FIG. 24.—HERODOTUS' MAP OF THE WORLD



BY COURTESY OF THE LIBRARY OF CONGRESS

FIG. 25. — SECTION OF THE PEUTINGER TABLE

the 14th century that a successful attempt was made to include in a map of the world at least some of the recently acquired knowledge of Africa and Asia. The Catalan map of the world of 1375, prepared for the king of France, was the work of a new and much improved technique of map making. The "T and O" and other medieval maps were schoolmen's maps, made to illustrate a preconceived and highly stylized view of the world. The Catalan map, on the other hand, derived much of its contents from portolan, or seamen's charts, which were drawn in as strictly factual a manner as the tools of the time allowed. While there is some doubt as to the originals of the portolan charts, there is agreement on certain points in their history. They were made possible by the extensive use of the magnetic compass; they conformed to a common, now lost, model in their outline, in their scale and in many minor details; and they were based, in part at least, on the pilot books or *periploi* of Greco-Roman origin.

The oldest portolan chart is the so-called Pisan chart, made around 1300. Its name is derived from the portolano, the pilot book that listed courses, anchorages and ports. Some 30 or so portolan charts made during the first half of the 14th century survive. All were drawn by Italians, of whom several are known by name, John of Carignano, Petrus Vesconte and Angelino Dalorto among them. All of these charts show the Mediterranean sea, the Black sea and parts of the Atlantic. There is evidence that they were used as early as 1270, and the general outline of the map itself, and much of the detail of the coast lines, did not change between 1300 and 1600. The portolan charts are more accurate than any medieval map. When the centre of chart making shifted from north Italy to the Balearic Islands and to Catalonia, much of the detail so well presented in these maps was incorporated in the Catalan map of 1375.

One of the important characteristics of all portolan charts is the network of lines radiating from several centres distributed all over the chart. These lines conform to the 8 or 16 principal parts of the compass rose, and they were probably used by seamen to lay out courses from port to port, in the manner used on modern navigation charts.

3. Mauro and **Behaim.**—The map makers' art of the middle ages culminated in the works of two men of the 15th century. Fra Mauro, a monk and cartographer of Venice, completed his world map in 1459. It shows the world in the shape of a wheel, and contains a wealth of accurate and important detail on Asia and Africa, taken from the intelligence accumulated during the previous two centuries. Martin Behaim (*q.v.*), a German who served the court of Portugal as astronomer during the great age of Portuguese discoveries, prepared a globe, the oldest terrestrial globe extant, for his native city of Niirnberg in 1492. On it the western coast of Europe and the east coast of Asia face each other across the waters of the Atlantic, and there is no indication as yet of the new world, to be discovered within a few months by Columbus.

4. Islamic Maps.——Map making among the Moslems did not match the accomplishments of their European contemporaries. The mathematical and astronomical skill of the Moslems. and the fact that Moslems sailing the Indian ocean used maps that had much in common with the European portolan charts, was not reflected in the primitive sketches that illustrate Moslem works of geography. The only medieval Moslem map of note, known through later copies, is the famous map of Idrisi, prepared in Sicily at the court of the Norman kings during the 12th century. Idrisi's map was based, in part, on Ptolemy, following his scheme of climates, and its portrayal of the Mediterranean and of the near east was far superior to that of any European map of the time.

5. Far East.—Maps were well known in China, Japan and Korea during the middle ages, yet no original maps are known to have survived. There were prototypes, such as the Gyogu map of Japan, probably first prepared during the 9th century, and maps of China and of the world known to the Chinese were made during the first centuries of the Christian era. The maps drawn in the far east were as self-centred as were medieval maps, and the mythical element occupies fully as important a place on them, regarding Europe, western Asia and much of Africa, as it does on their European counterparts, regarding the far east. (G. Kh.)

D. Early Modern Period

1. Revival of **Ptolemy.**—By 1400 Greek manuscripts of Ptolemy's *Geography* had reached Italy, and its contents became known to western Europe in the Latin translation made by

Jacobus Angelus in 1410, first in manuscript copies and from 1475 in printed editions. The world map and 26 regional maps derived from Ptolemy's text, drawn on a conical projection and graduated in latitude and longitude, were first printed at Bologna in 1477, from copperplates. The maps were redrawn in Florence, on a new trapezoidal projection, by the German monk Donis Nicolaus, whose maps were printed in the woodcut edition of Ulm (1482). The Geography was the first world atlas; it coloured geographical thought until the end of the 16th century, and 31 Latin or Italian editions with maps were printed before 1600.

"Modern" maps (tabulae novae) were early added to the Ptolemaic atlas, both in manuscripts and printed editions. The earliest was a map of the north drawn at Rome in 1427 by the Dane Claudius Claussøn Swart, known as Claudius Clavus. Cardinal Nicholas Krebs (1401–64), of Cusa (Cues, on the Moselle), drew the first modern map of Germany, which mas engraved in 1491. By the beginning of the 16th century the hemispheric division of the world, into the "old world" of Ptolemy and the "new world" of the discoveries in the west, was becoming familiar. The enlargement and correction of Ptolemy's world map by new knowledge derived from exploration called for increasing numbers of maps. The Strasbourg edition of Ptolemy (1513) had no fewer than 20 modern maps by its editor Martin Waldseemüller; and the edition by Sebastian Münster printed at Basel in 1545 had 32.

2. Cartography of the Discoveries.—The great discoveries of the 15th and 16th centuries, both those to the east and those to the west by Columbus and John Cabot and their successors, were laid down on compass charts. or portolan charts (see above), of traditional type, developed from that of the Mediterranean area. Chart making flourished in the Italian ports, notably Genoa, Ancona and Venice; and it is on charts drawn in these centres that the Portuguese voyages along the coasts of Africa are recorded, since only one Portuguese chart made before 1500 has survived. The Casa da India at Lisbon had however from an early date been responsible for training pilots and cartographers, and Portuguese chart makers were held in high repute throughout the 16th century, although the Portuguese authorities sought to keep their work secret. The Cantino world chart, which depicts the lands discovered in the east and west, was obtained surreptitiously in Lisbon in 1502 by Alberto Cantino, agent of Duke Ercole d'Este, of Ferrara. The leading Portuguese cartographers of the 16th century were Pedro Reinel and his son Jorge, Lope Homem and his son Diogo, Diogo Ribeiro, Fernão Vaz Dourado and Luis Teixeira. In Spain the Casa de la Contratación de las Indias, established at Seville in 1508, was charged with the supervision of charts and the maintenance of a master chart (*padrón* general); among its cosmographers were Nuño Garcia de Toreno (who prepared the charts for Magellan's circumnavigation), Ribeiro (who spent his working life in Spanish service) and Alonso de Santa Cruz. Between 1540 and 1566 a number of manuscript world maps were drawn, largely from Portuguese sources, by hydrographers of Dieppe, notably Pierre Desceliers and Nicolas Desliens.

Columbus' belief that Cathay could be reached by sailing westward was no doubt inspired by the study of a globe. Like the (now lost) world chart which the Florentine Paolo Toscanelli appears to have sent Columbus in 1474, Martin Behaim's globe (see above) encouraged belief in the western route by ascribing a width of only 126° longitude to the ocean separating Europe from Asia. Juan de la Cosa, who sailed with Columbus in 1492–94, drew the earliest surviving world chart showing the discoveries

in the new world by John Cabot, Columbus and the Spanish; this is dated 1500.

3. 16th-Century Chart.—The "plane chart," drawn from compass bearings and dead reckoning, with north-south lines parallel, had two serious defects for navigation. It did not represent the convergence of the meridians, and therefore falsified east-west distances in higher latitudes; and it did not allow for differences in magnetic variation. The first of these problems was to be solved only when Mercator's projection, employed in his world chart of 1569, came into use. The second was serious for navigation in American waters, where a large westerly variation was found; among the devices adopted to overcome it was the drawing of a second, "inclined" meridian, as on the chart of the North Atlantic by Pedro Reinel (*c.* 1504), to indicate local variation. Coastal charts, with "rutters" or sailing directions, were developed by northern seamen from the early 16th century. In the first printed sea atlas, the *Spieghel der zeevaerdt* (1584), by Lucas Janszon Waghenaer of Enkhuizen, the chartwork already shows many modern characteristics, notably soundings and the profile representation of shore marks.

4. 16th-Century Cartographers.— The maps and globes of the 16th century, as an index of contemporary geographical knowledge, illustrate the gradual modification of the Ptolemaic world picture to admit new concepts derived from discovery—the outlines of Africa, India and southeast Asia as revealed by the Portuguese voyages; the unbroken extension of America from the Arctic circle to Magellan strait; the existence and longitudinal span of the Pacific ocean, disclosed by Magellan.

The principal centres of cartographic activity, outside the Iberian peninsula, were Italy, the Rhineland, the Netherlands, France, Germany and Switzerland. Martin Waldseemüller (1470?–1518?), who worked at St. Dié in the Vosges, produced tuo large woodcut world maps; that of 1507, the earliest to use the name America, was compiled from "the tradition of Ptolemy and the voyages of Amerigo Vespucci and others," while the *Carta marina* of 1516 was drawn in chart style. Waldseemuller's world view was popularized by other German cartographers, notably Johannes Schoner (1477–1547), who worked at Niirnberg and produced four globes between 1515 and 1533; Peter Apian (1495–1552) of Ingolstadt; Kaspar Vopel (1511–61) of Cologne; and Sebastian Miinster (*q.v.*), who worked at Basel. The leading cartographer in France during the century was Oronce Finé (1494–1555) and in Italy Giacomo Gastaldi (*c.* 1500–65).

The Netherlands school of cartography stems from Gemma Frisius (1508–55) of Louvain, whose enlarged edition of Peter Apian's *Cosmographia,* with its world map, was frequently reprinted from 1533. Gemma applied himself to many geographical problems, including those of the longitude and the convergence of meridians. Among his pupils was Gerardus Mercator (*q.v.; see* also *Map Projections,* above), who assisted in the preparation of Gemma's pair of engraved globes (1535 and 1537) and published his own globes in 1541 and 1551. Mercator, who worked at Louvain until 1552 and thereafter at Duisburg, became the leading cartographer of the age; his principal maps were those of Palestine (1537), the world (1538), Flanders (1540), Europe (1554 and 1572) and the British Isles (1564), besides his world chart of 1569 (*see* fig. 31), his Ptolerny edition and his *Atlas.*

By the last quarter of the 16th century the main European centre of map production had shifted from Italy to the Netherlands, and particularly to Antwerp, where Abraham Ortelius and Gerard de Jode published their atlases (*see* below). In the northern Netherlands cartography developed with overseas enterprise. Petrus Plancius (1552–1622), first cartographer to the Dutch East India company, had a copious output, including two large printed world maps (1592 and 1594). In England, Flemish cartographers and map engravers gave an impetus to the art; the first English globes, those of Emery Molyneux, were engraved by Jodocus Hondius in 1592. In 1599 Edward Wright explained the construction of Mercator's projection in mathematical terms, and a world chart on this projection, ascribed to Wright, accompanied Richard Hakluyt's *Principall Navigations* (1598).

5. Regional Cartography.— The regional maps of the middle ages had been drawn from route surveys or eye sketches, supplemented by linear measurement. During the 15th century local maps constructed from the road system were made in Italy; and a woodcut map by Erhard Etzlaub of Niirnberg, printed in 1500 with the title *Das ist der Romweg,* showed the roads of central Europe and Italy with mileages between towns.

In the first half of the 16th century geometrical methods of survey, with more precise instruments for observation of angles, were introduced by geographers of Germany and the Netherlands, and the principle of triangulation was described in 1528 by Miinster and in 1533 by Gemma Frisius. This enabled a relatively large area to be surveyed more rapidly as well as more accurately

FIG. 28.— THEHEREFORD YAP (13TH CENTURY)

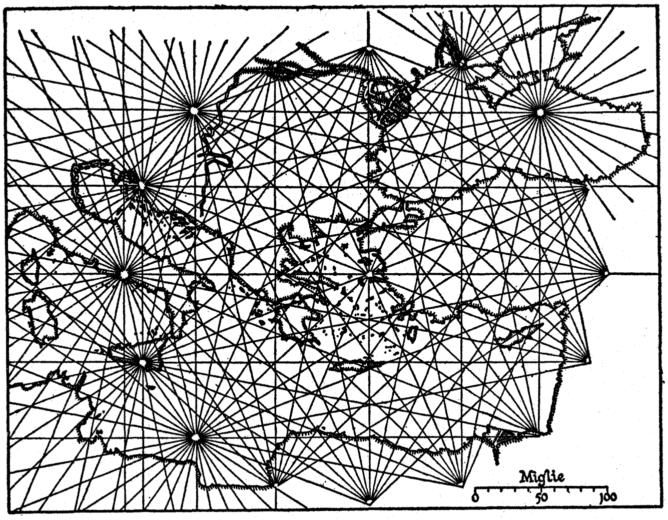

FIG. 29.— PORTOLAN CHART OF THE EASTERN MEDITERRANEAN AREA (1311) BY PETRUS VESCONTE

and many countries or regions were first mapped during the century. Among such maps may be mentioned Finé's France (152j), the maps of parts of Germany published by Miinster from 1545, Prussia (1542) by H. Zell, maps of Switzerland by Konrad Tiirst, Johann Stumpf and Aegidius Tschudi between 149j and 1538, the provinces of the Netherlands (1556–60) by Jacob van Deventer, Austria (1561) by Wolfgang von Lazius, Bavaria (1568) by Philip Apian. Scandinavia and the north were delineated by Olaus Magnus (1539); Russia and eastern Europe by Anton Wied (1542), Sigismund von Herberstein (1549) and Anthony Jenkinson (1562). The prototype for maps of Great Britain was that by "G. L. A." (George Lily) engraved at Rome in 1546 Many of these regional maps, including those of the British Isles by Humphrey Lhuyd (1j27–68), were reproduced in Ortelius' *Theatrum (see* below). The first survey of the English counties was made by Christopher Saxton (c. 1542–1606); his county maps were engraved during 1574–79 and his large map of England and Wales in 1583. The earliest atlas of the French provinces was published by Maurice Bouguereau at Tours in 1594. Here too may be mentioned the popular collection of views or plans of cities, the *Civitates orbis terrarum* (1573–1618), by G. Braun and Frans Hogenberg.

6. Printed **Maps** and Atlases.—Although the maps in the Italian editions of Ptolemy of the 15th century had been printed from engraved copperplates, the woodcut was the dominant medium for map reproduction until nearly the middle of the 16th century. From about 1540 copperplate engraving established itself, first in Italy, as the fittest technique for map printing, and this process was to maintain its ascendancy for four centuries.

The prototype of the atlas was the collection of Ptolemaic maps, increasingly supplemented by "modern" maps. In 1528 Münster appealed to German geographers to survey their regions and send him their maps, many of which were included in his edition of Ptolemy (1540) and in the successive editions of his *Cosmographia* from 1545. In Italy there was a copious production of engraved sheet maps, and such map dealers as Antonio Lafreri at Rome and G. F. Camocio and P. Forlani at Venice offered for sale sets of maps from their stock, covering the world and systematically arranged "in Ptolemy's order." The first modem atlas, however, compiled on uniform principles laid down by its editor, is the *Theatrum orbis terrarum* published at Antwerp in 1570 by Abraham Ortelius (*q.v.*). Its 70 maps on 53 plates, mainly engraved by Frans Hogenberg, were compiled from the best sources available and reduced to a common size and style; and the *Theatrum* was enlarged and kept up to date in successive editions until the last in 1612. Its rival, the *Speculum orbis terrarum* of Gerard de Jode (1509–91), published at Antwerp in 1578, was less popular.

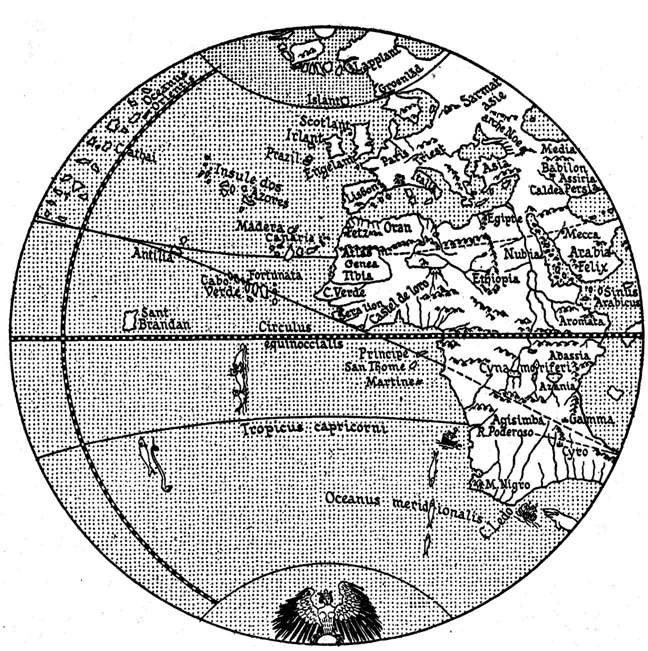
Mercator planned his ***Atlas*** (the first book of maps to which this name was given) as part of a great cosmographical project, earlier stages of which were represented by his world map (1569) and his edition of Ptolemy's maps (1578). The first two parts of the *Atlas,* engraved in his Duisburg workshop, appeared in 1585 and 1589; the third was published after his death by his son Rumold in 1595. In 1604 the plates were acquired from Rumold's heirs by the Amsterdam mapseller Jodocus Hondius.

7. 17th Century.—By 1600 Amsterdam had succeeded Antwerp as the centre of cartographic industry in the Netherlands, and the 17th century was the great age of Dutch map production. From the Amsterdam workshops of Jodocus Hondius (1563–1611), Willem Jansz Blaeu (1571–1638) and Jan Jansson (1596–1664), Frederik de Wit (*fl.* 1648–89) and other mapsellers, the European market was supplied with printed charts and sea atlases, globes. wall maps, town plans and views and (above all) atlas maps. Mercator's atlas was continually enlarged by Hondius and, after him, Jansson; Blaeu's first atlas, in two volumes, was published in 1635, and, like Jansson's, it had by 1660 expanded to 11 or 12 volumes. Blaeu became hydrographer to the East India company and the states-general, and his *Zee-spiegel* (1623) was the prototype of a long series of fine sea atlases by various map makers, notably Pieter Goos, J. A. Colom, A. Jacobsz and Hendrik Doncker. The earliest sea atlas drawn throughout on the Mercator projection was *L'Arcano del Mare*, compiled by Sir Robert Dudley and published at Florence in 1646. *Le Neptune françois ou atlas nouveau des cartes marines*, published at Paris in 1693, marked a further advance in hydrography; drawn on the Mercator projection, its charts laid down the positions of many places from "fixes" made by the French astronomers.

The most prolific and influential French cartographer of this period was Nicolas Sanson of Abbeville (1600–67), who established his Paris workshop about 1634 and published his first atlas in 1654. After his death his business was carried on, in turn, by his sons and by A. H. Jaillot (1640–1712); and his son-in-law Pierre Duval (1619–83) was also a productive cartographer. Their work foreshadowed the authority enjoyed by French cartography in the first half of the 18th century.

At the end of the century Johann Baptist Homann (1664–1724) of Niirnberg established a vigorous map business which continued into the next century. V. M. Coronelli (1650–1718), cartographer to the republic of Venice, produced many fine globes and maps, based on careful research.

In England, apart from the popular county atlas of John Speed, *The Theatre of the Empire of Great Britain* (1611–12), in which



BY COURTESY OF THE LIBRARY OF CONGRESS

FIG. 80.— THE WESTERN HEMISPHERE ACCORDING TO MARTIN BEHAIM'S GLOBE (1492)

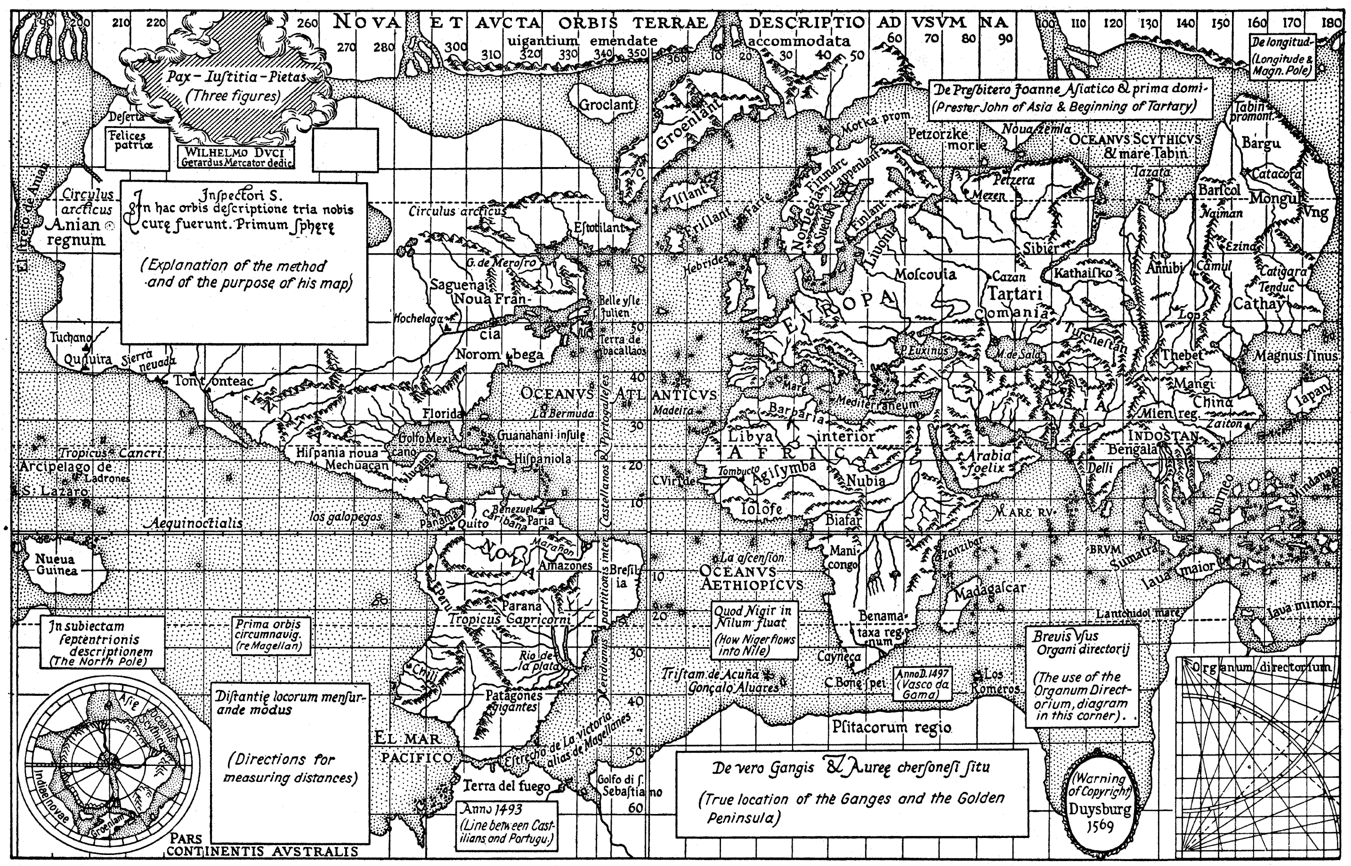


FIG. 31.—MERCATOR'S CHART OF THE WORLD (1569)

the maps were engraved by Hondius, map production languished until after 1660. The Restoration period saw a revival of activity; John Ogilby made the earliest survey of the English roads, published in his *Britannia* (1675), and the printing of charts began with the work of John Seller, John Thornton, Greenville Collins and others. In 1681–88 Collins first surveyed the coasts of Great Britain. Not until the 18th century, however, was English map production to overtake that of the Netherlands and France.

Reformation of Cartography.—During the 17th century few major new data were added to the world map by discovery, although these included the coast of Australia revealed by Dutch voyages, parts of the interior of North America explored by the French, and fuller knowledge of China contributed by Jesuit missionaries. Yet in this period the foundations of the modern map were laid by improvements in the technique of instrumental observation and survey, particularly the introduction of telescopic sights and the development of instruments for leveling and for the precise measurement of horizontal and vertical angles. In 1671 the Paris observatory was established, and from this time the latitude and longitude of an ever-increasing number of points were fixed by instrumental observations under the auspices of the French Académie Royale des Sciences.

The framework of an accurate world map depends on determinations of the size and shape of the earth, derived from measurement of the length of a degree along a meridian. Arcs of a meridian had been measured in 1606 by Willibrord Snell, in Holland, and in 1635 by Richard Norwood, in England. The measurement was attempted by more scientific methods in France in 1669–70 by Jean Picard, whose measured arcs were extended between 1700 and 1718 by J. D. Cassini (1625–1712) and his son Jacques, the first two directors of the Paris observatory. The geodetic data thus obtained served as the basis for the redrawing of the world map by French cartographers of the early 18th century.

Special Maps.—During the 17th century some of the earliest experiments were made in the drawing of maps to represent the data of special sciences in their geographical relationship. Edmund Halley's chart of the trade winds (1686) is the first meteorological map; and maps of the ocean currents were published by Athanasius Kircher in 1665 and by E. W. Happel in 1675. Attempts to illustrate magnetic variation on maps had been made by C. Burrus in 1630 and by Kircher in 1643; but the first variation charts based on observation were those of Halley (the Atlantic, 1701; the world, 1702). In these Halley introduced the isopleth, or curve-line of equal value, which was long known as the "Halleyan line." (R. A. Sn.)

E. Modern Period

In 1700 nearly half of the earth's surface was still unexplored or little known. After World War II the initial reconnaissance mapping of the earth was brought to its close in the antarctic wastes. For millenniums this task, with the related riddle of what lay beyond the margins of the "known world," had confronted the cartographer with his most challenging problem. From the beginning of the 18th century a more difficult problem has replaced it—that of mapping the known world to meet the demands of a civilization that has come to use maps for purposes never before dreamed of.

1. Transportation, Travel and Maps.—Transportation and travel always have been powerful stimulants to mapping. In the modern period, mapping the world's coast lines has been pushed forward along traditional lines, and many maps of wholly new kinds have been made to help ships move from place to place—maps of the sea floor, ocean currents, winds, storm tracks, air and water temperatures and the like—the making of which has yielded great quantities of scientific data as by-products. In the sparsely settled parts of Australia, Siberia, Latin America, western North America, and elsewhere, the first detailed reconnaissance mapping was often carried out as part of the search for routes for railways, and the precise leveling done in connection with the construction of railnays, canals and highways supplied many of the data upon which the earliest hypsometric mapping was based. Successive improvements in travel by road gave rise to the post-route and stage-route maps of earlier times and to the modern motorists' maps. The airplane. like the ship, has occasioned world-wide programs of surveying and observation to procure air navigation charts and meteorological maps for air traffic guidance and protection; it also has facilitated the task of mapping for countless other purposes. The airplane brought these revolutionary changes in cartography within three decades.

2. War and Maps.—War is another stimulant of human mobility and hence of cartography. The campaigns of Alexander the Great and Genghis Khan opened vast and little-known tracts for subsequent mapping, but in modern times the influence upon mapping of preparations for war has been greater than that of military campaigns as such. The small, lightly equipped armies of pregunpowder ages had little need for maps; local guides showed the way, and arrows and spears could find their targets without the aid of cartography. The advent first of artillery and later of the nation-in-arms changed the situation. The topographic mapping of modern Europe, which began in the 16th century and has been pursued comprehensively from the mid-18th century, was undertaken largely to facilitate the aiming of field guns, the finding of cover and the moving of large bodies of men and matériel. Napoleon was alert to the military value of topographic maps and did much for cartography.

World War II, coming as it did after aviation and photogrammetry had been well developed, far exceeded all previous wars in the extent of its effects upon map making. During its course immense areas, even in regions remote from the theatres of war, were flown over, photographed and mapped on the chance that the maps might be needed; and totally unprecedented in magnitude was the work of making new and reproducing old maps to show not only routes and targets of concern to the planners of military operations but also a variety of special matters of possible value to those directing the political, economic and psychological phases of the war.

During World War II two agencies of the United States armed forces are said to have printed about 650,000,000 copies of some 50,000 different maps.

3. Governmental Mapping.—As long as maps were used for relatively few socially indispensable purposes, cartography was left mostly in private hands. As the essential uses of maps have multiplied, however, certain basic cartographical enterprises, such as police, postal, water supply and other indispensable services, have been taken over by governments. At first these enterprises consisted mostly in the production of topographic maps and marine charts, but they have been extended to the mapping of minerals, soils, geological formations, climate, vegetation, land use and much else. Before the 19th century in most countries and until well into it in some, topographical mapping was based upon occasional surveys, and the maps were usually known by the names of the surveyors or engineers in charge (*e.g.*, the Cassini map of France, 1750–93; the Rizzi Zannoni map of Poland, 1772; the Dufour map of Switzerland, 1842–72). Eventually, however, the work was taken over on a continuing basis by great technical organizations such as the Ordnance survey of Great Britain (founded 1791), the Service Géographique de l'Armée in France (replaced in 1940 by the Institut Géographique National) and the Federal Topographic bureau of the Swiss general staff. Most of these. at least in Europe. have been set up by the armed forces or their responsible ministries. In the United States and Canada, by contrast, the principal governmental mapping agencies (*e.g.*, the U.S. coast and geodetic survey, founded as the U.S. coast survey in 1807; and the U.S. geological survey, founded in 1879) have been under civilian administration, a result in part, no doubt, of the freedom from fear of invasion that the geographical isolation of North America fostered until as late as World War II. During and after World War II the armed forces in the United States and Canada greatly enlarged the scope of their cartographical work.

4. Influence of Science and Technology.—The development of cartography during the modern period also has been affected profoundly by the general advancement of science and technology, and in particular by adaptations that have been made, one after another, of certain instruments and techniques to the uses of surveyors and cartographers. Foremost among these, in so far as the basic mapping of the visible features of the earth's surface is concerned, were the telescope in the 18th century and the camera in the 20th.

During the zoo years following its invention (about 1608), the telescope (*q.v.*) was increasingly put to use in the making of astronomical observations to determine geographical positions. It was also introduced into surveying and navigational instruments as an integral part of their structure, thus greatly enhancing their precision. By the mid-18th century, the telescope had had two important effects upon cartography: it had made possible the accurate construction of modern map projections (as, *e.g.*, in the work of J. H. Lambert) and it had helped furnish a quantity of astronomically and trigonometrically determined control points for topographic maps, marine charts and reference maps in general. Thus, largely by means of the telescope were obtained many of the new data upon which Guillaume Delisle, J. B. d'Anville and others based the extensive revision of earlier maps that has been called the cartographic reformation of the 18th century. Since this movement was mainly directed toward the correction of errors, it was, indeed, a reformation rather than a revolution. It led, however, to genuinely revolutionary changes toward the close of the century. Max Eckert, the German cartographer, writing in 1921, maintained that since the Renaissance no greater change had taken place in the general appearance, accuracy and construction of maps than that which differentiated the maps of the 19th century from their predecessors.

The years after Eckert expressed this view, however, saw a second and even more radical cartographical revolution, in which the camera played a part comparable to that of the telescope in the earlier reformation. Carried aloft in airplanes, the aerial camera advanced the mapping of the visible face of the earth at a speed and with a fullness of detail never before remotely approached and disclosed for mapping much that had remained invisible to earthbound observers (*e.g.*, facts of archaeological or botanical interest). Also, in the rooms where maps are actually produced, special cameras have effected hardly less spectacular improvements in the processes of compilation, drafting and reproduction. The application of photography to mapping gave birth to that new handmaiden of cartography and surveying, photogrammetry, with a whole repertory of techniques and a battery of instruments of its own.

During and after World War II, moreover, the cartographic revolution entered a second stage in which, for many operations, the use of electronic devices came to supplement or supersede the older optical and photographic techniques. (See also PHOTOGRAMMETRY.)

Another development of the modern period is maps that show,

FIG. 33.— PARTOF ERZ MOUNTAINS SOUTHEAST OF DRESDEN AS SHOWN ON JOHANN CHRISTOPH MULLER'S MAP OF BOHEMIA (1714–20). AN EARLY TOPOGRAPHICAL MAP ON WHICH RELIEF IS STILL REPRESENTED AS ON MEDIEVAL MAPS

by means of isolines or other symbols standing for specified quantities. the distribution of variables such as elevations, depths, temperatures, population densities, differences in wealth, etc. Such quantitative maps, now in universal use, were almost totally unknown before 1700. Edmund Halley's isogonic (compass-declination) map of certain oceans (1702), though not the very first of its kind, is the first known upon which isolines were used with fair success to show quantitative differences over large areas, and it inspired Alexander Humboldt many years later to propose that temperatures might be similarly shown by means of isotherms (1817). About 1730 Samuel Cruquius made the first recorded use of contour lines, when he employed them (not altogether correctly) to represent the depths of certain estuaries and rivers of the Netherlands coast, but contours were seldom used in the representation of land relief until the mid-19th century. While the barometer, thermometer and hygrometer were all greatly improved during the 18th century, they, too, were but little applied in hypsometric or meteorological mapping until the mid-19th century, for not until then had comparable data sufficiently numerous for cartographic purposes been assembled with their aid. Later a profusion of mechanical, optical, photographic, acoustical and electronic instruments for measuring conditions and forces in the depths of ocean, atmosphere and solid earth brought about an immense efflorescence of quantitative maps as tools of research and exposition in the various earth sciences (notably geophysics, geology and their allied fields of geomagnetism, meteorology, physical oceanography, geomorphology).

In many branches of the study of man and his affairs, historians, anthropologists, economists, sociologists, demographers and others also have come to depend, though to a lesser degree, upon quantitative maps based upon censuses and similar statistical inventories that likewise were unknown before 1700 and little used before the second half of the 19th century. Although such censuses are mentioned in the Bible. nobody seems to have thought of mapping the results until the early 19th century, when modern national census bureaus and the like had begun to gather large quantities of data for extensive areas. Notable pioneers in the advancement of statistical mapping were a British engineer, Henry Drury Harness (1804–83), whose population and traffic maps of Ireland appeared in 1837, and a German geographer, August Heinrich Petermann (1822–78), founder of the well-known geographical and cartographic journal Dr. *A. Petermanns Mitteilungen* (1855).

5. Outstanding Characteristics of Modern Cartography.—As a result of these various influences, cartography during the modern period differs essentially from the cartography of all earlier periods by reason of the great gains that have been made in the diversity, accuracy and quantity of maps produced.

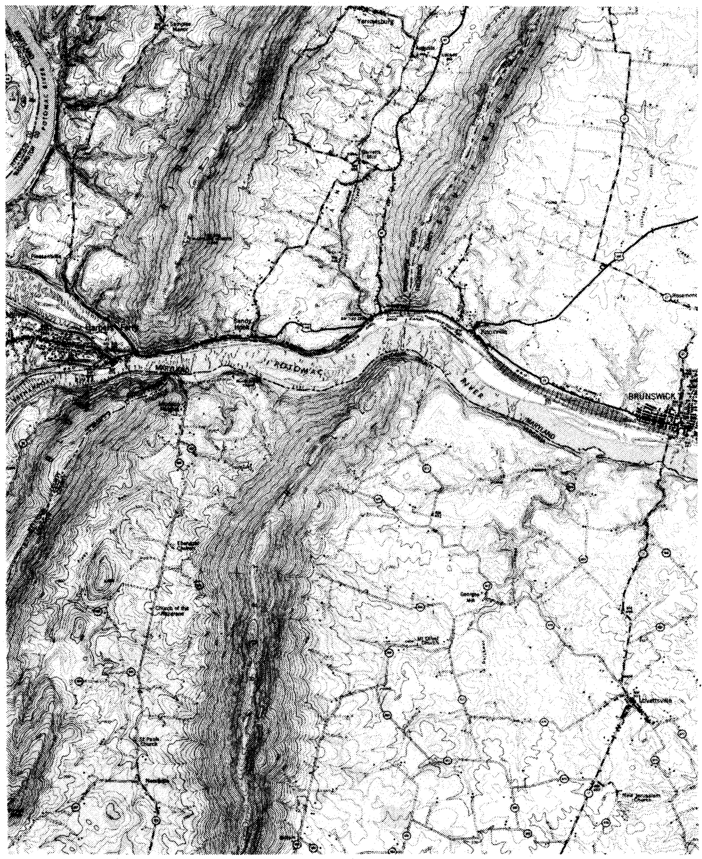
Before 1700 the facts presented on maps were restricted mostly to the salient, visible features of the earth's surface—bodies of water, mountains, towns, roads, forests—and to such portrayals of human beings, animals, monsters and curiosities as the draftsman saw fit to add in the blank spaces. Since most modern maps have been designed to serve utilitarian, educational or scientific purposes, few carry the pictorial embellishment that added charm to the maps of earlier times. In this respect the 18th century mas transitional: although 18th-century maps were somewhat more austere and accurate than those of the 17th century, a good deal of pictorial decoration was retained. By the 19th century it was almost wholly gone and today is found only on maps made in imitation of medieval and Renaissance models; indeed, all too many modern maps are in fact ugly. Nevertheless, it always has been understood that cartography can be not only accurate but also pleasing to the eye, and exquisite maps have been produced during the modern period, more, perhaps, in continental Europe than elsewhere. The artistry that the early cartographers lavished on embellishment has been largely replaced by ingenuity in the finding of new types of phenomena to map and new symbols with which to map them.

Every map obviously presents a definite, if not readily measurable. amount of information. If it were possible to measure the total amount of information concerning any area presented by all maps that cover it, and then divide this figure by the area's extent in square miles or similar units, a figure would result that might be called the "map-area ratio" of the area. Could maps be made showing the values of this ratio, they would disclose at a glance how relatively well mapped (or, at least, thoroughly mapped) different areas are or have been (as is now suggested by coverage maps, but only with respect to maps of specific types; *e.g.*, large-scale topographic maps, coast charts). World maps of map-area ratios for different dates during the modern period would show patterns conforming broadly with densities of population, but with the highest ratios and the greatest gains in areas where economic and educational levels have stood highest and risen most. Throughout the period by far the most numerous and extensive tracts of very well-mapped territory have doubtless lain in western Europe (including Germany). where topographic mapping to large scales has been supplemented by the intensive special mapping of a multitude of natural and cultural circumstances, past and present. Where such cartographical treasures have been accumulated, they have frequently, though not invariably, inspired the publication of national or regional atlases (see ATLAS).

Correlation between population and map-area ratios of course is not perfect; certain uninhabited or sparsely settled areas—such as frontier zones of strategic importance (*e.g.*, northeastern France). strips of wilderness along international boundary lines (*e.g.*, Alaska-Canada). submarginal farming areas under paternalistic governments. undeveloped areas that attract tourists or present problems of special scientific interest, and, especially, areas believed or known to contain valuable natural resources—have been well mapped. Conversely, certain areas have been less well mapped than the comparative prosperity and enlightenment of their inhabitants might suggest; this has been true of large parts of the United States, and perhaps also of the country as a whole.

The number of maps that the people of a village or city or nation own or make or use per capita could be called a map-population ratio. Such ratios, like map-area ratios. though not readily determined as actual figures. are useful as concepts. in that they suggest realms of investigation that have been neglected by historians of cartography, most of whose work has dealt with individual maps and cartographers rather than with the larger historical bearing of the subject.

Map-population ratios nould signify varying degrees of "map-mindedness," "map-dependence." and the like, and would also be found to correspond roughly mith differing economic and educational levels. In their map-population ratios, France, Germany, the Netherlands and Great Britain must have led the world by a wide margin in 1700, and, along with the United States, Canada



BY COURTESY OF THE LIBRARY OF CONGRESS

FIG. 34.— TOPOGRAPHIC MAP OF HARPERS FERRY, W.VA., ALSO SHOWING PART OF VIRGINIA AND MARYLAND (1953)

and the other more fully industrialized countries, are doubtless still in the lead. Here again, the ratios have probably stood higher in western European countries and lower in the United States than the respective relative levels of prosperity and education might lead one to expect. While it cannot be stated categorically that western European peoples make and use more maps per capita than Americans or Russians do, western European pre-eminence throughout the modern period in the production and use of maps for educational, scientific and scholarly purposes can hardly be questioned. This superiority is due, in part at least, to the high standards that have been set and consistently maintained by the great governmental cartographic establishments and certain of the geographical societies and geographical departments in the universities of western Europe, and also by such renowned old map-publishing houses as Justus Perthes in Gotha (name changed to Veb Hermann Haack Geographisch-Kartographische Anstalt in 1954), Bartholomew in Edinburgh and Hachette in Paris. Throughout the 19th century and until the eve of World War II Germany produced the best general reference atlases, but after that the lead passed to the U.S.S.R. American standards in atlas and school-map production rose after the 1920s.

Other articles related to maps and mapping are referred to in the article GEOGRAPHY (ARTICLES ON). See ATLAS; CHART: GEODESY; NAVIGATION; PHOTOGRAMMETRY; SURVEYING: etc. *See* also Index references under "Map" in the Index volume.

BIBLIOGRAPHY.—G. R. Crone, *Maps and Their Makers* (1953) and the first four chapters of Erwin Raisz, *General Cartography* (1938), give concise, well-balanced general accounts of the history of cartography. Raisz's chronological charts are useful for quick reference, and his iourth chapter deals mith American cartography. More elaborate are Leo Bagrow, *Die Geschichte der Kartographie* (1951), which deals with the development oi mapping, especially as an art and craft, until the mid-18th century; R. V. Tooley, *Map and Map-makers* (1949), essentially an annotated catalogue of maps dating mostly irom the period 1475–1877; R. A. Skelton, *Decorative Printed Maps of the 15th to 18th Centuries* (1952) and *Explorers' Maps* (1958). Max Eckert's monumental *Die Kartenwissenschaft* . . ., a vol. (1921, 1925), is a store-

house of detailed information concerning the history of cartography arranged according to categories of maps.

All these works include bibliographical references. *Inzago Mundi: A Periodical Review of Early Cartography* (1935–) contains articles and book reviews. For further bibliographical guidance *see* W. W. Ristow and Clara E. LeGear, *A Guide to Historical Cartography* (1954), the general cartographical periodical *Surveying and Mapping* (1941–), and current bibliography, *Bibliographie cartographique internationale* (1949–), as well as geographical periodicals and bibliographies, a fundamental source of data: since the history of cartography is inextricably interwoven with that of geography (*see* J. K. Wright and E. T. Platt, *Aids to Geographical Research*, 2nd rev. ed. (1947).

The history of cartography was in general neglected until the mid-19th century, when the first great collections of reproductions of early maps mere published (M. F. de Santarem, *Atlas composé de mappenzondes, de portulans . . . depuis le VIe jusqu'au XVII siècle*, 1842–53; E. F. Jomard, *Les monuments de la geographie . . .*, 1842–62). These paved the way for a succession of similar works, of which four may be cited as representative examples, covering broad subjects with great erudition: A. E. Nordenskiöld, *Facsimile Atlas to the Early History of Cartography* (1889), *Periplus: An Essay on the Early History of Charts and Sailing Directions* (1897); Konrad Miller, *Mappaemundi: Die altesten Weltkarten*, 6 vol. (1895–98), *Mappae arabicae*, 6 vol. (1926–31). Growing interest in the history of the geographical discovery, exploration and early surveying and mapping of particular parts of the world, especially the Americas but also notably Africa, central and northern Asia and the Pacific, inspired the publication of similar collections, together with commentaries and pertinent monographs and periodical articles (partially listed by Bagrow, *op. cit.*, pp. 378–383).

The 19th and 20th centuries have been given comparatively little attention in the study of the history of cartography. The characteristic plainness or austerity of most modern maps, together with their superabundance and the many complexities that are involved in studying them, have made them less appealing to scholars and collectors than the maps of earlier times have been. Three publications bearing on cartography in the modern period may be cited as representative: G. M. Wheeler, *Facts Concerning the Origin, Organization, Administration, Functions, History, and Progress, of the Principal Governnzent Land and Marine Surveys of the World* (1885); Walter Thiele, *Official Map Publications* (1938); W. W. Ristow, *Aviation Cartoguaphy: A Historico-Bibliographic Study of Aeronautical Charts* (1956).

(J. K. W.)

MAPLE, the name of approximately 150 species of trees and shrubs belonging to the genus *Acer* of the family Aceraceae (*q.v.*). Two unrelated species, *Flindersia brayleyana* and *Cryptocarya oblata,* are productive of timber known as Queensland maple and Macquarie maple, respectively.

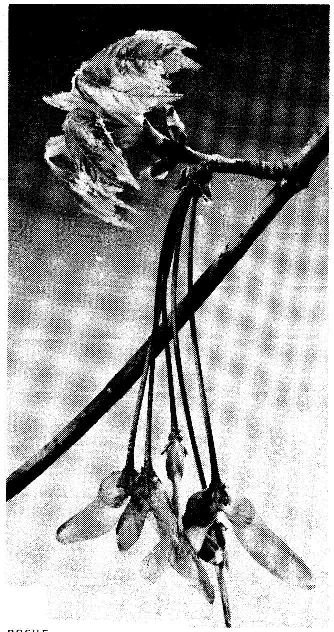
Maples feature opposite, deciduous (rarely persistent), mostly palmately lobed leaves. Their small (but en masse often showy) red, orange or greenish flowers appear before, with, or after leaf emergence. The two-winged samaralike fruits, sometimes referred to as keys, are also diagnostic. Several species are noted for their excellent timber; others are better known because of their ornamental use.

The North American flora includes 13 maples. Big-leaf maple (A. *macrophyllum*), the only commercial western species, is the second most important hardwood in the Pacific northwest. Ranging from Alaska to southern California, it often attains a height of 100 it. The wood is used for furniture and flooring; large burls occasionally found on old trees are sliced into fancy face veneers for decorative panels. A small, often prostrate or vinelike, understory tree, vine maple (A. *circinatum*) is the only other maple indigenous to the areas bordering the Pacific.

Box elder (*A. negundo*), a small transcontinental tree that occurs sparingly in nearly every state, features three- to seven-pinnately compound leaves, a characteristic rare among maples. Big-tooth maple (*A. grandidentatum*) and Rocky Mountain maple (A. *glabrum*) are small, little known trees of the Rocky mountain region.

Eight eastern species are divided into the hard, soft and mountain maple groups. Hard maples include the sugar (A. *saccharum*), black (A. *nigrum*), Florida *(A, barbartum)* and chalk *(A. leucoderme)* maples. The latter two species are small southern trees of little commercial value. Sugar maple, an important timber and shade tree, and with black maple the principal source of maple sirup (*q.v.*), extends from Newfoundland to North Dakota and south to Georgia and Texas. Often 90 ft. tall, its hard, pinkish-white wood is fabricated into furniture, flooring, musical instruments, sporting goods and a host of other commodities. Timber with wavy or curly grain or bird's-eye figure is prized for cabinetry. Black maple, restricted to the northeast and lake states, produces timber of comparable quality.

The soft maples, red (A. *rubrum*) and silver (A. *saccharinum*), respectively, are medium-sized trees of wide distribution east of the Great Plains. The former, the leaves of which are silvery white below, grows very rapidly and is used as a street and shade tree. Nowhere is there a tree more resplendent in its flamboyant crimson autumn foliage than the red maple. While the wood of neither species is the mechanical equal of the hard maples, both are similarly used.



ROCHE

LEAVES AND SEEDS OF THE RED MAPLE (ACER RUBRUM)

Striped maple (A. *pensylvanicum*), featuring smooth greenish bark striped with white, and the shrubby mountain maple (A. *spicatum*), are two understory species of northern forests. Hedge maple (A. *campestre*), of northern Europe and western Asia, is the only maple indigenous to Great Britain. Seldom exceeding a height of 20 ft., it is easily identified by its small leaves with rounded lobes.

The handsome sycamore maple (A. *pseudoplatanus*), an important timber tree of central Europe and western Asia, is a commonly used ornamental in the United States and Great Britain, as is also the Norway maple (A. *platanoides*), a lofty European and Asiatic timber tree. A variety, the Schwedler maple (var. *schwedleri*) with greenish-red to reddish-bronze leaves, is a widely planted ornamental.

Among the Asiatic species especially well suited for decorative and ornamental use, both in Europe and North America, are the small chinese maple *(A. truncatum)*, featuring deeply lobed, purplish-green leaves with truncate bases; dwarf maple *(A. ginnala)*, a compact shrub with three-lobed leaves; Japanese maple *(A. palmatum)* and its many varieties, featuring deeply dissected reddish to purplish foliage; and the hornbeam maple *(A. carpinifolium)* with unlobed foliage similar to the hornbeams.

(E. S. HR.)

MAPLE SIRUP is one of the few crops produced solely in North America and is one of the oldest, having been produced by Indians of the Great Lakes and St. Lawrence river regions prior to the arrival of white settlers. Maple sirup is obtained mostly from the "sap" (sweet water) of the sugar maple (*Acer saccharum*) but some is obtained from the black maple (A. *nigrum*). It is produced in commercial quantities in the United States in Vermont, New York, Pennsylvania, Michigan, Ohio, New Hampshire, Wisconsin, Massachusetts, Maine, Maryland, Minnesota and West Virginia, and in Canada in Quebec and Ontario, ranked in order of production. The same type and quality of maple products are produced throughout the area. Differences merely reflect idiosyncrasies of producers and equipment.

The production of maple sirup is subject to yearly climatic and economic fluctuations. A record crop was produced in 1860 and a very small crop in 1959. The sweet water "sap" of the maple tree from which sirup is made is different from the circulatory sap of the growing tree. When the tree is dormant the sap will flow from any wound, such as a tap hole, in the sapwood each time a period of freezing is followed by a period of thawing. The sap contains $1\frac{1}{2}\%$ to 3% solids, mostly sucrose. It does not contain either the colour or the flavour of maple sirup. These are imparted to it as the sap is concentrated by evaporation in open pans to 65.5° Brix.

Thirty to fifty gallons of sap are required to yield one gallon of sirup.

The usual maple sirup season begins in mid-January in the more southern states and ends in mid-April in the northern states, lasting four to six weeks in each place. Until the late 1910s the method of making maple sirup had remained almost unchanged over the more than 300 years of its history, with the exception of the development of the flue evaporator.

During the next 10 years modernization began. The equipment for drilling tap holes was mechanized, sanitary methods of sap handling effected. precision instruments for sirup making developed. plastic tubing adapted for the transportation of sap from the tap holes of entire sugar bushes to storage tanks, and central evaporator plants established which serve whole communities of sap producers.

All of these modernized methods improved and standardized maple products.

The major products of maple sap are pure and blended table sirups. confections (cream. hard and soft candies'), toppings for ice cream. flavourings and casing for cigarette tobaccos.

MAPLEWOOD: see SAINT LOUIS (Mo.).

MAQDISI (MUQADDASI), **AL-** (IBN ALMAD AL-MUKADDASI, *i.e.*, "the Jerusaleniite") (*c.* 946–*c.* 1000). Arab traveler and geographer, author of a noted work in Arabic on the lands of Islam entitled in one manuscript *Kitab al-Aqalim* ("The Book of Countries"), though another rnanuscript has a longer title. This work, published in 985 and based mainly on his personal observations during 20 years of travel (in the course of which he visited all the Moslem lands except Spain, Seistan and Sind), is a mine of detailed information on the populations. manners and economic life of these lands in the 10th century.

See *Bibliotheca Geographorum arabicorum,* ed. by M. J. de Goejc, vol. iii (1877; rev. 0 6) *See* also introduction tn vol. iv of the same work for a discussion by M. J. de Gocje of al-Muqaddasi and his work.

(H. A. R. G.)

MAR, EARLDOM OF. Mar. one of the ancient divisions of Scotland, comprised the larger portion of Aberdeenshire. extending from north of the Don southward to the Mounth. Like other such districts. it was in Celtic times under the rule of a mormaer. In the 12th century his place was taken by an earl, but no definite succession of earls appears until the 13th century. Earl Gratney (*fl. c.* 1300) married a sister of (King) Robert Bruce. who brought him the lordship of Garioch and castle of Kildrummy. which she held against the earl of Athole. an ally of the English (1335). Their son Donald was made regent in July 1332, but was defeated and slain at Dupplin the next month. His daughter and eventual heir. Margaret, brought the earldom to her husband. William. earl of Douglas. and on the accession of her daughter Isabel a troublous time followed. While she was living as a widow at her castle of Kildrummy. it was stormed by Alexander Stewart. a bastard, who forced her to execute a charter (Aug. 1404) settling the reversion to the earldom on himself and his heirs. This act she revoked by a charter of Sept. 1404. but on marrying him in December. she granted him the earldom for liie. the king confirming this in June 1405. After her death in 1408 the earl commanded the royal forces at the battle of Harlaw. when the lord of the Isles was defeated in 1411, and afterward acted as warden of the Marches.

In 1426 he resigned the earldom to the crown. the kina granting it by a fresh creation to him and certain heirs. with reversion to the crown. In the following centuries the earldom had a complicated and chequered history, the title eventually remaining in the Erskine family. As a result of the attainder of the 11th earl. John (16; j–1732). a prominent Jacobite (*see* below), the earldom remained under forfeiture for 108 years.

Alloa and other Erskine estate.: of the attainted earl were repurchased for the family. and descended to John Francis Erskine (1741–1825), his heir male, who was also his heir of line through his daughter. To him, in his 83rd year, as grandson and lineal representative of the attainted earl. the earldom was restored by act of parliament. His grandson. who succeeded him in 1828, inherited the earldom of Kellie (1619) and other Erskine dignities by decision of 1835.

At his death in 1866, his earldom of Mar was the subject of rival claims, and the right to the succession was not determined until 187j. For the prolonged proceedings for the settlement of this case, in which the decision of the house of lords (Feb. 25, 1875), in favour of the late earl's cousin and heir male, was reversed by a special act, the Earldom of Mar Restitution act in 1885, in favour of the son of the late earl's cousin, J. F. E. Goodeve (Erskine), see the authorities quoted below.

MAR, JOHN ERSKINE, 1ST OR 6TH EARL OF (d. 1572), regent of Scotland. was a son of John. 5th Lord Erskine (d. 1552), who was guardian of King James V, and afterward of Mary Queen of Scots. The custody of Edinburgh castle was in his hands. and during the struggle between the regent, Mary of Lorraine, and the lords of the Congregation he appears to have acted consistently in the interests of peace. When Mary Stuart returned to Scotland in 1561 Lord Erskine was a member of her council, and favoured her marriage with Lord Darnley. In 156j Erskine was granted the earldom of Mar (*q.v.*). As guardian of James, afterward King James VI. he prevented the young prince from falling into the hands of Bothwell. and when the Scottish nobles rose against Mary and Bothwell, Mar was one of their leaders. He took part in the government of Scotland during Mary's imprisonment at Lochleven, and also after her subsequent abdication. In 1571 he was chosen regent of Scotland, but he was overshadowed by the earl of Morton. He died at Stirling on Oct. 29, 1572.

MAR, JOHN ERSKINE, 2ND OR 7TH EARL OF (*c.* 1558–1634), Scottish politician. was the only son of the preceding. He was nominally the guardian of the young king James VI, n-ho lived with him at Stirling; but he was in reality a puppet in the hands of the regent, the earl of Morton; and he lost power when Morton was imprisoned. He was concerned in the seizure of James VI in 1582; but when James escaped the earl fled into the west of Scotland. Leaving his hiding place Mar seized Stirling castle. whereupon James marched against him, and he took refuge in England. Queen Elizabeth I interceded for him in vain, and Mar and his iriends gathered an army. entered the presence of the kina at Stirling. and were soon in authority (1585). Mar was restored to hia lands and titles. He became governor of Edinburgh castle and tutor to James's son. Prince Henry. and for his second wife he married Mary, daughter of Esmé Stewart. duke of Lennox.

In 1601 the earl was sent as envoy to London; there Elizabeth assured hirn that James should be her successor, and his mission was conducted with tact and prudence. Mar was created Lord Cardross in 1610; he was a member of the Court of High Commission and was lord high treasurer of Scotland from 161j to 1630. He died at Stirling on Dec. 14. 1634.

MAR, JOHN ERSKINE, 6TH OR 11TH EARL OF (1675–1732), Scottish Jacobite, was the eldest son of Charles. the jth earl (1650–89). He was associated with the party favourable to the English government; he was one of the commissioners for the union. and was made a Scottish secretary of state, becoming after the union of 1707 a representative peer for Scotland, keeper of the signet and a privy councillor. In 1713 Mar was made an English secretary of state by the Tories. hut under George I he was deprived of his office, and in 1715 he went in disguise to Scotland and placed himself at the head of the adherents of James Edward, the Old Pretender. Meeting many Highland chieftains at Aboyne he avowed a desire for the independence of Scotland,

and at Braemar in Sept. 1715 he proclaimed James VIII king of Scotland. England. France and Ireland. At Sheriifmuir, in Nov. 1715, Mar's forces were defeated by those of his opponent, Archibald Campbell, afterward 3rd duke of Argyll. Mar then met James Edward at Fetteresso; he fled with him to France. In the course of time he became thoroughly distrusted by the Jacobites. In 1721 he accepted a pension of £3,500 a year from George I, and in 1724 he left the Pretender's service. His later years were spent in Paris and at Aix-la-Chapelle. where he died in May, 1732. He had been attainted in 1716, and his only son, Thomas, Lord Erskine, died childless in March 1766.

Mar's brother. JAMES ERSKINE (1679–1754), was educated as a lawyer and became lord justice clerk of the court of session and Lord Grange in 1710. He took no part in the rising of 1715, although there is little doubt that at times he was in communication with the Jacobites, but was rather known for his sympathy with the Presbyterians. He became more famous, however, in connection with the story of his wife's disappearance. This lady, Rachel Chicelp, was a woman of disordered intellect; probably with reason she suspected her husband of infidelity. and after many years of unhappiness Grange arranged a plan for her seizure. In Jan. 1732 she was conveyed with great secrecy from Edinburgh to the island of Hesker, thence to St. Kilda, where she remained for about ten years: thence she was taken to Xssynt in Sutherland and finally to Skye. To complete the idea that she was dead. her funeral was publicly celebrated, but she survived until May 1745.

Meanwhile in 1734 Grange had resigned his judgeship and had become an English member of parliament; there he was a bitter opponent of Sir Robert Walpole.

He died in London on Jan. 20, 1754.

See the *Journal of tlze Earl of Mar* (1716); R. Patten, History *of the Late Rebellion* (1717); and A. Lang, History *of Scotland,* vol. iv. (1907).

MAR, SERRA DO, the name given to the Great Escarpment on the eastern margin of the Brazilian highlands. The escarpment extends all the way from Rio Grande do Sul to southern Bahia, but it is known as the Serra do Mar only in the middle section in Rio de Janeiro and São Paulo. Because of its name ("mountains of the sea") many map makers show this as a range of mountains rather than escarpment on the edge of a plateau. The escarpment stands between 2.600 and 3,000 ft. above sea level at its top; but in Rio de Janeiro state it is surmounted by the Serra dos Orgãos (7.36j ft.) which overlooks Guanabara bay at Rio de Janeiro. The escarpment was originally covered with a dense rain forest.

(P. E. J.)

MARABOUT, in Islam a hermit or devotee (Fr. from Arab *murabit,* "one who pickets his horse on a hostile frontier"). The word is derived from *ribat,* a fortified frontier station, which later came to mean a religious house or hospice (*zawiya*). In North Africa the marabouts enjoy extraordinary influence, being esteemed as living saints and mediators. They are liberally supported by alms, direct all popular assemblies, and have a decisive voice in intertribal quarrels and all matters of consequence. On their death their sanctity is transferred to their tombs (also called marabouts). where chapels are erected at, and gifts and prayers offered to, their tombs.

See DERVISH.

MARACAIBO, second largest city in Venezuela, the country's most important seaport and capital of the state of Zulia, is situated in the northwestern corner of the country on the west shore of the channei connecting Lake Maracaibo with the Gulf of Venezuela. Pop. (1961) 432,902. The city was a primitive coffee-exporting port of 40,000. mostly Indians and Negroes, until petroleum was discovered in' 1917. Within a decade Maracaibo became the country's oil metropolis: with paved streets, modern public services, tall office buildings, golf clubs, air-conditioned hotels, supermarkets and very substantial dwellings. Its population more than doubled during the 1920s, in spite of the climate. The city is located in a basin surrounded by higher land which prevents the steady trade winds from relieving the oppressive humidity. The annual average temperature is 82.4° F., ranging from an average of 80.6° F. in January to an average of 84.4° in August. The oil companies set up headquarters there. the government erected new buildings, the city installed electricity. Attractive modern suburbs reached out in all directions. Commerce thrived but living costs doubled.

Because of its strategic location near the outlet of the lake, Maracaibo has long been important as a trading centre although the channel connecting the lake with the Caribbean mas too shallow to permit the passage of large ocean freighters and tankers. A major dredging operation completed in 1957 (see MARACAIBO, LAKE) provided a major stimulus to the economy of all of northwestern Venezuela and quickened the entire maritime life of the city.

In addition to being one of the most important petroleum-exporting ports in the world, the city exports cacao. coffee, hides, fruits, vegetable oil and rimber. It imports manufactured products of all kinds and considerable food. It also serves as the transshipment point for nearly all the trade for northwestern Venezuela.

Maracaibo's oil industry is the result of foreign enterprise. Pou·erful oil groups own all the major concessions. Billions of dollars of American, British and Dutch capital have been invested, but in 19j6 Venezuelan capital, in alliance with foreigners, entered the industry. (L. WE.)

Maracaibo's wealth dates from the 20th century but its history goes back to the age of exploration. It was founded in 1571 by Alonso Pacheco. who gave it the name of Nueva Zamora. The shipment point for the inland settlements was originally a station named Gibraltar at the head of the lake, but its destruction by pirates in 1669 transferred this trade to Maracaibo. The city did not figure actively in the war for independence until Jan. 28, 1821, when the province declared its independence and alliance with Colombia. This ended the armistice between Simón Bolivar and Pablo Morillo and thereafter the city experienced the changing fortunes of war until its final capture by the revolutionists in 1823. In the years of destructive civil war, Maracaibo was usually much less involved than eastern and central Venezuela.

MARACAIBO, LAKE (LAGO DE MARACAIBO) a large lake in the northwestern corner of Venezuela. lies in the Maracaibo lowland immediately to the east of the Sierra de Perijá. It extends southward from the Gulf of Venezuela, into which it opens through a long neck. Roughly shaped like an oil drop hanging from a spout, the lake is 133 mi. long and 72 mi. wide and covers an area of about 5,000 sq.mi. In the southern portion the lake water is fresh but in the northern portion, where the tidal influence is stronger. it is somewhat brackish.

Lake Maracaibo receives the waters of many rivers, principally from the west and south sides. The heavy rainfall on the eastern slopes of the Eastern Cordillera (more than 86 in. annually) is responsible for the great volume of water discharged into the lake. The average annual precipitation over the entire basin is about 70 in. The area around the lake is hot and humid and its average temperature is reported to be the highest in South America.

Lake Maracaibo is the centre of the petroleum industry of Venezuela and of Latin America. About 90% of the oil produced is exported. hut untii 1957 the northern outlet of the lake was obstructed by a very large sand bar which allowed only shallow-draft (17,000 ton') tankers to enter and leave the lake. In that year, after many months of dredging and at a cost of $48,000,000, a new channel 3j ft. deep and 21 mi. long was opened. Now fully loaded 33.000-ton tankers are able to leave the lake.

The Lake Maracaibo basin (including the lake and adjacent land area) is one of the world's richest and best located oil-producing areas. Particularly outstanding are the 65 mi. along the east shore and the 15 mi. out into the lake. Thousands of derricks protrude from the water and thousands more line the shore. Underwater pipelines transport the oil to storage tanks on the land. Well over one-third of Venezuela's total oil production comes irom Lake Maracaibo. As oil contributes over 90% of the country's foreign exchange and many national revenues, the economic importance of Lake Maracaibo is considerable.

Much natural gas (wet gasj is obtained with the oil. For many years billions of cubic feet of this fuel were flared off: since there was no appreciable market. In the middle 1950s a petroleum corporation installed three plants several miles offshore for reinjecting gas into the oil-bearing formation with the purpose of recovering more oil and of conserving gas for potential future use. Enough pressure is put on the oil in the deposit to increase immediate production by 50% and ultimate recovery by 30%. One of these plants injects 300,000,000 cu.ft. of gas per day into the reservoir it serves.

Until 1918 Lake Maracaibo basin was one of the poorest and least important areas in the country. The people made a miserable living ignorant of the potential wealth at their feet. The oil industry there is the result of foreign (chiefly American. British and Dutch) enterprise, technological skills and capital. In the early 1960s less than 5% of the total production came from Venezuela-owned wells. (L. WE.)

MARACAY, capital of Aragua state in Venezuela. Pop. (1961) 134.123. A handsome city, it lies about 76 mi. W. of Caracas in the central highlands at an elevation of 1,500 ft. It was but a sleepy town until the dictator Juan Vicente Ghmez transferred his centre of activities there from Caracas. During his long dictatorship (1908–3j) he built up hlaracay until it became the actual if not the nominal capital of the country. The city is situated in excellent cattle country; by gaining possession of these pastures. Gómez virtually cornered the entire Venezuela cattle industry. He built a modern dairy plant and slaughterhouse at Maracay, with whose products he supplied the urban market in Caracas.

Determined to make the city the cultural and social centre of the nation. Gómez constructed the Hotel Jardín, with its Moorish arcades, second-story balconies, gracious patio and beautiful park and fountain; an opera house (never completed); a bull ring (an exact replica of the one in Seville); and military airports. The current importance of the city lies in its military training institutions and its school of agriculture and experiment station. (L. WE.)

MARAGHEH (MARAGHA), a town of Iran in the province of E. Azerbaijan. on the Safi river, in 37° 23′ N., 46° 16′ E., 80 mi. from Tabriz. Pop. (1956) 36,556. It is pleasantly situated in a narrow valley running nearly north and south at the eastern extremity of a well-cultivated plain opening toward Lake Urmia, which lies 18 mi. to the west. Two stone bridges in good condition. said to have been constructed during the reign of Hulagu Khan (1256–65), and since then several times repaired, lead over the Safid rud on the western side of the town. But the most notable monuments are five tomb towers, several badly ruined, dating from the 12th through the early 14th century. the earliest being the Gunbad-i-Surkh (1147). It is one of the finest examples of brickwork in Iran. The place is surrounded by extensive vineyards and orchards, well watered by canals led from the river. and producing great quantities of fruit. On a hill west of the town are traces of a famous observatory (*rasad*) constructed under the direction of the great astronomer Nasr-ud-Din of Tus. The building. which no doubt served as a citadel as well, enclosed a space of 380 yd. by 150 yd.. and the foundations of the walls were 4½ to j ft. in thickness. The marble. which is known throughout Iran as Maragha marble. is a travertine obtained at the village of Dashkesen (about 30 mi. N.W. of Maragheh). It is deposited from water. which bubbles up from a number of springs, in the form of horizontal layers. which at first are thin crusts and can easily be broken, but gradually solidify and harden into blocks with a thickness of 7–8 in. It is a singularly beautiful substance, of yellow. pink, greenish or milk-white colour, streaked with reddish. copper-coloured veins.

Journ.*, xiv, p. 517 (1899); Andre Godard, "Les Monuments de Maragha," *Athar-é-Iran*, I, p. 130 (1936); *A Survey of Persian Art*, vol. 2 and 3 *passim*.

MARAJO, an island at the mouth of the Amazon river in Brazil. 183 mi. long and 124 mi. wide; area 15,444 sq.mi. The main flow of the Xmazon passes to the north of Marajó, but numerous *furos* or narrow passages direct part of the water into the Pará river. an estuary that separates the island from the mainland to the south. The densely forested western half of the island is part of the overflow land (*várzea*) of the Amazon, but the slightly higher eastern half, underlain by sandstone, has extensive areas of treeless savannas (*campos*), which support large herds of cattle. Numerous archaeological mounds in the northeastern part of the island are rich in well-made pottery vessels and other objects that suggest an affinity with pre-Columbian Andean cultures. Soure, a modern town and beach resort on the Atlantic coast, is linked to Belém by overnight ferry service. (Js. J. P.)

MARANHÃO, a northern state of Brazil, bounded north by the Atlantic, east and southeast by Piaui, southwest and west by Goiás and Pará. Area 128,252 sq.mi. Pop. (1956 est.) 1,842,000. The coastal zone and the northwest corner of the state belong to the Amazon valley region. being a heavily forested plain traversed by numerous rivers. The eastern and southern parts, however, belong to the lower terraces of the great Brazilian plateau. broken by eroded river courses between which are high open plains. There are no true mountain ranges in Maranhão. those indicated on the maps being only plateau escarpments marking either its northern margin or the outlines of river valleys. The climate is hot. and the year is divided into wet and dry seasons, extreme humidity being characteristic of the former, but no part of the year is rainless. The heat, however, is greatly modified on the coast by the southeast trade winds.

The coast itself is broken and dangerous. there being many small indentations, which are usually masked by islands or shoals. The largest of these are the Bay of Turiaçu, facing which is the island of Tocansa, and several others of small size and the contiguous bays of Sio Marcos and Sio José, between which is the large island of Sio Luis, on which is the city of São Luis. The rivers of the state all flow northward to the Atlantic, and a majority of them have navigable channels. The Parnaiba forms the eastern boundary while the Tocantins and the Gurupí bound the state on the west.

The principal industries of Maranhão are agricultural, the highly fertile river valleys and coastal zone being devoted to the cultivation of sugar cane, cotton, rice, coffee. tobacco. *manioc* (cassava) and a great variety of fruits. Babassu nuts are an important export. The southern highlands are devoted to cattle raising. Phosphatic bauxite deposits that occur on Turiaçu Island at the mouth of the Maracaçumé river are undeveloped. In 1956 oil was discovered at Balsas, deep in the interior near the Goiás border. A railway, 250 mi. long, crosses the eastern part of the state connecting São Luis on the coast with Teresina, the capital of Piaui.

The capital is São Luis, pop. (1956 est.) 147.067 (mun.); other principal towns, with their population in 1950 are: Caxias 14.443'; Pedreiras 7,185; Rosário 5,316 and Viana 4,995.

The coast of Maranhão was first discovered by Vicente Yáñez Pinzhn in 1500. but it was included in the Portuguese grant of captaincies in 1534. The first European settlement was made by a French trading expedition under Jacques Riffault of Dieppe in 1594, who left a part of his men there when he returned home. Subsequently Daniel de la Rivardière. commissioned by the French crown. founded a colony on São Luis Island in 1612. The French were expelled by the Portuguese in 1615 and the Dutch held the island from 1631 to 1644.

In 1621 Ceará. Maranhão and Pará were united and called the Estado do Maranhão, which was made independent of the southern captaincies. Ceará was later detached, but the state of Maranhão remained independent until 1774, when it became subject to the colonial administration of Brazil. Maranhio did not join in the declaration of independence of 1822. but in 1823 the Portuguese were driven out by Admiral Lord Cochrane and the province became a part of the empire of Brazil. (Js. J. P.)

MARAÑÓN, a river of northeast Peru, rising in Lake Lauricocha in the southwest of Huánuco department, just north of Cerro de Pasco. about 100 mi. from the Pacific ocean. It flows 350 mi. northn-est between mountain ranges before descending eastward to enter the Amazon basin.

The Marañón, together with the Ucayali and Huallaga rivers which join it downstream, is one of the principal affluents of the Amazon (*q.v*). From its source, a series of unnavigable rapids characterize the Marafion for a distance of 350 mi.; it drops from a height of 12,000 ft. in the Andes to 575 ft. above sea level at Pongo de Manseriche. Navigation is only possible below Manseriche. The Marañón is navigable to Puerto Limón, a distance of 484 mi. (during both high and low water), for steamers of 4- to 8-ft. draft. From Puerto Limón to Manseriche, a distance of 74 mi., it is navigable by vessels of 2- to 4-ft. draft at any season.

The Marañón flows through a forested, sparsely inhabited region. Climatic conditions vary from a mountain climate in the upper extension of the river to rainy tropical in the Amazon basin. (J. L Tr)

MARANTACEAE, the arrowroot family. monocotpledonous perennials, comprising 26 genera and 300 species, all tropical and mainly American. The West Indian *Maranta arundinacea* is the source of arrowroot (*q* v.).

Various species of *Calathea* are cultivated for their ornamental foliage.

MARAS (Marash), a city in Turkey, east of the Jihan river at the foot of Mt. Taurus; pop. (1955) 44.306, and capital of the *vilayet* of the same name.

The American mission has a college there and the Americans and Jesuits, churches and schools. The climate for the greater part of the year is good. A railway connects hlaras with the Istanbul-Baghdad line.

History.——Maras was anciently a Hittite town and several Hittite monuments have been discovered including an inscribed lion and several stelae. As Marasi it appears in Assyrian records, but little or nothing is known of the town at that period. It reappears in history in the 2nd century A.D. with the name Germanicia. The identification of Germanicia with Maras has been questioned without any real justification. Nor is the attempt by Honigmann to distinguish two Germanicias in fairly close proximity likely to meet with favour. The Armenians have called Maras Kermanig since the 12th century at least. Heraclius visited the town in A.D. 640. Before 700 it had passed into Moslem hands. The Khalif Mu'āwiya rebuilt it and it figured in the struggles with the Byzantines; after 770, however, it remained definitely in Moslem hands. Hārūn al-Rashēd (786–809) strengthened its fortifications. The crusaders captured the town (1097), as did the Seljuks half a century later. It became part of the Turkish empire in the 16th century. In 1832 the Egyptian army in its march toward Constantinople stayed its advance there at the bidding of the powers. Maras was brought within the sphere of military operations consequent on the Franco-Turkish dispute of 1920–21.

MARAT, JEAN PAUL (1743–1793), French revolutionary leader, son of Jean Paul Marat, a designer of Cagliari in Sardinia. and Louise Cabrol of Geneva, was born at Boudry, Neuchâtel, on May 24, 1743. On his mother's death in 1759 Marat set out on his travels, and studied medicine for two years at Bordeaux, whence he moved to Paris, where he made use of his knowledge of optics and electricity to subdue an obstinate disease of the eyes. After some years in Paris he went to the Netherlands, and then to London, where he practised medicine. In 1773 he published a *Philosophical Essay on Man*. The book directly attacks Helvétius, who had in his *De l'esprit* declared a knowledge of science unnecessary for a philosopher. Marat declares that physiology alone can solve the problems of the connection between soul and body, and proposes the existence of a nervous fluid as the true solution. In 1774 he published *The Chains of Slavery,* which was intended to influence constituencies to return popular members, and reject the king's friends. In 1775 he published in London his *Essay on Cleets,* and in Amsterdam a French translation of the first two volumes of his *Essay on Marc.* In this year he visited Edinburgh, and was made an M.D. of St. Andrews. On his return to London he published an *Enquiry into the Nature, Cause, and Cure of a Singular Disease of the Eyes,* with a dedication to the royal society. In the same year there appeared the third volume of the French edition of the *Philosophical Essay on Man,* which exasperated Voltaire, whose attack made the young author more conspicuous. His fame as a doctor was now great, and on June 24, 1777, the comte d'Artois. afterward Charles X of France, made him physician to his guards with 2,000 livres a year and allowances.

Marat soon had an aristocratic practice. He presented memoirs on heat, light and electricity to the Académie des Sciences, hut the academicians were horrified at his temerity in differing from Newton and uould not receive him. In 1780 he had published at Neuchâtel a *Plan de législation criminelle,* founded on the principles of Cesare Beccaria. In April 1786 he resigned his court appointment. The results of his leisure were in 1787 a new translation of Sir Isaac Newton's *Optics,* and in 1788 his *Mémoires académiques, ou nouvelles de'couvertes sur la lumière.*

In the notoriety of the political life which was now to begin, his scientific and philosophical knowledge was to be forgotten, the high position he had given up denied, and he himself scoffed at as an ignorant charlatan, who had sold quack medicines about the streets of Paris, and been glad to earn a few sous in the stables of the comte d'Artois. In 1788 the elections for the states-general were the cause of a flood of pamphlets, of which Marat's *Offrande à la patrie* dwelt on much the same points as the famous brochure of the Abbé Siéyès: *Qu'est-ce que le tiers état?* In June 1789 he published a supplement to his *Offrande,* followed in July by *La constztution,* in which he embodies his idea of a constitution for France. and in September by his *Tableau des vices de la constztution d'Angleterre,* uhich he presented to the assembly. The latter alone deserves remark. The assembly was at this time full of anglomaniacs, who desired to establish in France a constitution similar to that of England. Marat had seen that England was at this time being ruled by an oligarchy using the forms of liberty, which, while pretending to represent the country, was really being gradually mastered by the royal power. His heart was now all in politics; and he decided to start a paper. At first appeared a single number of the *Moniteur patriote,* followed on Sept. 12 by the first number of the *Publiciste parisien,* which on Sept. 16 took the title of *L'Ami du peuple* and which he edited, with some interruptions, until Sept. 21, 1792.

The life of Marat now becomes part of the history of the French Revolution. From the beginning to the end he stood alone. He was never attached to any party, the tone of his mind was to suspect whoever was in power. About his paper, the incarnation of himself, the first thing to be said is that the man always meant what he said; no poverty, no misery or persecution, could keep him quiet; he was perpetually crying, "Nous sommes trahis." Whoever suspected any one had only to denounce him to the *Ami du peuple,* and the denounced was never let alone till he was proved innocent or guilty. Marat began by attacking the most powerful bodies in Paris—the constituent assembly. the ministers. the corps municipal, and the court of the Châtelet. Denounced and arrested, he was imprisoned from Oct. 8 to Nov. 5, 1789. A second time. owing to his violent campaign against Lafayette, he narrowly escaped arrest and had to flee to London (Jan. 1790). There he wrote his *De'nonczation contre Necker,* and in May dared to return to Paris and continue the *Ami du peuple.* He was embittered by persecution, and continued his vehement attacks against all in power. and at last, after the day of the Champs du Mars (July 17, 1790), against the king himself. All this time he was in hiding in cellars and sewers, where he was attacked by a horrible skin disease, tended only by the woman Simonne Evrard. who remained true to him. The end of the constituent assembly he heard of with joy and with bright hopes for the future, soon dashed by the behaviour of the legislative assembly. When almost despairing, in December 1791, he fled once more to London, where he wrote his *École du citoyen.* In April 1792, summoned again by the Cordeliers' club, he returned to Paris, and published no. 627 of the *Ami.*

The war was now the question, and Marat saw clearly that it was to serve the purposes of the Royalists and the Girondins, who thought of themselves alone. Again denounced, Marat had to remain in hiding until Aug. 10. The proclamation of the duke of Brunswick excited all hearts; who could go to save France on the frontiers and leave Paris in the hands of his enemies? Marat, like Georges Danton, foresaw the massacres of September. After the events of Aug. 10 he took his seat at the commune, and demanded a tribunal to try the Royalists in prison. No tribunal was formed, and the massacres in the prisons were the inevitable result. In the elections to the convention, Marat was elected 7th out of the 24 deputies for Paris, and for the first time took his seat in an assembly of the nation. At the declaration of the republic, he closed his *Ami du peuple*, and commenced, on the 25th, a new paper, the *Journal de la république française,* which was to contain his sentiments as its predecessor had done, and to be always on the watch. In the assembly Marat had no party; he would always suspect and oppose the powerful, refuse power for himself. After the battle of Valmy, Charles Dumourierz was the greatest man in France; he could almost have restored the monarchy; yet Marat did not fear to denounce him in placards as a traitor.

His unpopularity in the assembly was extreme, yet he insisted on speaking on the question of the king's trial, declared it unfair to accuse Louis for anything anterior to his acceptance of the constitution, and though implacable toward the king, as the one man who must die for the people's good, he would not allow Chretien de Malesherbes, the king's counsel, to be attacked in his paper, and speaks of him as a "sage et respectable vieillard." The king dead, the months from January to May 1793 were spent in an unrelenting struggle between Marat and the Girondins. Marat despised the ruling party because they had suffered nothing for the republic, because they talked too much of their feelings and their antique virtue, because they had for their own virtues plunged the country into war, while the Girondins hated Marat as representative of that rough red republicanism which would not yield itself to a Roman republic, with themselves for tribunes, orators and generals.

The Girondins conquered at first in the convention, and ordered that Marat should be tried before the Revolutionary Tribunal. But their victory ruined them, for on April 24 Marat was acquitted, and returned to the Convention with the people at his back. The fall of the Girondins on May 31 was a triumph for Marat. But it was his last. The skin disease he had contracted in the subterranean haunts was rapidly closing his life; he could only ease his pain by sitting in a warm bath, where he wrote his journal, and accused the Girondins, who were trying to raise France against Paris. Sitting thus on July 13, he heard in the evening a young woman begging to be admitted to see him, saying that she brought news from Caen, where the escaped Girondins were trying to rouse Normandy. He ordered her to be admitted, asked her the names of the deputies then at Caen, and, after writing their names, said, "They shall soon be guillotined," when the young girl, whose name was Charlotte Corday (*q.v.*), stabbed him to the heart.

The Convention attended his funeral, and placed his bust in the hall where it held its sessions. Louis David painted "Marat Assassinated," and a veritable cult was rendered to the Friend of the People, whose ashes were transferred to the Panthéon with great pomp on Sept. 21, 1794—to be cast out again in virtue of the decree of Feb. 8, 1795. (R An.)

Besides the works mentioned above. Marat nrote: *Recherches physiques sur l'électricité*, etc. (1782); *Recherches sur l'électricité médicale* (1783); *Notions élémentaires d'optique* (1764); *Lettres de l'observateur Bon Sens à M. de M. . . . sur la fatale catastrophe des infortunés Pilatre de Rozier et Romain, les aéronautes et l'aérostation* (1785); *Observations de M. l'amateur avec à M. l'abbé Sans* . . . etc. (1785); *Éloge de Montesquieu* (1785), published 1883 by M de Bresetz; *Les Charlatans modernes, ou lettres sur le charlatanisme académique* (1791); *I es Aventures du comte Potowski* (published in 1847 by Paul Lacroix, the "bibliophile Jacob"); *Lettres polonaises* (unpublished). Marat's works were published by A. Vermorel. *Oeuvres de J P. Marat, l'ami du peuple, recueillies et annotées* (1869). Tno of his tracts (1) *On Gleets,* (2) *A Disease of the Eyes,* were reprinted, ed. J. B. Bailey, in 1891.

MARATHI (or *Marāṭhī*) is the name of an important Indo-Aryan language spoken in western and central India.

Marathi occupies an irregular triangular area of approximately 100,000 sq.mi., having its apex about the district of Balaghat in the Madhya Pradesh (old Central Provinces) and for its base the western coast of the peninsula from Daman on the Gulf of Cambay in the north to Karwar on the open Arabian sea in the south. It covers parts of Maharashtra and Madhya Pradesh states with numerous settlers in central India and Madras. and is also the principal language of Portuguese India and of the northwestern portion of Hyderabad. The standard form of speech is that of Poona in Maharashtra, and in its various dialects it covers the larger part of that state.

Dialects.—Besides the standard form of speech, there is only one real dialect of Marathi. viz., Konkani (*Kōnkaṇī*), spoken in the country near Goa. There are also several local varieties; the Marathi of the Deccan. that of Madhya Pradesh (including Berar) and that of the northern and central Konkan are distinguishable. In the southern part of the district of Ratnagiri this latter Konkani variety of Marathi gradually merges into the true Konkani dialect through a number of intermediate forms of speech. There are also several broken jargons, based upon Marathi. employed in the hill country.

Relations With Other Indo-Aryan Languages.—Marathi has to its north, in order from west to east. Gujarati. Rajasthani. Western Hindi and Eastern Hindi. To its east and south it has the Dravidian languages, Gondi, Telugu and Kanarese. Marathi does not merge into any of the cognate neighbouring forms of speech, but possesses a distinct linguistic frontier. This isolated character of Marathi is partly due to the barrier of the Vindhya range which lies to its north and partly to the fact that none of the northern languages belongs now to the Outer Band. but they are in more or less close relationships to the language of the Midland (according to G. A. Grierson's classification). Eastern Hindi is more closely related to Marathi than the others, and in its bordering dialects may be found few traces of the influence of Marathi.

Written **Character.**—Marathi books are generally printed in the Nagari character (*see* SANSKRIT LANGUAGE), and this is also used in private transactions and correspondence. In the Maratha country it is known as the *Bālbōdh* ("instructing children." *i.e.,* "easy") character. A cursive form of Nagari called *Mōḍī*, or "twisted." is also employed as a handwriting. It is said to have been invented in the 17th century by Balaji Avaji. the secretary of the celebrated Sivaji. Each word can be written as a whole without lifting the pen from the paper.

Origin of the Language.—The word "Marathi" signifies the language of the Maratha country. It is the modern form of the Sanskrit *Māhārāṣṭrī* just as "Maratha" represents the old *Māhārāṣṭra,* or Great Kingdom. *Māhārāṣṭrī* was the name given by Sanskrit writers to the Prakrit spoken in Māhārāṣṭra. the great Aryan kingdom extending southwards from the Vindhya range to the Kistna, broadly corresponding to the southern part of Bombay state and to the state of Hyderabad. This Māhārāṣṭrī became the form of Prakrit employed as the language of lyric poetry and of the formal epic (*kāvya*). Dramatic works were composed in it, and it was the vehicle of the noncanonical scriptures of the Jaina religion. The oldest work in the language is the *Sattasai,* or "Seven Centuries of Verses," compiled at Pratiṣṭhāna on the Gōdāvarī. the capital of King Hāla, at some time between the 3rd and 7th centuries A.D.

General Character of the Language.—The Prakrits fall into two well-defined groups, an Inner, Śaurasēnī, and its connected dialects on the one hand, and an Outer, Māhārāṣṭrī, Ardhamāgadhī, and Māgadhī with their connected dialects on the other. These two groups differed in their phonetic laws. in their systems of declension and conjugation. in vocabulary and in general character. Suffixes such as *-alla, -illa, -ulla,* etc., can be added to any noun, adjective or particle in Māhārāṣṭrī and Ardhamāgadhī, but are hardly ever met in Śauraśēnī. These give rise to numerous secondary forms of words, which give a distinct flavour to the whole language.

Vocabulary.—Māhārāṣṭrī Prakrit. the most independent of the Outer languages, was distinguished by the large proportion of *dēśyas* (vocables whose origin cannot be traced to original Indo-Aryan sources) found in its vocabulary. and the same is consequently the case in Marathi, although the proportion of *tatsamas* (words identical with Sanskrit words) to *tadbhavas* (words derived from Sanskrit) in the language is fairly high. The proportion of Persian and. through Persian, of Arabic words in the Marathi vocabulary is comparatively low.

Phonetics.— In the standard dialect the vowels are the same as in Sanskrit, but *ṛ* and *l* only appear in words borrowed directly from that language (tatsamas). Final short vowels (a, *i* and u) have all disappeared in prose pronunciation, except in a few local dialects! and final i and u are not even written. After an accented syllable a medial a is pronounced very lightly. even when the accent is not the tnain accent of the word. Almost the only compound consonants which survived in the Prakrit stage were double letters, and in Marathi these are usually simplified, the preceding vowel being lengthened in compensation. It is not usual to lengthen the vowel in compensation in Ronkani, which appears to contain many relics of the old Prakrit (Saurāṣṭrī) spoken in the Gujarat country before the invasion from the Midland.

On the whole, the consonantal system is much the same as in other Indian languages. Nasalization of long vowels is very common, especially in Konkani. The palatals are pronounced as in Sanskrit, in words borrowed from that language or from Hindustani. and also in Marathi *tadbhavas* before i, i, *ẹ* or y. In other cases they are pronounced ts, *tsh,* dz, *dzh* respectively. There are two s-sounds in the standard dialect which are very similarly distinguished. *ś,* pronounced like an English sh, is used before i, i, *ē* or *y;* and *s,* as in English "sin," elsewhere. In the dialects *s* is practically the only sibilant used, and that is changed by the vulgar speakers of Konkani to h. Aspirated letters show a tendency to lose their aspiration, especially in Konkani. Generally speaking Marathi closely follows *Māhārāṣṭrī* when that differs from the Prakrits of other parts of India. There is similarly both in Marathi and *Māhārāṣṭrī* a laxness in distinguishing between cerebral and dental letters.

Declension.——Marathi retains the three genders, masculine, feminine and neuter. In Marathi the neuter denotes both inanimate things and animate beings when both sexes are included, or when the sex is left undecided. In the Konkani the neuter gender is further employed to denote females below the age of puberty. Numerous masculine and feminine words, however, denote inanimate objects. The rules for distinguishing the gender of such nouns must be learned from the grammars. For the most part. but not always, words follow the genders of the Sanskrit originals. Strong bases in *ā*—and these do not include tatsamas— are masculine. and the corresponding feminine and neuter words end in i and *ē* respectively. Sex is usually distinguished by the use of the masculine and feminine genders, and large and powerful inanimate objects are generally masculine, while small delicate things are generally feminine. In the case of some animals sex is distinguished by the use of different words.

A pleonastic suffix of *-(a)ka* (masculine and neuter), could in Sanskrit be added to any noun, whatever the termination of the base tnight be. Modern forms made with this pleonastic suffix, and ending in *ā,* i or *ē* are called strong forms, while all those made without it are called weak forms. As a rule the fact that a noun is in a weak or strong form does not affect its meaning. but sometimes the use of a masculine strong form indicates clumsiness or hugeness. Other pleonastic suffixes are employed in Marathi, usually with specific senses. Thus the suffix *-illa* generally forms adjectives, while *-da-ka* implies contempt.

The synthetic declension of Sanskrit and Prakrit has been preserved in Marathi more completely than in any other Indo-Aryan language. In the formation of the plural the Prakrit declensions are very closely followed by Marathi

The usual postpositions are: (1) Instrumental: *nẽ,* plural *nī̃,* "by " (2) Dative. *lā,* plural also *nā,* "to" or "for " (3) Ablative: *hū̃n, ūn,* "from." (4) Genitive: *tsā,* "of." (5) Locative: it, "in."

The accusative is usually the same as the nominative. but when definiteness is required the dative is employed instead. The termination ng, with its plural nī̃, is really the oblique form, by origin a locative, of the *nā* or *nō*. The suffix *nā* of the dative plural is derived from the same word. For the postposition *lā,* "for the benefit of," compare Hindi *liyē* and Gujarati *līdhē*. The genitive *gharātsā* is really an adjective meaning "belonging to the house," and agrees in gender, number and case mith the noun which is possessed. The suffixes *tsā,* ci, *cẽ,* are derived from the Sanskrit suffix tyakas, Prakrit *caō*, which is used in much the same sense.

Strong adjectives. including possessive adjectives, can be declined like substantives, and agree mith the qualified noun in gender, number and case Weak adjectives are not inflected in modern prose, but are inflected in poetry. Comparison is effected by putting the noun with which comparison is made in the ablative case.

The pronouns closely follow the Prakrit originals. There is no pronoun of the third person. its place being supplied by the demonstratives. In all the plural is employed honorifically instead of the singular.

Conjugation.— Marathi has two conjugations. The first as a rule consists of intransitive verbs, and the second, corresponding to the *e-* or causal-class. of transitive verbs but there are numerous exceptions.

In Marathi the old present has taken on the meaning of a habitual past. It is also the base of the Marathi future. which is formed by adding 1, or in the first person singular *n,* to the old present. In the second person singular the 1 has been added to a form derived from the Prakrit *uṭṭhasi,* which is also the origin of the old present *uthēs*. The remaining tenses are modern forms derived from the participles. The conjunctive participle is derived from the Apabhraṃśa form *uṭṭhiu,* to which the dative suffix *n* (old Marathi, ni, *niyā̃*) has been added.

Various tenses are formed by adding personal suffixes to the present, past or future passive participle. When the subject of the verb is in the nominative the tense so formed agrees with it in gender, number and person. In the present, the terminations are relics of the verb substantive, and in the other tenses of the personal pronouns.

The present tense is formed by compounding the present participle with the verb substantive. Further tenses are similarly made by suffixing, without compounding, various tenses of the verb substantive to the various participles.

Literature.— The modern vernacular literature of the Maratha country arose under the influence of the religious reformation inaugurated by Rāmānuja early in the 12th century. The earliest writer is Nāmdēv (13th century), whose hymns in honour of Vithoba, a personal form of Vishnu, are found in the Sikh Adi Guanth. Dnyānōbā, a younger contemporary, wrote a paraphrase of the Sanskrit *Bhagavad Gītā,* which is still much admired. Sivaji was a disciple of Rāmdās (1608–1681), who exercised great influence over him, and whose *Dāsbōdh,* a work on religious duty, is a classic. Contemporary with Rāmdās and Sivaji was Tukārām (1608–1694), a Śudra by caste, the greatest writer in the language. Being unsuccessful both in his business and in his family relations, he abandoned the world and became a wandering ascetic. His Abhangs or "unbroken" hymns are famous in the country of his birth, but do not rise to any great height as poetry. Other Marathi poets are Sridhar (1678–1728), who translated the *Bhāgavata Purāṇa,* and the learned Mayūra or Mōrōpant (1729–1793). Mahīpati (1715–1790) was an imitator of Tukārām, who collected the popular traditions about national saints.

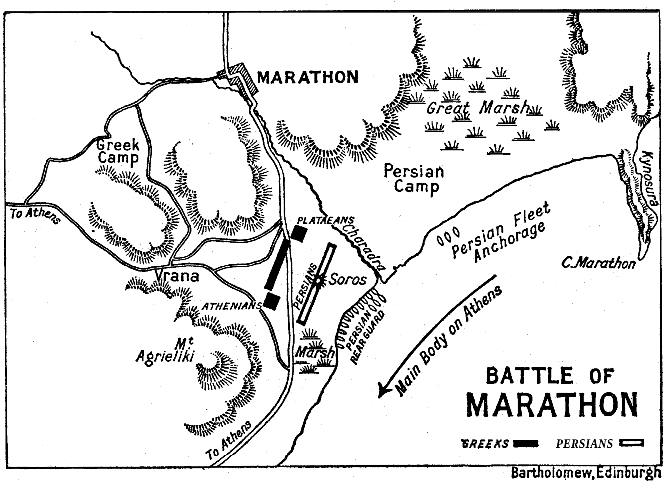
Lāvaṇīs or erotic lyrics by various writers are popular, and by western standards hardly proper. The *Pawaḍas* or mar ballads, mostly by nameless poets, are sung everywhere throughout the country. There is a small prose literature consisting of narratives of historical events (the so-called *Rakhars),* moral maxims and popular tales.

Konkani once had a literature of its own, which is said to have been destroyed by the Inquisition at Goa. Temples and manuscripts were burned wholesale. Under Roman Catholic auspices a new literature arose, the earliest writer being an Englishman, Thomas Stephens (Thomaz Esteyão), who came to Goa in 1579, wrote the first Konkani grammar and died there in 1619. Among other works, he was the author of a Konkani paraphrase of the New Testament in metrical form. *See* also INDO-ARYAN LANGUAGES.

Grierson, *Linguistic Survey of India,* vol. vii (1905). (ET. B.)

MARATHON, a plain about 5 mi. long by 2 mi. wide on the east coast of Attica 24 mi. N.E. of Athens. There is a large marsh at the northern end from which extremity the Kynosura promontory 1 mi. long ending in Cape Marathon forms an anchorage sheltered from the north and east. From the village of Marathon the Charadra brook bisects the plain and a small marsh lies at the southern end. There (490 B.C.) 9,000 Athenian and 1.000 Plataean heavy infantry defeated part of a Persian army under Datis and Artaphernes. During the Ionian revolt the Athenians and Eretrians had aided the rebels in the attack on Sardis. The Persian king, Darius, ordered his generals to "enslave Athens and Eretria and bring the slaves into his presence." *(Herodotus,* vi, 94.) Eretria, after a siege, was surrendered by treachery. The city was destroyed and the inhabitants enslaved. The Persian host, guided by Hippias, the former tyrant of Athens, landed at Marathon "thinking to do the same to the Athenians." *(Herodotus,* vi. 102.)

When news of the fall of Eretria reached Athens in 491 B.C. a



courier. Pheidippides, was sent to Sparta for aid. Miltiades, with knowledge of war and of the Persians. was selected as one of the Athenian generals under the Polemarch. Callimachus, and seems to have dominated the war council and dictated the plan of campaign. The Athenians marched on Marathon to delay the Persian advance in the passes leading to Athens and to enable the Plataeans and Spartans to join, On the march the Plataeans came up. The passes were found unoccupied and the Greeks took up a position in the Avlona valley covering the direct roads to Athens and flanking the southern road. The result was to pin down the Persians. Against the Greek position in a narrow valley with both flanks secured by hills they could not use their cavalry. To advance by the southern road would commit their column to a defile between the mountains and the sea and enable the Greeks to fall upon their rear while the main body would be unable to come up. To re-embark would expose part of their army to almost certain disaster. In spite of the Spartan delay on account of a religious festival, time fought for the Athenians.

While the Spartans were on the Isthmus of Corinth the Persians embarked their cavalry and part of their infantry to make a dash on Athens by sea. A rear guard, probably about 20.000 strong, was drawn up on the southern part of the plain parallel with the beach. Callimachus, probably on the advice of hliltiades, decided to attack—the date was probably Sept. 21. A mile from the Persian line the Greeks were marshalled, the centre thinned so as to extend the line to equal that of the Persians and to strengthen the Athenian right under Callimachus and the Plataeans on the left. Down the sloping plain moved the bronze-clad Greeks. When the ranks came within range of the Persian missiles they broke into a charge. The weak Athenian centre recoiled; but the shock of the heavy Greek wings crushed in and rolled up the Persian flanks. The victorious Persian centre was then dealt with. The hostile rear guard was destroyed losing 6.400 killed. The Greeks lost 192. The Athenians then marched back to Athens and arrived in time to forestall a landing by the Persian main body.

The failure of the Persians was the result of neglect of security measures and lack of aggressive action which resulted in failure to make use of superior numbers, and finally to a division of forces. The Greeks were prompt in action and sought to unite their strength for the decisive battle, and bring it to bear against a part of the Persian army. Tactically. the successful double envelopment of the hostile flanks foreshadowed the design of Cannae. If at Marathon the situation is unlikely to have been created intentionally, the opportunity at least was ably exploited. *See* GRAECO-PERSIAN WARS.

MARATHON RACE, a modern road race first staged at the revival of the Olympic games at Athens. Greece, in 1896. It commemorates the legendary feat of a Greek soldier, who in 490 B.C. is supposed to have run from Marathon to Athens, a distance of 22 mi. 1.470 yd., to bring news of his countrymen's victory over the Persians.

Michel Bréal of the Sorbonne at Paris originated the idea that the commemorative race should be added to the Olympic games program and, appropriately, the first marathon winner was a Greek, Spyros Louis.

Not until 1924 was the Olympic marathon distance standardized at 26 mi. 385 yd. The distance of the first race at the 1896 Olympics was 24 mi. 1.500 yd. At Paris (1900) the distance was 40 krn. (24.85 mi.); at St. Louis. blo.. (1904), 40 km.; at the 1906 unofficial Olympic games at Athens. 26 mi.; at London (1908), 26 mi. 385 yd.; at Stockholm (1912), 24 mi. 1,725 yd.; at Antwerp (1920), 26 mi. 990 yd.; at Paris (1924), 26 mi. 38j yd. From 1924 on each succeeding Olympic marathon was run over a 26 mi. 385 yd. course. The reason for the additional 38j yd. in 1908 was that the British Olympic committee decided to start the race from the royal residence at Windsor castle and finish in front of the royal box in the stadium at London.

Because marathon courses are not standardized, the International Amateur Athletic federation does not list a world's record for the event. Except for the Olympic games championship, perhaps the most coveted honour in marathon running is victory in the Boston (Mass.) Athletic association race, held annually after 1897. Athletes from all parts of the world have participated. For a period of 11 years (1945–56) the winners were exclusively from nations other than the United States; they represented Greece. Korea. Canada. Sweden, Japan, Guatemala and Finland.

The South African Comrades' marathon is run over a 54 mi. 1,100 yd. course. One year the race is from Durban to Pietermaritzburg, the next from Pietermaritzburg to Durban. When the race starts from Durban, the course is uphill to an elevation of 3,000 ft. in the first 18 mi., and there is a rise of 500 ft. in 1 mi., near the end of the course. It was in this race that Arthur F. H. Newton, one of the most remarkable all-time distance runners, aon his first success. In 1922, at the age of 39 and with no previous athletic experience, he won this endurance run from 87 other runners. In 1925, when 42, he ran the course in 6 hr. 14 min. 30 sec. Indoors, at Hamilton, Ont., in 1931, Newton ran 152 mi. 540 yd. in 24 hr. At the age of 51, he ran 100 mi. on the Bath-to-London road in 14 hr. 7 min. 10 sec.

Another example of the fact that in the marathon road race older runners have a chance for victory was Clarence De Mar of the U.S. who won the Boston Athletic association marathon for the seventh time in 1930. He began road racing in 1909 against the advice of his physician, who predicted he would die of heart disease. but De Mar outlived the doctor. In 1951 when 63 De-h'lar started and finished in his 1,000th road race.

Because so many races of this type were won by veterans, it was believed that a younger runner would not have a chance in a major event. However, in 1951 Shigeki Tanaka. a 19-year-old Japanese boy, won the Boston Athletic association marathon in 2 hr. 27 min. 45 sec.

In the matter of preparation for a 26 mi. 385 yd. road race it is considered necessary to train over that distance. At the 1952 Olympic games. however, the Czech Emil Zatopek won easily. setting an Olympic record of 2 hr. 23 min. 3.2 sec., even though he had never run the distance before and had no special training other than that used in his preparation for his successful attempts to nin also the 5,000- and 10,000-m. races.

MARATTI (MARATTA), **CARLO** (1625–1713), Italian painter. who became one of the two leading painters of the Roman school in the later 17th century (the other being G. B. Gaulli), was born on May 13, 1625, at Cammerino in the Marches. He went early to Rome where he studied under Andrea Sacchi. His reputation was established with his first public work, the "Nativity" (1650, S. Giuseppe dei Falegnami. Rome). A few years later he was noticed by Pope Alexander VII, and thereafter he secured an almost uninterrupted series of important cornmissions for altarpieces in Italian churches. Among these are "The Mystery of the Trinity Revealed to St. Augustine" (c. 1655, Sta. Maria dei Sette Dolori), "The Appearance of the Virgin to St. Philip Neri" (*c.* 1675, Palazzo Pitti, Florence), and "The Virgin With SS. Charles Borromaeus and Ignatius" (*c.* 1685, Sta. Maria in Vallicella). He also executed a number of decorative ceiling frescoes in Roman palaces and he was the most distinguished portrait painter in Italy during this period. His portraits include "Pope Clement IX" (Hermitage, Leningrad) and several of visiting Englishmen.

Maratti's early work shows the influence of Sacchi, through whom he learned to admire chiefly the art of Annibale Caracci and Raphael. Thus he became a convinced advocate of classicism, at least in theory, in opposition to the baroque painters, Pietro da Cortona, Gaulli and Padre Pozzo. But Maratti was only partly a classicist in practice. His work shows to the full the baroque quality of magnificence. and he was wholeheartedly engaged in the task of representing with the utmost splendour the dogmas of the Counter-Reformation. Maratti died in Rome on Dec. 1j, 1713.

MARAZION, a small seaport and seaside resort in the West Penwith rural district of Cornwall, Eng., on the shore of Mount's bay, about 11 mi. E.S.E. of Land's End by road. Pop. (1951) 1,293. A causeway of boulders and pebbles passable at low tide unites the township with St. Michael's Mount (*q.v.*). It has an ancient reputation as a market town, for a market granted to St. Michael's Mount in the 11th century appears from the first to have been held at Marazion. Three more fairs and three markets, held by the priors of St. Michael's Mount, were returned to their own land under Richard, king of the Romans! after which Ralph Bloyou procured for the town a market and a fair in 1331. One fair alone survives. A charter of incorporation was granted by Elizabeth I to Marazion in 1595 but borough privileges were lost in the time of Edward VI owing to the troubles of the religious rebellion.

Marazion owed its former prosperity to the throng of pilgrims who came to visit St. Michael's Mount. During the first half of the 16th century it was plundered by the French and by Cornish rebels, and the rise of the neighbouring borough of Penzance in the 17th century also seriously affected it.

Today it is a quiet town in surroundings of much beauty. Market gardening is extensively carried on and there is a fishing industry. The inscribed stones in the churchyard of St. Hilary, 1 mi. distant, date from the 4th century, one being in honour of Constantine the Great. It is said that St. Ives once paid a yearly sum for the whitewashing of St. Hilary's spire, to render it a better landmark.

MARBECK (MERBECK), **JOHN** (d. *c.* 158j), English theological writer and musician, was organist of St. George's Windsor, about 1540. Four years later he was convicted of heresy and sentenced to the stake, but received a pardon through the intervention of Gardiner, bishop of Winchester. In 1550 Marbeck published his *Booke* of *Common Praier noted* intended to provide musical uniformity in the use of the First Prayer Book of Edward VI. Marbeck's object was to provide a "playne tune" for daily officesof the church. His "playne tune" is defined by H. C. Colles (1879–1943), in Grove's *Dictionary* as "neither 'plain-song' in the technical sense (notes of undefined value) nor mensural music (notes of strict value), but a typically English compromise between the two, designed to guide the singer in his new problems of singing an accentual language in place of quantitative language." Other principles triumphed. but in the 19th century hlarbeck's excellent work was recognized. His *Booke* was reprinted in 1844 and the sung Eucharist in the English Church is largely based on his work. Marbeck compiled the first English concordance of the Bible, and several works of a strongly Calvanistic character. He died about 158j.

MARBECK, PILGRAM (*c.* 1490–1556), the outstanding 16th-century South German Anabaptist leader and writer (*see* ANABAPTISTS), was born at Rattenberg in the Inn valley of Tirol. By profession an engineer. he served first as a mining judge at his home town, whence he was expelled in 1528 as an Anabaptist, then as an engineer of water works for the cities of Strasbourg (1528–31, until his expulsion) and Augsburg (1544–56), where he died.

In Strasbourg he emerged as a vigorous Anabaptist leader, at first in close touch with the reformers Martin Bucer, Wolfgang Capito and Zell, with whom he had numerous theological discussions. Marbeck's three major theological works and two small pamphlets. with a total of over 2,000 pages, place him in the ranks of the top Anabaptist writers with the Dutch Menno Simons (*q.v.*) and Dirk Philips and the Hutterite Peter Riedemann. Two of these books, the *Vermahnung* (printed in 1542) and the *Verantwortung* (written in 1544–50 but never printed), both written in collaboration with Leupold Scharnschlager, arose out of his controversy with the spiritualist Kaspar Schwenckfeld. The Anabaptist group led by Marbeck, sometimes called Pilgramites, was never large and was absorbed into the Swiss Brethren about the middle of the 16th century.

MARBLE, DANFORTH (1810–1849), U.S. actor, who was famous for his character roles as a New Englander, was born at East Windsor, Conn., on April 27, 1810. His formal education was limited and he worked as a silversmith in Hartford, Conn , before appearing in minor roles on the New York stage.

Noted for his humorous Yankee dialect, Marble first gained wide popularity in 1836 when he appeared as Sam Patch in a play of the same name by E. H. Thompson. Thereafter Marble's name was associated with that Yankee hero and similar characters, and he performed with great popular success in leading cities on the Mississippi river and in the east. He also won acclaim for his comedy roles in London and in Scotland and Ireland.

Marble was sometimes called the "Game Cock of the Wilderness" (the title of one of his plays dealing with the experiences of a New Englander who travels to the western frontier).

He died in Louisville, Ky., on May 13, 1849.

MARBLE, a metamorphic rock used in many classic sculptures and buildings. Technically, the term (from the Greek *marmaros*, "stone," or "boulder") is restricted to granular limestones and dolomites that have been recrystallized under the influence of heat. pressure and aqueous solutions in metamorphic environments (see METAMORPHISM); commercially, it includes all decorative calcareous rocks that can be polished, as well as certain serpentines (verd antiques).

Marbles in the petrographic sense are massive and consist of a mosaic of calcite grains which under the microscope rarely show any traces of crystalline form but are traversed by minute cracks appropriate to the rhombohedra1 cleavage of calcite. Particularly in the more severely deformed rocks, the grains show stripes indicating polysynthetic twinning and may be elongated perceptibly in a particular direction or even crushed.

These marbles occur very often interbedded with mica schists, phyllites, gneisses and granulites, and are commonest in the older Paleozoic and pre-Cambrian layers of the earth's crust which have been deeply buried in regions of extreme folding and igneous intrusion such as the Appalachian belt of the eastern United States. The passage of limestones rich in fossils into true marbles as they approach such metamorphic regions is a common phenomenon; occasionally the recrystallization of the rock has not completely obliterated the organic structures; *e.g.*, at Carrara, Italy, and at Bergen, Norway.

Most of the white and gray marbles of Alabama, Georgia and western New England and that from Yule, Colo., are recrystallized rocks, as are a number of Greek and Italian statuary marbles famous from antiquity which are still quarried. These include the Parian marble, the Pentelic marble of Attica in which Phidias, Praxiteles and other Greek sculptors executed their principal works and the snow-white Carrara marble used by Michelangelo and Antonio Canova favoured by modern sculptors. The exterior of the National Gallery of Art in Washington, D.C., is of Tennessee marble, and the Lincoln memorial contains marbles from Yule, Colo., Alabama (roof transparencies) and Georgia (Lincoln statue).

Even the purest of the metamorphic marbles, such as that from Carrara, contain some accessory minerals, and in many they form a considerable proportion of the mass. The commonest are quartz in small rounded grains, scales of colourless or pale yellow mica (muscovite and phlogopite), dark shining flakes of graphite, iron oxides and small crystals of pyrite.

Many marbles contain other minerals which ere usually silicates of lime or magnesia. Diopside is very frequent and may be white or pale green; white bladed tremolite and pale green actinolite are found; the feldspar encountered may be a potassic variety, but is more commonly a plagioclase such as albite, labradorite or anorthite. Scapolite, various kinds of garnet, vesuvianite, spinel, forsterite. periciase, brucite. talc, zoisite, wollastonite. chlorite, tourmaline, epidote, chondrodite, biotite, sphene and apatite may be mentioned as possible accessory minerals Pyrrhotite, sphalerite and chalcopyrite may also be present in small amounts.

These minerals represent impurities in the original limestone which reacted during metamorphism to form new compounds. The alumina represents an admixture of clay; the silicates derive their silica from quartz and from clay; the iron came from limonite, hematite or pyrite in the original sedimentary rock. In some cases the original bedding of the calcareous sediments can be detected by mineral banding in the marble. The silicates, if present in any considerable amount, may colour the marble; *e* g., green from green pyroxenes and amphiboles, brown from garnet and vesuvianite, yellow from epidote, chondrodite and sphene. Black and gray colours result from the presence of fine scales of graphite.

Bands of calc-silicate rock may alternate with bands of marble, or form nodules and patches, sometimes producing interesting decorative effects, but these rocks are particularly difficult to finish because of the great difference in hardness between the silicates and carbonate minerals.

Later physical deformation and chemical decomposition of the metamorphic marbles often produces attractive coloured and variegated varieties. Decomposition yields hematite, brown limonite, pale green talc and, in particular, the green or yellow serpentine derived from forsterite and diopside which is characteristic of the ophicalcites or verd antiques. Earth movements may shatter the rocks, producing fissures afterward filled with veins of calcite; in this nay the beautiful brecciated or veined marbles are produced. Sometimes the broke fragments are rolled and rounded by the flow of marble under pressure, and pseudoconglomerates result.

The so-called onyx marbles consist of concentric zones of calcite or aragonite deposited from cold-water solutions in caves and crevices and around the exits of springs. They are, strictly speaking, neither marble nor onyx for true onyx is a banded chalcedony composed largely of silicon dioxide. Onyx marble was the "alabaster" of the ancients, a source of confusion since alabaster now is defined as a calcium sulfate rock (see GYPSUM). These marbles are usually brown or yellow due to the presence of iron oxide.

Well-known examples include the giallo antico ("antique yellow marble") of the Italian antiquaries (see ROME. The Ancient City: .Materials), the reddish-mottled Siena marble from Tuscany, the large Mexican deposits at Técali near Mexico City and at El Marmol. Calif., and the Algerian onyx marble used in the buildings of Carthage and Rome and rediscovered near Oued-Abdallah in 1849.

Unmetamorphosed limestones showing interesting colour contrasts or fossil remains are used extensively for architectural purposes. The Paleozoic rocks of Great Britain for example, include "madrepore marbles" rich in fossil corals and "encrinital marble" containing crinoid stem and arm plates with characteristic circular cross sections. The shelly limestones of the Purbeck formation and the Sussex marble, of Mesozoic age, consist of masses of shells of fresh water snails embedded in blue, gray or greenish limestone. They were a favourite material of medieval architects and may be seen in Westminster Abbey and a number of English cathedrals. Black limestones containing bituminous matter, which commonly emit a fetid odor when struck, are widely used; the well known **petit** granit of Belgium is a black marble containing crinoid stem plates.

Uses.—Marbles are used principally for buildings and monuments, interior decoration, statuary, table tops and novelties. Colour and appearance are the most important qualities overall. Resistance to abrasion, which is a function of cohesion between grains as well as the hardness of the component minerals, is important for floor and stair treads. The ability to transmit light is important for statuary marble, which owes its luster to light penetrating from $\frac{1}{2}$ to $1\frac{1}{2}$ in, and being reflected at the surfaces of deeper-lying crystals. Brecciated, coloured marbles, onyx marble and verd antique are used principally for interior decoration and for novelties. Statuary marble, the most valuable variety, niust be pure nhite and uniform in grain size. For endurance in exterior use marble should be uniform and nonporous to prevent the entrance of water that might discolour the stone or cause disintegration by freezing, and it should be free from impurities such as pyrite that might lead to staining on weathering. Calcite marbles exposed to atmospheric moisture made acid by carbon dioxide and sulfurous and other gases maintain a relatively smooth surface during weathering. but dolomite limestone may weather with an irregular, sandy surface from which the dolomite crystals stand out.

The principal mineral in marbles is calcite (*q.v.*); the fact that calcite varies in hardness, light transmission and other properties in various directions has a number of practical consequences in the preparation of some marbles. Calcite crystals transmit more light in one direction than in others, so that slabs prepared for uses in which translucency is significant are cut parallel to that direction. The bending of marble slabs has been attributed to the directional thermal expansion of calcite crystals on heating. The basal faces of calcite crystals are less rapidly soluble than those at right angles; a number of marble tombstones from the 1800s, cut so as to expose the basal faces, have withstood weathering better than those not so prepared.

Quarrying. — The use of explosives in the quarrying of marble is very limited because of the danger of shattering the rock. Instead, channeling machines utilizing chisel-edged steel bars make cuts about two inches wide and several feet deep. Wherever possible, advantage is taken of natural joints already present in the rock. and cuts are made in the direction of easiest splitting ("rift" or "grain"). which is a consequence of the parallel elongation of platy or fibrous minerals. The marble blocks outlined by joints and cuts are separated by driving wedges in drill holes. Mill sawing into slabs is done with sets of parallel iron blades which move back and forth and are fed by sand and water. The marble may be machined with lathes and carborundum wheels, and is then polished with increasingly finer grades of abrasive. *(See* also QUARRYING.)

Even with the most careful quarrying and manufacturing methods, at least half of the total output of marble is waste. Some of this material is made into chips for terrazzo flooring and stucco n-all finish. It is in various localities put to most of the major uses for which high-calcium limestone is suitable *(see* LIMESTONE).

MARBLEHEAD, a town of Essex county. Mass., U.S., is located 17 mi. N.E. of Boston. Built upon a rocky promontory. the town has narrow, twisted. hilly streets and a character of quaint charm. Among its historic buildings are the Jeremiah Lee mansion (1768). St. Michael's church (Episcopalian; 1714). the Old Brig (*c.* 1720). the Old Tavern (1680) and the Elbridge Gerry house.

Marblehead, originally part of Salem: was first settled in 1629 by a group of rugged fishermen from the Channel Islands and Cornwall, Eng. The village was known for its unruliness and disinclination to abide by many of the laws of the Puritan colony. It was incorporated as a separate town in 1649 and in the colonial period was an important commercial. fishing and shipbuilding port. After the passage of the Boston Port act (1774), it was made the port of entry in place of Boston. but its merchants invited the Boston merchants to use their wharves and warehouses. During the American Revolution many vessels set out from this port. the most famous being the "Lee." commanded by John Manley, which in Nov. 1775 captured the "Nancy," with a valuable and much needed cargo of military stores. The schooner "Hannah." manned and fitted there, was the first American warship regularly commissioned (Sept. 2. 1775. by Gen. George Washington) by authority derived from the continental congress. The port declined in importance after the War of 1812 and in the 19th century Marblehead turned to the manufacture of shoes. rope and cordage. The harbour. formed by a rocky peninsula known as Marblehead Neck, provides safe anchorage for craft of all kinds and has become a noted yachting centre. Marblehead is a suburban, residential and resort town. Manufactures include boats and marine equipment. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (L. G. BA.)

MARBOT, JEAN BAPTISTE ANTOINE MARCELIN, BARON DE (1782–1854), French soldier. son of Gen. Jean Antoine de Marbot (1754–1800), who died in the defense of Genoa under Masséna, was born at La Rivière (Corrèze) on Aug. 18. 1782 He joined the republican army as a volunteer in 1799. He was aide-de-camp to Marshal Xugereau, commanding the VII corps, in the war against Prussia and Russia in 1806–07. After this he served in the Peninsular War under Lannes and Masséna, in the Russian War of 1812 and the German campaign of the following year. After a slow recovery from the wounds he had received at Leipzig and Hanau, he was promoted general of brigade by Napoleon during the Hundred Days, and took part in. and was wounded at, the battle of Waterloo. He was exiled at the second restoration and only returned to France in 1819. His intimacy with the duke of Orleans secured him important military positions. Under the July monarchy he was present at the siege of Antwerp in 1832. He was promoted lieutenant-general in 1836. From 1835 to 1840 he served in various Algerian expeditions. and in 1845 he was made a member of the Chamber of Peers.

Three years later. at the fall of Louis Philippe. Marbot retired into private life. He died at Paris on Nov. 16. 1854. Marbot's fame rests on the fascinating *Memoirs of His Life and Campaigns* (1891; Eng. trans.. 1902).

His elder brother: ANTOINE ADOLPHE MARCELIN DE MARBOT (1781–1844), served in Napoleon's campaigns of 1808 to 1812, and again in the Hundred Days. He returned to the army after 1830.

MARBURG (MARBURG AN DER LAHN), a university town in the *Land* of Hesse. Germany, on the right bank of the Lahn. 60 mi. by rail north of Frankfort-on-Main, on the main line to Cassel. Pop. (1950) 39.530. Marburg is first historically mentioned in a document of the beginning of the 13th century, and received its municipal charter from the landgrave Louis of Thuringia in 1227. By 1247 Marburg had already become the second town of Hesse. and in the 15th and 16th centuries it alternated n-ith Cassel as the seat of the landgraves. In 1529 the famous conference between Luther and Zwingli on the subject of Transubstantiation took place there in the Rittersaal of the Schloss. The hill on nhich the town lies is crowned by the Schloss, a Gothic building. the most noteworthy parts of which are the Rittersaal, dating from 1277–1312. and the little chapel. This Schloss is now the repository of the archives of Hesse. The Elizabethenkirche, in the purest Early Gothic style. was erected by the grand master of the Teutonic Order in 1235–83, to contain the tomb of St. Elizabeth of Hungary. who was the wife of the landgrave Louis. She built a hospital there. and died in 1231, worn out with works of charity. In 1235 she was canonized at the instance of the Teutonic Knights who were zealous in promoting her cult. Her rich silver-gilt sarcophagus may still be seen, but the Protestant zeal of Landgrave Philip the Generous caused him to remove the body to some unknown spot in the church.

The Lutheran church is another Gothic edifice, mainly 15th century. The town hall. built in 1512, and several houses in the Renaissance style. also deserve mention. The University of Marburg, founded in 1527, was the first university established without papal privileges, and acquired a great reputation throughout Protestant Europe.

Marburg is the seat of a district court. Marburg pottery is renowned: and soap. iron wares and surgical instruments are also manufactured there.

MARBURG, COLLOQUY OF, the name given to a conference of divines held in 1529 in the interests of the unity of Protestant Germany. The circumstances in which it mas held, the influence of the-men who conducted its deliberations, and the result of its proceedings, combine to render it of no small importance for the history of the Reformation in Germany.

The measures taken by the Catholic party to resist the progress of the Reformation. especially by resolutions at Speyer (1526 and 1529), would be met only by the united force of all the princes and states subscribing to the Evangelical teaching; and this unity was wanting. The feud which raged round the doctrine of the Lord's Supper had already broken out before the first diet of Spires, and had aroused great and immediate excitement. At a very early period. however. efforts were made to allay the dissension. Strassburg pronounced for conciliation; but the most powerful and zealous champion of peace was to be found in the landgrave Philip of Hesse, who recognized the absolute necessity—from a political standpoint—of the union of all German Protestants. It was obvious that a permanent coalition could not be expected unless some definite understanding on the debated point could be attained; and the landgrave succeeded in bringing about a conference or "colloquy" at Marburg, in October 1529.

The proceedings opened on the 1st of October with conferences between Luther and Oecolampadius, and Melanchthon and Zwingli: then on the two following days the discussion proper—confined almost entirely to Luther and Zwingli—was held before the landgrave and his guest Duke Ulrich of Württemberg, in the presence of more than fifty persons. As regards the main point of contention, *i.e.,* the doctrine of the Lord's Supper, no agreement was found practicable; and the private conversations on the 4th of October, which formed the sequel of the debate, carried matters no farther. Since the landgrave, however, was reluctant to see the colloquy brought to an absolutely fruitless close, he requested Luther to draw up a list of the most important points of doctrine on which it might yet be possible to arrive at some degree of unanimity. This was done on the 4th of October; and a few alterations were introduced to meet the wishes of the Swiss deputies. The *Articles of Marburg*, which thus came into being, contain the doctrine of the Trinity, of the personality of Christ, of faith and justification, of the Scriptures, of baptism, of good works, of confession, of government, of tradition and of infant baptism. The fifteenth article, treating of the Lord's Supper, defines the ground common to both parties even in this debatable region, recognizing the necessity of participation in both kinds, and rejecting the sacrifice of the Mass. It then proceeds to fix the point of difference in the fact that no agreement had been reached on the question "whether the true body and blood of Christ are corporeally present in the bread and wine."

See T. Kolde, *s.v.* "Marburger Religionsgespräch," in *Realencyklopädie f. protestant. Theologie,* 3rd ed. xii. 248 *seq.*

MARC, FRANZ (1880–1916), German painter, one of the leaders of the "Blue Rider" Expressionist movement, was born in Munich on Feb. 8, 1880. His father was a minor landscape and genre painter. Marc studied at the Munich academy under Wilhelm Diez. A trip to Paris in 1903 brought him into contact with Impressionism, while the Art Nouveau movement in Munich made him conscious of the problems of formal structure. Perhaps the strongest influence on his early work was Van Gogh, but he did not fulfill the potentialities of his genius until he discovered the nonobjective paintings of Wassily Kandinsky (*q.v.*) with their pure colour and form. In 1911 he and Kandinsky edited the book *Der Blaue Reiter,* one of the great documents of modern art. The almanac also gave its name to a significant movement in Expressionism: the "Blue Rider." Whereas Kandinsky renounced the objective, Marc was drawn to nature, especially the animal motif, in which he sought a pantheist empathy with the vibrations and rhythms of nature. In 1913 and 1914 he created his most important paintings, "The Tower of Blue Horses," the "Fate of the Beasts" and "The Unhappy Tyrol." Influenced by nonobjectivity, Cubism and Futurism, he worked with sonorous colours and crystalline forms which interpenetrate to create an organic harmony. He used colour and form to dismantle the material and the objective and to help create the world of the spirit. Finally, he painted a series of entirely nonobjective paintings. In 1914 Marc joined the German army; he was killed near Verdun on March 4, 1916.

MARCA, PIERRE DE (1594–1662), French prelate and historian, born at Gan, near Pau, on Jan. 24, 1594, attracted the notice of Richelieu by his support of the Catholic cause in the south during the wars of religion. Richelieu brought him to Paris as counsellor of state in 1640. He defended the "Gallican liberties" in the famous treatise. *De concordia sacerdotii et imperii, seu de libertatibus ecclesiae gallicanae* (1641). He was governor of Catalonia during the French occupation and, after holding various ecclesiastical preferments, was nominated archbishop of Paris in succession to De Retz in February 1662. He died on June 29 of the same year. Marca made a minute study of the archives of Béarn and of the history of Catalonia. His *Histoire de Béarn* (1640) is valuable for the number of charters and other documents which it contains. *Marca hispanica* (1688), left unfinished at his death, was completed by his friend Baluze.

MARCANTONIO (MARCANTONIO RAIMONDI): *see* RAIMONDI, MARCANTONIO.

MARCASITE, a mineral with the same chemical composition as pyrite, being iron disulfide, FeS_2, but crystallizing in the orthorhombic instead of the cubic system. Apart from crystalline form, the appearance and physical characteristics of marcasite (sometimes known as white iron pyrite) are very similar to those of pyrite, and in the absence of distinct crystals it is difficult to distinguish between the two species. The colour is pale bronze-yellow; on freshly fractured surfaces the colour is tin-white, but this rapidly tarnishes on exposure to air. The lustre is metallic and brilliant; the streak is greyish black; the hardness is 6 to 6.5; the specific gravity is 4.89. In the course of time. specimens of marcasite usually disintegrate, forming ferrous sulfate and sulfuric acid. In nature marcasite is frequently altered to hydrated iron oxide. goethite (*q.v.*) or limonite (*q.v.*). Under weathering conditions it is less stable than pyrite.

Distinctly developed single crystals of marcasite are rare; more often crystal aggregates occur twinned on a prism plane producing pentagonal stellate groups of fine crystals. This frequent twinning gives rise to characteristic forms, with many re-entrant angles, to which the names "spear pyrites" and "cockscomb pyrites" are applied. The commonest state of aggregation is that of radially arranged fibres, the external surface of the mass being globular, nodular or stalactitic in form.

Marcasite is found in metalliferous veins associated with lead and zinc ores (Joplin, Mo.; Galena, Ill.). It is frequently found in sedimentary deposits. In the chalk of the southeast of England nodules of marcasite with a fibrous radiated structure are abundant, and in the chalk marl between Dover and Folkestone fine twinned groups of "spear pyrites" are common. Marcasite is often associated with organic matter: for example, as a concretion around organic remains; or in the plastic clay of the brown coal formation at Littnitz, near Carlsbad (Karlovy Vary), Czech., where it has been extensively mined for the manufacture of sulfur and ferrous sulfate. (A. J. F.)

MARCEAU, FRANÇOIS SEVERIN DESGRAVIERS (1769–1796), French general, was born at Chartres on March 1, 1769. He studied law, but joined the army in 1785. He joined in the attack on the Bastille (July 14, 1789), and then took his discharge from the regular army. Later he joined the National Guard, and in March 1792 became lieutenant-colonel of a battalion of the Eure-et-Loire, taking part in the defence of Verdun in 1792. He was re-employed as captain in the regular service, but in 1793 was imprisoned for some time with other officers as a "suspect." On his release he fought at Saumur against the Vendéen royalists, and rescued Bourbotte (June 10, 1793) from the insurgents Marceau became general of division (Nov. 10), and with Kléber, who became his personal friend, won important victories near Le Mans (Dec. 12–13) and Savenay (Dec. 21), but after their retirement from the war they were only saved from arrest and execution by the intervention of Bourbotte. After spending the winter of 1793–94 in Paris, Marceau took command in the army under Jourdan in which Kléber also served, and distinguished himself in the campaigns of 1794 and 1795. In the campaign of 1796 Marceau's men covered Jourdan's retreat over the Rhine. He fought the desperate actions on the Lahn (Sept. 16 and 18), and at Altenkirchen on Sept. 19 received a mortal wound, of which he died on the 21st. His body was burned, and his ashes, which at the time were placed under a pyramid designed by Kléber, were transferred in 1889 to the Panthéon at Paris.

See Maze, *Le Général Marceau* (1888); Parfait, *Le Général Marceau* (1892); and T. C. Johnson, *Marceau* (London, 1896).

MARCEL, ETIENNE (d. 1358), provost of the merchants of Paris under King John II, came from a family of drapers. He is mentioned as provost of the Grande-Confrérie of Notre Dame in 1350. In 1354 or 1355 he succeeded Jean de Pacy as provost of the Parisian merchants. His political career began in 1356, when John was made prisoner after the battle of Poitiers. In conjunction with Robert le Coq, bishop of Laon, he played a leading part in the states-general called together by the dauphin Charles (later Charles V of France) on Oct. 17. A committee of 80 members, constituted on their initiative, pressed their demands with such insistence that the dauphin prorogued the states-general; but financial straits obliged him to summon them once more on Feb. 3, 1357, and the promulgation of an edict of reform was the consequence. John forbade its being put into effect, whereupon a conflict began between Marcel and the dauphin, Marcel endeavouring to set up Charles II of Navarre in opposition to him. The states-general assembled again on Jan. 13. 1358. and on Feb. 22 the populace of Paris, led by Marcel, invaded the palace and murdered the marshals of Champagne and Normandy before the prince's eyes. Thenceforward Marcel was in open hostility to the throne. After vainly hoping that the insurrection of the Jacquerie might turn to his advantage, he next supported the king of Navarre, whose armed bands infested the neighbourhood of Paris. On the night of July 31 Marcel was about to open the gates to them, but Jean Maillart prevented the execution of this design and excited the mob that killed Marcel before the Porte Saint-Antoine.

Frémaux, "La Famille d'Etienne Marcel." in the *Mémoires de la société de l'histoire de Paris et de l'Ile de France,* vol xxx (Paris, 1903); R. Delachenal, *Histoire de Charles V*, vol. i (Paris, 1908).

MARCELLINUS, ST., according to the Liberian catalogue, became bishop of Rome on June 30, 296; his predecessor was Caius or Gaius. He is not mentioned in the *Martyrologium hieronymianum,* or in the *Depositio episcoporum,* or in the *Depositio martyrum.* The *Liber pontificalis,* basing itself on the Acts of St. Marcellinus, the text of which is lost, relates that during Diocletian's persecution Marcellinus was called upon to sacrifice, and offered incense to idols, but that, repenting shortly afterward, he confessed the faith of Christ and suffered martyrdom with several companions. According to the *Liber pontificalis,* Marcellinus was buried, on April 26, 304, in the cemetery of Priscilla, on the Via Salaria, 2j days after his martyrdom; the Liberian catalogue gives as the date Oct. 2j. After a considerable interregnum he was succeeded by Marcellus, with whom he has sometimes been confounded.

See L. Duchesne, *Liber pontificalis,* I, lxxiii–lxxiv, 162–163, and II, 563.

MARCELLO, BENEDETTO (1686–1739). Italian composer, was born in Venice on Aug. 1, 1686. He was a pupil of Lotti and Gasparini, but was intended by his father for the law. In 1711 he was a member of the Council of Forty, and in 1730 went to Pola as *provveditore.* He retired after eight years to Brescia in the capacity of *camerlingo,* and died there on July 24, 1739. Being of patrician birth, he never held any official musical appointment. Marcello is best remembered for his *Estro poetico-armonico* (Venice, 1724–26), a musical setting for voices and strings of the first 50 psalms, as paraphrased in Italian by G. Giustiniani. Charles Avison and John Garth brought out an edition with English words (London, 17j7). His other compositions include the opera *Arianna,* the oratorio *Giuditta,* concertos (1701), *Canzoni madrigaleschi* (1717) and cantatas. He was also a poet, translated John Dryden's *Timotheus* as a text for one of his cantatas, wrote a libretto for Ruggieri's opera *Arato in Sparta* and a satirical pamphlet, *Il teatro alla moda* (1720) which is still one of the most important early documents in the history of opera.

A catalogue of his works is given in *Monatshefte fur Musikgeschichte,* vol. xxiii (Berlin, 1891).

MARCELLUS, the name of two popes.

MARCELLUS I, pope and saint, was elected to succeed Marcellinus, after an interval of three or four years, either in 307 or as late as May 308, during the reign of the Roman emperor Maxentius. The severe penances that he imposed on Christians who had lapsed under the recent persecution led to rioting, and he was banished from Rome early in 309. He died shortly afterward and is commemorated in the Western Church on Jan. 16.

MARCELLUS II (Marcello Cervini). born on May 6, 1501, was made cardinal priest of Sta. Croce in Gerusalemme by Paul III in 1539. As one of Paul's legates presiding at the first sessions (1545–47) of the Council of Trent, he incurred the anger of the emperor Charles V by his jealous defense of papal prerogative. Elected pope on April 9, 1555, in succession to Julius III, he died three weeks later, on April 30.

MARCELLUS, a Roman plebeian family belonging to the Claudian gens. Its most distinguished members were:

MARCUS CLAUDIUS MARCELLUS (*c.* 268–208 B.C.), one of the Roman generals during the Second Punic War and conqueror of Syracuse. He first served against Hamilcar in Sicily. In his first consulship (222) he was engaged, with Gnaeus Cornelius Scipio as colleague, in war against the Insubres and won the *spolia opima* for the third and last time in Roman history by slaying their chief Viridomarus or Virdumarus (Polybius ii, 34; Propertius v, 10, 39). In 216. after Cannae. he took command of the remnant of the army at Canusium and, although he was unable to prevent Capua's going over to Hannibal, saved Nola and southern Campania. Consul for the third time in 214 he was sent to Sicily, where he stormed Leontini and besieged Syracuse. but the skill of Archimedes repelled his attacks. He took it after a two years' siege and set the example of carrying away the art treasures of a captured city. Consul again in 210, he took Salapia in Apulia, which had revolted to Hannibal; and as proconsul, in 209, he attacked Hannibal near Venusia. In his last consulship (208), he and his colleague, while reconnoitring near Venusia, were unexpectedly attacked, and Marcellus was killed. His successes have been exaggerated by Livy, but the name often given to him, the "sword of Rome," was well deserved.

See Livy xxiii, 14–17, 41–46; xxiv, 27–32, 35–39; xxv, 5–7, 23–31; xxvi, 26, 29–32; xxvii, 1–5, 21–28; Polybius viii, 5–9, x, 32; Appian, *Hannibal,* 50; Florus ii, 6.

M. CLAUDIUS MARCELLUS, an inveterate opponent of Julius Caesar. During his consulship (51 B.C.) he proposed to remove Caesar from his army in March 49, but was outmanoeuvred by Curio. He scourged a citizen of Novum Comum in order to flout Caesar's grant of privilege to the city. In Jan. 49 he vainly tried to put off declaring war against Caesar until an army could be got ready. He followed Pompey to Greece and. after Pharsalus, retired to Mytilene, where he practised rhetoric and studied philosophy. In 46 the senate successfully appealed to Caesar to pardon him, this being the occasion of Cicero's speech *Pro Marcello.* Marcellus left for Italy, but was murdered in May by one of his own attendants, P. Magius Chilo, at the Peiraeus. Marcellus was a thorough aristocrat. He was an eloquent speaker (Cicero, *Brutus,* 71) and a man of firm character. although not free from avarice.

See Cicero, *ad Familiares,* iv, 4, 7, 10, and *ad Atticum,* v, 11; Caesar, *De Bello Gallico* i, 2; Suetonius, *Caesar,* 29; G. Boissier, *Cicero and his Friends,* Eng. trans. (London, 1897).

M CLAUDIUS MARCELLUS (*c.* 42–23 B.C), son of C. Marcellus and Octavia, sister of Augustus. In 25 he was adopted by the emperor and married to his daughter Julia. This seemed to mark him out as the heir to the throne. In 2j he accompanied the emperor to Spain; but in 23, when curule aedile, he died at Baiae. Great hopes had been built on the youth, and he was celebrated by many writers, especially by Virgil in a famous passage (*Aeneid,* vi, 860). He was buried in the Mausoleum of Augustus, and hugustus himself pronounced the funeral oration. The Theatrum Marcelli was afterward dedicated in his honour.

See Horace, *Odes,* i, 12; Propertius iii, 18; Dio Cassius liii, 28, 30; Tacitus, *Annals,* ii, 41; Suetonius, *Augustus,* 63; Velleius Paterculus ii, 93.

MARCH, AUSIAS (1379–1459), Catalan poet, was born at Valencia. An undisguised follower of Petrarch, he carries the imitation to such a point that he addresses his *Cants d'amor* to a lady whom he professes to have seen first in church on Good Friday; so far as the difference of language allows. he reproduces the rhythmical cadences of his model, and in the *Cants de mort* touches a note of brooding sentiment peculiar to himself. The success of his metrical innovation no doubt encouraged Boscán (*q.v.*) to introduce the Italian metres into Castilian.

9. Napoleon pray, Central United States

MARCH EARLS OF, title derived from the "marches" or boundaries (1) between England and Wales, and (2) England and Scotland, and held severally by great feudal families possessed of lands in those border districts. The earls of March on the Welsh borders were descended from Roger de Mortemer (so called from his castle of Mortemer in Normandy), who was connected by marriage with the dukes of Normandy. His son Ralph (d. *c.* 1104) figures in Domesday as the holder of vast estates in Shropshire, Herefordshire and other parts of England, especially in the west; and his grandson Hugh de Mortimer, founder of the priory of Wigmore, Herefordshire, was one of the most powerful of the barons reduced to submission by Henry II. The Mortimers, however, continued to exercise almost undisputed sway, as lords of Wigmore, over the western counties and the Welsh marches.

I. Welsh Marches.—ROGER DE MORTIMER (*c.* 1286–1330), 8th baron of Wigmore and 1st earl of March, being an infant at the death of his father, Edmund, was placed by Edward I. under the guardianship of Piers Gaveston, and was knighted by Edward in 1306. Through his marriage with Joan de Joinville, or Genevill, Roger acquired increased possessions on the Welsh marches, including the important castle of Ludlow, and extensive estates in Ireland, whither he went in 1308 to enforce his authority. This brought him into conflict with the De Lacys, who turned for support to Edward Bruce, brother of Robert Bruce, king of Scotland. Mortirner was appointed lord-lieutenant of Ireland by Edward II. in 1316, and at the head of a large army drove Bruce to Carrickfergus, and the De Lacys into Connaught. About 1318 he began to interest himself in the growing opposition to Edward II. and his favourites, the Despensers; and he supported Humphrey de Bohun, eari of Hereford, in refusing to obey the king's summons to appear before him in 1321. Forced to surrender to the king at Shrewsbury in 1322, Mortirner was consigned to the Tower of London, whence he escaped to France in Aug. 1324. At the French court Queen Isabella found Roger Mortimer; she became his mistress and refused to return to England so long as the Despensers retained power as the king's favourites. Isabella's relations with Mortimer compelled them to withdraw to Flanders, where they obtained assistance for an invasion of England. Landing in England in 1326, they were joined by Henry, earl of Lancaster; London rose in support of the queen; and Edward took flight to the west, where he was captured in November, and compelled to abdicate in favour of his son. The country was now ruled by Mortimer and Isabella, who procured the murder of Edward II. in the following September. In 1328 Mortimer was created earl of March. The jealousy of Lancaster having been excited by March's arrogance, Lancaster prevailed upon the young Edward III., to throw off the yoke of his mother's paramour. March was arrested and conveyed to the Tower. Accused of assuming royal power and of various other high misdemeanours, he was condemned without trial and hanged on Nov. 29, 1330, his vast estates being forfeited to the Crown. His eldest son, Edmund. was father of Roger Mortimer (*c.* 1328–60), who was knighted by Edward III. in 1346, and restored to his grandfather's title as 2nd earl of March.

EDMUND DE MORTIMER (1351–1381), 3rd earl of March, was son of Roger, 2nd earl of March, by his wife Philippa, daughter of William Montacute, 1st earl of Salisbury. Being an infant at the death of his father, Edmund, as a ward of the Crown, was placed by Edward III. under the care of William of Wykeham and Richard Fitzalan, earl of Arundel. The young earl married in 1368 Philippa, only daughter of Lionel, duke of Clarence, and of Elizabeth, daughter and heiress of William de Burgh, 6th lord of Connaught and 3rd earl of Ulster. The earl of March, therefore, not only became the representative of one of the chief Anglo-Norman lordships in Ireland in right of his wife Philippa, but the latter, on the death of her father shortly after her marriage, stood next in succession to the crown after the Black Prince and his sickly son, afterwards King Richard II. This marriage had, therefore, far-rezching consequences in the history of England, giving rise to the claim of the house of York to the crown of England, contested in the Wars of the Roses. He died at Cork in 1381. The earl had two sons and two daughters, the elder of whom, Elizabeth, married Henry Percy (Hotspur), son of the earl of Northumberland. His eldest son Roger succeeded him as 4th earl of March and Ulster.

ROGER DE MORTIMER, 4th earl of March and Ulster (1374–98), succeeded to the titles and estates of his family when a child of seven, and a month afterwards he was appointed lord-lieutenant of Ireland. March's daughter Anne married Richard earl of Cambridge, son of Edmund duke of York, fifth son of Edward III.; their son Richard, duke of York, was father of King Edward IV., who thus derived his title to the crown and acquired the estates of the house of Mortimer.

EDMUND DE MORTIMER (1391–1425), 5th earl of March and Ulster, son of the 4th earl, succeeded to his father's claim to the crown as well as to his title and estates. When Richard II. was deposed and the crown seized by Henry of Lancaster in 1399, the young earl of March and his brother Roger were kept in custody by Henry IV., who, however, treated them honourably, until March 1405, when they were carried off by the opponents of the Lancastrian dynasty, of whom their uncle Sir Edmund Mortimer and his brother-in-law Henry Percy (Hotspur) were leaders in league with Owen Glendower. The boys were recaptured, and in 1409 were committed to the care of the prince of Wales. On the accession of the latter as Henry V., in 1413, the earl of March was restored to his estates, his brother Roger having died some years previously; and he continued to enjoy the favour of the king in spite of a conspiracy in 1415 to place him on the throne. March accompanied Henry V. throughout his wars in France, and on the king's death in 1422 became a member of the council of regency. He died in Ireland in 1425, and as he left no issue the earldom of March in the house of Mortimer became extinct, the estates passing to the last earl's nephew Richard, who in 1435 was officially styled duke of York, earl of March and Ulster, and baron of Wigmore. Richard's son Edward having ascended the throne in 1461 as Edward IV., the earldom of March became merged in the crown.

See T. Rymer, *Foedera*, etc. (1704–32); T. F. Tout, *The Political History of England*, vol. iii., ed by W. Hunt and R. L. Poole (1905); W. Dugdale, *Monasticon anglicanum* (3 vols., 1655–73); W. Stubbs, *Constitutional History of England* (1874–78), vol. ii.

II. Scottish Marches.—The Scottish earls of March were descended from Crinan, whose son Maldred married Algitha, daughter of Ughtred, earl of Northumberland, by Elgiva, daughter of the Saxon king Aethelred. Maldred's son Cospatric, or Gospatric, was made earl of Northumberland by William the Conqueror; but being soon afterwards deprived of this position he fled to Scotland, where Malcolm Canmore, king of Scotland, granted him Dunbar and adjoining lands. Two generations of Cospatrics followed in lineal succession, bearing the title of earl, but without territorial designation. Cospatric II witnessed the charter of Alexander I founding the abbey of Scone in 1115. The 3rd earl, also named Cospatric, a liberal benefactor of Melrose abbey, died in 1166, leaving two sons, the younger of whom was the ancestor of the earls of Home. The elder son, Waltheof, was the first of the family to be styled "comes de Dunbar," about 1174. He was one of the hostages for the performance of the Treaty of Falaise for the liberation of William the Lion in 1175. Waltheof's son Patrick Dunbar (the name Dunbar, derived from the family estates, now becoming an hereditary surname), styled 5th earl of Dunbar, although his father had been the first to adopt the territorial designation, was keeper of Berwick castle, and married Ada, natural daughter of William the Lion. His grandson Patrick, 7th earl, headed the party that liberated King Alexander III. in 1255 from the Comyns, and in the same year was nominated guardian of the king and queen by the Treaty of Roxburgh. He signed the Treaty of Perth (July 6, 1266) by which Magnus VI. of Norway ceded the Isle of Man and the Hebrides to Scotland. His wife was Christian, daughter of Robert Bruce.

PATRICK DUNBAR, 8th earl of Dunbar and 1st earl of March, claimed the crown of Scotland in 1291 as descendant of Ada, daughter of William the Lion. He was one of the "seven earls of Scotland," a distinct body separate from the other estates of the realm, who claimed the right to elect a king in cases of disputed succession. He was the first of the earls of Dunbar to appear in the records as "comes de Marchia," or earl of March. He was favourable to the English interest in Scottish affairs, and he did homage to Edward I. In 1298 he was appointed the English king's lieutenant in Scotland.

PATRICK DUNBAR (1285–1369), 9th earl of Dunbar and and earl of March, son of the preceding, gave refuge to Edward II. after Bannockburn, and contrived his escape by sea to England. Later, he made peace with Robert Bruce, and by him was appointed governor of Berwick castle, which he held against Edward III. until the defeat of the Scots at Halidon Hill (July 19, 1333). His countess, known in Scottish history and romance as "Black Agnes," daughter of Thomas Randolph, earl of Moray (Murray), and grandniece of Robert Bruce, is famous for her defence of Dunbar castle against the English under the earl of Salisbury in 1338. This lady succeeded to the estates and titles of her brother, John Randolph, 3rd earl of Moray. The earldom of Moray passed after her death to her second son, John Dunbar, who married Marjory, daughter of King Robert II.

GEORGE DUNBAR (d. 1420), 10th earl of Dunbar and 3rd earl of March, great-nephew of the 8th earl and warden of the marches, accompanied Douglas in his foray into England in 1388, and commanded the Scots after Otterburn. He afterwards quarrelled with the Douglases, and when his lands were seized, fled to England, where he was welcomed by Henry IV. He fought on the English side at Homildon Hill; and, having revealed to Henry the defection of the Percies, who were in league with Douglas and Owen Glendower, he fought against those allies at Shrewsbury (July 23, 1403). Becoming reconciled with Douglas, he returned to Scotland in 1409, and was restored to his earldom by the regent Albany.

GEORGE DUNBAR, 11th earl of Dunbar and 4th earl of March, was one of the negotiators for the release of James I. of Scotland in 1423 from his captivity in England, and was knighted at that king's coronation. In 1434, however, on the ground that the regent had had no power to reverse his father's forieiture for treason, March was imprisoned and his castle of Dunbar seized by the king; and the parliament at Perth declared his lands and titles forfeited to the Crown.

The earldom of March in the house of Dunbar having thus been forfeited to the Crown, James II. in 1455 conferred the title, together with that of warden of the marches, on his second son Alexander, duke of Albany; but this prince entered into treasonable correspondence with Edward IV. of England, and in 1487 the earldom of March and the barony and castle of Dunbar were again annexed to the crown of Scotland.

The title of earl of March was next held by the house of Lennox. (*See* RICHMOND, EARLS AND DUKES OF; and LENNOX.)

The title of earl of March in the peerage of Scotland, by another creation, was conferred in 1697 on William Douglas, second son of William, 1st duke of Queensberry. (*See* QUEENSBERRY, EARLS, MARQUISES AND DUKES OF.)

See Andrew Lang, *History of Scotland* (4 vols., 1900–07); Sir Bernard Burke, *A Genealogical History of Dormant and Extinct Peerages* (1866); Sir Robert Douglas, *The Peerage of Scotland* (2 vols., 1813); Lady Elizabeth Cust, *Some Account of the Stuarts of Aubigny in France* (1891).

MARCH, FRANCIS ANDREW (1825–1911), U.S. philologist, lexicographer and educator, whose special field of study was the English language, was born on Oct. 25, 1825, in Millbury, Mass. He graduated in 1845 from Amherst college, where his attention was turned to the study of Anglo-Saxon by Noah Webster After teaching in secondary schools and at Amherst, he went in 1855 as a tutor to Lafayette college, Easton, Pa., where in 1857 he became professor of English language and comparative philology—the first chair of the kind established. In 1907 he became professor emeritus.

In 186j he published *Method of Philological Study of the English Language,* and in 1870 *A Comparative Grammar of the Anglo-Saxon Language,* a monumental work, and *An Anglo-Saxon Reader,* both marking a new era in the study of English in America. To the "Douglass Series of Christian Greek and Latin Classics," which he edited, he contributed *Latin Hymns* (1874). In 1879–82 March nas director of the American readers for the Philological Society's *New English Dictionary.* His article "On Recent Discussions of Grimm's Law" in the *Transactions and Proceedings* of the American Philological association for 1873 in large part anticipated Verner's law. With his son, Francis Andrew March, (1863–1928), who was also a professor at Lafayette and a noted lexicographer, he edited *A Thesaurus Dictionary of the English Language* (1903). March died in Easton, Pa., on Sept. 9, 1911. Peyton Conway March (*q.v.*) was also his son.

MARCH, PEYTON CONWAY (1864–1955), U.S. soldier, was born at Easton, Pa., on Dec. 27, 1864. He graduated from Lafayette college, Easton, in 1884 and four years later from the U.S. Military academy, West Point, N.Y. March graduated from the artillery school in 1898, and on the outbreak of the Spanish-American War went to the Philippines, remaining there three years and rising to the grade of lieutenant colonel of volunteers. After honourable discharge from the volunteers in 1901, he was appointed captain of artillery in the regular army. From 1903 to 1907 he was a member of the general staff and in 1904, during the Russo-Japanese War, was with the Japanese army in Manchuria as observer. He was promoted to major in 1907, lieutenant colonel in 1912 and colonel in 1916. Soon after the entrance of the U.S. into World War I in 1917, he was made a brigadier general, U.S.A., and later major general of the national army and, in Sept. 1917, major general of the regular army. In 1917 he was with the A.E.F. in France in charge of the U.S. artillery forces. In March 1918 he was appointed acting chief of staff, and the following May chief of staff with the rank of general. On June 30, 1920, his rank reverted to that of major general, and at his own request he was retired irom active service Nov. 1, 1921. As chief of staff of the army, March reorganized the war department and consolidated the regular army, national guard and national army divisions into a single army—the U.S. army. March died April 13, 1955, in Washington, D.C.

MARCH, an urban district in the Isle of Ely county constituency, Cambridgeshire, Eng., 30 mi. N. of Cambridge by road. Pop. (1951) 12,996. Area 30.9 sq.mi. It lies on a ridge in the fen country and the tower of the town hall (headquarters of the Isle of Ely county council) is a landmark for miles. St. Wendreda's church, dating from *c.* 1343, has a 16th-century double hammer-beam roof; the grammar school was founded in 1696. March is an agricultural and market centre, mainly for root crops, and with a sugar-beet factory. The five railways converging at March superseded the old Nene river as a means of transport.

MARCH (Lat. *Martius),* the third month of the modern calendar, has 31 days. According to tradition the earliest Roman calendar, ascribed to Romulus, had only ten named months, March through December, the "dead season" of midwinter being left undesignated; to these ten January and February were later added by Numa Pompilius. Though the historical evidence for these early calendars is disputed, it is clear, if only from the names of the numbered months (*e.g.* December, "tenth month"), that March was originally the first month, the starting point for the annual cycle of religious festivals. It was only in or after 153 B.C., when Jan. 1 was finally fixed as the date for new magistrates to take office. that the civil calendar prevailed over the religious, and January thus came to be regarded as the first month. Since early spring was the season for renewed activity both in agriculture and in warfare, March was appropriately named for the god Mars, who seems to have been originally both a god of war and the protector of vegetation.

Memorable dates in this month include March 1j ("the Ides of March"), on which Julius Caesar was assassinated, and St. Patrick's day, March 17. Since the Council of Nicaea (A.D. 325) the date of Easter, the chief movable feast of the Christian calendar, has been calculated from the vernal equinox, reckoned as March 21. Until the passage of the 20th amendment to the Constitution, presidents of the United States were normally inaugurated on March 4. This amendment, adopted in 1933, modified the provisions of the 12th amendment and set the date for the inauguration on Jan. 20. (F. R. WN.)

MARCHAND, JEAN BAPTISTE (1863–1934), French general and African explorer, was born at Thoissey (Ain) on Nov. 22, 1863. After four years' service in the ranks. he was, in 1887, appointed a sublieutenant. In 1889 he was on active service in Senegal. was twice wounded, and made a chevalier of the Legion of Honour. In 1898 he carried out his historic occupation of Fashoda *(see* EGYPT: *Modern History)* and for this he was promoted to commander in the Legion of Honour. In 1902 he was made colonel and shortly after the outbreak of war in 1914 he was appointed to command the colonial brigade of the 14th corps, and in 1915 was promoted a temporary general of brigade. A few months later he assumed command of the 10th (colonial) division and was wounded in Sept. 1915. On April 4. 1917, he was promoted general of division. He retired in 1919, and received the grand cross of the Legion of Honour in 1920. Marchand died Jan. 14, 1934.

MARCHAND, JEAN HIPPOLYTE (1883–1941), French painter. was born in Paris on Nov. 22, 1883. He studied with Leon Bonnat and Luc Merson (1902–06), but deserted conventional styles, and exhibited at the Salon des Indépendants in 1908. He visited Russia and England on several occasions. Though Marchand came under the influence of Cubism between 1910 and 1912, his work was not greatly affected by it. His human forms are treated with power and discretion, while his landscapes and still life are tinged with an intense melancholy. He died in Paris on Oct. 10, 1941.

MARCHE, or LA MARCHE. a former province of France. Geographically it corresponds to the northern part of Limousin, from which it was detached in the 10th century by the overlords, the counts of Poitiers, to form a military march or border district against the Norman invaders coming from the Loire valley (whence its frequent name of Marche Limousine). It had no precise borders and was originally made of two different districts. Haute Marche in the east along the Creuse, around Guéret, and Basse Marche in the west, on the Vienne, around Charroux, Le Dorat and Bellac. They were nearly separated by fiefs held directly from the counts of Poitiers (Bridiers, Peyrat, Bourganeuf) and episcopal lordships (Bénévent. Le Grand-Bourg-de-Salagnac). Its neighbours, Poitou, Berry, Bourbonnais and Auvergne. encroached on its territory, annexing Combrailles. Boussac and Gouzon. Later on, in the 13th century, it was increased by the union of Ahun and the viscounty of Aubusson, after which it remained unaltered until the Revolution. It embraced the greater part of the modern department of Creuse, a considerable part of northern Haute-Vienne and a fragment of Indre.

La Marche had been given in the middle of the 10th century by William III. duke of Aquitaine. to Boso the Old. head of the house of Charroux, who took the title of count. In 1091, by the marriage of Adalmadis of Charroux with Roger of Montgommery, it passed to the house of Montgommery, which kept it until 1177, when Audibert of Montgommery sold it to Henry II. It was thenceforth under the English king until 1199, when King John gave it to Hugh IX of Lusignan, but next year John tried to take it back, having quarrelled with the Lusignans. Hugh X of Lusignan made an alliance with Henry III during the minority of Louis IX but was obliged, after the battles of Taillebourg and Saintes (1242), to submit to the French king and to recognize Alphonse of Poitiers as overlord. Hugh XIII died childless in 1303, and Philip IV of France united the county to the crown in 1308. In 1311, however, it nas made an apanage for Philip's third son, Charles (afterward King Charles IV). for whom Philip V elevated it to the rank of *comté-pairie* in 1316 and who reunited it to the crown for a few years (1322–27) and then gave it to Louis of Bourbon. The Bourbon family held it for the next two centuries, except the years from 143j to 1477, when it was owned by the family of Armagnac. In 1527, after the treason of the constable of Bourbon, Francis I confiscated it and made it part of the domain of the French crown. During the two last centuries of the monarchy. Marche lost its unity. Haute Marche becoming part of the *généralité* of Moulins, Basse Marche part of that of Limoges. But the whole province was under the jurisdiction of the *parlement* of Paris, while Limousin depended from Bordeaux. Agriculture was subsequently developed, as in Limousin (*q.v.*), but Marche has no industry except the famous manufactures of tapestry at Aubusson, which started in the 14th century. (F. CT.)

MARCHES, THE (or MARCHE), a territorial division (region) of Italy, embracing from north to south the provinces of Pesaro and Urbino, Ancona, Macerata, and Ascoli Piceno. Pop. 1,364,030 (1951). It is bounded by Emilia on the north, the Adriatic on the east, the Abruzzi on the south, and Umbria and Tuscany on the west. The chief rivers, all of which run into the Adriatic eastward and northeastward, are the Metauro (anc. *Metaurus, q.v.*) and the Tronto (anc. *Truentus),* the latter forming the southern boundary of the Marches for some distance. Except for the river valleys and the coast strip (often very narrow), the general level is more than 500 ft. above the sea. The lower hills are largely composed of loose, clayey, unstable earth, while the Apennines are of limestone. The province of Pesaro and Urbino falls within the boundaries of the ancient Umbria (*q.v.*), while the territory of the other three belonged to Picenum (*q.v.*). The railway from Bologna to Brindisi runs along the coastline of the entire territory.

At Fano there is a branch to Fermignano, on the line from Fabriano to Urbino; at Falconara, near Ancona, it is joined by the main line from Foligno and Rome; at Porto Civitanova is a branch to Macerata, San Severino and Fabriano (a station on the line from Ancona to Rome and the junction for Urbino): at Porto S. Giorgio is a branch to Fermo and Amandola, and, at Porto d'Ascoli, a branch to Ascoli Piceno.

History.—For early history of the territory of the Marches, *see* PICENUM. From the Carolingian period onward the name Marca begins to appear—first Marca Fermana for the mountainous part of Picenum, Marca Camerinese for the district farther north, including a part of Umbria, and Marca Anconitana for the former Pentapolis. In 1080 Marca Anconitana was given in investiture to Robert Guiscard by Gregory VII, to whom the countess Matilda ceded the Marches of Camerino and of Fermo. In 1105 we find the emperor Henry IV investing Werner with the whole territory of the three marches under the name of March of Ancona. It was afterward once more recovered by the church and governed by papal legates. It became part of the kingdom of Italy in 1860. Pictorial art of the Marches since the 13th century has become the object of considerable interest.

Agriculture and Industry.—Owing largely to the *métayage* system the soil is fairly highly cultivated.

Silk industries, making of strawplait and straw hats, rearing of silk worms and cocoons, with sugar refining, tobacco, terra-cotta manufacture, brickworks and ironworks, came to be the chief occupations of the people of the Marches next after agriculture and pastoral pursuits.

Another important branch of activity is the paper industry, especially at Fabriano. Limestone quarries and sulphur mines supply building stone and sulphur to the regions of central Italy; chalk and petroleum were also found. Ancona was developed as a good harbour. Fishing is carried on along the entire coast.

MARCHESI, MATHILDE (née MATHILDE GRAUMANN) (1826–1913), German singer and teacher, was born at Frankfort-on-Main on March 26. 1826. She made her debut as a singer in 1844, but in 1849 began her teaching career, speedily earning a wide reputation at the conservatories of Vienna and Cologne, as well as in London and Paris. In 1852 she married Salvatore Marchesi. Cavaliere de Castrone (d. 1908), a well-known singer and teacher. Among Madame Marchesi's pupils were Emma Calvé, Emma Eames, Melba, Emma Nevada, Gabrielle Kraus and Etelka Gerster. She published various works on the technique of singing, and in 1897 a volume of reminiscences, *Marchesi* and *Music*. She died in London on Nov. 17, 1913.

Her daughter, Blanche Marchesi (1863–1940), was also a famous singer and teacher.

MARCIAN (*c.* 390–457), emperor of the east (450–457), was born of humble parentage in Thrace, and entered the army at an early age. Eventually through the influence of Aspar and Ardaburius he became a captain of the guards, and later tribune and senator. On the death of Theodosius II he was chosen as consort by the latter's sister and successor, Pulcheria. Marcian repudiated the payment of tribute to Attila, and reformed the finances. He repelled attacks upon Syria and Egypt (452) and quelled disturbances on the Armenian frontier (456). The other notable event of his reign is the Council of Chalcedon (451).

See Gibbon, The Decline and Fall of the Roman Empire, ed. by Bury (1896), iii 384, iv 444–445; J. Bury, The Later Roman Empire (1889), i 135–136.

MARCIANUS (c. A.D. 400), Greek geographer, was born at Heraclea in Pontus. Two of his works have been preserved in a mutilated condition. In the first, the Periplus of the Outer Sea, in two books, in which he proposed to give a complete description of the coasts of the eastern and western oceans, his chief authority is Ptolemy; the distances from one point to another are given in stades, with the object of rendering the work easier for the ordinary student. The second, the Periplus of the Inner Sea (the Mediterranean), is a meagre epitome of a similar work by Menippus of Pergamum, who lived during the times of Augustus and Tiberius. It contains a description of the southern coast of the Euxine from the Thracian Bosporus to the river Iris in Pontus. A few fragments remain of an epitome by Marcianus of the 11 books of the *Geographumena* of Artemidorus of Ephesus.

MARCION (fl. 2nd century A.D.), the leader of a vigorous heretical movement in early Christianity, the most striking tenet of which was the doctrine of two Gods: one the Creator and Judge; the other, the God whom Jesus revealed. Since nothing from Marcion's hand has survived, and any information about him must be derived from the occasional and often biased comments of such orthodox opponents as Tertullian (Against *Marcion)* and St. Epiphanius (Panarion), scant knowledge of the man himself is available. Obviously a person of considerable originality and force, he hailed from Sinope (Sinop) in Bithynia-Pontus, where his father is said to have been the Christian bishop. He appears to have become a shipowner and a man of some wealth. His early life is altogether obscure but toward the middle of the 2nd century he emerged as an influential teacher in Rome. It is likely that this activity in the Roman Church followed upon similar activity farther to the east. It has been argued that Polycarp's epistle to the Philippians (c. A.D. 130) reflects the presence and influences of Marcion in Macedonia. Having reached Rome (c. A.D. 137), he was associated for a time with Cerdo, an important Gnostic teacher, and it is possible that some of the features of his thought are to be ascribed to Cerdo's influence. But Marcion was not a true or typical Gnostic despite his dualism and docetism (*q.v.*). He thought of himself as being a devoted disciple of Paul, who, he claimed, was the only true apostle. Because he looked upon the Jewish Scriptures, which were also at that time the Scriptures of the early church, as belonging to the inferior Creator-God, he repudiated them and set up in their place for his followers a new scripture consisting of a gospel (closely resembling that of Luke) and the Epistles of Paul. He also composed the Antitheses, a work in which the law and the gospel were sharply contrasted. Marcion was a gifted organizer as well as a brilliant and persuasive teacher, and the movement he established became both widespread and powerful. The date of his death is unknown. See also MARCIONITES; GNOSTICISM.

See A. von Harnack, *Marcion:* das Evangelium vom *fremden* Gott (1921 and 1924). (J. Kx.)

MARCIONITES. Marcion (*q.v.*) exercised a major influence upon the development of Christianity in the 2nd century, an influence to be seen both in what the church took from him—especially a renewed attention to the writings of St. Paul—and in the measures adopted to oppose what was quickly perceived to be a dangerous perversion of the Gospel. Marcion was not merely an exponent of heresy or the leader of a school of thought verging on Christianity, but also a founder of churches that were at first serious rivals to orthodox Christianity and kept themselves in being for centuries.

Marcion's theology centred upon his conviction that Christianity was something wholly new. Unable to reconcile the God revealed in Jesus with the God described in the Old Testament, he severed the Christian revelation from its roots in past history and taught that Jesus had come to reveal the true God, as yet wholly unknown, a God of pure love who had now for the first time acted in the material universe by sending His Son to redeem men from it. The Old Testament was not rejected as untrue; it was revelation of a kind. But the god whom it truly revealed, the god of the Jews, the demiurge (*q.v.*) was an inferior being who had fashioned the material universe, including man, and ruled it on the principle of law and obedience. He was powerful, but not omnipotent; at best, he was just, at worst, capricious, wrathful and violent. Although not in himself the principle of evil, he was not the principle of good. The Messiah of the Old Testament was not identified with the Son of the true God. In redeeming men from sin and death, Jesus, the Son of God, was also rescuing them from the demiurge, who would eventually pass away together with his material universe. In all this Marcion was convinced that he had the support of St. Paul, indeed that he alone properly understood the apostle. In Paul he saw, above all else, the antithesis between law—the principle of the demiurge, of the Old Testament and of the Jews—and gospel—the principle of the God of love and of redemption in Jesus. With law went rewards and punishments, justification by works of obedience, while to gospel belong faith, liberty and grace. He also made the most (and more) of Paul's distinction between flesh and spirit. It cannot be doubted that Marcion was genuinely trying to interpret St. Paul; that the contemporary church was showing signs of a legalism contrary to the spirit of Paul and had an inadequate understanding of his profoundest teachings; or that Marcion was honestly facing real problems—in general, the problem of evil, and, in particular, the problem of the character of God as described in the Old Testament. He refused to adopt the method of allegorical exegesis which removed the latter difficulty for most Christians in an age which knew little of biblical criticism or "progressive revelation."

On the other hand, it is equally clear that Marcion perverted the teaching of St. Paul and that his own views had certain other sources. How Marcion's doctrine was related to gnosticism (*q.v.*) has often been a matter of controversy. He was unlike some leading gnostic teachers in that he eschewed all theories of aeons and emanations from God, had no fantastic mythology of redemption and did not so classify men by their natures that salvation was assured to one class and denied to another: for him, salvation was received by faith in Jesus Christ, indeed in Christ crucified. But it seems wrong to distinguish him from the gnostics on the ground that, while they were primarily philosophers, he was essentially religious; for the gnostic systems were normally offered as religions of redemption from evil and death. Marcion's kinship with gnosticism is inescapably evident in his attitude to matter and to the flesh; matter (at least according to his early critics) he treated as the principle of evil, and the flesh, if not intrinsically evil (as he probably believed), was for him unworthy of redemption. Hence his Christology was docetic; Christ had no true human nature (see DOCETISM). Though Marcion emphasized the place of the Cross and of suffering in redemption, it is doubtful whether he could consistently do this. Unlike Paul, he did not wrestle with the reconciliation of love and justice in one God, so that his doctrine of redemption, the core of his teaching, was after all shallow and un-Pauline. The same was probably true of his notion of faith and grace.

Marcion organized his followers into churches outwardly similar to those of the catholic church. They had an episcopal ministry, practised (illogically, his critics said) the sacraments of baptism and the eucharist and lived ascetically, renouncing marriage. Further, they possessed a Bible, the first fixed canon of Christian scriptures. Marcion accepted only St. Luke's Gospel and ten Pauline epistles (*i.e.,* he excluded the Pastorals and Hebrews); and these he mutilated, cutting out anything inconsistent with his own beliefs. Besides furnishing the epistles with prologues, Marcion gave his churches a guide to their interpretation in his

Antitheses, a book that has not survived but that can be reconstructed in part from Tertullian's *Against Marcion.*

The existence of such churches compelled the catholic church to take Marcion very seriously. After the earlier skirmishers, such as Justin Martyr, Irenaeus attacked him, among the gnostics, in his *Against the Heresies* (*c.* 185), as did Tertullian in his longest work, *Against Marcion* (*c.* 207), and elsewhere. It was easy to attack his arbitrary treatment of the text of those books which he himself accepted as Scripture, to press against him the argument from history and prophecy and to assert the necessary unity of the God of creation and redemption, the goodness of matter as God's creation and, therefore, the full reality of Christ's humanity (technically, Marcion's Christology was not only docetic but also modalist, the Son being conceived as no more than a manifestation of the Father); but also, if the church was to reject the dualism of good and evil (or imperfect) gods or of God and matter as the answer to the problem of evil, it had to develop its alternative solution. Hence the renewed emphasis upon the doctrine of the Fall evident in Irenaeus, Tertullian and Origen. Further, Marcion's misuse of St. Paul had to be countered by an even deeper interpretation of his essential message. This was largely provided by Irenaeus. Tertullian also emphasized the redemption of all creation (including the resurrection of the flesh) and brought out the continuity of sacred history: the good God had not been absent from his creation before the Incarnation. Marcion's canon produced a crystallization of the church's own, with apostolic authorship as the criterion. Paul, of course! was accepted, but so were Peter and John. Other Gospels with apostolic authority were set with St. Luke's; and further attention was drawn to the importance of the apostles by the inclusion of Acts. More generally, apostolicity was advanced as a principal mark of the true church in reply to Marcion and to other gnostics who took too little account of history and of tradition or who claimed to have secret revelations of their own. The church appealed to the apostolic writings and to the tradition preserved in churches of apostolic origin, seen in worship and in the apostolic rule of faith and guarded by the bishops in manifest succession of office in each local church — often, it was believed, from the days of the apostles themselves. Marcion did not create catholicism by causing a development, in reaction to himself, which would not otherwise have occurred: the concept of canonicity, respect for apostolic tradition, creeds and an authoritative ministry were none of them novelties. Rather he quickened the pace of the movement toward that presentation of "the catholic church" which is worked out in, for instance, Tertullian's *De praescriptione haereticorum.* That the dangers of excessive rigidity, traditionalism and institutionalism were not completely avoided is probable, and Montanism (*q.v.*) may be interpreted as in part a reaction from these aspects of catholicism. (*See* also GNOSTICISM.)

Marcionite churches spread rapidly through the empire, but the movement lost impetus in the west before the 3rd century was over. They probably merged into Manichaeism (*q.v.*). That they flourished longer in the east was shown by Cyril of Jerusalem (*c.* 350), who supposed that any city may contain a Marcionite conventicle; by Theodoret of Cyrrhus (in the middle of the 5th century), who converted many Marcionites in his diocese; and by Esnik's writings against those in Armenia. Clear traces of Marcionism proper were lost after the 7th century, but the dualism of the Marcionites, their suspicion of the flesh and their asceticism reappeared in other sects, such as the Paulicians and Bogomils, as well as in the Manichees. More modern tendencies among Christians to dismiss the Old Testament are often called Marcionism, while theologians who distrust natural theology and natural law sometimes express their understanding of the uniqueness of revelation in Christ in terms which recall those of Marcion himself.

BIBLIOGRAPHY.—The chief ancient authorities are Irenaeus and Tertullian, as cited above. Modern study is based on A. von Harnack, *Marcion: das Evangelium vom fremden Gott,* no. 45 of *Texte und Untersuchungen zur Geschichte der altchristlichen Literatur* (1921; 2nd ed. 1924), with his *Neue Studien zu Marcion* (1923) in which he replied to his chief critics. Harnack's views drew attention to Marcion's greatness and influence, but overstated them. *See* also E. C. Blackman, *Marcion and His Influence* (1948, 1950); also John Knox, *Marcion and the New Testament* (1942). (S. L. G.)

MARCOMANNI, the name of a Suevic tribe "men of the mark, or border." They were often in conflict with the Roman empire, and gave their name to the Marcomannic war, a struggle waged by the emperor Marcus Aurelius against them. The Marcomanni disappeared from history during the 4th century, being probably merged in the Baiouarii, the later Bavarians.

See SUEBI; and E. Devrient, "Hermunduren und Markomannen" in *Neues Jahrb. f. das klassische Altertum* (1901), 51.

MARCONI, MARCHESE **GUGLIELMO** (1874–1937), Italian physicist, the inventor of a practical system of communicating intelligence without the use of connecting wires between sending and receiving points, was born in Bologna on April 25, 1874, the son of an Italian country gentleman who had married the daughter of Andrew Jameson of County Wexford, Ire. Educated first in Bologna and later in Florence, Marconi then went to the technical school of Leghorn, where he studied physics under Vincenzo Rosa and had every opportunity of investigating electromagnetic (or Hertzian) wave technique, following the earlier mathematical work of Clerk Maxwell and the experiments of Heinrich Hertz, Édouard Branly, Oliver Lodge, Augusto Righi and others.

In 1894, Marconi began experimenting at his father's estate in Pontecchio, near Bologna, using comparatively crude apparatus: an induction coil with a spark discharger controlled by a Morse tapping key at the sending end and a simple filings coherer at the receiver. After preliminary experiments over a short distance, he first improved the coherer and made it self-restoring in operation; then, by systematic tests, he showed that the range of signalling was increased by using a vertical aerial with a metal plate or cylinder at the top of a pole connected through the spark gap to a similar plate on the ground. In this way, the range of signalling was increased to about $1\frac{1}{2}$ mi., and Marconi had convinced himself of the importance of this new system of communication. It was at this period also that he conducted some simple experiments with reflectors around the aerial to concentrate the radiated electrical energy into a beam instead of spreading it in all directions.

As he received little encouragement to continue his experiments in Italy, he was advised by his mother's relations to go to England; and in Feb. 1896 he arrived in London and met William Preece, engineer in chief of the post office, who offered him every assistance and encouragement. Marconi filed his first patent in England in June 1896 and, during that and the following year. he gave a series of successful demonstrations in some of which he used balloons and kites to obtain greater height for his aerials. He was able to send signals over distances up to 4 mi. on Salisbury plain and to nearly 9 mi. across the Bristol channel. These tests, together with Preece's lectures on them, attracted considerable publicity both in England and abroad; and, in June 1897, Marconi went to Spezia, where a land station was erected and communication was established with Italian warships at distances up to 12 mi.

There was, however, still a good deal of scepticism about the useful application of this means of communication and lack of interest in its exploitation. But Marconi's cousin Jameson Davis, a practising engineer, financed his patent and was instrumental in the formation of the Wireless Telegraph and Signal Co., Ltd., the name of which was changed in 1900 to Marconi's Wireless Telegraph Co., Ltd. John Ambrose Fleming, who was to patent the first two-electrode thermionic valve in 1904, became scientific adviser to the company, the efforts of which for some time were devoted to assisting Marconi in his continuous endeavour to show to the full the possibilities of this new means of communication. A further step was taken in 1899, when a wireless station was established at South Foreland for communicating with Wimereux in France, a distance of 31 mi.; and in the same year British battleships had exchanged messages at 75 mi.

In Sept. 1899, Marconi equipped two U.S. ships to report to newspapers in New York city the progress of the yacht race for the America cup. This was another great success, which aroused world-wide excitement and led to the formation of the American Marconi company. The following year the Marconi International Marine Communication Co.. Ltd., was established for the purpose of installing and operating services between ships and land stations. In 1900 also, Marconi filed the famous patent No. 7777 for "Improvements in Apparatus for Wireless Telegraphy." This was based on the earlier work of Sir Oliver Lodge in tuning wireless transmitters and receivers, which enabled several stations to operate on different wave lengths without mutual interference.

Marconi's great triumph was, however, yet to come. In spite of the opinion expressed by some distinguished mathematicians that the curvature of the earth would limit practical communication by means of electric waves to a distance of 100–200 mi., Marconi succeeded in Dec. 1901 in receiving at St. John's, Nfd., signals transmitted across the Atlantic ocean from Poldhu in Cornwall. This achievement created an immense sensation in every part of the civilized world; and, though much remained to be learned about the laws of propagation of radio waves around the earth and through the atmosphere, it was the starting point of the vast development of radio communications, broadcasting and navigation services that took place in the next 50 years, in much of which moreover Marconi himself continued to play an important part.

During a voyage on the U.S. liner "Philadelphia" in 1902, Marconi received messages from distances of 700 mi. by day and 2,000 mi. by night. He thus first discovered the fact that, because some radio waves travel by reflection from the upper regions of the atmosphere, the conditions of transmission or propagation are sometimes more favourable at night than during the hours of daylight. It was in 1902 also that Marconi patented the magnetic detector; and during the next three years he developed and patented the horizontal directional aerial. Both of these devices improved the efficiency of the communication system. In 1910, assisted by H. J. Round, he received messages at Buenos Aires, Arg., from Clifden in Ireland over a distance of about 6,000 mi., using a wave length of about 8,000 m. In 1912 he introduced the timed-spark system of generating pseudocontinuous waves in place of the damped trains of waves produced by the older spark transmitters. This effected a considerable improvement in the selectivity of transmission and reception with a further gain in efficiency. The system was used for several years at many important long-distance stations; and by its means Marconi sent the first messages ever transmitted by wireless from England to Australia, in Sept. 1918.

In spite of the rapid and widespread developments then taking place in the various aspects of wireless and its applications to communication, to navigation and to the safety of life at sea, Marconi's intuition and urge to experiment toward greater accomplishments were by no means exhausted. It was in 1916, during World War I, that he saw the possible advantages of electric waves, shorter than those used before. For example, the shorter waves permitted the use of reflectors round the aerial, which in wartime minimized the interception of the transmitted signals by the enemy and also effected an economy in signalling. After tests in Italy (20 years after his original experiments with reflectors), Marconi continued the work in Great Britain with C. S. Franklin and, on a wave length of 15 m., received signals over a range of 20–100 mi. In 1923 the experiments were continued with G. A. Mathieu on board the steam yacht "Elettra," which had been specially fitted up. From a transmitter of 1 kw. at Poldhu, signals were received at a distance of 1,400 mi., much louder than those from Caernarvon on a wave length several hundred times as great and with 100 times the power at the transmitter. Thus began the development of short-wave wireless communication which, with the use of the beam aerial system for concentrating the energy in the desired direction, constitutes the basis of nearly all modern long-distance radio communication. It was in 1924 that the Marconi company obtained a contract from the post office for the establishment of short-wave communication between England and the countries of the British Commonwealth.

A few years later Marconi returned to the study of still shorter waves and. with the aid of valve-oscillator technique, examined the range possibilities of wave lengths of about half a metre. At these very short wave lengths, a parabolic reflector of moderate size gives a considerable increase in radiated power in the desired direction, and experiments conducted off the coast of Italy in the yacht "Elettra" soon showed that useful ranges of communication could be achieved with small powers at the transmitter. In 1932, Marconi installed a very short-wave radio telephone system between the Vatican and the pope's palace at Castel Gandolfo. In later work, Marconi once more demonstrated that even radio waves as short as 5j cm. are not limited in range to the horizon or optical distance between transmitter and receiver.

Marconi received many honours and several honorary degrees: he was created a knight of Italy (1902); made a freeman of Rome (1903); awarded half the Nobel prize for physics, the Albert medal of the Royal Society of Arts and, in the United States, the Franklin and John Fritz medals (1909); appointed an honorary Grand Cross of the Victorian Order (1914); sent as plenipotentiary delegate to the peace conference in Paris (1919), in which capacity he signed the peace treaties with Austria and with Bulgaria; created marchese and nominated to the Italian senate (1929); and chosen president of the Royal Italian Academy (1930). Marconi died in Rome on July 20, 1937, and was accorded a state funeral by the Italian government. At his own wish, he was buried at his native town of Bologna. (R. L. S.-R.)

MARCUS, SAINT, pope in 336 (Jan. 18–Oct. 7) or, as other sources claim, from 337 to 340, is credited with having established the right of bishops of Ostia to consecrate new popes. He also is said to have founded the present church of S. Marco in Rome, and another over the Catacomb of Balbina, but a letter alleged to have been sent by him to Athanasius is now regarded as spurious.

His feast day is Oct. 7. (G. E. McC.)

MARCUS AURELIUS ANTONINUS (121–180), Roman emperor and Stoic philosopher, was born in Rome A.D. 121, the date of his birth being variously stated as April 6, 21 and 26. His original name was Marcus Annius Verus. His father Annius Verus (prefect of the city and thrice consul), who came of Spanish stock, had received patrician rank from Vespasian. Marcus was three months old when his father died, and was thereupon adopted by his grandfather. Hadrian adopted, as his successor, Titus Antoninus Pius (uncle of Marcus), on condition that he in turn adopt both Marcus (then 17) and Lucius Ceionius Commodus, the son of Aelius Caesar, who had originally been intended by Hadrian as his successor. but had died before him. Marcus had been, at the age of 15, betrothed to Fabia, the sister of Commodus; the engagement was broken off by Antoninus Pius, and he was betrothed to Faustina, the daughter of the latter. In 139 the title of Caesar was conferred upon him and he dropped the name of Verus. The full name he then bore was Marcus Aelius Aurelius Antoninus, Aelius coming from Hadrian's family, and Aurelius being the original name of Antoninus Pius. In 140 he was made consul. He was educated, not at school, but by tutors, Herodes Atticus and M. Cornelius Fronto (*q.v.*), in the usual curriculum of rhetoric and poetry; but Stoicism attracted him from the first, and at 25 he definitely abandoned Fronto, whose training was wholly literary. to learn philosophy under Rusticus the Stoic, and law under L. Volusius Moecianus. A Stoic he remained in practice, but retained the humanity of his disposition.

Emperor.—Antonipus Pius died in 161, having recommended as his successor Aurelius, then 40 years of age, without mentioning Commodus, his other adopted son, commonly called Lucius Verus. It is believed that the senate urged Aurelius to take the sole administration. But he admitted Verus as his partner, giving him the tribunician and proconsular powers, and the titles Caesar and Augustus. In the first year of his reign Faustina gave birth to twins, one of whom became the emperor Commodus.

Aurelius' reign was largely occupied in defending the empire against attacks from all sides. First of all the Parthians under Vologeses III broke into Syria. Verus went out in nominal command of the war against them, which was really conducted by Avidius Cassius. The war was concluded in 165, but the returning army brought a pestilence with them that spread over the whole empire. Aurelius accompanied Verus in wars in Pannonia and Noricum in 167–8, and peace was made with the Marcomanni in 168. Early in 169 Verus died, leaving Aurelius sole emperor. In the autumn of 169 war again broke out on the Rhine-Danube frontier, and Marcus Aurelius lived almost entirely at Carnuntum for three years. The Marcomanni were eventually driven out of Pannonia and almost annihilated, and in 174 Aurelius won over the Quadi the celebrated victory of the "thundering legion," commemorated on the column of Antonina.

Germany. — Aurelius next marched to Germany. There news reached him that Avidius Cassius, the commander of the Roman troops in Asia, had revolted and proclaimed himself emperor (175). But after three months Cassius was assassinated, and his head was brought to Aurelius, who with characteristic magnanimity, persuaded the senate to pardon all the family of Cassius.

During his journey of pacification, Faustina, who had borne him 11 children, died. Aurelius trusted her while she lived, and mourned her loss.

After the death of Faustina and the pacification of Syria, Aurelius proceeded, on his return to Italy, through Athens, and was initiated in the Eleusinian mysteries. He gave large sums of money for the endowment of chairs in philosophy and rhetoric, with a view to making the schools the resort of students from all parts of the empire. Along with his son Commodus he entered Rome in 176, and obtained a triumph for victories in Germany. In 177 occurred that persecution of Christians, the share of Aurelius in which has been the subject of so much controversy. Meanwhile the German War continued, and the two Quintilii, who had been left in command, begged Aurelius once more to take the field.

Death. — In this campaign Aurelius, after a series of successes, was attacked, according to some authorities, by an infectious disease, of which he died after a week's illness, either in his camp at Sirmium (Mitrovitz), on the Save, in Lower Pannonia, or at Vindobona (Vienna), on March 17, 180, in the fifty-ninth year of his age. Other accounts are: (1) that he was poisoned in the interests of Commodus (Dio. Cass. lxxi, 33, 4), (2) that he died of a chronic stomachic disease; the latter is perhaps the most likely. His ashes (according to some authorities, his body) were taken to Rome. By common consent he was deified and all those aho could afford the cost obtained his statue or bust; for a long time his statues held a place among the penates of the Romans Commodus, who was with his father when he died, erected to his memory the Antonine column (now in the Piazza Colonna at Rome), round the shaft of which are sculptures in relief commemorating the miracle of the thundering legion and the various victories of Aurelius over the Quadi and the Marcomanni. A bronze equestrian statue was set up in the Forum, now on the Capitol.

Aurelius was consistently hostile to Christianity, and persecution, unknown or forbidden under earlier reigns, was systematically pursued under his directions. His attitude was logical enough. The State religion was to him an essential part of the imperial system, and the Christians, particularly in their opposition to emperor-worship, were a danger to the established order.

In his work on the internal administration Marcus Aurelius was equally untiring. His reign is especially notable for legal reforms, and an attempt to arrest the fall in the legitimate birth-rate. His provincial administration was not made easier by the drain on the Treasury caused by the defence of the empire. Against his will he had to increase taxation, and he risked alienating his soldiers by refusing an increase of pay. Last of a line of emperors who all seemed to come little short of the Stoic ideal of the philosopher king, Marcus Aurelius was the best of them all.

Philosophy. — The book which contains the philosophy of Aurelius is known by the title of his *Reflections*, or *Meditations*, although that is not the name which he gave to it himself (Td εἰς ἑαυτόν). Of the genuineness of the work no doubts are now entertained. It is believed that he wrote also an autobiography, which has perished. The *Meditations* were written, it is evident, as occasion offered—in the midst of public business. and on the eve of battles on which the fate of the empire depended—hence their fragmentary appearance, but hence also much of their practical value and even of their charm.

Throughout his life he was a practising, but he was not strictly an orthodox, Stoic. In his hands Stoicism is a practical rule of life, not a philosophy of quietism. In the *Meditations* are no speculations on the absolute nature of the deity, and no clear expressions of opinion as to a future state. He is, above all things, a practical moralist. The goal in life to be aimed at, according to him, is not happiness, but tranquillity, or equanimity. This condition of mind can be obtained only by "living conformably to nature," that is to say, one's whole nature, and as a means to that man must cultivate the four chief virtues, each of which has its distinct sphere — wisdom, or the knowledge of good and evil; justice, or the giving to every man his due; fortitude, or the enduring of labour and pain; and temperance, or moderation in all things. It is no "fugitive and cloistered virtue" that Aurelius seeks to encourage; on the contrary, man must lead the "life of the social animal." While he held that the prime principle in man is the social, "the next in order is not to yield to the persuasions of the body, when they are not conformable to the rational principle which must govern." This divinity "within a man," this "legislating faculty," which, looked at from one point of view, is conscience, and from another is reason, must be implicitly obeyed. He who thus obeys it will attain tranquillity of mind.

What gives the sentences of Marcus Aurelius their enduring value and fascination, and renders them superior to the utterances of Epictetus and Seneca, is that they are the gospel of his life. His precepts are simply the records of his practice. To the saintliness of the cloister he added the wisdom of the man of the world; he was constant in misfortune, not elated by prosperity, never "carrying things to the sweating-point," but preserving, in a time of universal corruption, unreality and self-indulgence, a nature sweet, pure, self-denying, unaffected.

Dickson, London, 1886); for the Aurelius column, E. Petersen. A. von Domaszewski, and G. Calderini, *Die Marcussäule* (Munich, 1896), with historical introduction by Th. Mommsen. (5) The *Meditations* were published by Xylander in 1j58; the best critical edition is that of J. Stich in the Teubner series (Leipzig, 1882; 2nd ed., 1903). Translations exist in almost every language; that of George Long (1862, re-edited 1900) has been superseded by those of G. H. Rendall (1898, with valuable introduction) and J. Jackson (1906, with introduction by Charles Bigg). (6) For the correspondence of Aurelius and Fronto, *see* Robinson Ellis, *Correspondence of Fronto and M. Aurelius* and *Class Rev.* vol. 34 p. 14 (1904).

MARCY, WILLIAM LEARNED (1786–1857), American statesman, was born in Southbridge, Mass., on Dec. 12, 1786. He graduated at Brown university in 1808, studied law, was admitted to the bar in Tray, N.Y., and began practice there in 1810. During the War of 1812 he served as a captain of volunteers and on Oct. 22, 1812, took part in the storming of the British post at St. Regis, Can. In 1816 he became recorder of Troy, but he was removed from office in 1818 by his political opponents. As editor of the Troy *Budget* he was a vigorous supporter of Martin Van Buren, and when Van Buren's followers acquired control of the legislature in 1821 Marcy was made adjutant general of the New York militia. From 1823 to 1829 Marcy was comptroller of the state, an office then especially important on account of the large expenditures for internal improvements, and during this period he became the leading member of the famous "Albany regency" (*q.v.*), a group of able Democratic politicians who exerted a powerful influence throughout the state by their control of the party patronage and machinery. He was one of the associate justices of the New York supreme court from 1829 to 1831, presiding over the trial of the alleged murderers of William Morgan and in other important cases, and was a member of the United States senate from Dec. 1831 to July 1832, when he resigned to become governor of New York. In a speech in the senate defending Van Buren against an attack by Henry Clay. Marcy made the unfortunate remark that "to the victors belong the spoils of the enemy" and thereby became widely known as a champion of the proscription of political opponents. He served as governor of New York for six years (1833–38 inclusive). As governor he secured the enactment, in 1838, of a general banking law, which abolished the monopoly features incident to the old banking system. In 1844–45 he was recognized as one of the leaders of the "Hunkers," or regular Democrats in New York, and an active opponent of the "Barnburners." He was secretary of war under Pres. James Polk from 1845 to 1849 and as such discharged with ability the especially onerous duties incident to the conduct of the Mexican War.

From 1853 to 1857 he served the term as secretary of state in the cabinet of Pres. Franklin Pierce. Few cabinet officers in time of peace have had more engrossing duties. His circular in 1853 to American diplomatic agents abroad, recommending that, whenever practicable, they should "appear in the simple dress of an American citizen," created much discussion in Europe; in 1867 his recommendation was enacted into a law of congress. In 1853 Marcy secured the negotiation of the Gadsden treaty (*see* GADSDEN, JAMES), by which the boundary dispute between Mexico and the United States was adjusted and a large area was added to the federal domain. The expedition of William Walker (*q.v.*) to Nicaragua in 1855 further complicated the Central American situation. The diplomatic relations of the United States and Spain growing out of the noted "Black Warrior Case" furnished, perhaps, the most perplexing of Marcy's problems, and it was largely due to his influence that war was averted. However, he was not averse to increasing his popularity and his chances for the presidency by obtaining Cuba in an honourable manner, and it was at his suggestion that James Buchanan, J. Y. Mason and Pierre Soulé, the ministers, respectively, to Great Britain, France and Spain, met at Ostend and Aachen in Oct. 1854 to discuss the Cuban question. But the remarkable "Ostend Manifesto" (*q.v.*), the outcome of their conference, was quite unexpected, and Marcy promptly disavowed the document. In domestic affairs Marcy was a shrewd, but honest partisan; in diplomacy he exhibited the qualities of a broadminded, patriotic statesman, endowed, however, with vigour, rather than brilliancy, of intellect. He died at Ballston Spa, N.Y., on July 4, 1857.

For his early career, consult J. S. Jenkins, *Lives of the Governors of New York* (1851); and for his work as secretary of state, *see* James Ford Rhodes, *History of the United States,* vol. i and ii (1892), and an article by Sidney Webster, "Mr. Marcy, the Cuban Question, and the Ostend Manifesto," *Political Science Quarterly,* vol. viii (1893); J. B. Moore, "A Great Secretary of State," *Pol. Sci. Quart.,* vol. xxx, pp. 377–396 (1915); "Diary and Memoranda of William L. Marcy, 1849–51," *American Hist. Rev.,* vol. xxiv, pp. 444–462, 641–653 (1919); De Alva S. Alexander, *A Political History of the State of New York* (1906–1923).

MAR DEL PLATA, Argentine coastal city, primarily important as a seaside resort and known to Argentines as the "Pearl of the Atlantic," located 250 mi. S. of Buenos Aires. in Buenos Aires province. Pop. (1960) 203,093. Settled in the 1850s as site for a meat-salting plant, Mar del Plata did not become a resort area until the early 20th century. Extensive beaches, a pleasant climate, night clubs and a government-controlled casino add to the tourist attraction. The harbour is an important port for the Argentine fishing fleet, and large canneries have been built to process the catch. (Js. R. S.)

MARDI GRAS: *see* SHROVE TUESDAY.

MARDIN, a town in the il (province) of the same name in Kurdistan, Turk.. and about 30 mi. N.W. of Nisibin, on the line of the Baghdad railway. The town is of some importance on the caravan route between the east and west. From Mardin one road leads west to Urfah and so to Aleppo or Aintab. A second runs northwest to Diarbekr. Southeast runs the road to the Tigris and so to Mosul and Baghdad. The town is the centre of a rich agricultural district, the principal products being wheat, barley and sesame. A certain amount of wool is produced, and there is a small cotton and woolen weaving industry. The population is very mixed and was (1960) 27,390 for the city and 354.112 for the province. It includes Arabs, Armenians, Jacobites, Kurds and a medley of Asiatics.

MARDONIUS (fl. 479 B.C.), Persian general, was the son of Gobryas, one of the conspirators against Smerdis the Magian. He married Artazostra, daughter of Darius Hystaspis, and in 492 was sent to succeed Artaphernes in the settlement of Ionia with a special commission to attack Athens and Eretria. Contrary to the usual Persian policy, he restored democracies in Ionia and then crossed the Hellespont and invaded Thrace and Macedonia. His fleet was wrecked off Athos with enormous loss, and Mardonius abandoned further progress and came back to Aria; he was superseded in 490. On the accession of Xerxes, Mardonius was one of the chief instigators in the invasion of Greece. After Salamis he persuaded Xerxes to return, and he himself stayed behind with a large army. He was defeated by Pausanius and killed at Plataea in Sept. 479.

See Herodotus: books vi–ix; *Diod.* xi, i, 28–31.

MARDUK, a late name for the god of the city of Babylon, uho appears regularly in the classical Sumerian liturgies under the titles *Asar-lu-dug* and *Enbilulu.* The original title is *Asaru,* which occurs in the old pantheon at Fara, *c.* 3200 B.C., and so far as known, long before the city of Babylon was founded. *Asaru, Asar-ri,* is a title of this, originally inferior. deity of the cult of Enki at Eridu, as son of the water god, a deity of lustration. His connection with Babylon, which is first mentioned as a small city by Sargon in the 28th century B C., may be original and very old. The title *Marduk* lays special emphasis upon his solar aspect. It is certain that all the older titles of this god, Asaru, Asar-alim, Asar-alim-nun-na, Asarludug, describe him as an inferior deity of the water cult of Eridu, and how he came to be transferred to Babylon is at present inexplicable. *Alim* means the mythical fish ram, symbol of his father, the water god of Eridu, and *Asaru* was the god of lustration at Habur in Eridu. Asarludug means "Asaru who restores man to happiness," and describes his original activity as agent of Enki in all magical rituals of the water cult against demons. Marduk is pre-eminently the god of the magicians in Babylonian and Assyrian religion, and this was his sole sphere in the original Sumerian pantheon.

With the rapid rise of Babylon under the 11 kings of the 1st dynasty (2169–1870 B.C.), the priests of the local cult looked for some means of increasing the respect due to the god of the great capital and a theological reason for it. Inasmuch as the Sumerian pantheon had been universally accepted by the Accadians, and had now a firm hold upon the religious beliefs of the Semites in Assyria, Cappadocia and the Amoritic western country, it was impossible to make *Asaru* one of the three heads of the trinity; these were securely held by Anu, Enlil and Enki. But the old war and sun god Ninurta, Zamama, son of Enlil, was largely drawn upon to make Asaru also a sun god, and more especially the god of the spring sun. This addition to his original character as a god of lustration and magic was brought about by rewriting the Sumerian legend of Creation in which Kinurta championed the gods against the dragon of Chaos, the storm demon Zû, and then created the world. The new Semitic version in six books attributed this victory of the gods to Marduk. The name itself was introduced at this time, *amar-udu, amar-utu,* and means "young bull, the sun," becoming. after the regular rule of Sumerian loanwords, *Marutukku, Marudukku, Má-rû-tu-*[*uk-ku*], *Maruduk, Merduku, Marduk.* (*See* S. Langdon, *Oxford Editions of Cuneiform Texts,* vol. vi. 99, 113, and *Cuneiform Texts . . .* in the British Museum, vol. xxv. 34. ii. 17.) The Hebrew transcription is Merodak, and the Greek, *Maradouchos, Mardakos, Mardokos, Maradach.*

In the Semitic version of the Epic, Marduk's birth and education are described. The old theological view, that he was the son of Enki or Ea of Eridu, is preserved, except in the Assyrian editions, where he is displaced by Ashur, son of Lahmu. The legend of how he was unanimously raised to the rank of a great god (in the convocation of the gods), because of his magical power to cause objects to vanish and reappear, and for his promise to go forth to battle with Tiamat, Kingu and the dragons of darkness, is one of the principal episodes of the epic. After Tiamat was slain and the dragons bound, Marduk created heaven and earth, the constellations and planets, and fixed their movements. Finally, he ordered man to be created on the advice of his father, Ea. Kingu was then slain and from his blood "mankind" was created. This was the Eridu legend of the creation of man, but in the rival Nippurian school his creation is said to have been by the mother goddess, Aruru, from clay. Undoubtedly the Hebrew legend of the creation of Adam from clay combines the legend of Marduk and Aruru.

Upon the epic of Creation and the myth of the conquest of light over darkness is based the Babylonian new year festival, which is described in the article BABYLONIA AND ASSYRIA. For the later identification of Marduk with Tammuz and the Resurrection of Bêl, *see* TAMMUZ. So completely did Marduk finally dominate the religion of Babylonia that he is chiefly known to Greek and Roman writers as "lord," Bêlos, *see* BĒL. A text proves that in the late period theological speculation went so far as to assimilate all the important deities to Marduk, but this advance toward real monotheism was obviously confined to priests at Babylon. (*See* Jensen, *Keilinschriftliche Bibliothek,* vi. pt. 2, p. 118.) Unlike other great and older deities, Marduk had no temples and shrines outside his own city. The Sumerian cities of the south never admitted his new rôle in the pantheon, but only his original names and character as an inferior water deity of Eridu. At Babylon his temple, Esagila, and his stage tower, Etemenanki, were the largest of the kind in Babylonia and Assyria. To Esagila, at least in the late period, all the statues of the great gods of Babylonia were brought in ships and wagons to assemble in the hall of convocation (Dukug) and fix the fates of men for the coming year at the Nisan festival.

Marduk's principal rôle in astronomy was as the planet Jupiter; as such he was known as Shulpaé, a title of a deity which originally had no connection with Asaru or Marduk. The title belongs originally to Enlil, the ancient *Bêl* of Nippur, and is found in the oldest inscriptions. The planet must have been known as *mul Shulpaé,* and identified with Enlil before the 22nd century, otherwise the name would not have been chosen for Marduk when the theologians assigned to him the largest of the planets.

MARE, the female of any animal of the family *Equidae,* particularly of the horse. It is also used of the camel. To find a "mare's nest" is an old saying for a purely imaginary discovery. In "night-mare," an oppressive or terrifying dream, the termination is a word for a goblin, supposed to cause these dreams: *cf.* ELF.

MARE CLAUSUM and **MARE LIBERUM** (Lat. for "closed sea" and "free sea")! in international law terms associated with the historic controversy which arose out of demands on the part of different states to assert exclusive dominion over areas of the open or high sea. Thus Spain and Portugal laid claim to exclusive dominion over whole oceans, Great Britain to the narrow seas. and so on. These claims gave rise to vigorous opposition by other powers and led to the publication of Hugo Grotius' work *Mare liberum* (1608). In *Mare clausum,* written in 1617–18 and published in 1635, John Selden asserted "that the sea by the law of nature or nations is not common to all men but capable of private dominion or property as well as the land."

A formula was found, on the other hand, by Cornelius van Bynkershoek in his *De dominio maris* (1702), for the restriction of dominion over the sea to the actual distance which could be protected by cannon range; *i.e.,* three marine miles (see WATERS, TERRITORIAL; HIGH SEAS).

MAREE, LOCH, is a fresh-water loch in the county of Ross and Cromarty, Scot. Its name commemorates St. Maelrubha, who in 671 founded a monastery at Applecross and a chapel on Isle Maree. The lake is 123 mi. long from Kinlochewe, at the head of the dam erected in the 16th century (or earlier) by the iron-smelters of the Cheardach Ruardh, or Red Smiddy, on the river Ewe, by which it drains to the sea. Its greatest breadth is just over 2 mi. at Slattadale, and the greatest depth 367 ft. There are over 30 islands, covering an area of nearly 1 sq.mi. and lying mostly north and east of Slattadale. The largest is Eilean Subhainn, or St. Swithin's Isle, which contains two small lakes. For two-thirds of its length the loch is flanked by mountains. On the northeast the principal heights are Ben Slioch (3,217 ft.), Ben Lair and Beinn Airidh Charr, and, on the southwest, the peaks of Ben Eay, four of which exceed 3,000 ft. Sea trout and salmon are taken in the loch. The National Nature reserve at Kinlochewe was the first of its kind established in Great Britain.

MARÉES, HANS VON (1837–1887), German painter, was born at Elberfeld on Dec. 24, 1837. In 1853 he went to Berlin, where he studied for two years under Steffeck. For the next eight years he worked chiefly in Munich, coming under the influence of the historical school, and in 1864 he went to Italy, where he lived for about 20 years. He also traveled in Spain and France and spent some time in Berlin. In 1873 he received his most important commission, the painting of frescoes in the library of the Zoological museum at Naples. Although ambitious, Marées lacked self-confidence, and in the latter part of his life ceased to exhibit his work. He died in Rome on June 5, 1887, a disappointed and practically unknown man. When his works were collected at the Munich exhibition in 1891, their value became apparent, as in "The Oarsmen," a subject he often painted.

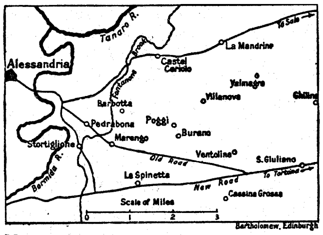
MAREMMA, a marshy region of Tuscany, Italy, from the mouth of the Cecina to Orbetello, 15 to 25 mi. broad. In Etruscan and Roman times the Maremma was a populous and fertile coast plain, with considerable towns situated on the hills—Populonia, Rusdellae, Cosa, etc.—and was drained by subterranean canals, which were brought to light when excavations were in progress for the building of railways. The decline of agriculture at the end of the Republic led to a conversion of the land to pasture, and the fall of the Empire resulted in neglect of watercourses. Leopold II. of Tuscany (1822–1844) made the first successful efforts to counteract malaria by drainage, filling up of swamps, and establishment of new farms, and since his time continuous efforts have been made with considerable success.

See C. Iiicolosi, *Il Litorale Maremmano; La Montagna* ***Maremmanu*** (Bergamo, Arti Grafiche, 1911), well illustrated.

MARENGO, a village of north Italy, on the road between Alessandria and Tortona, and $4\frac{3}{4}$m. E.S.E. of the gates of the former. It is situated on the Fontanone brook, a small affluent of the Tanaro which marks the western edge of the plain of Marengo, the scene of the great victory won by Napoleon Bonaparte over the Austrians under Baron Melas (1729–1806) on June 14, 1800. The antecedents of the battle are described under FRENCH REVOLUTIONARY WARS.

The French army, uncertain of its opponent's position, had advanced westward from the Scrivia towards Alessandria on the 12th, and its outposts had reached the Bormida on the evening of the 13th. But contact with the main Austrian army was not obtained, and on the assumption that it was moving towards either Valenza or Genoa Bonaparte weakened his army by considerable detachments sent out right and left to find the enemy and to delay his progress. Unknown, however, to Bonaparte Melas's army was still at Alessandria, and on the morning of June 14 it filed out of the fortress and began its advance into the great plain of Marengo, one of the few favourable cavalry battle-grounds in north Italy.

Gen. Victor had not carried out Bonaparte's evening order to destroy the bridges over the Bormida, and the dispersion of the French army allowed only a fragmentary, though most energetic, resistance to be offered to the Austrian onset. The latter, considerably delayed at first by the crossing of the river Bormida, broke up into two columns,[1] advanced, the right by the main road on Marengo, the left on Castel Ceriolo. The former, personally commanded by Melas, was 20,000 strong, and Gen. Victor, its immediate opponent, about 10,000, or including some 5,000 of Lannes' corps who fought on his right, about 15,000 strong; the Austrians were, moreover, greatly superior in guns (in all 192 to 14) and cavalry. The French disputed every yard of ground, holding their first line until they had by fire and counter-attack forced practically the whole of the Austrian right to deploy, and two hours passed before the Austrians managed to reach the Fontanone brook. But Victor's troops, being disorganized and short of ammunition, had then to retire more rapidly across the plain. The retreat was orderly, according to Victor's report, and made in echelon from the centre, and it is certain that at any rate the regiments held together, for the 6,000 Austrian sabres found no opportunity to charge home. Many guns and wagons were, however, abandoned.



MAP OF MARENGO, THE SCENE OF NAPOLEON'S VICTORY OVER THE AUSTRIANS, JUNE 14, 1800

On the French right, opposed to the column of Lieut.-Field-Marshal Ott, was Lannes, with some 4,000 men (excluding Watrin's division which was with Victor) against 7,500. He too was after a time forced to retire, with heavy losses. Thus, about 11 A.M., Bonaparte, who was at some distance from the field, became convinced that he had to deal with Melas's army. At once he sent out his staff officers to bring back his detachments, and pushed forward his only reserve, Monnier's division, to support Lannes and Victor. But before this help arrived Lannes had been driven out of Castel Ceriolo, and Victor and Watrin forced back almost to San Giuliano. A little after 2 P.M. Monnier's division (3,500) came into action, and its impetuous advance drove the Austrians out of Castel Ceriolo. But after an hour it was forced back in its turn, and by 3 P.M., therefore, the 20,000 French troops, disordered and exhausted, and in one line without reserves;[2] held a ragged line of battle to the right and left of San Giuliano. The best that could be expected was a prolongation of the struggle till nightfall and a fairly orderly retreat. Melas, slightly wounded and believing that the battle was won, returned to Alessandria, leaving a younger man, his chief of staff Zach, to organize the pursuit.

Then followed one of the most dramatic events in military history. Of the two detachments sent away by Napoleon in search of the enemy, one only received its orders of recall. This was Boudet's division of Desaix's corps, away to the south at Rivalta and at noon heading for Pozzolo-Formigaro on the Alessandria-Genoa road. At 1 P.M. a brief message, "Revenez, au nom de Dieu!" altered the direction of the column, and between 4 and 5, after a forced march, the division, headed by Desaix, came on to the battle-field. It was deployed as a unit and moved forward at the word of command along the main road Alessandria-Tortona, the sight of their closed line giving fresh courage to the men of Lannes and Victor. Then, while on the other side Zach was arraying a deep column of troops to pursue along the main road, Napoleon and Desaix, themselves under fire, hastily framed a plan of attack. All arms were combined. First, Marmont with eight of Boudet's guns and ten others (the rest had been abandoned in the retirement) came into action on the right of the road, replying to the fire of the Austrian guns and checking their advanced infantry; close in rear of the artillery was Desaix's infantry with the remnants of Lannes' and Victor's troops rallying on its right and left; on Lannes' right, still facing Ott's column, was Monnier, supported by the Consular Guard of horse and foot; lastly 400 sabres of Kellermann's cavalry brigade, which had already been engaged several times and had lost heavily, formed up on the right of Desaix. About 5 P.M. Desaix advanced against the head of the Austrian main column formed by Zach. He himself fell in the attack, but the onset of his intact troops drove back the leading Austrians upon their supports, and at the critical moment when the attack of Boudet's single weak division had almost spent its force, Kellermann with his 400 sabres sallied out of the French line. Marmont had brought up two guns to assist the infantry, and as he fired his last round of case-shot the cavalry raced past him to the front, wheeled inwards against the flank of the great column, and rode through and through it. Zach was taken prisoner with more than 2,000 men, and Kellermann, rallying some of his troopers, flung himself upon the astonished Austrian cavalry and with the assistance of the Consular Guard cavalry defeated it. The "will to conquer" spread along the whole French line, while the surprise of the Austrians suddenly and strangely became mere panic. Lannes, Victor and Monnier advanced afresh, pushing the Austrians back on Marengo. A few Austrian battalions made a gallant stand at that place, while Melas himself, as night came on, rallied the fugitives beyond. Next day the completely exhausted, but victorious, French army extorted from the dazed Austrians a convention by which all Italy up to the Mincio was evacuated by them. The respective losses were: French about 4,000, Austrians 9,500.

See the French official *Campagne de l'armée de rtserve*, vol. ii., *by* C. de Cugnac.

[1]A third column was sent out to the extreme right (3,000 under O'Reilly). This destroyed a small French detachment on the extreme left, but took little or no part in the main battle.

[2]The Austrians, too, fighting in "linear" formation had few reserves. About one-third only of the imperial forces in Italy was actually engaged in the battle.

MARENZIO, LUCA (before 1560–1599), Italian composer, was born probably at Coccaglia in the Bergamask before 1560. According to some accounts he was descended from a noble family of Bergamo. He was a pupil of Giovanni Contini, organist of Brescia, and began to publish books of madrigals at an early age. In 1581 he was in Venice and from 1582 to 1585 in Rome, where he was at one period chapel-master to the Cardinal d'Este. For two years he held a handsome appointment at the court of Poland, but 1595 found him back in Rome with an appointment at the Papal chapel. In Rome he became a warm friend of Cardinal Aldobrandino, the pope's nephew. He died in Rome on Aug. 22, 1599. Marenzio's most important compositions consist of the 16 books of madrigals, 5 books of vilanelles and airs, 2 books of motets and 1 mass. (The complete list is in Eitner's *Quellen-lexikon.*) The 5-part and 6-part madrigals in two books are in the British Museum. The *Musica transalpina* (1588) contains some of his works, and several motets are included in Proske's *Musica divina* (1853).

See also "Marenzio" *in* Grove *Dictionary* of *Music and Musicians.*

MAREOTIS, the most westerly of the lakes in the Delta of Egypt (Arab. *Mariut*). On the narrow strip of land separating the lake from the Mediterranean the city of Alexandria is built. (*See* EGYPT and ALEXANDRIA.) In classical times its shores were a region of great fertility, and in the middle ages the lake was practically dry. During the siege of Alexandria in 1801 the British cut the ridge of dunes at Aboukir and flooded the area with sea water. Now, by means of pumps, the water-level of the lake is kept about 8 ft. below sea-level, and cultivation has been largely restored.

MARE'S-TAIL, the popular name for an aquatic herb known botanically as *Hippuris vulgaris* (water milfoil family Hippuridaceae). Mare's-tail grows on margins of lakes, ponds and similar localities and has a submerged stout creeping rootstock, from which spring many jointed cylindrical stems bearing numerous narrow leaves close set in whorls. The minute greenish flowers are borne in the leaf axils. Like many fresh-water plants it has a wide distribution, occurring in arctic and temperate regions in the northern hemisphere. It reappears in southern South America.

MARET, HUGUES-BERNARD, Duc de Bassano (1763–1839), French statesman and publicist, was born at Dijon. After receiving a sound education, he entered the legal profession and became advocate at the King's Council at Paris. The interest aroused by the debates of the first National Assembly suggested to him the idea of publishing them, conjointly with Méjean, in the *Bulletin de l'Assemblée.* The publicist Charles Joseph Panckoucke (1736–1798), owner of the *Mercure de France* and publisher of the famous *Encyclopédie* (1781), persuaded him to merge this in a larger paper, the *Moniteur universel,* which gained a wide repute for correctness and impartiality. He was a member of the moderate club, the Feuillants; but after the overthrow of the monarchy on Aug. 10, 1792 he accepted an office in the ministry of foreign affairs, where he sometimes exercised a steadying influence. On the withdrawal of the British legation from Paris Maret went on a mission to London, where he had a favourable interview with Pitt on Dec. 2, 1792. All hope of an accommodation was, however, in vain. After the execution of Louis XVI. (Jan. 21, 1793), the chief French diplomatic agent, Chauvelin, was ordered to leave England, while the French Convention declared war (Feb. 1, 1793). These events precluded the possibility of success attending a second mission of Maret to London in January. He was sent to Naples as ambassador of the French Republic; but he was captured by the Austrians, and was only released in 1795 when the duchess of Angoulême was set free. Maret took part in the negotiations with Great Britain at Lille during the summer of 1797, until the *coup d'état* of Fructidor frustrated any peace. On the return of Bonaparte from Egypt in 1799 Maret joined the general's party which came to power with the *coup d'e'tat* of Brumaire (Nov. 9–10. 1799).

Maret now became one of the First Consul's secretaries and shortly afterwards secretary of state. The *Moniteur,* which became the official journal of the state in 1800, was placed under his control. In 1804 he became minister; in 1807 he was named count, and in 1809 he received the title of duc de Bassano. His personal devotion to the emperor was of that absolute unwavering kind which Napoleon highly valued. Maret accompanied Napoleon through most of his campaigns, including that of 1809; and in the spring of 1811 he replaced Champagny, duc de Cadore, as minister of Foreign Affairs. In this capacity he concluded the treaties between France and Austria and France and Prussia, which preceded the French invasion of Russia in 1812. He was with Napoleon through the greater part of that campaign; and after its disastrous conclusion helped to prepare the new forces with which Napoleon waged the equally disastrous campaign of 1813. But in November 1813 Napoleon replaced him by Caulaincourt, duc de Vicence.

Maret, however, as private secretary of the emperor, remained with his master through the campaign of 1814, as also during that of 1815. After the second restoration of the Bourbons he was exiled, and retired to Gratz where he occupied himself with literary work. In 1820 he was allowed to return to France, and after the Revolution of 1830, Louis Philippe, king of the French, made him a peer of France; he also held two high offices for a few days. He died at Paris in 1839. He shares with Daru the honour of being the hardest worker and most devoted supported in Napoleon's service; but it has generally been considered that he carried devotion to the length of servility, and thus often compromised the real interests of France. This view has been contested by Baron Ernouf in his work *Maret, duc de Bassano,* which is the best biography.

For Maret's mission to England in 1792 and his work at Lille in 1797, *see* Augustus W. Miles, *Letters on the French Revolution.*

MARGARET, a female proper name, which became very popular in all Christian countries as that of Saint Margaret (*q.v.*). (Fr. *Marguerite,* It. *Margherita,* Ger. *Margareta,* fr. Lat., *margarita,* Gr. μαργαρίτης, a pearl.)

MARGARET, ST. (Sancta Margarita), virgin and martyr, is celebrated by the Church of Rome on July 20. According to the legend, she was a native of Antioch, daughter of a pagan priest named Aedesius. She was scorned by her father for her Christian faith, and lived in the country with a foster mother keeping sheep. Olybrius, the "praeses orientis," offered her marriage as the price of her renunciation of Christianity. Her refusal led to her being cruelly tortured, and after various miraculous incidents, she was put to death about 275 A.D. Among the Greeks she is known as Marina, and her festival is on July 17. She has been identified with St. Pelagia (*q.v.*)—Marina being the Latin equivalent of Pelagia — who, according to a iegend, was also called Margarito. The cult of St. Margaret was very widespread in England, where more than 250 churches are dedicated to her.

See *Acta sanctorum,* July, v. 24–45; *Bibliotheca hagiographica, Latina* (Brussels, 1899), n. 5303–13; Frances Arnold-Forster, *Studies in Church Dedications* (London, 1899), i. 131–133 and iii. 19.

MARGARET, ST. (*c.* 1045–1093), queen of Malcolm III. Canmore king of Scotland, was the daughter of the English prince Edward, son of Edmund Ironside, and sister of Edgar Aetheling. In 1067 the widow and children of Edward fled from Northumberland and sought the protection of the Scottish king. The marriage of Malcolm and Margaret was followed by several invasions of Northumberland by the Scottish king, probably in support of the claims of his brother-in-law Edgar. A considerable portion of the old Northumbrian kingdom had been reduced by the Scottish kings in the previous century, but up to this time the English population had little influence upon the ruling element of the kingdom. Malcolm's marriage undoubtedly improved the condition of the English, and under Margaret's sons, Edgar, Alexander I. and David I., the Scottish court practically became Anglicized. Margaret died on Nov. 17, 1093, four days after her husband and her eldest son Edward, who were slain in an invasion of Northumberland. She rebuilt the monastery of Iona, and was canonized in 1251 on account of her benefactions to the Church.

MARGARET (1353–1412), queen of Denmark, Norway and Sweden, the daughter of Valdemar IV. of Denmark, was born in 1353 and married ten years later to King Haakon VI. of Norway. Her first act, after her father's death (1375), was to procure the election of her infant son Olaf as lung of Denmark. Olaf died in 1387, having in 1380 also succeeded his father; and in the following year Margaret, who had ruled both kingdoms in his name, was chosen regent of Norway and Denmark. She now turned to Sweden, where the nobles were in arms against their unpopular king, Albert of Mecklenburg.

At a conference held at Dalaborg castle, in March 1388, the Swedes were compelled to accept all Margaret's conditions, elected her "Sovereign Lady and Ruler," and engaged to accept from her any king she chose to appoint. On Feb. 24, 1389, Albert, who had returned from Mecklenburg with an army of mercenaries, was routed and taken prisoner at Aasle near Falkoping, and Margaret was now the omnipotent mistress of three kingdoms. Stockholm, then almost entirely a German city, still held out; fear of Margaret induced both the Mecklenburg princes and the Wendish towns to hasten to its assistance; and the Baltic and the North Sea speedily swarmed with the privateers of the *Viktualien brodre* or *Vitalianer,* so called because their professed object was to revictual Stockholm. Finally the Hansa intervened, and by the compact of Lindholm (1395) Albert was released by Margaret on promising to pay 60,000 marks within three years, the Hansa in the meantime to hold Stockholm in pawn. Albert failing to pay his ransom within the stipulated time, the Hansa surrendered Stockholm to Margaret in September 1398, in exchange for very considerable commercial privileges.

It had been understood that Margaret should, at the first convenient opportunity, provide the three kingdoms with a king who was to be her nearest kinsman, and in 1389 she proclaimed her infant cousin, Eric of Pomerania, king of Norway. In 1396 homage was rendered to him in Denmark and Sweden likewise, Margaret reserving to herself the office of regent during his minority. To weld the united kingdoms still more closely together, Margaret summoned a congress of the three councils of state to Kalmar in June 1397; and on Trinity Sunday, June 17, Eric was crowned king of Denmark, Norway and Sweden. The proposed act of union divided the three *Rigsraads,* but the actual deed embodying the terms of the union never got beyond the stage of an unratified draft. Margaret revolted at the clauses which insisted that each country should retain its own laws and customs, and be administered by its own dignitaries, as tending to prevent amalgamation, but she avoided every appearance of an open rupture.

A few years after the union of Kalmar, Eric, now in his eighteenth year, was declared of age and homage was rendered to him in all his three kingdoms, but during her lifetime Margaret was the real ruler of Scandinavia. So long as the union was insecure, Margaret had tolerated the presence near the throne of "good men" from all three realms (the *Rigsraad,* or council of state, as these councillors now began to be called); but their influence mas always insignificant. In every direction the royal authority remained supreme. The offices of high constable and earl marshal were left vacant; the *Danehoffer* or national assemblies fell into desuetude, and the great queen, an ideal despot, ruled through her court officials acting as superior clerks Margaret also recovered for the Crown all the landed property which had been alienated during the troublous days of Valdemar IV. This so-called "reduktion," or land-recovery, was carried out with the utmost rigour, and hundreds of estates fell to the Crown. Margaret also reformed the Danish currency. In foreign politics she maintained a strict system of neutrality. On the other hand she spared no pains to recover lost Danish territory. Gotland she purchased from its actual possessors, Albert of Mecklenburg and the Livonian Order, and the greater part of Schleswig was regained in the same way. Margaret died suddenly on board her ship in Flensborg harbour on Oct. 28, 1412.

MARGARET (1489–1541), queen of Scotland, eldest daughter of Henry VII., king of England, by his wife Elizabeth, daughter of Edward IV., was born at Westminster on Nov. 29, 1489. She married James IV. of Scotland on Aug. 8, 1503, but the scanty dowry given by her avaricious father embittered the relations between the two kingdoms, which the marriage, although accompanied by a treaty of perpetual peace. did nothing to heal. The whole of Margaret's life after her marriage was an unending series of intrigues, first with one political faction then with another; her conduct being mainly influenced by considerations affecting her pocket.

Margaret was crowned at Edinburgh in March 1504. Between 1507 and 1510 two sons and a daughter were born, all of whom died in infancy; in 1512 she gave birth to a son who succeeded his father as James V.; in 1514 she bore a posthumous son, Alexander, created duke of Ross, who died in the following year. A dispute with her brother Henry VIII. over a legacy was a contributory cause of the war which ended at Flodden, where James IV. was killed in Sept. 1513, having by his will appointed Margaret sole guardian of her infant son, now James V. Scotland was divided mainly into two parties, one in favour of alliance with England, and the other with France. The leader of the latter was John Stewart, duke of Albany, next heir to the crown of Scotland after Margaret's sons; Margaret herself for the most part inclined to the English faction; and when Albany returned to Scotland from France on the invitation of the Scottish parliament in the spring of 1514, the conflict grew almost to civil war. Her marriage to Archibald Douglas, earl of Angus, on Aug. 6, 1514 alienated many of the nobility, especially the earls of Arran and Home, and made her entirely dependent on the house of Douglas. It also furnished the council with a pretext for removing her from the regency and guardianship of the king in favour of Albany in July 1515. She fled to England in September, where a month later she bore to Angus a daughter, Margaret, who afterwards became countess of Lennox, mother of Lord Darnley and grandmother of James I. of England.

In 1516 Margaret went to her brother's court in London, while Angus, much to his wife's displeasure, returned to Scotland, where he made peace with Albany and was restored to his estates. The rivalry between the French and English factions in Scotland was complicated by private feuds of the Hamiltons and Douglases, the respective heads of which houses, Arran and Angus, were contending for the supreme power in the absence of Albany in France, where at the instance of Henry VIII. he was detained by Francis I. Margaret, quarrelling with her husband over money matters, sided at first with Arran and began to agitate for a divorce from Angus. In this she was probably aided by Albany, who found an unexpected ally in the queen-mother, Margaret being temporarily alienated from the English party by her brother Henry's opposition to her divorce. When Albany returned to Scotland in 1521 his association with Margaret gave rise to the accusation that it was with the intention of marrying her that he favoured her divorce from Angus. As Albany was strongly supported by the Scottish parliament, Angus found it necessary to withdraw to France till 1524. During these years there was constant warfare between the English and the Scots on the border, but in May 1524 Albany was obliged to retire to France. Henry VIII. continually aimed at securing the person of his nephew, the king of Scots, but he was proclaimed a reigning sovereign in July 1524. The queen-mother married Henry Stewart, second son of Lord Avondale, immediately after her divorce from Angus in 1527. Margaret and her new husband, who was created Lord Rlethven, now became for a time the ruling influence in the counsels of James V. But when her desire to arrange a meeting between James and Henry VIII. in 1534 was frustrated by the clergy and the council, Margaret in her disappointment revealed certain secrets to Henry which led to her being accused by her son of betraying him for money and of acting as an English spy. She died at Methven Castle on Oct. 18, 1541.

Bain (2 vols, Edinburgh, 1890); John Leslie, *Hzstory of Scotland,* ed. by *T*. Thompson (4 vols., Edinburgh, 1830); Sir H. Ellis, *Original Letters Illustrative of Englzsh History* (182j-46).

MARGARET (1283–1290), titular queen of Scotland, and generally known as the "maid of Norway," was the daughter of Eric II., king of Norway, and Margaret, daughter of Alexander III., king of Scotland. Her mother died soon after Margaret's birth, and in 1284 the estates of Scotland decided that if Alexander died childless the crown should pass to his granddaughter. In March 1286 Alexander was killed and Margaret became queen. The English king Edward I. was watching affairs in Scotland, and in 1289 a marriage was arranged between the infant queen and Edward's son, afterwards Edward II. Margaret sailed from Norway and reached the Orkneys, where she died in Sept. 1290. Some mystery surrounded her death, and about 1300 a woman from Leipzig declared she was Queen Margaret. The impostor, if she were such, was burned as a witch at Bergen.

See A. Lang, *History of Scotland,* vol. i. (Edinburgh, 1904); A. O. Anderson, *Early Sources of Scottish History, A.D. 500–1286,* vol. *a* (1922).

MARGARET MAULTASCH (1318–1369), countess of Tirol, nicknamed Maultasch (pocket-mouth) on account of the shape of her mouth, was the daughter and heiress of Henry, duke of Carinthia and count of Tirol. When Henry died in 1335 Carinthia passed to Albert II., duke of Austria; but Tirol was inherited by Margaret and her young husband, John Henry, son of John, king of Bohemia, whom she had married in 1330. This union was not a happy one, and the Tirolese disliked the government of Charles, afterwards the emperor Charles IV., who ruled the county for his brother. Margaret combined with the Estates and expelled her husband, being supported by the Emperor Louis IV., who, declaring her marriage null and void, married her in 1342 to his own son Louis, margrave of Brandenburg, whom Margaret then pronounced Count of Tirol. The local nobles were, however, soon discontented with their new rulers. Supported by the Pope, who placed the Emperor and his son under the ban, they attacked Margaret, who defended herself bravely until her husband put down the rebellion. Louis died in 1361 and Margaret's only son, Meinhard, in 1363 On Sept. 29, 1363, Margaret handed over Tirol to Rudolph IV., duke of Austria, and retired to Vienna, where she died on Oct. 3, 1369. She lived long in the memory of the people of Carinthia, who regarded her as an amazon, and called her the *Wicked Gretl.*

See A. Huber, *Geschichte der Vereinigung Tirols mit Oesterreich* (Innsbruck, 1864). Her story is the subject of Lion Feuchtwanger's novel *The Ugly Duchess.*

MARGARET OF ANJOU (1430–1482), queen of England, daughter of René of Anjou, titular king of Naples and Jerusalem, was born on March 23, 1430. She married Henry VI. king of England on April 23, 1445. Her marriage had been negotiated by William de la Pole, duke of Suffolk, and when she came to England, Suffolk and his wife were her only friends. Naturally she fell under his influence, and supported his policy. This, added to her French origin and sympathies, made her unpopular. Her active share in politics began after Suffolk's fall in 1450. She not only supported Edmund Beaufort, duke of Somerset, in his opposition to Richard of York, but concerned herself also in the details of government, seeking pecuniary benefits for herself and her friends. As a childless queen her influence was limited; and when her only son, Edward, was born on Oct. 13, 1453, her husband was stricken with insanity. From this time she was the ardent champion of her husband's and son's rights; to her energy the cause of Lancaster owed its endurance, but her implacable spirit contributed to its failure.

When York's protectorate was ended by Henry's recovery in January 1455, Margaret, not content with the restoration of Somerset and her other friends to liberty and office, pushed her politics to extremes. The result was the defeat of the Lancastrians at St. Albans, and for a year Margaret had to acquiesce in York's power. Ultimately, in October 1456 at Coventry, she procured some change in the government. Though formally reconciled to York in March 1458, she continued to intrigue with her partisans in England. and even with friends in France. After the Yorkist failure at Ludlow in 1459, Margaret embittered the struggle by a wholesale proscription of her opponents in the parliament at Coventry. She was not present with her husband at Northampton on July 10, 1460. She made her way to Scotland, and from Mary of Gelderland, the queen regent, purchased the promise of help at the price of surrendering Berwick. Margaret was still in Scotland at the date of Wakefield, so was not, as alleged by hostile writers, responsible for the barbarous treatment of York's body. But she was with the northern army which defeated Warwick at St. Albans on Feb. 17, 1461; for the executions which followed she must bear the blame. After Towton Margaret with her husband and son once more took refuge in Scotland.

A year later she went to France, and with help from her father and Louis XI. equipped an expedition which landed in Northumberland in October, and achieved some slight success; but on the way to seek further help from Scotland the fleet was overwhelmed in a storm. In the spring she was again trying to raid Northumberland. In August 1463 she crossed to Sluys in Flanders. She was almost destitute, but was courteously treated by Charles the Bold, then count of Charolais, and joined her father in France. Margaret never lost her hopes of her son's restoration. But when at last the quarrel between Warwick and Edward IV. brought her the opportunity, it was with difficulty that she could consent to be reconciled to so bitter an enemy. After Warwick's success and Henry's restoration Margaret still remained in France. On the day of Warwick's defeat at Barnet (April 14) Margaret and Edward landed at Weymouth. Three weeks later the Lancastrians were defeated at Tewkesbury, and Edward was killed. Margaret was captured a few days after, and brought to London where for five years she remained a prisoner. Finally Louis XI. ransomed her under the Treaty of Pecquigny, and she returned to France in January 1476. Margaret lived for six years in Bar and Anjou, in poverty and dependent for a pension on Louis, who made her surrender in return her claims to her father's inheritance. She died on April 25, 1482 and was buried at Angers cathedral.

BIBLIOGRAPHY.—For contemporary English authorities *see* under HENRY VI. French authorities and especially the *Chroniques* of George de Chastellain, and the *Mémoires* of Philippes de Comines contain much that is of value. The *Letters of Margaret of Anjou* (Camden Soc., 1863) have small historical importance. There have been numerous biographies, the chief is Mrs. Hookham's *Life of Margaret of Anjou* (1872).

MARGARET OF AUSTRIA (1522–1586), duchess of Parma and regent of the Netherlands from 1559 to 1567, was a natural daughter of Charles V. Her mother, Margaret van Ghent, was a Fleming. She was brought up by her aunts Margaret of Austria and Maria of Hungary, who were successively regents of the Netherlands from 1507 to 1530 and from 1530 to 1555. In 1533 she was married to Alexander de' Medici, duke of Florence, who was assassinated in 1537, after which she became the wife of Ottavio Farnese, duke of Parma, in 1542. The union proved an unhappy one. Like her aunts, who had trained her, she was a woman of masculine abilities, and Philip II., when he left the Netherlands in 1559 for Spain, acted wisely in appointing her regent. In ordinary times she would probably have proved as successful a ruler as her two predecessors in that post, but her task was very different from theirs. She had to face the rising storm of discontent against the Inquisition and Spanish despotism, and Philip left her but nominal authority. He was determined to pursue his own arbitrary course, and the issue was the revolt of the Netherlands. In 1567 Margaret resigned her post into the hands of the duke of Alva and retired to Italy. She died at Ortona in 1586.

Rachfahl, *Margaretha von Parma, Statthalterin der Niederlande, 1559–1567* (Munich, 1895); also bibliography in *Cambridge Modern History,* iii. 795–809 (1904).

MARGARET OF AUSTRIA (1480–1530), duchess of Savoy and regent of the Netherlands from 1507 to 1530, daughter of the archduke Maximilian of Austria, afterwards the emperor Maximilian I., was born at Brussels on Jan. 10, 1480. In April 1497 she was married at Burgos to the Infant John, heir to the throne of Castile and Aragon. She was left a wido , however, a few months later. In 1501 Margaret became the wife of Philibert II., duke of Savoy, who only survived until 1504. The sudden death of her brother the archduke, Philip the Handsome (Sept. 25, 1506), opened out to her a new career. In 1507 she was appointed by her father regent of the Netherlands and guardian of her nephew Charles, afterwards the emperor Charles V. Charles came of age in 1515, but he entrusted Margaret with the regency, and she held the post until her death in 1530. She was a wise and prudent ruler, of masculine temper and intrepidity, and capable in affairs of state. She is noted for her part in conducting preliminary negotiations with Louise of Savoy, mother of Francis I of France, leading toward the treaty of Cambrai (1529) between Francis and Charles V. Under that treaty, known as la *paix des dames* ("ladies' peace"), Francis renounced his claims on Milan and Naples but retained Burgundy.

MARGARINE, or OLEOMARGARINE, has been variously defined during its history. In the U.S. it is defined in the standard of identity promulgated under the federal Food, Drug and Cosmetic act as a plastic food prepared from one or more vegetable and animal fats intimately mixed with one or more variations of cow's milk together with table salt and several other permitted optional ingredients in small quantities. It may also be defined as a plastic, solid, fat food consisting of 80% (U.S. legal minimum) edible fat, which carries dispersed in it the balance of the product, namely, an aqueous portion consisting primarily of skim milk and salt.

The ingredients in margarine, then, are those found in its edible fat portion and in its milk portion. The edible fats used have varied widely since the 1870s when the manufacture of margarine began, the trend having been from the animal fats predominantly in use earlier, to the vegetable fats predominantly in use in the mid-20th century in the C.S. In European countries whale oil has been and is widely used, but it was never commonly used in the U.S. Animal fats used in the U.S. included lard, oleo oil and tallow; a wide variety of the vegetable fats have been used, principally cottonseed, soybean. peanut and corn oils in the 1950s; and nut oils, such as coconut, palm and palm kernel oils before 1935.

Usually there are such ingredients as vitamins A and D, vegetable lecithin. emulsifiers and similar materials dissolved in the liquid fats used in making margarine, while in the milk portion there are dissolved the salt and other ingredients readily mixable with milk. These two portions are then thoroughly mixed to produce an emulsion which is chilled to a solid, kneaded to a suitable mass and packaged.

Margarine was developed in the late 1860s by the French chemist Hippolyte Mège-Mouriès, who not only received recognition for his achievement in France and other European countries, but was also granted a U.S. patent in 1873. Out of Mège-Mouriès' early experience and process, uhich was unduly complicated. there grew the generally simple process in the 1870s and 1880s in the U.S. of churning the melted margarine fat blend with milk and salt, solidifying the churned mixture by chilling with cold water, working mechanically (kneading) the chilled mass to a plastic consistency and packaging, all by means of typical butter-working equipment of the time.

Primarily as a result of the efforts of competitive industries, margarine was subjected in the United States and elsewhere to severe restrictive legislation. The Oleomargarine act of 1886 was the earliest significant U.S legislation on the subject. This law, together with subsequent amendments to it (1902, 1930), imposed a prohibitive tax on yellow margarine, levied high licence fees on all manufacturers, wholesalers and retailers of the product, and in other respects subjected the manufacture and sale of this food to numerous restrictions. The result was not only to prevent margarine from reaching its normal consumption level but for a very long time to prevent the sale of any yellow margarine. There was also a wave of similar state legislation, in which practically every state took part.

An important development in margarine processing occurred in the mid-1930s. Before that time, most vegetable fat margarine was made from imported oils, such as coconut, palm and palm kernel oils. While these oils were perfectly wholesome. the anti-margarine groups used this situation to support the continued restrictions on margarine and even to advocate additional ones on the basis that such use of foreign oils was inimical to the best interests of the C.S. farmer. After considerable research, manufacturers of margarine in the U.S. finally found in the mid-1930s how to make a satisfactory margarine from domestic vegetable oils. The resultant increase in the use of cottonseed and soybean oils stimulated the interest of cottonseed and soybean farmers and processing groups in the elimination of discriminatory restrictions on margarine; in the 1940s consumer groups in the U.S. also became interested in the elimination of this legislation.

The efforts of domestic, agricultural and consumer groups to have margarine freed from what they considered unfair legislation culminated in success in 1950, when congress repealed all the federal taxes and licence fees on margarine made in the U.S. This action was followed by similar action of state legislatures, and within a relatively short time thereafter, most of the state prohibitions against yellow margarine were repealed.

In addition to the development of the use of domestic vegetable fats in margarine, other improvements by modern scientific methods were made. In 1923 it was first fortified with vitamins A and D. In 1941, following extensive public hearings, the United States Food and Drug administration established a definition and standard of identity for margarine which, in turn, were revised and brought up to date in 1952. This standard prescribed the mandatory and the optional ingredients to be used in the manufacture of margarine, and served not only as government recognition of the wholesomeness of the product, but also as a protection to the consumer. As a result of these developments and other scientific advances, margarine has been accepted by the U.S. public to an extent comparable with its acceptance in many European countries.

Nutritionally, the value of margarine as a food fat is primarily as a source of food fuel (calories) and of other nutritional factors. From the early 1950s, all margarine manufactured in the U.S. was fortified with at least 15,000 U.S.P. units of vitamin A to the pound. The caloric value of margarine is derived from food fats widely used and accepted by many people in forms other than margarine. See also Index references under "Margarine" in vol. 24.

MARGARITA ISLAND (ISLA DE MARGARITA), also known as the Isle of Pearls, is the largest of 70 islands making up the state of Nueva Esparta (*q.v.*) in Venezuela, and is about 12 mi. N. of the peninsula of Araya. Of the 75.899 persons in the state in 1950, 72,229 were concentrated on the island. Margarita is about 40 mi. long from east to west, has an area of 414 sq.mi. and a coast line of 198 mi., with many natural harbours. It is in reality two islands joined by a low, narrow isthmus. The highest elevation on the island is the peak of Macanao, 2,493 ft. After 1950 the government enlarged its road-building program, and in 1957 the official claim was that the island had 200 mi. of improved roads. There is an airport at Porlamar. Water is a fundamental problem of the island population; drinking water is brought from the mainland. Farming and grazing is carried on but the island is a net importer of foodstuffs.

La Asunción (pop. [1950] 4,510), on the eastern end of the island, is the capital of the state. It was founded in 1524 by Marcelo Villalobos. Porlamar (pop. [1950] 14,769), is the most important city. It is the centre of a pearl fishing industry that dates back to the early 16th century and which is closely controlled by the government in order to guarantee its continuance. Pampatur (pop. [1950] 2,506), the leading port, is located on a protected bay. Juangriego (pop. [1950] 3,928), located on the north side of the island, is a major fishing centre; its canned products are sold throughout the nation.

Tile and ceramics are manufactured on the island. Shoes and hats made from sisal, produced locally, have a national market. The building of fishing boats is an established industry, as is the manufacture of salt. After World War II Margarita won favour as a tourist area.

The island of Margarita was discovered by Columbus in 1498 on his third voyage. The pearl industry of Margarita and the surrounding islands sprang up soon thereafter. The life span of the Indian divers was short and the raiding of the mainland for replacements led to bloody reprisals by the natives. In 1j61 the crazed Lope de Aguirre ravaged the island before menacing the mainland. Fifteen years later (1576) it was visited by British pirates. In 1662 Pampatar was razed by the Dutch. For a long time Margarita was attached to Cumaná, but in the 18th century it was made administratively independent. Its traders rendered invaluable assistance to the revolutionists in the wars of independence; Simon Bolivar used the island as a base of operation in 1816, and the Spanish general Pablo Morillo was driven from its shores in 1817. In recognition of its contribution to the independence movement Margarita, with the surrounding smaller islands, was renamed Nueva Esparta ("New Sparta").

The population of Margarita is predominantly indigenous; the Spanish ancestry is traceable chiefly to the Canary Islands. Since 1920 the island has attracted immigrants from abroad, but at the same time many islanders have migrated to the mainland in search of favourable employment. There are on the island a liceo (high school) and three institutions which provide commercial instruction. (J. J. J.)

MARGATE, a municipal borough and seaside resort in the Isle of Thanet parliamentary division of Kent, Eng., 16 mi. N.E. of Canterbury by road. Pop. (1961) 45,708. Area 10.9 sq.mi. During the summer it is served by pleasure steamers from London. The municipality owns 9 mi. of sea front, with promenades along almost the whole distance. and has provided concert pavilions, winter gardens, bathing pools and other amenities for the summer visitors, which are the town's chief industry. There are some light industries south of the town. Margate suffered considerably from air raids in World War II, and in 1951 new government offices were built.
