Besides the famous and far-spreading Use of Sarum, other Uses, more local and less known, grew up in various English dioceses. In virtue of a recognized diocesan independence, bishops were able to regulate or alter their ritual, and to add special masses or commemorations for use within the limits of their jurisdiction. The better known and the more distinctive of these Uses were those of York and Hereford, but we also find traces of or allusions to the Uses of Bangor, Lichfield, Lincoln, Ripon, St. Asaph, St. Paul's, Wells and Winchester. The Eucharistic service was contained in the volume called the Missal (*q.v.*), as the ordinary choir offices were contained in the volume known as the Breviary (*q.v.*).

Period IV. The Reformed Church.—The Anglican liturgy of Reformation and post-Reformation times is described under the heading of COMMON PRAYER. BOOK OF, but a brief description may be added here of the liturgies of other reformed churches. The liturgy of the Scottish Episcopal Church in nearly its present form was compiled by Scottish bishops in 1636 and imposed—or, to speak more accurately, attempted to be imposed—upon the Scottish people by the royal authority of Charles I. in 1637. The prelates chiefly concerned in it were Spottiswood, bishop of Glasgow; Maxwell, bishop of Ross; Wedderburn, bishop of Dunblane; and Forbes, bishop of Edinburgh. Their work was approved and revised by certain members of the English episcopate, especially Laud, archbishop of Canterbury; Juxon, bishop of London; and Wren, bishop of Ely. This liturgy has met with varied fortune and has passed through several editions. The present Scottish office dates from 1764. It is nou used as an alternative form with the English communion office in the Scottish Episcopal Church. The general arrangement of its parts approximates more closely to that of the first book of Edward VI. than to the present Anglican Book of Common Prayer. (See Bishop J. Dowden, The Annotated Scottish *Communion Service,* 1884.)

American Liturgy.—The Prayer Book of "the Protestant Episcopal Church" in America was adopted by the general convention of the American church in 1789. It is substantially the same as the English Book of Common Prayer, but among important variations we may name the following: (a) The arrangement and wording of the order for Holy Communion rather resembles that of the Scottish than that of the English liturgy, especially in the position of the oblation and invocation immediately after the words of institution. (b) The Magnificat, Nunc dimittis and greater part of Benedictus were disused; but these were reinstated among the changes made in the Prayer Book in 1892, (c) Ten selections of Psalms are appointed for use as alternatives for the Psalms of the day. (d) Gloria *in excelsis* is allowed as a substitute for Gloria *Patri* at the end of the Psalms at morning and evening prayer. In addition to these there are many more both important and unimportant variations from the English Book of Common Prayer.

The Irish Prayer Book.—The Prayer Book in use in the Irish portion of the United Church of England and Ireland was the Anglican Book of Common Prayer, but after the disestablishment of the Irish church several changes were introduced into it by a synod held at Dublin in 1870. These changes included such important points as: (a) the excision of all lessons from the Apocrypha, (b) of the rubric ordering the recitation of the Athanasian Creed, (c) of the rubric ordering the vestments of the second year of Edward VI., (d) of the form of absolution in the office for the visitation of the sick, (e) the addition to the Catechism of a question and answer bringing out more clearly the spiritual character of the real presence.

The Presbyterian Church.— The Presbyterian churches of Scotland at present possess no liturgy properly so called. Certain general rules for the conduct of divine service are contained in the *Directory for the Public Worship of God* agreed upon by the assembly of divines at Westminster, with the assistance of commissioners from the Church of Scotland, approved and established by an act of the general assembly, and by an act of parliament, both in 1645. In 1554 John Knox had drawn up an order of liturgy closely modelled on the Genevan pattern ior the use of the English congregation to which he was then ministering at Frankfort. On his return to Scotland this form of liturgy was adopted by an act oi the general assembly in 1560 and became the established form of worship in the Presbyterian church until the year 1645, when the Directory oi Public Worship took its place. Herein regulations are laid down for the conduct of public worship, ior the reading of Scripture and for extempore prayer before and aiter the sermon, and in the administration of the sacrament of baptism and the Lord's Supper, for the solemnization of marriage, visitation of the sick and burial of the dead, ior the observance of days of public fasting and public thanksgiving, together with a form of ordination and a directory for family worship.

LITVINOV, MAKSIM MAKSIMOVICH (1876–1951), Russian politician, was born at Bielostok. When 17 he entered military service as a volunteer and while in the army became interested in Marxism. When his service was completed. he became a member of the Kiev committee of the Social Democratic party. One of the members of that committee proved to be a police agent and the committee was arrested. After a year and a half in prison Litvinov with 11 companions escaped, went abroad and took an active part in the *Iskra,* the Social Democratic newspaper. Litvinov joined the Bolshevik section of the party, returned to Russia illegally in 1903, and worked there as a member of the central committee until the revolution of 1905. He attended the London congress as a delegate from the Riga committee, and later took part with Maxim Gorky in founding *Novaya Zhizn (The New Life).*

After the failure of the attempted revolution of 1905 Litvinov lived abroad, and organized the sending of weapons to the revolutionaries in the Caucasus. After the Nov. 1917 revolution in Russia he was appointed diplomatic agent of the soviet government in England. He was subsequently arrested as a hostage for Bruce Lockhart, for whom he was exchanged. As assistant commissar for foreign affairs he took part in the initiation of peace negotiations with Estonia, in negotiations at Copenhagen with England, in the Genoa conference and, as president of the Russian delegation, in the subsequent conference at The Hague. Litvinov continued to take a leading part in disarmament conferences, both in Moscow and Geneva. From 1930 to 1939 he was people's commissar for foreign affairs. He died Dec. 31, 1951.

LIU-CHOU (Liuchow), a city in central northern Kwangsi Chuang Autonomous Region, China. Pop. (1953) 158,800. Until 1937 it was called Maping. An important U.S. advance airbase was located there during World War II. The city is located 300 mi. northwest of Canton on the Liu Chiang, which drains southeastern Kweichow, and is at the head of year-round junk navigation, and steam launch navigation in the summer. Liu-chou is an important transportation centre for roads and railroad lines leading north into Hunan, northwest into Kweichow, and south toward Vietnam. Coal is mined, and lumber produced, to the northwest. The city, in the early 1960s, was developing into a regional centre of light industry, with the beginnings of heavy industry, and was growing rapidly in population. (J. E. Sr.)

LIUDPRAND (Liutprand, Luitprand) (*c.* 922–*c.* 972), Italian chronicler, whose works are a major source for the history of Italy and Germany in the 10th century. Of noble Lombard family, he joined King Hugh's retinue as a page; after Hugh's fall (947) he entered the service of King Berengar who sent him on an embassy to Constantinople (949). Having quarreled with Berengar on his return, he found refuge at the court of Otto I, where he rose to a prominent position. Otto made him bishop of Cremona in about 961, and in the iollowing year he was present at Otto's imperial coronation. Having become one of the king's principal diplomatists, he went in 968 on another embassy to Constantinople, to'demand the hand of a Greek princess for the future Otto II. He died probably in 972.

A Lombard patriot and enemy of Berengar, Liudprand became a loyal adherent of Otto I; and his writings are coloured by his political enmities and loyalties, as well as by his personal prejudices, as for instance against the Greeks. While his *Antapodosis,* an account of events from 888 to 949, is directed against Berengar and Willa, his *Historia Ottonis* is meant to justify the emperor's ecclesiastical policy; and his *Relatio de legatione Constantinopolitana* may have been intended to serve as political propaganda for the resumption of the war against the Byzantines. But despite their strongly polemical and often biased character, his works are among the most valuable historical sources for the history of Italy and the empire during his time. Liudprand knew Greek and had a considerable knowledge of Roman literature; and his works constitute an important document of contemporary classical learning. The most recent edition of Liudprand's works is by J. Becker, in *Monumenta Germaniae Historica in usum scholarum,* 3rd ed. (1915) ; Eng. trans. by F. A. Wright (1930).

See W. Wattenbach-R. Holtzmann, *Deutschlands Geschichtsquellen im Mittelalter. Deutsche Kaisevceit, I,* 2 (1948) ; M. Lintzel, *Studien über Liutprand von Cremona* (1933). (N. R.)

LIU SHAO-CH'I (1898–), president of the People's Republic of China and a leading theoretician of the Chinese Communist party, was born of poor peasant parents in Ning-hsiang district, Hunan province, probably in 1898, though some sources give 1905. Liu attended middle school in Ch'ang-sha and studied in Shanghai and at the Peking university. He joined the Communist party in 1921 and became a labour organizer in Shanghai. In 1921 he was sent to the Far Eastern university in Moscow. The next year he returned as a labour organizer in coal-mining districts along the Kiangsi-Hunan border. In 1927 he was elected to the central committee of the Communist party. After a second sojourn in Moscow, he began organizational work in the Kiangsi Soviet and was later commissar of the New Fourth army. He was elected to the Politburo in 1942 and later served in other high offices. His theoretical essays became standard texts in Communist China. In 1949 Liu was made vice-chairman of the central government council in Peking. On April 27, 1959, he succeeded Mao Tse-tung as chairman (president) of the People's Republic of China. (R. C. N.)

LIVER (Hepar). The liver is a gland, the largest in the body. It is located in the upper right part of the abdominal cavity. It is rather soft, so that the surrounding organs push in its surface (as shown in fig. 1), but as soon as the living liver is taken out of its position, as during surgery, the depressions disappear. Its weight of approximately 1.5 kg. (3.3 lb.) presents about one-fiftieth of the total body weight. The liver has many different functions, each of which is based on its strategic location in the blood stream. It is a filter and clearing station that purifies blood; a storage place for food, particularly for sugar and vitamins; a producer of proteins of various kinds and of antibodies;

FIG. 1.—POSTERIOR SURFACE OF THE LIVER

and a gland that aids in digestion and acts as a remover of waste. All vertebrate animals and only vertebrate animals possess a liver.

Animal liver in man's diet is an important source of protein and fat and vitamins, especially of vitamins A, D, E and vitamin B complex. Because of its high content of iron, copper and particularly of vitamin B_{12} it is useful in the dietary control of certain kinds of anemia.

Functions.—The liver is a mass of cells through which the stream of venous blood flows as it returns from the intestine to the heart (fig. 2). As the blood passes through the wall of the gut, foodstuffs and occasionally poisonous substances are added to it. Laden with these materials, the blood passes immediately through the liver, which acts as a filter, removing noxious substances, destroying or inactivating poisons by chemical means and removing bacteria.

The liver also acts as a storehouse, taking nutritional material from the blood and storing it for future use. Among the stored

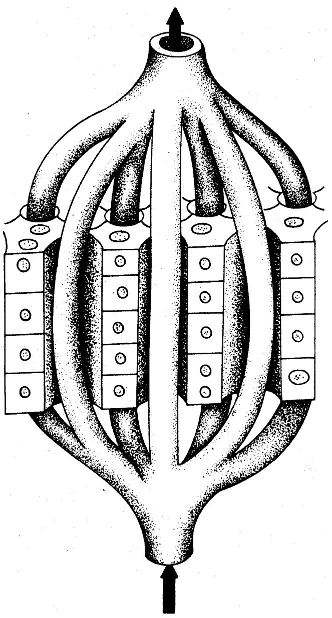

FIG. 2.—SCHEMATIC DRAWING OF THE LIVER AND ITS RELATIONSHIP TO THE GUT AND HEART

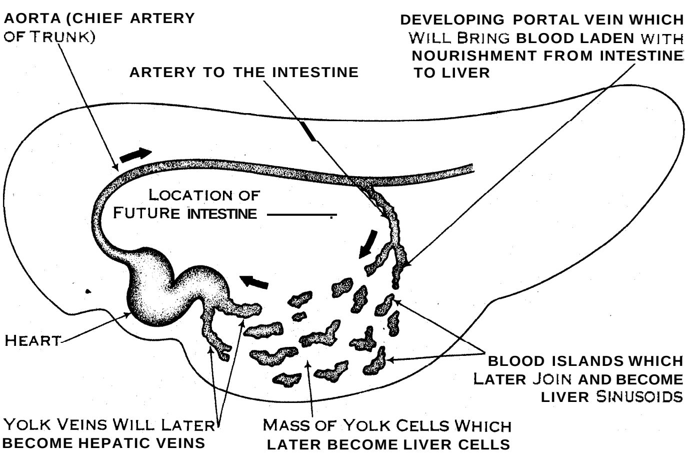
substances is sugar, which is taken from the blood under the influence of the hormone insulin (*q.v.*), produced in the pancreas. The sugar is converted into storable glycogen, which remains in the liver cells until it is needed for energy production, at which time it is reconverted into sugar under the influence of another pancreatic hormone, glucagon.

Fat, vitamins and other foodstuffs also are stored in the liver cells. Purification and storage are by no means the only functions of the liver. As the blood flows through it, the liver adds to the blood plasma proteins, among which albumin, fibrinogen, globulins, prothrombin and heparin are important. The liver also adds antibodies to the blood, which counteract disease-producing poisons (toxins) produced by bacteria. Thus it is a part of the defense system of the body.

Not only does the liver receive materials from the intestine via the blood stream, but it also is connected with the intestine by a system of tubes through which a stream of bile flows from the liver into the gut. Bile is a green liquid, secreted by the liver, that contains many different substances, among them bile acids: which aid in fat digestion, and bile salts, which help in the absorption of fat and fat soluble substances such as vitamins A, D, K and E. Many red blood cells are destroyed in the bone marrow, spleen and liver. Hemoglobin, which gives these blood cells their red colour, is thus released and flows freely in the blood. The liver picks up this dye and transforms it into bilirubin (a reddish pigment) and biliverdin (a greenish pigment), which flow with the bile into the intestine and are responsible for the brown colour of the feces. Waste products of the body activity, such as urea and uric acid, are excreted by the liver through the bile stream. Cholesterol also is eliminated from the liver through the bile, but most of it is rcabsorbed by the intestine and thus is not lost.

Embryological Development.—Developmentally, the liver is the successor of the yolk sac of lower vertebrates. Its development is best exemplified in the amphibians. The female frog produces eggs in her ovary. In these eggs, a great amount of nutritive material (fat, protein and sugar) called yolk is deposited.

The egg is laid in the water, and an embryo, then a young larva and later a tadpole develop from it. The yolk is activated and put at the disposal of the developing organism. Most of the cells that contain yolk are located in the belly of the embryo, just behind the newly formed heart (fig. 3). Hollow spaces develop in the mass of yolk cells. These spaces enlarge and become connected with each other and with the heart, and blood cells develop in them. Thus, through these primitive blood vessels in the yolk sac, the nourishing substances that are liberated from the stored yolk come into the blood and, by way of the heart, are pumped into all parts of the larva. Meanwhile, the intestine develops. Blood vessels grow from the main artery toward and around the intestine and from there toward the yolk sac. These blood vessels hook up with the network of blood vessels in the yolk sac.



(LARGE ARROWS INDICATE DIRECTION OF BLOOD FLOW)

FIG. 3.—YOLK SAC OF A FROG LARVA

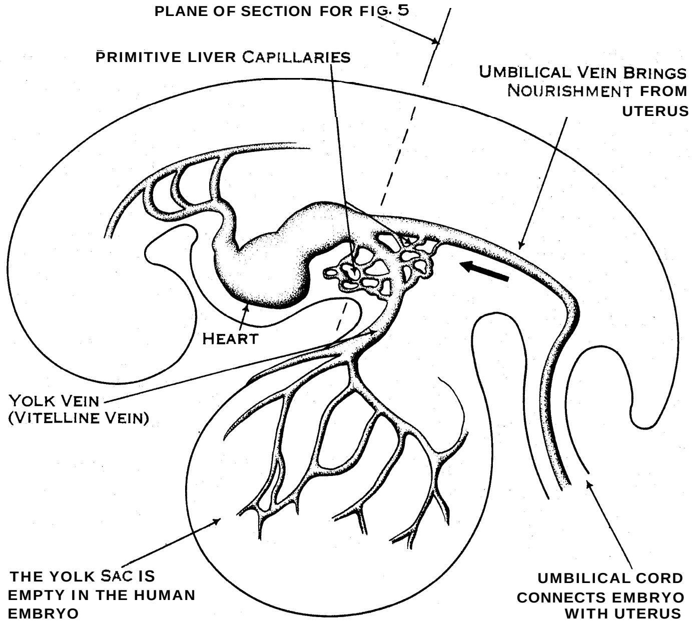


FIG. 4.—YOLK SAC OF THE HUMAN EMBRYO

Gradually, the cells in that region are depleted of yolk. At about the time the yolk has been used up, the mouth of the young tadpole opens, and it begins to eat. The food that it eats is digested in the gut, and through the wall of the gut penetrates into the blood vessels connected with the vessels in the former yolk sac. These vessels are surrounded by the cells that formerly contained the yolk. They are now empty and ready to store food again, but they are no longer yolk cells. They have become liver cells and can perform all the functions that liver cells must perform.

What were formerly yolk vessels are now called liver sinusoids. The yolk sac has become a liver. Since the liver produces bile, which must flow into the intestine, some liver cells arrange themselves so that they form the wall of a system of tubes, called bile ducts.

The main bile duct into which they all converge is termed the common bile duct. This common bile duct grows until it reaches the intestine and opens into it.

In man the development is quite different. The human embryo develops in the uterus, where it receives nourishment from the blood of the mother, and therefore the human egg contains almost no yolk. However, since man descended from lower verte-

FIG. 6.—A PORTION OF THE LIVER MURALIUM AND LABYRINTH

brates, the early human embryo has a yolk sac. This yolk sac is empty; yet, as if it were to remind us of our lower vertebrate ancestry, a dense net of blood vessels (the vitelline vessels) develops in its wall. A little later is developed a second system of blood vessels (the umbilical vessels.), which bring nourishment from the uterus. The vitelline and umbilical veins join just behind the heart and enter into the heart together. From the fork of their junction a network of blood capillaries grows into a mass of embryonic connective tissue (called septum transversum). (See fig. 4.) This capillary network has an outlet into the heart.

Many cells detach themselves from a ventral outpocketing of the wall of the primitive gut at its anterior junction with the yolk sac. Others detach themselves simultaneously from the lining (mesothelium) of the body cavity (fig. 5). These cells from both sources (entodermal and mesodermal) migrate into the spaces between the vitelline-umbilical capillaries in the septum transversum and surround the capillaries completely. They become liver cells.

Immediately they assume the primary function of liver cells—that is, storage of food that is brought to them from the uterus through the umbilical veins. The bile ducts develop from liver cell; and join in the common bile duct, which in turn joins the intestine.

In the chick the liver arises from tubular extensions of the gut wall. Unfortunately this exceptional type of development has become the basis for standard descriptions of liver development in textbooks.

The liver of the embryo has the additional function of producing blood cells, a function that in the adult is carried on by the bone marrow.

Among vertebrate animals, 20 different modes of liver development have been found. But regardless of the method by which the liver develops, the end result is always the same. It is as if several houses were to be built according to the same floor plan and elevations, but with different building materials and methods of construction. At the end, each house is wallpapered inside and covered with stucco externally so that they all look alike, and no one except a construction expert can tell how each house was built.

This observation is contradictory to the biogenetic law of Johannes P. Müller and Ernst Haeckel and to the laws of embryogenesis of Karl Ernst von Baer, which tell us that the embryos of various species are alike, but that the adults differ. Although there is much truth in these "laws," the comparative

FIG. 7.— MURALIUM OF LIVER CELLS WITH NETWORK OF BILE CANALICULI

embryology of the liver shows that they are by no means universal.

The livers of embryos of various species are extremely different, while the livers of adult vertebrates are in essence all alike.

Structure.— G. G. Simpson, in *The Meaning of Evolution,* has explained that if an organ shows great variations in adults from species to species, that organ must be adequate but it cannot be perfect. But if an organ is of equal construction throughout the entire range of its occurrence, then that organ must be perfect. Any divergent construction would be inadequate, and a better construction would be impossible. How, then, is this perfect liver built that can perform so many different tasks? Its construction is extremely simple, yet almost nothing was known about its microscopic structure prior to 1949 and almost nothing was known about its gross anatomy before 1952.

The liver of every vertebrate animal (including man) is a continuous mass of cells tunneled by a maze of connected cylindrical spaces (fig. 6) in which a network of specialized blood capillaries is suspended. One should imagine the liver to be a huge building with a maze of crooked hallways and long, narrow, crooked rooms.

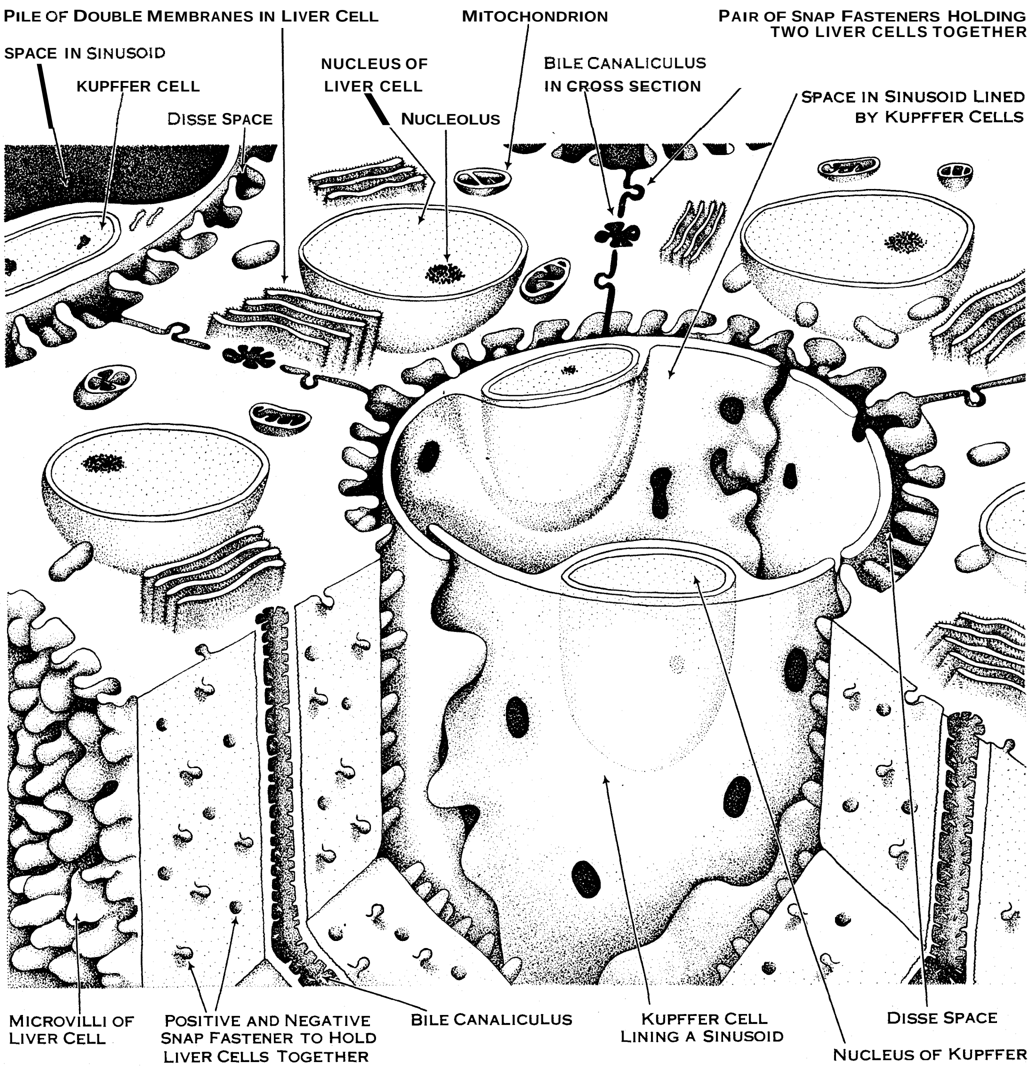

FIG. 8.—STEREOGRAM SHOWING THE SUBMICROSCOPIC STRUCTURE OF THE LIVER CELLS, KUPFFER CELLS AND BILE CANALICULI, AS REVEALED THROUGH ELECTRON MICROSCOPY BY FAWCETT, VOGEL AND RUTTNER

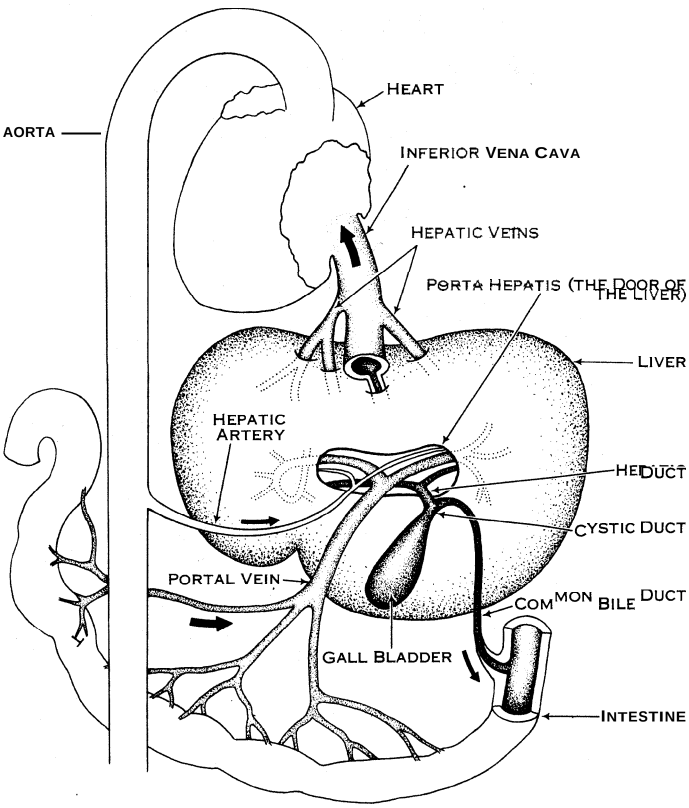

FIG. 9.—PORTA HEPATIS, THROUGH WHICH THE PORTAL VEIN AND HEPATIC ARTERY ENTER THE LIVER AND THROUGH WHICH THE BILE DUCTS LEAVE IT. PORTAL VENOUS BLOOD COMES FROM THE INTESTINE; HEPATIC ARTERIAL BLOOD COMES FROM THE MAIN ARTERY OF THE BODY, THE AORTA. BILE FLOWS THROUGH THE COMMON BILE DUCT INTO THE INTESTINE. THE BLOOD, AFTER PASSING THE LIVER, FLOWS THROUGH THE HEPATIC VEINS AND THE INFERIOR VENA CAVA BACK INTO THE HEART

Neighbouring rooms (the lacunae hepatis) are openly connected with each other, forming a three-dimensional labyrinth (the labyrinthus hepatis) (fig. 6). The walls between them are built not of stones but of liver (hepatic) cells (fig. 7). In lower vertebrates these walls (laminae hepatis) are two cells thick, while in songbirds and mammals, including man, they are only one cell thick. Such a system of connected walls is known as a muralium (from *murus*, "stone wall").

The liver of lower vertebrates, since its laminae are two cells thick, is a muralium duplex; that of higher vertebrates is a muralium simplex. The hepatic cells that compose the liver walls are connected, as the electron microscope shows, by little pegs that fit into depressions of neighbouring cells exactly in the manner of snap fasteners (fig. 8).

Between adjacent liver cells are minute tubes, the bile canaliculi, so small that they can rarely be seen in the light microscope (fig. 7). Electron microscopy shows that protoplasmic threads (microvilli) project into the bile canaliculi (fig. 8). The bile canaliculi together form networks of polygonal meshes, each surrounding an individual hepatic cell (fig. 7). Each liver cell possesses one, two or three spherical nuclei, each containing a nucleolus.

The size and number of the nuclei depends on the volume of each individual cell; this volume, in turn, depends on the location of the cell in the muralium, as shown in fig. 7. The hepatic cell also contains many mitochondria and piles of double membranes composed chiefly of ribonucleic acid. On the side toward the lacunae, the liver cells are studded with fingerlike and leaflike projections visible only by electron microscopy.

In the lacunae are suspended specialized capillaries, the successors of the yolk vessels, known as sinusoids. These sinusoids are lined by flat cells, called Kupffer cells after their discoverer, which have the ability to engulf and digest (phagocytize) particles of dirt, worn-out blood cells and bacteria. Until 1957 the Kupffer cells were believed to form an uninterrupted lining of the sinusoids. Electron microscopy, however, shows that there are spaces between them and pores in them through which liquid can pass directly from the blood stream to come into immediate contact with the myriads of submicroscopically small projections of the liver cells that pervade the narrow space (Disse space) between the solid part of the liver cells and the Kupffer cells.

The numerous functions of the liver are all carried out by the Kupffer cells and the hepatic (liver) cells. Much is known about their structure, but it appears that the more details are learned, the less is understood about their astonishing variety of function.

Gross Anatomy.—The liver receives its chief blood supply from the intestinal capillaries that converge to form the mesenteric veins. These, together with a vein from the spleen and a few small veins from the stomach, converge into a short but thick vessel called the portal vein. This is so named because it enters the liver at its "door" (porta hepatis) (fig. 9). This door is a deep and broad depression in the postero-inferior (dorso-caudal) surface of the liver. The portal vein divides, in the porta hepatis, into a left and a right trunk, from which a number of branches (rami venae portae) arise. These branches were unknown to anatomists in 1952, although Francis Glisson had described them in all detail in 1654, but in 1952 an accident led to their rediscovery. They are shown and named in fig. 10.

The liver acts upon the portal venous blood, as noted above. But for all this work, the liver needs energy, which it must derive from the combination of carbon (contained in foodstuffs) with oxygen.

Oxygen is provided by a relatively small artery, the hepatic artery (fig. 9), the smaller branches of which accompany the rami venae portae. The branches of both the portal vein and the hepatic artery empty into the sinusoids.

Blood flows through the sinusoids into tributaries of the hepatic veins. The latter empty into the inferior vena cava, which returns

FIG. 10.—POSTERIOR VIEW OF HUMAN LIVER. SHADED AREAS INDICATE HEPATIC VEINS: WHITE AREAS, PORTAL VEIN BRANCHES

the blood to the right atrium of the heart (figs. 9 and 10).

The porta hepatis is not only the entrance door for portal and arterial blood but also the exit for bile. The minute bile canaliculi converge inside the liver into ductules (little tubes), small ducts, large ducts, and then into ducts so thick that they can be seen with the naked eye. These ducts run along the portal vein branches. but the bile in them flows in the direction opposed to that of the blood flow. The bile ducts of ever-increasing calibre finally converge in the porta hepatis into the hepatic duct.

Outside the liver, the hepatic duct divides into two large branches. One of them, the cystic duct, ends in a large sac, the gall bladder. The internal lining of the gall bladder is thrown into many folds whereby its surface is increased. The cells lining it bear many tiny projections (microvilli). The gall bladder serves for short-term storage of bile, and at the same time it takes (through the microvilli) water out of the bile, making the bile more concentrated. If this concentration is carried to excess, gallstones consisting chiefly of cholesterol are formed. The other branch of the hepatic duct is the common bile duct. This duct leads into the upper part of the small intestine, the duodenum. At its exit, the common bile duct is guarded by a ring muscle, the sphincter of Oddi. Some animals, such as the horse. do not possess a gall bladder, a fact showing that the gall bladder is not necessary for life.

LNERMORE, MARY ASHTON [RICE] (1821–1905), U.S. reformer, was born in Boston, Mass., on Dec. 19, 1821. She studied at the female seminary at Charlestown, Mass., and taught French and Latin there. She also taught in a plantation school in southern Virginia, and for three years conducted a school of her own in Duxbury, Mass. Upon returning from Virginia, she had joined the abolitionists, and she took an active part in the Washingtonian temperance movement. This movement was started in 1840 by habitués of a Baltimore, Md., tavern, who then founded the Washington Temperance society, named in honour of George Washington. The movement spread rapidly in 1841–43, but by the close of 1843 it had nearly spent its force. The members of the society made a pledge not to drink spirituous or malt liquors, wine or cider. Women organized Martha Washington societies as auxiliary organizations. In 1845 she married Daniel Parker Livermore (1819–99), a Universalist clergyman. During the Civil War, as an associate member of the U.S. sanitary commission, and as an agent of its northwestern branch, she organized many aid societies, contributed to the success of the Northwestern Sanitary fair in Chicago in 1863 and visited army posts and hospitals. After the war she devoted herself to the promotion of woman suffrage and to temperance reform, founding in Chicago in 1869 *The Agitator*, which in 1870 was merged into the *Woman's Journal* (Boston), of which she was an associate editor until 1872. She served as president of the Illinois, the Massachusetts and the American woman suffrage associations. She lectured in the United States, England and Scotland, and contributed to magazines. Her writings include *The Children's Army*, temperance stories (1844); *Thirty Years Too Late*, a temperance story (1848); *A Mental Transformation* (1848); *Pen Pictures*, short stories (1863); *What Shall We Do With Our Daughters? and Other Lectures* (1883); *My Story of the War* (1888); and *The Story of My Life* (1897). With Frances E. Willard she edited *A Woman of the Century: Biographical Sketches of Leading American Women* (1893). She died at Melrose, Mass., on May 23, 1905.

LIVERPOOL, EARLS OF. CHARLES JENKINSON, 1st earl of Liverpool (1729–1808), English statesman, was born at Winchester, April 26, 1729, eldest son of Col. Charles Jenkinson (d. 1750) who had commanded the Blues at Dettingen, and mas descended from Anthony Jenkinson (d. 1611), who in 1558 had been the first Englishman to penetrate into central Asia. Charles Jenkinson was educated at Charterhouse and at University college, Oxford, where he graduated M.A. in 1752. He entered parliament for Cockermouth in 1761 and joined the connection of Lord Bute. He soon secured the favour of George III; after Bute's retirement in 1765 he led the "king's friends" in the house of commons for many years, and was popularly supposed to enjoy the full confidence of the king. He held a series of minor offices: under-secretary of state, 1761–63; a secretary to the treasury, 1763–65; junior lord of the admiralty, 1766, and of the treasury, 1767–70; master of the mint, 1775–78. He also became a privy councillor in 1772 and bought the rich sinecure of clerk of the pells in Ireland in 1775. From 1778 to 1782 he was secretary-at-war, during the American Revolution. In 1786 he moved to the house of lords as Baron Hawkesbury and became president of the board of trade under William Pitt. holding that office with respectable efficiency for 1j years. He was created earl of Liverpool in 1796, and died in London. Dec. 17, 1808. His treatise on *Coins of the Realm* was authoritative enough to be reprinted by the Bank of England as late as 1880.

His son ROBERT BANKS JENKINSON, 2nd earl (1770–1828), prime minister for a longer consecutive period (1812–1827) than any other since Pitt, was born June 7, and educated at Charterhouse and at Christ Church, Oxford. where he made friends with George Canning. He witnessed the fall of the Bastille on July 14, 1789, and next year—before he came of age—was elected member of parliament for the pocket borough of Appleby. He spoke seldom, but strikingly; became a member of the India board in 1793, M.P. for Rye in 1796, and master of the mint in 1799; and as Henry Addington's foreign secretary negotiated the brief peace of Amiens in 1801. He was raised in 1803 (in his father's barony of Hawkesbury) to lead the house of lords. He was home secretary in Pitt's last administration (1804–06), and wisely refused to become prime minister when Pitt died (he accepted instead the lord wardenship of the Cinque Ports). In Lord Portland's government (1807–09) he was again home secretary, and was secretary of state for war and the colonies under Spencer Perceval (1809–12), effectively supporting Wellington's Peninsular campaigns. When Perceval was killed, Liverpool succeeded him as prime minister, and held that office continuously until crippled by paralysis early in 1827. He died at Kingston, Dec. 4, 1828.

The successful foreign policies of Castlereagh and Canning were carried through in close consultation with Liverpool, whose information on foreign affairs was as sound as his judgment was solid; eventually he and Canning worked in perfect unison. A severe home policy, which included the repressive measures of 1817–19 and support of George IV against Queen Caroline, has left him a bad reputation. Yet he was an excellent and conscientious administrator, and did much (*e g.*, by abolition of sinecures) to reform the public service and make it more fit to deal with the problems of the new industrial England. He also played a decisive role in stabilizing the currency. His relations with Huskisson were always cordial, and he warmly encouraged Huskisson's efforts at the board of trade to free commerce from the restrictions of the old economy (1823–27). His policy of keeping the question of Roman Catholic emancipation "open," and still more his own manifest integrity, held together the whole of Pitt's old connection, a party and a cabinet bitterly divided on the Catholic issue, for many years longer than they could have survived without him.

Though twice married, the 2nd earl had no children, and the earldom and barony became extinct when his half-brother died, leaving three daughters, in 1851. They were revived for the son of one of these daughters, CECIL GEORGE SAVILE FOLJAMBE (1846–1907), a Liberal politician who held court appointments under Victoria and Edward VII. His eldest son, ARTHUR WILLIAM DE BRITO SAVILE FOLJAMBE (1870–1941), 2nd earl of the second creation, was governor of New Zealand, 1912–17, and its first governor general, 1917–20.

See C. D. Yonge, *Life and Administration of the 2nd Earl of Liverpool*, 3 vol (London. 1868), and W. R Brock, *Lord Liverpool and Liberal Toryism, 1820 to 1827* (Cambridge, 1941), both based on the Liverpool papers now in the British Museum. (M. R. D. F)

LIVERPOOL, a city and county and parliamentary borough in Lancashire, Eng., the second largest seaport of Great Britain, 202 mi. N.W. of London by road, on the right bank of the estuary of the Mersey, the centre of the city being about 3 mi. from the open sea. On the north the city is partly bounded by the borough of Bootle, along the shore of which the line of docks is continued. Pop. (1961) 747,790. Area 42.7 sq.mi.

The form of the city is that of an irregular semicircle, the base line formed by the docks and quays extending about 9 mi. along the northeast bank of the estuary, the latter varying in breadth from 1 to 2 mi The city lies on a continuous slope of sandstone varying in gradient toward the river. The old borough, which lay betu een the pool, now filled in, and the river, was a mediaeval pattern of narrow alleys, and during the 16th and 17th centuries it was visited several times by plague. When the town expanded and spread up the slopes beyond the pool, conditions improved.

The irregular semicircular shape of the city is broadly zoned as follows: Lying along the river's edge are the docks and quays, together with the ancillary warehousing and other port facilities, as uell as a variety of industrial plants closely associated with the import and export of merchandise. The commercial and shopping area forms the centre of the semicircle and occupies broadly the site of mediaeval Liverpool. Around the city centre are the older suburban residential and industrial districts, formed around the original outlying villages which were absorbed by boundary extensions. Beyond these and up to the city boundary are the 20th-century private and municipal residential areas with generous parks and open spaces.

As one of the two most important ports in Great Britain, Liverpool was an important German target for aerial bombardment during World War II and sustained considerable damage, not only to commerce and industry but also in its residential areas; 6,500 dwellings were totally destroyed, and over 125,000 damaged.

History and Municipality.— During the 8th century colonies of Norsemen settled on both sides of the Mersey. After the Conquest the site of Liverpool formed part of the fief granted by the Conqueror to Roger de Poictou. Although Liverpool is not named in Domesday it is believed to have been one of the six berewicks, or subordinate manors: dependent on the manor of West Derby therein mentioned, and cultivated by 53 villeins. 62 bordarii or day labourers. 3 plowmen. 6 herdsmen. 1 horseman. 2 bondmen and 3 bondwomen. After various forfeituresand regrants from the crown, it was handed over by Henry II to his falconer Warine. In a deed executed about 1191 by John, earl of Morton, afterward King John, who was then lord of the Honour of Lancaster, in which he confirms Henry Fitzwarine in the possession of Liverpool, the name of the town first occurs. Probably its most plausible derivation is from the Norse *Hlithar-pollr,* "the pool of the slopes." Another possible derivation is from the Prov. E. lever, the yellow flag or rush. O.E. *laefer,* any rushlike or swordbladed plant. *(See* the *New English Dict., s.v.* "Levers.")

Besides his Honour of Lancaster. Prince John possessed also the lordship of Ireland, and he therefore needed a port where men and supplies could be shipped. Into the tidal waters of the Mersey a small stream ran forming a pool at its mouth. This pool could provide harbourage for the largest vessels of those days. and lay conveniently near to the castle of West Derby. After his accession to the throne. John repurchased the manor from Fitzwarine, giving him other lands in exchange. On Aug. 28. 1207, he issued letters patent granting Liverpool the same status as any other free borough upon the sea and invited his subjects to take up "burgages," or allotments, in the new town, which was built along the brow of the hill on which Castle street and the town hall are erected. The high cross stood near the present town hall, and there the main line of street was intersected by another line extending from the riverside to the Townsend bridge. which crossed the pool where the end of Dale street now is. Considerable use was made of Liverpool in the 13th century for shipping stores and reinforcements to Ireland and Wales. In 1229 a charter was granted by Henry III confirming in detail that previously granted by his father. making Liverpool a free borough forever, and authorizing the formation of a merchants' guild. Several charters were granted until the reign of William and Mary, whose charter was that under which the town was governed until the Municipal Reform act of 1835. In 1880, when the diocese of Liverpool was created. the borough was transformed into a city by royal charter, in 1888 it became a county borough, and in 1893 the style and dignity of lord mayor was conferred on its chief magistrate.

Liverpool sent no representatives to parliament in 1264, but in 1296 the borough sent two members, and again in 1307. The next time it sent members was in 1547. In 1588 the borough was represented by Francis Bacon.

Under the Municipal Reform act of 1835, the boundaries of the original borough were extended and there were several extensions afterward. In 1932 was added the township of Speke, where the municipal airport was established. Since 1951 Liverpool has returned nine members to parliament: for Edge Hill, Exchange, Garston, Kirkdale, Scotland, Toxteth Park, Walton-on-the-Hill, Wavertree and West Derby.

The crown revenues from rents and the royal customs were leased from time to time, sometimes to the corporation, at other times to private persons. The first lease was from Henry III in 1229, and in the same year the borough, with all its appurtenances, was bestowed with other lands on Ranulf, earl of Chester, from whom it passed to the earl of Derby, who seems to have built Liverpool castle between 1232 and 1237. The lands of his grandson. Robert de Ferrers, were confiscated in 1266 when Liverpool passed into the hands of Edmund, earl of Lancaster.

The corporation of Liverpool has possessed from a very early period considerable landed property, the first grant having been made by Thomas. earl of Lancaster, in 1309. This land was originally of value only as a source of supply of turf for firing, but in modern times it has become profitable building land. A large proportion of the southern district is held in freehold by the corporation and leased to tenants for terms of seventy-five years, renewable on a fixed scale of fines. Liverpool again became the property of the crown when Henry IV inherited it from his father John of Gaunt. In 1628 Charles I sold Liverpool to certain merchants of London, who, in 1635, reconveyed the crown rights, including the fee-farm rent of £14, 6s. 8d. to Sir Richard Molyneux, then Viscount Molyneux of Maryborough, for the sum of £450. In 1672 all these rights and interests were acquired by the corporation and in 1777 converted into a perpetuity. With the growth of commerce these dues enormously increased, and became a cause of great complaint by the shipping interest. In 1856, by act of parliament, the town dues were transferred to the Mersey Docks and Harbour board on payment of £1,500,000, which was applied in part to the liquidation of the bonded debt of the corporation amounting to £1,150,000.

During the Civil War the town was fortified and garrisoned by the parliament. It sustained three sieges and in 1644 fell to Prince Rupert.

Liverpool's trade developed slowly. From £10 per annum, in the beginning of the 13th century, the crown revenues had increased toward the end of the 14th century to 638; but then they underwent a decline. The black death, about 1360, carried off a large part of the population. The Wars of the Roses in the 15th century retarded progress for at least a century. during which period the crown revenues diminished from f38 and were finally leased at £14, 6s. 8*d*., at which they continued until the sale by Charles I. It is, however, not safe to conclude that the reduced fee-farm rent represents an equivalent decline in prosperity: the privileges conferred by the various leases differed widely and may account for much of the apparent discrepancy. The true rise of the commerce of Liverpool dates from the Restoration. Down to that period its population probably never exceeded about 1,000. Its trade was chiefly with Ireland, France and Spain, exporting fish and wool to the continent, and importing nines, iron and other commodities. The rise of the manufacturing industry of south Lancashire, and the opening of the American and West Indian trade, gave the first impulse to the progress which has continued. By the end of the 17th century the population had increased to 5.000. In 1699 the borough was constituted a parish distinct from Walton. In 1709, the small existing harbour was found insufficient to accommodate the shipping, so a met dock was constructed with floodgates impounding the water, so as to keep the vessels floating during the recess of the tide. The name of the engineer was Thomas Steers.

About now the Liverpool merchants entered on the slave trade, into which they were led by their connection with the West Indies. In 1700 the "Liverpool Merchant" carried 200 Negroes from Africa to Barbados; in 1730, encouraged by parliament, Liverpool went heartily into the new trade. In 1751, 53 ships sailed from Liverpool for Africa, of 5,334 tons in the aggregate. The ships sailed first to the west coast of Africa, where they shipped the slaves, and thence to the West Indies, where the slaves were sold and the proceeds brought home in cargoes of sugar and rum. By the end of the century five-sixths of the African trade centred in Liverpool. Just before its abolition in 1807 the number of Liverpool ships engaged in the traffic was 185, carrying 49,213 slaves in the year. Another branch of maritime enterprise which attracted the attention of the merchants of Liverpool was privateering, which, during the latter half of the 18th century, was a favourite investment.

The abolition of the slave trade did not bring to Liverpool the ruin which had been prophesied, and trade with the fast developing North American continent was further increased by the introduction of steam-driven ships in the early 19th century. The reformed town council, after a few years of acute political dissension, displayed a pioneering spirit in the field of public health, encouraged to do so, no doubt, by the problems arising from the mass immigration from Ireland after the famines of the 1840s. Liverpool appointed W. Duncan the first medical officer of health in 1846. As the town became more wealthy there was an increase of interest in cultural affairs. In 1849 the Philharmonic hall was opened and by the Act of 1852 Liverpool had one of the first libraries in the country. A museum was provided by Sir William Brown and an art gallery by Sir A. B. Walker. These buildings, together with the Picton reading room, form an impressive group opposite St. George's hall.

In the 20th century the opening of the Mersey tunnel had greatly increased the flow of traffic passing through Liverpool on a north-south axis and has brought residential and industrial areas of Cheshire and Staffordshire into closer touch with Liverpool and southwest Lancashire. Since World War II large blitzed areas in the centre of the city had to be cleared, but it was not until 1952 that the major tasks of central redevelopment could be commenced. Large suburban estates had also been developed at Norris Green. Dovecot, Speke. Kirkby and Croxteth.

The original supply of water was from wells in the Triassic sandstone. In 1847 an act was passed under which extensive works were constructed and extended later at Rivington, about 25 mi. distant. The vast increase of population led to further requirements, and in 1880 another act gave power to impound the waters of the Vyrnwy, a tributary of the Severn. These works were completed in 1892 and a second pipeline added in 1905. The capacity of the Vyrnwy reservoir is more than 13,000,000,000 gal. and the catchment area 23,150 ac. in extent. A third pipeline was opened in 1938 and work on a section of a fourth pipeline began in 1953.

Prior to 1699 Liverpool came within the parish of Walton-on-the-Hill, but in that year the chapel of ease of Our Lady and St. Nicholas at the pierhead separated from its parent to become the first parish church. A second church. that of St. Peter, erected by the corporation was founded and, together, these with a number of subsequent churches, served until the increasing population made the establishment of a see of Liverpool imperative. A public subscription was launched which realized £100,000 and as a result the see was formed in 1880 with the parish church of St. Peter serving as procathedral. The foundation stone of the new cathedral was laid in 1904 and the see is comprised of 223 parishes. Warrington is a bishopric suffragan.

The Roman Catholic archdiocese of Liverpool embraces the old hundreds of West Derby. Leyland and the Isle of Man. It was formed as a bishopric in 1850, raised to an archbishopric in 1911 and embraces 196 parishes. The parish church of St. Nicholas, Copperas hill, serves as procathedral. The foundation stone of the new cathedral was laid in 1933.

Architectural Features.—Although the city possesses many buildings of considerable architectural merit, the development of the commercial and shopping centre on the site of the mediaeval town has obliterated practically all traces of the earlier buildings. The town hall, opened in 1754 and designed by John Wood of Bath, is of particular merit. It is a rectangular building in the Corinthian style, surmounted by a dome which was added after a disastrous fire in 179j. The old Bluecoat hospital (built 1717), a Queen Anne group built around a courtyard off Church street, is a fine example of its period. It suffered considerable damage in World War II, but was later rehabilitated. Fine examples of 19th-century domestic architecture are to be found in Rodney street and in the Abercromby square area around the university. These dwellings were formerly the residences of Liverpool merchants. Outstanding among many buildings in the Classic Revival style is St. George's hall, designed by Harvey Lonsdale Elmes and completed in 1854. This imposing building, in addition to providing a large public hall, also houses the assize courts, and is surrounded by open spaces and gardens sufficiently extensive to enable its splendid classic proportions to be appreciated. After the death of Elmes in 1847, the building was completed by C. R. Cockerell, who also designed other important buildings in the city. Adjacent to St. George's hall is the impressive group of buildings in William Brown street. comprising the Technical college, the city museum, the Picton Reading room and the Walker Art gallery. The permanent collection in this gallery is regarded as one of the finest in the provinces.

Of the many modern buildings of architectural merit. the most famous are the three oyerlooking the river at the pierhead, which comprise the Royal Liver building, the Cunard building, and the offices of the Mersey Docks and Harbour board. The Philharmonic hall, replacing the old one that had been burned down, was opened in 1939. It is a finely proportioned concert hall with excellent acoustics for orchestral concerts and its own Philharmonic orchestra.

Of the two cathedrals being built in Liverpool in 1953, the Anglican cathedral was begun in 1904 when the foundation stone was laid by Edward VII. The architect, Sir Giles Gilbert Scott, has taken full advantage of the excellent site, and the cathedral is the most important 20th-century addition to the city's skyline. The building is designed in the Gothic style and is built of red sandstone with copper roof. The Lady chapel was consecrated in 1910, and the choir, east transepts and chapter house in 1924. The organ, dedicated in 1926, is the largest in the country (5 manuals, 10,925 pipes). The ultimate length of the cathedral will be 619 ft. The interior height is 116 ft.—14 ft. higher than Westminster abbey.

The construction of the Roman Catholic cathedral of Christ the King, to the design of Sir Edwin Lutyens, was begun in 1933. The original designs have been substantially modified (1955) and the size reduced by more than one-third. One of the outstanding features retained is the domed central space, 178 ft. in diameter.

Arts, Education and University.—The free library, museum and gallery of arts, established and managed by the city council, was originated in 1852. The first library building was erected by Sir William Brown. The Derby museum, containing the collections of Edward, the 13th earl: was presented by his son. The Mayer museum of historical antiquities and art was contributed by Joseph Mayer, F.S.A. (1803–86), who presented his collections to Liverpool in 1867. The museum contains an unrivalled collection of Wedgwood and Liverpool ware. Sir Andrew Walker (1824–93) erected in 1877 the art gallery which bears his name. Large additions mere made in 1884, the cost being again defrayed by Sir Andrew Walker. The permanent collection of paintings includes the William Roscoe collection of old masters and the bequest (1923 and 1927) of James Smith of Blundellsands of 28 pictures of G. F. Watts. 4 sculptures by Rodin, many etchings and engravings by Albrecht Diirer, Seymour Haden and James Whistler, together with a large number of modern works. British and foreign. The Picton circular reading room was built by the corporation and opened in 1879. Adjoining it is the Hornby library of fine art books, prints and bindings. There is a technical library, used by industrialists and scientists, and, in the business quarter of the city, an important commercial library. As well as two theatres and two variety palaces there is the Playhouse repertory theatre where many actors and actresses, later to become famous, have started their careers.

Sunday schools were founded in 1784 as the result of a town meeting and these were soon followed by private day schools. Of the semiprivate schools founded in the 19th century by public subscription the Liverpool institute (182 j) and Liverpool college (1840) still continue, the former as a day grammar school maintained by the local authority since 1903, the latter as an independent public school and local authority's grammar school since the division in 1907.

One-third of the 140,000 schoolchildren in Liverpool are Roman Catholic and these children are educated in schools provided by that denomination. A smaller proportion of schools is provided by the Church of England for children of that communion. and there is a Hebrew school for Jewish children. All these schools are maintained by the local authority or are administered as direct grant schools. There are many other educational institutions including separate colleges of technology, commerce, building and art and five teachers' training colleges. of which one is for physical training and one is for domestic science.

University college. Liverpool, founded by the citizens of Liverpool, received its charter of incorporation in 1881. Three years later it was accepted as a member of the federal Victoria university, and at the same time the Royal Infirmary Medical school, which had been established since 1844, became a member of the college. By 1900 there was a staff of 25 professors and 60 lecturers, and a student body of nearly 600.

On the dissolution of the Victoria university, a royal charter, granted in 1903, established the University of Liverpool. Degrees in engineering were instituted and, later, degrees in architecture; in 1904 the New Veterinary college of Edinburgh was transferred to Liverpool and a chair of veterinary medicine and surgery was founded.

After World War I development was rapid. Between 1920 and 1939 many new buildings and extensions were constructed. including the Jane Herdman Memorial Geology laboratories (1929), the Leverhulme building of the school of architecture (1933), an extension to the students' union (1935), the Harold Cohen library (1938) and Derby hall, a hall of residence for men students (1938). In 1942, a veterinary field station was opened at Willaston. Wirral. thus continuing the development of a science with which the university has always been prominently associated.

The extension of university education since World War II has brought an increase in staff, students and accommodation; the number of its chairs is 59 and the faculties of the university are those of arts (responsible for degrees in commerce, architecture and civic design, as well as for degrees in arts): science, including a department of oceanography, with the only chair in oceanography in the British Commonwealth, which works in close conjunction with the marine biological station maintained at Port Erin, and with the Liverpool Observatory and Tidal institute; medicine. including the school of dental surgery; law; engineering; and veterinary science. The Liverpool School of Tropical Medicine, though separately incorporated, is governed by a committee representative of the university and the merchants and shipowners of Liverpool; and its students take the university postgraduate diploma in tropical medicine and hygiene.

In 1948 a plan for the future development of the university was published, and the city council has reserved a site in its own redevelopment plan for the purpose, with Abercromby square as its approximate centre. The jubilee of the university was celebrated in May, 1953.

Docks and Railways. — The docks of the port of Liverpool on both sides of the Rlersey are owned and managed by the Mersey Docks and Harbour board. On the Liverpool side they extend along the estuary 6 mi., of which $1\frac{1}{4}$ mi. is in the borough of Bootle. The Garston docks. 6 mi. above Liverpool, are also within the city boundary. The Birkenhead docks have not such a frontage, but extend a long way backward. The water area of the Liverpool docks and basins is 460 ac. with a lineal quayage of nearly 28 mi. Birkenhead docks contain a water area of about $181\frac{1}{4}$ ac., with a lineal quayage of $9\frac{3}{4}$ mi. The system of enclosed docks was begun by the corporation in 1709. The Gladstone docks, opened 1927, are among the best equipped in the world. The sill is 20-ft. below datum level and the entrance is 130-ft. nide and the area with branch docks is nearly 54 ac. A fine graving dock is part of the system. Down to 1843 the docks were confined to the Liverpool side of the Mersey. In 1843 a scheme for docks in Birkenhead was carried through, proved unsuccessful. and was acquired in 1855 by Liverpool. The Birkenhead docks were for many years only partially used, but are now an important centre for corn milling, the importation of cattle, and export trade to the east.

The first portion of the great landing stage, known as the George's Landing stage, was constructed in 1847. This was 500-ft. long. In 1857 the Prince's Landing stage. 1,000 ft.-long, was built to the north of the George's stage and distant from it 500 ft. In 1874 the intervening space was filled up and the George's stage reconstructed but. being destroyed by fire, was reconstructed a second time. In 1896 it was extended farther north, and its length is now 2,534 ft. and its breadth 80 ft. It is supported on floating pontoons (about zoo) connected nith the river wall by 10 bridges. besides a floating bridge for heavy traffic 550 ft. in length and 35 ft. in width. The southern half is devoted to the traffic of the Mersey ferries, of which there are three — New Brighton, Seacombe and Birkenhead. The northern half is used by ocean-going steamers and their tenders. The warehouses for storing produce form a prominent feature in the commercial part of the city. In addition to general produce warehouses. grain warehouses have been constructed by the dock board at Liverpool and Birkenhead: with machinery for discharging, elevating, distributing, drying and delivering. Warehouses for the storage of tobacco and wool have also been built by the board. The Stanley tobacco warehouse is the largest of its kind in the world, the area of its fourteen floors being some 36 ac.

There are four terminal passenger stations in Liverpool. They are: Lime street, Exchange. Central and Riverside. Connection with Wirral is effected by the old Mersey tunnel (opened 1886), and by the new road tunnel completed in 1928. (See BIRKENHEAD; TUNNEL.) The Liverpool overhead electric railway running along the line of docks from Seaforth to Dingle was opened in 1893, and in 1905 a junction was made with the L.M.S. railway by which through passenger traffic between Southport and Dingle was established. In 1895 the Riverside station at the Prince's dock was completed by the Mersey Docks and Harbour board, giving direct access from the landing stage to the railway system.

Trade and Commerce. — The port is the traditional centre of business life in Liverpool and the adjoining districts that go to make up Merseyside. It is second only to London among British "general" ports, with extensive passenger interests to add to its handling of materials and goods of virtually every type. The total tonnage of these in an average year is of the order of 15,000,000, carried in some 32,000 sea-going vessels.

The commerce of Liverpool, channelled through its port. has a main emphasis on North and South America. West Africa. the Mediterranean countries, the Indian subcontinent and Australasia — a very large proportion of the trading world. The main imports are of raw materials and commodities (13,870,000 tons in 1952, excluding bulk oil), headed by grain and cereals to an extent of well over 1,000,000 tons annually (1,300,000 tons of flour and grain in 1951), together with a multitude of lesser cargoes, for use or manufacture in and around Liverpool or in the upcountry areas of industry which it serves. From these areas. principally of Lancashire, the midlands and west Yorkshire, come in return the chief exports of Liverpool — iron and steel, machinery, and manufactured goods of all types from the heaviest products to pottery. textiles and fine goods. compiling a list as long as the concerns of British overseas trade. The export tonnage in 1952 was 5,564,000.

The port is the hub of the wheel of Merseyside and in that hub are the ships, the building and fitting of ships, the manning, victualling, and servicing of ships that are known throughout the world. Packed around that hub are major facilities of banking and insurance, of warehousing and of every branch of commercial life and, packed equally, are industries to process imported materials as close as possible to the quays. For Merseyside has the largest flour-milling centre in Europe, its sugar and oil refineries are world-famous, oilseed crushing is a substantial industry and the same line of industrial thought is followed by biscuit, confectionery, rubber and soap factories, somewhat further from the main port area but well within local boundaries. In 1951, 951,000 tons of sugar and molasses were imported and 525,000 tons of oil.

In the late 1920s this picture, with some modifications, would have represented the sum of Liverpool's commerce and industry. But the trade recession which paralysed the world then had a particularly serious effect on Liverpool, dependant as it was on a maximum passage of the world's goods and, at the worst of the recession, some 100,000 of Liverpool's citizens were unemployed. To insure against a repetition of this, by spreading the risk over as wide and productive a field as possible, the Liverpool City corporation took special statutory powers (in 1936) which have since been imitated by many other authorities, both central and municipal—powers to bring work to the worker by means of special facilities, of finance, siting and construction, made available to manufacturing industry. The corporation's industrial estates at Speke, Kirkby and Aintree cover a total acreage of 2,741, and each is on a principal approach to the city from its inland areas of chief contact. The effect, when allied to the efforts of the state since World War II and of private enterprise throughout, has been to add a third partner, manufacture, to the older and better-known interests of Liverpool's life. There are now large factories for electrical and electronic apparatus, diesel engines, jet engines, tires and heavy chemicals. Other products include antibiotics, clocks, scientific instruments, pharmaceutics and matches. The social process involved, of converting a measurable part of a dock-side population, accustomed for many generations to casual labour, into an industrial population, working regularly, has been both interesting and successful.

As a result, Merseyside's registered working population of 580,000 has an infinitely greater industrial element than its grandfathers would have believed possible. The port and all to do with it remains the largest employer of that labour, followed by light engineering, chemicals and pharmaceuticals. food and foodstuffs, the services of commerce and inland transport and a very large number of smaller activities, each substantial in itself and completing the composition of an area which has at least taken definite steps in the direction of economic balance.

LIVERSIDGE, ARCHIBALD (1847–1927), English chemist, was born on Nov. 17, 1847 in London, and studied at the Royal School of Mines and the Royal College of Chemistry, and entered Christ's college, Cambridge. In 1867 he became instructor in chemistry at the Royal School of Naval Architecture, and three years later university demonstrator in chemistry at Cambridge.

Liversidge was professor of chemistry at the University of Sydney from 1873 to 1908. In 1879 he founded the faculty of science at bydney university, and also the school of mines (1890). Liversidge gave an impetus to technical education in Australia. He founded the Australasian Association for the Advancement of Science in 1885. acted as secretary (1888–1909) and president (1888–90). In 1902 he founded the Sydney section of the Society of Chemical Industry and served as its first chairman (1903–05).

His researches were chiefly in mineralogy; he collected and analyzed meteorites. He also wrote papers on the origin of the gold nuggets in Australian alluvial deposits. His most important work is *The Minerals of New South Wales* (1888). but he was also the author of a *Report upon Technical Education and Museums* and of more than a hundred technical papers, most of which treated matters relating to chemistry and mineralogy.

Liversidge died in Surrey on Sept. 26. 1927.

LIVERWORTS, constitute a subdivision of the Bryophyta (*q.v.*), to which also belong the mosses. The liverworts differ from the mosses principally in the structure of the spore-bearing plants (sporophytes), described below. All mosses are leafy. but some of the liverworts lack leaves or, if leafy, are usually flatter than the majority of mosses. The leafless forms may be ribbonlike or otherwise flattened and ruffled, but most liverworts have leaflike appendages on the stems.

No liverwort has any important economic significance. although some (*Marchantia* and *Conocephaleum*) long ago were thought to have medicinal value for liver ailments in accordance with the Doctrine of signatures (*see* SIGNATURE). In nature they play a

FIG. 1.—SECTION THROUGH MARCHANTIA THALLUS CONSISTING OF UPPER EPIDERMIS WITH PORES, AIR CHAMBERS WITH COLUMNS OF CELLS CONTAINING CHLOROPLASTS, REGION WITH FEW CHLOROPLASTS, AND LOWER EPIDERMIS BEARING SCALES AND RHIZOIDS

role as pioneers on newly exposed substrata in the reducing of rocks and woody materials to soil, in retarding soil erosion and in providing food and homes for small animals.

The liverworts may be divided into two groups: Hepaticae and Anthocerotae.

Hepaticae.—Sometimes called the hepatics. these liverworts may be divided into the leafy and the thalloid forms. the latter being flattened ribbons or rosettes without leaflike structures on the stems. The thalli vary in size from one-sixteenth to one inch in width.

The best-known thalloid species is *Marchantia polymorpha*, which appears like a green forking ribbon approximately one-half inch in width. It has an upper and lower epidermis nith scales along the middle of the latter. The portion between the upper and lower epidermis is filled with walled cavities. each with an opening through a fixed pore in the upper epidermis. The cavities

have short, green, cactoid filaments scattered in them.

These thalloid plants are haploid; *i.e.*, are gametophytes with a single set of chromosomes. They are unisexual, and eventually stalklike branches are formed. If female. the sexual branch somewhat resembles a palm tree or an umbrella without its fabric. The female sex organs (archegonia) are hung beneath the rays. The male branches terminate in a flattened, scalloped, screwhead-like structure with male sex organs (antheridia) buried in small-mouthed cavities in the upper surface. At maturity the male cells (sperms) may swim from the ruptured antheridia to the female plants and thence to the female cell (egg) contained in the enlarged. basal portion (venter) of the archegonium. The fertilized egg (zygote, formed by union of sperm and egg) by apical growth matures into a spore-bearing plant which is diploid; *i.e.*, a sporophyte with a double set of chromosomes. It consists of a foot embedded basally in the venter, a stalk (seta) which attaches the foot to the spheroidal spore-bearing capsule (sporangium). all of which develops within the archegonium. At maturity the cells of the seta rapidly elongate, bursting the archegonium and exposing the capsule. The capsules do not have a columella, and the spores are covered by a compact wall of one or two layers of cells. The spores are often mixed with slender. hygroscopic cells (elaters) which may effect spore dispersal when the capsule splits open or ruptures as a result of wall deterioration.

FIG. 4.— MARCHANTIA POLYMORPHA, SHOWING THE ARCHEGONIUM. WHICH ENCLOSES THE OVUM OR EGG

The spore germinates on moist substrata and after a short (three or four cells) threadlike phase grows into the ribbonlike gametophyte.

The leafy members of the Hepaticae often resemble mosses but usually can be recognized by the fact that they have only two rows of leaves (also characteristic, however, of the moss genus, *Fissidens*) or two rows of large leaves and a third row of small leaves on the side of the stem toward the substrate. They vary from species microscopic in size to those in which single leaves may be easily seen without a lens.

In Trichocolea, Ptilidium and others, the leaves are subdivided into hairlike segments. In *Frullania* and Jubula they have a small, pouchlike lobe bent up behind the main portion of the leaf. Some leaves have entire margins; others have long, marginal teeth. Some are smooth; others are rough with pimplelike projections (papillae).

The sexual life cycle of the leafy species is not essentially different from that of the thalloid forms. The antheridia are borne in the axils of leaves; the archegonia are usually terminal. The sporophyte usually has a longer seta than many of those in the thalloid species.

In addition to reproduction by sexual means, liverworts also produce vegetative reproductive bodies (gemmae) of various shapes and sizes. Some are formed on the surface or edges of leaves or thalli; others are borne in specialized structures in the form of cups or flasks. New plants are also formed by growth from fragments and by branching and subsequent death of the older portion.

Anthocerotae.—These, often called hornworts, do not constitute a very large group of the liverworts. American genera include Anthoceros, Phneoceros and Notothylas. They differ from the hepatics in a number of characteristics, the most important of which is the indeterminate basal growth of the needle-shaped sporophyte. Thus, arises the unique situation in which mature spores may be falling from the top of the apically split sporophyte while new ones are being initiated at the base. Also. there is no seta and the foot is large and irregular.

The cells of the hornwort sporophyte have two large chloroplasts containing starch-producing bodies called pyrenoids;

FIG. 6.— BLASIA PUSILLA, A LIVERWORT WHICH PRODUCES TWO TYPES OF GEMMAE. ONE OF WHICH GROWS INTO A NEW PLANT

cells of the hepatics have several to many small chloroplasts without pyrenoids

The sporophyte has a sterile central column (columella) and pores (stomata) in the epidermis; these structures are not present in the hepatics. The latter have unicellular elaters. if present; the hornworts usually have irregular multicellular elaters.

The gametophyte is not leafy but a thallus which has cavities, often opening by slits through the lower surface. containing symbiotic colonies of the blue-green alga *Nostoc*. The cells of the gametophyte each have a single. large chloroplast.

The sex organs (antheridia and archegonia) are somewhat similar to those of the hepatics but are sunk in the upper surface of the gametophyte, the antheridia occurring in cavities and the archegonia appearing as an integral part of the thallus.

The sexual life cycle is similar to that of the hepatics except for the different shape of certain structures as described above. Vegetative reproduction may occur through natural division of the thallus.

The Xnthocerotae are interesting for several reasons. The large pyrenoid-containing chloroplasts appear primitive; in contrast, the basal indeterminate gron th of the sporophyte makes it appear related to more advanced plants. They are the lowest plants in the plant kingdom to exhibit stomata. These structures, plus the indeterminate growth of the sporophytes, have led some botanists to suggest that they represent a type ancestral to the ferns. However, in spite of certain primitive characters they are probably the most highly evolved of the liverworts and represent the current end of a line rather than an ancestral form.

The symbiotic relationship between the alga *Nostoc* and the thalli of the Xnthocerotae suggests that the host may receive nitrogen-containing compounds or other beneficial materials from the alga.

The Xnthocerotae are usually found in the moist, dim woodlands of tropical and warm temperate regions. In North America they are occasionally collected in southern Canada.

LIVERY, originally the provision of food, clothing. etc.. to household servants. The word is an adaptation of the Anglo-French *livrée,* from *livrer,* "to deliver," in the special sense of distributing.

In the sense of a fixed allowance of provender for horses. it survives now only in "livery stable." *i.e.,* an establishment where horses and carriages are kept or let out for hire. From the meaning of provision of food and clothing the word is applied to a uniform worn by the retainers and servants of a household. In the 15th century in England a badge. collar or other insignia, the "livery," was worn by all those who pledged themselves to support one of the great barons in return for his promise of "maintenance," *i.e.,* of protection against enemies; thus arose the custom of "livery and maintenance." suppressed by Henry VII. The members of the London city companies *(see* LIVERY COMPANIES) wore a distinctive costume or "livery," whence the term "livery companies." In law, the term "livery" means "delivery," the legal handing of property into the possession of another; for "livery of seisin" see FEOFFMENT.

LIVERY COMPANIES, the name of a class of institutions in the city of London which at one time were universal in Europe. The gild (see GCILDS) in the 12th century "has many aspects, social. religious and economical, and it is unwise to look for any single origin for so complex an institution." The gilds assumed generally the character of corporations in the reign of Edward III.

Many of them had been chartered before: but their privileges, hitherto exercised only on sufferance and by payment of their terms, were now confirmed by letters patent. Edward III himself became a member of the fraternity of Linen Xrmourers, or Merchant Taylors, and other distinguished persons followed his example.

George VI was a freeman of the Grocers'. Drapers'. Fishmongers' and Merchant Taylors' companies, honorary freeman of the Needlemakers', Permanent Master of the Shipwrights'. and Admiral of the Master Mariners'. From Edward III's time they are called livery companies. The charters were regranted. generally in the original form, by successive sovereigns upon payment of a fine to the king's hanaper.

In 1684, on receipt of writs quo warranto, the companies surrendered their governance to the king—Charles 11—who granted a charter which abolished the right of election of wardens vested by earlier charters in the liverymen of the companies, increased the number of the courts of assistants and conferred membership for life upon the persons selected for these offices. James II. just before his departure to exile, restored the ancient privileges.

All proceedings were formally canceled by Act of Parliament 2, William and Mary session I, chapter 8. But even in cases where liverymen form an integral element in the administration of their companies' affairs; the system introduced by Charles II is followed in essentials.

The authority of the company extended to the general welfare, spiritual and temporal. of its members. In the regulation of trade they possessed extensive powers. They required everyone carrying on the trade to join the company, to prevent monopoly or enhancement of prices. There was no question of a monopoly until the degeneration of the craft gilds into limited corporations of capitalists. In the regulation of trade the goldsmiths had the assay of metals, the fishmongers the oversight of fish, the vintners of the tasting of wine, etc.

The companies enforced their regulations on their members by force and by fines. Many of their ordinances looked to the domestic affairs and private conduct of the members. The grocers ordain "that no man of the fraternite take his neyghbor's house yᵗ is of the same fraternite, or enhaunce the rent against the will of the foresaid neyghbor." The wearing of beards was forbidden. Football was prohibited. Attempts to restrict marriage to daughters of liverymen were made and failed. Members reduced to poverty by adventures on the sea, increased price of goods, borrowing and pledging, or any other misfortune, are to be assisted "out of the common money, according to his situation, if he could not do without."

From Gild to Charitable Trust.—But the companies gradually lost their industrial character. The richer members engrossed the power and the companies tended to become hereditary and exclusive. Persons became members who had nothing to do with the craft, and the rise of great capitalists and the development of competition in trade made the regulation of industry by means of companies no longer possible. The usurpation of power on the part of the richer members encountered, still encounters, opposition. In the Goldsmiths' company in 1529 the mode of electing officers, and the system of management generally, was challenged by three members who called themselves "artificers," poor men of the craft of goldsmiths. The dispute was carried into the court of chancery and the star chamber. The artificers accused the company of changing the constitution of the society, by persons who "were but merchant goldsmiths, and had but little knowledge in the science." In 1531 the three complainants were expelled from the company, and then the dispute seems to have ended. In most cases their regulative functions have disappeared. The Fishmongers company still carries out the supervision of certain Acts with vigour and success. The Goldsmiths carry out the assay of the Pyx. Throughout the companies have been owners of property and managers of charitable trusts.

The City and the Companies.—The ordinance of Edward II. required freemen of the city to be members of one or other of the companies. By the ordinance of 49 Edw. III. (1375), the trading companies were to nominate the members of common council, and the persons so nominated alone were to attend both at common councils and at elections. An ordinance in 7 Richard II. (1383) restored the elections of common councilmen to the wards, but corporate officers and representatives in parliament were elected by a convention summoned by the lord mayor from the nominees of the companies. An act of common council in 7 Edw. IV. (1467) appointed the election of mayor, sheriffs, etc. to be in the common council, together with the masters and wardens of the companies. By 15 Edw. IV. masters and wardens were ordered to associate with themselves the honest men of their mysteries,[1] and come in their best liveries to the elections; that is to say, the franchise was restricted to the "liverymen" of the companies. At this time the corporation exercised supreme control over the companies, and the companies were still genuine associations of the traders and householders of the city. The delegation of the franchise to the liverymen was thus, in point of fact, the selection of a superior class of householders to represent the rest. By 19 Henry VII. (1504) ordinances and by-laws were required to be submitted for approval to the chancellor, chief justices of either Bench or the Justices in eyre. This act still remains in force and by-laws or ordinances which have not been thus validated are devoid of authority. The corporation lost its control over the companies, and the members of the companies ceased to be traders and householders; the liverymen were no longer a representative class, and the Reform Acts of 1832 and 1867 reformed the representation in several particulars which was practically abolished by the Representation of the People Act of 1918. The liverymen of the companies, being freemen of the city, still elect the lord mayor, sheriffs, chamberlain and other corporate officers.

Taxing the Companies.—The wealth and organization of the companies made them a most appropriate instrument for the enforcement of taxation. The loan of £21,263 6s. 8d. to Henry VIII., for his wars in Scotland, in 1544 seems to be the first instance of a pecuniary grant to the crown. The confiscation of ecclesiastical property at the time of the Reformation affected many of the trusts of the companies; and they were compelled to make returns of their property devoted to religious uses, to pay over the rents to the crown and to purchase the trusts from their corporate funds. In course of time the taxation of the companies became "a regular source of supply to government," which when money was wanted for public works, informed the lord mayor, who apportioned the sums required among the various companies, and issued precepts for its payment. Contributions towards setting the poor to work, erecting the Royal Exchange, cleansing the city ditch, discovering new countries, furnishing military and naval armaments, for men, arms and ammunition for the defence of the city, are among the purposes thus served.

The livery companies in existence in 1940 were the following:

Apothecaries	Fishmongers	Musicians
Armourers and Brasiers	Fletchers	Needlemakers
Bakers	Founders	Painter Stainers
Barbers	Framework Knitters	Pattern Makers
Basket Makers	Fruiterers	Paviors
Blacksmiths	Gardeners	Pewterers
Bowyers	Girdlers	Plasterers
Brewers	Glass Sellers	Plumbers
Broderers	Glaziers	Poulters
Butchers	Glovers	Saddlers
Carmen	Gold and Silver Wyre-drawers	Salters
Carpenters	Goldsmiths	Scriveners
Clockmakers	Grocers	Shipwrights
Clothworkers	Gunmakers	Skinners
Coach and Coach-harness Makers	Haberdashers	Spectacle Makers
Cooks	Horners	Stationers and News-paper Makers
Coopers	Innholders	Tallow Chandlers
Cordwainers	Ironmongers	Tin Plate Workers
Curriers	Joiners	Turners
Cutlers	Leathersellers	Tylers and Brick-layers
Distillers	Loriners	Upholders
Drapers	Makers of Playing Cards	Vintners
Dyers	Masons	Wax Chandlers
Fanmakers	Master Mariners	Weavers
Farriers	Mercers	Wheelwrights
Feltmakers	Merchant Taylors	Woolmen

The Parish Clerks and the Watermen and Lightermen, though non-livery companies of the City of London, have sometimes been included.

In 1927 the Company of Master Mariners was constituted by Royal Charter and, in remembrance of the connection of the Mercer's Company, the first of all the companies, with the Merchant Adventurers and the maritime activities of earlier days, a loving cup was presented to the newly constituted company.

The following are the twelve great companies in order of civic precedence: Mercers, Grocers, Drapers, Fishmongers, Goldsmiths, Skinners, Merchant Taylors, Haberdashers, Salters, Ironmongers, Vintners, Clothworkers. The "Irish Society" was incorporated under James I. as "the governor and assistants of the new plantation in Ulster, within the realm of Ireland." The twelve companies contributed the sum of £60,000 for the scheme to settle a Protestant colony in the lands forfeited by the Irish rebels. The companies divided the settlements into twelve, under the paramount jurisdiction of the Irish Society. The charter of the society was revoked by the court of star chamber in the reign of Charles I., but a new one was granted by Charles II., under which the society still acts. The situation has been changed by the operation of the Land Purchase Act of 1903.

Livery Company Charities— Most of the companies administer charities of large value under schemes of the Charity Commissioners, the Board of Education, the Endowed School Commissioners and the Court of Chancery. Education in particular has benefited. The Mercers' Company administers St. Paul's school under Dean Colet's will, and in 1902 built a girls' school—now of the first rank. Mercers' school is one of the oldest schools in London. The Drapers administer Bancroft's school (1727) and Howell's school for girls, Denbigh. Queen Mary College (formerly the East London college), an important centre of university education in London, was built up by the company and has received from its

[1]Properly the word should be spelled, as it was originally, "mistery"; it comes through the O.Fr. ***mestier,*** modern ***métier,*** from Lat. ***ministerium,*** service, employment, and meant a trade or craft, and hence the plays acted by craftsmen and members of gilds were called "mystery plays" (*see* DRAMA). For the word meaning a hidden or secret rite, with which this has so often been confused, see **MYSTERY**.

corporate funds grants approximating £400,000. The Merchant Taylors' company maintains their school, removed in 1933, from the City to Sandy Lodge, Northwood, Middx., with admirable results. The Skinners' school at Tonbridge is of the first order. The City and Guilds of London Institute was developed from the initiative of the Cloth-workers company in 1875 by the joint action of the companies, and is now incorporated in the Imperial College.

Constitution of the Companies.—The constitution of the livery companies usually embraces (1) the court, which includes the master and wardens, and is the executive and administrative body (2) the livery or middle class, being the body from which the court is recruited; and (3) the general body of freemen, from which the livery is recruited. Some companies admit women as freemen. The freedom is obtained either by patrimony (by any person over 21 years of age born in lawful wedlock after the admission of his father to the freedom), by servitude (by *bona fide* apprenticeship to a freeman of the company) or by redemption which is in some cases wisely allowed only where an ancestor in the male line has had the freedom which his descendants have omitted to or been unable to acquire. Purchase is still regarded as rather disreputable. Admission to many of the companies is subject to the payment of considerable fees. Gift of the freedom is a recognized mode of expressing admiration for high public service. A royal commission was appointed in 1880 to inquire into all the livery companies, into the circumstances and dates of their foundation, the objects for which they were founded, and how far those objects were being carried into effect. A very valuable *Report and Appendix* (4 vols. 1884) was published, containing, *inter alia,* information on the constitution and powers of the governing bodies, the mode of admission of members of the companies, the mode of appointment, duties and salaries and other emoluments of the servants of the companies, the property of, or held in trust for the companies, its value, situation and description.

LIVESTOCK FEEDS: *see* FEEDS, ANIMAL.

LIVESTOCK JUDGING is an art requiring the ability to select animals, on the basis of outward appearance, or phenotype (*see* HEREDITY: *Heredity of Quantitative Characters*), and for those characteristics associated with excellent productive performance. It attempts to correlate the appearance factors which will result in the reproduction of meat animals (beef cattle. sheep and swine) which will produce carcasses of high quality with a large proportion of edible cuts. It attempts to select dairy cows for milk production and horses for draft work or performance under the saddle or in harness. Although not a true science, it has served well throughout the world as a tool for livestock breeders to improve their herds and flocks (*see* ANIMAL BREEDING).

Increased emphasis is being placed in modern livestock judging of meat animals on rate of gain, feed efficiency and carcass quality, items that can be measured accurately, and eventually the grand champion or first prize animal will have to excel in both live appearance and carcass quality. Many times the best steer, lamb or hog on foot has not been the best in the carcass. Breeding animals (bulls, cows, rams, ewes, boars and sows) will be judged by rate of gain, feed efficiency, reproductive efficiency, milk production (dairy cows) and performance of progeny as well as on live appearance. Livestock judging will then become a combination of an art, based upon eye selection, and a science, based on performance records.

Whenever any characteristic of livestock ceases to be of productive value, it ceases to have a major place in livestock selection. Many times too much emphasis is placed on some minor fancy of a breeder, such as shade of hair colour; and thus the livestock breeder or judge loses sight of the fundamental basis for selection. Although many of these nonproductive characteristics have their place in contributing to the style and beauty of an animal, they should never be emphasized to the degree of masking the real purpose of livestock production; *i.e.,* the provision of meat, milk and wool. The accompanying sample judging card for beef cattle indicates the main points considered in livestock judging.

Beef Judging Card

Points to Consider	Placing			
	1st	2d	3d	4th
I. General appearance: straight top-line, deep, broad, uniform in width, low-set, compact, symmetrical stylish, standing squarely, trim middle . . .				
II. Form:				
1. Head—muzzle broad, nostrils large, eyes large and clear; face short, clean and slightly dished, forehead broad; ears medium size and fine texture; horns medium size and well shaped				
2. Neck—thick, short, blending smoothly into shoulders; throat clean				
3. shoulder—smooth, well-covered with flesh, compact on top; shoulder vein smooth and full				
4. Breast—wide, full; brisket neat and trim with little dewlap.				
5. Forelegs—short, strong; arm full, shank medium fine				
6. Chest—deep, wide, girth large, crops full .				
7. Back—wide, straight and thickly covered .				
8. Loin—wide, straight and deep-fleshed . .				
9. Ribs—well sprung and smoothly covered with firm flesh				
10. Flanks—full and low				
[illegible]				
[illegible] ..., level and free from patchiness				
13. Thighs—deep, broad, wide and full. . .				
14. Twist—full and deep				
15. Legs—straight, strong; shanks medium fine .				
III. Finish: deep, mellow, firm covering especially over back, ribs and loin; freedom from patchiness and rolls desired. (Finish is of great importance in fat classes, but is not so important in breeding classes as long as the ability to take on finish is indicated).				
IV. Quality: smooth in frame and finish; hair fine, soft; hide mellow; bone medium-size and clean . .				
V. Dressing percentage: well finished, not paunchy, medium weight hide. (Not considered in judging breeding cattle)				
VI. Breed and sex character: (Applies only to breeding classes)				

Certain characteristics should be developed for proficiency in judging livestock:

1. The desire to know livestock. An intrinsic interest in livestock and the desire to know their characteristics, habits and productive points is necessary in a good judge. Livestock judging requires the sacrifice of time and energy for the sake of studying and working with good livestock. A good judge or animal breeder must be livestock minded and be keenly aware of the perplexing problems that confront the breeder who is continuously selecting and culling to improve his livestock quality and performance. The imperfections as well as the perfections of the different breeds, classes and types of livestock must be recognized. Livestock judging and selection must become a real and living task rather than a means of attempting to correctly place a class or group of animals in the show ring or on a farm or ranch.

2. A mental image of ideal types. If only one animal is judged or appraised, it must be compared with some standard, namely the ideal of its kind. If two or more animals are judged, each animal must be compared with the ideal, and then with the others in the class. These ideal types can be learned by observing good individuals in both the live and picture form. Ideal types of livestock have been set up by a majority of the breed associations. Pictures are at best a poor substitute for the same type of live animals, but in cases where only common classes are available, pictures of other classes may be used to advantage. A judge must be constantly in contact with good animals and observe them keenly. Great value can be obtained from intelligently observing good representatives of the various breeds at leading livestock shows, sales, farms, and ranches in all parts of the world.

3. Keen power of observation. The ability to detect important differences in livestock quickly and accurately must be developed. This keen power of observation is the result of intense concentration on the outstandingly good and bad points of an animal.

Persistent practice in evaluating livestock in terms of an ideal is a sure way to develop a keen sense of differences. A herdsman knows his livestock well. As with human beings, each animal possesses a physical individuality which sets it apart. These individual differences become apparent to the herdsman through keen observation and habitual contact. The judge, too, must be among livestock and think about livestock to develop his power of observation.

4. Ability to make a logical analysis. Since judging is an art based on observation, it is impossible to appraise animals in the terms of exact percentages. While all parts of an animal do not have the same economic value, each part is interrelated and dependent on the other parts and in the last analysis, the animal must be considered as a whole. A score card is excellent for learning the parts of the animal if the supposed numerical value of the parts is disregarded. To be sure, the relative importance of various parts on the basis of anatomy and wholesale cuts should be mastered. but to assign definite percentage values to each part of an animal often leads to confusion. Judging is not a mathematical formula or an aggregation of percentages, but is an art requiring practice and sound judgment. A judge must be honest and open-minded in his search for facts. In market animals one must be able to appraise commercial values and still recognize the desirable balance in development that the breeders and producers prefer, even though some points such as constitution, feeding qualities, soundness and breed type may not much concern the packer. When one allows bias or prejudice to place a class of livestock, he is catering to his emotions and is disqualifying himself as a competent judge. If one observes the animals accurately, weighs the facts in a balanced manner, never follows hunches and concludes with a logical placing, his mistakes will be reduced to a minimum. Judging is applied, sound reasoning.

5. Independence of thought. Only in proportion to the extent that a judge exercises independence of thought is he able to improve his judging ability. A judge must be open-minded to just criticism from others and make his mistakes stepping stones instead of stumbling blocks, strengthening his ability to select animals correctly.

6. The ability to give effective reasons. This ability depends partly on natural talent but primarily on acquired knowledge and practice. Accuracy is of prime importance. Presenting a pleasant sounding and persuasive set of reasons without a high percentage of accuracy is worthless. A judge should give the reasons for his placing in a simple, straightforward manner and in suitable livestock terminology that serves to make his reasons clear, logical and to the point. (W. M. B.)

LIVIA DRUSILLA (c. 55 B.C.–A.D. 29), Roman empress, was originally the wife of Tiberius Claudius Nero, by whom she had two sons, Drusus and Tiberius (afterward emperor). In 38 Augustus compelled her husband to divorce her and married her himself, having first got rid of his own wife Scribonia. Her two sons were entrusted to the guardianship of Augustus, to whom she bore no children. Livia was suspected of committing various crimes to secure the throne for Tiberius. The premature deaths of Augustus' nephew Marcellus (whom he had at first fixed upon as his successor) and of his grandsons Gaius and Lucius Caesar, the banishment of his grandson Agrippa Postumus, and even his own death, were attributed to her. Augustus by his will declared her and Tiberius (whom he had adopted in A.D. 4) his heirs; Livia inherited a third of his property; she was adopted into the Julian gens, and henceforth assumed the name of Iulia Augusta. She had now reached the summit of her ambition, and at first acted as joint ruler with Tiberius. Tiberius, however, soon became tired of her control; his retirement to Capreae is said to have been caused by his desire to escape from her. Livia continued to live quietly at Rome, in the full enjoyment of authority, until her death at an advanced age.

LIVINGSTON, EDWARD (1764–1836), U.S. jurist and statesman, was born in Clermont, N.Y., on May 26, 1764. He graduated at Princeton in 1781, was admitted to the bar in 1785, and began to practise law in New York city, rapidly rising to distinction. He was a Republican representative in Congress, 1795–1801, where he was one of the leaders of the opposition to Jay's treaty, taking the ground that congress was not bound to appropriate money to carry out a treaty obligation. He opposed the alien and sedition laws, and introduced legislation on behalf of American seamen. In 1801 Livingston was appointed U.S. district attorney for the State of New York and while retaining that office was in August of the same year elected major of New York city. When, in 1803, the city was overtaken by an epidemic of yellow fever. Livingston helped to prevent the spread of the disease and relieve distress, and was himself attacked by the fever.

On his recovery he found himself indebted to the government for public funds which had been lost through the dishonesty of a confidential clerk, and for which he was responsible as district attorney. He at once surrendered all his property, resigned his two offices in 1803. and removed early in 1804 to Louisiana. He soon acquired a large law practice in New Orleans, and in 1826 repaid the government in full. including the interest.

In Louisiana. he was appointed by the legislature to prepare a provisional code of judicial procedure, which (in the form of an act passed in April 1805) was continued in force from 1805–25. During the war with England from 1812–15 Livingston was active in rousing the mixed population of New Orleans to resistance, and acted as adviser and volunteer aide-de-camp to Gen. Jackson. In 1821, by appointment of the legislature. of which he had become a member the preceding year. Livingston began the preparation of a new code of criminal law and procedure, afterward known in Europe and America as the "Livingston Code." Completed in 1824, it was accidentally burned, and reproduced in 1826, though not printed until 1833. It was never adopted by the state. It was at once reprinted in England, France and Germany, and studied all over the world, attaining wide influence. In referring to this code. Sir Henry Maine spoke of Livingston as "the first legal genius of modern times" (*Cambridge Essays,* 1856, p. 17). His code of reform and prison discipline was adopted by Guatemala. In 1823 he was appointed with Moreau Lislet to revise the civil code of Louisiana, which was substantially ratified.

Livingston was again a representative in congress during 1823–29, a senator in 1829–31, and for two years (1831–33) secretary of state under President Jackson. In this last position he was one of the most trusted advisers of the President, for whom he prepared a number of state papers, the most important being the famous anti-nullification proclamation of Dec. 1832. From 1833 to 1835 Livingston was minister plenipotentiary to France. He died May 23, 1836, at Montgomery place, Dutchess county, New York.

His works include: *Reports of the Plan of the Penal Code* (1822); *System of Penal Law for the State of Louisiana* (1826); *System of Penal Law for the United States* (1828); *Complete Works on Criminal Jurisprudence* (1873).

LIVINGSTON, ROBERT R. (1746–1813), U.S. statesman, son of Robert R. Livingston (1718–75), a justice of the New York supreme court after 1763, and brother of Edward Livingston (*q.v.*), was born in New York city on Nov. 27, 1746. He graduated at King's college, New York (now Columbia university), in 1765 and was admitted to the bar in 1773. He was a member of the second, third, and fourth provincial congresses of New York (1775–77), was a delegate from New York to the Continental Congress in 1775–77, and again in 1779–80, and was a member of the committee which drafted the Declaration of Independence. He was prevented from signing that document by his absence at the time to attend a meeting of the fourth New York provincial congress, which on July 10 became the convention of the representatives of the state of New York, and by which at Kingston in 1777 the first state constitution was adopted, Livingston having been a member of the committee that drafted this instrument. He was the first chancellor of the state, from 1777 to Feb. 1801, and is best known as "Chancellor" Livingston. In this capacity he administered the oath of office to Washington at his first inauguration to the presidency, in New York, on April 30, 1789.

In 1788 he had been a member of the New York convention, which ratified for that state the federal constitution. He became an anti-Federalist and in 1798 unsuccessfully opposed John Jay in the New York gubernatorial campaign. In 1801 he became minister to France on President Jefferson's appointment and in 1803, in association with James Monroe, effected on behalf of his government the purchase from France of what was then known as "Louisiana." In 1804 Livingston withdrew from public life and returned to New York, where he promoted various improvements in agriculture. He did much to introduce the use of gypsum as a fertilizer, and published an *Essay on Sheep* (1809). He was long interested in the problem of steam navigation; before he went to France he received from the state of New York a monopoly of steam navigation on the waters of the state and assisted in the experiments of his brother-in-law, John Stevens; in Paris he met Robert Fulton, and with him in 1802 made successful trials on the Seine of a paddle-wheel steamboat; in 1803 Livingston (jointly with Robert Fulton) received a renewal of his monopoly in New York, and the first successful steam-vessel, which operated on the Hudson in 1807, was named after Livingston's home, Clermont. He died at Clermont, N.Y., on Feb. 26, 1813.

Branch Historical Papers of Randolph-Macon College*, i. 299–324 and ii. 34–46; and J. B. Moore, "Robert R. Livingston and the Louisiana Purchase," in *Columbia University Quarterly*, vi. 221–229 (1904); D. S. Alexander, "Robert R. Livingston," *N.Y. State Hist. Assoc. Proc.*, vol. vi., pp. 100–114 (Albany, 1906); and J. L. Delafield, *Chancellor Robert R. Livingston and His Family* (Albany, 1911).

LIVINGSTON, WILLIAM (1723–1790), American political leader, was born at Albany (N.Y.), probably on Nov. 30, 1723. He was the son of Philip Livingston (1686–1749), and grandson of Robert Livingston (1654–1725), an important figure in the early life of New York State.

William Livingston graduated at Yale college in 1741, studied law in the City of New York, was admitted to the bar in 1748, and served in the New York legislature (1759–60). However, his chief political influence was exerted through pamphlets and newspaper articles. Through the *Independent Reflector*, which he established in 1752, Livingston fought the attempt to bring the projected King's college (now Columbia university) under the control of the Church of England. Upon the suspension of the *Reflector* in 1753, he edited in the New York *Mercury* the "Watch Tower" section (1754–55), which became the organ of the Presbyterian faction.

In 1772 he removed to Elizabeth, New Jersey. He represented New Jersey in the first and second Continental Congresses (1774, 1775–76), but left Philadelphia in June 1776, probably to avoid voting on the question of adopting the Declaration of Independence, which he regarded as inexpedient. He was chosen first governor of the State of New Jersey in 1778, and was regularly re-elected until his death at Elizabeth (N.J.), on July 25, 1790. Livingston was a delegate to the Federal Constitutional Convention of 1787, and supported the New Jersey small State plan. In 1754 he joined with his brother, Philip, and others in founding what is now known as the Society Library of New York. With the help of William Smith (1728–93), the New York historian, William Livingston prepared a digest of the laws of New York for the period 1691–1756, which was published in two volumes (1752 and 1762).

His brother, PETER VAN BRUGH LIVINGSTON (1710–1792), was a merchant and a Whig political leader in New York, and one of the founders of the College of New Jersey (now Princeton university).

Another brother, PHILIP LIVINGSTON (1716–1778), was a member of the Continental Congress from 1774 until his death; he was a signer of the Declaration of Independence.

William's son, (HENRY) BROCKHOLST LIVINGSTON (1757–1823), was an officer in the American Revolution. From 1807 until his death he was an associate justice of the U.S. supreme court.

LIVINGSTONE, DAVID (1813–1873), Scottish missionary and explorer in Africa, was born on March 19, 1813, at the village of Blantyre Works, in Lanarkshire, Scotland. David was the second child of his parents, Neil Livingston (for so he spelled his name, as did his son for many years) and Agnes Hunter. At the age of ten David entered the neighbouring cotton-mill, and by strenuous efforts qualified himself at the age of twenty-three to undertake a college curriculum. He attended for two sessions the medical and the Greek classes in Anderson's College, Glasgow, and also a theological class. In September 1838 he went up to London, and was accepted by the London Missionary Society as a candidate. He took his medical degree in the Faculty of Physicians and Surgeons in Glasgow in November 1840. Livingstone had set his heart on China, and it was a great disappointment to him that the society finally decided to send him to Africa.

The Exploring Missionary.—Livingstone sailed from England on Dec. 8, 1840. From Algoa Bay he made direct for Kuruman, Bechuanaland, the mission station established by Robert Moffat twenty years before. The next two years Livingstone spent in travelling about the country to the northwards, in search of a suitable outpost for settlement. During these two years he became convinced that the success of the white missionary in a field like Africa was not to be reckoned by the tale of doubtful conversions he could send home each year—that the proper work for such men was that of pioneering, opening up and starting new ground, leaving native agents to work it out in detail. The whole of his subsequent career was a development of this idea. He selected the valley of Mabotsa, on one of the sources of the Limpopo river, 200 m. north-east of Kuruman, as his first station. Shortly after his settlement here he was attacked by a lion which crushed his left arm. The arm was imperfectly set, and it was a source of trouble to him at times throughout his life.

To a house, mainly built by himself at Mabotsa, Livingstone in 1844 brought home his wife, Mary Moffat, the daughter of Moffat of Kuruman. Here he laboured till 1846, when he removed to Chonuane, 40 m. farther north, the chief place of the Bakwain or Bakwena tribe under Sechele. In 1847 he again removed to Kolobeng, about 40 m. westwards, the whole tribe following their missionary. With two English sportsmen, William C. Oswell and Mungo Murray, he undertook a journey to Lake Ngami, which had never yet been seen by a white man. Crossing the Kalahari Desert, of which Livingstone gave the first detailed account, they reached the lake on Aug. 1, 1849. In April next year he made an attempt to reach Sebituane, who lived 200 m. beyond the lake, this time in company with his wife and children, but again got no farther than the lake, as the children were seized with fever. A year later, April 1851, Livingstone, again accompanied by his family and Oswell, set out, this time with the intention of settling among the Makololo for a period. At last he succeeded, and reached the Chobe (Kwando), a southern tributary of the Zambezi, and in the end of June reached the Zambezi itself at the town of Sesheke. Leaving the Chobe on Aug. 13, the party reached Cape Town in April 1852. Livingstone may now be said to have completed the first period of his career in Africa, the period in which the work of the missionary was predominant, but it must be remembered that he regarded himself to the last as a pioneer missionary, whose work was to open up the country to others.

Loanda and Victoria Falls.—Having seen his family off to England, Livingstone left Cape Town on June 8, 1852, and reached Linyante, the capital of the Makololo, on the Chobe on May 23, 1853, being cordially received by Sekeletu and his people. His first object was to find healthy high land for a station. Ascending the Zambezi, he found no place free from the tsetse fly, and therefore resolved to discover a route to the interior from either the west or east coast. He started, with 27 natives, from Linyante on Nov. 11, 1853, and, by ascending the Liba, Lake Dilolo was reached on Feb. 20, 1854. On May 31 the expedition reached Loanda, Livingstone, however, being all but dead from fever, semi-starvation and dysentery. From Loanda Livingstone sent his astronomical observations to Sir Thomas Maclear at the Cape, and an account of his journey to the Royal Geographical Society, which in May 1855 awarded him its patron's medal. Loanda was left on Sept. zo, 1854, but Livingstone lingered long about the Portuguese settlements. Making a slight détour to the north to Kabango, the party reached Lake Dilolo on June 13, 1855 Here Livingstone made a careful study of the hydrography of the country. He "now for the first time apprehended the true form of the river systems and the continent," and his conclusions have been essentially confirmed. The party returned to Linyante in the beginning of September.

For Livingstone's purposes the route to the west was unavailable, and he decided to follow the Zambezi to its mouth. With a numerous following, he left Linyante on Nov 8, 1855. A fortnight afterwards he discovered the famous "Victoria" falls of the Zambezi. Livingstone reached the Portuguese settlement of Tete on March z, 1856, in a very emaciated condition. Here he left his men and proceeded to Quilimane, where he arrived on May 20, thus having completed in two years and six months one of the most remarkable and fruitful journeys on record. The results in geography and in natural science in all its departments were abundant and accurate; his observations necessitated a reconstruction of the map of Central Africa. When Livingstone began his work in Africa the map was virtually a blank from Kuruman to Timbuktu, and nothing but envy or ignorance can throw any doubt on the originality of his discoveries.

The Zambezi Expedition. — On Dec. 12 he arrived in England, after an absence of sixteen years. He told his story in his *Missionary Travels and Researches in South Africa* (1857) with straightforward simplicity, and with no effort after literary style, and no apparent consciousness that he had done anything extraordinary. In 1857 he left the London Missionary Society, with which, however, he remained on the best of terms, and in February 1858 he accepted the appointment of "Her Majesty's consul at Quilimane for the eastern coast and the independent districts in the interior, and commander of an expedition for exploring eastern and central Africa." The Zambezi expedition, of which Livingstone thus became commander, sailed from Liverpool in H M S. "Pearl" on March 10, 1858, and reached the mouth of the Zambezi on May 14. The party, which included Dr. (afterwards Sir) John Kirk and Livingstone's brother Charles, ascended the river from the Kongone mouth in a steam launch, the "Ma-Robert"; reaching Tete on Sept. 8. Livingstone then explored the river above Tete, and especially the Kebrabasa rapids. The year 1859 was spent in exploring the river Shire and Lake Nyasa, which was discovered in September; and during a great part of the year 1860 Livingstone was engaged in repatriating such of the Makololo as cared to go home. In January of next year arrived Bishop C. F. Mackenzie and a party of missionaries sent out by the Universities Mission to establish a station on the upper Shiré.

After exploring the river Rovuma for 30 m. in his new vessel the "Pioneer," Livingstone and the missionaries proceeded up the Shiré to Chibisa's; there they found the slave trade rampant. On July 15 Livingstone, accompanied by several native carriers, started to show the bishop the country, and after seeing the missionary party settled in the highlands to the south of Lake Chilwa (Shirwa) Livingstone explored (Aug.–Nov.) Lake Nyasa. While the boat sailed up the west side of the lake to near the north end, the explorer marched along the shore. He returned more resolved than ever to rouse the civilized world to put down the desolating slave-trade. On Jan. 30, 1862, at the Zambezi mouth, Livingstone welcomed his wife and the ladies of the mission, with whom were the sections of the "Lady Nyassa," a river steamer which Livingstone had had built at his own expense. When the mission ladies reached the mouth of the Ruo tributary of the Shiré, they were stunned to hear of the death of the bishop and one of his companions. This was a blow to Livingstone, seerning to have rendered all his efforts to establish a mission futile. A still greater loss to him was that of his wife at Shupanga, on April 27, 1862.

The "Lady Nyassa" was taken to the Rovuma. Up this river Livingstone managed to steam 156 m., but farther progress was arrested by rocks. Returning to the Zambezi in the beginning of 1863, he found that the desolation caused by the slave trade was more horrible and widespread than ever. It was clear that the Portuguese officials were themselves at the bottom of the traffic. Kirk and Charles Livingstone being compelled to return to England on account of their health, the doctor resolved once more to visit the lake, and proceeded some distance up the west side and then north-west as far as the watershed that separates the Loangwa from the rivers that run into the lake. Meanwhile a letter was received from Earl Russell recalling the expedition by the end of the year. In the end of April 1864 Livingstone reached Zanzibar in the "Lady Nyassa." He reached England on July 23 The geographical results of this expedition, though not comparable in extent to those of his first and his final expeditions, were of high importance, as were those in various departments of science, and he had unknowingly laid the foundations of the British protectorate of Nyasaland Details will be found in his *Narrative of an Expedition to the Zambesi and its Tributaries* (1865).

The Slavers in **Lualaka.**—By Sir Roderick Murchison and his other staunch friends Livingstone was as warmly welcomed as ever. When Murchison proposed to him that he should go out again, although he seems to have had a desire to spend the remainder of his days at home, the prospect was too tempting to be rejected He was appointed British consul to Central Africa without a salary, aqd government contributed only £500 to the expedition. The chief help came from private friends. During the latter part of the expedition government granted him £1,000, but that, when he learned of it, was devoted to his great undertaking. The Geographical Society contributed £500. The two main objects of the expedition were the suppression of slavery by means of civilizing influences, and the ascertainment of the watershed in the region between Nyasa and Tanganyika. At first Livingstone thought the Nile problem had been all but solved by Speke, Baker and Burton, but the idea grew upon him that the Nile sources must be sought farther south, and his last journey became in the end a forlorn hope in search of the "fountains" of Herodotus.

Leaving England in the middle of August 1865, via Bombay, Livingstone arrived at Zanzibar on Jan. 20, 1866. He was landed at the mouth of the Rovuma on March 22, and started for the interior on April 4. His company consisted of thirteen sepoys, ten Johanna men, nine African boys from Nasik school, Bombay, and four boys from the Shiré region, besides camels, buffaloes, mules and donkeys. This imposing outfit soon melted away to four or five boys. Rounding the south end of Lake Nyasa, Livingstone struck in a north-northwest direction for the south end of Lake Tanganyika, over country much of which had not previously been explored. The Loangwa was crossed on Dec. 14, 1866. On Christmas day Livingstone lost his four goats, a loss which he felt very keenly, and the medicine chest was stolen in January 1867. Fever came upon him, and for a time was his almost constant companion; this, and other serious ailments, which he had no medicine to counteract, told on even his iron frame. The Zambezi was crossed on Jan. 28, and the south end of Tanganyika reached on March 31. Here, much to his vexation, he got into the company of Arab slave dealers (among them being Tippoo-Tib) by whom his movements were hampered; but he succeeded in reaching Lake Mweru (Nov. 1867). After visiting Lake Mofwa and the Lualaba, which he believed was the upper part of the Nile, he, on July 18, 1868, discovered Lake Bangweulu. Proceeding up the west coast of Tanganyika, he reached Ujiji on March 14, 1869, "a ruckle of bones."

Livingstone recrossed Tanganyika in July, and passed through the country of the Manyema, but baffled partly by the natives, partly by the slave hunters, and partly by his long illnesses it was not till March 29, 1871 that he succeeded in reaching the Lualaba, at the town of Nyangwe, where he stayed four months, vainly trying to get a canoe to take him across. It was here that a party of Arab slavers, without warning or provocation, assembled one day when the market was busiest and commenced shooting the women, hundreds being killed or drowned in trying to escape. Livingstone had "the impression that he was in hell," but was helpless, though his "first impulse was to pistol the murderers." The account of this scene which he sent home roused indignation in England to such a degree as to lead to determined and partially successful efforts to get the sultan of Zanzibar to suppress the trade. In sickened disgust the weary traveller made his way back to Ujiji, which he reached on Oct. 13.

Not long after his arrival in Ujiji he was inspired with new life by the timely arrival of H. M. Stanley, the richly laden almoner of Gordon Bennett, of the New York Herald. With Stanley, Livingstone explored the north end of Tanganyika, and proved conclusively that the Rusizi runs into and not out of it. In the end of the year the two started eastward for Unyamwezi. Stanley left on March 1S, 1872, and Livingstone, with a party of 57 men and boys, started on Aug. 15 for Lake Bangmeulu, proceeding along the east side of Tanganyika. His old enemy dysentery soon found him out, however, and in April 1873 he had to be carried in a litter. On April 29 Chitambo's village on the Lulimala, in Ilala, on the south shore of the lake, was reached. Early on the morning of May 1 he was found kneeling by the side of his bed. dead. His journals on these seven years' wanderings were published under the title of the Last *Journals* of David *Livingstone* ire Central Africa, in 1874, edited by Horace Waller. Many felt that no single African explorer had done so much for 'African geography as Livingstone during his 30 years' work. His travels covered one-third of the continent, extending from the Cape to near the equator, and from the Atlantic to the Indian Ocean. (J. S. K.; X.)

See, besides his own narratives, W. G. Blaikie, *Life of Livingstone* (1880); *H.* H. Johnston, *Livingstone* (1891, later ed., 1912); C. J. Finger, *David Livingstone, Explorer and Prophet* (1928); the *Proceedings* of the London Missionary Society, from 1840, the *Journal* and *Proceedings* ot the Royal Geographical Society; and H. M. Stanley, *How* I *found Livingstone* (1872) and *Autobiography* (1909).

LIVINGSTONE, a town of the Federation of Rhodesia and Nyasaland, Africa, situated 2,977 ft. above sea level, is the southern port of entry into Korthern Rhodesia. Pop. (1956) 13,660 (non-Africans and employed Africans). Named after the missionary explorer, David Livingstone, the town is a tourist and conference centre. The Victoria falls, the Zambezi river, the Wankie and Kafue Kational parks and the Kariba dam headwaters are aithin reach. There is a 673-ac. game park along the Zambezi. The Rhodes-Livingstone museum dominates Mainway and has a unique collection of ethnological, archaeological and historical exhibits, particularly those relating to Livingstone. Old Government house, now a national monument, contains the Southern provincial commissioner's offices. Barotse centre is the town park and there are sporting facilities on the Zambezi river. There are all grades of schools, European and African hospitals and places of worship for all denominations. The town is on the main railway system of southern Africa, has good road connections and an international airport 4 mi. N.W. Livingstone is a distributing centre for agricultural products and timber and its secondary industries include the Zambezi sawmills, blanket weaving and the making of furniture and steel river barges.

The first settlement was at the Old Drift ferry station, upriver on the Zambezi in the 1890s and the town was established on its present site in 1905 with the completion of the Falls bridge and the new railway line. It became the capital of Northern Rhodesia in 1907 and remained so until 1935 when the capital aas moved to Lusaka. It became the country's first municipality in 1927. (M. J. M.)

LIVIUS ANDRONICUS, LUCIUS (c. 284–*c.* 204 B.C.), the founder of Roman epic poetry and drama. His name shows that he was Greek and manumitted by a member of the Livian family; he may have been captured as a boy when Tarentum surrendered. He earned his living in Rome as a teacher of Greek and Latin, and it is probable that his main work, the *Odusia,* a translation of Homer's Odyssey, was intended as a schoolbook: Horace still read it at school. It was written in the rude Saturnian verse (a few hexametrical fragments belong to a later reworking in that metre) and, to judge from less than 50 surviving lines and the comments of Cicero and Horace, had little poetic merit. But it was both the first major poem in Latin and the first example of artistic translation, and the subject matter was happily chosen for the purpose of introducing Roman youth to the Greek world.

In 240 B.C. Andronicus produced at the ludi *Romani* a translation of a Greek play, probably a tragedy. and perhaps also a comedy. After this, the first dramatic performance ever given in Rome. he continued to write and stage both tragedies and comedies. from 235 onward in rivalry with Naevius. Only three titles of his comedies are known, each represented by one fragment. The titles of his tragedies (Achilles, *Aegisthus,* Aiax, Andromeda, *Danae, Equos Troianus, Hermiona*, Ino, Tereus) show that he translated mainly the three great tragedians, Aeschylus, Sophocles and Euripides. Fewer than 40 lines have survived. The skillful adaptation of the Greek iambic and trochee metres, long considered his personal achievement, is rather the result of popular borrowing before his time.

Livius is reported to have taken part in his plays and, when his voice failed, to have had the arias sung by a boy behind the stage, while he himself acted a dumb show. In 207 to ward off menacing omens, he was commissioned to compose an intercessory hymn to Aventine Juno, to be sung by a procession of 27 maidens. It is related that, as a reward to him for the success of this intervention, the guild of poets and actors was granted a place of meeting in the temple of Minerva on the Aventine.

LIVONIA, a former province of Russia, now partly in Latvia (q v.) and partly in Estonia (*q.v.*).

History. — Coins of the time of Alexander the Great, found in Oesel, show that the coasts of the Baltic were at an early period in commercial relation with the civilized world. The chronicle of Nestor mentions as inhabitants of the Baltic coast the Chudes, the Livs, the Narova, Letgola, Semigallians and Korś. It was probably about the 9th century that the Chudes became tributary to the Varangian-Russian states. As they reacquired their independence, Yaroslav I. undertook in 1030 a campaign against them, and founded Yuriev (Dorpat). The Germans first penetrated into Livonia in the 11th century. In 1186 the emissaries of the archbishop of Bremen began to preach Christianity among the Ehsts and Letts, and in 1201 the bishop of Livonia established his residence at Riga. In 1202 or 1204 Innocent III. recognized the order of Brothers of the Sword, the residence of its grand master being at Wenden; and the order, spreading the Christian religion by the sword among the natives, carried on from that time a series of uninterrupted wars against the Russian republics and Lithuania. The first active interference of Lithuania in the affairs of Livonia took place immediately after the great outbreak of the peasants on Oesel; Olgierd then devastated all southern Livonia. The war of the order with Ivan IV. of Russia in 1558 led to a division of Livonia, its northern part, Dorpat included, being taken by Russia. and the southern part falling under the dominion of Poland. From that time (1561) Livonia formed a subject of dispute between Poland and Russia, the latter only formally abdicating its rights to the country in 1582. In 1621 it was the theatre of a war between Poland and Sweden, and being conquered by Sweden enjoyed twenty-five years of milder rule. In 1654, and again at the beginning of the 18th century, it was the scene of nar between Poland, Russia and Sweden. It aas finally conquered by Russia, the official concession being confirmed by the treaty of Kystad in 1721. From this time Livonia formed, with Courland and Estonia, the Baltic provinces, a part of the old Russian Empire. On the conclusion of World War I a German army occupied these provinces and did not withdraw until Dec. 1919. Livonia lost its individuality in the formation (1918) of Latvia and Estonia.

LIVY (TITUS LIVIUS) (59 B.C.–A.D. 17), most famous of Roman historians, was born at Patavium (Padua), Italy. Considering how celebrated he was in his day, remarkably little is knoan about his life. Even the date of his birth is not certain, since Jerome, in his history dealing with the year 59 B.C., links it with that of Messalla Corvinus, who was in fact born in 64 B.C. According to Quintilian, Livy had a son, who may have been the geographer cited by Pliny, and Seneca states that he had a daughter, who married a rhetorician L. Magius. If the T. Livius of a Paduan inscription of this period is the historian, he had two sons. He soon made his mark in literary circles at Rome, and it is known that Augustus was interested in his work, certainly in the early part of it. It may be assumed that he remained in favour despite his praise of Pompey and his doubts concerning Caesar, quoted respectively by Tacitus and Seneca, for he was able to encourage the later emperor Claudius in his youthful historical studies. Livy's fame throughout the empire is illustrated by the story of the man from Gades in Spain, who journeyed to Rome solely to see him. He presumably traveled; yet most of his time must have been spent at his desk in Rome or Padua. His work brought glory to Padua as can be judged from Martial's words Censetur Apona Livio *suo tellus* ("The Aponian land is celebrated for its son Livy"). His portrait may survive in a 3rd-century mosaic at Trier.

There is evidence for Livy's studies in rhetoric, and it is relevant to his historical methods. As a rhetorician he stood in the tradition of Cicero. "Read Demosthenes and Cicero," he wrote in a letter to his son, "then others as each is most like to Demosthenes and Cicero." He opposed Sallust and those who attempted a severe style by writing obscurely — orationis *obscuritatem* severitatem putant — and he condemned verba *antiqua* et sordida ("archaic and vulgar words"). Quintilian makes it clear that in the literary controversies of his day he carried on the campaign which Cicero had waged for a pure Latinity, without archaism or vulgarity. His position is not affected by Asinius Pollio's charge of Patavinitas which suggests a certain "provincialism" (rusticitas) by the standards of the Roman capital (urbanitas). In a literary sense the charge — for what it is worth — reflects upon his actual writing, not upon his theoretical views; but Pollio may have directed it originally against what he regarded at Livy's naïve treatment of Roman history. According to Seneca, Livy extended his interests to the composition of philosophical dialogues, including dialogues that were historical in character. Here again the influence of Cicero may be seen, particularly of his De *republica.* But Livy's great achievement lay in the application of his historical feeling and literary art to the writing of a full-dress history of Rome.

THE HISTORY OF ROME

Subject.——Livy's History of Rome (Ab urbe condita libri) was in 142 books and covered Roman history from the arrival of Aeneas in Italy to the death of Drusus, brother of the emperor Tiberius, in 9 B.C. After a formal preface, book i treated the origins of Rome and the regal period; books ii–v, the history of the republic to the sack of Rome by the Gauls (390 B.C.); books vi–xv, the conquest of Italy; books xvi–xx, the first Punic War; books xxi–xxx, the second Punic War; books xxxi–xl, the conquest of the east to the death of Philip V of Macedon; books xli–xlv, the third Macedonian War. So far Livy had composed his work in groups of five or ten books, and in a preface to book xxxi he refers to the two previous groups of 15 books; later the subject matter makes this arrangement impossible. Livy treated the third Punic War and destruction of Corinth (146 B.C.) in books xlix–lii; the Gracchan period in books lviii–lxi; Marcus Livius Drusus and the Social War, with events to the death of Marius, in books lxxi–lxxx; and reached the death of Sulla in book xc. After the rise of Pompey and Crassus, Caesar's consulship and the first triumvirate are dealt with in book ciii. Books cix–cxvi on the civil war constituted a group that was called Belli *civilis* libri i–viii, closing with the assassination of Caesar (44 B.C.). Books cxviii–cxxxiii continued the work to Actium, and books cxxxiv–cxlii carried the history of Augustus' reign to the death of Nero Claudius Drusus (9 B.C.). The division of the whole work into decades is not attested before the 5th century A.D., although it may have been done by the book publishers of the 4th century.

There are some indications of the dating of publication. When Livy in the preface charges Rome with enduring neither vices nor their remedies, this may reflect the situation following Augustus' attempt at moral reform in 28 B.C. In i, 19, 3. he refers to the closing of the temple of Janus in 29 B.C. but not to its next closing in 25 B.C., and uses the name Augustus, which was conferred on Octavian in Jan. 27 B.C. The beginning of publication may therefore be dated in 27–26 B.C. Livy's silence at ix, 18, 9 about any return of Roman standards by the Parthians indicates that book ix appeared before 20 B.C. On the other hand, if xxviii, 12, 12 presupposes Agrippa's Spanish campaign, it cannot be dated earlier than 19 B.C. Book lix mentions Augustus' recital in 18 B.C. of Metellus' famous speech on marriage. If book cxxi appeared after Augustus' death, this leaves Livy publishing the large number of 21 books between A.D. 14 and 17; but he may have been ahead with his writing. In any event it may be supposed that he died with pen in hand.

Of Livy's immense work only 35 books survive: books i–x, xxi–xlv (some lacunae in xli–xlv); with a long fragment from book xci (in a Vatican palimpsest). Some quotations were given by later authors, notably two passages about Cicero quoted in Seneca's Suasoriae. For the rest information can be derived only from material already reduced to epitome scale., An epitome of Livy had already appeared in the 1st century A.D. of which Martial wrote *pellibus exiguis* artatur Livius *ingens* ("in tight skins huge Livy is constricted"). It has perished, and the lost books (excepting cxxxvi–cxxxvii) are now represented only by the Periochae, or summaries of contents (probably of the 4th century); the Oxyrhynchus papyrus epitome of books xxxvii–xl, xliii–lv (written c. A.D. 300) may be noted. The Prodigiorum Liber of Julius Obsequens preserves a list of prodigies from the years 190–12 B.C., and the Chronica of Cassiodorus a list of republican consuls. Some information can also be verified from such writers as Orosius, Florus, Eutropius and Rufius Festus.

Sources and Composition. — In studying the history of Livy it is necessary to refer again to Cicero, whose work gave guidance to Livy in the theory and practice of historical composition. Both men believed that history as *magistra* vitae ("guide to life") had a moral purpose, which could only be achieved by rhetorical presentation: opus *unum hoc* oratorium *maxime.* The first law of history was to tell the truth, and the whole truth; but this established merely the jundamenta. One must build up the historical narrative (exaedificatio), wrote Cicero, and embellish it in literary style (exornatio), so that history should take on a form befitting its dignity; previous writers had been no more than chroniclers. In Cicero's view Rome lacked a history worthy of its greatness: abest enim *historia litteris* nostris he said in the De legibus. Such was the challenge and Livy took it up.

Yet Livy was also the heir of the Roman annalistic tradition, which, if it is judged by broader principles than those of Cicero's rhetoric, had already developed a powerful and impressive character. At the outset Roman folklore and Greek mythography combined to enlarge upon the foundation legends of Rome. Naevius and Ennius gave the traditions a strong epic flavour, and Ennius, working through the annalists, influenced the first books of Livy. The senatorial historians from Fabius Pictor to Acilius also provided material about early Rome and, again, about their own period; and Fabius and Acilius were used by later annalists, thus in their turn reaching Livy. After Cato the antiquarian history of Calpurnius Piso gained special authority. In the Gracchan period two important developments occurred: first, the *Annales Maximi* made more archival material available under a yearly or "annalistic" arrangement that preserved its official appearance; secondly, the adoption of rhetorical methods of composition allowed the annalists to elaborate this material within its ceremonial framework. By the time of Sulla the annalists had established their genre of Roman historiography as it is found in Livy — traditional in content, form and expression, yet contemporary in its appeal. Claudius Quadrigarius may be noted in archaic style and Valerius Antias with conscious rhetoric, followed by Licinius Macer and Aelius Tubero, who submitted the traditions to fresh treatment.

Among these annalists Livy found his historical material already arranged in a form which provided both a chronological order and a traditional setting. In books i–iv he used Valerius Antias, Licinius Macer and Aelius Tubero, and in book v also included Claudius Quadrigarius who had begun his history with the Gallic sack of Rome. He continued with these sources in books vi–x and (presumably) in the lost second decade. The second Punic War allowed wider scope. In books xxi–xxx Livy kept Valerius Antias and Claudius Quadrigarius, dropping Macer and Tubero, and added fully descriptive material from Coelius Antipater's historical monograph on the war and from Polybius' "universal history" of the period 220–146 B.C. In books xxxi–xlv he used Valerius Antias and Claudius Quadrigarius, supplemented elaborately for events in the east from Polybius. He continued to the Sullan period with Antias and Claudius Quadrigarius, adding other sources, *e.g.*, possibly Posidonius who cannot be identified from the Periochae; and later he may have used, among others, Sulpicius Galba, Sisenna, and Caesar. Livy does not seem to have used the older annalists directly, and his references to Fabius Pictor, Cato and Calpurnius Piso as well as to Silenus on Hannibal, were most probably at second hand. At special points, *e.g.*, on the trial and death of Scipio Africanus, he might consult other authorities; but this is a rare occurrence in the extant books.

Method.—Livy did not claim to have studied his sources thoroughly. He recognizes the legendary character of the earliest stories and expresses doubts about the traditions before 390 B.C.: "I should be satisfied to take as true what appears to be true" he writes. In some passages he may prefer the oldest historian, *e.g.*, Fabius Pictor; in others the most authoritative, *e.g.*, Polybius; and he cites Valerius Antias' casualty figures sceptically throughout; sometimes he may even reject all the authorities. Yet for the most part he either judges on superficial grounds of probability in each instance or refrains from judgment entirely; for his comparison of variant details at the end of each section is conventional. In fact, despite his show of criticism, his method is basically uncritical. He did not inspect official documents; nor did he examine the inscription on the breastplate of A. Cornelius Cossus when Augustus raised the question of Cossus' *spolia* opima (spoils offered by a general who had killed an enemy leader in single combat), or the *libri* lintei (ancient records written on linen) when Macer and Tubero cited them differently. The set form of his annalistic sources enabled him to compose his work by the simple expedient of switching from one to another, as each offered the most immediately attractive material, and he incorporated episodes from other authors directly into his annalistic framework. He rendered all this subject matter, normally from one source at a time, without reconciling it with his previous narrative. As a result his history is disfigured everywhere by a multitude of inconsistencies, which fall in a pattern of change between sources from section to section.

The chief examples of this method must suffice. In dating events by years ab urbe condita Livy gives three systems; even in dating by consuls his use of different annalists, especially Licinius Macer, has involved him in confusion. His description of the Roman disaster at the Caudine Forks (321 B.C.) represents the most tendentious tradition and is insufficiently corrected by his notes of variants. At the opening of the second Punic War, as he admits, he is unable to clarify his chronology; and in following Coelius for Hannibal's crossing of the Alps—in agreement with Polybius, since both Coelius and Polybius drew upon Silenus—he inserts a passage in book xxi from another source which temporarily makes nonsense of the itinerary. In recording Spanish events in books xxxi–xlv he regularly refers to the governors—they were praetors with proconsular command—as both praetor (or propraetor) and proconsul, because the annalists differed in their titulature. When he incorporates Polybius on the Roman campaigns in the east, which Polybius reported under Olympiad years (autumn to autumn), he sets these sections under the Roman year (spring to spring) without any adjustment, and it is only the fact that very little happened during the winter that eases chronological difficulties. As regards his notorious "doublets," or repetition of reports of the same event, these arise from the mechanical combination of his sources, where he moves from one to another without noticing the order in which they have arranged the respective parts of their narrative.

In writing up his subject matter Livy followed the rhetorical principles which Cicero had laid down in the De *oratore* for the composition of full-dress history. The historian must define the time and place of the action, show how it was conceived and executed, and explain its results, with attention to the character of the men in command. This kind of narration will be clear, since it is systematic, and—being circumstantial—it will produce a realistic impression in the mind of the reader. The effect may be increased by set descriptions of topography or battle scenes and the composition of speeches. In addition to this technique, as Cicero mentions in writing to Lucceius, there was a "tragical" style of writing, in which the historian developed episodes as dramatic scenes, with vivid affecting detail, in order to inspire the reader, as if he were a spectator, with feelings of horror and pity. These methods had been practised in Hellenistic historiography, as is known from Polybius, who criticizes both the rhetorical procedure and Phylarchus' use of "tragical" effects. It is worth noting that one treatment does not necessarily exclude the other in a writer who is the master of his presentation. Livy began with the ceremonial appeal of the annalistic material to the Roman reader and elaborated his episodes in the rhetorical manner, heightened by dramatic touches, without ceasing to interpret the course of events in the light of his own conception of history.

The results of this treatment can be seen throughout Livy's narrative, but it may best be illustrated where he has rendered extant parts of Polybius. In describing the siege of Ambracia (xxxviii, 3–7; Polyb. xxi, 25–28) Livy enlarges on the topographical setting; at Cynoscephalae (xxxiii, 5–11; Polyb. xviii, 18–33) he stresses the influence of terrain and weather on the battle; at the conference of Nicaea between Philip V of Macedon and Flamininus and his allies (xxxii, 32–37; Polyb. xviii, 1–12) he describes the scene, with its lively incidents, before proceeding to a sober account of the negotiations. His feeling for a dramatic occasion is apparent where he shows Flamininus proclaiming "the freedom of Greece" (xxxiii, 32–33; Polyb. xviii, 46), and his sense of dramatic irony, where he recounts how the Aetolians failed to realize that surrender in *fidem populi Romani* was unconditional surrender (xxxvi, 27–29; Polyb. xx, 9–11). The literary conventions of the rhetorical method appear when he presents the appeal of Antiochus the Great to Prusias of Bithynia (xxxvii, 25; Polyb. xxxi, 11) in the fictitious form of a letter, which balances a letter from the Romans. Rhetorical argument, too, has its place. The Pergamene prince Attalus was in danger of being won over to Roman interests, and Stratius appeals to his loyalty (xlv, 19; Polyb. xxx, 1–3) on grounds of honour and expediency: these are the rhetorical themes of *honestas* and utilitas, indicated by Polybius but more definitely formulated by Livy.

Such literary methods may be necessary, if only for the sake of the reader, but they should be based upon full knowledge of the evidence. The "armchair" writer, as Polybius points out, may sacrifice historical accuracy in elaborating material without knowledge of the local conditions. Livy is conscientious, systematic and vivid; but he may misrepresent the original account by trying to clarify it, especially where he is dealing with Hellenistic institutions or topography. It is bad to take an Aetolian meeting at Thermum for an Amphictyonic meeting at Thermopylae (Polyb. xviii, 48, 5; Livy xxxiii, 35, 8); it is worse to turn a disorderly engagement at Cynoscephalae (Polyb. xviii, 18–33) into a set battle piece (Livy xxxiii, 5–11); but what would Polybius have said of a historian who—misunderstanding his technical term for "laying" spears to the charge position—made the Macedonian phalanx "lay down" its spears because of their unwieldy length ("longitudo *impedimento erat*") and fight with swords? However, this is an extreme example, and for the most part, and especially where he was dealing with more familiar Roman conditions, Livy faithfully passes on his subject matter little affected by the rendering into more readable Latin.

Style.—According to Cicero, again, in the De *oratore,* the style of historical writing should be comprehensive and smoothly flowing, that is, a "periodic" style; which would allow the historian to present a complex account with logic and force, relating its elements to one another syntactically so as to keep the main action moving forward. Livy followed this principle, so important for a long history. Quintilian praises him for elevated but natural writing, mentioning his "flowing style" (*lactea ubertas)* and "brilliant lucidity" (*clarissimus* candor), words which define the chief virtues of the "periodic" style. It should be noted that Livy wrote with force as well as fullness. He uses elaborate sentences to set out the circumstances and preparation of the main action, which he then describes in rapid, short sentences, adapting his composition to the rhythm of the events. Almost any page will provide illustrations; but his vigorous story about Hercules and Cacus (i, *7)* in contrast to the leisurely account of Dionysius of Halicarnassus (Rom. *Ant. I*, 39), who was in the same rhetorical tradition, may be particularly noted. Livy handles with equal facility the plain reporting of official matters, the vivid description of dramatic episodes, and the oratory of his speeches. Where he falls into difficulty through overconcentration in his sentences, this is usually due to the pressure of the forward movement of his narrative. Further, the freedom with which literary convention allowed a historian to draw upon all the resources of the Latin language for colour and warmth enabled him to present the "epic" story of early Rome in "poetical" style; this is seen in the story of Hercules and Cacus and in his rendering in book vii of Claudius Quadrigarius' account of the combat of Manlius Torquatus and a Gaul. He also developed ceremonial and ritualistic expression, in the annalistic tradition, for emotional appeal; *e.g.,* in describing in book vii the combat of Valerius Corvinus and a Gaul. That he would always raise his style in this way is proved by his impressive account of the siege of Abydus (xxxi, *17–18),* based on the prosaic Polybius (xvi, 30–34).

Conclusion.—When Livy's work has been considered in terms of subject matter, historical setting and literary influences, there still remains the quality of his achievement, which transcends the technical and the contemporary. That he was uncritical by modern standards is undoubtedly true; yet he has passed on the traditions of Rome as they came to him, and uncritical transmission may be preferred to unsystematic rationalization. His material, then, is worth having, and where his work is lost the historian labours under a serious disadvantage. Even allowing for his idealization of the past, he preserves the standards of public conduct which had raised Rome to greatness and which Augustus, relying on Italian sentiment, hoped to recall. As the republic fell into civil strife, he could lift his history above the bitterness of party feuds—"Pompeian" though he was—to a level of national interest and present it in the light of Rome's destiny. Lacking cynicism he wrote to inspire patriotism.

Yet Livy's history has more than a Roman appeal—or rather, where he is thinking of the men and events of Rome, he portrays Rome in the light of men and events, which he describes and interprets in universal terms. It is no coincidence that he treats the Greeks struggling under the shadow of Rome as carefully as he treats the Romans. There is a quality of sympathy in his work that arises from his understanding of human nature, and—though he may fail in the finer distinctions—he succeeds in his main purpose, especially where he depicts not only individuals but groups acting under the stress of emotion. Herein lies the true greatness of Livy's history. His imagination fuses and fires his rhetorical technique and stylistic skill, giving spontaneity to his composition, so that he stirs the mind and moves the heart. The Romans of his day felt his power; Romans of the later empire looked to him to revivify their pagan traditions; and men of the Renaissance—such men as Petrarch and Machiavelli—took his instruction into their own experience. Since modem criticism has done its work on his subject matter, it is permissible to return to his historical conception and the artistry with which he has presented it.

LI YUAN-HUNG (1864–1928), president of the Chinese republic, was born in the province of Hupeh, and educated at the Pei-yang naval college at Tientsin. He served in a cruiser during the war with Japan, and later was in charge of fortifications at Nanking. He accompanied the Viceroy Chang Chih-tung to Wuchang, and twice visited Japan to study its educational system and army organization. In 1911 he had risen to the rank of divisional commander and was among the first military officials to realize the force of the revolutionary movement. In consequence he was empowered to negotiate peace at Shanghai, and upon the foundation of the republic became its first vice-president.

Upon the death of Yuan Shi-kai he succeeded as president and held office until the temporary restoration of the boy emperor in July 1917, when he resigned, remaining for the next five years in Tientsin. In 1922 he was prevailed upon to resume the presidency, but in September of the following year he was compelled to resign in favour of Tsao Kun. Li Yuan-hung at an early date opposed "Tuchunism"; *i.e.,* the system of military governorships, and advocated divesting the tuchuns of administrative duties; he worked for the reunification of the country by negotiation instead of by force but was unsuccessful. He died in retirement in Tientsin on June 5, 1928.

LIZARD. Lizards and their close relatives snakes are the dominant reptiles of the present day. The order Squamata, to which both belong, probably originated in Triassic times (about 200,000,000 years ago) from a group of extinct forms, the Eosuchia, that had earlier given rise to another stock of which there is a single surviving species, the tuatara. The Squamata differ from the tuatara and from crocodiles and alligators in many anatomical features of which the most significant, as an indicator of relationship, is the presence of not more than one bony arch across the temple instead of two. Lizards are usually distinguishable from snakes by the presence of limbs; but many lizards are limbless and, so closely are the two groups allied, that in these instances there is no single external character which will easily differentiate them.

Like all other cold-blooded animals, lizards flourish most abundantly in tropical and subtropical regions, the numbers of individuals and species diminishing toward the northern and southern borders of the temperate zones; only a few species penetrate to the Arctic circle or slightly beyond it, the limit being set by the presence of permanently frozen subsoil, which prevents hibernation out of reach of frost.

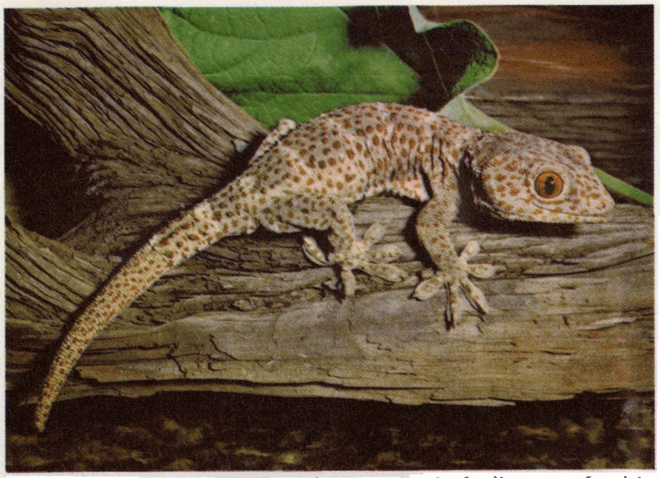
None of the present day lizards is thoroughly aquatic (some extinct forms were), and none is an efficient flier; but lizards are adapted to almost every other environment and mode of life, showing a correspondingly great diversity of size, shape and structure. As in almost all reptiles the skin has a protective layer of ceratinous scales that is periodically renewed from beneath, the old layer being sloughed away. The shape and size of the scales vary in the different families and with the mode of life; in active, noncryptozoic forms maximum flexibility of the skin is achieved by reduction of the scales to small, nonoverlapping

HARDUN, OR STARRED LIZARD

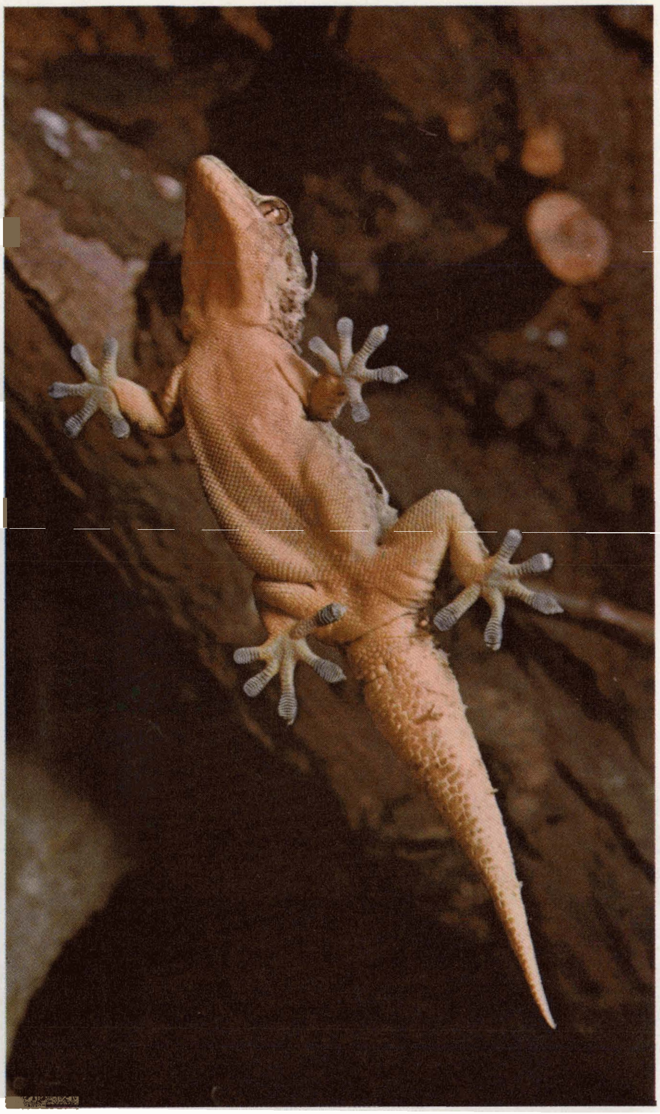
Agama stellio, a north African agamid that prefers a climate of extremely high temperatures

PHOTOGRAPH, JOHN MARKHAM

LIZARD



Tokay (*Gekko gecko*), largest member of the gecko family. It is found in Indo-Malaya, usually in or near areas of human habitation



Underside of a Moorish or wall gecko (*Tarentola mauritanica*) showing the pads on the feet, an adaptation that permits this lizard to climb any kind of surface. It is found chiefly in north Africa, Spain and Yugoslavia

Australian bearded lizard or bearded dragon (*Amphibolurus barbatus*), an agamid, in an attitude of defense with its throat puffed out and its mouth open

Meller's chameleon (*Chamaeleo melleri*), a large species found in Africa. True chameleons are found only in the eastern hemisphere

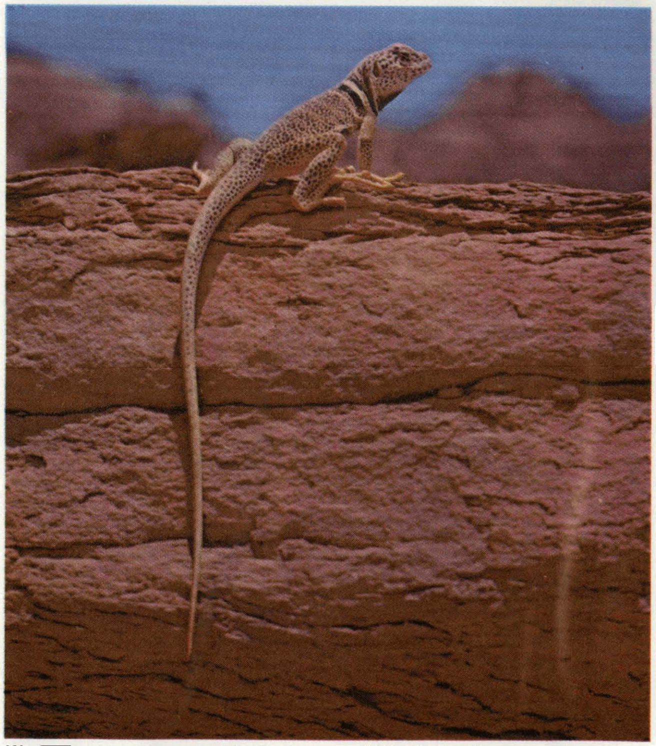
South African chameleon (*Chamaeleo pumila*), an arboreal species with a prehensile tail

AGAMIDS, GECKOS AND TRUE CHAMELEONS

PHOTOGRAPHS, (TOP LEFT) JOHN H. GERARD, (TOP RIGHT) JOHN MARKHAM, (CENTRE LEFT) JOHN WARHAM, (BOTTOM LEFT) CY LA TOUR AND THE DETROIT ZOO, (BOTTOM RIGHT) EDWARD VAN BAERLE

Southern prairie lizard (***Sceloporus undulatus consobrinus***), a spiny lizard of Texas and northern Mexico

Texas horned lizard (***Phrynosoma cornutum***), of southwestern U.S., the so-called "horned toad" sold in pet stores



Western collared lizard (***Crotaphytus collaris baileyi***), one of the lizards that runs on its two hind feet with its body upright. Found in western U.S.

Common or green iguana (***Iguana iguana***), whioh may grow to a length of more than six feet (including the tail). Found in tropical Central a d South America

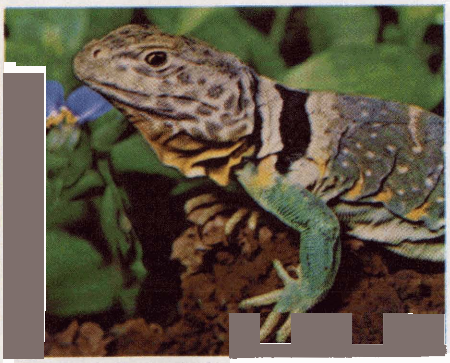
Close-up of the head of a male northern fence lizard (*Sceloporus undulatus hyacinthus*) showing the brilliant blue marking of the throat and side of belly. Ranges over east and south central US.

IGUANIDS

PHOTOGRAPHS, (TOP LEFT, CENTRE LEFT, BOTTOM RIGHT) JOHN H. GERARD, (TOP RIGHT, BOTTOM LEFT) WILLIS PETERSON

Brown colour phase of the green anole (*Anolis carolinensis*), also known as the American "chameleon." Ranges over southeastern U.S.

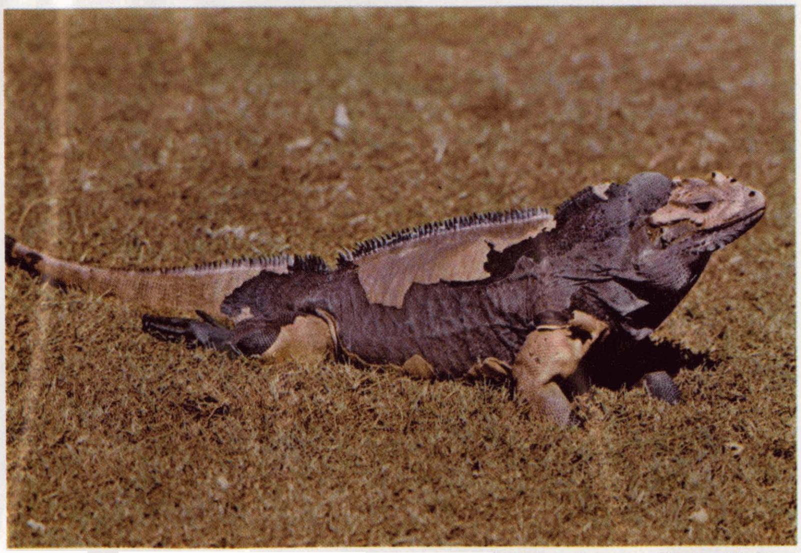
Cuban ground iguana (*Cyclura macleayi*), one of the most primitive types of iguanas. Found on a few islands of the West Indies and Caribbean area



Close-up of the head of an eastern collared lizard (*Crotaphytus collaris* collaris). Found in central southern U.S.

Marine iguana (*Amblyrhynchus cristatus venustissimus*) shown in its native habitat, the rocky shore of Hood Island, one of the Galapagos group

Desert iguana (*Dipsosaurus dorsalis*) of southwestern U.S. a herbivorous species. Like several other iguanids, this species employs bipedal locomotion



Rhinocerous iguana (*Cyclura* cornuta), one of the largest ground iguanas. The mottled appearance of this specimen is due to sloughing or shedding of the skin, a phenomenon usually associated with periods of growth in reptiles. Occurs on a few islands of the West Indies

IGUANIDS

LIZARD

Blue-tongued skink (*Tiliqua scincoides*) of Australia, among the largest of the family, with a length up to about two feet

Western skink (*Eumeces skiltonianus*), which ranges from Canada to Baja California. The brilliant blue tail is common among young skinks of several genera

Trachysaurus rugosa, commonly known as the stump-tailed or shingle-back skink. The scales overlap like those of a pine cone. Australian

Broad-headed skink (*Eumeces laticeps*), an arboreal, woodland species found in most of the south central and southeastern US.

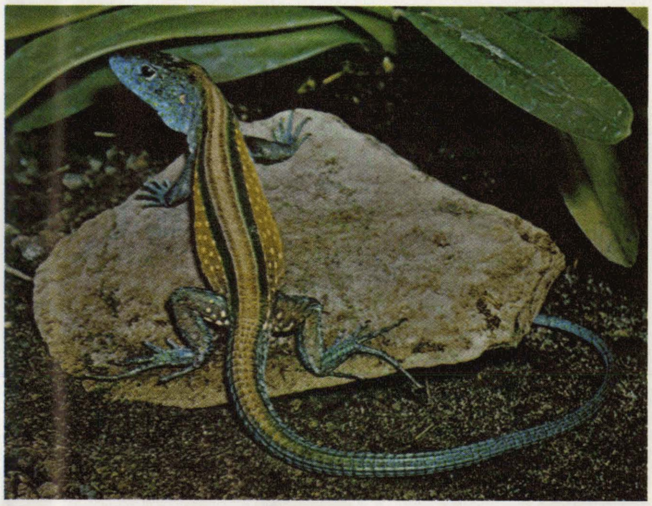
African skink (*Mabuya perrotetii*). Other *Mabuya* species are widely distributed in tropical regions of both hemispheres

SKINKS

Red worm lizard (*Amphisbaena alba*) of South America. Reaching a length of about 1½ ft., this lizard is only occasionally teen above ground

Scheltopusik or glass lizard (*Ophisaurus apodus*), largest of the snakelike anguid lizards, will grow to a length of almost four feet. Found in south-eastern Europe and southwestern Asia

Six-lined race runner (*Cnemidophorus sexlineatus*), found in southeastern and south central U.S., is, like all race runners (or whiptails), noted for its speed



Cnemidophorus lemniscatus, the strand race runner, of South America, uses bipedal locomotion when running at top speed

Golden or northern tegu (*Tupinambis nigropunctatus*), me of the largest of tho telld family. Found in South America

WORMLIKE LIZARDS AND TEIIDS

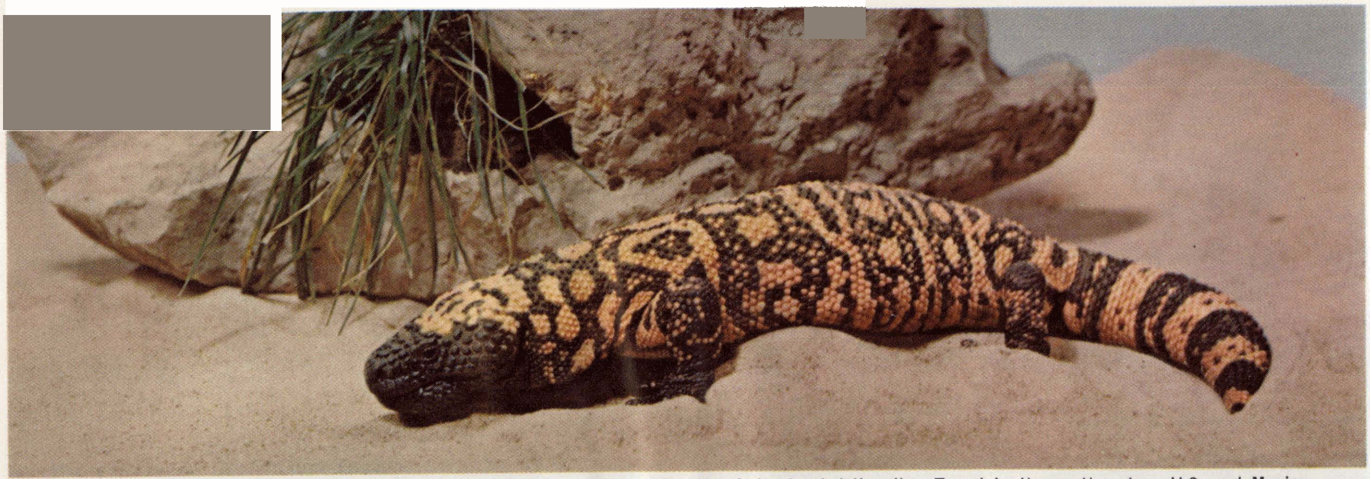
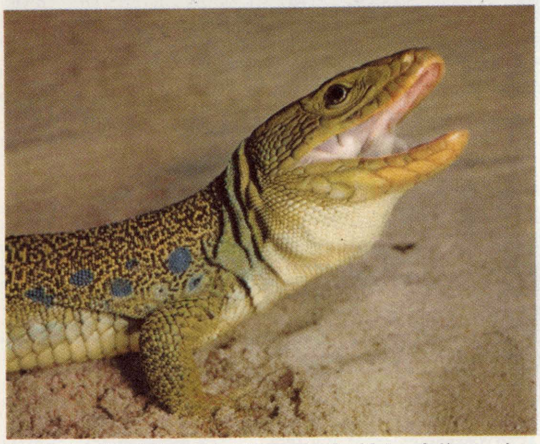
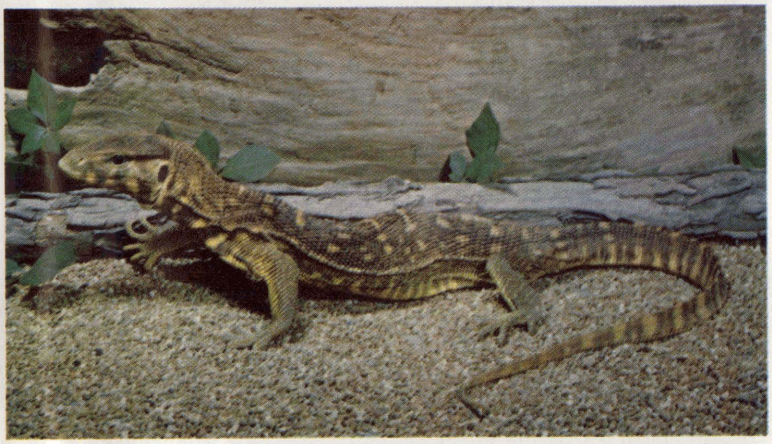
LIZARD



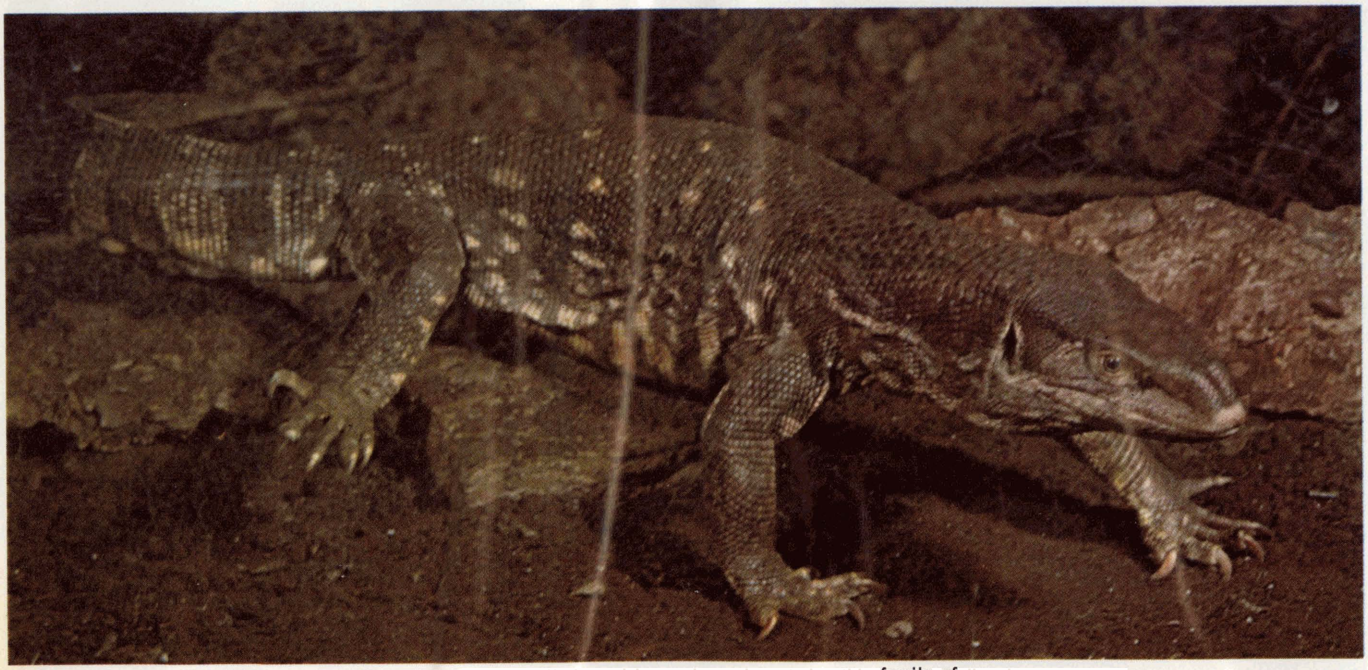
Gila monster (*Heloderma suspectum*), one of two venomous lizards known (the other is the beaded lizard). Found in the southwestern U.S. and Mexico



Head of a jeweled lacerta (*Lacerta lepida*), of the western Mediterranean area, largest member of a family found throughout Europe and Africa



Indian yellow monitor (*Varanus flavescens*). Monitors constitute a family of large, carnivorous lizards widely distributed in Africa, the middle east, southern Asia and Australia



African savanna monitor (*Varanus exanthematicus*). Strong limbs and large claws characterize this family of lizards

MONITORS, LACERTIDS AND THE GILA MONSTER

granules; among desert dwellers there is a tendency for some of them, particularly on the head and tail, to be enlarged to form spines; burrowing and cryptozoic forms achieve a slippery surface by the development of smooth, highly polished overlapping scales. The skin is often re-inforced by bony plates, which lie beneath the superficial scales (though corresponding with them in size and shape), and these may form a continuous protective armour. Other defensive, or sometimes offensive, devices associated with the skin and scales are the occasional development of horns, fringing folds that break up the animal's outline and colouring. The colour pattern may be fixed and of any protective type or there may be a highly developed mechanism for rapid colour change. This mechanism consists of numerous star-shaped cells (chromatophores) each containing granules of pigment or a highly refractive substance, guanine. The granules are capable of movement within the cell and the cells themselves are capable of limited movement toward or away from the surface of the skin. Movement of a cell toward the surface and dispersal of its granules displays its particular colour to the maximum. Changes may result from the direct stimulation of the chromatophores by light or heat but the cells are under the control of the central nervous system. In consequence stimuli received through any of the sense organs may induce reactions and these will not be automatic and stereotyped but modified by such factors as associated memories and the individual's physiological condition.

The sense organs exhibit some modifications found also in other vertebrate groups, but a few are peculiar to the lizards or shared only with the snakes. Replacement of movable eyelids by a fixed, transparent, protective covering of the cornea is a characteristic of snakes found also in many lizards, but in the latter group a peculiar condition is sometimes found in which eyelids are normally movable but a transparent window is developed in the lower one. The median eye of primitive vertebrates persists in some lizards in a more complete form than in any other living animals except the tuatara. This, the parapineal organ, consisting of cornea, lens, retina and' nerve connection to the brain, lies beneath a transparent or translucent scale on the top of the head; it is clearly an organ of vision but not an efficient one. Another sense organ modification shared with snakes concerns Jacobson's organ, which in other vertebrates is part of, and continuous with, the olfactory system and functions by smelling the food that is in the mouth. In the Squamata Jacobson's organ is completely separated from the other nasal structures and appears as two separate pouches opening on the roof of the mouth. Into these pouches the tips of the bifid tongue are thrust after they have collected particles from external objects that are being investigated, or even from the air.

Though the majority of lizards are creepers (reptile from the Latin *repere,* "to creep") they exhibit many modifications for locomotion in different environments. For scampering over loose, shifting sand the area of the feet is increased by the development of lateral fringes on the digits. For climbing either among rocks or in trees the scales beneath the hands and feet may be spinose to provide the equivalents of additional claws, or there may be adhesive discs; for arboreal life the chameleons have the extreme specialization of the digits bound together into opposable bundles like tongs, and a prehensile tail. The larger and more active terrestrial forms, such as the monitors, are no longer restricted to creeping but can run with the body held clear of the ground and some iguanas and agamas when alarmed can rise and run on the hind limbs only. Reduction of digits and limbs in connection with burrowing habits or life among dense, tangled vegetation has occurred many times but only in those families in which the essential muscle (rectus *superficialis*) is present for the production of the sinuous lateral undulations that are the basis of serpentiform movement. Other modifications associated with burrowing habits are elongation and slimming of the body, elimination of a distinct neck, reduction of eyes, reduction of the outer and middle ear and the development of a smaller but more compact and stronger skull. In the truly subterranean burrowers the tail is short and blunt, but the trend of those living in dense herbage is in the opposite direction, the tail being sometimes more than four times as long as the head and body. Gliding flight has been achieved by a few oriental species comprising the genus Draco. As in the gliding mammals (flying squirrels and flying lemurs) the wings are extensions of the skin on the flanks but in the lizards this patagium is supported by five or six enormously elongate ribs. Flipperlike limbs for swimming were possessed by the extinct, marine mosasaurs but no modern lizards are aquatic to the same extent though many live in close association with fresh water, and one (Amblyrhynchus) with the ocean. These swim readily by means of their laterally compressed tails whose area is increased by crests of enlarged bladelike scales.

The great majority of lizards are insectivorous and consequently there is relatively little diversification of the teeth, which are mostly simple and peglike. Even among the insectivorous forms, however, there may be some differentiation into incisors, canines and molars (though these are not homologous with the similarly named teeth of mammals) and the molars may be elaborated by the development of additional cusps even to the extent of being serrated. Some of the larger forms tend to be omnivorous scavengers and in them teeth are enlarged and strengthened. Others again, notably among the iguanas and agamas are herbivorous and sometimes the anterior teeth may be fused together to form a long, cutting edge for grazing. Two major specializations for the capture of prey are found, one being the extraordinary tongue of the chameleons (*q.v.*) and the other the venom apparatus of the Gila monsters (see Helodermatidae below).

As in all reptiles fertilization is internal and the developing embryo is provided with an amnion and allantois. Secondary sex characters associated with courtship are of widespread occurrence in the different families. Frequently the males are brilliantly coloured during the mating season and there is usually a simple display pattern by this sex. This may consist in no more than some bobbing of the head, but there is often inflation of the body, and more particularly the throat, which may be equipped with a specially dilatable and brilliantly coloured dewlap. Hedonic glands, opening by a series of pores on the hinder side of the thighs or on the preanal region, are of common occurrence in males.

The majority of lizards lay eggs with a tough parchmentlike shell; these are usually buried in the ground and incubation is effected by the sun's heat. There are, however, many forms in which the eggs are retained in the female's oviducts for a longer period, in some instances until the eggs are on the point of hatching. In these ovoviviparous forms the normal thick protective eggshell is reduced to a thin transparent membrane. which is ruptured by the young lizard at the moment the egg is laid. Rupture of the eggshell, whether there is external incubation or not, is facilitated by a special forwardly directed tooth on the middle of the upper jaw, the egg tooth, which is shed after it has served its purpose. In both the oviparous and ovoviviparous types the whole of the food material for the development of the embryo is provided by the egg yolk, but in two families, the Scincidae and Gekkonidae, there is true viviparity of a simple type. In these lizards, although the eggs contain much yolk, the embryo is supplied additionally through a primitive type of placenta (*q.v.*).

The number of species of lizards extant today is of the order of 2,500. They are grouped into 18 families based on anatomical features which are discussed in the general article on reptiles.

1. *Gekkonidae.*—Geckoes (*q.v.*). Most geckoes have a soft, granular skin though it is often beset with conical or trihedral tubercles, and the vast majority lack movable eyelids. The family has a world-wide tropical and subtropical distribution and shows considerable tolerance of climatic and environmental conditions. Most species are climbers and have adhesive pads on the fingers and toes, and one genus, the African Lygodactylus also has a similar adhesive pad on the tip of the tail. This organ is extremely fragile in most geckoes and is also more variable in shape in this group than in any other family. (A regenerated tail may be quite different in shape from the original one, and always has simpler and more uniform scales.) Many geckoes have a true voice as distinct from the hissing noises, which are all that most

lizards are capable of. None of the group has adopted burrowing habits or suffered limb degeneration. Several species have folds of skin fringing the flanks. tail and sides of the limbs and it has been claimed that these membranes enable the oriental Ptychozoon to parachute or glide from one branch ta another. Whether this is true or not, there is no doubt that similar fringes in other forms are effective aids to concealment. The classical example is the Madagascar *Uroplates,* which is almost invisible when at rest on a tree trunk or branch; in it the edges of the folds are irregular so that the outline of the animal is obscured and its cryptic colouring, resembling a patch of lichen, merges smoothly into that of the background. Although two genera, both confined to New Zealand, are viviparous, with a simple type of placenta, most other geckoes lay eggs with a hard, calcareous shell. Perhaps it is this hard eggshell that accounts for another unique feature of geckoes, a double egg tooth; in other lizards there are germs of two egg teeth, but only one develops. The largest member of the family is the Indo-Malayan Gekko gecko (vernacular names tokay, tuk-kaa or tuck-too, in imitation of the call note), which is less than 18 in. over-all. The smallest is one of the tropical American species of Sphaerodactylus (wood slaves in the West Indies). These creatures, some less than 1½ in. in length when fully adult, live among the dead leaves of the forest floor and possess a unique development of the claws, which are disposed in a plane at right angles to the normal and can be retracted horizontally into a large sheath. Geckoes are often to be found in and about human dwellings; where sanitary arrangements are defective they may be carriers of pathogenic organisms such as *Salmonella.*

2. *Pygopodidae.*—A small assemblage of lizards confined to Australia and New Guinea which have some anatomical features in common with the geckoes, but which are all snakelike and without functional limbs. None has movable eyelids nor any external traces of fore limbs, though there are vestiges of a shoulder-girdle; the hind limbs are present as a small scaly flap on each side of the vent. They are semiburrowers, to be found in grass or among tangled scrub herbage or in loose soil. In the grass-dwelling forms such as Lialis and *Pygopus* the tail is inordinately long, up to twice as long as the body, and fragile.

3. *Iguanidae.*—(*See* IGUANA.) An ancient and generalized family confined in modem times to the new world and Madagascar, with a single form (Brachylophus) in the Fiji and Tonga islands. Presumably the family at one time had a world-wide distribution; one fossil genus has been found in Europe.

4. *Agamidae.*—This family is the old-world analogue of the Iguanidae. The two groups are mutually exclusive in their territorial ranges, the agamas being confined to Europe, Africa, Asia and Australia. Each group has invaded the same kinds of environment within its own territory with many strikingly similar evolutions of form. The agamids are mostly insectivores, and these have the teeth differentiated into simple incisors, enlarged canines and laterally compressed more or less tricuspid molars. Scales are relatively small (though they may form spines), there are no enlarged plates on the head (except for the scale under which lies the pineal eye), and there are no bony plates under the scales. Movable eyelids and limbs are always well developed and the tail is not autotomous. The shape of the body varies considerably, ground-dwelling forms tending to be horizontally flattened and arboreal species to be compressed from side to side. The genus Agama, with more than 40 species, is a generalized, ground-dwelling type common throughout Africa, the near east and southeast Europe; most of them are cryptically coloured in shades of brown, but the males often develop brilliant red or blue heads and throats, the latter being distended and pulsated in courtship. Dilatation of the throat, and special structures developed in association with it, is a common habit throughout the family, the gesture being either part of a courtship display or a threat. In the Australian frilled lizard (Chlamydosaurus) the neck has an erectile collar, consisting of a fold of skin which when not in use hangs like a cape about the shoulders. When the lizard is angered or frightened this cape is erected so that it stands out like an enormous ruff and at the same time the mouth is widely opened, displaying its saffron-yellow interior. The gesture is impressive but is mostly bluff and if further molested the animal usually flees, running swiftly on the hind limbs only. This habit of running on the hind legs is shared by other members of the family, including Physignathus, found from Australia to Tonkin, some of whose species are semiaquatic, living on the banks of streams and taking to the water readily when disturbed. Bipedal running is also frequent among iguanid lizards. It is in the Indo-Malayan region that the greatest diversity and the most bizarre developments are to be found. The extreme among the inexplicable modifications is probably in *Lophura amboinensis* found in the Philippines, Java, Celebes and the Moluccas. This animal reaches 3 to 4 ft. in length, of which the tail accounts for 2½ ft. or more and has a high saillike crest supported by enormously developed spines from the vertebrae. Like the iguanid *Basiliscus,* it has fringed toes, which enable it to run across water. Horns on the tip of the snout, similar to those of chameleons, are found in genera such as Ceratophora of Ceylon and *Harpesaurus* of Java. Parallelism with chameleons extends also to the development of a prehensile tail (*Cophotis* of Ceylon, Sumatra and Java), to bony ridges above the eyes in Lyriocephalus (which also has a globular excrescence on the tip of the snout) and to remarkable powers of colour change in genera such as Calotes, which, like the American anoles (family Iguanidae), are sometimes erroneously known as chameleons. This phenomenon is associated more with emotional changes and physical conditions than with colour of the background and is most marked at the breeding season either during courtship or when males are in combat. Calotes *versicolor,* known in some parts of its range as the bloodsucker, is extremely pugnacious during this period when the males develop a brilliant scarlet or crimson colour that may be restricted to the head and shoulders or may involve almost the whole of the body. The acme of specialization in the family is in the arboreal flying lizards (Draco) of the Malayan region.

Most of the forms hitherto mentioned are either insectivorous or have a mixed diet and it is surprising that the most exclusively herbivorous members of the group live in the Saharo-Sindian desert belt. They are the mastigures (Uromastix), heavily built lizards with short limbs and a short but heavy tail armed with whorls of strong spines. Spinosity, also associated with desert life, reaches its maximum in the Australian thorny devil (Moloch) ; this is a small, squat. short-tailed creature, which is liberally beset all over with spines, the largest being on the snout and above the eyes.

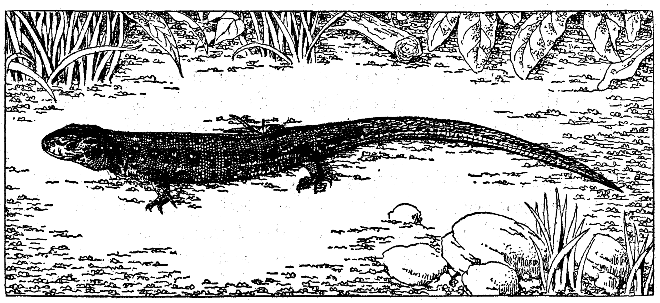
5. *Chamaeleontidae.*—Chameleons (*q.v.*). Arboreal lizards with many unique specializations including the grouping of the fingers and toes to form opposable bundles for grasping twigs and branches and an enormously protractile tongue for catching insect prey.

6. *Xantusiidae.*—A small Central and western American group of lizards with geckolike eyes lacking movable eyelids. The body is covered with small granular scales, with or without some scattered enlarged tubercles on its upper surface, but the lower surfaces and the top of the head have larger, platelike scales; there is no bony armour under the scales. Xantusia is found in the arid regions of the southwest of the United States, Lepidophyma in Central America and Cricosaura in Cuba.

7. *Scincidae.*—The largest lizard family with a cosmopolitan distribution. All members of the group have relatively large overlapping, platelike scales underlain by bony plates, which form a complete armour. Compared with such families as the Iguanidae and Agamidae the skinks show relatively little diversity of form and scale modifications, nor have they powers of rapid colour change though the colours are often brilliant. A widespread colour feature in the group is a sky-blue or turquoise tail, particularly in young individuals. In the vast majority, the scales are uniform in size and smoothly polished, but sometimes they have one or more raised longitudinal ridges (keels) that continue beyond their edges to form spines. In the Australian stump-tails (*Trachysaurus*), for example, the keels are wide and blunt and each scale resembles that of a pine cone; in other Australian forms of the genus Egernia the keels are enlarged and prolonged to form effective, thornlike spines, particularly on the broad tail. The

family is noteworthy for the extent to which there is limb degeneration in association with cryptozoic or burrowing habits. There is every gradation between well-developed limbs, each with five digits, and complete absence of any external traces of limbs; in the intermediate stages it may be the fore limb that shows greater reduction and loss of digits than the hind limb or the reverse may be the case, and it seems certain that limb reduction has taken place many times within the family. One such evolutionary line in Africa culminates in a group of blind, limbless burrowers that is sometimes given family status under the name Feyliniidae and the American genus Anelytropsis which resembles the Feyliniids is probably a parallel development. Another modification of which gradational stages can be traced is the development of a fixed transparent covering over the eye similar to that found in some other families and in all snakes. This modification may be associated with burrowing habits but is also found in nonburrowers. In the most primitive condition the Iower eyelid is still movable but a few scales in the centre of it are enlarged and transparent; in more advanced stages, as for instance in the genera Leiolopisma and Emoia almost the whole of the lower lid has lost its scaly character and is transparent; the most advanced stages in genera such as Panaspis, Ablepharus and Ophiseps, have the lower lid immovable in the "closed" position and also more or less fused along its edge with the upper lid. Most skinks lay eggs but a few species of Leiolopisma, Hinulia and Chalcides are truly viviparous, the later stages of foetal development being nourished through a simple placenta; this phenomenon is also reported for certain snakes (Denisonia) and for two New Zealand geckoes but is not known to occur in any other recent reptile. The skink, the species that has given its name to the whole family, is a small desert-dwelling lizard of the Sahara and Arabian deserts that when dried, pondered and swallowed was formerly regarded as a panacea for many ills, and as an aphrodisiac, and is still esteemed by primitive tribes both as a food and a drug. It shares with a few close relatives from the same region the ability to "swim" through loose sand by modifications similar to the moles among mammals; it has a pointed, wedge-shaped snout, tiny eyes and short, broad, paddlelike limbs, with broadly fringed fingers and toes.

8. *Dibamidae.*—A single genus (*Dibamus*) of degraded, blind, burrowing lizards of unknown ancestry found from New Guinea to Annam and the Nicobar Islands. In females the fore limbs are absent and the hind limbs, also; in males the latter are represented by a pair of small scaly flaps. The general appearance is wormlike. both head and tail being of the same diameter as the elongate body and there being no recognizable neck. The snout is covered



BY COURTESY OF THE AMERICAN MUSEUM OF NATURAL HISTORY
THE SAND LIZARD OF ENGLAND AND THE CONTINENT. A SPOTTED SPECIES. NEVER ATTAINING TO A LENGTH OF MORE THAN NINE INCHES

with a thickened shield and the eyes are minute and concealed beneath the skin. The body is covered with smooth overlapping scales and there is no bony armour beneath them. Reproduction is by eggs which, like those of the geckoes, have a brittle calcareous shell.

9. *Lacertidae.*—These are the true lizards of the old world exclusive of Madagascar and Australasia; their northern limits coincide approximately with the southern edge of the permafrost zone (*i.e.,* where the subsoil remains frozen even through the summer) and they are the dominant lizards of Europe. All are terrestrial and the family shows relatively little diversity of form and no tendencies toward limb degeneration. The head is covered by enlarged, symmetrically disposed plates each with a corresponding bony plate beneath it; the body scales lack any such bones and are generally small and granular on the back, but enlarged to form rectangular plates on the under surfaces; the tail is almost always long and slender and fragile. Two species, both of the genus Lacerta, occur in Great Britain. The common or viviparous lizard (L. vivipara), which also occurs over a large area of northern Europe is plentiful throughout Great Britain and ako occurs in Ireland, though scattered there. The scientific name is slightly misleading since the species is really ovoviviparous and not viviparous; *i.e.,* the eggs are retained within the mother's body until they hatch but the embryos obtain their nutriment solely from the yolk material in the egg; in the Pyrenees it has been reported that eggs may be laid before the young are ready to emerge. The other British Lacerta, the sand lizard, always lays eggs and despite its scientific name, L. agilis, is a more heavily built and less nimble species. Though common enough in north central Europe this species is relatively rare in Britain and is restricted to a few areas of sand dunes or sandy subsoil. Females of the species are inconspicuously coloured, being gray-brown with longitudinal rows of large darker blotches enclosing white spots. Males, however, are a beautiful dark emerald green with a row of conspicuous black-bordered white circles on the sides of the neck and the flanks, and their colour sometimes leads to erroneous records of another species, the true green lizard (L. viridis) which is a much larger species common throughout western and southern Europe. It is there and especially in the Mediterranean region, that the genus Lacerta is dominant. Everywhere wall lizards are to be found and they show great variability particularly in colour and pattern. Almost every small island has a recognizably different form and on the mainland, too, there are almost endless variations from place to place with or without intergradation from one to the next. Some of the colour forms are associated with special environmental conditions and may be caused by them; for instance on small barren rocky islands where there is little or no vegetational cover the lizards are almost always black or nearly so. But in most cases there is no obvious cause and effect relationship and it seems that here is an instance of one kind of evolutionary development in progress—the formation of local races as precursors of distinct species. Circular sky-blue spots on the flanks are of common occurrence in the family and the handsomest of the European lizards is the eyed lizard, which has rows of spots, each one black bordered, on a green ground colour. In Africa and the near east the lacertids show great tolerance of arid climatic conditions. Acanthodactylus has the area of the fingers and toes increased by fringes of elongate scales and is thereby enabled to run over soft sand. Probably in connection with life in desert and semidesert conditions the eyelids of lacertids have undergone the same modifications as those of other families, viz., the development of a transparent window in the lower lid and, where the window is perfect, fusion of the lower lid with the upper so that the delicate cornea is never exposed. This condition is found in the Indian *Cabrita* and in Ophiops, a genus that ranges from Algeria to Madras, India.

10. *Cordylidae.*—The plated lizards and Zonures from southern Africa and Madagascar with resemblances to the Scincidae and Lacertidae. The head is covered with enlarged scales with bony plates beneath them and both back and belly have relatively large, almost rectangular scales, which form linear series longitudinally and transversely; beneath them is a bony armour. The result is a somewhat rigid shield on the back and a similar one covering the belly. Flexibility is provided in several of the genera by an inverted box pleat along each flank; this inturned fold of skin is covered with small granules and is devoid of bony plates. Most of the group have well-developed limbs but Chamaesaura and Tetradactylus of South Africa, show various stages in limb reduction, the most degenerate species being snakelike with limbs represented by mere stumps devoid of recognizable digits. Chamaesaura is a dweller among dense herbage and possesses to a marked degree the elongate tail often found in association with that environment; the tail is four times as long as the rest of the animal. Cordylus (*Zonurus*), on the other hand, is a rock dweller and has a short

tail with enlarged scales forming whorls of large spikes. These must surely deter would-be predators trying to extract it from crannies in which it has taken refuge.

11. *Teiidae.*—An American family whose typical members superficially resemble the Lacertidae of the old world, the head being covered with large symmetrical plates, the back usually with small granules and the belly with rectangular plates in regular transverse series. Genera such as Kentropyx, Ameiva, and *Cnemidophorus* (race runners in the U.S.) found from the south and west of the U.S. and the West Indies to Patagonia, resemble the old-world genus *Lacerta* not only in general appearance but in the multiplicity of local races or subspecies. The family as a whole, however, shows a much greater range of form and adaptability than the Lacertids. The teyous (*Tupinambis*), found from the Guianas to tropical Argentina resemble the monitors (see *Varanidae* below) in size (up to 4 ft. or more), form and habits; they are general predators and scavengers. *Crocodilurus* of the Amazon basin is probably semiaquatic and has a flattened tail with a double crest, like that of a crocodile. *Dracaena,* another large species of the same region, has large oval crushing teeth in connection with its molluscivorous diet. In the smaller forms there is progressive reduction of the limbs and development of a window in the lower eyelid; *Alopoglossus* of Ecuador and Peru has a few enlarged semitransparent scales on the lower eyelid; Pantodactylus of southern Brazil and northern Argentina is a rather elongate form with an undivided transparent disc, and *Gymnophthalmus* and Micrablepharus have, like some skinks and lacertids, the transparent lower eyelid fused with the upper. *Anadia* of Central America and Ecuador is elongate but with the limbs pentadactyle; *Scolecosaurus* is serpentiform with three or four clawed fingers and toes and burrows in humus and rotten wood, feeding principally on termites. Bachia and *Iphisa* of northern South America exhibit the greatest degree of degeneration in the family; the body is elongate and serpentiform, the eye minute but still equipped with functional eyelids, the scales no longer granular or overlapping but squarish and arranged in regular longitudinal and transverse rows like those of the amphisbaenids, the fingers reduced to clawless tubercles or quite absent and the hind limbs having perhaps a single toe. One of the most remarkable modifications is in the Trinidad species *Proctoporus shrevei* which lives in the half light of caves on Mt. Aripo. The males have a series of white spots along their flanks, each being a transparent area of thickened skin. These appear to be crude lenses, for it is reported that if a beam of light strikes the animal each spot reflects it like a cat's eye on the highway in the light of an automobile headlamp.

12. *Amphisbaenidae.*—A family highly specialized for subterranean life. All are wormlike in appearance and only one genus, Chirotes of western Mexico and lower California, has any external trace of limbs; in it the fore limb alone persists and, though short, it has five, four or three digits. The head of all amphisbaenas is small, no wider than the body, and the bones of the skull are much stouter than in other lizards. Eyes are minute and completely covered by the skin though they may be visible through the scales. The conducting apparatus of the ear, instead of being connected to an ear drum to pick up sound waves, is connected with the lower jaw and chin to transmit soil vibrations. The head is covered by a few enlarged plates but the outer covering of both head and body, though of the same horny material as normal reptilian scales is a thin sheet. The skin on the body and tail is divided into small rectangular segments, which form regular annuli, and carries no pigment except, sometimes, black; in consequence the animals are always somewhat pink owing to the blood colour showing through. The name, derived from Greek words meaning "both go," arises from the ability to progress either backward or forward and the fact that the tail is so short and blunt that it is scarcely distinguishable at a glance from the head. All the species are completely subterranean in habits and are predators on burrowing invertebrates, particularly ants and termites. They are found in the Iberian peninsula, from Asia Minor southward throughout Africa and from the southern U.S. southward to Argentina.

13. *Helodermatidae.*—Lizards with small, tuberclelike scales and with recurved, grooved teeth. This family contains the only known poisonous lizards, the Gila monster (Heloderma *suspectum*) of Arizona, New Mexico and Utah, and the Escorpión (Heloderma horridum) of Mexico. These are sluggish, heavy-bodied creatures with weak limbs, short stumpy tails and a warning coloration of alternating rings of blackish-brown and yellow or pinkish-orange. The poison apparatus consists of a row of glands along the inside of the lower lip whose openings lie near the bases of the grooved teeth. When the animals bite they deliberately chew the object and in this way a considerable amount of venom is worked into the wounds through the channels of the teeth. The food consists chiefly of small lizards on which the poison acts fairly rapidly, but the bite is not as a rule fatal to man.

14. *Lanthanotidae.*—The rare Bornean lizard Lanthanotus was for a long time regarded as a close relative of the Gila monster. Recently, however, it has been shown to he allied to the monitors and even more closely to some of their extinct relatives the mosasaurs and dolichosaurs. Although it is by no means snakelike in general appearance it possesses many of the structural features to be expected in an ancestor of the snakes, a fact which supports the hypothesis that the snakes are derived from some platynotan (monitorlike) lizard.

15. *Anguidae.*—A small family, chiefly American, but with a few species in Europe and the Indian region; all the species have large, overlapping scales with osteoderms beneath them. *Gerrhonotus* of North and Central America and Celestus of the West Indies, Central and South America are genera with well-developed, pentadactyle limbs; *Ophisaurus* has the limbs reduced to a pair of small stylets on each side of the vent and has a peculiar distribution, three species occurring in the United States, one in Mexico, another in India and Burma, and still another in southern Europe and Morocco. The European species (O. apus) is the "Scheltopusik" or glass snake, the latter name bestowed on account of the extreme fragility of its tail, which, if the creature is roughly handled, breaks into several fragments. The American species have similar habits and the same vernacular name.

Anguis, another genus, has no external rudiments of limbs; its sole species, A. *fragilis,* known in England as the slowworm or blindworm, is a snakelike creature, frequenting grassy banks and ditches and is one of the few animals that preys largely on slugs.

16. *Xenosauridae.*—Two montane lizard genera, one Mexican (Xenosaurus) and one Chinese (Shinisaurus), resemble the Anguidae in many features but have some differences in common, including reduction of the osteodermal armour; on the head the osteoderms are consolidated with the underlying bones but elsewhere they are reduced to small isolated nodules. *Shinisaurus* looks like a miniature, foot-long, crocodile and is semiaquatic. It frequents the banks of streams into which it plunges when disturbed, seeking refuge at the bottom under rocks and stones.

17. *Anniellidae.*—A single genus (Anniella) of elongate and limbless, burrowing lizards from California related to the Anguidae in much the same way as the Dibamidae are to the Scincidae. They are wormlike, with no external vestiges of limbs and minute eyes covered by scales. The scales are soft and without bony plates. The colour is silvery, each scale edged with brown and with a narrow dark line down the middle of the back.

18. *Varanidae.*—Monitors. An old-world family of large lizards which, despite the fact that its members are successful in many different habitats shows little diversity of form. All are typically lizardlike in general appearance with heavy bodies, slender tails, which are not fragile, and with well-developed pentadactyle limbs armed with powerful claws. The neck is longer and more flexible than in most other lizards and the tongue is snakelike, forked and protrusible. The head and body are covered with small granular scales and there is either no bony armour or the osteoderms are small and widely separated. The family is an old one, fossils as old as the Cretaceous being known, and it is closely allied to the extinct semiaquatic dolichosaurs and marine mosasaurs. The living varanids are found in Africa, Arabia, southern Asia and Australia. Some, such as the Nile monitor (Varanus *niloticus*)

and the Indo-Malayan water monitor (*V. salvator*) frequent the vicinity of rivers and streams and take readily to the water, swimming by lateral undulations of their vertically flattened tails, the limbs being held close to the sides; others such as the desert monitor (V. *griseus*) which ranges from North Africa to the Caspian sea and northwestern India are restricted to arid country, and others again are semiarboreal. But most of the species are adaptable and are not inseparably associated with any restricted environment. All the species are carnivorous, most of them indiscriminately so with no objection to carrion, and are active predators; some will eat fruits such as melons and cucumbers, several regularly prey on the eggs of crocodiles and turtles, digging out the nests, and the semiaquatic forms often feed on mussels.

Monitors are the largest lizards of the present time and the largest species is the Komodo dragon (V. *komodoensis*), which is found on the two small East Indian islands of Rincha and Komodo and on the adjacent part of Flores. Exaggerated and sensational stories accumulated around this creature, until it was studied in the field by E. R. Dunn in 1926. It has the heaviest build of any of the monitors but it also has a relatively short tail so that a specimen 9-ft. long has a body three or four times as heavy and bulky as that of, say, a water monitor of the same overall length. This led, by inapplicable arithmetic, to stories of go-ft. specimens; the maximum size is probably about 10 ft. It is a diurnal animal that preys mainly on small wild pigs.

The largest number of forms is to be found in Australia where the rare Queensland species, *V. giganteus* is a close rival to the Komodo dragon in size. Monitors can all run at a considerable speed though this, again, is often exaggerated and probably does not exceed 10 m.p.h. and that for only a short distance. When angered they inflate themselves, hissing violently, lashing the tail and threatening with widely opened mouth. The threat may be no idle one since both bite and tail slap can be effective, but it may be no more than bluff; the African *V. exanthematicus,* will sometimes, after threatening, sham dead, rolling over on its back and remaining inert until the danger is past. All the species lay large oval, soft-shelled eggs, which are deposited in holes in the ground or in termite nests. (H. W. P.)

LIZARD PENINSULA, or THE LIZARD, terminates in Lizard point, Cornwall, Eng., the southernmost point of Great Britain, in 49° 56' 30" N., j° 12' W. The beam from the Lizard lighthouse is visible for 21 mi. The cliff scenery is magnificent; the coast is fretted into small bays, caves pierce the cliffs and bold isolated rocks fringe the shore; Kynance and Mullion coves are particularly beautiful. The dark green and purple colouring of the serpentine rock, of which most of the peninsula is formed, is remarkable; it is used for building and worked into ornaments. Most of the peninsula is 200–300 ft. above sea level and on the thin soil Cornish heath is a characteristic plant. Lizard Town, at the southernmost extremity, is a straggling village. The nearest town of importance is Helston (*q.v.*), 11 mi. N. by road from Lizard point. At Poldhu, 2 mi. N. of Mullion, a monument marks the spot where' Marchese Guglielmo Marconi sent and received the first trans-Atlantic radio messages in 1901. There are remains of ancient settlements. The name (Lis-ard) means "high court."

LJUBLJANA, a city of Slovenia, Yugos., on the Ljubljana river. Pop. (1961) 133,386. It is a Roman Catholic see, founded in 1461, with a Renaissance cathedral, lavishly frescoed, and several beautiful churches. There are various educational institutions including a university and societies for the promotion of science and literature. While under Austrian rule it was the centre of the Slovene national movement, the first Slovene newspaper having been published there in 1797, while the Prince Bishop was one of the chief promoters of the Yugoslav movement.

Ljubljana became an important transportation centre and is a busy industrial city with a number of suburbs. Industries developed there include cotton, woollen, porcelain, paper, furniture, boot, tobacco, soap, pottery, firehose, match and chemical manufacturing, and a foundry work, breweries, distilleries, leather tanneries and brickfields. After the draining of the surrounding plain, the city became a beautiful spot, and a favourite summer resort and tourist centre.

It is dominated by the mediaeval fortress on the height of the Schlossberg, from which a magnificent view is obtained.

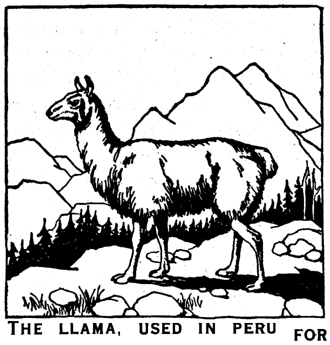
Ljubljana lies on the trade route from east to west, and legend says that it was founded by Jason. It is supposed to occupy the site of the ancient Emona or Aemona, founded by the emperor Augustus in 34 B.C. It was besieged by Alaric in 400 and desolated by the Huns in 451. In 900 it suffered much from the Magyars, who were, however, defeated there in 914. In the 12th century the city passed into the hands of the dukes of Carinthia; in 1270 it was taken by Ottokar of Bohemia; and in 1277 it came under the Habsburgs.

In 1809 the city was twice taken by the French, and from 1809 to 1813 it became the seat of their general government of the Illyrian provinces. From 1816–49 Ljubljana was the capital of the kingdom of Illyria. It is historically known from the congress of Laibach. In 1895 it suffered severely from an earthquake. In 1941 Ljubljana became the capital of the part of Slovenia annexed by Italy, and the centre of resistance to Italian occupation. It was occupied by Germany from 1943 to 1945. From 1949 the city was the capital of Slovenia and Ljubljana oblast.

LJUNGGREN, GUSTAF HAKAN JORDAN (1823–1905), Swedish man of letters, born at Lund on March 6, 1823, was educated at Lund university, where he was professor of German (1850–1859), of aesthetics (1859–1889) and rector (1875–1885). He had been a member of the Swedish academy for 20 years at the time of his death in September 1905. His most important work, *Svenska vitterhetens hafder efter Gustav III's död* (j vol., Lund, 1873–1895), is a comprehensive study of Swedish literature in the 19th century.

His other works include: *Framställning af de förnämste estetiska systemerna* (an exposition of the principal system of aesthetics; 2 vol., 1856–60); *Svenska dramat intill slutet af 17 århundradet* (a history of the Swedish drama down to the end of the 17th century, Lund, 1864); an edition (1864) of the *Epistlar* of Bellman and Fredman, and a history of the Swedish academy in the year of its centenary (1886). His scattered writings were collected as *Smarre Skrifter,* 3 vol. (1872–81).

LLAMA, the larger of the two domesticated members of the camel-tribe indigenous to South America. The llama *(Lama guanicoe glama)* is a domesticated derivative of the wild guanaco, which has been bred from time immemorial as a beast of burden, its sure-footedness and endurance rendering it almost the equal of the mule. Chiefly found in southern Peru, it attains a larger size than the guanaco and is usually white, spotted with brown or black, or sometimes altogether black. The following account was given by Augustin de Zarate in 1544:



THE LLAMA, USED IN PERU FOR CENTURIES AS A BEAST OF BURDEN

"These sheep of Peru are large enough to serve as beasts of burden. They can carry about 100 lb. or more, and the Spaniards used to ride them, and they would go four or five leagues a day. When there is a man on one of them, if the beast is tired and urged to go on, he turns his head round and discharges his saliva, which has an unpleasant odour, into the rider's face. These animals are of great use and profit to their masters, for their wool is very good and fine, particularly that of the species called pacas; and the expense of their food is trifling, as a handful of maize suffices them, and they can go four or five days' without water. Their flesh is as good as that of the fat sheep of Castile."

The disagreeable habit of spitting is common to all the group.

In a wide sense the term llama is used to designate all the South American Camelidae. *(See* TYLOPODA.)

LLANBERIS, a small town of Caernarvonshire, Wales, $7\frac{1}{2}$ mi. E.S.E. of Caernarvon by road. Pop. of civil parish (1951) 2,333.

It is a favourite tourist centre, being situated between two lakes, Llyn Padarn and Llyn Peris, the latter of which lies at the foot of the fine Llanberis pass (1,169 ft.), and being also the starting point for the easiest ascent of Snowdon, which rises to the south-east. At Llanberis is the station of the Snoudon railway. Nant Peris, the old village. is about 2 mi. S. at the foot of the pass. Near Llyn Peris are the ruins of the 13th-century Dolbadarn castle. Although picturesquely situated, slate quarrying has spoiled the appearance of Llanberis, but the great Dinorwic quarries export fine slate to all parts of the world. A road over Llanberis pass leads through Nant Gwynant to Beddgelert.

LLANDAFF, a ward (since 1922) in the county borough of Cardiff, Wales, 2 mi. N.W. of Cardiff. Pop. (1951) 19,859. It stands on high ground sloping toward the southern bank of the Taff. Of Llandaff's first two bishops, St. Teilo flourished in the latter half of the 6th century and St. Dubricius died in 612. Geoffrey of Monmouth died and was buried at Llandaff (1154). By the 12th century the see had acquired great wealth (as may be seen from the Book of *Llandaff,* a mediaeval inventory of its land), but after the reign of Henry VIII it became impoverished, and its Early English cathedral was left to decay. In the 18th century a new church, in debased Italian style, was built amid the ruins. This was demolished and the old cathedral restored in the mid-19th century, the chancel arch of Bishop Urban's building, erected in 1120 being incorporated. The restored cathedral was, however, badly damaged in an air raid on Cardiff in 1941, when St. Michael's Theological college, removed to Llandaff from Aberdare in 1907, also suffered. The palace or castle built by Urban was destroyed about 1402, after which Mathern near Chepstow became the episcopal residence until about 1690, when it fell into decay. leaving the diocese without a residence until Llandaff court was acquired during Bishop Alfred Ollivant's time (1849–82). Of the old palace only the gatehouse remains. Money bequeathed by Thomas Howell, a merchant, who died in Spain in 1540, maintains an intermediate school for girls, managed by the Drapers' company, Howell's trustees. Llandaff diocese, one of the six dioceses of the church in Wales, embraces a substantial portion of Glamorgan.

LLANDOVERY, a market town and municipal borough in the Carmarthen parliamentary division of Carmarthenshire, Wales, 27 mi. E.N.E. of Carmarthen by road. Pop. (1951) 1,857. Area 1.9 sq.mi. The place probably owes its Welsh name of *Llan-ym-*ddyfri (ddyveri), "the church amid the waters," to the proximity of Llandingat parish church to the streams of the Towy, Bran and Gwydderig. Llandovery stands on the site of a Roman fort, probably called Alabum. Being at the head of the fertile vale of Towy, it was a strategic site in the middle ages. The 12th-century castle frequently changed hands and was partly burned by Gmffydd ap Rhys (d. 1137). In 1485 Llandovery was incorporated by a charter from Richard III, a privilege confirmed by Henry VIII and by Elizabeth I whose charter is still held by the corporation. In the 17th century the vicarage of Llandingat was held by the celebrated Vicar Rhys Prichard (1579–1644), whose book *Canwyll* y Cymry *(The* Welshman's Candle), a collection of religious poems written in colloquial Welsh, was the most famous book produced during the Renaissance in Wales. In the early 19th century Llandovery was known for its printing press, which has published many books on Wales. Thomas Phillips founded Llandovery college in 1848, and there Welsh boys are able to study their native language and literature. Llandovery is a market, fair and cattle mart centre.

LLANDRINDOD WELLS, an urban district in the Brecon and Radnor parliamentary division of Radnorshire, Wales, 21 mi. N.W. of Hereford by road. Pop. (1951) 3,212. Area 2.4 sq.mi. It is the seat of county administration. Situated in a lovely setting to the east of the Wye river, about 700-ft. above sea level, it is a health and holiday resort with trout, salmon and other fishing, and a golf course. As early as 1696 it became known for its mineral springs, and is affiliated to the British Spas federation. About 2 mi. N. is the Roman fort of Castell Collen.

LLANDUDNO, a seaside town and urban district in the Conway parliamentary division of Caernarvonshire, Wales, 47 mi. W.N.W. of Chester by road. Pop. (1951) 16,715. Area 7.7 sq.mi. It lies between the limestone headlands of Great Orme (northwest) and Little Orme (east), on a peninsula formed by the Irish sea and the Conway river, and has two sandy shores. On Great Orme are prehistoric sites, including a camp and a burial chamber; copper mines, now disused, that were worked by the Romans; and the old parish church of St. Tudno, believed to occupy the site of an oratory erected by its patron saint in the 7th century. Llandudno has grown from a village into a health and holiday town with two golf courses, Alpine displays in the Happy valley, magnificent views from a marine drive encircling the Orme, and steamers operating from Llandudno pier to Liverpool, the Isle of Man and Anglesey in the summer.

Lewis Carroll frequently visited Dean Liddell and his daughter Alice at their residence in the town and a memorial to him stands on the west shore.

LLANELLY, a seaport and municipal borough in the Llanelly parliamentary division of Carmarthenshire, Wales, on the Lliedi, 19 mi. S.S.E. of Carmarthen by road. Pop. (1951) 34,476. Area 3.2 sq.mi. The town derives its name from the dedication of the parish church to the Celtic saint Elliw or Elli. With the beginning of the Industrial Revolution Llanelly became important for its lead smelting works, shipbuilding and flannel industries. In 1804 copper works were established but gradually the old industries were superseded by the manufacture of tinplate. The first tinworks opened in 1847 and others followed in 1852–53, until, in 1888, 92 mills were in operation. This industry declined when the Ebbw Vale strip mill was set up, and the town became a colliery centre and collecting ground for the anthracite from the Gwendraeth valley. Secondary industries, including potteries, iron foundries and chemical works, also grew up. The tinplate industry was revived in the mid-20th century by the opening of a cold reduction plant at Trostre, on the outskirts of Llanelly, to work with the huge Margam strip mills in Glamorgan. Other steelworks have also been built. In 1955 the Towy water scheme was opened. The port, which exported many tons of coal in the 19th century, ceased operating for trading purposes in 1951, but the north dock was let to the admiralty for the laying up of reserve fleet vessels.

Llanelly was a borough by prescription in the old lordship of Kidwelly; by royal charter granted by George V, it was incorporated in 1913. In the same year its first mayor presented Parc Howard to the town, the grounds of uhich are used for recreation and the house for a museum, art gallery and tearooms. The town also has a mining and technical institute, a junior technical school and a school of art. There are two miles of sands along the shore.

LLANGOLLEN, a market town and urban district in the Denbigh parliamentary division of Denbighshire, Wales, 23 mi. S.W. of Chester by road. Pop. (1951) 3,274. Area 4.9 sq.mi. Lying in the green Vale of Llangollen, on the Welsh Dee, there crossed by a 14th-century bridge, the town is much visited in the summer. Coracles are still used on the river, which contains trout and salmon. The scanty remains of Castell Dinas Bran, built early in the 13th century, stand on a hill about 1,000-ft. above sea level. At Plas Newydd, a black and white house now owned by the council, lived the "Ladies of Llangollen," Lady Eleanor Butler (d. 1829) and Sarah Ponsonby (d. 1831), eccentric Irishwomen who entertained Thomas de Quincey, Sir Walter Scott and William Wordsworth. The Llangollen International Musical Eisteddfod, instituted in 1947, is annually held in July. The ruins of the Cistercian abbey of Valle Crucis, founded c. 1200, lie 1½ mi. N.W. There are brewers, tanners and sheet-metal workers in the town.

LLANIDLOES, a market town and municipal borough in the Montgomery parliamentary division of Montgomeryshire, Wales, in the Severn valley, 30 mi. E. of Aberystwyth by road. Pop. (1951) 2,341. Area 1 sq.mi. The parish church of St. Idloes (a 7th-century saint) has a 14th-century tower capped with a wooden belfry of Welsh border type, and a fine early 13th-century arcade, transferred from Cwmhir abbey (Radnorshire] in 1542. The town grew up under the protection of its motte and bailey castle, and in 1280 Owen of Arwystli, prince of Powys, obtained a charter establishing the fairs and Saturday markets of Llanidloes.

Full civic privileges, granted about 1300, are still retained. The half-timbered market hall, standing on oaken legs at the town centre, is the only surviving example in Wales. It still possesses its ancient curfew bell. From 1933 it has housed a museum of local history and industry. Flannel weaving and lead mining flourished in the 19th century but after 1918 both industries declined and are now extinct. The present interests of the town are mainly agricultural but there is a foundry (established 1850), and a tannery for sheep and goatskin leathers (1908). There is a weekly market and a monthly fair. A new cattle market was opened in 1955. Llanidloes was an active centre of Chartism, and for five days was in the hands of the rebels when the weavers rose in arms in 1839. The eastern slopes of Plynlimon, 10 mi. E., are now part of the vast Hafren forest, covering several thousand acres.

LLANO ESTACADO (STAKED PLAINS), a portion of the high plains of the United States covering an area of approximately 30,000 sq.mi. in western Texas and eastern New Mexico; the northern half is known as the Panhandle. The "break of the plains" bounds the area on the east; the Mescalero ridge overlooking the Pecos valley is the western margin; the Canadian river valley is at the northern edge; while in the south the region grades imperceptibly into the Edwards plateau. The present surface is composed of a mantle of silts, sands and gravels. Porosity of surface materials, levelness of terrain and semiaridity have combined to eliminate nearly all water erosion. The flatness of the surface is striking. Locally, small saucerlike depressions, varying in diameter from a few feet to almost a mile, and in depth from a few inches to several tens of feet, partially break the surface monotony. These hollows retain water for a short time after rains and a few contain permanent though varying amounts of water.

Soils of high inherent fertility have evolved in the region, but their usefulness is restricted by meagre rainfall, high evaporation rates and periodic droughts. Blistering summers are succeeded by cool uinters, strong winds are omnipresent, and weather extremes are commonplace. "Short grass," largely grama and buffalo grass, cloaks the uncultivated portions of the region.

Extensive grazing, dry-land farming of wheat and grain sorghums, localized irrigated cotton production, and the pumping of natural gas and petroleum are the principal economic pursuits of the area. Lubbock and Amarillo, Tex. (*qq.v.*), are the most important cities of the region, but a less than salubrious climate, monotonous landscape and isolation combine to restrict population densities.

See also TEXAS: Physical Features; UNITED STATES (OF AMERICA): *Physiography*: Interior Plains. (A. H. DR.)

LLANOS, Spanish American name for the vast plains or prairies of northern South America, extending from the Atlantic ocean to the Andes, and bounded by the coastal ranges in the north and by the Orinoco river (*q.v.*) and its Guaviare tributary on the south. The region which covers about 125,000 sq.mi. in Venezuela and 100,000 sq.mi. in eastern Colombia, has a hot climate, supports little wild life and is sparsely populated.

The plains slope gently from a few hundred feet elevation at the base of the mountains toward the Orinoco and are broken here and there by low mesas. Many tributaries of the Orinoco drain the plains and flow in relatively straight courses. The largest of these are the Apure river (*q.v.*), the Arauca and the Meta, which rise in the far western part of the llanos.

The llanos are alternately flooded and dry in response to conditions of weather and terrain. The rainy season begins in May and reaches a peak between June and October when much of the area becomes flooded. The swollen rivers slowly recede during the dry season (December–March) and the land becomes parched and baked, the grass becoming brown and brittle for lack of moisture. Dense forests are confined to the stream courses and near the base of the mountains. The typical vegetation is tall, coarse grass with some dry, scrubby forests and scattered palms. Soils are chiefly infertile laterites, though fertile alluvial soils are fairly extensive.

Cattle were introduced into the llanos in 1548 and have been the mainstay since colonial days. The plains are Venezuela's most important stockbreeding region, accounting for two-thirds of the nation's cattle. Although plagues of insects make life difficult and herds must be driven to higher land during flood, several million head range widely in a region where fences are rare. Because of distance, much of the beef is shipped by air from such centres as San Fernando de Apure, the largest town in the central llanos, to Caracas. Irrigated agriculture has been developed in several places in the upper llanos since the eradication of malaria and the construction of large dams.

The *llanero*, the tough, hard-riding herdsmen and skilled horseman of the plains, played an important role during the Venezuelan war of independence and has been an ardent supporter of successive revolutionary caudillos. See also VENEZUELA and COLOMBIA. (D. R. D.)

LLANQUIHUE, province of southern Chile bordering the northern shores of Ancud gulf, bounded on the north by Osorno province, and extending from the Pacific to Argentina. Area 7,107 sq.mi. Pop. (1952) 139,986. The western half of Llanquihue is a rolling country of forests and pastoral and farm land; the east is a rough, volcano-studded, cordilleran landscape of deep glaciated valleys, lakes and virgin forest. It is noted for sports fishing. Chile's largest lake, Llanquihue (marginal to the mountains) and Lake Todos los Santos mark a scenic trans-Andean route to Argentina which draws sizable summer tourist traffic to Puerto Varas, Ensenada, Petrohué and Peulla. The provincial capital, Puerto Montt (*q.v.*) pop. (1952) 28,944, affords road access to the scenic southern coast line of the province and air and water service to island and mainland points extending from the Gulf of Ancud to Punta Arenas (*q.v.*). Rail, air, road and sea communications are available to Santiago-Valparaiso. Summers are comfortable; winters are cool and very wet.

The province was formed in 1937 by dismembering Chiloé province. Less than 15% of its area is considered arable but about 50% of its gainfully employed people are in agriculture. Beef, dairy products, potatoes, wheat, fruit and wool are important. The increasing significance of sugar beets results from the construction of a beet sugar factory at Llanquihue in 1958. Lumbering, farm product processing, tourism, shipbuilding, fishing and the canning of seafood support large segments of the population. Since 1853 German pioneers and their descendants have played an important economic role. (J. T.)

LLANTWIT MAJOR (Welsh, *Llanilltyd Fawr*), a small town in the Cowbridge rural district of Glamorganshire, Wales, 1 mi. from the coast and 19 mi. W.S.W. of Cardiff by road. Pop. of civil parish (1951) 2,892. Weapons and implements of the Bronze Age were discovered in a tumulus in the town. Castle Ditches, a triple line of earthworks, commands the entrance to the creek of Colhugh, once the port of Llantwit. At Caermead (1 mi. N.N.W.) there were discovered in 1888 the remains of a large Roman villa. Llantwit Major castle, now a ruin, was scheduled as an ancient monument.

The town derives its name from St. Illtyd or Iltutus (c. 520), a native of Brittany who, having come under the influence of St. Cadoc, abbot of Llancarfan (6 mi. E.N.E.), established at Llantwit a monastic college which became a famous seat of learning and was associated with the Celtic saint movement in Wales. SS. Samson, Paul Aurelian and Gildas, the historian, are said to have been educated there. The monastery later became a cell of Tewkesbury abbey and was finally destroyed at the Dissolution, the only remains being the gatehouse and the dovehouse. The present church of St. Illtyd is the result of a sequence of buildings dating from the time of its foundation in the 12th century until the 15th century. It is now divided into the Old church and the New church; the old (western) part, thought to have been the parish church, contains a collection of Celtic crosses, effigies, etc., and the New, probably the monks' chapel, has a Jesse rod niche and is used as the parish church. The ruined chantry was finally destroyed by German action in 1940. The toun hall is Tudor. Llantwit lies in a fertile district and its people depend to some extent upon agriculture, but the greater proportion is employed at nearby royal air force stations.

About 2½ mi. W. is St. Donats castle, which has been inhabited continuously since the early 13th century.

LLEWELYN, the name of two Welsh princes.

LLEWELYN I, AP IORWERTH (d. 1240), prince of north Wales, was born after the expulsion of his father, Ionverth, from the principality. In 1194, Llewelyn recovered the paternal inheritance and by 1201 was the greatest prince in Wales. At first he was a friend of King John, whose illegitimate daughter, Joanna, he married (1201); but the alliance soon fell through, and in 1211 John reduced Llewelyn to submission. In the next year Llewelyn recovered all his losses in north Wales. In 1215 he took Shrewsbury. His rising had been encouraged by the pope, by France and by the English barons. His rights were secured by special clauses in the Magna Carta. But he never desisted from his wars with the Marchers of south Wales, and in the early years of Henry III he was several times attacked by English armies. In 1234, however, a truce was concluded at Middle. In 1239 Llewelyn retired into a Cistercian monastery.

LLEWELYN II, AP GRUFFYDD (d. 1282), prince of north Wales, succeeded his uncle David in 1246, but was compelled by Henry III to confine himself to Snowdon and Anglesey. In 1254 Henry granted Prince Edward the royal lands in Wales. The steady encroachment of royal officers on Llewelyn's land began immediately, and in 1256 Llewelyn declared war. The Baron's War engaged all the forces of England, and he was able to make himself lord of south and north Wales. Llewelyn also assisted the barons. By the treaty of Shrewsbury (or Montgomery; 1267) he was recognized as overlord of Wales; and in return Simon de Montfort was supplied with Welsh troops for his last campaign. Llewelyn refused to do homage to Edward I, who therefore attacked him in 1277. He was besieged in the Snowdon mountains until hunger made him surrender and conclude the humiliating treaty of Conway (1277). He was released, but in 1282 he revolted again, and was killed in a skirmish with the Mortimers, near Builth in central Wales.

Lloyd, *History of Wales From the Earliest Times to the Edwardian Conquest,* 2 vol., 3rd ed. (London, New York, 1939); J. G. Edwards (ed.), *Littere Wallie* (London, 1940); F. M. Powicke, *King Henry III and the Lord Edward,* 2 vol. (Oxford, 1947); J. E. Morris, *The Welsh Wars of Edward I* (Oxford, 1901).

LLOYD, MARIE (1870–1922), English music-hall artist, who may be said without exaggeration to have been the incarnation of the London or cockney genius for low comedy, which grew to its height in the 19th century. She was born in Feb. 12, 1870. the daughter of John and Matilda Wood. She first appeared at the Eagle music hall in 1885 under the stage name of Bella Delmore. Six weeks later she adopted the stage name of Marie Lloyd, which she retained. She was responsible for a series of music-hall entertainments, songs, sketches, etc., which placed her in the front rank among artistes of her day. She introduced to the British public a series of studies in cockney humour, *e.g.,* "Everything in the garden's lovely," "Oh, Mr. Porter, whatever shall I do" and "One of the Ruins that Cromwell knocked about a bit." She was married (1) to Percy Courtney, (2) to Alec Hurley, a singer of coster songs (d. 1913), and (3) to Bernard Dillon, a jockey. She died on Oct. 7, 1922. (E. I. J.)

.**LLOYD, WILLIAM** (1627–1717), English clergyman, successively bishop of St. Asaph (1680), of Lichfield and Coventry (1692), and of Worcester (1699), was born at Tilehurst, Berks., and was educated at Oriel and Jesus colleges, Oxford. Lloyd was an indefatigable opponent of the Roman Catholic tendencies of James II, and was one of the seven bishops who were arrested and tried for refusing to have the Declaration of Indulgence read in their dioceses. Lloyd was a stanch supporter of the revolution. His chief publication was *An Historical Account of Church Government as it was in Great Britain and Ireland when they first received the Christian Religion* (London, 1684, reprinted Oxford, 1842). He died at Hartlebury castle on Aug. 30, 1717.

LLOYD GEORGE OF DWYFOR, DAVID LLOYD GEORGE, 1ST EARL (1863–1945), British statesman who led his country to victory in World War I, was born at Manchester on Jan. 17, 1863. His father, William George, died about two years after David's birth, leaving the family in poor circumstances. Mrs. George's brother, Richard Lloyd, a shoemaker at Llanystumdwy, and pastor of the Campbellite Baptists there, became their chief support; it was from him that young David obtained his earliest views of practical and political life, and also the means of starting, at the age of 14, on the career of a solicitor.

Having passed his law preliminary, he was articled to a firm in Portmadoc, and in 1884 obtained his final qualifications. In 1888 he married Margaret, daughter of Richard Owen of Criccieth. From the first he managed to combine his solicitor's work with politics, becoming secretary of the South Caernarvonshire Anti-tithe league; and his local reputation was made by a successful fight, carried to the high court, in defense of the right of Nonconformists to burial in the parish churchyard. In the first county council elections for Caernarvonshire he played a strenuous part on the Radical side, and was chosen an alderman; and in 1890, at a by-election for Caernarvon Boroughs, he was returned to parliament by a majority of 18 over a strong Conservative opponent. He held his seat successfully at the contests in 1892 and 1895, his reputation as a champion of Welsh nationalism, Welsh nonconformity and extreme radicalism becoming thoroughly established. In the house of commons he was a prominent guerrilla fighter, conspicuous for his audacity and pungency of utterance, and his capacity for obstruction while the Conservatives were in office. During the South African War he was specially vehement in opposition to Joseph Chamberlain, and took the "pro-Boer" side so fiercely that he was mobbed in Birmingham at the end of 1901 when he attempted to address a meeting at the town hall. But he had already been again returned for Caernarvon Boroughs in the election of 1900 and in the ensuing parliament he came still more to the front by his resistance to the Education act of 1902.

As the leader of the Welsh party, and one of the most dashing parliamentarians on the Radical side, his appointment to office when Sir Henry Campbell-Bannerman became premier at the end of 1905 was generally expected; but his elevation direct to the cabinet as president of the board of trade was somewhat of a surprise. His settlement of the railway dispute in 1906 was universally applauded; and the bills he introduced and passed for reorganizing the port of London, dealing with merchant shipping, and enforcing the working in England of patents granted there, and so increasing the employment of British labour, were greeted with satisfaction by the tariff reformers, who congratulated themselves that a Radical free trader should thus throw over the policy of *laissez faire.* The president of the board of trade was the chief success of the ministry, and when H. H. Asquith became premier in 1908 and promoted Lloyd George to the chancellorship of the exchequer, the appointment was well received even in the City of London. For that year the budget was already settled, and it was introduced by Asquith himself, the ex-chancellor; but the provision of the finance for old-age pensions was left to Lloyd George. The money was raised by the new taxation provided for in the budget of 1909–10.

Chancellor of the Exchequer. *The Budget Struggle, 1909–1910.*—For 1909–1910 a considerable deficit, of about £16,000,000, was in prospect. Lloyd George and Winston Churchill were conspicuously in alliance in advocating the use of the budget for introducing drastic reforms in regard to licensing and land, which the resistance of the house of lords prevented the Radical party from effectingby ordinary legislation. When Lloyd George, on April 29, introduced his budget, its trenchant character, however, created widespread dismay in the City and among the propertied classes. In a lengthy speech, which had to be interrupted for half an hour while he recovered his voice, he ended by describing it as a "war budget" against poverty, which he hoped, in the result, would become "as remote to the people of this country as the wolves which once infested its forests." The excitement over the budget entirely monopolized public attention for the year, and while the measure was defended by Lloyd George in parliament with much suavity and by Asquith, Sir Edward Grey and R. B. Haldane outside the house of commons with tact and moderation, the feelings of its opponents were exasperated by a series of denunciatory public speeches at Limehouse and elsewhere from the chancellor of the exchequer, who kindled the passions of the working classes against the landed classes and the peers. When the Finance bill went up to the house of lords, Lord Lansdowne gave notice that on the second reading he would move "that this House is not justified in giving its consent to this bill until it has been submitted to the judgment of the country," and on Nov. 30 this motion was carried by an overwhelming majority of peers. The government passed a solemn resolution of protest in the house of commons and appealed to the country; and the general election of Jan. 1910 took place amid unexampled excitement. The Unionists gained 100 seats over their previous numbers, but the constitutional issue undoubtedly helped the government to victory, won indeed the votes of the labour members and Irish nationalists.

Events had now made Lloyd George and his financial policy the centre of the Liberal party program, but party tactics for the moment prevented the ministry, which remained in office, from simply sending the budget up again to the lords and allowing them to pass it. There was no majority in the commons for the budget as such, since the Irish nationalists only supported it as an engine for destroying the veto of the lords and thus preparing the way for Irish Home Rule. Instead, therefore. of proceeding with the budget, the government allowed the financial year to end without one, and brought forward resolutions for curtailing the powers of the lords, on which, if rejected by them, another appeal could be made to the people. (See PARLIAMENT.) Hardly, however, had the battle been arrayed when the king's death in May upset all calculations. A conference was arranged between four leaders from each side—Lloyd George being one—to consider whether compromise on the constitutional question was not feasible. The budget for 1909–10 went quietly through, and the chancellor introduced his budget for 1910–11 which left matters precisely as they were.

The 1910 conference of British party leaders lasted from June until November. The conferring leaders nearly arrived at a comprehensive and far-reaching scheme of agreement, affecting all the disputed issues—the house of lords, Home Rule, tariffs and conscription. But the six months of secrecy ended in detaching the leaders from their followers. While the leaders had passed into a mood of conciliation, the followers were still living in an atmosphere of party warfare. On both sides the proposals put forward were regarded as surrenders. Lloyd George was ready to come to bold settlements if they would save the country from civil strife. He and A. J. Balfour agreed in this attitude, but party tides still ran too strong.

National Insurance.—In Dec. there took place the second of the two 1910 general elections. The Liberal government had refused to go to the polls until they obtained the promise of the king that, if they were successful, he would consent to employ his prerogative of peer making in order to carry the parliament bill. That promise was reluctantly given by King George V. Lloyd George was returned for Caernarvon Boroughs for the seventh time with an enhanced majority (1,208). But a second national campaign within one year proved too much for his strength, and he was stricken by serious throat trouble for some months. During this compulsory retirement he prepared the National Insurance bill of 1911. This was the first of a series of measures for improving the condition of the British working class by the method of social insurance. The idea was first applied by Otto Bismarck, and Lloyd George had made a study of the German insurance system during a holiday visit to central Europe in autumn, 1908. Old-age pensions had been already passed into law; and thus it was that the British system of old-age pensions originally took a noncontributory form.

Lloyd George applied the contributory insurance principle first to invalids and the sick, and the proposal produced a formidable social and political crisis in the autumn of 1911. Lloyd George was proposing a new habit to the British people, and at the first shock it was profoundly unpopular. All classes rose against it. There followed a succession of political revolts; and it seemed as if the combination of forces—of the Conservatives, the press and the public—opposed to the bill would be sufficient to swamp it. By-election after by-election was lost by the Liberal government. The party managers were in favour of postponement; but Lloyd George held on. He eased the passage of the bill by a series of conferences with all the disturbed parties, and achieved its third reading early in Dec. 1911. He followed it with an Unemployment Insurance bill which was extended in subsequent years over the whole working class.

Land Reform.—In 1912 Lloyd George approached the reform of the English land system by way of a land committee. He sketched the main lines of his policy in a series of speeches throughout 1912 and 1913. But just as he approached this venture his way was barred by two events—one personal and the other national. The first was known as the "Marconi affair," which produced a grave crisis in Lloyd George's career. He had been persuaded by his friend Sir Rufus Isaacs (later Lord Reading) to take £2,000 worth of shares in the American branch of the great Marconi company at a moment when the British post office was discussing the terms of a contract with the British company. The two companies were legally separate, but their fortunes were closely linked. Such a speculation on the part of a chancellor of the exchequer was at best highly imprudent, and the affair became the subject of an inquiry by a committee of the house of commons. Lloyd George and Isaacs were acquitted of all blame by the Liberal majority but censured by the Conservative minority. The majority report was accepted by the house but the episode undoubtedly damaged Lloyd George's prestige for the time being.

Already overshadowed by these events, the land proposals were now effectively blocked by the far greater crisis of Irish civil war. Ulster, organized by Sir Edward Carson (later Lord Carson), threatened an alarmed defiance of the government. This defiance had its first effect in the revolt of the officers at the Curragh against the orders issued for carrying out the prospective Home Rule policy. Faced with the possibility of a military revolt both at the Curragh and at Aldershot, Lloyd George devoted all his energies to preserving civil peace. But at this moment, at the heart of this Irish crisis, there came the vaster and more momentous challenge of World War I.

The Outbreak of War.—Lord Grey of Fallodon in his memoir, Twenty-Five Years, *1892–1916* (1925), gives a vivid account of the state of division that prevailed in the Liberal cabinet in the fortnight before the outbreak of war. During that period the attitude of Lloyd George was deeply affected by his position as chancellor of the exchequer. On Aug. 1, 1914, the governor of the Bank of England headed a deputation to No. 11 Downing street, urging the policy of neutrality upon the government. On Monday, Aug. 3, when the Germans invaded Belgium, he telephoned to Downing street withdrawing the opposition of the City, and declaring that they were now in favour of war. This change of opinion in the City was highly dramatic, but it reflected the attitude of the chancellor of the exchequer. Lloyd George at first was not in favour of Great Britain's being drawn into a contest between the two great warring groups of Europe unless some British interest or some British obligation were clearly involved. Accordingly during the previous week he did not take up the decisive attitude against Germany which he had adopted in 1911, when he held the view that the claim of Germany to go to war with France over Morocco clearly involved a British guarantee (under the Entente). Once Belgium was invaded, however, and the neutrality treaty of 1839 defied, all hesitation left him. Thus it was that Lloyd George entered upon a new phase of his career—that of war statesman.

The first great civilian duty of the war fell on Lloyd George. As chancellor of the exchequer, he had to secure the finances of the country. He called together the governors of the leading banks and arranged a moratorium which prevented a panic. All the gloomy forecasts of the breakdown of finance by the opponents of the war were dissolved into thin air. During the first ten months of the war he remained chancellor of the exchequer; and thus on him fell the main financial responsibility. All parties were agreed that he placed British finance on an impregnable foundation.

Minister of **Munitions.**—The insufficient supply of shells and guns at the front was exposing British armies to an intolerable inequality of loss. This fact, together with a major crisis in the admiralty broke up the Liberal government, May 19, 1915, and substituted for it the first coalition administration, of Asquith and Bonar Law. The government was entirely reconstituted. Perhaps the most important change was the creation of a ministry of munitions—offered to and accepted by Lloyd George. This ministry was boldly entrusted with the whole function of providing war armaments, hitherto part and parcel of the duties of the war office. The new enterprise was rather a national movement than an ordinary office of state. The government workshops at Woolwich and elsewhere had been modelled to supply arms for a small peace army. Now that Lord Kitchener was calling forth from the nation an army of 2,000,000 there had to be a corresponding effort to supply them with weapons. In order to achieve this, Lloyd George put forth all his powers as a stimulating orator and organizer. He first called on the private armament firms to make a new and gigantic combined effort. But this was not enough. He was compelled to create a vast network of new factories and workshops, and to rally a huge army of workers, both men and women.

It was one thing to raise so gigantic an army. It was another thing to apply it to its full use and value. On all these questions Lloyd George in 1915–16 held vigorous views. He was not content to confine himself to the function of creating guns and shells. In the beginning of 1915 he began to pour out to the cabinet a succession of memoranda, in which he endeavoured to put before them the full seriousness of the military situation following upon the collapse of the Russian attack in the spring and summer of 1915.

The policy and strategy laid before the cabinet in the Lloyd George memoranda in the year 1915 were never fully adopted. In the language of the time, the cabinet was divided between westerners and easterners—those who looked for a decision only on the western front, and those who believed that victory could be quickened by transferring part of the British effort to the near east. The division ended in a compromise which resulted in the expedition to Salonika. But Lloyd George aimed at something far larger—nothing less than a considerable diversion of armies from the west to the east of Europe. He proposed and contemplated the diversion of an army of at least 1,000,000 from the western to the eastern front. With the development of the German submarine warfare Lloyd George's eastern idea became less and less practicable; and with the increase of the German armies the danger of a German breakthrough in the west finally held the Eritish armies to their task. But in early 1915 these facts had not been fully disclosed.

War Office.—As 1915 advanced, Lloyd George's general discontent with the conduct of the war grew stronger. It extended to home as well as foreign policy. The war required a continual supply of vast armies. Such armies, Lloyd George now began to perceive, could not be secured by the voluntary principle alone. He became a vehement advocate of conscription in the autumn of 1915. But Liberal sentiment was against it, and Asquith hesitated. At last Lloyd George swung the cabinet into conscription; and only one minister—Sir John Simon—resigned. Everything possible had now been done to supply the generals both with men and with munitions. But the question of policy remained, and there Lloyd George's discontent continued to grow. The tragic death of Kitchener by the sinking of the cruiser H.M.S. "Hampshire" on June 5, 1916, created a vacancy at the war office to which Asquith, not without some misgivings, decided to appoint Lloyd George. In this new position of power he obtained a firmer grip on the military machine at the front, and in particular he carried out a drastic reform of communications in France.

From these lesser tasks his mind mas diverted to the main issue of victory or defeat by the tremendous tragedy that befell the Allied cause in the autumn of 1916. Rumania, tempted by Russia into the war on the side of the Allies at an unseasonable moment, was violently attacked by Gen. A. von Mackensen and dramatically crushed before the eyes of the distant and helpless Allies. In vain Lloyd George appealed to the cabinet to make some effort to save Rumania. Italy had entered the war in the previous year, and the Russian armies were still in being—could nothing be done? Nothing was done; and for the moment Rumania was blotted out. But the event had a profound effect on the mind of Lloyd George. He was convinced that the war was being mishandled and on Dec. 1, 1916, he formally put his views before Asquith.

Collapse of the Asquith Government.—His main contention was that so large a war committee as then existed could not conduct the war to victory. He proposed a smaller and more efficient body of three or four men, solely devoted to this one object of winning the war. What was wanted was unified and unsleeping control. But he proposed—and here was the crux of the political situation—that the existing prime minister should not be chairman of the committee. That was where the dividing line came. For frankly and definitely Lloyd George had ceased to believe in Asquith as war leader. Asquith's pride was touched to the quick; and it was quite clear that he profoundly resented the proposal, although he himself had first named Lloyd George as chairman of the new war committee. On Dec. 2, Lloyd George was under the impression this his proposal had been accepted. But friends intervened on both sides: the Northcliffe press in favour of Lloyd George, and Asquith's friends in favour of a chief whose loyalty had always commanded a fit return of personal devotion. On Dec. 4, 1916 the Times published a leading article displaying exultation over Asquith's defeat, and immediately Asquith wrote to Lloyd George breaking off the agreement. In the afternoon of that day Asquith resigned office. He received authority from the king to form a new ministry. He wrote to Lloyd George asking him to join on condition that he—Asquith—as prime minister should be chairman of the new war committee. Lloyd George refused that condition and placed his office at Asquith's disposal.

Already, on Dec. 3, the Conservative rank and file had met. They had decided at first against following Lloyd George, whereupon Bonar Law had emphatically said that, in that case, they could not count on his leadership. He and his friends refused to join the new ministry and so Asquith's efforts to reform his coalition without Lloyd George broke down. The king then sent for Bonar Law. But as some of the Liberals and the Labour party refused to support him, he too failed to form a government, although Lloyd George offered to serve under him. The king then called a conference at Buckingham palace and tried to form a new coalition ministry under Bonar Law, with the offer of the woolsack to Asquith. Asquith refused. Thereupon the king sent for Lloyd George, as he was clearly the only possible premier.

PRIME MINISTER

The **New War** Policy.—Lloyd George attempted to rally all parties behind him. He succeeded with the Conservatives and the Labour party, and a certain number of Liberals. But the bulk of the Liberal ex-ministers stood aside and began to form a group known as the Independent Liberal party. Lloyd George was now in sole command of his own war policy. The small war cabinet which he instantly appointed fully carried out the hopes of its founders. It sat from day to day, and often twice a day. Records were kept of its meetings, and Lloyd George formed a small Downing street secretariat in order to keep in close touch with the various ministries. The result was a general quickening up of war decisions and a more decisive control of the whole machine of government.

During 1917 Lloyd George pressed forward his idea of unified command of the Allied armies. He was now completely convinced that the war could only be won if fhe Allies were to face Germany with the same concentrated authority that Germany had established over its own partners. He was faced, ho ever, with a steady resistance from the high military command, whose leading figures, Sir Douglas Haig and Sir William Robertson, he profoundly mistrusted.

On Oct. 24, 1917, an event finally decided him to force the matter of unified control to a decision. On that day the Austro-German armies under Karl von Bulow broke through the lines of the Italian armies and drove them back to the line of the Tagliamento with the loss of 300,000 men and 2,000 guns. Italy stood for the moment in peril of a defeat equal to that of Serbia and Rumania in the preceding years. Lloyd George was determined that this defeat should not take place. He compelled the western commands to send an army of infantry and artillery, English and French, under Gen. H. C. Plumer through the Mont Cenis tunnel to northern Italy, which arrived in the nick of time.

The End of the War.—Having achieved this task, Lloyd George, with characteristic swiftness, determined to press on with the matter of unified control. On his journey back to England he stopped in Paris on Nov. 12, 1917, to make a speech in which he plainly announced that divided control meant defeat. In Feb. 1918 Lloyd George dismissed Robertson, who as chief of the imperial general staff had steadily resisted his plans, and replaced him with Sir Henry Wilson. During the winter the Germans brought across Europe a fresh army of 2,000,000 men released by the collapse of Russia after the Bolshevik revolution of Nov. 1917, and the first blow fell on March 21, when 40 German divisions attacked and broke through the British line west of St. Quentin. On rhe following days the British line withdrew 15 mi., and the military struggle that followed lasted five months. Lloyd George was indomitable in this supreme crisis and met it by two principal steps. One was the assertion of full unity of control, and the other was the bringing over of the U.S. armies.

Pres. Woodrow Wilson had not contemplated sending his armies to Europe until they were fully trained. In that case the U.S. armies would be too late. Lloyd George therefore made a definite appeal to President Wilson to send all he could immediately. No fewer than 2,000,000 U.S. soldiers were carried across the Atlantic, in spite of the submarines. during April and May 1918. But mere numbers were still useless without unity. Visiting France in the first week of May 1918, Lloyd George held a decisive combined meeting of the military and civil powers, in which, supported by Lord Milner and Georges Clemenceau, he was at last able to persuade the British generals to accept the supreme command of Marshal Ferdinand Foch. Lloyd George was, however, confronted with one more political crisis. In May Gen. F. B. Maurice, recently dismissed from an important post in the war office, challenged the veracity of certain government statements about manpower on the western front. Underlying this challenge was the old struggle between the westerners and the easterners, and Lloyd George insisted on making the ensuing debate an issue of confidence. He won easily but Asquith and about 100 Liberals voted against him. The tide of battle at last turned on Aug. 8, 1918. Seven great battles were fought after this event, but from August until November the German armies were steadily driven back. Finally, on Nov. 11, came the collapse of the German resistance and the acceptance of armistice terms of defeat by the new German government. "Germany is doomed,)' cried Lloyd George, speaking at the Mansion house on Nov. 9, 1918, and he proved a true prophet. The Allies had won the war.

Victory having been achieved, it now remained to make peace. There were inevitable delays. Lloyd George deemed it necessary first to strengthen his position by an appeal to the country. The effect was an overwhelming victory for Lloyd George, he being returned to power by a majority of 249 over all the independent groups. Nevertheless his political position was precarious. The Liberal party was divided; Asquith and all those who had voted against Lloyd George at the Maurice debate were denied the so-called "Coupon"—the joint letter from Lloyd George and Bonar Law endorsing their support of coalition candidates. Great though Lloyd George's prestige was, he had in reality become the prisoner of the Conservative party which constituted three-quarters of his support in the house.

The first meeting of the Peace conference took place on Jan. 18, 1919, at the Palace of Versailles, and it proved an impressive gathering of the representatives of all the 30 countries which had taken part in the defeat of the central powers. The whole British empire was represented at Paris among the colleagues of Lloyd George.

It soon became obvious that so big an assembly could not really arrive at peace. The Allied negotiators gradually narrowed to an inner council of ten, which was soon reduced to three—Lloyd George, Wilson and Clemenceau. Roughly, the position behind the scenes was that Lloyd George and Wilson worked for a peace of conciliation, while Clemenceau worked for a peace of victory. The French started with a claim to extend their frontier up to the left bank of the Rhine. Wilson and Lloyd George together succeeded in moderating this claim. But they were compelled to hand over the Saar valley for 15 years as part of the compromise. Other compromises took place in regard to Silesia and the Polish corridor. Wilson's contribution to the settlement was the League of Nations covenant. When the crisis came and President Wilson threatened to leave the conference unless the covenant was placed first in the treaty, Lloyd George supported Wilson.

The Treaty of Versailles.—Lloyd George's freedom was much hampered by press attacks from home, and at one moment Lord Northcliffe organized a mandatory telegram from over zoo members of parliament rebuking him for a tendency to weaken on the demands to Germany. Lloyd George returned to London to face his critics in parliament and secured a huge majority. There can be no doubt, however, that these symptoms of discontent at home diminished his authority and weakened his resistance to the military policy of France. At this point, for instance, he agreed (as he found Wilson had already done) to the French claim to occupy the left bank of the Rhine for 15 years, which he had hitherto attempted to limit to a much shorter period. On May 6 a draft of the treaty was completed, and was presented to the German foreign minister. Count Ulrich Brockdorff-Rantzau, on the following day. Germany instantly pleaded for various important modifications. During the six weeks of parley that followed Lloyd George played the part of conciliator. Wilson hardened against Germany, and took the view that he was pledged to the treaty as it stood. On June 22 the national assembly authorized the signing of the treaty, and on June 28 it was signed at Versailles by the German envoys. Lloyd George returned to England and defended the treaty before parliament, which unanimously ratified it on July 3 Shortly after he was awarded the Order of Merit.

Domestic Discontents.—Having made peace abroad, Lloyd George returned to restore peace at home, which was just as much in peril. The long strain of the World War and the terrible losses of men and material had left Great Britain gravely wounded and weakened. A series of industrial struggles began with the London railway strike in Feb. 1919, followed a few weeks later by the first of the coal crises. Lloyd George averted a strike on the coal fields by appointing a royal commission, with Mr. Justice Sankey as chairman which recommended a two-shillings' increase in wage and an immediate adoption of the seven-hours' day. The concessions were granted and a strike was averted. But when the majority of the commission went on to recommend nationalization of the mines, Lloyd George refused to adopt the suggestion. In Oct. 1919 the railwaymen precipitated a national strike; and once more Lloyd George had to play the part of national conciliator. He brought the strike to an end by a compromise settlement fixing wages according to the scale of living.

During the next two years the Lloyd George coalition government passed a series of agreed measures on housing, suffrage and land. But as time went on it became clear that the country was financially more exhausted than had been supposed. The first postwar boom gradually passed into a slump, and there arose from the whole country a cry for economy which expressed itself in an antiwaste campaign of the utmost vigour. By-election after by-election was lost to the government, and the country was swept by financial panic. Lloyd George met it by a drastic measure. He appointed a small committee, with Sir Eric Geddes as chairman, to revise the whole of Britain's national finance. As a result of its sweeping report—the "Geddes axe"—widespread economies were effected in all departments.

Fall of the Ministry.—These measures weakened Lloyd George's Radical support. More serious, a number of factors began to diminish his hold upon the Conservatives. In March 1921 his friend and wartime partner, Bonar Law, resigned on grounds of health. His successor as Conservative leader, Austen Chamberlain, was not so closely in touch with the rank and file of the party, and lacked his predecessor's gift of stating unpalatable truths to the prime minister. Conservative loyalty was strained to the utmost by events in Ireland, where civil war had broken out between the Sinn Fein party and the government, and both sides were responsible for brutal outrages. In June 1921 the government decided to open peace negotiations. and after many months of discussion the famous Irish treaty was signed at midnight on Dec. 6. It conceded dominion status to south Ireland and left Ulster a separate province governed under the provisions of the Government of Ireland act of 1920. Lloyd George was fully supported by his Conservative colleagues in the cabinet, but the majority of the party disliked the settlement, and from then onward a diehard group began to campaign openly for the breakup of the coalition. In the summer of 1922 their discontent was increased by the so-called honours scandal—allegations that Lloyd George had been trafficking in the sale of honours in return for contributions to his own party fund. The truth about these transactions remains obscure, but Lloyd George's reputation suffered permanently. In the autumn of 1922 a grave crisis in foreign policy arose, and the government's well-justified determination to resist a Turkish invasion of Europe (the "Chanak Incident," Sept. 1922) frightened the Conservative party with the danger of renewed war. On Oct. 19, 1922, a meeting of the party at the Carlton club to decide whether to fight the next election as part of a coalition. Bonar Law, emerging from retirement, spoke against the coalition, and was supported by a majority of 261. Lloyd George at once resigned, being succeeded by Bonar Law who gained a conclusive victory over all other parties in the election which followed.

OPPOSITION LEADER

Throughout the vicissitudes of the general elections which followed in the autumns of the following years (1923 and 1924) Lloyd George remained a leader of opposition. He reunited his followers with the independent Liberals after the election of 1922, and devoted his energies to identifying the Liberal party with a policy of economic reconstruction. In 1924 he published *Coal and Power,* which outlined a comprehensive scheme for the more efficient utilization of the natural resources of the country. Nevertheless the reunited Liberal party failed to gain strength and in the general election of 1924 its numbers in the house of commons, controlled by Asquith and Lloyd George, sank to 40 members. Lloyd George continued his active efforts to rouse the country to the need of further domestic reform to meet the home crisis: and in the early autumn of 1925 he issued a big land program which he proceeded to advocate throughout the country.

By the elevation of Asquith to the peerage as the Earl of Oxford and Asquith (1925) Lloyd George succeeded to the Liberal leadership in the house of commons. In Feb. 1926 he carried his land proposals, with few modifications. through a Liberal convention. But the Liberal party still showed no signs of revival in the country. His national and parliamentary position was in strange contrast to the size of his following; and that created a strange diversity of opinion in the forecasts of his future. In May, during the general strike, Lloyd George expressed opinions not in accord with those of Lord Oxford and the other Liberal leaders. His idea was that the government should negotiate with the strike leaders without delay, instead of declining to do so until the strike had been called off. He ridiculed the view that the general strike was aimed at the constitution. A somewhat acrimonious correspondence between him and Lord Oxford followed, and the party, both in and out of the house of commons, was acutely divided upon the question. At last in Oct. 1926, Lord Oxford resigned the Liberal leadership. For a time worse dissensions followed. Lord Grey's small but weighty group reprobated Lloyd George. The latter, however, was soon recognized by almost the whole of Liberalism as the indispensable man and he secured its enthusiastic allegiance. He provided a fighting fund out of the large resources placed under his personal trusteeship by his supporters when prime minister. From the spring of 1927 onward he threw himself with ceaseless energy into the task of stirring up his party throughout the country. An important committee working in the same spirit proposed in the "Yellow Book" an elaborate industrial policy. For some time the by-elections seemed to show signs of a real "Liberal Revival," but at length the Labour party resumed its old rate of progress chiefly at Liberal expense. The position of Lloyd George in the late autumn of 1928 was unprecedented and enigmatical. In the general election of 1929 the Liberal party (*q.v.*) under his leadership returned 59 members.

After the formation of the national government, and the general election of 1931, Lloyd George remained in opposition. but held aloof from party politics. His *War Memoirs* were published in six volumes (1933–36). On Dec. 31, 1944, he was elevated to the peerage as Earl Lloyd George of Dwyfor. He died on March 26, 1945.

Lloyd George's first wife died in 1941 and in 1943 he married Frances Louise Stevenson, who had been his private secretary since 1913. Of the four children of his first marriage, two entered politics. Gwilym (1894–   ) entered parliament as a Liberal in 1922 and as Liberal and Conservative member for Newcastle on Tyne, became home secretary and minister for Welsh affairs in 1954. Megan (1902–   ) was a Liberal member of parliament from 1929 to 1951 and deputy leader of the party, 1949–51, but subsequently joined the Labour party.

CHARACTER AND ACHIEVEMENTS

"What is this glittering whirl at the centre of our public life?" asked one of Lloyd George's many critics. It is not an easy question to answer. His personality is something of an enigma to the historian. It is easy to list his qualities: his eloquence; his extraordinary charm and persuasiveness; his sense of wit and fun; his capacity to see to the heart of problems whose complexity baffled lesser men; his profound sympathy with oppressed classes and races; his genuine hatred of those who abused power, whether that power was based on uealth or caste or military might. But there mas an obverse side to these virtues: his love of devious methods; his remarkable, albeit temporary, gullibility in the face of Hitler and the nazis; the carelessness and want of discretion—some would use severer words—over appointments and honours; the defeatism in World War II, which contrasted so sadly with his earlier courage.

The truth is that Lloyd George, for all his greatness, aroused in many people a profound sense of mistrust. "England, a country subject to fogs and possessing a powerful middle class. needs grave statesmen." wrote Disraeli. Lloyd George, like Disraeli himself, was never a grave statesman. Like Disraeli too he was not even English, and it was in the English middle class, represented in politics by Stanley Baldwin and Neville Chamberlain, that he inspired the acutest misgivings. They were both determined to exclude him from office, and it would be wrong to ascribe his long years in the political wilderness solely to the declining fortunes of the Liberal party. It is perhaps significant of his defects that Lloyd George. though possessing a host of acquaintances and a number of sycophants, never had a really intimate friend. Winston Churchill was the only political personage who habitually addressed him in letters as "My dear David." There was in him a streak of ruthlessness which left little room for the cultivation of personal friendship. Lord Beaverbrook, who knew him well, wrote: "Once he is estranged there is none of that lingering afterglow which makes us still cherish memory and hesitate to strike the sometime companion."

For these and other reasons he was never able to recover the position he had lost in 1922. It was one of the tragedies of the interwar years that in an era not notable for political talent the one man of genius in politics, who might have found some solution for Britain's economic malaise, should have been condemned to remain an impotent spectator on the sidelines. But his earlier achievements make his place in history secure. He laid the foundations of the welfare state. He led Britain to victory in what seemed then the greatest of all wars. For 16 years from 1906 to 1922 he dominated the political scene. In the words of Churchill addressing the house of commons after Lloyd George's death: "When the English history of the first quarter of the twentieth century is written it will be found that the greater part of our fortunes in peace and in war were shaped by this one man." (See also LIBERAL PARTY.)

LLOYD OF DOLOBRAN, GEORGE AMBROSE LLOYD, 1ST BARON, created 1925 (1879–1941), British politician and administrator, was born on Sept. 19, 1879, at Dolobran, Montgomeryshire, and was educated at Eton and Cambridge. He travelled aidely in Burma, India, Little Tibet, the Himalayas, Egypt, Morocco and Asia Minor. In 1905 he was appointed attaché to the British embassy at Constantinople. During World War I he saw service in Egypt, Gallipoli. Russia, Mesopotamia and with the sherif of Mecca's forces in the Hejaz. gaining the D.S.O. in 1917. He was Conservative M.P. for West Staffordshire from 1910 until 1918, governor of Bombay from 1918 until 1923, and M P. for Eastbourne from 1924 to 1925. From May 192j until 1929 he was high commissioner of Egypt and the Sudan. He was created G.C I.E. in 1918 and G.C.S.I. in 1924. In 1940 he entered the Churchill cabinet as colonial secretary. He was appointed leader of the house of lords shortly before his death Feb. 4, 1941.

LLOYD'S. The corporation of Lloyd's is an old London institution in which all forms of insurance except long-term life and financial guarantee can be effected. Its constitution and methods are unique because the corporation as such does not subscribe policies, the risks being accepted by individuals each signing for a specified sum for which he alone is responsible. Policies can be subscribed only by underwriting members, each of whom has before election to place with the corporation securities to an amount fixed by the committee, in no case less than £5,000 and in most cases much more, the amounts required being proportionate to the business underwritten. The number of underwriting members was more than 3,900 in 1955. Elaborate precautions have been taken to render the security of Lloyd's policy unimpeachable. The liability of each individual is unlimited. Each underwriter's accounts are subjected to an annual audit, when the auditor must certify that the underwriting assets of each underwriter are sufficient to meet his underwriting liabilities calculated in accordance with stringent regulations laid down by the committee.

Lloyd's has for two centuries been a centre for the collection and diffusion of maritime information. At every seaport of any importance and at many inland towns throughout the world Lloyd's agents are established to collect information, to give assistance in casualties and to survey and assess damaged cargo. There were in 1955 approximately 1,joo such agencies and subagencies.

Lloyd's Coffeehouse.—Lloyd's has had a remarkable and indeed a romantic history. A certain Edward Lloyd, the oldest record of whom is in the year 1688, kept a coffeehouse first in Tower street and afterward in Lombard street which, with other similar houses, became the resort of businessmen, some of whom were willing to subscribe policies insuring against sea risks. It thus became convenient for those seeking insurance, instead of going from office to office in search of insurers, to go to a coffeehouse where. instead of only one, several insurers might be found. At this time this was the only means of placing marine risks, but in 1720 charters were granted to the London and the Royal Exchange Assurance corporations, but no other companies or partnerships were allowed to insure marine risks. The grant of these charters was strenuously opposed by private underwriters for it had the effect of conferring a monopoly, but, as the corporations transacted a comparatively small amount of marine insurance, the virtual monopoly thus created became a powerful factor in stimulating the growth of insurance by individuals. As Lloyd's coffeehouse gradually became the centre for such insurance its power and importance developed during the early 18th century. In 1696 Lloyd printed a newssheet called *Lloyd's News* which, however, was soon dropped due to its publication of an erroneous statement of no importance in a report of the proceedings of the house of lords. *Lloyd's News* was not a specialized shipping paper and it was not until 1734 that *Lloyd's List* was established. This was devoted mainly to shipping news and as it has appeared continuously ever since it is the oldest London newspaper excepting the *London Gazette*. In the meantime, Lloyd had died in 1713 but the coffeehouse in Lombard street (on part of the site later occupied by Coutts' bank) was carried on under the same name, a name which has survived all the vicissitudes of the institution which bears it and which has been adopted all over the world as that of a sort of tutelary genius of shipping. It is for example curious to note that several foreign shipping companies bear the name of an English coffeehouse keeper of the 17th century.

In 1774 Lloyd's. under the guidance of John Julius Angerstein, perhaps the most outstanding personality who has appeared in its history, took up its abode in the Royal Exchange where it remained for more than a century and a half during a tenancy broken only by the period of rebuilding after the fire of 1838. In 1928 a new building was opened on the site of the East India house. and in 1952 the foundation stone was laid of another new building. The move to the Royal Exchange in 1774 was signalized by a departure from the status of a proprietary coffeehouse, the "Masters" as they were called becoming tenants at will to the subscribers. The outbreak of the French war in 1793 led to a period of remarkable expansion during which Lloyd's advanced in wealth and importance although the underwriters were at times subjected to losses which strained their resources; in 1794–95 one underwriter, Robert Sheddon, paid out losses of £190,000. During 1793–181j Lloyd's became an institution which exerted a salutary influence on the direction of naval operations in relation to sea-borne trade. It carried an insurance of more than £600,000 on bullion and specie from Veracruz, Mex. It is found constantly influencing the admiralty in regard to convoys. At a time when the state made no provision for war victims, Lloyd's inaugurated many subscriptions for that purpose, culminating in the Patriotic Fund established in 1803, which still existed in 1955 and which received great augmentations during World Wars I and II. Gifts of plate were made to Lord Nelson and to the captains at Trafalgar. A portion of the Nelson plate and a Trafalgar cup designed by John Flaxman later came into the possession of Lloyd's.

In 1811 under the influence of Joseph Marryat, M.P., father of the novelist Frederick Marryat, and himself a man of unusual ability, Lloyd's prepared the may for incorporation by the curious expedient of inducing the subscribers to sign a trust deed vesting the corporate funds in the committee of treasury and imposing bylaws on the subscribers. It was moreover at this period that the system of Lloyd's agencies was initiated, and the duties defined.

Incorporation, 1871.—In 1870 the control of the society over its members was found wanting. This led to the Act of Incorporation (Lloyd's act, 1871) which formed the constitution of Lloyd's as it still existed in 1955. The society was given power to make its own bylaws, to acquire real and personal property, and to do all acts in its corporate name. By the Act of Incorporation the society was restricted to marine insurance but by Lloyd's act, 1911, the power was given to carry on insurance of every description. Although individual initiative is still a most striking characteristic of Lloyd's the powers and activities of the corporate body have increased. The measures designed to make the security of a Lloyd's policy unquestionable were taken almost entirely after the act of 1871. Under the Assurance Companies acts. 1909 and 1946, special provisions are included with which Lloyd's underwriters comply.

There is no more striking illustration of the practical conservatism characteristic of Lloyd's, than the Lloyd's policy of marine insurance. Its germ is found in a Florentine policy of 1523. Its substance goes back to the 17th century. when a common printed form was gradually evolved. One of the first acts of Lloyd's, as a society, was to revise this form, with a view to resisting certain attempted innovations, and the policy, "revised and confirmed" on Jan. 12, 1779, was still in use in 1955, with practically no alterations and only three additions, the "Waiver clause" (1874), the clause excluding war risks (1898) and the "Frustration clause" (1919). In many respects the old form is inadequate to the requirements of modern commerce; but almost every phrase has been judicially interpreted and it is felt that revision would lead to much litigation. Its inadequacy has been rectified by the use of clauses devised to meet the special requirements of each class of insurance, which are printed separately and then affixed to the policy.

LLOYD'S REGISTER OF SHIPPING, a society for the survey and classification of merchant shipping, which has set the standard for the construction and maintenance of ships throughout the world. While the head office is in London, the society is international in scope. It is governed by the industry it serves, without any element of governmental control, and its revenue is devoted to the furtherance of the objects for which it was established. The society had its origin, like the insurance institution known as the Corporation of Lloyd's (*q.v.*), in the coffeehouse kept by Edward Lloyd in the city of London in the reign of Charles II. For the assistance of underwriters and merchants who frequented the coffeehouse, a list of the ships offered for insurance of hulls and cargo proved useful. These lists became in 1760 a printed volume with a strictly limited circulation. Thus originated the register book and it is interesting to find that by 1775 the familiar A1 was used to denote the highest class of ship.

Differences arose regarding standards of classification, and in 1800 the shipowners published their own book. In 1834 the two registers were united under the name of Lloyd's Register of Shipping, and for the first time standard rules for shipbuilding were issued. In the reconstituted society the management was vested in a committee elected by the merchants, underwriters and shipowners of London, but from time to time representatives were added from shipping centres in the United Kingdom, and of shipbuilders, engineers and steelmakers, so that by 1955 it had more than 100 members. In addition to a strong technical committee which deals with the formulation of rules, there are local committees at Liverpool and in Scotland, and national committees in the United States, Australia and New Zealand, Canada, Denmark, France, the Netherlands, Spain and Sweden.

The register book is published annually in three volumes. The first contains particulars of all known seagoing merchant ships afloat of 100 or more tons gross, while the second and third volumes contain additional information of a technical nature and lists of shipowners, shipbuilders, docks and harbours of the world, etc. Registers of British and American yachts are also published, as well as quarterly and annual statistics regarding ships under construction throughout the world and ship casualties.

The society's main activity is the supervision of the construction of ships and their machinery, from the examination of plans and testing of material, through the various stages of building, up to the trial trip, and the holding of regular periodical surveys throughout the ship's life to ensure that she is fit to retain the society's class. Comprehensive rules providing standards of construction for ships and their propelling, electrical and refrigerating machinery are published by the society, and a staff of 850 surveyors is employed to carry out the highly specialized duties undertaken. These include the calculation and fixing of load lines on behalf of 41 different nations in accordance with the International Load Line convention, 1930, and the issue of safety certificates under the International Convention for the Safety of Life at Sea, 1948. Representatives are stationed at all principal ports and engineering centres throughout the world and the magnitude of the operations of Lloyd's Register may be gathered from the fact that, in 1954, 42% of the world's merchant tonnage was classed with the society, and 65% of the tonnage under construction was intended to receive the society's class.

A relatively new feature of the society's work is the inspection during manufacture and subsequent erection of material for land installations such as oil refineries, electric and atomic power stations, railways and chemical plants. (W. J. FN.)

LLWCHWR, an urban district in the Gower parliamentary division of Glamorgan, Wales, j mi. N.W. of Swansea and bounded on the west by the Loughor river. Pop. (1951) 25,882. Area 27.7 sq.mi. The district comprises four small towns: Gorseinon, the administrative and business centre, with steel and tinplate works; Loughor, the old borough which gives its name to the district and contains the ruins of a 13th- to 14th-century castle. a Perpendicular church and a fine modern bridge; Gowerton, a modern steel town where a "Flannel and Pleasure" fair has been held annually from early times; and Pontardulais, a modern tinplate manufacturing and coal-mining town, possessing the 12th-century church of St. Teilo, isolated on the river plain a little way out of the town. Pontardulais has gained a reputation for its music.

LOACH. The loaches (Cobitidae) are cyprinoid fishes, elongate in form, naked or with very small scales, with three to six pairs of barbels, with the air bladder reduced and wholly or partly enclosed in a bony capsule, and with the pharyngeal teeth in a single series. More than zoo species are known, mostly from mountain streams in central and southern Asia; three species occur in Europe, and one in Abyssinia. They are small fishes, few species attaining a length of 12 in. In low and stagnant ponds, loaches come to the surface and swallow air, the intestine serving as an organ of respiration. The British species, both of which extend through Europe and northern Asia to Japan, are the stone loach (Nemachilus barbatula) and the spined loach (*Cobitis* taenia); the latter has a movable lateral ethmoid, forming a bifid spine, which at rest lies in a groove below the eye.

LOAD LINE. A line (or rather the combination of a circular disk with horizontal line passing through its centre) which is placed on the side of a vessel to indicate the limit of loading when going into the open sea. The disk is 12 in. in diameter, and the upper edge of the line passes through the centre of the disk. The distance between this centre of disk and the edge of the uppermost continuous deck of an ordinary ship at the middle of the length is termed the "freeboard" (*q.v.*). The centre of the disk indicates the appropriate freeboard for the summer season; other lines give the loading for the tropical, winter and winter North Atlantic seasons.

See SHIPPING INDUSTRY.

LOANDA (LUANDA) : see ANGOLA.

LOANGO, a region of the west coast of Africa, extending from the mouth of the Congo to the mouth of the Ogowe. Prior to Africa's partition by European powers, it formed a kingdom by that name (also known as Brama) but was divided between French Equatorial Africa, the Portuguese district of Kabinda and the Belgian Congo. The roadstead of Loango, an insignificant coastal place, remained the only testimony of former grandeur. The inhabitants belong to the Bantu groups of Mayombe and Bakongo; older reports refer to the Loango inhabitants as Bafiote.

The early history of Loango is unknown. During the 15th and 16th centuries Portuguese merchants visited the kingdom which appears to have been founded by the king of the kingdom of Congo, located south of the Congo river. Although a vassal state as late as 1570, it achieved independence toward the end of that century and began to conquer some of the adjacent kingdoms. In the 17th century Loango became divided into many small, politically ineffective states. During this time the country was an important source of slaves for the new world. It was largely under Portuguese control, except for a brief period (1641–48) when the Dutch assumed control of the country's lucrative slave trade. By the middle of the 19th century the kingdom had been reduced in influence. In 1883 the king of Loango signed a treaty placing his country under the protection of France; it became part of the middle Congo territory. (H. A. WF.)

LOATUKO, the name by which a tribe formerly variously known as Latuko, Lotuko, Latouka. Latuka, etc., is known. The language known by this name is spoken over an area to the east of Bahr-el-Jebel, between 5° and 4° N. latitude. The language is one of a group of 26 designated the Nilo-Equatorial group, containing such well-known tongues as Bari, Nandi, Masai and Turkana. These languages have an interesting feature in the use of tones whose object is the fixation of the meaning of a word in cases where its position in the sentence is not sufficient to show this. In some of the allied languages the role of the tones is definite and fixed; for example in Masai the high tone indicates that the word is the subject of the sentence. while the low tone shows that the word is the complement of the next.

The Loatuko-speaking tribes, so far as they are known, comprise the Loatuko, the Lokoiya and the Lango (*q.v.*), the last named apparently a northern section of the originally Shilluk-speaking Lango of Uganda, who have been dominated by the Loatuko and come to speak their language. All are dolichocephalic, but the Loatuko, with an average stature of about 70 in., are taller by about 2 in. than the Lokoiya and Lango.

The social organization of the Loatuko is the best known of the group. Each of a number of independent territorial groups, often at enmity, has at its head a rain maker, who is its supreme chief. There is a clan organization with descent in the male line, and at death everyone becomes the animal associated with his clan. Besides the rain maker, there are a number of "fathers of the land," of very real power in the magico-religious sphere There are large stockaded villages, such as Tirangore (Tirangole), as well as hill villages, such as Logurun. with its homesteads scattered irregularly about the hillside. In some hill villages there are megalithic stone circles, with stones up to five or six ft high, built up to the present day and used as squatting places for the men. The Loatuko have initiation ceremonies into manhood, in which the lighting of a new fire by friction is one of the essential features.

There is a cult of the dead, concerning which little became known. while the nature of Naijok, perhaps associated with the firmament, has been even less understood. The remains of near relatives are dug up some months after burial and the bones exposed in pots under trees and in rock shelters. the reason as stated being the promotion of the fertility of their women. The bones of rain makers are treated with considerably more ceremony and form the chief contents of the rain shrines where great rain ceremonies take place. The Loatuko occupy mountainous country east of Gondokoro on the upper Nile. (C G. S.; X.)

LOBACHEVSKI, NIKOLAI IVANOVICH (1792–1856), Russian mathematician, the founder of a system of non-Euclidean geometry, was born in Nizhni-Novgorod, on Dec. 2 (new style; Nov. 21, old style), 1792. He studied in Kazan university, began teaching there in 1812, and was professor from 1822 to 1846. Lobachevski was one of the first mathematicians to become convinced of the possibility of a geometry different from that of Euclid and the first to publish, in 1829, such a system (see GEOMETRY: Non-Euclidean). Presented in a form hard to understand, it was met in the beginning with derision. Some recognition came during his lifetime (election to the Gottingen Scientific society in 1842) but full appreciation of his work came only at the end of the century, when the non-Euclidean geometries, by suggesting a new way of looking at space, had important implications for theoretical physics and the development of the theory of relativity. In addition to his work in geometry. Lobachevski proved an excellent administrator. At Kazan university. where he was rector from 1827 to 1846, he helped organize the teaching staff and arranged and enriched its library. He also furnished instruments for its observatory, collected specimens for its museums and provided it with proper buildings. In order to be able to supervise the erection of the buildings, he studied architecture. Efficient measures taken by Lobachevski during an outbreak of cholera in 1830 and a disastrous conflagration in 1842 prevented great losses in personnel and equipment of the university. He died at Kazan on Feb. 24 (new style), 1856.

Geometrische *Untersuchungen,* first published in 1840, was translated into English by G. B. Halsted (1891; new ed., 1914).

See F. Engel, N. I. Lobatchewsky (1899); a complete biography in Russian by V. F. Kagan (2nd ed. 1948); E. T. Bell, Men *of Mathematics* (1937). (G Y. R.)

LOBANOV-ROSTOVSKI, ALEXIS BORISOVICH, PRINCE (1824–1896), Russian statesman, was born on Dec. 30, 1824, and educated at the lyceum of Tsarskoe Selo. At the age of 20 he entered the diplomatic service, and became minister at Constantinople in 1859. In 1863 he retired but at the close of the Russo-Turkish War in 1878 he was sent as ambassador to Constantinople. In 1879 he was transferred to London, and in 1882 to Vienna; and in March 1895 he succeeded De Giers as foreign minister. In this position he showed much of the caution of De Giers, but adopted a more energetic policy in European affairs generally. Russian influence in the Balkan peninsula suddenly revived, and Russia's Balkan policy in the next years seemed to foreshadow the creation of a Balkan confederation hostile to Turkey; in reality Lobanov was merely trying to establish a strong Russian hegemony among these nationalities, and he did not desire a new crisis in the eastern question until such time as Russia could act independently of foreign powers. Accordingly, when Lord Salisbury proposed energetic action to protect the Armenians, Russia assumed the role of protector of the sultan and vetoed the proposal. At the same time efforts were made to weaken the triple alliance. the principal instrument employed being the entente with France. which Lobanov helped to convert into a formal alliance. In the far east he became the protector of China. Japan was compelled to give up its conquests on the Chinese mainland, so as not to interfere with the future action of Russia in Manchuria. Lobanov died on Aug. 30, 1896.

LÖBAU, a town of Germany, in the district of Dresden, on the Lobau water. 12 mi. S.E. of the town of Bautzen. Pop. (1950) 17,442. Löbau is first mentioned as a town in 1221; it received civic rights early in the 14th century and, in 1346, became one of the six allied towns of Lusatia. It suffered severely during the Hussite war and was deprived of its rights in 1547.

LOBBY, a corridor or passage, an anteroom, or entrance hall in a building. The entrance lobbies to legislative buildings are often convenient places for interviews between members of the legislature and the public. The pressure thus brought to bear upon members of legislative bodies has given rise to the expressions "lobbying" (q v.) and "lobbyist."

LOBBYING. In its broadest sense lobbying is the attempt of individuals and groups to influence public policy while avoiding direct political responsibility. Lobbying is a compulsive and universal political phenomenon. Narrower definitions of the term have caused increasing unrest among political scientists. For years, the popular, journalistic image was that of selfish private interests attempting by pernicious means to influence public officials, particularly legislators, in order to realize goals inconsistent with the public interest. But what means are "private" or are "selfish"? What goals are inconsistent with the "public interest"? Was the Boston Tea Party, which certainly was aimed at influencing public policy, an attempt by "selfish interests" using "pernicious means" to achieve "goals inconsistent with the public interest"? King George III would have said yes; Samuel Adams would have said no.

A free society by definition is one in which all comers are free to voice their divergent opinions and to petition their rulers for a redress of grievances. These basic constitutional rights make lobbying both certain and, in its most desirable forms, highly visible and useful in democratic societies. Some of the more obvious values of lobbies in a free society are the following: (1) they make articulate the demands, grievances and creative ideas of the many segments of the public which comprise a democratic order, and often preclude festering pockets of social unrest and group frustration; (2) they often provide to busy legislators and executives expert opinions on highly complex matters; (3) they are mutually suspicious watchdogs who sniff out each other's subtle importunities and make these visible to preoccupied public officials and the public at large; (4) they serve as mediums for disseminating information about public issues to important segments of the community.

This patent identification of lobbying with free societies tends to obscure the fact that at least some lobbying occurs in all political societies, including dictatorships and other tyrannies. It can be said with some justification, for example, that Moses "lobbied" the tyrant Pharaoh. Even the most ruthless of 20th-century dictatorships, Communist and Fascist, have been responsive to at least a few powerfully based or culturally persistent group interests; *e.g*, Junker and industrial interests in Nazi Germany, and pressures for cultural autonomy in some of the peripheral states of the Soviet Union. But many diverse interests, of course, have been concealed behind the monolithic façade of totalitarianism, and others have been totally and ruthlessly suppressed or destroyed. It is therefore fair to say that by democratic standards one index of a healthy political society is the number of visible lobbies actively contending in the public forum.

United States.—Lobbying in the United States has taken many forms: the open representation of group interests before legislative committees and administrative tribunals, the "buttonholing" of public officials in legislative lobbies (the origin of the term), offices, hotels, bars, restaurants or homes; telephoning, or the writing of letters or telegrams, to public officials, or the organizing of "grass-roots" campaigns for this purpose; the provision (or the withholding) of services or money to candidates during political campaigns with an implied *quid* pro *quo;* the making available of research and writing services to public officials; the designing of campaigns to influence major public-opinion formers in the press, radio, television and in other lobbies, in an attempt by indirection to build public attitudes or to weave an irresistible coalition of private pouer. Lobbying may be carried on by full-time officials of a single, vast pressure group; by lone operators with many "accounts"; or by simple petitioners taking time out from other things to state their hopes or their grievances. The real professionals in the lobbying business are often iormer congressmen, or iormer public officials, hired because they "know their way around.!'

In the Cnited States, lobbying as a subject oi serious investigation and analysis is a 20th-century phenomenon. Awareness of some of the underlying issues, however, is at least as old as the beginnings oi American independent national life. As Madison wrote in 1788 in no. 10 of the *Federalist Papers:* "A landed interest, a manufacturing interest, a mercantile interest, a monied interest, and many lesser interests, grow up of necessity in civilized nations, and divide them into different classes, actuated by different sentiments and views. The regulation oi these various and interiering interests iorms the principal task oi modern legislation, and involves the spirit oi party and faction in the necessary and ordinary operations oi government."

The problem oi lobbying became particularly serious in the United States in the final third of the 19th century when economic power was oiten rapidly acquired and ruthlessly abused. During the 1870s and early 1880s, for example, the power oi the railroad companies became so great that a dozen or more state legislatures and large segments oi the United States congress could well be said to have become pawns of the captains of that great industry. But as the railroads and the other great trusts of the latter part oi the 19th century were gradually tamed by public opinion, statute law and the competition of rival groups, the grosser techniques oi direct lobbying (bribery, women, wine, lifetime railway passes, etc.) were gradually withdrawn in favour of more genteel, indirect and, unfortunately in some circumstances, less visible methods oi wielding influence over public policy. Actually, the attempts in the United States in the 20th century to curb by law the evils of lobbying have been aimed almost exclusively at making lobbying practices more visible. Since 1890, which marked the passage of the first lobby registration act (Massachusetts), almost two-thirds of the states have passed laws specifically (if, on the whole, ineffectively) designed to focus the spotlight of publicity upon organized interests which attempt to influence legislative policy. Most of the remainder of the states have "improper practices" laws directed only at patently venal lobbying activities such as bribery and blackmail.

At the national level, interest in the problem of lobbying was first marked in 1907 when three bills on the subject were introduced in the congress. But it took almost 40 years oi abortive legislative measures and intermittent special investigations beiore a federal statute was actually passed. The major provisions oi the Federal Regulation of Lobbying act (title iii of the Legislative Reorganization act of 1946, 60 Stat. 839; 2 U.S.C. 261–270) are two: (1) any person who shall engage himself for pay or for consideration for the purpose of attempting to influence the passage or defeat of any legislation by the congress of the United States shall, before doing anything in furtherance of such object, register with the clerk of the house of representatives and the secretary of the senate; (2) every person, including an organization, who receives or spends money for lobbying must file cumulative quarterly statements with fhe clerk of the house of representatives and the secretary of the senate showing total contributions and expenditures for this purpose, complete with names and addresses oi contributors and recipients.

Both the senate and house reports accompanying the bill stated that the act ". . . does not apply to organizations formed for other purposes whose efforts to influence legislation *are merely incidental to the purposes for which formed"* (italics supplied). This enormous loophole, the summary and superficial character of information required in the quarterly reports, the absence oi publicity given to the list of registrants and backers and the failure of the act to provide for proper administration or eniorcement have repeatedly called into question its value. The same kinds of criticisms have been leveled with even more justification at most of the state laws in this field.

The dilemma of how to draft meaningful lobbying regulation or registration statutes without running afoul of constitutional rights or without creating unanswerable problems of definition and enforcement was pointed up by two major congressional investigations in the 1950s: the house select committee on lobbying under the chairmanship of Rep. Frank Buchanan (Dem., Pa.) (1950) and the senate special committee to investigate political activities, lobbying and campaign contributions under the chairmanship of Sen. John McClellan (Dem., Ark.) (1957).

The senate committee, particularly, emphasized that all except a few lobbying practices were so indirect or incapable of precise legal circumscription that conflicting views existed as to whether they were in fact, or in a constitutional sense should be, subject to the registration and reporting provisions of any federal lobbying act. For example, what about campaigns addressed to the public through newspapers, magazines, television or radio, containing implicit—but not explicit—appeals to the public to contact congress to influence legislation? Or, what about the preparation and distribution of books, pamphlets or data by research groups, which might influence legislation, but which were prepared without any specific intent to produce a particular legislative action? And yet, if these indirect and imprecise categories are excepted from lobbying statutes, how meaningful is it to spotlight the residue of traditional and more direct lobbying practices? And does it make sense to spotlight attempts to influence legislative action if no attempt is made to spotlight attempts to influence executive, administrative, political party and even certain kinds of judicial action? These have been some of the continuing issues raised by attempts to develop protection against the abuses of lobbying in the United States.

The constitutionality of the key registration and coverage provisions (eniorcement provisions were not involved) oi the 1946 Lobbying act was tested and upheld in 1954 by the supreme court in *United States* v. *Harriss* (347 U.S. 612). It is clear, however, that the supreme court will continue to look with the greatest care at possible iniringements of basic freedoms in the application or extension of existing legislation in this area.

Although they have varied greatly in influence over the years, some oi the most poweriul lobbies in the United States in the 20th century have been the following: for business, the National Association of Manuiacturers, the Chamber of Commerce of the United States and the Committee for Constitutional Government; ior labour, h American Federation of Labor-Congress oi Industrial Organizations (a d its most poweriul constituent unions) and the railroad brotherhoods; for agriculture, the American Farm Bureau federation, the National Grange, the National Milk Producers' federation and the National Farmers' union; and for veterans, the American Legion and the Veterans of Foreign Wars. Other powerful pressure groups (some oi them now deiunct or moribund) have included the Anti-Saloon league, the American Medical association, the American Petroleum institute, the American Retail federation, the Distilled Spirits institute, the League of Women Voters, the National Association of Electrical Companies and the National Education association.

Great Britain.— Lobbying in the United Kingdom has not been studied as extensively as in the Cnited States but the beginnings of an interesting descriptive literature developed in the 1950s. Because of Britain's reasonably disciplined party structure and because of the power of the prime minister and cabinet in the formulation of policy, it has rarely been recognized that pressure groups have probably been as influential in the United Kingdom as they have been in the United States. Some groups such as the large trade unions and key parts of the co-operative movement, for example, have been powerfully based policy-shaping elements within the Labour party. Business associations such as the British Employers' coniederation, the Federation of British Industries and the National Union of Manuiacturers have at times had a considerable indirect voice in Conservative party policy. A single agricultural association, the National Farmers' union, has contained up to 90% of the total farms in England and Wales; and, of course, as in all free societies, the United Kingdom has had a bewildering array of proiessional, religious, social-sectional and commodity interests which have attempted through direct and indirect contacts with government departments, with members of parliament and with various leaders influential in each party to influence public policy. But, as in the United States and other modern democracies, the worst excesses of lobbying have generally been checked in the United Kingdom by a combination of vigilance among competing groups and in the press, and by the ethics oi responsible civil servants and political leaders dedicated to the indispensable, if vague, norm of the public interest.

Beer, "The Future of British Politics," *Political Quarterly,* vol. 26, pp. 33–43 (1955), "Pressure Groups and Parties in Britain," *American Political Science Review,* vol. 50, pp. 1–23 (1956). (S. K. B.)

LOBE, any round projecting part, specifically the lower part of the external ear, one of the parts into which the liver or lung is divided, also one of several parts of the brain, divided by marked fissures. *(See* LIVER; RESPIRATORY SYSTEM, ANATOMY OF; BRAIN: *Anatomy of the Brain.)* The diminutive "lobule" is applied to a similarly shaped portion of a gland, *e.g.,* breast. liver, when of microscopic size.

LOBELIA, the typical genus of the family Lobeliaceae, named after Matthias de Lobel, a native of Lille, botanist and physician to James I. It numbers about 250 species, natives of nearly all the temperate and warmer regions of the world, excepting central and eastern Europe and western Asia. They are annual or perennial herbs or undershrubs, rarely shrubby, although the "tree" lobelias found at high elevations on the mountains of tropical Africa are remarkable arborescent forms. The water lobelia (*L. dortmanna,* named by Linnaeus after Dortmann, a Dutch druggist), occurs throughout the north temperate zone. *L. urens* is only found in England, on heaths, etc., in Dorset and Cornwall. The genus is distinguished from *Campanula* by the irregular corolla and completely united anthers, and by the excessive acridity of the milky juice. The species earliest described and figured appears to be L. *cardinalis,* under the name *Trachelium americanum sive cardinalis planta,* "the rich crimson cardinal's flower"; Parkinson (1629), says, "it groweth neere the riuer of Canada, where the French plantation in America is seated." It is a native of the eastern United States (see CARDINAL FLOWER). This and several other species are cultivated as ornamental garden plants, *e.g.*, dwarf blue L. erinus from south Africa, which, with its numerous varieties, forms a familiar bedding plant, much used for edging. L. splendens and L. fulgens, growing from one to two feet high, from Texas and Mexico, have scarlet flowers; L. *tupa*, a Chilean perennial six to eight feet high, has reddish or scarlet flowers; L. tenuior, with blue flowers, is Australian and grown in the greenhouse, while L. georgiana, from North America, as well as L. *siphilitica* and its hybrids, also have blue flowers. The last-named was introduced in 1665. The hybrids raised by crossing cardinalis, fulgens, splendens and siphilitica constitute a fine group of fairly hardy and showy garden plants little known in America.

The species Lobelia *inflata*, the Indian tobacco of North America, is used in medicine, the entire herb, dried and in flower, being employed. The species derives its specific name from its characteristic inflated capsules. It is somewhat irritating to the nostrils, and is possessed of a burning, acrid taste. The chief constituent is a volatile liquid alkaloid (cf. nicotine) named lobeline, which occurs to the extent of about 30%. This is pungent, with a tobaccolike odour, and is very poisonous. From it is made a medicinal tincture of lobelia, used in treating spasmodic asthma and chronic bronchitis. Fatal cases of poisoning are not uncommon, even if only a few leaves or capsules and their seeds are ingested. Milder manifestations include vomiting, nausea, coma or convulsions. (N. TR.; X.)

LOBI, a long-headed, light-complexioned and well-proportioned people living in the Gaoua district of Upper Volta. There are traces of exogamy. They live in scattered groups of one or more united households without social organization, and there are no considerable villages. Descent is matrilineal. Inheritance goes to the brother and then to the son. The Lobi practise private vendetta, and use poisoned arrows (stropanthus). They are cultivators and cattle raisers, and animists in religion.

See H. Labouret, "La terre, la chasse et la guerre parmi les populations du Lobi," Annuaires et *Mémoires,* Comite' d'e'tudes *Historiques* et *Scientifiques* de *l'Afrique* occidentale *française* (1916–17).

LOBITO: see ANGOLA.

LOBO, FRANCISCO RODRIGUES (1579–1622), Portuguese poet, best known for his pastoral eclogues, was born in 1579 at Leiria, where he lived until he went to the University of Coimbra to study law. After taking his degree he entered the service of the duke of Braganza. Lobo was drowned in the Tagus, probably before the end of 1622. Some biographers have traced his Jewish descent and possible noble birth, but this is uncertain.

His first book of poems—*Romanceiro* (1596)—reveals a refined sensibility and skill in describing the moods of nature. At this time he was deeply influenced by Luis de Góngora y Argote, and 57 of the 61 poems were in Spanish, which remained a second language for Portuguese writers until the end of the 17th century. Lobo's last work, Jornada (published posthumously, 1623), a series of short poems welcoming Philip 111 to Lisbon. was written in pure Castilian. Although Lobo preferred writing pastoral poems—*e.g., Éclogas* (1605)—he also wrote an epic in 20 cantos on Dom Nuno Álvares Pereira, *O* Cortdestabre, (1609) but the narrative is monotonous and lacks Camões' vigour and inspiration. Lobo's pastoral trilogy—A Pviataveva (1601), *O* Pastor *Peregrino* (1608) and *O* Desenganado (1614)—contains his best eclogues. In the countryside where he was brought up, on the banks of the rivers Lis and·Lena, his shepherds and shepherdesses discourse wittily on the wiles and whims of love and the weariness of life. A similar pessimism, tempered with philosophical resignation, informs the prose dialogue *Corte na* Aldeia (1619), in which the author discusses, through his characters, such subjects as the harm resulting from the extinction of the Portuguese court under Spanish rule, the best system of education and the new theories of literary expression. Lobo has won a high place in Portuguese literature for his vivid descriptions of the countryside and for the sincerity of his lyrics.

See R. Jorge, Francisco Rodrigues Lobo (1920); C. A. Ferreira, "Francisco Rodrigues Lobo—Fontes inéditas para o estudo da sua vida e obra," in *Biblos,* vol. xix (1943). (L. DE S. R.)

LOBO, JERONIMO (1593–1678), Jesuit missionary, was born in Lisbon, Port., and entered the Order of Jesus at the age of 16. In 1621 he was ordered as a missionary to India, and in 1622 he arrived at Goa. With the intention of proceeding to Abyssinia, whose negus (emperor) Segued had been converted to Roman Catholicism by Pedro Paez, he left India in 1624. He disembarked on the coast of Mombasa, and attempted to reach his destination through the Galla country, but was forced to return. In 1625 he set out again, accompanied by Mendez, the patriarch of Ethiopia, and eight missionaries. The party landed on the coast of the Red sea, and Lobo settled in Abyssinia as superintendent of the missions in Tigré. He remained there until the death of Segued. Forced by persecution to leave the kingdom, in 1634 Lobo and his companions fell into the hands of the Turks at Massawa, who sent him to India to procure a ransom for his imprisoned fellow missionaries. He obtained the ransom, but could not induce the Portuguese viceroy to send an armament against Abyssinia. He embarked for Portugal, and after he had been shipwrecked on the coast of Natal, and captured by pirates, arrived at Lisbon. He obtained no support, and in 1640 he returned to India, and was elected rector and afterwards provincial of the Jesuits at Goa. He died in Lisbon on Jan. 29, 1678.

Lobo wrote an account of his travels in Portuguese, which appears never to have been printed, but was deposited in the monastery of St. Roque, Lisbon. Balthazar Telles made large use of the information therein in his *Historia* geral da Ethiopia a Alta (1660), often erroneously attributed to Lobo (see Machado's Bibliotlteca *Lusitana*). Lobo's own narrative was translated from a manuscript copy into French in 1728 by the abbé Joachim le Grand, under the title of Voyage *historique d'Abissinie.* In 1669 a translation by Sir Peter Wyche of several passages from a manuscript account of Lobo's travels was published by the Royal society (translated in M. Thévenot's *Relation* des voyages in 1673). An English abridgment of Le Grand's edition by Dr. Johnson was published in 173j (reprinted 1789). In a *Mémoire justificatif* en *réhabilitation* des *pères* Pierre Paez et *Jérôme* Lobo, Dr. C. T. Beke maintains against Bruce the accuracy of Lobo's statements as to the source of the Abai branch of the Nile.

See A. de Backer, *Bibliothèque* de la *Compagnie* de *Jésus* (ed. by C. Sommervogel, vol. iv, 1893).

LOBSTER, an edible crustacean found on the coasts of the north Atlantic and Mediterranean. The name is sometimes loosely applied to any of the larger Crustacea of the shrimplike or macrurous Decapoda, especially to such as are used for food.

The true lobsters, forming the family Homaridae, are distinguished by having the first three pairs of legs terminating in chelae or pincers. The first pair are large and massive. The common lobster (Homurus *gammarus*) is found on the European coasts from Norway to the Mediterranean. The American lobster (H. *americanus*), which should perhaps be ranked as a variety rather than as a distinct species, is found on the Atlantic coast of North America from Labrador to Cape Hatteras. A third species, found at the Cape of Good Hope, is of small size and of no economic importance. Both in Europe and in America the lobster is the object of an important fishery. It lives in shallow water. in rocky places and is usually captured in lobster pots, or creels, made of wickerwork or of hoops covered with netting, and having funnel-shaped openings permitting entrance but preventing escape. These traps are baited with pieces of fish, preferably stale, and are sunk on ground frequented by lobsters, the place of each being marked by a buoy. In Europe the lobsters are generally sent to market in the fresh state, but in America, especially in the northern New England states and in the maritime provinces of Canada, the canning of lobsters is an important industry. The European lobster rarely reaches 10 lb. in weight. though individuals of 1; lb. have been found, and in America there are authentic records of lobsters weighing from 30 to 34 lb. The latter specimen was just about 2 ft. long, with a crushing claw (the larger) measuring 15 in. long and 20½ in. in girth. Most of the U.S. catch comes from Maine.

The Norway lobster (*Nephrops norvegicus*) is found, like the common lobster, from Norway to the Mediterranean. It is a smaller species, found in deeper water and is generally captured by trawling.

The names rock lobster, spiny lobster, sea-crawfish and "langouste" refer to members of the family Palinuridae, readily distinguished from the Homaridae by the fact that the first legs are not provided with chelae or pincers. The European rock lobster (Palinurus vulgaris) ranges from southern Great Britain to the Mediterranean. All species are taken for food wherever they occur, especially in Florida and the West Indies, the Pacific coast of North America, Juan Fernandez. Australia, New Zealand and South Africa. Spears, traps and hoop nets are used in their capture.

The Murray lobster of Melbourne and Sydney is a large species of crayfish (Euastacus armatus), much used for food.

(See CRAYFISH; CRUSTACEA; MALACOSTRACA.) (W. L. ST.)

LOCAL EDUCATION AUTHORITY: see EDUCATION, HISTORY OF.

LOCAL GOVERNMENT. Some degree of local government characterizes every state in the world: the degree is all-significant. Local government means authority to determine and execute measures within a restricted area inside and smaller than the whole state. The variant, local self-government, is important for its emphasis upon the freedom of the locality to decide and act.

There is more than a technical importance in the difference between the two terms, because they are related to the distinction sometimes drawn between deconcentration and decentralization. Local government is often, but not necessarily, related to the former; local self-government to the latter. That distinctions have been made is important, even if they are blurred. By deconcentration some have meant that for the mere convenience of a congested central government some functions have been devolved to administration on the spot, rather than from the centre, but still administered through officials appointed by and responsible to the centre. Authority and discretion are vested in the centre. On the other hand, decentralization represents local government in areas where the authority to decide has been devolved to a council of locally elected persons acting in their own discretion with officials they themselves freely appoint and discipline.

The term local self-government has been traditionally used of local government in Great Britain and Germany. Thus the constitution of the west German republic says, "The *Gemeinden* (that is, local authorities) must be safeguarded in their right to regulate, under their own responsibility, all the affairs of local community within the limits of the laws." On the other hand, the constitution of the French fourth republic said, "The French Republic, one and indivisible, recognizes the existence of local administrative units. . . . The local administrative units shall be governed freely by councils elected by universal suffrage." This expresses the spirit of deconcentration. The Union of Soviet Socialist Republics constitution (chap. VII) makes provision for "the local organs of state power," but offers no breath of decentralization.

However tightly bound to the central office's authority and regulations, a degree of discretion in its local officials is unavoidable. Often. again, the fairly pure organs of local self-government, *e.g.,* a British county borough council, are obliged to execute the purposes of the central government. Primarily units of local self-government, they are simultaneously units of local obligation acting as ordered by the central government, for services, *e.g.,* education and police, willed and imposed by it.

Thus modern local government has a twofold aspect—it is a mixture of both deconcentration and decentralization, of central convenience and an acknowledgment that not all authority ought to be exerted by the centre. The mixture is revealed by the extent to which some of the powers exercised by local government units are exercised compulsorily and under fairly strict control by central authority with financial assistance, while others are not. This mixture produces the high complexity of modern local government. Further, local government is a departmentalization of the state's work, based on the territorial distribution of services, as contrasted with (a) division into departments at the centre, or, (b) as in the decentralization of functions to public corporations, such as the British Coal board or the metallurgical trust (Glavki) in the U.S.S.R. In local government, territorial distribution of power is the essence.

The history of local government in western Europe, Great Britain, the Gnited States and Russia, exhibits the growing awareness of its significance. This awareness is a product of a development of parochial and town life which began long before the modern state emerged between the 15th and 17th centuries. Any central control over these and other areas was, until the 18th century, rather scanty, though sometimes, as under Jean Baptiste Colbert in France or in 17th century Prussia already overlaid by the heavy hand of the central *Intendants* in the former and the war commissariat in the latter. Many Germanic states were nothing but cities; *e.g.,* the Hanse towns. In England and especially New England, the local units, parishes, towns, cities emerged from their origins as spontaneous self-governing units; so, also in Russia, although there the tsars took strict control of the cities through their provincial governors and over the *Mir*—the village-cum-agricultural unit—through taxes. the police and the *boyars;* the state colonized some cities from the beginning. The various local units were gradually integrated by the state which exacted obligations from them regarding peace. crime and police duties, taxes. military supplies, assistance to the poor and highways. By ordinances or statutes or judicial decisions local units were subordinated, so that the idea of an inherent right to self-government was extinguished. By the 19th century all local units were legal creatures of the state, subsidiary in authority on principle and acting independently by sufferance alone.

Indeed, the battle for the continuance of local self-government is desperate though not hopeless. The local freedoms of the 19th century were challenged by (1) speed of communications which has reduced administrative space time; (2) demands of a planned economy; (3) growth of nationwide parties with social welfare programs uniform for all parts of the nation; (4) growth of a consciousness favouring a national minimum of services; (5) realization that the best technical administration of modern utilities requires areas knitted together by a central plan and different from the traditional ones; (6) needs of civil defense against air attack. These are powerful forces working against claims to purely self-regarding government.

More than ever, on the other hand, local freedom is supported by need for (1) intimate local knowledge and variation; (2) intensity of local interest and enlistment of loyalty and co-operation; (3) small areas for easy impact of the citizen-consumers upon officials-producers; (4) an accessible area of political education; (5) counterweight to the abuse of central power; (6) the democratic value of a plurality of political experience and confidence. In all plans, decentralization, whether to a regional corporation such as the Tennessee Valley authority in the U.S., or to reformed traditional units, is pressing, necessary and fruitful.

COMPARATIVE STUDY OF CHARACTERISTICS

The chief characteristics of local government, which may be studied by comparison of Great Britain, France, Germany, the U.S. and the U.S.S.R. are (1) constitutional status; (2) areas and authorities; (3) powers; (4) finance and local freedom; (5) organization; (6) central controls.

Constitutional Status.—In Great Britain, the local authorities are subordinate corporations formed by acts of parliament or charters. Their powers and immunities derive from statute and judicial interpretation. They have many obligatory duties and a vast field of permissive powers. Each authority is independent within the sphere of power authorized by the central government: there is no hierarchy of authorities. Slight tutelary control over the health and roads services of the urban and rural districts has been given to the counties. Local councilors are freely elected and constitute the local executive as well as the legislature. There is no appointment or ratification of local executives by the central government, though certain important local officials require qualifications stipulated thereby. The local authorities combine many functions, and are not, like the school or sanitary districts so frequent in the U.S., single function or authorities created for a specific purpose. The local finances—rates—are locally raised in amount and appropriated in detail with practically no interference by the centre. Though local authorities have considerable freedom to use their permissive powers, and even their obligatory ones, they operate within judicial controls lest they act beyond their powers or are negligent, and are under continuous central administrative controls. A condition of local central partnership characterizes the system. Though the central controls have increased markedly in the last 30 years, local powers have also greatly increased. The local units are powerful. They exercise an important influence over the central administration through their members of parliament, and through their increasingly large representation on advisory councils and committees officially attached to the several departments. The nationwide associations of the different classes of local authorities exercise an advisory and representative influence on the centre and sustain the standard of local administration, as, similarly, the German association, the Deutscher Stadtetag, does.

French local government differs from the English in being both hierarchical and centralized. Though the municipal code of 1884 gives the municipalities a wide general scope of activity, these communes and *départements* are limited by strong central controls over their budgets, modified for the bigger cities by political influence. The inspectorial system, strong in Great Britain, because the relationship of government to the localities is direct, is of less consequence in the French, where hierarchical control seeps down through the *préfet* of the *département.* Obligatory functions which must be carried out by the municipalities can be inscribed by both the *maire* and the *prdfet.* The *prdfet* may be removed by the central authority at its discretion—he is appointed by it; the *maire,* until 1884 appointed by the central government, since elected by the local council, is removable by the central government for default in acting as the law requires, and is suspendible by order of the *préfet* for similar cause for from one to three months. Judicial control over the activities of local government is very heavy, culminating in the supreme administrative court, the *conseil d'ktat.* The rather severe centralization of French local government, a legacy of the *ancien rdgime,* jolted by the Revolution but radically re-established by Napoleon, is considerably criticized, but decentralization is very unlikely. The rural nature of France, despite many cities, and the fear of the divisive political passions of the people, most recently of the Communist party, militate against local freedom.

German local government (omitting the Nazi interlude) attempted to unite the agelong pride in free and enterprising civic life with the full popular enfranchisement that came first only in 1919. Its hierarchical system, with strong central surveillance reaching back to the 18th century, was a little eased during the Weimar period. The position of the local executives. *Bürgermeister* or *Magistrat,* ratifiable by the central government, was much troubled by the universal suffrage of 1919 which replaced the oligarchic three-class system. A very wide scope of authority was accorded to the *Gemeinde,* whether rural or urban, by the basic laws, such as the Prussian *Stadteordnung* of 1808, the *Kreisordnung* of 1872 and the *Provinzialordnung* of 1873. Though this authority came to be limited by financial stringency, German cities showed great enterprise and developed many utilities. The Nazi system in general kept the framework of areas and authorities but abolished all elections and substituted appointed councilors and executives dominated by Nazi *Gauleiters.* After World War II, the several states were glad to revive local self-government and the constitution guaranteed it.

In the U.S. the main features of the constitutional status of local authorities are the variety of arrangements in the various states and the large degree of freedom of the local units deriving from early English township forms reinforced by migration into new lands. Nevertheless. that freedom is subordinate and defined by state statutes and charters giving corporate status. The special charter, referring to individual cities; the general charter, which is a state-wide municipal code; the charter which confers status by classifying the local units for privileges—these are various means of trying to give the local units a status which relieves them of the need for repeated application to the legislature, while subjecting them to a firm pattern of permissions and limits. Amendments, however, still require suppliancy to the legislature; and growth requires powers in addition to the general grant.

In 26 states home rule charters, granted by the legislature, allow the city to draft its own charter by a local convention, sometimes requiring legislative ratification, sometimes not. Another system allows the local units to choose from among several forms of charter provided in a state general law. There is much independence and vigour, no hierarchy, little central administrative control and much judicial control to hold the units within their charter and statutory position. There are increasing direct relations between federal government and local units.

The local government system of tsarist Russia was one of absolute centralized hierarchy, executed through the governors of the 78 *guberniya,* with police, military and taxation powers, and the scantiest recognition of rights of local government. Provincial and village governments were dominated by the landlords who had an *ex officio* right to chairmanship of local administration, especially of the *zemstvo,* set up in 1864 to govern the provinces under strict control of the imperial governors. The *zemstvo* (with an indirect and unequal class franchise), nevertheless, made progress in educational, health, welfare and agricultural development in spite of the tsarist techniques of tyranny. The soviet constitution of 1936 and the decree on the city soviets (1933) and specific economic and social planning decrees give extraordinarily wide specified powers to the local units, but very rigorously subject them to hierarchical control of the next higher authorities upward to the central government of the various republics, and in some cases to the union itself. Authority and direction are heavily centralized and animated in the last resort by the all-union ministry of state administration and the public prosecutors. All units from lowest to highest are manipulated in unity by the ubiquitous activities of the Communist party, the members of which are required by the rules to form cells for administrative "fulfillment."

Generally speaking, then, local government as local self-government, is discernible more fully in the British and American environment than elsewhere, rather more in the German than in the French and hardly at all in the U.S.S.R. Yet centralization and control of units originally holding authority themselves are not inconsistent with vigorous first-line activity by the local units in the matters entrusted to them.

Areas and Authorities.—Local authorities in England and Wales are (from smaller units upward): 13,000 parishes (of minimal importance even in rural areas); 1.047 rural and urban districts (mainly health and minor roads authorities and some water supply); 309 noncounty boroughs like the districts, some of which, however, have police forces and elementary education and housing authorities—both about to disappear; 83 county boroughs, being great towns of 50.000 population and above, with the widest scope of local services including the public utilities; and 62 county councils, being mixed urban and rural areas. The county boroughs are independent of the counties; all other units have some of the services in their area rendered by the county council in whose area they fall.

In addition to these authorities, there are 2,000 joint authorities, councils, committees or boards, established to administer burials, water and electricity, sewerage and hospitals. There is a tendency in all countries to rely more upon such unions where the services are of a large-scale nature compared with the traditional units having responsibility. Local authorities are mutually independent: unanimity is required for joint schemes, which are amply permitted in the statutes. Even some counties are far too small for large-scale administration, while extremes of size in area and population may be encountered in each of the above-named classes of authorities.

Areas can be reformed after a procedure of local inquiry conducted by the central ministry of local government followed in the case of the creation and extension of county boroughs by legislation, and in the other cases by central administrative sanction. For the districts a maximum decennial review of areas is called for. In 1926 the creation of county boroughs was set back by the stipulation that the minimum population must be 75,000 in place of 50,000, as the counties suffered from the subtraction of area and taxable capacity. The movement for technically more justifiable regions is strong, but cannot prevail against local inertia and the claim that small areas are needed to activate democratic vitality. Nationalization of the electric and gas utilities facilitated the reform of the local units of production and distribution.

The French local government units are, in a downward order: 90 *dkpartements;* 311 *arrondissements;* 3,031 *cantons;* and 38,000 communes. The first-and the last are genuine units of local government; the middle two are only convenient administrative subdivisions and electoral, tax and *gendarmerie* districts. The *dd-partements* vary in size from 185 sq.mi. to more than 4,000 sq.mi., with an average population of 500,000. This framework, which serves the centralizing authority of the state, was established in 1790 to unify France by abolishing the traditional 35 *généralités* which partly coincided with and partly cut across the ancient provinces. The communes are the basic roots of local government. The name applies to units from the smallest village up to the capital. The span is from several acres to 400 sq.mi.; and from fewer than 100 people to the 3,000,000 people of Paris. Two-thirds have fewer than 500 inhabitants. Powers and practical hierarchical control vary accordingly, within the uniform pattern of the law. Area alterations can be made only by parliamentary statute, preceded by local vote, inquiry and acceptance by the *département* and *conseil d'état*. There is a regionalist movement which has been unsuccessful.

Indeed civil disruption fomented by the Communists in 1947 led to further centralization; France was divided into eight regions centring in the army commands in which all governmental power may instantaneously at need be transferred to the regional superprefects in emergencies; they are called inspectors general of administration on mission extraordinary, or I.G.A.M.E.

The German areas of local government are (in Germany as a whole): more than 50,000 *Gemeinden* (like the communes) divisible into *Stadt* and *Land,* urban and rural (one-third of the population live in the latter). Then, upward, the *Kreis* (equivalent roughly to county in England and the U.S.;) above this again, the *Regierungsbezirk* (government district), a unit of central government control and police authority; and above, the *Provinz* (only in Prussia, which was disintegrated after World War II).

There are also numerous joint authorities for roads, schools, health, fire, agriculture, water, gas and electricity. The *Gemeinden* exhibit an enormous diversity of area and population. There are *Stadtkreis* and *Landkreis;* the former, where the population is above 25,000, is a city-county (like the English county borough). There is a rather special kind of holding company local authority, the *Amt*, to administer the common affairs of some contiguous villages while they still remain separate *Gemeinden.* More important area changes require parliamentary statute. Free agreement among the local authorities is practically unobtainable. The impetus toward city-countyship is enormous, for the same reasons as toward county boroughship in England. The Nazi municipal order of 1935 gave wide powers of areal change to the national cabinet.

Whereas all other nations combine most local government functions in single compendious areas, the U.S. has distributed many of these, especially education. health and parks, to special authorities. The area structure of local government in the U.S. has a different foundation according to the historic settlements. In the south and south central region the chief unit is the county; in the north central, the combined county and township; in New England, the town. In some states, the people of each county may vote to divide the county into townships. There were altogether in the mid-1950s, about 3,050 counties. There were about 17,200 towns and townships; about 16,780 municipalities or cities; 67,350 (a decrease of 40% in 20 years) school districts, and about 12,320 other special function districts—in all, about 116,700 (a decrease of 25% over the last 20 years). The area of the counties varies from one to 20.000 sq.mi.—most generally, 400 sq.mi. to 600 sq.mi. The smallest had 227 inhabitants, the largest (Cook county, Ill., with Chicago) more than 4,500,000. The average was 45,000. Forty-four of the approximately 3,050 counties were completely urban; 77 contain central dominating cities. Some of the functions such as taxation, judicial registrations and records, first instance judicial action through the county court and justices of the peace and elections! are those of modern central rather than local authorities. Others like education, highways and bridges. social welfare, poor law, hospitals, pensions: health, defectives and delinquents are serious burdens on nonpopulous areas. Services remain inefficient or the state takes them over, for consolidation of counties is resisted. Some unions of counties have been formed for hospital and poorhouse administration.

Inset in the county is the city, with its own powers! and in direct relationship with the state government. Sometimes both city and county conduct for two concentric areas many similar services with substantial duplication of staff and organization. The cities are the areas of the heaviest integration of local government services. As elsewhere, there is antagonism between city and county, and the federal authority after the 1930s became an important direct supporter of city unemployment, public works, municipal utility and housing schemes. Towns, which are mostly but not exclusively semirural communities, and are fairly populous, in New England, New York, Pennsylvania and the north central states, play the part of the counties elsewhere and have city functions and sometimes city status also. As a part of a township or a county, there are habited centres, called villages or boroughs, a minimum of population usually being demanded by the state legislature before such a subdivision may become self-governing. Area problems in the U.S. revolve round the adjustment of county and city, and the problem of metropolitan areas. Here also, political vested interests and simple inertia obstruct modernization by the legislatures.

In Russia the tsarist areas replaced by territories or regions (*oblast*), include 4,411 districts *(raion)*, 1,442 cities and 459 boroughs (within cities), 2,307 settlements and 74,490 villages. At the top of the pyramid is the supreme soviet of the union republic. The upward relationship may be expressed in Lenin's phrase, "centralized supervision with decentralized activity." Within the cities of 100,000 there are subordinate soviets. of which Moscow has 240. Cities of more than 50,000 and specially important places of lesser population receive a status independent of the *raion* hierarchy and are directly subordinate to the republics. Attached to these cities are surrounding rural settlements which fully participate in the city government, but possess village soviets also. The republics enact these connections. A marked reduction of the local middle units of government has occurred since 1917, for urbanization since 1920 increased the soviet areas fifteenfold by the mid-1950s, and they were still in flux.

Powers.—Broadly speaking, the spatially big authorities in the hierarchy are concerned with financial and administrative supervision of the primary units, the provision of environmental and institutional and police services, and technical and financial supplements and assistance to the smaller authorities.

Authority to act is always a combination of specific grant and general grant by the central authority, sometimes with modifications by the administrative supervisory authorities and the courts.

In Great Britain, the specific grant of power is supreme. Powers are granted to the various classes of local authorities by general statutes, and by special addition to individual local authorities in private or local acts. The powers granted by general statute are either permissive; *e.g.,* libraries, or compulsory; *e.g.,* education or hospitals for infectious disease. The powers appear in the great statutes such as the Municipal Corporations act (1835) and the Local Government act (1933), which may be termed constitutive, or in acts on education or police, which may be called functional. The permissive powers offer remarkably wide opportunities for initiative. Where local authorities petition parliament for private acts, they may obtain the opportunity to pioneer, if they prove desirability and financial capacity, and successful administration is sometimes followed by granting extension of powers to all authorities. The merit of the system of specific grants is the addition of the good sense of the central authority to that of the local electorate in determining new services, which necessarily involve controls over local citizens and power to raise taxes. All the bigger authorities have a rather restricted by-law making poaer, heavily controlled by the courts.

In France and Germany the municipalities are given by the constituent statutes a general authority to act for the good proper to the municipality. But what is proper is legally challengeable by citizens, rind administratively by the central departments. Initiative is limited by the claims of other communities, private enterprise and the state organs. Also there are functions obligatory on the local units — from 50% to 80% measured in expenditures — prior to the discretibnary ones. The approval of the higher administrative authorities and the administrative courts is needed for utilities so that not very much is accomplished. In Germany from 1890 on, the cities proceeded remarkably with municipal enterprise. Despite specific grant in Great Britain. that country was probably unmatched in the extent of municipal management of utilities till the nationalization referred to.

In the United States counties have specific grants. The cities receive their powers in the charters. These are stated specifically, but in broad outline, while additional powers are granted from time to time.

The Russian republic constitution grants to all local authorities the power to "direct the cultural, political and economic construction of their respective territories," and the power to make decrees within the laws of the union and the republic. and then specifies further by requiring the local soviets to set up executive departments. The local soviets are generically unbounded in these powers, but in all are minutely subject to central plans.

The powers actually exercised by modern local authorities in the middle of the 20th century were immensely in advance of anything known in the early 19th century. Then the main services were highways, police, public assistance. the removal of health nuisances, perhaps fire fighting, perhaps infectious diseases, here and there public education. In Great Britain about 80% of the work of the local authorities came to include the modern social services and municipal enterprise: in other countries the situation was similar or was becoming so. The powers usually exercised by local authorities included education up to high school and technical schools (in the U.S sometimes colleges and universities); public health in a variety'of environmental and personal services; mental diseases; housing provision and management; town planning, zoning, building regulation; poor relief and, in the U.S., local administration of social security services; small holdings, allotments; parks and open spaces and playgrounds; agricultural improvement and land drainage. agricultural education; roads and bridges; streets; public lighting; fire fighting; police (larger authorities only, except in the U.S.); lower instance justice; foods and drugs. and weights and measures inspection; enterprises of gas, electric power, transport by trams and bus, water supply (in the German cities, laundries, milk supply, bakeries, theatres, concerts); and land purchase In the soviet system. the local soviets are subordinated units in the vast industrial and agricultural plans, the local soviets in their turn bringing the collective farms under especially stringent tutelage.

The tendency was toward more local powers, because all government was getting more power, but the development of planned economy, social security, public medical care and civil defense transferred the decision making and higher direction to the bigger authorities, though not excluding the smaller from direct local execution with much latitude therein.

Finance and Local Freedom. — The finances of local authorities have a bearing upon their administrative freedom. The crucial points are (1) their authority to raise revenue; (2) freedom of budget making; (3) the revenue basis; (4) the magnitude of their expenditures. Only (1) and (2) are discussed.

1. Revenue may be raised by authority of the general codes or the special statutes conferring powers. In France, tax freedom is limited by the need of superior authorization of the budget. In the Soviet Union the fully planned economy limits tax freedom, and the constitution itself requires that all local soviet budgets fit into, and be previously sanctioned by, the budgets of the republics.

In Great Britain and the United States, the principal financial limitations are on loans. In the former, previous administrative authority is required; in some states of the latter, limitations of total indebtedness are prescribed. The former introduces national investment policy and higher technical examination of the projects. German cities have wide financial freedom, though loans require higher sanction.

2. Local budgets need no superior approval, either in Great Britain or the U.S. In France, the *maire's* and the *préfet's* approval is required and they may require balancing and inscribe mandatory expenditures or invalidate optional expenditures. The German system also requires compulsory appropriations when higher authorities consider that provision is inadequate. In the soviet government, the higher authorities exercise penetrating control over revenue raising, appropriations and budgets.

In Great Britain grants-in-aid from the central authority play a very important financial and administrative role; in the U.S. rather less so. but with growing importance. In France and Germany the sharing of taxes with the central government was more important relatively than grants-in-aid. Grants and the form they take are instruments of superior control, regulation and stimulation. The ratio of revenue from local sources to total revenues from these and central grants in the late 1950s found Britain in the class of 40%–49%, Germany and the U.S. in the 60%–69% class and France in the 80%–89% class, while throughout the world (omitting the U.S.S.R.) there was a marked concentration around 20%–29%. In the Soviet Union, the local soviets draw revenue from the communized property allotted to them as public corporations by the union. Then they may add to the state turnover tax a percentage sanctioned by the superior local authorities to meet expenditure on functions authorized by them, these higher levels controlling their budget in minute detail.

Organization. — Local councils are elected by practically universal franchise for terms of three or four years, soviets for two. Soviet local elections are conducted by the Communist party; but nonparty members nominate and are nominated. Nearly 80% of the members of the village soviets and 40% of the city soviets are nonparty, but only four out of ten chairmen of the village soviets and practically none of the big city soviets are nonparty. The Communist party intelligentsia almost monopolizes the executive committees which run the government almost uncontrolled by the soviet. The local government statutes of all the countries concerned prescribe certain kinds of internal organization — mayor, chairman, aldermen, committees and commissions for executive and legislative operations and management of the permanent staffs.

Some significant differences deserve notice. The English form of internal organization is that of all-party committees each in touch with the technical or expert directors of departments. The only co-ordinator is the town or county clerk, in collaboration with the mayor or chairman who is annually elected from the council. The committees have a very large degree of delegated authority, subject to ratification by the council, but not to tax, raise a loan or make a contract. The French system has the centrally appointed *préfet* dominating the *de'partement* council; in the municipalities, the council elects the mayor. The former works with a secretary-general appointed by the central government. A small standing committee of the council, called the *commission départementale,* controls and co-operates with the *pre'fet* as regards the budget, the audit of expenditures and civic property. It has further delegated powers from the council. but not to tax or spend. The *maire* is served by a number of *adjoints,* chosen from the council by seniority and value of services to the commune, who supervise the various departments of municipal activity, and jointly act as an advisory body to the *maire* and draw up the budget.

In the German system, in the county, the chief executive is the *Landrat,* appointed by the central government, who co-operates with a small executive committee of the county council. In the rural communes, a chairman or *Biirgermeister* is elected by the council, and works with assistants or aldermen chosen by the councilors. The various states of Germany have diverse practices. In some there is a kind of bicameral system, called *Magistrat.* The elected council co-operates with the *Magistrat,* which is an administrative board of officials and some laymen chosen by the council led by the *Burgermeister*, the principal official—but since World War II, the *Magistrat's* power has been reduced to a suspensive veto only. In the *stadtrat* system, the elected council is singly the supreme authority, and works with an elected first *Bürgermeister,* but has an appointed second *Burgermeister* as its administrative officer. The system prevails in Bavaria. There is also the *bürgermeister* system, as in North Rhine-Westphalia, where the elected council has supreme authority, chooses its *Bürgermeister* who has a suspensive veto over the council's resolutions, and then a professional *Stadtdirektor* like a G.S. city manager, appointed for 12 years, as chief of administration.

In the U.S. system there are four conspicuous forms of organization: the town meeting, the commission system, the council and mayor system, the city manager system. In the first. the meeting of taxpayers settles main lines of policy, chooses selectmen and officials, accepts the budget, controls administration and checks expenditures. It is unwieldy for large cities. These then may be administered by a small number of commissioners elected simultaneously as heads of the executive departments and are collectively the general government of the city. The system encourages disintegration of leadership, and is on the decline. Elsewhere a council and some officials and the mayor are elected at the same time. There is a separation of legislative and executive authority at an enormous cost of energy which produces some but not all the desirable progress.

From the mid-1910s to the end of the 1950s, the city manager system developed strongly, until it applied to 1,275 cities, towns and counties, a great part of the increase coming after World War II. The elected council appoints an executive, a career official to energize, manage and appoint the officials, and to co-ordinate and make the budget—this official operating side by side with the elected mayor. The city manager is no tsar; he serves the council, and the local statutes give him a strong status, but it cannot be stronger than the authority of the council. His indefinite tenure may be cut short. In general, the United States system is distinguished by its use of the initiative and referendum, especially necessary in the commission form.

In the soviet system, the local soviet elects a presidium or executive committee from its members. This body is the formulator of policy as well as the executive—the council discusses and ratifies. The presidium is assisted by experts or interested citizens co-opted onto its committees. This practice of co-option was originated in Britain; many countries now practice it. The Soviet Union and some German states require of councilors an annual or semiannual "open house" to the public. Soviet councilors may be recalled by dissatisfied constituents, but this happens very rarely.

During the 19th century, local administration, having small power, was a field of much unpaid service, patronage and spoils. The merit and career system advanced. Appointments are made by the chief executive officials in the French and German systems, but according to general statutory qualifications and tests. In England, the central government by law prescribes the basic qualifications of some officials—the medical officer of health, the sanitary inspector, the police, teachers, etc., but appointment and management are fully by the local authorities, though since 1946 a nationwide examination and appointment and salary code has been fashioned and introduced by the local authorities' associations. Some officershave the right of appeal to the central authority against dismissal; *e.g.*, medical officers of health. In practically all large authorities and most small, a career service prevails. In the U.S. it has been estimated that civil service appointments total about 55% in the cities, and about 30% in the counties.

Central Control.—The intensity and techniques of administrative control by the central authorities are indexes of the limitation of local self-government. General tutelage is characteristic of France, Germany and Russia. It operates through continuous organized hierarchical vigilance and intervention downward from the designated central department through the higher to the lower levels of local authorities. In Great Britain statutory rules and orders made by the designated central department administering the statutes relating to local functions, advice, admonition, exhortation, preparation of scientific memoranda and reports of experience are parts of tutelage.

The sanction of administrative schemes is a more severe and specific form of central control: it is strong though not fully comprehensive in England. In France and Germany it is more comprehensive and in the Soviet Union it is total through the agencies already mentioned. In the U.S., higher sanction is rare and applies to welfare and public works schemes assisted by the federal authority, and occasionally to highways, education and hospitals financially assisted by the states.

Submission of periodic reports is universal, but applies in the U.S. mainly to the services already mentioned, and in some states to the local accounts. The growth of standards, scientific definition, forms and statistical analysis after the middle of the 19th century was a powerful instrument of centralization, since both local and central officials can be of one mind in reporting and deciding answers to governmental problems.

Audit of local accounts by central officials is severe and important in England; in France and Germany it is hierarchical, going finally in each case to the special courts of accounts. In the U.S., though accounting and fiscal practices are in some cases state regulated and the election of local auditors required, external and compulsory audit hardly exists. Inspection by central officers is the most distinctive feature of the English system, having been carried to a highly comprehensive and efficient stage in which the inspectors are not only investigating and enforcement-assisting agents. but counsellors on good practices, and flexible intermediaries between the capital and the localities. There is also inspection in the French and German systems, but it is overshadowed by the centralist form of the system. In the U.S. the small amount of inspection is related only to the services already mentioned. Action in default is very limited and rare in England; practically nonexistent in the U.S.; has been practised in Germany; is unnecessary in France because previous sanction *(tutelle)* and obligatory expenditure prevent local default. The central power to remove the French *maire* or the *prkfet* may be borne in mind. Stern hierarchical and party and newspaper criticism is designed to obviate local default in the U.S.S.R., but self-seeking and inefficiency often produce defects punished by recall.

Finally, personnel rules are laid down by the English central authority for some key officials; the office of *préfet* in France in 1945 was made a career service, intermingled with service in the central administration, following successful graduation from the government-sponsored École Nationale d'Administration. A few states in the U.S. exert some small influence on the civil service conditions of the localities; in Russia, the local soviets use the graduates of technical schools as screened by the Communist party. The payment or withholding of grants constitutes a sanction of these various instruments of central control. This is especially strong though flexible in England; much less so in France and Germany; firm over its small field in the U.S.; while the soviet system relies on other incentives, mainly fear or revolutionary zeal. In France and Germany, local authorities are subject to control by appeal to the administrative courts; in Britain, to the ordinary courts; in the U.S.S.R. no such appeals to a judiciary are entertainable, and the only recourse is to the hierarchy or the prosecutor's office.

Variety and development are marks of contemporary local government. Larger areas for local government with more central direction are on the way. Many new functions are impending. The feeling of attachment to the old areas is a retarding factor; the recognition that the small area has continuous human values and certain long-run technical advantages in assisting consumer control over administrators will force centralization to assume accommodating forms. The great associations of municipalities and the professional officials already contribute considerably to the efficiency of the localities, and their services are destined to be even more valuable as moderators of centralization. Yet the forces of modern large-scale economic organization and civil defense weaken the scope and independence of local self-government.

LOCAL OPTION. The term local option has been used to refer to a variety of permissive laws effective locally only after affirmative vote by the local electorate; for example, laws allowing political subdivisions a choice between forms of government or methods of representation.

It has particular significance, however, in alcoholic beverage control. In this context local option. or local veto as it is called in England, refers to a liquor control system under which each locality is permitted to vote upon the existence of legal dispensaries within its boundaries.

Early History.—Local option was a natural outgrowth of earlier licensing plans. As early as the 16th century English alehouses were licensed by the sessions of the peace and in the American colonies, though the licensing authority was first exercised by the governor. the advent of the American Revolution found the tradition of local licensing firmly established. The history of Massachusetts is typical; in 1633 it was provided that none should sell wine or strong water nithout leave of the governor or deputy governor. In 1645 the licensing authority nas shifted to the quarter courts and two years later to the county courts. In 1680 a provision was adopted prohibiting the court from issuing licences uithout the prior approval of the selectmen of the town in which the licensee sought permission to operate.

These provisions, and similar ones in the other colonies, were directed at policing the propriety and good morals of public houses and were not designed to implement total prohibition. The birth of the vigorous temperance movement of the 19th century coincided. however, with a trend toward the popular election of the county courts and their successors, and it was natural that the pressures of the early prohibition movement should be focused upon these officers. The reasoning of the prohibitionists ran thus: if the local governing body can deny one licence, it can deny all licences and local prohibition will be a reality. The problem became one of electing officials committed to a policy of "no licence."

The "no licence" movement met with several legal and practical obstacles. In 1844 the supreme court of North Carolina held that the discretion vested in the county court was not broad enough to sustain a policy of denying all applicants for retail liquor licences as "injurious to good morals" (*Attorney General* v. *Justices of Guilford,* 27 *N.C.* 315). In those states in which no legal objection was raised, although results in the rural areas were gratifying to the prohibitionists, temperance leaders were generally disappointed at their inability to carry the larger cities and towns and turned their attention to pressure for state-wide prohibition.

Local option in the sense of direct vote by locality on the question of prohibition came into vogue as a grudging concession to these pressures. The democratic flavour of local choice was never accepted by temperance workers. Theirs was a moral fight with a single ultimate goal. The *Cyclopedia of Temperance end Prohibition,* p. 394 (New York. 1881) frames the issue with candour. "By far the greatest of local option's defects is its rotten basis as to morals, where its presumptious elective system appears most audacious. With its majority rule set up as an origin of right, the results are most destructive to all proper conceptions of divine law." Within this ultimate objective, however, prohibitionists were willing to carry on their fight at all levels, adhering to the slogan provided by Judge Robert Pitman of Massachusetts, "Wherever license prevails, wrest every inch of territory you can for prohibition; wherever prohibition prevails, never surrender an inch to license, except from dire necessity" (*Alcohol and the State,* New York, 1877). By 1906, 30 states were operating under local option and more than half of all the counties. 60% of all the incorporated towns and villages and 70% of all the townships in the United States were dry.

Later History.—Local option in the United States disappeared, of course. with national prohibition. With repeal, though the older system of local licensing generally gave way to some form of central regulation, typically U.S. states returned to local option.

The plans varied greatly both as to voting unit and as to the alternatives placed before the electorate. In the typical state. cities and counties (incorporated towns often voting separately) may choose between total prohibition, sale of wine and malt beverages. package sale of distilled spirits and sale by the drink. Initiative in such elections is customarily left to petition by a fixed percentage of the qualified electors and elections may be held every year or two years.

In some communities elections may be held in a single precinct constituting at times not more than a few square blocks. Where precinct elections are permitted, however, they are usually considered as a device for protecting residential neighbourhoods from the influx of taverns, rather than an opportunity for an expression of wet or dry sentiment.

By the second half of the century, only two states in the United States still had state-aide prohibition. Mississippi and Oklahoma; in both of these dry states, however, alcoholic beverages could be sold providing they did not contain more than 4% (Mississippi) or 3.2% (Oklahoma) of alcohol by weight.

There were provisions for local option in approximately three-fourths of the states in the mid-1950s. The Distilled Spirits institute estimated that about 24,000,000 persons, including those in Mississippi and Oklahoma, lived in areas which prohibited the sale of distilled spirits. (J. D. Ls.; X.)

LOCAL TAXATION: see TAXATION, LOCAL.

LOCARNO (Ger. *Luggarus*), a town in the Swiss canton of Ticino (Tessin), of which until 1881 it was one of the three capitals (the others being Bellinzona and Lugano, qq v.). It is a health resort (pop., 1950, 7,767) built at the north end of Lago Maggiore.

Locarno is 14 mi. S.W. of Bellinzona by rail. An electric railway, opened in 1923, connects it with Domodossola and the Simplon via the Centovalli; another electric railway runs from Locarno along the Maggia valley.

The town was taken from the Milanese by the Swiss in 1512 and was subject to them until 1798, when it became a part of the canton Lugano in the Helvetic republic. In 1803 it became part of the new canton of Ticino. In its Palace of Justice in 1925 were held the sittings of the Locarno conference. *(See* LOCARNO, PACT OF.)

LOCARNO, PACT OF, a series of agreements made in 1925 whereby Germany, Belgium. France. Great Britain and Italy mutually guaranteed the peace in western Europe, and Germany undertook to arbitrate disputes with Belgium, France, Czechoslovakia and Poland. The treaties were initialed at Locarno, Switz., on Oct. 16 and signed in London on Dec. 1.

The pact was significant because it marked a break from the atmosphere of World War I, and former enemies committed themselves to a peaceful policy among themselves. The pact was, in a sense, a substitute for the Geneva protocol negotiated by the League of Nations in 1924 but never ratified.

The agreements consisted of (1) a treaty of mutual guarantee between Germany, Belgium, France, Great Britain and Italy; (2) arbitration agreements between Germany and Belgium and Germany and France; (3) a note from the former Allies to Germany explaining the use of sanctions against a covenant-breaking state as outlined in art. 16 of the League of Nations covenant; (4) treaties of guarantee between France and Poland and France and Czechoslovakia.

The treaty of guarantee provided that the German-Belgian and Franco-German treaties as fixed by the treaty of Versailles (*q.v.*) were inviolable; that Germany, Belgium and France would never attack, invade or wage war against each other except in "legitimate defense" or in consequence of a League of Nations obligation; that they would settle their disputes by pacific means; and that in case of an alleged breach of these undertakings, the signatories would come to the defense of the party adjudged by the League to be the party attacked and also in case of a "flagrant violation." The treaties between France and Poland or Czechoslovakia provided for mutual support against unprovoked attack.

To allay Russian suspicions. Germany in April 1926 concluded a neutrality pact with the Soviet Union and reaffirmed the treaty of Rapallo (*q.v.*), but this did not prevent Germany from joining the League in Sept. 1926. A further consequence of the pact was the evacuation of the Rhineland in 1930 five years ahead of schedule.

The clear meaning of Locarno was that Germany renounced the use of force to change its western frontiers, but agreed only to arbitration as regards its eastern frontiers, and that Great Britain promised to defend Belgium or France but not Poland and Czechoslovakia.

In March 1936 Germany sent troops into the Rhineland, which had been demilitarized by the treaty of Versailles, declaring that the situation envisaged at Locarno had been changed by the Franco-Soviet alliance of 1935. France regarded the German move as a "flagrant violation" of Locarno. but Great Britain declined to do so. and no action was taken. Germany made no effort to arbitrate its dispute with Czechoslovakia in 1938 or with Poland in 1939.

See William *M.* Jordan, *Great Britain, France, and* ***the*** *German Problem, 1918–1939* (1943). (B. E. S.)

LOCH, HENRY BROUGHAM LOCH, 1ST BARON (1827–1900) M.P., of Drylaw, Midlothian, was born May 23, 1827. After two years' naval service, he entered the East India company's military service, and in 1842 was commissioned in the Bengal light cavalry. In the Sikh war in 1845 he served on the staff of Sir Hugh Gough. In 1852 he became second in command of Skinner's Horse. At the outbreak of the Crimean war in 1854, Loch left India, and raised a body of irregular Bulgarian cavalry, which he commanded throughout the war. In 1857 he was appointed attaché to Lord Elgin's mission to the east, was present at the taking of Canton, and in 1858 brought home the treaty of Yedo. In April 1860 Loch again accompanied Lord Elgin to China, as secretary of the new embassy sent to secure the execution by China of its treaty engagements. The embassy was backed up by an allied Anglo-French force. With H. S. Parkes he negotiated the surrender of the Taku forts. During the advance on Peking Loch was chosen with Parkes to complete the preliminary negotiations for peace at Tungchow. They were accompanied by a small party of officers and Sikhs. On the discovery that the Chinese were planning an attack on the British force, Loch rode back and warned the outposts. He then returned to Parkes and his party under a flag of truce. All were made prisoners and taken to Peking, where the majority died from torture or disease. Parkes and Loch were at first put in irons, but were afterward more leniently treated. After three weeks their release was agreed, but they had only been liberated ten minutes when orders were received from the Chinese emperor, then a fugitive in Mongolia, for their immediate execution. Loch never entirely recovered his health after his experience in a Chinese dungeon.

Returning home Loch was made C.B., and for a while was private secretary to Sir George Grey, then at the Home Office. In 1863 he was appointed lieutenant-governor of the Isle of Man. In 1882 Loch accepted a commissionership of woods and forests, and two years later was made governor of Victoria. In June 1889 he succeeded Sir Hercules Robinson as governor of Cape Colony and high commissioner of South Africa.

The Boers were at the same time striving to frustrate Cecil Rhodes's schemes of northern expansion and planning to occupy Mashonaland, to secure control of Swaziland and Zululand and to acquire the adjacent lands up to the ocean. Loch firmly supported Rhodes, and, by informing Pres. Stephanus Kruger that troops would be sent to prevent any invasion of territory under British protection, he effectuallycrushed the "Banyailand trek" across the Limpopo (1890–91). Loch, however, with the approval of the imperial government, concluded in July–August 1890 a convention with President Kruger respecting Swaziland, by which, while the Boers withdrew all claims to territory north of the Transvaal, they were granted an outlet to the sea at Kosi bay on condition that the republic enter the South African Customs union. This convention was concluded after negotiations conducted with Kruger by J. H. Hofmeyr on behalf of the high commissioner, and was made at a time when the British and Bond parties in Cape Colony were working in harmony. The Transvaal did not, however, fulfil the necessary condition. and in view of the increasingly hostile attitude of the Pretoria administration to Great Britain Loch advocated the annexation by Britain of the territory east of Swaziland, through which the Boer railway to the sea would have passed. He induced the British government to adopt his view and on March 15, 1895, it was announced that these territories (Amatongaland. etc.), would be annexed by Britain. Meantime Loch had travelled to Pretoria to use his personal influence with President Kruger on behalf of the Uitlanders, and obtained the withdrawal of the commandeering regulations. In the following year he entered a strong protest against the new Transvaal franchise law. In 1895 he returned home and was raised to the peerage. He died in London on June 20. 1900.

LOCHABER, a district of southern Inverness-shire. Scot., stretching approximately from Loch Linnhe to Glen Spean and Loch Lochy. The scenery, wild and beautiful, includes Ben Nevis, through which a 15-mi. tunnel is part of the Lochaber hydroelectric scheme, designed to make use of a catchment area of 303 sq.mi. The powerhouse is close to Fort William. Pop. (1951) 9,330.

LOCHES, a town in France, capital of an arrondissement of Tours, in the *département* of Indre-et-Loire, 29 mi. S.E. of Tours by rail, on the left bank of the Indre. Pop. (1954) 4,181. Loches (the Roman Leucae) grew up around a monastery founded about joo by St. Ours and belonged to the counts of Anjou from 886 until 1205. when it was seized from King John of England by Philip Augustus, and from the middle of the 13th century until after the time of Charles IX the castle was a residence of the kings of France.

The picturesque town lies at the foot of the rock on which stands the castle of the Anjou family. surrounded by an outer wall and consisting of the old collegiate church of St. Ours. the royal lodge and the donjon. The church of St. Ours (10th, 12th centuries) has huge stone pyramids surmounting the nave and a beautifully carved west door. The royal lodge, built by Charles VII and used as the subprefecture, contains the tomb of Agnès Sorel and the oratory of Anne of Brittany. The donjon includes, besides the ruined keep (12th cent.), the Martelet, celebrated as the prison of Lodovico Sforza, duke of Milan. who died there in 1508, and the Tour Ronde, built by Louis XI and containing the famous iron cages in which state prisoners were confined.

Beaulieu ès-Loches, suburb of Loches, contains the remains of the 11th-century abbey church of the Holy Sepulchre. The chancel is of the 15th century.

LOCHGELLY, a small burgh of Fifeshire, Scot., about 7 mi. N.E. of Dunfermline by road. Pop. (1951) 9,103. The town, which is fairly modern, owes its present prosperity to the collieries in its immediate vicinity. The small Loch Gelly, from which the town takes its name, is situated $\frac{1}{2}$ mi. S.E., and has on its northern bank Lochgelly house, formerly a seat of the earl of Minto.

To the northeast rises the Benarty hill (1.167 ft.). Hallyards, about 2 mi. S.E. of Lochgelly, is a ruined house that once belonged to Sir William Kirkcaldy of Grange, who there received James V after his defeat at Solway Moss in 1542, and in 1570–72 held Edinburgh castle for James's daughter, Queen Mary.

LOCHGILPHEAD, a small burgh of Argyllshire, Scot.. at the head of Loch Gilp, a small arm on the western side of Loch Fyne, and at the eastern entrance to the Crinan canal, $38\frac{1}{2}$ mi. S. of Oban by road. Pop. (1951) 1,229. It is the administrative centre for the district of Mid-Argyll and a holiday resort. The disappearance of the herring from the loch has killed the once-flourishing fishing industry.

LOCHMABEN, a royal and small burgh of Dumfriesshire, Scot.. $8\frac{1}{2}$ mi, N.E. of Dumfries by road. Pop. (1951) 1,127. It is a delightfully situated holiday resort in Annandale, with several lakes and the Waters of Ae, Kinnel and Dryfe in the neighbourhood. In the parish church is a bell said to have been presented to the original kirk by Robert Bruce, whose statue stands in front of the town hall. At the southern end of Castle Loch are the ruins of Lochmaben castle, dating from the 13th century. where local tradition declares that Bruce was born. He exempted his followers in the district from feudal service and their descendants—the "kindly tenants of Lochmaben"—were confirmed in their tenure by the court of session in 1824. The Bruces had been closely associated with Lochmaben since David I granted Annandale to the second Robert Bruce.

The Lochmaben vendace. a small kind of whitefish, is found only in a few small lakes round Lochmaben. It is captured in fine nets and is considered a delicacy. There is another vendace. called the Cumberland vendace, in Lakes Derwentwater and Bassenthwaite. Lochmaben is famous for curling, and a team entirely composed of shoemakers (souters) who held their own against all comers once added the phrase "to souter" to the vocabulary of the sport. the word indicating a match in which the winners scored "game" to their opponents' "love."

LOCHNER, STEPHAN (c. 1400–1451), one of the most attractive of German painters. who is often compared to Fra Angelico and is considered to have brought the Cologne school to its peak of achievement, was born about 1400 in Meersburg. His name has come down to us through Albrecht Durer's diary of his journey through the Netherlands. in which he remarks that at Cologne he has had Master Stephan's tablets unlocked. By this he means the great, well-preserved triptych which presents the "Adoration of the Magi" and, on the wings, SS. Ursula and Gereon and their followers—that is, the patrons of Cologne. Formerly in the chapel of the town hall, it is now in the cathedral. In this work Lochner fills out the idealism of the older painters of the Cologne school with a seemingly inexhaustible wealth of naturalistic observation in the figures and composition, while the splendid plasticity of the draperies lends them a monumental dignity.

Lochner came to Cologne about 1430; he must previously have been in the Netherlands. The earliest work he did in Cologne was an altarpiece for the church of St. Lawrence. Only the centrepiece with the "Last Judgment" is now in Cologne (Wallraf-Richartz museum); the inner sides of the wings with the martyrdom of the apostles are in the Städel in Frankfurt. while the outer sides with "standing saints" are in the Pinakothek in Munich. The disconcertingly impressive posing of the saints and of the damned. with their back views and half-inducted profiles. the precise representation of the overturned tombstones and of the plants—this realistic vision came to Lochner through suggestions from the circle of the Limburg brothers. But his eye would never have moved beyond individual things if he had not attempted in the central picture to bind the various themes into a unity. In the light and delicate treatment of the objects and the people the work is already masterly.

A little later Lochner painted a small panel with "St. Jerome Meditating in his Study," a "Crucifixion with Saints" (Nürnberg), and for St. Katharine's, the church of the Teutonic order, a two-winged altarpiece painted on both sides, each with three saints. These are in the National gallery in London and the museum in Cologne.

In the later 1430s Lochner must have been in the Netherlands again, where he encountered the art of Van Eyck. The first work to reflect this influence is the "Madonna with the Violets," which was done for Elisabeth von Reichenstein, the abbess of the St. Cecilia chapter, about 1443. Van Eyck's influence is noticeable above all, however, in Lochner's chief work, the great town hall altarpiece described above. and in a charming little "Nativity." In 1447 he became a member of the town council, and from the same year dates the splendid "Presentation in the Temple" (Darmstadt museum), which was originally in St. Katherine's. The exquisite "Madonna in the Rose Bower" (Cologne museum) was painted soon afterward.

In 1451 Lochner died, probably being carried off by the plague. He had come to Cologne from afar, but he was in the deepest sense closely related to the city's genius. He became one of the greatest of Col'ogne's painters, subduing the naturalism of his early works and building up colour and form into a festal solemnity of representation.

Lochner must have had a highly productive workshop during all his years in Cologne. From it originated such works as the Gulbenkian collection's "Presentation in the Temple" (1445), Cologne museum's "Madonna in the Garden of Paradise With Saints," two altarpiece wings with St. John and Mary Magdalene now in the Pannwitz collection, and an "Adoration of the Christ Child" painted on canvas in the Diocesan museum in Cologne. Book illumination was also done in the workshop.

See O. H. Forster, *Stefan Lochner* (1938); A. Stange, *Deutsche Malerei der Gotik*, vol. iii, pp. 94–112 (1938). (A. SE.)

LOCK, MATTHIAS, English 18th-century furniture designer and cabinetmaker. The dates of his birth and death are unknown. He was a clever craftsman, a disciple of Chippendale, and was possibly in partnership with Henry Copeland. He belonged to that flamboyant school which derived its inspiration from Louis XV models, until he fell under the classical influence of Robert Adam so completely that it is often difficult to distinguish between them.

Many of Lock's original drawings are preserved in the Victoria and Albert museum, South Kensington, while the pieces themselves are often bolder and more solid than is suggested by the author's representations of them.

Among his works, some of which were issued in conjunction with Copeland, are: *A New Drawing Book of Ornaments* (n. d.); *A New Book of Ornaments* (1768); *A New Book of Pier Frames, Ovals, Girandoles, Tables, etc.* (1769); and *A New Book of Foliage* (1769).

LOCK. A device to prevent unauthorized entry to any building, room, container or hiding place, or to prevent seizure or movement of portable objects without the knowledge of the owners. The device may be mechanical, electrical, hydraulic or electronic in action. Its primary function is to fasten together temporarily two separate objects, such as a door to its frame. or a cover to a box by means of a bolt, bar, hook or wedge.

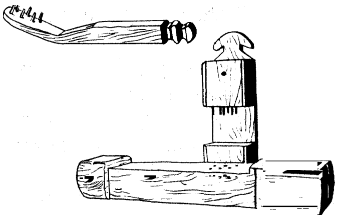

FIG. 1.—AN ANCIENT EGYPTIAN LOCK AND KEY

Proof that locks were in use at least as long as 4,000 years ago was furnished by the discovery of a wooden lock apparently from one of the doors of the ruined palace of Khorsabad near Nineveh. By the mid-1950s, no earlier examples had been found although historians suggest that locks of similar design were in use in previous civilizations. because their counterparts had been found in places far remote from ancient Egypt. Archaeologists working in such widely separated places as the Faeroe Islands, off the coast of Scotland, Japan and Norway had found almost identical models. When the prophet Isaiah said, "and the key of the house of David will I lay upon his shoulder" (xxii, 22), he probably alluded to a lock of this type. Fig. 1 shows an ancient Egyptian lock dismantled. Both the lock and the key are constructed entirely of wood.

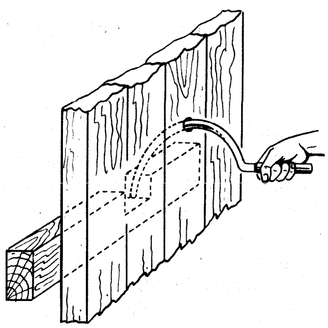

FIG. 2.—GREEK LOCK WITH HOOK KEY

The vertical piece of wood, the staple, is fixed to the doorpost and contains in the upper part movable pins, in this case, six in number; the crosspiece is the bolt. The pins in the staple fall into corresponding holes in the [illegible] by corresponding pins fixed on the key. Only the key made specially to fit the lock could operate it and a reasonable degree of security was achieved.

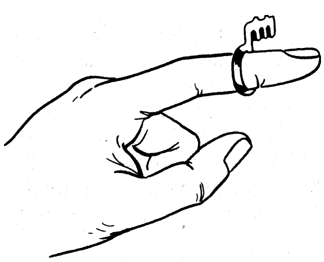

FIG. 3.— ROMAN FINGER RING KEY

The early Greeks employed a sliding bolt or bar in their locks, securing it by threading a rope through a hole and tying an intricate knot. Since only the owner could tie and retie the knot in exactly the same pattern, unauthorized entry could be detected easily. Security in this era depended upon the erstwhile thief's willingness to risk discovery and the certain punishment of death. The so-called Gordian knot of Greek mythology may have had its origin in this locking device.

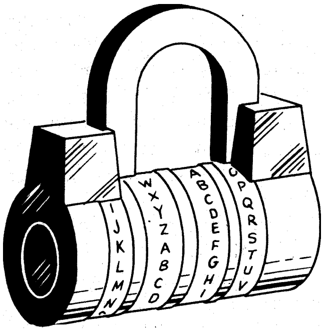

FIG. 4.— COMBINATION PADLOCK

Another Greek lock used in Homer's time (probably earlier than 800 B.C.) consisted of a wooden crossbar suspended by brackets on the inside of the door. The keyhole made its first appearance here. The bolt was moved to the locked or open position by inserting a large hook similar in appearance to a farmer's sickle through the keyhole far enough to reach the bolt. Fig. 2 shows the principle. The keys measured up to three feet in length. Carried on the shoulder, a key of this size and weight would also lend itself for use as a weapon of defense.

Metal locks came into being with the Romans. They used iron for the bodies of the locks and bronze for the keys. As a result, the locks themselves corroded and disintegrated, leaving no examples for future observation. Only the bronze keys remain. From these it has been learned that the Romans were the first to use wards or obstacles in the keyholes to prevent any but the correctly shaped key to move the bolt. Another contribution of the Roman lockmakers was the development of small keys, which were often attached to finger rings (fig. 3) so that they could be safely carried.

FIG. 5.—17TH-CENTURY LOCK AND KEY FROM TOURNEY. AIX-LA-CHAPELLE

Along with the Romans, the early Russians, Hindus and Chinese are credited with the development of the portable lock or padlock. Craftsmanship of the highest form found expression in these devices, which often took the form of birds. fish, dogs and geometric patterns. Gold and silver inlays and filigree work decorated their exteriors. From the east also, was introduced the puzzle lock, which contained hidden keyholes or disguised buttons to be pressed before the locks would open.

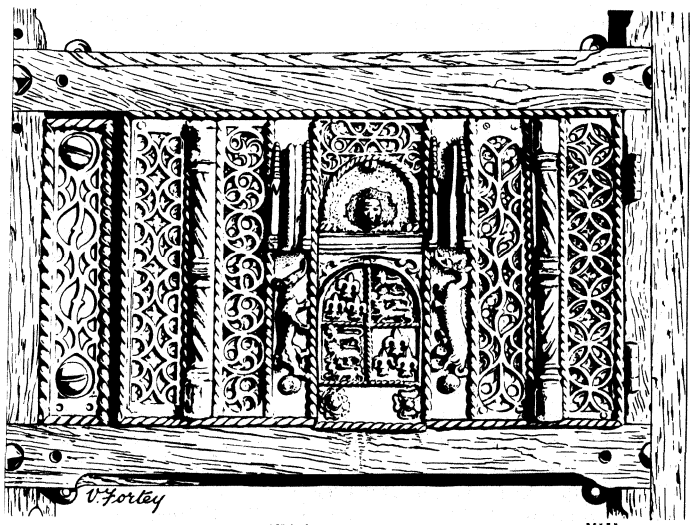

FIG. 6.— THE BEDDINGTON LOCK, BELONGING TO HENRY VIII

Combination locks had their beginnings with the Chinese. These were in padlock form and consisted of a number of lettered rings revolving around their bolts. When the correct combination of letters was set in a straight line, the bolt could be withdrawn from the rings. Fig. 4 shows a facsimile of a letter or combination padlock.

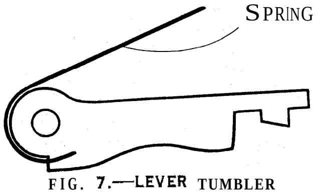

FIG. 7.—LEVER TUMBLER

The mediaeval and Renaissance periods produced locks of very beautiful-design as regards their exterior cases, but small attention was paid to security and convenience. Fig. 5 is a 17th-century lock of French origin. It measures 17¼ in. x 9½ in. and the key is 7¾ in. long. Fig. 6 shows a 16th-century lock 14 in. x 8 in., which belonged to Henry VIII. It is said that wherever he went the lock went with him and was screwed to his bedroom door.

Although locks of the mediaeval and Renaissance periods were massive and mechanically intricate, they had additional features to frighten away the boldest of thieves. There were locks that shot bullets at the would-be burglar, locks that would cut off his fingers if he attempted to reach the bolt works, and springs that ejected knives to stab him if he tampered with the keyhole.

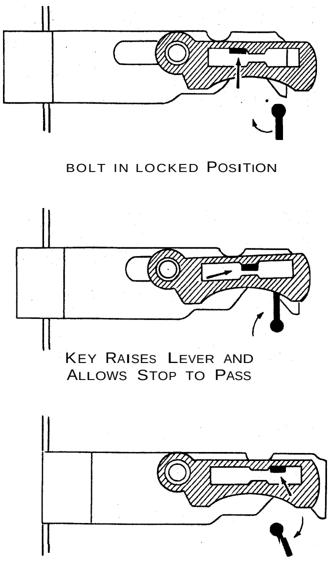

FIG. 8.— ACTION OF LEVER TUMBLER IN STAGES OF UNLOCKING

Improvements and Inventions.—Modern lock history began in the 18th century when French locksmiths employed lever tumblers (fig. 7) in their locks. Until that time, lock security depended upon intricately designed keyways, and obstructions placed around the keyhole to prevent all but the correct key from turning in the lock. These baffles. however. did not discourage the lock picker, who soon learned how to bypass them. The lever tumbler, acting as a secondary safety device, dropped into a notch in the bolt and secured it against moving or sliding until it was lifted up by the proper key.

In 1778 Robert Barron of England improved the construction by attaching a "stop" or stump on the bolt and devising a slotted lever tumbler that had to be raised an exact, specified height before the stop could pass through the slot (fig. 8). By employing several such tumblers, he achieved excellent security against pass-keys and lock picks. This principle is used in present day lever tumbler locks.

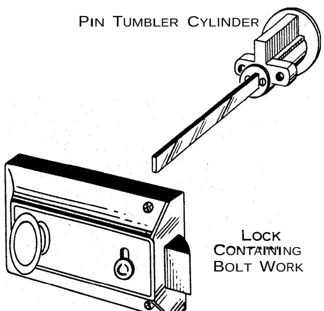

FIG. 9.—TYPICAL CYLINDER LOCK SEPARATED TO SHOW THE TWO MAJOR PARTS

Cylinder Locks.—In 1861, Linus Yale, Jr., of the United States revolutionized the lock industry with his invention of the pin tumbler lock. His contribution was threefold: he designed his lock so that it could be produced by machine tools on a mass production basis; he separated the key mechanism (pin tumbler cylinder) from the bolt (fig. 9), thus permitting application of his cylinder to any thickness of door, and to any style or position of bolt works; he eliminated the need for long, heavy keys since it was no longer necessary to penetrate the door to reach the bolt works. Fig. 10 shows a cutaway view of a pin tumbler cylinder with five pin tumblers. The inner cylinder, or plug, is prevented from rotating because the pins in the upper section extend into the plug thereby locking it securely. Fig. 11 shows the same cylinder with the correct key inserted. Each notch of the key has raised the lower segment of each tumbler to the surface of the plug. Hence. the plug is free to rotate as shown in the illustration. Literally, hundreds of thousands of variations requiring as many different keys are made available by merely changing the lengths of the pins. Additional individuality is obtained by varying the grooves of the keyway. When the word "lock" is used in connection with a pin tumbler cylinder lock, it refers to the assembly containing the bolt works. The pin tumbler cylinder is called simply the cylinder.

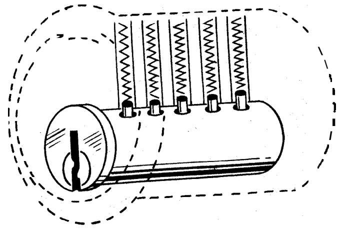

FIG 10—PIN TUMBLER CYLINDER IN LOCKED POSITION

The disk tumbler cylinder (fig. 12) is a variant of the pin tumbler cylinder. Instead of segmented pins, the locking function is provided by movable wafers or disks which lock the plug to the body of the cylinder. The use of disk tumbler cylinders is limited to low-priced locks.

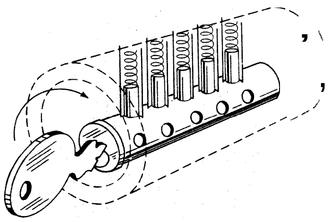

FIG. 11—PIN TUMBLER CYLINDER IN UNLOCKING POSITION

A further variation of the cylinder construction is the side bar cylinder (fig. 13), which is used in millions of motor vehicles. This cylinder contains six disk tumblers which are notched at the sides.

When the correct key is inserted. all six notches fall into alignment. The side bar immediately springs into the notches. thereby releasing the plug from the body of the cylinder and alloning it to rotate.

Modern locks are classified into six major groups. Fig. 14 to 17 illustrate the common types. A rim lock (fig. 14) is applied directly to the surface of the door. The mortise lock (fig. 15) fits into a cutout or cavity, which has [illegible] the fact that the tumbler mechanism is contained in the knob. This type was invented in 1909 by Ernest Schlage. A cabinet lock (fig. 17), as its name implies, is used on a cabinet door or drawer. A padlock (fig. 18) is a hanging lock which may be used in conjunction with two staples, a chain or a hinge type device known as a hasp. An electric switch lock (fig. 19) is a pin tumbler or disk tumbler lock that completes an electric circuit when the key is turned. These types are used in motor vehicles, electric panels and safety devices. While motor vehicle door locks appear to be another group, they are actually variations of the foregoing types, which have been designed specifically for use in metal doors.

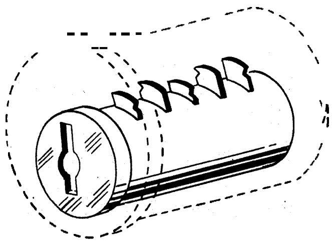

FIG. 12.— DISK TUMBLER CYLINDER

In addition to the groups listed above, there are special purpose [illegible] the inside of a room in case of emergency, but are secure against attack from the outside. Another type is the utility lock, which is used on parking meters and vending machines. There are coin box locks, billard cue locks, bottle top locks, gun trigger locks, bicycle locks, telephone locks and many other specially designed devices to guard specific objects.

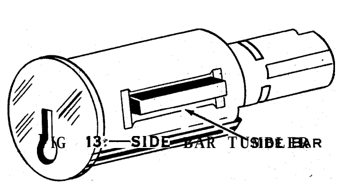

FIG. 13.—SIDE BAR TUMBLER

Master Keyed Locks.—Where many locks are used in one building or a series of buildings, the number of keys a person would have to carry could become a heavy burden. Although the simplest idea would be to set up all locks alike so that one key could operate them, the security feature would be lost. Everyone could open his neighbour's lock and vice versa. To avoid this situation, modern lockmakers and locksmiths employ "master key systems." By equipping each

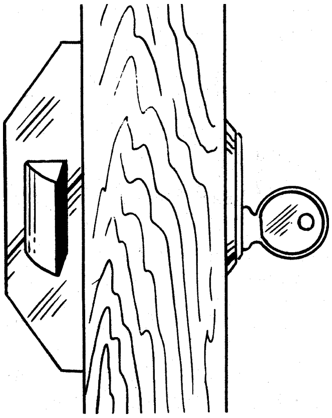

FIG. 14.—RIM LOCK

cylinder with an additional set of pin tumblers. each lock can be operated not only by a private key, but also by a master key that can open every lock in the establishment. This system is particularly useful in commercial buildings where individual tenants must have access to their own rooms, but not to their neighbour's, and where the landlord or custodian must have access to all rooms in case of emergency.

In some cases, the reverse of a master key system is required. For example, when a number of tenants in a building require access to a common entrance, they desire to use the keys for their rooms to open the entrance door also. The arrangement of tumblers in the entrance door lock is similar to that of the master key system in that additional pins are added. The pins, however, are added to the one lock only. This arrangement is known as the Maison system.

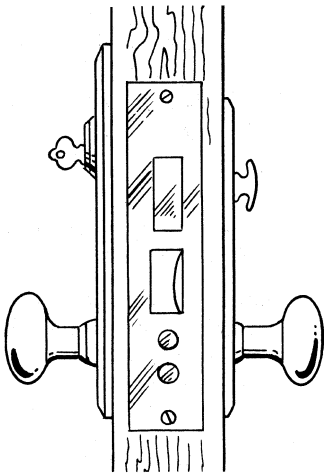

FIG. 15.— MORTISE LOCK

Combination Locks.—Combination locks are used primarily on safes, money chests and record cabinets, and do not require the use of a key. Fig. 20 illustrates a typical safe lock. It affords good security because the mechanism is completely enclosed. It has no keyway through which picks can enter. To open this lock, the operator is required to employ a given succession of numbers on the dial, which causes the tumblers within the lock to wheels

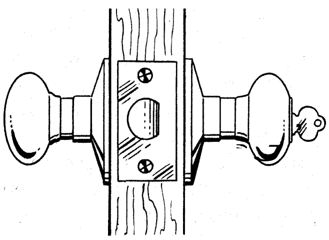

FIG. 16.—KEY-IN-KNOB LOCK

align themselves in such a manner that the bolt or locking levers become free to move into the unlocked position. A modern safe lock has three to five wheels. depending upon the factor of security required.

The use of combination locks in modern times dates from 1862 when Linus Yale, Jr., introduced them. Although minor improvements were added, the basic design remained unaltered until 1947 when Harry C. Miller invented the manipulation-proof combination lock. The need mas imperative, because by this time skilled burglars had learned to open ordinary combination locks by the sense of touch.

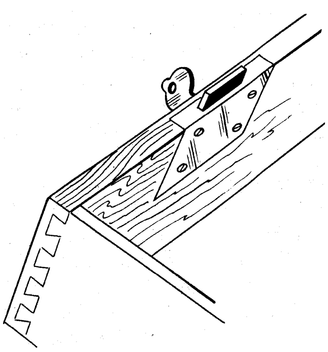

FIG. 17.— CABINET DRAWER LOCK

Time Locks.—In the latter part of the 19th century, bank robbers employed a new technique. They seized the officers or custodians, kidnapped and tortured them to obtain the combination of the locks. Thereupon they would proceed to the bank under cover of night and open the vault.

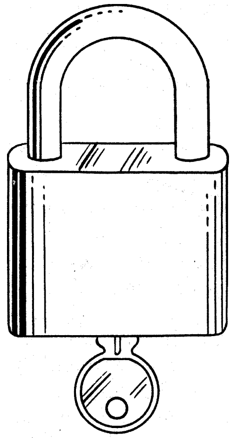

FIG. 18.—PADLOCK

To prevent this, James Sargent of Rochester, N.Y., invented the time lock in 1872. This device prevented the opening of the vault until such time as the bank was open for normal business. The time lock, which consists of a series of watch movements in addition to a combination lock, is standard equipment in almost every bank or depository throughout the world.

Safe-Deposit Locks.—The growth of the use of safe-deposit boxes, where people can store securities, valuable papers and jewels in a fireproof and guarded building, created a new need for locks of greater security. Since such depositories were placed in public buildings, additional precautions were necessary to prevent unauthorized persons from stealing keys and representing themselves as the renters of the boxes. Accordingly, a safe-deposit lock is so designed that two keys are required to open it. One key is in the possession of the box renter. Upon recognition of the renter, the guard and renter use their keys to open the box together. An additional feature,

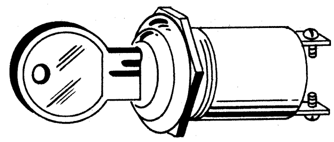

FIG. 19.—SWITCH LOCK

found in more expensive safe-deposit box locks, is the changeable key system. The combination or arrangement of the tumblers in such a lock may be changed by the insertion of a special key which frees the tumblers from their former set position. Upon the insertion of a new key, the tumblers rearrange themselves into a pattern that conforms to the new key. This feature prevents the transference of the key used by a former box holder to a new holder.

Electronic and Remote Control Locks.—The need for maximum security in the military establishments of various governments and in prisons has led to the development of complex locking systems that are combined with alarms, recording devices and automatic controls. In the mid-1950s, a series of research programs developed remote control devices by which vaults and compartments might be opened by someone situated miles away. Although these devices may fall more properly in the category of electronic, electric or hydraulic systems, they are considered by the lock industry to be the natural outgrowth of the quest for greater physical security and, as a consequence, lie within the lockmakers' field of research.

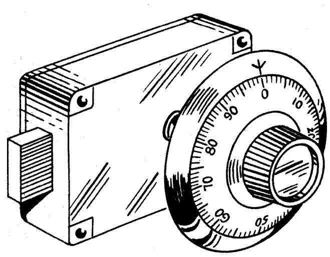

FIG. 20.— SAFE LOCK

Although almost every civilized country in the world has its lockmakers, the major producers at mid-20th century were the United States, Great Britain and Germany. In the bid for the world market, Australia, Canada, Denmark, France, the Netherlands, Italy, Japan and Sweden played increasingly important roles.

LOCK, in canal or dock engineering, a watertight chamber, closed by gates at each end, used as a means of transferring vessels from one level or reach of a canal or canalized river to another;

or at the entrance of a dock to enable vessels to be raised from a lower to a higher level, or vice versa.

Entrance locks are not usually embodied in the construction of dock works unless the range of tide is considerable, exceeding 14 ft. or thereabouts. An analogous principle is used in compressed air working where air-locks are employed for the transfer of men and materials from atmospheric to higher pressures and vice versa.

LOCKE, DAVID ROSS: *see* NASBY, PETROLEUM V.

LOCKE, JOHN (1632–1704), English philosopher. the inspirer of the Age of Enlightenment and of Reason in England and in France and. more than a quarter of a millennium after his death, still a powerful influence on the life and thought of the west, was born on Aug. 29, 1632, at Wrington, Somersetshire. His father, a small landowner and attorney. was a strict but genial Puritan who fought on the parliamentary side in the Civil War. The relations between father and son were ideal and left their mark on Locke's educational theory. In 1646 he entered Westminster school. Probably the warnings in *Some Thoughts concerning Education* against learning by rote and against beginning the study of languages by grammar were suggested by his own experiences at school. In 1652 he entered Christ Church, Oxford. then under John Owen, the Puritan dean and vice-chancellor of the university.

For some years after Locke entered. Oxford was ruled by the Independents. who were among the first in England to advocate religious toleration. But Locke's hereditary sympathy with the Puritans was gradually lessened by the intolerance of the Presbyterians and the fanaticism of the Independents, and he had no use for the scholastic philosophy still taught at Oxford. From 1661 to 1664 he was lecturing in Greek. rhetoric and philosophy. The works of Descartes gave him a relish for philosophy, although he often differed from them. We find him experimenting in chemistry in 1663, also in meteorology. in which he was always interested. Locke's religious disposition attracted him to theology. but he felt that he had no real vocation for holy orders and turned to medicine as a possible profession. Then began his friendship with Robert Boyle and with Thomas Sydenham. Sydenham adopted empirical methods in medicine, just as Boyle did in chemistry, and Locke interested himself deeply in the experiments of both.

In 1666, soon after his return from accompanying Sir Walter Vane on his mission to the elector of Brandenburg. Locke met Lord Ashley, afterward first earl of Shaftesbury. This was the beginning of a lasting friendship, sustained by common sympathy with liberty—civil, religious and philosophical. In 1667 he moved to Exeter house. Lord Ashley's London residence, to become his confidential secretary. Although he retained his studentship at Christ Church, he found a home with Shaftesbury for 1j years.

At Exeter house Locke held informal reunions to discuss debatable questions in moral and political philosophy, science and theology. One of these, in 1670, is historically memorable. "Five or six friends," he says in opening the *Essay,* "meeting at my chamber, and discoursing on a subject very remote from this, found themselves quickly at a stand by the difficulties that arose on every side." Locke proposed to attempt some criticism of man's abilities and of the limits of his understanding. What was thus "begun by chance, was continued by entreaty, written by incoherent parcels, and, after long intervals of neglect, resumed again as humour and occasions permitted." In 1690, the issue was given to the world as *An Essay concerning Humane Understanding.*

The discussion here referred to took place in 1671, and later in the same year Locke wrote two drafts of the *Essay* which are extant in the valuable Lovelace collection of his papers. The study of these papers in the 20th century shed a flood of fresh light on the *Essay* itself and on Locke's philosophy generally. They consist of a large collection of letters, notebooks! journals, catalogues of his library, etc., with many manuscript pieces. In addition to the two drafts of the *Essay,* some of the more important manuscripts in the collection belonging to this period bear the following titles: *Treatise on Civil Magistrates,* 1660; *Essays on the Law of Nature, 1663; An Essay concerning Toleration,* 1667. They reveal Locke's early interest in questions of moral and political philosophy, in toleration and in those matters which afterward concerned him in his published works. Though the latter did not appear for another two decades or so it is clear that throughout these years Locke seized every opportunity to meditate upon the problems discussed in them.

The fall of Shaftesbury in 167j and his own ill-health drove Locke from English political circles to France, where he spent three years, partly at Montpellier and partly in Paris.

In Paris he met men of science and letters—Peter Guenellon, the Amsterdam physician; Ole Romer. the Danish astronomer; Nicolas Thoynard, the critic; Melchisédech Thkvenot, the traveller: Henri Justel, the jurist: and François Bernier, the expositor of Pierre Gassendi. But there is no mention of Nicolas Malebranche or of Antoine Arnauld. In 1679 Locke resumed his relations with Shaftesbury, at Thanet house in Aldersgate, London. It was a time of plots and counterplots. and in the end Shaftesbury was committed to the Tower. tried and acquitted. More insurrectionary plots followed in 1682, after which, suspected at home, Shaftesbury escaped to Holland and died at Amsterdam in Jan. 1683. In these two years Locke was much at Oxford and in Somerset; but our information concerning his activities is scant. The letters of Humphrey Prideaux and of John Fell show that Locke was suspected at court. Correspondence with his Somerset friend. Edward Clarke. of Chipley, describes Locke's life in those troubled years and reveals the opening of his intimate intercourse with the Cudworth family. The letters allude to toleration in the state and comprehension in the church and show an indifference to theological dogma.

In 1683, Locke retired to Holland, then the asylum of exiles in search of liberty of thought, where he spent more than five years. For a time he was in danger of arrest at the instance of the English government. After months of concealment at Amsterdam, under the assumed name of Dr. Van der Linden he escaped; but he was deprived of his studentship at Christ Church by order of the king, and Oxford was thus closed against him. In Holland he met Philipp van Limborch, the Remonstrant professor of theology, and Jean Le Clerc, whose *Bibliothèque universelle et historique* was then the chief organ in Europe of men of letters. Locke contributed several articles. It was his first appearance as an author, although he was now 54 years of age.

The *Essay* was finished in Holland, and a French epitcme appeared in 1688 in Le Clerc's journal, the forecast of the larger work. Locke was then at Rotterdam, where he was a confidant of political exiles, including Gilbert Burnet and Charles Mordaunt (later 3rd earl of Peterborough and Monmouth); and h became known to William of Orange. William landed in England in Nov. 1688; Locke followed in Feb. 1689, on the ship which carried the princess Mary.

After his return to England Locke emerged into European fame. Within a month after he reached London he had declined an offer of the embassy to Brandenburg and accepted the modest office of commissioner of appeals. His defense of religious liberty, the *Epistola de Tolerantia,* was published at Gouda in the spring of 1689 and translated into English in the autumn by William Popple, a Unitarian merchant in London. *Two Treatises oj Government,* in defense of the right of ultimate sovereignty in the people, followed, with the intention of demonstrating William III's right to the throne. The *Essay concerning Humane Understanding* appeared early in 1690. He received £30 for the copyright.

The course of public affairs disappointed him, for the settlement at the Revolution fell short of his ideal of toleration and civil liberty. In spring 1691 he went to live at Oates manor in Essex, the country seat of Sir Francis Masham. Lady Masham was the accomplished daughter of Ralph Cudworth and had been his iriend before he went to Holland. At Oates he enjoyed for 14 years as much domestic peace and literary leisure as was consistent with broken health and sometimes anxious visits to London on public affairs. In his letters and otherwise we have pleasant pictures of its domestic life and the occasional visits of his friends, among others Lord Peterborough, the Lord Shaftesbury of the *Characteristics,* Sir Isaac Newton, William Molyneux and Anthony Collins.

The *Letter concerning Toleration* involved him in controversy. An *Answer* by Jonas Proast of Queen's college, Oxford, had drawn forth in 1690 a *Second Letter*. A rejoinder in 1691 was followed by Locke's elaborate *Third Letter for Toleration* in 1692. In the latter year he also addressed to Sir John Somers *Some Considerations of the Consequences of the Lowering of Interest, and Raising the Value of Money*. When he was in Holland he had written letters to his friend Clarke of Chipley about the education of his children. These letters formed the substance of *Some Thoughts concerning Education* (1693). which remains an educational classic. Sor were the "principles of revealed religion" forgotten. The subtle theological controversies of the 17th century made him anxious to show the simplicity of fundamental Christianity. In the *Reasonableness of Christianity as delivered in the Scriptures* (anon., 1695), Locke sought to separate the teaching of Jesus from later accretions. This involved him in controversies that lasted for years, and his *Vindication,* followed by a *Second Vindication* in 1697, added fuel to this fire. Above all, the great *Essay* was assailed and often misinterpreted by philosophers and divines. John Norris having criticized it in 1690, Locke's second winter at Oates was partly employed in *An Examination of Père Malebranche's Opinion of Seeing all Things in God* and in *Remarks upon some of Mr. Norris's Books,* tracts which throw light upon his own ambiguous theory of perception through the senses (they were published after his death). *A* second edition of the *Essay,* with a chapter added on "Personal Identity" and numerous alterations in the chapter on "Power." appeared in 1694. The third, a reprint. was published in 1695. John Wynne's well-known abridgment helped to make the book known in Oxford, and his friend William Molyneux introduced it in Dublin. In 1695 a revival of controversy about the currency diverted Locke's attention. Events in that year occasioned *Short Observations on a Printed Paper intituled "For Encouraging the Coinage of Silver Money in England and Keeping it there"* and *Further Considerations concerning Raising the Value of Money*.

In 1696 Locke accepted a commissionership on the board of trade which entailed frequent visits to London. In the autumn Edward Stillingfleet. bishop of Worcester, in his *Vindication of the Doctrine of the Trinity,* charged Locke with disallowing mystery in human knowledge, especially in his account of the metaphysical idea of "substance." Locke replied in Jan. 1697. Stillingfleet's rejoinder appeared in May, followed by a *Second Letter* from Locke, to which the bishop replied in the following year. Locke's *Third Letter* was delayed until 1699, in which year Stillingfleet died. One of the ablest of the other critics of the *Essay* was John Sergeant, a Catholic priest, in *Solid Philosophy Asserted against the Fancies of the Ideists* (1697). He was followed by Thomas Burnet, William Sherlock, Henry Lee and others. The *Essay* itself meanwhile spread over Europe, impelled by the name of its author as the chief philosophical defender of civil and religious liberty. The fourth edition appeared in 1700, with important additional chapters on "Association of Ideas" and "Enthusiasm." What was originally meant to form another chapter appeared among Locke's posthumous writings as *The Conduct of the Understanding,* one of his most characteristic works.

In 1700 Locke resigned his commission at the board of trade and devoted himself to biblical studies and religious meditation. He turned to the Epistles of St. Paul and applied the spirit of the *Essay* and the ordinary rules of critical interpretation to a literature which he venerated as infallible. The results, *A Paraphrase and Notes on St. Paul to the Galatians* and *A Paraphrase and Notes on the Epistles to the Corinthians* were published in 1705 and in 1706; and a tract on *A Discourse of Miracles,* written in 1702, also appeared posthumously. His last days were occupied in beginning a *Fourth Letter on Toleration,* never finished, in reply to an attack made by Jonas Proast in 1704. Locke died on Oct. 28, 1704, and was buried by the parish church of High Laver.

(A. C. F.; R. I. *A.)*

LOCKE'S PHILOSOPHY

Theory of Knowledge.—Locke was thoroughly suspicious of the view that a thinker could work out in his study by pure reason alone the truth about the universe. Much as he admired Descartes, he feared this speculative spirit in him, and he despised it in the scholastic philosophers. In this sense he rejected metaphysics. Knowledge of the world around us could only be gained by experience and reflection on experience, and this knowledge was being gained by Boyle. Sydenham, Christiaan Huygens and Newton. They were the true philosophers who were advancing knowledge. Locke set himself the humbler task. as he conceived it, of understanding how this knowledge was gained. What was "the original. certainty and extent of human knowledge, together with the grounds and degrees of belief, opinion and assent"?

Empiricism.—As for "the original", the answer was plain. Knowledge of the world around us began in sense-perception, and knowledge of ourselves in introspection, or "reflection" in Locke's language. It did not begin in innate knowledge of maxims or general principles, and it did not proceed by syllogistic reasoning from such principles. In the 17th century there had been much vague talk about innate knowledge, and in book i of the *Essay concerning Humane Understanding* Locke examines this talk and shows its worthlessness. The case that he makes against innate ideas, being now of historic interest only, need not detain us. In book ii of the *Essay* he begins by claiming that the sources of all knowledge are sense-experience and reflection; they are not themselves, however, instances of knowledge in the strict sense, but they provide the mind with the materials of knowledge—and already Locke is opening the door for the phenomenalism and the idealism of the future. Sense-experience is not direct knowledge of the world as it is. The senses provide the mind with "material"; he is not sure what to call the material so provided, perhaps "species" (as the Scholastics did) or "notions", but he finally decides on "ideas." These are the objects "before the mind," but we must not assume that the ideas are the physical objects. Rather they represent them; and though we may concur with common sense that, for instance, physical things have size, shape, weight, as they appear to have, yet in respect to colour, taste, smell and so on we may seriously doubt whether things are as they appear to be in sense-experience. In a word. Locke accepts the representative theory of sense-perception and holds that while some of the representations are exact copies of the physical, most of them are not. On this basis he distinguishes between what he calls primary qualities, such as size, weight, etc., and secondary, such as colours, tastes, smells and sounds.

Locke now proceeds to group and classify the ideas, with a view to showing that the origin of all of them lies in sensation and reflection. For though they are immediately "before the mind" not all of them are simple. Many of them are compounded and their simple parts can be revealed on analysis. It is these simples alone which are given in sensation and reflection. Out of them the mind forms complex ideas, though Locke is ambiguous on this point. For while he uses the language of "forming" or "compounding" and speaks of the "workmanship" of the mind. yet the compounding is frequently in accordance with what is perceived "to go together" and is not arbitrary. A conflict is apparent between Locke's desire to sustain the common-sense view that we do know physical objects and the demands of his compositionalist theory that all ideas can be reduced to the simple ideas of sensation and reflection of which they were originally compounded. Further troubles met him in his attempt to classify ideas. While the idea of a particular apple may be a complex of round, sweet, red, etc., what of the general idea of apple? And what of ideas of relation, such as taller than, identical with, etc.? Locke's compositionalism in this part of the *Essay* is patently insecure; yet its purpose is clear. namely, to provide him with a method of showing that all ideas, however remote they may appear to be from sense-experience and reflection. are in fact derived from these sources and from no other. This applies even to the idea of infinity itself. Ideas of space, time and number and mathematical ideas are derived, too, from simple ideas; Locke saves himself from the difficulties inherent in this position by the superficiality of his treatment.

So, too, his reflections upon cause and effect, had they been elaborated, would undoubtedly have led him into acute difficulties.

He does admit one failure. As an empiricist he can give no account of the idea of substance; it is, he thinks, essential and not to be denied, and yet it is not a simple idea given in sensation or reflection nor is it derived from simple ideas so given. In fact he can say little of it; it is "a-something-I-know-not-what." Thus the case for empiricism cannot be said to be entirely established by book ii, but Locke thinks it strong enough for him to persist in the view that our knowledge of the physical world is wholly derived from sense-perception.

Self-Knowledge.—Some of our ideas are not of things outside us, but are reflexive and of ourselves. Locke finds it necessary to classify these in book ii and in doing so sets doun the foundations of empirical psychology. His source of information is introspection and rarely the observation of behaviour. His account of sense-perception is celebrated for its appreciation of the part which the interpretative mind plays in perceiving; he makes valuable remarks on memory, on discerning, on comparing, on madness, on pleasure and pain, on the emotions and on the association of ideas.

He holds that we have an intuitive knowledge of our own existence and supposes that we exist as material and immaterial substances, but he is none too clear about this and at one point plays with the idea that we are simply material substances to which God has "superadded" a power of thinking. His most valuable contribution. however, is his account of personal identity. Having distinguished between different types of identity, he argues that personal identity depends on self-consciousness. I am the person who did so-and-so 20 years ago because I can remember myself doing it. This is the key to the identity of persons.

Language.—Locke tells us that book iii. on language, "cost him more pains" than any other book of the Essay; yet it is the book which has been most neglected. To understand our thinking and knowing we must understand the language with which we think and communicate our thoughts. Words are conventional signs; but signs, according to Locke, not immediately of things but of ideas of things, so that he carries his theory of ideas into his account of language. Frequently, the idea signified by the word is not clear and sometimes we use words when we have no ideas corresponding to them. This is particularly so in the case of general words, without which language would be so impoverished as to lose most of its worth What is involved in the use of general words? The answer, in Locke's mind, is bound up with the theory of universals Does the general word stand for a particular idea which is used in a representative capacity? Or is the universal nothing more than a creation of the mind, through abstraction, to which is attached a name? Or, again, is it simply the manner in which we desire that this general word be used? Locke considers these matters without giving a definite answer, but in dealing with natural substances he is inclined strongly toward a conceptualism, according to which the use of general words is possible only because in using them we have in mind "nominal essences," that is to say, not the real essences of things but what we mean by these general words. On this view what we mean is the concept, something we have ourselves brought about, the "workmanship of the understanding." Locke also discusses the names of simple ideas and of relations, and it is interesting to find the crude beginnings of a discussion of what are today called logical or operative words.

Book iii contains also a valuable account of definition, which denies the theory that all definition must be per genus et *differentiam.* The final chapters deal with the inevitable imperfections of language and with avoidable abuses.

Conclusions.—After the consideration of the "materials" of knowledge in book ii and of language in book iii, Locke is ready to discuss the nature and extent of human knowledge. It is noticeable that the tone of book iv is more rationalistic than is that of the previous books, and this is because the scepticism which emanated from his empiricism drove him to find the ideal of knowledge in the indubitable certainties of mathematics. Here he was on common ground with the rationalists of his day, and indeed the direct influence of Descartes seems to be observable in the opening chapters of book iv. Knowledge is perception; not sense-perception but intellectual perception or intuition. We do not, however. gain all the knowledge that we require by direct intuition: we have frequently to proceed discursively, that is. by demonstration. But even when this is so, each step in the demonstration is observed intuitionally, so that knowledge in the strict sense is essentially intuitive. "This part of knowledge is irresistible and, like bright sunshine, forces itself immediately to be perceived, as soon as ever the mind turns its view that way; and leaves no room for hesitation, doubt or examination."

Unfortunately, what can be so intuited is limited, as is too what can be demonstrated. We need not confine strict knowledge entirely to mathematics. but the intuition of relations within the physical world is beyond us Books ii and iii have shown that we deal directly with ideas and nominal essences and that the inner nature of real things cannot be known by us, so that "science." in the exact sense of perfectly certain knowledge, is not possible in this sphere. The only possibility of intuiting, consistent with books ii and iii, is that within the world of ideas, an ideal world, be it noted, which is for Locke empirically derived and not intellectual in character. Kno ledge in general term, he accordingly defines as the intuition or "perception of the connection of and agreement, or disagreement and repugnancy, of any of our ideas." If we keep ourselves within ideas—and this is the case in mathematics, for instance—we gain indubitable knowledge, but when we deal with ideas "whose archetypes are without them" we are less sure.

The connections between ideas may be of four kinds: (1) identity or diversity; (2) relation, such as larger than, wider than, etc.; **(3)** co-existence, such as the co-existence of malleableness and yellowness in my idea of gold; and (4) real existence. Of these four, knowledge of identities and differences is as wide as the ideas themselves: if, that is to say, we have the idea of a spade we know that that idea is itself, and that it is not the idea, for example, of a hammer.

Secondly, in dealing with the relations between ideas which are their own archetypes, for instance in mathematics, we need seek no further than the intuition or perception itself. But when, thirdly, we affirm co-existences there is an implied reference beyond the idea to the thing itself; and clearly this is also the case when, fourthly, we say that something exists. In these cases, therefore, our certain knowledge is not likely to extend very far.

In other words, Locke is distinguishing here between logical and factual truth. Of the former, he thinks, certain knowledge is possible but not of the latter.

In spite of this, and somewhat inconsistently, Locke thinks we do have knowledge approaching certainty in our "sensitive knowledge" of the existence of physical things. Further, we intuit our own existence. In these cases knowledge which is not an apprehension of a relation between ideas is none the less certain But he makes it clear that, for the most part, when we talk of knowledge of the physical world and of ourselves, such knowledge is probable and not certain. He recognizes the need for a logic of probability; though he does little himself in the chapters devoted to probable knouledge at the end of book iv to meet that need. Yet it should be added that the important regular-sequence theory of induction, afterward developed by Berkeley and Hume, is put forward in the pages of Locke's Essay. He speaks, too, in book iv, though only briefly, of "habitual knowledge" and is aware of the dispositional element in knowledge.

Political **Theory.**—Locke's most important work on political philosophy is that entitled Two Treatises of Government (1690). The first treatise is a refutation of Sir Robert Filmer's defense of the divine right of kings; the second and more important treatise refutes the absolutist theory of government as such, particularly that found in Hobbes' Leviathan, though the latter work is not mentioned. The whole sets out the political philosophy of the revolution of 1688 and seeks to help "establish the throne of our great restorer, our present King William." Locke defines political power as "a right of making laws, with penalties of death, and consequently all less penalties for the regulating and preserving of property and of employing the force of the community in the execution of such laws, and in the defence of the commonwealth from foreign injury, and all this only for the public good." He seeks to show the inevitability of this institution in terms of the theories of natural law and of social contract, now discredited. The outcome of his explanation is that only such political power can be justified as is genuinely "for the public good." This means that government is a trust. forfeited by a ruler who fails to secure the public good. The ruler's authority, that is to say, is conditional rather than absolute. Nor does the individual abrogate all his rights when he enters a civil society. He has established his right to property. by "mixing his labour" with things originally given to mankind in common, but now made his own by his labour. (Here in germ is the labour theory of value) He has the right to expect political power to be used to preserve his property, in his own person and in his possessions. He has the right to think as he chooses, to worship as he wishes. to freedom in speech. In fact the one right which he gives up in entering a civil society is the right to judge and punish his fellow man which is his right in the state of nature. He quits his "executive power of the law of Nature" and "resigns it to the public"; he himself makes himself subject to the civil law and finds his freedom in voluntary obedience. "Freedom of men under government is to have a standing rule to live by . . . a liberty to follow my own will in all things where that rule prescribes not, not to be subject to the inconstant, uncertain, unknown arbitrary will of another man." To secure this freedom, Locke favoured a mixed constitution: the legislative should be an elected body, whereas the executive is usually a single person. the monarch; and he argues for a separation of legislative and executive powers. The people are ultimately sovereign, though it is not always clear on Locke's theory where the immediate sovereignty lies. But the people always have the right to withdraw their support and overthrow the government if it fails to fulfil its trust. In economic theory Locke adopted the principles of the mercantilists.

Moral Philosophy.—One searches in vain for a consistent moral theory in Locke. His view that morality can be a science, as certain as mathematics, is well known. This might imply a rationalism, and there are indeed rationalist trends in his moral philosophy; although sometimes when advocating a science of morals he seems to have in mind simply the possibility of an exact analysis of the terms used in moral discourse and the clarification of moral statements. At other times, he puts forward a hedonist theory. "That we call *good* which is apt to cause or increase pleasure or diminish pain in us." But not every good is moral good: "*Moral* good and evil is only the conformity or disagreement of our voluntary actions to some law, whereby good or evil is drawn on us, from the will and power of the law-maker." On this view law rests on God's will, "the true ground of morality," though in saying this Locke does not appear to be consistent with what he says elsewhere of the law of nature.

On the question of free will, discussed in the *Essay*, Locke's position at first is determinist, but in the second edition he tries—not very successfully. it must be admitted—to defend the indeterminist theory by holding that man can always "*suspend* the execution and satisfaction" of any of his desires.

Theory of Education.—A good education, in Locke's view, attends to both the physical and the mental. The body is not to be coddled, on the contrary it is necessary that it should be hardened in various ways. The good educator insists on exercise, play and plentiful sleep, "the great cordial of nature." Young children should be allowed to give vent to their feelings and should be restrained rarely; "the chief art is to make all that they have to do sport and play too." As for mental training, character comes first before learning; the educator's aim is to instil virtue, wisdom and good breeding into the mind of the young. Parents, too, must interest themselves in their children's upbringing and, as far as possible, have them near; for no educative force is more powerful than the good example of parents. A stock of useful knowledge must be imparted. languages, the pupil's own and another modern language together with Latin (Locke thought the practice in his day of teaching Hebrew, Greek and Arabic generally was misguided); geography, history, some anatomy; mathematics, as the "powers of abstraction develop"; and later a little civil law and an introduction to morals, natural science and philosophy. For recreation, training in the arts, crafts and useful hobbies should be available, but these should not take up too much of a young man's time.

Religion.—Locke's reaction against the "enthusiasm" of the sects in his youth had been sharp, and he disliked religious fanaticism throughout his life. He was a broad, tolerant Anglican anxious to heal the breach in English Protestant ranks. His own views on church government and on the priesthood were close enough to those of the dissenters to have made union possible, for he favoured the liberal views of the Latitudinarians, of the Cambridge Platonists and of the Remonstrants of Holland. This becomes manifest in his *Reasonableness of Christianity,* while his commentaries on the Epistles of St. Paul make him one of the pioneers of modern biblical criticism. Two essentials, and two alone, he thinks, are involved in being a Christian: first, that a man should accept Christ as God's Messiah, secondly, that he should live in accordance with Christ's teaching. His point of view is not far removed from that of the Deists on the one hand and the Unitarians on the other, yet he cannot be grouped with them. Christianity, though reasonable, needs revelation as well as reason, for human reason alone is inadequate: there is an experience of God "through His Spirit" without which all religion is empty. However, any act of persecution in the name of religious truth is wholly unjustified, since our knowledge and understanding are so confined.

Bibliography.—After the *Posthumous Works of Mr. John Locke* had appeared in 1706, *The Works of John Locke* were published in 1714 (3 vol.), the second edition in 1722, the third in 1727, the fourth in 1740, the tenth in 1801 (10 vol.). The *Essay concerning Humane Understanding* appeared in 1690 and three other editions appeared in Locke's lifetime; *see* the edition by A. C. Fraser, 2 vol. (Oxford, 1894). *Two Treatises of Government* appeared in 1690; new ed. by J. W. Gough (London, 1946). Both the *Essay* and the *Treatises* are published in the Everyman Library (London, 1947 and 1953). *Some Thoughts concerning Education* appeared first in 1693; *see* J. W. Adamson (ed.), *Locke's Educational Writings,* 2nd ed. (Cambridge, 1922). Two early drafts of the *Essay* have been published, the first by R. I. Aaron and J. Gibb (Oxford, 1936), the second by B. Rand (Cambridge, Mass., London, 1931). *See* also *Essays on the Law of Nature,* ed. by W. von Leyden (London, 1954).

The standard life is H. R. Fox Bourne, *The Life of John Locke,* 2 vol. (London, 1876). *See* also Peter, Lord King, *The Life of John Locke,* 2nd ed., 2 vol. (London, 1820); and J. Lough (ed.), *Locke's Travels in France, 1675–1679* (Cambridge, 1953). Collections of Locke's letters have been published by H. L. Ollion (Paris. 1908) and by B. Rand (London, 1927).

General commentaries include R. I. Aaron, *John Locke* (London, 1937; 2nd ed., London, 1955); S. Alexander, *Locke* (London, 1908); D. J. O'Connor, *John Locke* (Harmondsworth, 1952). James, *The Life of Reason: Hobbes, Locke and Bolingbroke* (London, New York, 1949). (R. I. A.)

LOCKE, *MATTHEW* (*c.* 1630–1677), English musician, perhaps the earliest English writer for the stage, was born at Exeter, where he became a chorister in the cathedral. His music, written with Christopher Gibbons (son of Orlando Gibbons), for James Shirley's masque *Cupid and Death,* was performed in London in 1653. He wrote some music for Sir William Davenant's *Siege of Rhodes* in 1656; and in 1661 was appointed composer in ordinary to Charles II. During the following years he wrote a number of anthems for the Chapel Royal, and excited some criticism on the score of novelty, to which he replied with considerable heat (*Modern Church Music; pre-accused, censured and obstructed in its Performance before His Majesty, April 1st, 1666, etc.*; copies in the Fitzwilliam museum, Cambridge, and the Royal College of Music). A good deal of music for the theatre followed, the most important being for Davenant's productions of *The Tempest* (1667) and of *Macbeth* (1672), but some doubt as to this latter has arisen, Henry Purcell, John Eccles and Richard Leveridge, being also credited with it. He also composed various songs and instrumental pieces, and published some curious works on musical theory.

Locke died in Aug. 1677, an elegy being written by Purcell.

LOCKE, WILLIAM JOHN (1863–1930), English novelist and playwright, born on March 20, 1863, in Georgetown, Demerara, was educated at Trinidad and St. John's, Cambridge. He died at Paris on May 15, 1930.

He wrote *The Morals of Marcus Ordeyne* (1905); *The Beloved Vagabond* (1906, dramatized 1908); *Stella Maris* (1913); *The Wonderful Year* (1916); *The Rough Road* (1918); *The House of Baltazar* (1920); *The Mountebank* (1921); *The Coming of Amos* (1924); *The Great Pandolfo* (1925); *The Old Bridge* (1926); *Ancestor Jorico* (1929). His original plays include *My. Cynic* (1899); *The Lost Legion* (1900): *and The Man from the Sea* (1910).

LOCKERBIE, a small burgh of Dumfries, Scot., in the district of Annandale, 12 mi. N.E. of Dumfries by road. Pop. (1951) 2,621. It is near the Roman road and of the Roman camps in the vicinity the best preserved is Burnswark (Birrenswark). Lockerbie is famous for its sheep sales. particularly for the great August lamb fair. The Tower of Lockerbie was once the stronghold of the Johnstones. long the ruling family under whose protection the town grew up. At Dryfe Sands, about 2 mi. W., the Maxwells were almost exterminated by the Johnstones in 1593, hence "Lockerbie Lick" became a proverbial expression, signifying an overwhelming defeat.

LOCKHART, JOHN GIBSON (1794–1854), Scottish writer and editor, was born on July 14, 1794, in the manse of Cambusnethan in Lanarkshire. He was sent to the Glasgow high school, where he showed himself clever rather than industrious. He fell into ill-health, and had to be removed from school before he was 12; but on his recovery he was sent at this early age to Glasgow university, and displayed so much precocious learning, especially in Greek, that he was offered a Snell exhibition at Oxford. He was not 14 when he entered Balliol college, where he acquired a great store of knowledge outside the regular curriculum. He read French. Italian, German and Spanish, was interested in classical and British antiquities, and became versed in heraldic and genealogical lore. In 1813 he took a first class in classics in the final schools. For two years after leaving Oxford he lived chiefly in Glasgow before settling to the study of Scottish law in Edinburgh, where he was called to the bar in 1816. A tour on the continent in 1817, when he visited Johann W. von Goethe at Weimar, was made possible by the kindness of the publisher, William Blackwood, who advanced money for a promised translation of Friedrich von Schlegel's *Lectures on the History of Literature,* which was not published until 1838. Edinburgh was then the stronghold of the Whig party, whose organ was the *Edinburgh Review,* and not until 1817 did the Scottish Tories find a means of expression in *Blackwood's Magazine.*

After a somewhat humdrum opening, *Blackwood* suddenly electrified the Edinburgh world by an outburst of brilliant criticism. John Wilson (Christopher North) and Lockhart had joined its staff in 1817. Lockhart no doubt took his share in the caustic and aggressive articles which marked the early years of *Blackwood;* but he was not responsible for the virulent articles on Samuel Taylor Coleridge and on "The Cockney School of Poetry"; *i.e.,* on Leigh Hunt, John Keats and their friends. He has been persistently accused of the later *Blackwood* article (Aug. 1818) on Keats. but he showed at any rate a real appreciation of Coleridge and William Wordsworth. He contributed to *Blackmood* many spirited translations of Spanish ballads, which in 1823 were published separately. In 1818 he met Sir Walter Scott, and the acquaintance soon ripened into an intimacy which resulted in a marriage between Lockhart and Scott's eldest daughter Sophia, in April 1820.

The Lockharts spent the winters in Edinburgh and the summers at a cottage at Chiefswood. near Abbotsford. In 1820 John Scott, the editor of the *London Magazine,* wrote a series of articles attacking the conduct of *Blackwood's Magazine,* and making Lockhart chiefly responsible for its extravagances. In a duel in 1821 between Christie and Scott. Scott was killed.

Between 1818 and 1825 Lockhart worked indefatigably. In 1819 *Peter's Letters to His Kinsfolk* appeared, and in 1822 he edited Peter Motteux's edition of *Don Qnixote,* to which he prefixed a life of Miguel Cervantes Saavedra. Four novels followed: *Valerius* (1821), *Some Passages in the Life of Adam Blair, Minister of Gospel at Cross Meikle* (1822). *Reginald Dalton* (1823) and *Matthew Wald* (1824). But his strength did not lie in novel writing. In 1825 Lockhart accepted the editorship of the *Quarterly Review,* which had been in the hands of Sir John Taylor Coleridge after William Gifford's resignation in 1824. He had established his literary position, and, as the next heir to "Milton Lockhart," the property of his unmarried half-brother. William. he was sufficiently independent, though he had abandoned the legal profession. In London he had great social success, and was recognized as a brilliant editor.

He contributed largely to the *Quarterly Review* himself, his biographical articles being especially admirable. He showed the old railing spirit in an amusing but violent article in the *Quarterly* on Alfred Tennyson's *Poems* of 1833, in which he failed to discover the mark of genius. He continued to write for *Blackwood;* he produced for *Constable's Miscellany* in 1828 what remains the most charming of the biographies of Robert Burns; and he undertook the superintendence of the series called "Murray's Family Library," which be opened in 1829 with a *History of Napoleon.*

But his *magnum opus* was the *Life of Sir Walter Scott, 7* vol., (1837–38; 2nd ed.. 10 vol., 1839). Lockhart was taxed in some quarters with ungenerous exposure of his subject, but to most minds the impression conveyed by the biography a-as, and is, quite the opposite. Thomas Carlyle did justice to many of its excellencies in a criticism contributed to the *London and Westminster Review* (1837). Lockhart's account of the transactions between Scott and the Ballantynes and Archibald Constable caused great outcry; and in the discussion that followed he showed unfortunate bitterness by his pamphlet, "The Ballantyne Humbug Handled." The *Lift? of Scott* has been called, after James Boswell's *Johnson,* the most admirable biography in the English language.

Resigning the editorship of the *Quarterly Review* in 1853, he wintered in Rome, and being taken to Abbotsford by his daughter Charlotte (Mrs. James Robert Hope-Scott), he died there on Nov. 25, 1854.

Lockhart's *Life,* 2 vol. (1897), was written by Andrew Lang. A. W. Pollard's edition of the *Life of Scott* (1900) is the best.

LOCKPORT, seat of Niagara county, in western Yew York, U.S., 25 mi. N.K.E. of Buffalo, and part of the Buffalo standard metropolitan area. The city owes its name to five double locks of the Erie canal (now part of the New York State Barge Canal system), which overcome a difference of 66 ft. between the levels of Lake Erie and the Genesee river. Abundant electric poner from Niagara falls serves diversified manufacturing interests, including pulp and paper, flour. wallboard, plastics. textiles, brooms, glass, foundry, brass and bronze products. automobile radiators and parts and sundry machine shop products. Located in the heart of the Niagara frontier fruit belt, the district is noted for its apple, peach and cherry orchards. Quarrying of limestone is also significant. In 1792–93, the Holland Land company bought the present Lockport site. and in 1816 sold most of it to Esek Brown, a local tavern proprietor. and 14 others. In 1822 the settlement was made the county seat and in the following year it became a temporary headquarters for construction on the Erie canal. Lockport was incorporated as a village in 1829 and as a city in 1865. For comparative population figures *see* table in NEW YORK: *Population.*

(A. G. SE.)

LOCKYER, SIR JOSEPH NORMAN (1836–1920), English astronomer, a pioneer in the application of the spectroscope to the sun and stars, was born at Rugby on May 17, 1836. Educated partly on the continent, He obtained a clerkship in the war office in 1857 and was appointed secretary to the royal commission on science in 1870. He became professor of astronomical physics in the Royal College of Science in 1881 and director of the Solar Physics observatory in South Kensington in 1885; he conducted eight governmental expeditions for observing total solar eclipses between 1870 and 1905.

Lockyer initiated, in 1866, the spectroscopic observations of sunspots; announced, in 1868, that the prominences were upheavals in a layer around the sun, which he named the chromosphere, and applied C. J. Doppler's principle to the sun in 1869. In 1865, Lockyer and P. J. C. Janssen, working independently, discovered a spectroscopic method of observing solar prominences without the aid of an eclipse, and to commemorate this discovery a medal bearing the names of both astronomers was struck by the French government in 1872. With the co-operation of Lady Lockyer, he built an observatory at Sidmouth where he carried out many important photographic and spectroscopic researches. He inaugurated the periodical *Nature* in 1869 and edited it until a few months before his death at Salcombe Regis. Devon, on Aug. 16, 1920. He received a Rumford medal from the Royal society in 1874 and was vice-president of the society in 1892–93. He was created knight commander of the Bath in 1897.

In addition to his many scientific papers, Lockyer wrote Stonehenge and Other British Stone Monuments Astronomically Considered (1906) and *Inorganic Evolution* (1900).

See T. M. and W. L. Lockyer, *Life* and Work *of Sir Norman Lockyer* (1928). (O. J. E.)

LOCMARIA, a village of western France, on the west shore of the Gulf of Morbihan. in the *département* of Morbihan. $8\frac{1}{2}$ mi. S. of Auray by road. Pop. (1954) 112. Locmaria has a small port, and oyster culture is carried on close to it. Roman remains are to be seen, but the place owes its fame to the very large megalithic monuments in the vicinity. A great menhir, broken into four pieces by lightning in the 18th century, measured about 67 ft. in height and from 9 to 13 ft. in thickness.

LOCOMOTION, ANIMAL. It is characteristic of animals that they can move about in search of food, foothold and mates, or away from enemies and hurtful influences; this locomotion is effected in a great variety of ways, from the seemingly simple amoeboid flowing of many one-celled animals to the complex, coordinated muscular movements of higher forms.

MANY-CELLED ANIMALS

Among multicellular animals there are four chief methods, which, following F. W. Gamble, may be illustrated by picturing a man in a boat.

Pulling. — The man may reach forward with a boat hook. fasten it to some prominence like a tree root, and pull the boat forward. This is the pulling method, and is well illustrated by leeches and starfishes. When looping along, the leech exhibits the following order: fixing its mouth and loosening the posterior sucker, it pulls its body forward, contracting its longitudinal muscles. At the end of this process the posterior sucker has been brought forward almost to touch the margin of the mouth, and the body is arched upward like a croquet hoop. Then the posterior sucker being fixed, the mouth is freed, and the body is protruded forward to a new position of attachment. This protrusion is effected by a contraction of circular and diagonal muscles. which squeeze the body forward. The mouth is re-attached, the posterior sucker is loosened, and the sequence is repeated.

Punting. — The man may stand up in the boat and use a pole as a lever, pressing it against the floor of the stream. This "punting" is one of the commonest modes of animal locomotion, being exhibited by all the animals that have firm appendages usable as levers against a base. A beetle hurrying across the roadway, a crab walking over a rock. a frog jumping among the grass, an ostrich sprinting at full speed. a man walking — all are using levers which propel the body forward by pressing against a hard surface. Sometimes there are complications, which, however, do not essentially affect the principle of the method employed. Thus the fresh-water mussel may make its flabby "foot" tense with blood, close a sphincter muscle nhich prevents backflow, and then pull the ploughsharelike organ backward against the sand. thus pushing its body forward. The foot has to be re-extended before the next step is taken. This method approaches pulling as does the locomotion of snails, chitons and slugs; these forms creep over solid surfaces by means of their fleshy foot, the muscular waves of which propel the animal along.

Sculling. — The man in the boat may stand in the stern and "scull," using a single oar to displace masses of water alternately to right and left. This is a common method among swimming animals, such as fishes and whales. In most fishes the swimming organ is that part of the body extending beyond the anus. It consists almost entirely of strong W-shaped blocks of muscle, dovetailed into one another, and centred in the flexible backbone. By alternately bending and straightening the posterior body, masses of uater are displaced, and thus the fish is propelled forward. In cetaceans (whales, dolphins, etc.) locomotion is similar, but a complication is introduced by the adaptive shape of the tail flukes. In true seals (Phocidae) the hind limbs are permanently turned backward and bound up with the short tail, forming a unified functional propeller. The principle is the same in cases like sea snakes and swimming leeches, where the gripping of the water and the using of it as a resistant mass, against which to contract, extend over the whole length of the body.

Rowing. — The man in the boat may row, the principle being the simultaneous exertion of pressure on each side. Thus the platypus rows in the water with its webbed forefeet, and the turtle with its paddles. Rowing in the air is the essence of flight in birds. bats and insects, though here part of the energy must be expended in keeping the body from sinking. Brittle stars or ophiuroids sometimes strike the sand with their posterior arms and may be said to row along the solid substratum, and in the mole's rapid turning in the ground the forelimbs are used like oars as if the animal was rowing in the ground. The insect known as the water boatman (*Notonecta*) swims back-downward in the pool, using its long third pair of legs as oars. In many birds of the auk family the wings are used as well as the feet in swimming underwater.

Other Methods. — The analogy of the man in the boat becomes somewhat forced when applied to out-of-the-way modes of animal locomotion. of which a few examples may be given. A jellyfish swims by alternately expanding and contracting the disclike or bell-like body. The rapid contraction drives the water out from the mouth of the bell, and the medusa is propelled in the opposite direction. Cuttlefishes expand their mantle cavity, and having filled it with water proceed to close it by a hook-and-eye contrivance, so that the water cannot leave by the way it entered, but is forced, as the cavity contracts, through a narrow funnel. As the jet comes out with considerable strength, the body is driven rapidly through the water, with the head and tentacles extended in the wash. The same method of propulsion by a posterior outgush of water is seen in larval dragonflies. Somewhat unusual, again, is the way in which lobsters jerk themselves tail-foremost in the water by suddenly flexing the posterior body (abdomen) forward and downuard. This displaces a mass of water toward the head. On occasion the common scallop (Pecten) can jerk itself off the sea floor with an energetic snap of its shell valves, and continue swimming thus for some time.

In some ways the strangest mode of animal locomotion is exhibited by the common sea urchin (Echinus) on a firm flat surface. This animal habitually moves by means of its tube feet, and also utilizes its spines, which are swayed on ball-and-socket joints by basal muscles. But Echinus is also able to tumble along on the tips of the five teeth of its chewing apparatus (Aristotle's lantern) which project out of the mouth. The lantern can be swayed from side to side by powerful muscles, and the locomotion is a stumbling along on the tips of the teeth. The sea urchin's track shows at short intervals the indentations of the teeth, and marks of spines in between.

Mechanisms of Locomotion. — The movements of most multicellular animals are effected by muscles, and there is an important distinction between the unstriped or smooth muscle of sluggish animals, such as tapeworms, and the striped or striated muscle of ordinary active animals (see MUSCLE AND MUSCULAR SYSTEM). The most important general fact is that unstriped muscles contract slowly, and are therefore found in sluggish animals, and in the slowly moving parts of active animals, as the walls of the food canal and arteries. Apart from these and similar exceptions, the muscle fibres in active animals are cross-striped and quickly contracting. Some of the lower animals such as turbellarian and nemertean worms are covered with cilia, fine hairlike projections (see CILIA) which assist in locomotion; but above the level of these two classes cilia cease to be locomotor except in larval forms, like the trochospheres of marine annelids and mollusks and in newly hatched tadpoles. Starfishes and some other echinoderms are richly provided with external cilia, but these are used for wafting food particles, not for locomotion. Above nemerteans cilia become of great internal importance, for they may line a windpipe, an excretory tube, a female genital duct and so forth. Myonemes are contractile plasmic threads, anticipations of muscle fibres, but intracellular. An instance of their occurrence is the axial filament inside the noncontractile sheath of the stalk of the bellanimalcule (Vorticella).

See F. W. Gamble, *Animal Life* (1908). (J. A. TH.; X.)

VERTEBRATES

Except for primitive kinds of animals that wait for food to come to them, it is necessary for all animals to move in search of nourishment and to escape from enemies. Hence, locomotion has perhaps been the largest single factor in the progressive evolution of the bodily form of vertebrates, if not of all active animals. In simplest terms, as in the amoeba, locomotion is merely the shifting of the centre of gravity; and this involves only a horizontal factor. In the vast majority of cases, however, there is concerned also a vertical factor, for elevating the body above the surface, and this brings in equilibrium. There can be no effective locomotion without balance. Vertebrates employ two main methods for movement. One is the wriggling of the body through the environment, and the other is by means of limbs. The latter is accomplished by the swing of the limb about the hip or shoulder as a hub, to move the foot forward, and then the limb is swung from the foot to move the body forward. The principles are simple, but friction of moving parts, physiology of nerve and muscle, bodily form and constitution introduce a vast complexity to the subject.

In Water.—Aquatic locomotion of vertebrates is accomplished either by undulations of the body or action of the limbs. Speedy fish, salamanders and lizards undulate the body in a series of curves in the horizontal plane. As the centre of gravity is in the forward half of the body—or rather of the total length—the lashing of the usually flattened tail thrusts obliquely backward against the water and drives the animal forward. Fish do not swim rapidly with their paired fins but use these for stabilizers or for slow, creeping movements. There are two sorts of limb movements used by quadrupedal mammals and birds when swimming. One employs a direct thrust against the water, as in rowing, used by surface swimming birds and terrestrial mammals, and is inefficient. The other employs an oblique thrust, as in sculling with a single oar or in the screw of a steamer. It is a much more efficient method but is evolved from the other and is used by almost all birds when swimming underwater, by the forelimbs of sea lions and the hind limbs of hair seals and walruses. High adaptation for swimming involves a fusiform or cigar-shaped body, with centre of gravity forward of the middle; flattening and broadening of the tail vertically in fish and reptiles (ichthyosaurs) and horizontally in mammals (sirenians, cetaceans) and eventual disappearance of the external part of the hind limbs.

On Land.—Terrestrial locomotion is of many kinds, but for practical purposes these may be divided into movements by means chiefly of the body, chiefly of four limbs and chiefly of two limbs. Movement by means of body action is illustrated in lizards or salamanders with reduced limbs, and in snakes, and involves what may be termed swimming on land, where the resistance of the water is replaced by inequalities of the surface against which the curves of the body may thrust. Thus, a snake glides through grass or climbs a bush. A snake can travel only inefficiently over a smooth surface; but some snakes are able, in varying degree, to assist locomotion by action of their ventral scales, which are alternately slightly raised and lowered by muscular action. Vertebrates with large bodies and small limbs progress chiefly by throwing the body from side to side, thus advancing first one of a pair of limbs and then the other. In these, locomotion still is chiefly by the trunk and its muscles.

Development and Use of Limbs.—As the limbs develop in size and power, they take over an increasing proportion of the function of locomotion and the contortions of the trunk are reduced. In primitive limbed vertebrates, the body rests upon the ground when not in movement, the leg action is laboured, the legs are directed to the side and have a somewhat circular motion. Typically, diagonal limbs are used together, so that the animal actually trots, in slow or fast tempo. As locomotor facility evolves, the limbs operate increasingly in the fore-and-aft plane, the limb segments are straightened so that the animal has its feet more beneath the centre of gravity and the body is held above the ground when at rest. In speedy vertebrates, every weighty part of the body contributes to the dynamics of locomotion, in balancing, counterbalancing and shifting the centre of gravity. In heavy-tailed animals (most dinosaurs, kangaroos) the conformation of the tail is determined mainly by locomotional needs. Length of neck is determined mostly by feeding habits in connection with length of leg, but weight of head and length of neck together have a very strong effect upon gait, as also has length of body.

Gaits *of Four-footed* Animals.—Gaits of quadrupeds may most conveniently be divided into symmetrical and asymmetrical gaits, and the former again subdivided into those in which each foot is placed separately and in which the feet are placed in pairs. In the walk, each foot of a quadruped is placed at regular time intervals. In typical sequence the advancement of a front foot is followed by the diagonal hind foot, and then the other front foot. The tempo may be so slow that three feet are always on the ground, or so fast that in some phases only a single foot is on the ground at a time. The latter gait is then termed the running walk, or single-foot. It is not quite so speedy as the trot or pace and few animals adopt it naturally, without training, except the elephant, whose only speedy gait it is. The centre of gravity is shifted with each footfall, or four times in each cycle; so, at speed, this is a tiring gait.

There are two different symmetrical gaits in which the feet are placed in pairs. When diagonal feet are so placed, this is termed the trot; and, when laterals, the pace or amble. At slow tempo, in which two feet are always on the ground, the former is used by sluggish or clumsy animals, particularly of broad beam, like heavy lizards, tortoises and badgers. At speed, during which there is an interval of suspension, with no feet on the ground, it is the intermediate gait (between walk and gallop) favoured by most sizable mammals, for the reason that it involves the least shifting of the centre of gravity and so is the least fatiguing, at a given rate of travel. It is also favoured at top speed by certain mammals that have very heavy antlers or necks too short to swing properly with the rhythm of their gallop, like bull moose and caribou.

In the pace, the lateral limbs, of first one side and then the other, are used in unison. In successive steps the centre of gravity must therefore be shifted from side to side, and this it is inconvenient to do at slow tempo. Accordingly, no animal is known to employ this gait in walking. At a faster tempo it is employed by some dogs (most often setters) and camels; occasional horses take to it naturally. Any trotting horse may be taught to pace by means of a harness and it is thought by some to be a shade faster than the trot. It has the advantage of escaping interference by the hind with the forefeet but seems to be more tiring.

The only asymmetrical gait is the gallop, and by this method the great majority of mammals travel at their greatest rate. This gait is characterized by unevenness of the interval between footfalls, of the support pattern and of the shifts in the centre of gravity. There is typically but one period of body suspension during each cycle. In short, all details of this gait are grouped in sequential phases. The fact that the gallop is the fastest gait in most mammals fitted for rapid progression is due to a combination of circumstances: in each cycle there is a single summation of effort and a single recovery, thus allowing time for a rhythmic swing of every part of the body, which the symmetrical gaits do not afford;

the body is bent and extended in the vertical plane, adding to the strength of the limb effort; a head of considerable weight and neck of considerable length help by swinging back and forth; hind legs act together, or in close sequence, to give the animal a forward thrust; the forelegs are used to keep the body from falling, to thrust it upward in preparation for the following cycle and to a minor extent to assist the forward motion. The lope or canter is largely an artificially induced slow gallop, for the comfort of the rider. The footfall sequence in the gallop varies to a great degree with the speed or kind of animal. In most typical patterns, one hind foot (either) is followed by the other, widely spaced, and then either by the diagonal (transverse gallop) or the ipselateral (lateral gallop) forefoot, the other forefoot following. A galloping horse may lead with either front foot or change from one to the other, probably to rest its muscles. Horses, as well as rhinoceroses, goats, sheep, cattle, camels and cats, seem to prefer the transverse gallop, while the lateral gallop is favoured by dogs, deer, antelope and giraffe. The interval of total suspension of the horse is after the second forefootfall; of the deer, after the second hind footfall, while in the whippet both occur. Very active mammals with short legs or long, limber bodies gallop with the hind legs close together or even employ them as a unit to accomplish the half bound or the bound; but so far as known, the forefeet are always used separately. Mention should be made of the peculiar gait of the mule deer, which at speed spurns the ground with all four feet in unison, a most effective gait for mounting steep hills.

The kinds of animals that are adapted to rapid quadrupedal locomotion are so numerous that it is impossible in a sentence or two to describe the anatomical details correlative thereto. In general there is a lengthening of the limbs and lightening of their terminal portions. The lower leg and forearm are lengthened relative to the thigh and upper arm, and finally the metacarpals and metatarsals become much elongated and reduced in number, while toe walking and finally a hoofed posture is assumed. As the legs become longer, the neck must keep pace in grazing kinds, and this development is of the greatest assistance to speed. Cursorial mammals lacking a long neck may be recompensed by having a very limber back.

Gaits of Two-footed Animals.—Bipedal gaits comprise the two-time walk and run, using the hind feet alternately, and the one-time hop or leap, the latter termed saltatorial progression. Both are very specialized modes of locomotion. The former is evolved from the trot and is attributable to the developmental ascendancy of the hind legs over the forelegs, or the specialization of the latter for other purposes, as in gibbons and birds. This is illustrated by some speedy lizards with large hind legs, as the basilisk. When progressing at low speed the latter is quadrupedal, but at high speed the forelegs are too small to equal the stride of the longer pair, and the animal rises upon its hind legs. This probably was also the explanation of bipedalism in dinosaurs. A long or heavy tail, for balance, is a decided advantage in the development of this type of locomotion. The case of man is somewhat different, and he developed bipedalism despite the absence of a tail. Man is an enigma in many respects. In spite of his long legs he is not specialized cursorily and is a very poor runner for his size. Doubtless his bipedalism was greatly helped, if not determined, by the way in which his ancestors used the arms for purposes other than progression, as for holding tools and carrying objects, as many other primates may be observed to do in lesser degree. Most bipedal dinosaurs had long tails for balancing, and rather short necks, while the true tails of birds are practically absent, and they rely upon the back and forth action of their long necks for equilibrium when walking. At speed, cursorial birds are prone to spread their wings for balance.

The bipedal hop or ricochet, using both feet in unison, may have been developed in two ways: by the ancestors of birds, hopping from branch to branch, and by small mammals that used this method for passing over low plant growth in their path, as deer mice may be observed to do. The gait that is most comfortable is the one favoured by an animal. It is doubtful whether an animal weighing more than a few pounds would adopt the bipedal hop, but after the gait had once become established in the behaviour pattern it could be retained during an increase in bodily size. In moderate development it is probably more advantageous for dodging than for actual speed. In high specialization it involves great elongation of the hind legs, particularly a relative increase in the terminal segments and reduction in the number of digits.

At the same time a compensating reduction in the length of the forelimbs takes place.

A short neck and a long tail, usually with a terminal tuft of hair in the case of rodents, is of advantage. It is true that frogs have no tail, but they are fitted for a single mighty leap into a place of refuge, or for erratic hopping about without proper balance to attain real linear speed.

Other Modes of Locomotion.—Brachiation, or swinging from limb to limb by the arms, is a method of locomotion followed by gibbons, orangutans, chimpanzees and in modified form by the spider monkey. The most expert of these is the gibbon. Brachiators have very long arms, long fingers and small thumbs.

Climbing, or scansorial locomotion, is done by many amphibians, reptiles and mammals but involves no special gaits or pronounced modifications.

Gliding is followed by flying squirrels of dissimilar relationships in North America, Africa and Asia; by Australian flying phalangers and by Asiatic flying lemurs, by means of membranes stretching between their widely spread limbs and assisted by a furry, flattened tail. They can thus travel in a descending line from one tree to another.

True *flight* is possible only in the extinct pterodactyls, in birds and in bats (see FLIGHT [NATURAL]).

ONE-CELLED ANIMALS

Among unicellular organisms locomotion is effected by flagella, by cilia, by myonemes and in an amoeboid fashion. Each flagellum or cilium is a thread of protoplasm, sometimes with an axial filament. It is alternately flexed and straightened, as one might bend one's arm at the elbow and elongate it again. It is interesting to notice that among multicellular animals also cilia are very common, from the lowest to the highest, except in nematodes and arthropods, where the abundant chitin apparently precludes their development.

Amoeboid movement, probably the most primitive mode of animal locomotion, has been much studied; but it is difficult to form a clear picture of what happens. An ordinary amoeba, a naked blob of living matter, protrudes blunt fingerlike processes and draws others in, continually altering its shape but not its volume. It glides along at the rate of about three-quarters of an inch an hour. It is probably in some way gripping the substratum by a very delicate external plasma-membrane, which is continually giving way anteriorly, and being reinstated posteriorly. This film is the seat of surface-tension effects, and the tension seems to increase anteriorly and decrease posteriorly. But attentive scrutiny shows that the amoeba is rather rolling than gliding. For a definitely recognizable particle may be seen moving along the upper surface of the cell, in the direction in which the amoeba is moving, then disappearing over the front, and, after a while, re-appearing at the posterior end; and so da capo, as if there were a "caterpillar-wheel"-like movement. Moreover, there is a deeper protoplasmic streaming, connected with intricate physical and chemical changes. There are indications of rapid changes of the protoplasm from "sol" to "gel" states and back again (see PROTOPLASM and PROTOZOA). It is very interesting to notice that this most primitive mode of locomotion is retained in varied expression even in higher animals; *e.g.,* in the outgrowing tip of embryonic nerve cells and in the excursions of phagocytes.

For a more complete discussion on locomotion among the Protozoa see L. H. Hyman, *The* Invertebrates: Protozoa Through Ctenophora, vol. 1 (1940). (J. A. TH.; X.)

LOCOMOTOR ATAXIA (synonyms, tabes *dorsalis,* syphilitic posterior spinal sclerosis), a progressive degeneration of the nervous system, caused by syphilis, involving the posterior columns of the spinal cord with other structures and causing muscular inco-ordination and disorder of gait and station. The essential symptoms—stamping gait, and swaying with the eyes shut, the occurrence of blindness and of small fixed pupils—were recognized by M. H. Romberg (1851), but it was the clinical genius of G. Duchenne and his masterly description of the symptoms which led to its acceptance as a definite disease (1858); he named it locomotor ataxia after its most striking symptom. In 1869 Argyll Robertson discovered that the eye pupil is inactive to light but acts upon accommodation in the great majority of cases. This most important sign is named the Argyll Robertson pupil. With a greater knowledge of the widespread character of this disease and its manifold variations in the complex of symptoms, the tendency among neurologists is to revert to the term employed by Romberg—tubes dorsalis. "Locomotor ataxia," although it expresses a characteristic feature of the disease. has this objection: it is a symptom which does not occur in the first (preataxic) stage of the disease; indeed many years may elapse before ataxia comes on, and sometimes the patient, after suffering long from the disease, may die from an iritercurrent complication, without being ataxic.

There are three stages: (1) the preataxic, (2) the ataxic and (3) the bedridden paralytic. The duration of the first stage may be from one or two years, up to 20 years or even longer. In this stage various symptoms may arise. The patient usually complains of shooting, lightninglike pains in the legs, which he may attribute to rheumatism. If a physician examines him he will almost certainly find the knee jerks absent and Argyll Robertson pupils present; probably on enquiry he will ascertain that the patient has had some incontinence or retention of urine. In other cases, temporary or permanent paralysis of one or more muscles of the eyeball (which causes squint and double vision), a failure of sight ending in blindness, attacks of vomiting (or gastric crises). painless spontaneous fractures of bones and dislocations of joints, failing sexual power and impotence, may lead the patient to consult a physician, when this disease will be diagnosed, although the patient may not as yet have had locomotor ataxia. All patients, however, if they live long enough, pass into the second ataxic stage. The sufferer complains of difficulty of walking in the dark; he sways with his eyes shut and feels as if he would fall (Romberg's symptom) ; he has the sensation of walking on wool, numbness and formication of the skin, and many sensory disturbances in the form of partial or complete loss of sensibility to pain, touch and temperature. These disturbances affect especially the feet and legs, and around the trunk at the level of the fourth to the seventh ribs, giving rise to a "girdle sensation." There may be a numbed feeling on the inner side of the arm, and muscular inco-ordination may affect the upper limb as weil as the lower, although there is no wasting or any electrical change. The ataxic gait is characteristic, owing to the loss of reflex tonus in the muscles, and the absence of guiding sensations from all the deep stxuctures of the limbs. muscles, joints, bones, tendons and ligaments, as well as from the skin of the soles of the feet; therefore the sufferer has to be guided by vision as to where and how to place his feet This necessitates the bending forward of the body, extension of the knees and broadening of the basis of support; he generally uses a walking stick or even two, and he jerks the leg forward as if he were on wires, bringing the sole of the foot down on the ground with a nide stamping action. If the arm be affected, he is unable to touch the tip of his nose with the eyes shut. Sooner or later he passes into the third. bedridden stage, with muscles wasted and their tonus so much lost that he is perfectly helpless.

The complications which may arise are intercurrent affections due to septic conditions of the bladder, bedsores, pneumonia, vascular and heart affections. About 10% of the cases, at least, develop general paralysis of the insane. This is not surprising seeing that it is due to the same cause, and the etiology of the two diseases is such as to lead many neurologists to consider them one and the same disease affecting different parts of the nervous system. *Tabes dorsalis* occurs with much greater frequency in men than in women. (See VENEREAL DISEASES.)

Its incidence became much rarer because of the great improvement in the treatment of early syphilis and the increase in public knowledge of proper prophylaxis.

LOCOWEED, certain North American species of the genera Astragalus and Oxytropis of the Leguminosae (pea family), found mainly in arid and semiarid regions of the western and southwestern United States, which when ingested cause a cattle disease called loco ("mad"). Animals so poisoned stagger and become stuporous. The toxic properties may result from selenium absorption by the plant (some Astragalus species), or an unknown intrinsic alkaloid (in certain Oxytropis species). Some Astragalus species also produce a poison which does not induce true locoism. Wholesale eradication appears to be impossible, but individual plants may be killed chemically.

LOCRI, a people of ancient Greece (Gr. Λοκροί), inhabiting two distinct districts, one extending from the northeast of Parnassus to the northern half of the Euboean channel, between Boeotia and Malis, the other southwest of Parnassus, on the north shore of the Corinthian gulf, between Phocis and Aetolia. The former were divided into the northern Locri Epicnemidii, situated on the spurs of Mt. Cnemis, and the southern Locri Opuntii, so named from their chief town Opus. Homer mentions only these eastern Locrians; their national hero in the Trojan War is Ajax Oileus, who often appears afterward on Locrian coins. The Opuntians were thought by some to be of "Lelegian" origin (see LELEGES), but they were Hellenized early (though matriarchal customs survived among them). The westerly Locri "in Ozolae" on the Corinthian gulf, a rude and barbarous people, make no appearance in Greek history till the Peloponnesian War. The Locrian dialect resembles that of Elis. A colony of Locrians settled, about the end of the 8th century B.C., at the southwest extremity of Italy. Their founder was Euanthes. See LOCRI below.

LOCRI, an ancient city of Magna Graecia, Italy. The original inhabitants were, it has recently been ascertained, of Sicilian race (MacIver, Iron Age, 210). They occupied the Zephyrian promontory (Capo Bruzzano some 12 mi. N. of Capo Spartivento), and though after three or four years they moved 12 mi. north, still near the coast, 2 mi. S. of Gerace Marina below the modern Gerace, they still retained the name of Locri Epizephyrii to distinguish them from the Ozolian and Opuntian Locri of Greece itself. The foundation of Locri goes back to about 683 B.C. It was the first Greek community to have a written code of laws given by Zaleucus in 664 B.C. From Locri were founded the colonies of Meisma and Hipponium. It repelled the attacks of Croton and found support in Syracuse against Rhegium: it was thus an active adversary of Athenian aggrandisement. Pindar extolls it in the 10th and 11th Olympian odes. Stesichorus (*q.v.*) was indeed of Locrian origin. Dionysius I of Syracuse selected his wife from Locri: its territory was then increased, and the circuit of its walls was doubled, but it lost its freedom. In 356 B.C. it was ruled by Dionysius II. From the battle of Heraclea to the year 205 (when it was captured by P. Cornelius Scipio Africanus Maior, and placed under the control of his legate Q. Pleminius), Locri was continually changing allegiance between Rome and her enemies; but it remained an ally. It was destroyed by the Saracens in 915.

Excavations in 1889–90 discovered an Ionic temple (the Doric style being usual in Magna Graecia) at the northwest angle of the town—originally a cella with two naves, a closed pronaos on the east and an adytum at the west, later converted into a hexastyle peripteral temple with 34 painted terra cotta columns. This was destroyed about 400 B.C. and a new temple built on the ruins, heptastyle peripteral, with no intermediate columns in the cella and opisthodomos, and with 44 columns in all. The figures from the pediment of the twin Dioscuri, who according to the legend assisted Locri against Crotona, are in the Naples museum. The environs yielded many archaic terra cottas, and large trenches, covered with tiles, contained some 14,000 scyphoi arranged in rows. A Doric temple was also cleared under the house called Casa Marafioti: the fine equestrian group in terra cotta from the western gable is, with other objects from Locri, in the museum at

Syracuse. There was also a sanctuary of Persephone from which came numerous votive tablets of the 5th century B.C. Much work has also been done in cemeteries, most of the tombs belonging to the 5th and 4th centuries, though the earliest are pre-Hellenic (9th–7th centuries).

The city walls. the length of-which was nearly 5 mi., consisted of three parts—the fortified castles (φρούρα) with large towers, on three different hills, the city proper, and the lower town—the latter enclosed by long walls running down to the sea. Under Rome, the city was restricted to the plain near the sea. Prehistoric objects confirm the accounts of Thucydides and Polybius that the Greek settlers were preceded by Siculi.

See Orsi in *Notizie degli* Scavi (1901–17). (T. A.)

LOCUS, a term used in geometry with the meaning suggested by the Latin *locus,* place. In plane geometry it is the curve (including a straight line) which contains all points in the plane that satisfy a given condition, and which contains no points that do not satisfy the given condition; *e.g.,* in a plane the locus of a point at a given distance from a fixed point is the circle of which the fixed point is the centre and the given distance is the length of the radius. The term is also applied to figures in space of three dimensions, the locus corresponding to the circle being a sphere (considered as a surface). The locus is then a curve surface. The finding of the locus of an equation, or inversely, is a basic problem of analytic geometry (*q.v.*). Among the loci there considered are the conic sections (*q.v.*). The term is readily extended to higher dimensions.

LOCUST, any of certain insects of the family Acrididae (see ORTHOPTERA) which at times multiply greatly and migrate long distances in destructive swarms. In Europe, the term "locust" connotes large size; smaller acridids are called grasshoppers (*q.v.*). In North America "locust" and "grasshopper" are used for any acridid. Unfortunately cicadas (order Hemiptera) are also called locusts or harvest locusts; the 17-year locust is the periodical cicada.

The Phases of Locusts.—In 1921 B. P. Uvarov satisfactorily explained for the first time the sporadic coming of locust swarms and the apparent disappearance of the insects between times by the phase theory, later substantiated and elaborated by many workers. Each plague species exists in two phases, solitary and gregarious, connected by transitional forms. The extreme phases differ in coloration, form, physiology and behaviour. Solitary phase nymphs vary in colour and pattern, adjust their colour to

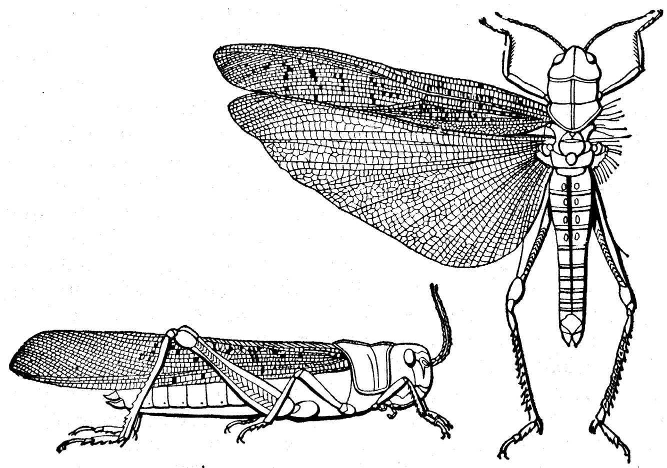

FIG. 1.—LOCUSTA MIGRATORIA IN ITS MIGRATORY PHASE

This insect is one of the chief locusts of the old world and in this phase causes great destruction to crops and other vegetation

match that of their surroundings, do not congregate, have low metabolic and oxygen-intake rates and are sluggish. Gregarious phase nymphs have a black and yellow (orange) coloration of fixed pattern, are gregarious, have high metabolic and oxygen-intake rates and are active and nervous; their temperature is higher because their dark pigments absorb more radiation. Adults differ less in colour, but often notably in form. The solitary phase has shorter wings, longer legs, narrower pronotum with higher crest and larger head; the gregarious phase has a more saddle-shaped pronotum with broader shoulders and long, ample wings.

Progeny of the solitary phase, reared in crowds, change toward the gregarious type; and if the crowding is of sufficient degree and duration, the extreme of the gregarious migratory phase is produced. Progeny of the gregarious phase, reared in isolation, revert to the solitary phase. By rearing single nymphs in constantly agitated cages J. C. Faure (1932) showed that the effects of crowding result from the unceasing activity it induces. The solitary phase is the normal state of the species, while the gregarious phase is a physiological response to violent fluctuations in the environment. Within the territory of each species its solitary phase exists at all times and in a wide variety of oecological conditions. Swarms do not form in the regions most favourable to the species, but in marginal areas where suitable habitats are restricted and climatic balance is delicate. Here a succession of

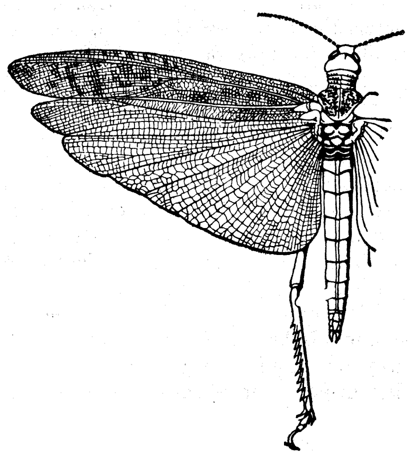

FIG. 2.—OLD WORLD LOCUST (SCHISTOCERCA GREGARIA)

favourable seasons enables the restricted populations to expand into adjoining areas, but return of unfavourable conditions forces the enlarged populations back into the small permanently habitable areas and crowding results. The exact circumstances vary with the species and region. Thus the outbreak areas of *Locusta* migratoria are of four oecological types: (1) deltas of rivers entering the Caspian and Aral seas and Lake Balkash (and similar situations in China and Africa), surrounded by arid sandy tracts; here the extent of the grassland habitat of the locust changes greatly as a result of irregularities of floods; (2) grassland areas adjoining deserts, subject to extreme fluctuations in precipitation with corresponding changes in extent of habitable area; (3) islands of dry warm soil in central Russia, a region generally too cold and wet for the species; there overcrowding occurs after several exceptionally warm dry years; (4) grasslands produced by periodic burning in the unfavourable, humid, tropical forestlands of the Philippines; their extent varies greatly, leading to frequent overcrowding and production of the gregarious phase.

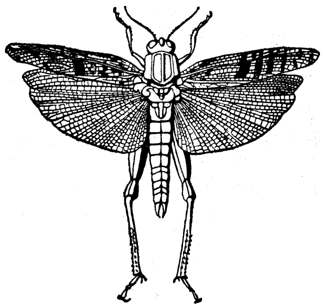

FIG. 3.—CALLIPTAMUS ITALICUS, COMMON IN SOUTHERN EUROPE

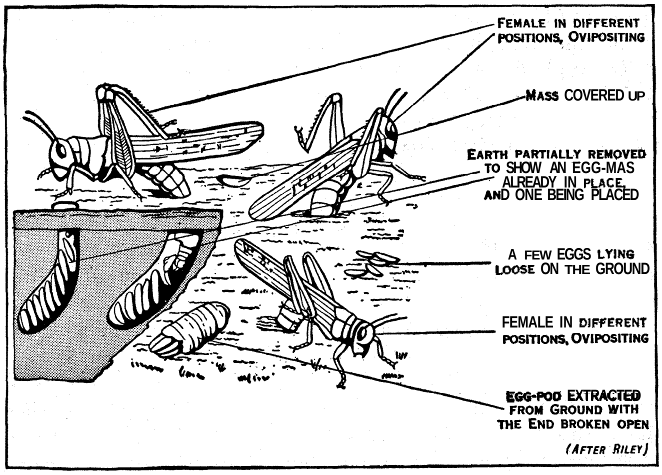
Locusts of the gregarious phase are restless and irritable; the bands of nymphs wander, and adult swarms take flight spontaneously on warm dry days when their body temperature is high. The muscular activity of flight further raises their temperature, and a swarm can therefore cease flying only when conditions change. Rain, a drop in temperature or nightfall will usually stop a flight. The distances travelled may be great; swarms have been seen 1,200 mi. at sea and *Schistocerca gregaria* reached England in 1869, probably from west Africa. The flights are not purposive and often end in destruction of the swarm. Some swarms are very large; a flight of the desert locust across the Red sea in 1889 was estimated as 2,000 sq.mi. in extent. The gregarious instinct is strong, and swarms remain compact even when reduced to small size by high mortality; they are dispersed, with resultant transformation into the solitary phase, only by storms and other external factors.

Important Species.—The migratory locust *(Locusta migratoria,* with its races *rossica, migratoria, migratorioides, capito* and *manilensis)* has a wider range than any other acridid. It is found in grasslands throughout Africa. most of Eurasia south of the Taiga forest, the East Indies, tropical Australia, and New Zealand. The desert locust *(Schistocerca gregaria)* inhabits dry grasslands and deserts from Africa to the Punjab. Its swarms arrive during the summer monsoons in India; in autumn they migrate to Iran and Arabia with others from Africa, and thence spread to soviet Asia, Syria, Palestine and Egypt. In late fall some return to India and East Africa, where breeding occurs during the next monsoon rains. The smaller Italian and Moroccan locusts *(Calliptamus italicus* and *Dociostaurus maroccanus)* do much injury in the Mediterranean area; the second is found discontinuously east to Turkestan. In South Africa the brown and red locusts *(Locustana pardalina* and *Nomadacris septemfasciata)* are both very destructive. In Central and South America the chief migratory species is the South American locust *(Schistocerca paranensis)*, of which the nonmigratory *S. americana* of the United States may possibly be the solitary phase. The Rocky mountain locust or lesser migra-



BY COURTESY OF THE U.S. DEPT. OF AGRICULTURE

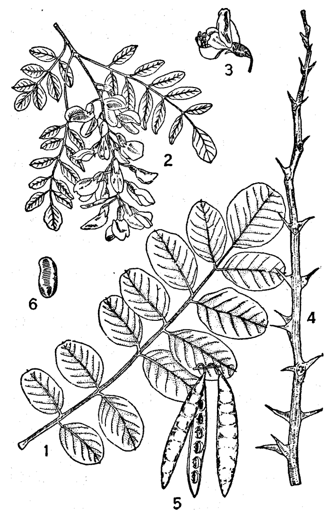
FIG. 4.—ROCKY MOUNTAIN LOCUST (MELANOPLUS SPRETUS)

tory grasshopper (*Melanoplus mexicanus* phase *spretus*) wreaked havoc on the prairie farms of Canada and the United States in the 1870s, but later disappeared; it is probably the gregarious phase of the common and widespread *M. mexicanus* (*atlanis*), which is, with the clear-winged grasshopper (*Camnula pellucida),* a major crop pest in North America. Many other species of Acrididae in different regions occasionally increase to plague proportions, but few of them compare in economic importance with those named above.

Control Measures.—Once well started, a locust plague is almost impossible to check, and only palliative measures can be taken. These have included destruction of egg-masses laid by invading swarms (1,300 tons were destroyed in Cyprus in 1881), trenches to trap the nymphs, hopperdozers (wheeled screens, upon striking which locusts fall into troughs containing water and kerosene), poison baits and aeroplane dusting of swarms and breeding grounds with insecticides. The control problem is made difficult by the great extent of the territory affected, with many invasions beginning in sparsely populated, undeveloped regions. Permanent control requires both national and international action. It is possible because locust swarms do not arise simultaneously over wide regions, but in a few localized outbreak areas, many of which are known. From 1930–38 five International Locust conferences were held. In 1932 the Anti-Locust Research centre was set up in London; it directed international surveys and field studies and, during World War II, large-scale campaigns in Africa and Asia against the desert locust. Warnings were given of incipient outbreaks and swarm movements, and control measures were planned and supervised. Ultimately many outbreak areas may be made oecologically unsuitable for production of the gregarious phase, when the oecology and behaviour of each plague species are better known.

Faure, *Bulletin of Entomological Research* (vol. 23, 1932); A. D. Imms, *Entomological News* (vol. 55, No. 7, 1944); also works on Orthoptera (*q.v.*). (T. H. HL.)

LOCUST, any tree of the genus *Robinia,* which comprises about 15 species native to North America and Central America, belonging to the family Leguminosae. The best-known species (*R. pseudoacacia*) was introduced into Europe in 1636. This tree, the black locust, often erroneously called acacia, is widely cultivated as an ornamental tree. It grows from 30 to 60 ft. high, and bears long, graceful compound leaves with 9 to 17 bright-green oblong leaflets, and white fragrant flowers in loose pendulous racemes, recalling the laburnum. There are many varieties, varying in the method of growth, the presence or absence of thorns (persistent spinose stipules) on the branches and the colour of the flower.



FROM HARRAR, "GUIDE TO SOUTHERN TREES" (MCGRAW-HILL BOOK COMPANY, INC.)

BLACK LOCUST

1. Leaf. 2. Cluster of flowers. 3. Individual flower, enlarged. 4. Twig. 5. Fruit. 6. Seed

In the eastern United States, where it is native, the black locust may have a trunk three or four feet in diameter. It is a valuable timber tree, the wood being heavy, hard, strong, close-grained and durable.

The clammy locust (*R. viscosa*), a tree sometimes 40 ft. high, with pinkish flowers, and the rose acacia or bristly locust (*R. hispida*), a small shrub, with showy rose-coloured flowers and hispid twigs, both native to the southeastern United States, are also cultivated for ornament.

The shipmast locust, a variety of black locust, is used extensively in reforestation projects, and as a good street tree resistant to dust, wind and smoke. The honey locust (*q.v.*) is a different genus of leguminous tree, *Gleditsia.* (N. TR.; X.)

LÓCZY, LAJOS (1849–1920), Hungarian geologist. who first scientifically described the mountains that connect the Kuen-Lun chains with the northeast Indian chains behind the Red basin of Szechwan. Born at Pressburg (Bratislava) on Nov. 2. 1849. he studied at the Zürich polytechnic, obtaining his engineer's diploma in 1874, and from 1877 to 1880 traveled through India and China as geologist to the expedition of Count Bela Széchenyi which he described in his principal work (1890). In 1886 he became professor of geology at the University of Budapest, and in 1908 director of the Hungarian Geological institute. He completed geological researches in China, in Hungary and, during World War I, in Serbia. His researches concerning the steppe formations of the Gobi and the northern Hwang-Ho territory are also of great importance. His other important work is a monograph on the Hungarian lake Balaton, in which the formations of the region are explained. His posthumous works include a new geological map of pre-World War I Hungary, and a book on the geology of west Serbia, which revolutionized the geological map of Serbia. He died at Balatonaracs on May 13, 1920.

LODER, BERNARD CORNELIUS JOHANNES (1849–1935), Dutch jurist. From 1873 to 1908 Loder practised as a lawyer in Rotterdam and from 1908 to 1921 was a judge of the high court of justice of the Netherlands. In 1905, 1909, 1910 and 1922 he represented the Netherlands at the diplomatic Sea conferences at Brussels. He presided at the conference of the Scandinavian kingdoms, Switzerland and the Netherlands, held in 1920. The Permanent Court of International Justice at The Hague appointed him its first president in 1922 and he retained this position until early in 1925.

LODGE, EDMUND (1756–1839), English writer on heraldry, was born in London on June 13, 1756, son of Edmund Lodge, rector of Carshalton, Surrey. He held a cornet's commission in the army, from which he resigned in 1773. In 1782 he became Blue Mantle pursuivant at arms in the College of Arms. He subsequently became Lancaster herald, Norroy king-at-arms, Clarencieux king-at-arms, and, in 1832, knight of the order of the Guelphs of Hanover.

He died in London on Jan. 16, 1839. He contributed the literary matter to *Portraits of Illustrious Personages of Great Britain* (1814, etc.). known familiarly as "Lodge's Portraits." His chief work on heraldry was *The Genealogy of the existing British Peerage* . . . (1832; enlarged ed., 1859).

LODGE, HENRY CABOT (1850–1924), U.S. statesman and author, was born in Boston, Mass., on May 12, 1850. He graduated from Harvard college in 1871 and the Harvard Law school in 1875; was admitted to the Suffolk (Mass.) bar in 1876; and from 1876–79 was instructor in American history at Harvard. He was a member of the Massachusetts house of representatives in 1880–81, and of the national house of representatives from 1887–93. In 1893 he was elected U.S. senator from Massachusetts, a place he continued to hold for nearly 32 years.

His continuous service in the senate brought recognition during the closing years of the Roosevelt administration and under Taft as one of the most prominent of the Republican leaders. He was a member of the Alaskan Boundary Commission of 1903, and of the U.S. Immigration Commission of 1907. He served as permanent chairman of the Republican national conventions of 1900, 1908 and 1920. During the Republican-Progressive split which led to the election of Woodrow Wilson in 1912, Lodge maintained his personal friendship with Roosevelt, while he held true to his long-established principles of party regularity by supporting Taft, the Republican nominee.

In 1914 Lodge supported Wilson's demand for the repeal of the Panama tolls exemption, but lost confidence in him as a result of the president's handling of the Mexican problem in 1914, and thereafter became one of his principal critics. He opposed Wilson's Caribbean policy and Colombia treaty, and desired the entrance of his country into World War I after the sinking of the "Lusitania." In Jan. 1916 he offered a resolution calling for armed intervention in Mexico.

With the entrance of the United States into World War I, Lodge called for united support of the president in all policies that might increase the war effort of the United States, although he opposed the Overman act, designed to organize war-making agencies. Wilson's peace policies were another matter. In 1915 and 1916 Lodge had advocated a league of nations and the principle of compulsory arbitration. But the conviction that the United States must always keep its word, which had led Lodge to support President Wilson's demand for the repeal of the Panama Canal tolls exemption in 1914, led him to oppose President Wilson's draft of the League. He felt that it embodied commitments which, when the moment came, the United States would not and could not keep. In 1918 Lodge became Republican floor leader of the senate and chairman of the foreign relations committee. He believed: that the League of Nations and the Versailles treaty should be separated; that the League covenant should be changed to provide that the United States should determine for itself what were and what were not domestic questions; that the United States should have more than mere equality of voting with the small countries: and that the League should not commit the United States to preserve the territorial integrity and political independence of League members except with the consent of congress. These beliefs were sustained in essence 25 years later when the senate dealt with the United Nations charter. Lodge succeeded in attaching to the treaty embodying the League of Nations reservations to carry out these beliefs. Wilson refused to accept the reservations. On March 19, 1920, the treaty, which had been reintroduced, having been previously defeated both with and without reservations, failed by seven votes to secure the necessary two-thirds vote of the senate, the Democratic senators voting against it at the wish of the president.

As the successful leader of the opposition to Wilson, Lodge's prestige was increased. He served as one of the four U.S. delegates at the Washington Conference on the Limitation of Armaments in 1921. His influence waned after he opposed Harding's proposal for joining the World Court, but he was re-elected to the senate in 1922 by a narrow margin. He died at Boston on Nov. 9, 1924, at the age of 74.

Senator Lodge was one of the chief congressional figures of the last decade of the 19th and the first two decades of the 20th centuries. Regarded by some as cold and distant in manner, he enjoyed the prestige indicated by his popular appellation, the "scholar in politics," and held the respect of his colleagues on both sides of the senate.

His literary production started early and continued until the close of his life. In 1873–76 he edited the *North American Review* with Henry Adams; and in 1879–81, with John T. Morse, Jr., he edited the *International Review*. In 1884–90 he was an overseer of Harvard college. His doctoral thesis at Harvard was published with essays by Henry Adams, J. L. Laughlin and Ernest Young, under the title *Essays on Anglo-Saxon Land Law* (1876). He wrote: *Life and Letters of George Cnbot* (1877); *Alexander Hamilton* (1882), *Daniel Webster* (1883) and *George Washington* (2 vol., 1889), in the American Statesmen series; *A Short History of the English Colonies in America* (1881); *Studies in History* (1884); *Boston* (1891), in the Historic Towns series; *Historical and Political Essays* (1892); with Theodore Roosevelt, *Hero Tales From American History* (1895); *Certain Accepted Heroes* (1897); *The Story of the American Revolution* (2 vol., 1898); *The War With Spain* (1899); *A Fighting Frigate* (1902); *A Frontier Town* (1906); with J. W. Garner, *A History of the United States* (4 vol., 1906). He edited *The Works of Alexander Hamilton* (9 vol., 1885–86); *The Federalist* (1891); *André's Journal* (1903); and *Education of Henry Adams* (1918).

See William Lawrence, *Henry Cabot Lodge* (1925); John A. Garraty, *Henry Cabot Lodge: a Biography* (1953). (C. SEY.; H. C. L.)

LODGE, HENRY CABOT, (1902–), U.S. political figure and ambassador to the United Nations, was born in Nahant, Mass., July 5, 1902, the grandson of Henry Cabot Lodge (*q.v.*). He studied in France, graduated from Middlesex school, Concord, Mass., in 1920 and Harvard university *(cum laude)* in 1924. Six of Lodge's ancestors served in the U.S. senate; his grandfather spearheaded the senate defeat of the Versailles treaty at the end of World War I. Lodge prepared for politics through an active career in journalism as a reporter for the *Boston Evening Transcript* and later as editorial writer for the *New York Herald Tribune*. He served two terms on the Massachusetts general court, 1933–36. In 1936 he was elected as a Republican to the U.S. senate from Massachusetts, and was re-elected in 1942. In 1941 and 1942 he went on extended active duty as a reserve officer with the U.S. army. In Feb. 1944 he resigned his senate seat to go on active duty with the U.S. army. He won re-election in 1946 but his senate seat was successfully challenged by Rep. John F. Kennedy in 1952. In that year Lodge had devoted much of his time to promoting the presidential campaign of Gen. Dwight D. Eisenhower. In 1953 President Eisenhower appointed him as permanent U.S. representative to the United Nations with ambassadorial rank and cabinet membership. In the sena'e, Lodge was liberal on domestic issues and consistently voted for a strong national defense. His military service in Libya, Italy, France and Germany strengthened his conviction that the UN was the only instrument for working toward world peace. Lodge's cabinet status gave him more freedom in shaping U.S. policy in the UN than had been enjoyed by his predecessors. He played a prominent role in many critical UN debates and was escort officer for Nikita Khrushchev's tour of the U.S. in 1959. In July 1960 the Republican convention nominated Lodge for the vice-presidency on a ticket headed by

Vice-Pres. Richard M. Nixon. In November they lost to the Democratic ticket headed by Sen. John F. Kennedy. (C. P. C)

LODGE, SIX OLIVER JOSEPH (1851–1940), English physicist who studied lightning and electricity and was a leader in psychic research, was born at Penkhull, Staffordshire, on June 12. 1851. He entered Cniversity college, London, in 1872, and obtained his doctorate in 1877. In 1875 he was appointed reader in natural philosophy at Bedford College for Women. and in 1879 he became assistant professor of applied mathematics at University college, London. Two years later he was called to the chair of physics in University college, Liverpool, where he remained until in 1900 he was chosen first principal of the new Birmingham university. He retired from this position in 1919 He was knighted in 1902. His original work includes investigations on lightning, the seat of the electromotive force in the voltaic cell, the phenomena of electrolysis and the speed of the ion, electromagnetic waves and wireless telegraphy, the motion of the ether near the earth and the application of electricity to the dis-, persal of fog and smoke. In addition to numerous scientific memoirs he wrote, among other works, *Lightning Conductors and Lightning Guards, Signalling Across Space Without Wires* (1897), *Modern Views of Electricity* (1889), Electrons (1907) and *The Ether of Space* (1909).

After 1910 Sir Oliver Lodge became increasingly prominent in psychic research. A strong believer in the possibility of communicating with the dead, he interested himself in a serious endeavour to reconcile science and religion. Among his publications dealing with this subject are *The Survival of Man* (1909) and *Raymond, or Life and Death* (1916). *See* also his autobiography *Past Years* (1931). He died on Aug. 22, 1940 at Lake, near Salisbury.

LODGE, THOMAS (*c.* 1557–1625), English miscellaneous writer. chiefly remembered as a lyric poet and the author of the prose romance *Rosalynde* (the source of *As You Like It*), was a son of Sir Thomas Lodge, lord mayor of London in 1562. Born between May 1557 and April 1558, probably in London, he entered the Merchant Taylors' school in 1571, Trinity college, Oxford, in 1573 (graduating in July 1577), and Lincoln's Inn, London. in April 1578. His earliest work (*c.* 1579) is an unlicensed pamphlet in reply to Stephen Gosson (*q.v.*), which Gosson answered in *Plays Confuted in Five Actions* (1582), censuring Lodge as "little better than a vagrant, looser than liberty, lighter than vanity itself." His mother's will (Sept. 1579) shows that he had soon wearied of the law and that his family found him spendthrift and not to be trusted with money.

An Alarum Against Usurers (1584) answered Gosson's attack on his character, and its exposure of the ways in which young heirs were lured into extravagance and debt almost certainly reflects personal experience. Lodge appended to the *Alarum* both a prose tale, *The delectable Historie of Forbonius and Prisceria,* and a verse lament, *The Lamentable Complaint of Truth Over England,* and this collection foreshadowed the ways in which he chiefly employed his pen for the next 12 years: in verse (*Scillaes Metamorphosis,* 1589; *Phillis,* sonnets and other poems, 1593; *A fig for Momus,* eclogues, satires and epistles, 1595); in romances (*Rosalynde,* 1590; *Robert, Second Duke of Normandy,* 1591; *Euphues Shadow,* 1592; *William Longbeard,* 1593; *A Margarite of America,* 1596); and in pamphlets (*Catharos,* 1591; *The Divel Conjured,* 1596; *Wits Miserie, and the Worlds Madnesse,* 1596; *Prosopopeia,* 1596). In 1594 he published *A Spiders Webbe* (last heard of in the sale of John Hutton's books, 1764) and also two plays: *The Wounds of Civill War* and *A Looking Glasse for London and England* (the latter written in collaboration with Robert Greene).

As an alternative to this effort to maintain himself by writing. Lodge tried the career of adventurer. In the dedications to *Rosalynde* and *A Margarite of America* he mentions two voyages: the first to Terceira and the Canary islands, and the second to South America with Thomas Cavendish on his disastrous last voyage (Aug. 1591) ; but neither seafaring nor literary enterprise served to keep him from poverty and he found a more secure profession when he graduated in medicine at Avignon (Jan. 1598). He was incorporated M.D. of Oxford in 1602 and practised in the Netherlands, where he took refuge at times as a recusant, and in London, where he died in 1625. Apart from *A Treafise of the Plague* (1603) and *The Poore Mans Talentt* (a manual of domestic medicine, first printed by the Hunterian club, 1881), the works of the latter part of his life are translations: of selections from Luis de Granada (1601), of the works of Josephus (1602), of the prose works of Lucius Annaeus Seneca (1614), and of a French commentary on the *Semaine* of Du Bartas (1621).

Much of Lodge's work before 1600 was, in fact, surreptitious translation, the result partly of the stress laid on imitation in literary theory and partly of financial need, which encouraged mere compilation. The latter accounts for his poorest work (*Catharos* and *Tlze Divel Conjured*); the former gives importance and quality to his best. But in spite of some crude hackwork, there is no doubt of the genuineness of his literary interests and abilities. He had no gift for drama or for finding copy without the aid of books, but in most of his verse and some of his romances he showed a capacity for selection and assimilation which was creative. The first and last of his verse collections (*Scillaes Metamorphosis* and *A fig for Momus*) are historically important as forward-looking in both matter and style. Many of his well-known lyrics first appeared in his romances where the link between poem and story encouraged some interesting experiments. Of the romances, *Rosalynde,* deservedly popular on its own account, is rivaled only by *A Margarite of America,* an arresting and dramatically plotted tale combining Senecan motives with the artifice of Euphuism and Arcadian romance in a manner which cannot be entirely credited to its source. This was. according to Lodge, "a historie in the Spanish tong" which he found in the Jesuit college at Santos during his visit to Brazil and, although doubt has sometimes been cast on this claim, the Jesuit library was certainly pillaged by Cavendish's followers. Of the prose pamphlets, *Wits Miserie* is, with the *Alarum,* the most readable for its Nashe-like cameos of London life. It is this ready response to fashions of one kind and another that makes Lodge's work important: having "so written as he had read." he is representative of an age schooled to draw both matter and style from literary models, and the variety of his work (to which he so often drew attention) gives him a place in the history of an unusual number of literary kinds.

BIBLIOGRAPHY.—*The Complete Works,* ed. by Edmund Gosse, 4 vol. (Hunterian club, 1883) includes everything but the translations. On Lodge's life, *see* especially C J. Sisson, *Thomas Lodge and other Elizabethans* (1933); Alice Walker, "The Life of Thomas Lodge," *Review of English Studies,* Ixx (1933–34). (AE. WR.)

LODI, town and episcopal see of Lombardia, Italy, province of Milano, 20½ mi. S.E. of Milan by rail, on a hill above the right bank of the Adda, 230 ft. above sea level. Pop. (1951) 29,231. The city is' in a very rich dairy district. The cathedral (1158), with Gothic façade and 16th-century lateral tower, has a restored interior. The church of the Incoronata, erected by Battaggio (1487 onward) in Bramantesque style, is an elegant octagonal domed structure, decorated nith frescoes by the Piazza family, natives of the town. and four large altarpieces by Calisto Piazza. The 13th-century Gothic church of San Francesco has 14th-century paintings. The Palazzo Modegnani has a fine gateway in the style of Bramante, and the hospital a cloistered quadrangle. Besides an extensive trade in cheese (Lodi producing more Parmesan than Parma) and other dairy produce, there are manufactures of hemp ropes, linen, silk, majolica and chemicals.

The ancient Laus Pompeia lay 3½ mi. W. and the site is still occupied by a considerable village, Lodi Vecchio, with the old cathedral of S. Bassiano. In the middle ages Lodi was second to Milan in northern Italy. A dispute with the archbishop of Milan about the investiture of the bishop of Lodi (1024) began a long feud. In 1111 and again in 1158 the Milanese laid the whole plsce in ruins. A number of the Lodigians had settled on Colle Eghezzone; and their village soon grew up under the patronage of Frederick Barbarossa into a new city of Lodi (1162). Lodi was before long compelled to enter the Lombard league, and in 1198 it formed an offensive and defensive alliance with Milan, on which after 1416 it became dependent. The duke of Brunswick captured it in 1625 in the interests of Spain; and it was occupied by the French (1701), by the Austrians (1706), by the king of Sardinia (1733), by the Austrians (1736), by the Spaniards (1745) and again by the Austrians (1746). On May 10, 1796, was fought the battle of Lodi between the Austrians and Napoleon, which made the latter master of Lombardy.

LODZ, a *voivodship* (province) in the west of Poland, bounded on the northeast by the province of Warszawa, on the northwest by Poznan, and on the south by the province of Kielce. Area, 6.589 sq.mi.; pop. (1931). 2,632,434; (1960) 1,597,600. The province was occupied by Germany in World War II but was returned to Poland in 1945. The southern part of the province is a continuation of the plateau of Kielce; the northern part consists of lowlands washed by the Warta and its tributary, the Prosna. It was formerly covered by forests and lakes and formed the lesser principalities of Kalisz, Sieradz and Łęczyca. The forests have been mostly destroyed, and agriculture and cattle breeding are extensively carried on, the crops principally raised being rye, wheat, oats, barley and potatoes. But the importance of the area was increased by the rapid rise of the textile industry in Lodz. Pabjanice, Tomaszów, Zgierz and other towns. Cotton spinning and weaving is the most important industry, but woollens, linens, silks and other fabrics are also manufactured. while the embroideries of Kalisz are of importance. The whole area suffered almost complete destruction during World War I, and had to face new economic problems after the restoration of the factories. Previously designed to supply the Russian and oriental markets, the textile industry of Lodz specialized in coarse materials and neglected the finer fabrics. After 1918, however, the greatly enlarged home market and the markets of western Europe demanded finer materials. and great changes were made to meet the new situation. The revival of the industry was amazing, in spite of the relative lack of new capital. Lodz again suffered heavily from war during the German invasion of Sept. 1939. It was immediately overrun by German forces under Gen. Johannes Blaskowitz, and Berlin announced the capture of Lodz, the chief city, on Sept. 9. By a decree signed in Berlin Oct. 8. 1939. and effective after Nov. 1, the whole province was incorporated into Germany proper.

The chief towns of the province, which is the most thickly populated area of Poland after Silesia, are Lodz (708,400), Piotrków (53,000), Pabjanice, Tomaszów, Zgierz, Łęczyca and Sieradz.

LODZ, a city and *voivodship* (province) within but independent of Lodz *voivodship* in central Poland and the seat of a Roman Catholic bishopric, lies 907 ft. above sea level on the watershed of the Vistula and Oder rivers, 81 mi. S.W. of Warsaw. Pop. (Sept 1, 1939. est.) 672,000; (Dec. 1950 census) 620,183; (1960) 708.400, Administrative area: 81.8 sq.mi. The town is built about a seven-mile-long north-south thoroughfare, Piotrkowska street, which links Independence and Freedom squares. Two other parallel thoroughfares are Kosciuszko avenue to the west and Kilinski street to the east. These thoroughfares are crossed in an east-west direction by many streets named for prominent Poles.

From an insignificant place at the beginning of the 19th century Lodz grew rapidly into the main centre of the Polish textile industry. The first mills were founded during 1815–30 when the government of Congress Poland encouraged industrialization. But the period of great expansion began in 1851 when the tsarist government abolished the customs frontier between Congress Poland and Russia proper, thus opening a big market for Lodz manufacture. Between 1860 and 1897 the town's population rose from 26.000 to 314,000. Between 1840 and 1906 its administrative area was 10.4 sq.mi.; between World Wars I and II it was increased to 22.8 sq.mi. In 1931 Lodz had 604.629 inhabitants; including 62% Poles, 30% Jews and 7% Germans. In the mid-1950s about 70% of the population was employed in the textile industry.

Before World War II Lodz had no institutions of higher education. There were 9 in 1957, including a university, a school of engineering and 249 other schools. There were also 22 hospitals with twice as many beds as in 1945. After World War II water supply, drainage and public transport were greatly improved.

Lodz was the main centre of the Polish Socialist movement before World War I. Between 1915 and 1918 and again from 1939 to 1945 the town was under German occupation. During the second occupation it was renamed Litzmannstadt (after a general who distinguished himself in Nov. 1914) and the town and its province were incorporated into the greater reich. After Poland's liberation, Warsaw having been destroyed and Lodz being almost untouched, many central administrative offices were accommodated in Lodz. (Ln. S.)

LOEB, JACQUES (1859–1924), German-U.S. pioneer in experimental biology, was born at Mayen (near Coblenz), Ger., on April 7, 1859, and studied at Berlin and Munich before receiving an M.D. degree from the University of Strasbourg in 1584.

Lectures on highly metaphysical philosophy he attended in Berlin in 1880, as a young man seeking an understanding of the human mind. appear to have turned him against all things metaphysical and to have exerted a marked influence on his future thought and career.

His work in biology began at the universities of Wiirzburg (1886–88) and Strasbourg (1888–90), and at the Naples biological station (1889–91). In 1891 he went to the United States, becoming successively professor at Bryn Mawr college, Bryn Mawr, Pa., (1891–92), The University of Chicago (1892–1902) and the University of California, Berkeley (1902–10). In 1910 he became a member of the Rockefeller Institute for Medical Research in New York city and continued in that position until his death on Feb. 11, 1924, while vacationing in Bermuda. Much of his experimental work was done at the Marine Biological laboratory at Woods Hole, Mass.

Loeb's continued insistence upon a mechanistic concept of life and his denial of all metaphysical views assumed the proportions of a crusade and brought him into conflict with' the vitalistic school, which still had strong supporters among biologists. Although Isaac Newton had enunciated the basic principles of physics about two centuries earlier, Loeb worked in the period of the great success of the Newtonian principles in the physical sciences.

The conservation of matter and of energy, the second law of thermodynamics and James Clerk Maxwell's electromagnetic theory relating light and electricity had been established. J. Willard Gibbs had begun his investigations, organic chemistry had received its great impetus from the contributions of F. A. Kekulé and rapid advances in the synthesis of organic compounds were being made. The successful culmination of the basic Newtonian mechanistic system had led to its general acceptance in the physical sciences; all thinking in the sciences was being carried out in its terms.

The lifework of Loeb was devoted to the application of Newtonian principles to living systems. The introduction of non-Newtonian principles, such as quantum mechanics, and the uncertainty principle, although begun while Loeb was still active, came too late to exert any appreciable influence on the concept that guided his work.

Popular interest, attended by some controversy, was attracted to Loeb's experiments on artificial parthenogenesis, beginning in 1899, when he succeeded in bringing about the development of larvae of the sea urchin from unfertilized eggs by exposing them to controlled changes in their environment; this work was later extended to the production of parthenogenetic frogs, which he raised to sexual maturity. In addition to artificial parthenogenesis, Loeb is remembered for his work on the physiology of the brain, animal tropisms, regeneration and the duration of life. In his later years he made important contributions to the theory of colloidal behaviour, applying the principles of Gibbs and of F. G. Donnan to the chemistry of proteins.

LOEFFLER, CHARLES MARTIN TORNOV (1861–1935), composer, was born at Miihlhausen, Alsace, Jan. 30, 1861. Part of his childhood was spent in Russia near Kiev, but he was educated in Switzerland. He studied the violin under Leonard and Massart at the Paris Conservatoire and under Joachim at the Berlin Hochschule, taking composition in Paris under Guiraud and in Berlin under Kiel. In 1881 he went to the United States, and played violin in the Boston Symphony orchestra, but resigned in 1903 to devote himself to composition. Among his significant works after 1903 were: *A Pagan Poem* for orchestra and piano; *Memories of My Childhood,* another symphonic poem; and *Canticle of the Sun,* commissioned by Mrs. Elizabeth Sprague Coolidge, with Mme. Povla Frijsh as soloist, for the opening of the Chamber Music hall, Library of Congress, Oct. 1925, outstanding in that first memorable chamber music festival in the capital of the United States. Other compositions were *Quartet in A Minor; Les Veillées de l'Ukraine;* and *Divertimento in A Minor,* both for orchestra and violin; *The Death of Tintagiles* for orchestra and viola d'amore; *Deux Rhapsodies* for oboe, viola and piano; *Divertissement Espagñol* for orchestra and saxophone; *By the Waters of Babylon,* a setting of Psalm 137, for female chorus; *For One Who Fell in Battle,* eight-part chorus; *Hora Mystica,* symphony; music for four strings to the memory of Victor Chapman; two symphonic poems, *La Bonne Chanson* and *La Villanelle du Diable; Three Movements; Fantastic Concerto* for orchestra and violoncello; and several songs.

LOESS. Typical loess is a soft, porous rock, pale yellowish or buff in colour; one characteristic property is its capacity to retain vertical or even overhanging walls in the banks of streams. These vertical walls exist in China, where they stand in some places 500 ft. high and contain innumerable cave dwellings; ancient roads. too, have worn vertically downward deep into the deposit, forming trenchlike ways. This character in the loess of the Mississippi region in the United States gave rise to the name "bluff formation." A coarse columnar structure is often exhibited on the vertical weathered faces of the rock. Another characteristic is the presence throughout the rock of small capillary tubules, which appear to have been occupied by rootlets; these are often lined with calcite.

Loess usually is calcareous; some geologists regard this as an essential property, and when the rock has become decalcified, as it frequently is on the surface by weathering. they call it loessloam. In the lower portions of a loess deposit the calcium carbonate tends to form concretions, which on account of their mimetic forms have been called loess dolls. Bedding is absent from typical loess. The mineral composition varies somewhat in different regions, but the particles are always small; they consist of angular grains of quartz, fine particles of hydrated silicates of alumina, mica scales and undecomposed fragments of feldspar, hornblende and other rock-forming silicates.

In Europe and North America loess deposits are associated with the margins of the great ice sheets of the glacial period; thus in Europe they stretch irregularly through the centre eastward from the northwest of France, and are not found north of the 57th parallel. Most geologists are agreed that the true loess is an aeolian or wind-borne rock, formed most probably during periods of tundra or steppe conditions. But it seems clear that certain deposits classed as loess in western Europe do not really belong to this category, being of alluvial origin and related to the brick earths of southeastern England. *See* PLEISTOCENE EPOCH; WIND EROSION AND DEPOSITION: *Dust Storms and Dust Deposits; see* also references under "Loess" in the Index volume. (F. J. P.)

LOEW, MARCUS (1870–1927), motion-picture executive and pioneer motion-picture theatre owner, was born May 8, 1870, in New York city, son of an Austrian immigrant. Leaving school at the age of nine to help support his family, he later found modest prosperity in the fur business.

Attracted by the new popularity of moving pictures Loew owned a chain of nickelodeons by 1905 and thereafter acquired many leading theatres for combined vaudeville and motion-picture exhibition.

In 1920 Loew's, Inc. purchased a production company named Metro Pictures Corp., and in 1924 the Goldwyn Pictures Corp (from nhich Samuel Goldwyn had resigned) was absorbed. The name became Metro-Goldwyn-Mayer to represent the newly hired management group headed by Louis B. Mayer.

Loew died on Sept. 5, 1927, almost at the end of the silent film era. His estate was estimated at $30,000,000. Neither flamboyant nor notably original. Loew was a show-business consolidator who made possible some of Hollywood's finest film achievements.

See Bosley Crowther, *The Lion's Share* (1957). (R. D. MacC.)

LOEWI, OTTO (1873–1961), German pharmacologist and Nobel laureate, was born at Frankfurt am Main on June 3, 1873, and was educated at Strasbourg and Munich universities. After becoming doctor of medicine in 1896, he devoted himself to physiological chemistry and pharmacology. In 1898 he was appointed assistant in the pharmacological institute at Marburg, and in 1901–02 he spent some months at University college, London, under E. H. Starling. Returning to Marburg, he was made titular professor of pharmacology in 1904, but in 1905 he went to Vienna as associate professor. From 1909 to 1938 he was professor of pharmacology in Graz, Aus. In 1940, he went to the United States, becoming research professor at the College of Medicine of New York university. He died in New York city on Dec. 25, 1961.

In 1936 Loewi and his lifelong friend Sir Henry Hallett Dale received jointly the Nobel prize for medicine for discoveries relating to the chemical transmission of nerve impulses. Between 1921 and 1926 Loewi and his colleagues showed that stimulation of the nerves in the perfused frog's heart led to the appearance of a substance which could readily inhibit a second heart receiving the perfused fluid from the first. This substance was finally shown to be acetylcholine, which had been first isolated from biological material by Dale in 1914. Loewi's experiments provided the first definite proof that chemical substances were concerned in the transmission of nervous impulses. He also carried out important researches on diabetes, digitalis, adrenaline and the vegetative nervous system, and in 1908 he devised "Loewi's test" for pancreatic function. (W. J. BP.)

LÖFFLER, FRIEDRICH AUGUST JOHANNES (1852–1915). German bacteriologist, one of the greatest names in the history of bacteriology, was born at Frankfurt an der Oder on June 24. 1852, the son of an army surgeon. He studied medicine at Würzburg university and at the Friedrich Wilhelm university in Berlin and. after serving in the Franco-German War, he obtained his M.D. degree at Berlin in 1874 After further service as an army doctor he became an assistant in the imperial health department (1879–84), where he was closely associated with Robert Koch. In 1888 he was appointed professor of hygiene at Greifswald and he was rector of that university, 1903–07. In 1913 he succeeded G. Gaffky as director of the Robert Koch Institute for Infectious Diseases in Berlin. He died in Berlin on April 9, 1915.

In 1884 Loffler discovered *Corynebacferium diphtheriae,* the causal organism of diphtheria, and simultaneously with P. Roux and A. Yersin he indicated the presence of diphtheria exotoxin. Among his other notable achievements were the discovery of *Pfeifferella mallei,* the causative organism of glanders (1882), the discovery of the cause of swine erysipelas and swine plague (1885), and of *B. typhi murium* (1891). In collaboration with P. Frosch he found that foot-and-mouth disease is caused by a filter-passing virus, the first occasion on which a virus was recognized as the cause of an animal disease. (W. J. BP.)

LOFFT, CAPEL (1751–1824), English miscellaneous writer, was born in London on Nov. 14, 1751. He was educated at Eton and at Peterhouse college, Cambridge, which he left to become a member of Lincoln's inn. He became the patron of Robert Bloomfield. the author of *The Farmer's Boy,* and secured for him the very successful publication of that work. Byron, in a note to his *English Bards and Scotch Reviewers,* ridiculed Lofft as "the Maecenas of shoemakers and preface-writer general to distressed versemen; a kind of gratis *accoucheur* to those who wish to be delivered of rhyme, but do not know how to bring forth." He died at Montcalieri, near Turin, Italy, on May 26, 1824.

LOFOTEN AND VESTERAALEN, a group of islands off the northwest coast of Norway, between 67° 30' and 69° 20' N., and between 12° and 16° 35' E., part of the Norwegian county of Nordland. The extreme length of the group from Andenaes, at the north of Andö. to Rost, is about 150 mi.; the aggregate area, about 1,560 sq.mi. It is separated from the mainland by the Vestfjord, Tjaeldsund and S'aagsfjord, and is divided into two sections by the Raftsund between Hindo and Öst-Vaagö. To the west and south of the Raftsund lie the Lofoten Islands proper, of which the most important are Öst-Vaagö, Vest-Vaago and Moskenaesö; east and north of the Raftsund are the islands of Vesteraalen, the chief being Hindo, Lango and Andö. The islands, which are of granite or gneiss, are a partially submerged mountain range, and are lofty and rugged. The highest points are hloisalen (4,153 ft.) on Hindo and Higravstind (3,809 ft.) on Öst-Vaagö, near the Raftsund and Troldfjord.

The long line of jagged peaks seen from the Vestfjord forms one of the most striking prospects on the Norwegian coast. The channels which separate the islands are narrow and tortuous, and generally of great depth; they have remarkably strong tidal currents, particularly the Raftsund and the famous Maelstrom, or Moskenstrom, near Moskenaes. Though situated within the Arctic circle, the climate of the Lofoten and Vesteraalen group is not rigorous and the coast is never frozen. The isothermal line which marks a mean January temperature of 32° F. runs south from the Lofotens, passing east of Bergen onward to Gothenburg and Copenhagen. The prevailing winds are from the southwest and west, the mean temperature is 38.5" F., and the annual rainfall is 43.34 in.

In summer the hills have only patches of snow. Much of the interior is bleak cranberry moor. Cattle are reared, but the growth of cereals (chiefly barley) is insignificant.

The characteristic industry is the cod fishery carried on along the east coast of the Lofotens in the Vestfjord in the spring. During the season this employs many thousands from all parts of Norway. The fish, dried on the cliffs during early summer, ordinarily are exported from Bergen to Spain, Holland, Great Britain, Belgium, etc., and the fish heads are used as cattle food. Industries arising out of the fishery are the manufacture of cod-liver oil and of artificial manure in factories at Svolvaer, Henningvaer, Kabelvaag, etc. The summer cod fisheries and the lobster fishery are also valuable.

Herring is taken in large quantities off the west coasts of Vesteraalen. Svolvaer, built on rocky islands off Öst-Vaagö, is the "capital" and chief port and trading centre; and Kabelvaag is another fishing port. Lödingen also, at the head of the Vestfjord on Hindo, is a port of call. A church existed at Vaagen (Kabelvaag) in the 12th century and Hans Egede, the missionary of Greenland, was pastor. Steamers trade between Hamburg or Oslo and Hammerfest, and local communication is chiefly by small boats, for there are few roads.

The largest island in the group, and indeed in Norway, is Hindo, with an area of 849 sq.mi. On Andö there is a bed of coal at the mouth of the Ramsaa.

Lofoten became well known in World War II as the scene of British commando raids against the Germans.

LOFTUS, ADAM (*c.* 1533–1605), archbishop of Xrmagh and Dublin, and lord chancellor of Ireland, was educated at Cambridge. He accompanied the earl of Sussex to Ireland as his chaplain in 1560, and three years later was consecrated archbishop of Armagh by Hugh Curwen, archbishop of Dublin. In 1567 he was translated to the archbishopric of Dublin, where the queen looked to him to carry out reforms in the church. On several occasions he temporarily executed the functions of lord keeper, and in Aug. 1581 he was appointed lord chancellor of Ireland. It was largely through his influence that the corporation of Dublin granted the lands of the priory of All Hallows as a beginning of the endowment of Trinity college, of which he was named first provost in the charter creating the foundation in 1591. Loftus died in Dublin on April j, 1605.

See J. R. O'Flanagan, *Lives of the Lord Chancellors of Ireland* (1870).

LOG, MARITIME, an instrument for measuring the speed of a ship through the water. From its original meaning the term has come to be applied to the daily progress of a ship and also to the full written record of the voyage of a ship or flight of an airplane. The more exact term for such a written record is "logbook."

The oldest type of log of a practical nature was the "chip log." It consisted of the log chip, log reel, log line and log glass. The chip was a small piece of pie-shaped wood with a small lead weight on its circular side that caused it to float upright in the water and resist being towed. The log line was attached to the chip by a three-part bridle. one part fastened to a peg in the chip that could be pulled out by a jerk on the line when it was desired to haul in the chip. The part of the line, about 15 fathoms in length. next to the chip was called the "stray line" and its limit was marked by a piece of bunting. The remainder of the line was kept on the reel until used. It was marked off at intervals of $47\frac{1}{4}$ ft. by pieces of cord, called "knots," worked into the log line. The log glass was a 28-second sandglass. The measurements of the log line and time were based on the following equation:

$$\frac{47\frac{1}{4}\text{ ft.}}{6{,}080\text{ ft. (nautical mile)}} = \frac{28\text{ sec.}}{3{,}600\text{ sec. (hour)}}$$

To measure speed with the log, the chip with peg in place was dropped into the water from the stern and the log line was allowed to pay out from the reel. When the piece of bunting marking the end of the stray line unwound from the reel the sandglass was inverted. After 28 seconds had elapsed the number of knots that had passed overboard was counted. The number of knots that ran out in 28 seconds was the speed of the ship in nautical miles per hour. Some log lines were marked by bits of cloth to indicate fifths of a knot. For higher speeds a 14-second glass was used and the number of knots running out was multiplied by two.

The chip log gave the speed only at the time it was used. The desirability of knowing the distance run over an extended period of time brought into use many different types of patented rotating logs. In these the chip was replaced by a rotator, similar to a propeller, towed astern by a braided line. The revolutions of the rotator were transmitted by the braided line to a clockwork recording device on the stern of the ship where the result appeared on a dial as nautical miles made through the water. Because of the location of the recording dial on the stern rail, or taffrail, these logs are commonly known as taffrail logs. Many logs utilizing a rotator to indicate the distance traveled have been used, but all are liable to error if the rotator is fouled by floating weeds. At speeds greater than 15 knots in rough sea they are not accurate.

Logs installed in modern U.S. ships ascertain the ship's speed by means of a Pitot tube. A typical log built by the Pitometer Log corporation consists of a tube projecting through the bottom of the ship into undisturbed water. The tube is projected through a sea valve so it can be replaced if damaged or if the vessel enters shoal water. The tube has one forward-facing orifice called the dynamic-pressure orifice and two orifices at right angles to it called the static-pressure orifices. When the ship is stopped the pressure is the same in the dynamic and static connections but when the vessel steams ahead the dynamic pressure exceeds the static pressure. This difference in pressure varies as the square of the ship's speed.

Another part of the log consists of a small variable-speed electric motor driving a centrifugal water pump. In such a pump the dynamic pressure produced by the pump varies as the square of the speed of the motor. The pressure produced by the speed of the ship is exerted against a bellows which is balanced by pressure produced by the pump. Movement of the bellows operates the speed control of the motor making it exactly balance the pressure produced by the ship. With this accomplished, the speed of the pump and motor corresponds to the speed of the ship.

Attached to the shaft of the electric motor is a magneto which generates voltage proportional to the speed of the ship. This voltage is transmitted to the navigating bridge where it actuates the equivalent of a voltmeter whose graduated dial constantly indicates the speed of the ship in knots. The pump motor also drives a counting device which counts the revolutions made by the motor and transmits this information to the bridge as nautical miles steamed through the water. The dials on the bridge furnish the same information as the speedometer in an automobile. This type of log may also be arranged to draw a graph on a moving paper tape indicating the speed of the ship continuously during an entire voyage.

Since there is no continuous flow of water through the Pitot orifices the possibility of the openings being clogged with drifting material is slight, and since the actuating pressure is the difference between static and dynamic pressure there is no error caused by change in draft of the ship. (M. R. D.)

LOGAN, JOHN, also known as TAHGAHJUTE (*c.* 1725–1780), American Indian leader, by birth a Cayuga, the son of Shikellamy, a white man who had been captured when a child by the Indians, had been reared among them and had become a chief. John Logan lived for some time near Reedsville. Pa.. and moved to the banks of the Ohio river about 1770. He was not technically a chief but acquired great influence among the Shawnees. into which tribe he married. He was on good terms with the whites until April 1774, when, friction having arisen between the Indians and the whites, a band of marauders, led by one Greathouse, attacked and murdered several Indians, including Logan's sister and other relatives. Believing that Capt. Michael Cresap was responsible for this murder, Logan sent him a declaration of hostilities, the result of which was the bloody conflict known as Lord Dunmore's war. Logan refused to join the Shawnee chief, Cornstalk, in meeting Gov. Dunmore in a peace council after the battle of Point Pleasant, but sent him a message now famous as an example of Indian eloquence. Logan took to drink and in 1780 was killed near Lake Erie by his nephew, whom he had attacked.

See Brantz *Mayer's Tah-gah-jute or Logan the Indian and Captain Michael Cresap* (Baltimore, *1851;* 2nd ed. Albany, 1867) and F. B. Sawvel, *Logan the Mingo* (1921).

LOGAN, JOHN (1748–1788), Scottish poet, was born at Soutra, Midlothian, in 1748. In 1771 he was presented to the charge of South Leith, but was not ordained till two years later. In 1770 he published *Poems on Several Occasions by Michael Bruce.* In 1781 he published his own *Poems.* Logan was accused of having appropriated in his *Poems* (1781) verses written by Michael Bruce (*q.v.*). The statements of John Birrell and David Pearson on behalf of Bruce were included in Dr. Anderson's *Life of Logan.* The charge of plagiarism has been revived from time to time.

LOGAN, JOHN ALEXANDER (1826–1886), American soldier and political leader, was born in what is now Murphysborough, Ill., on Feb. g, 1826. He had no schooling until he was 14; he then studied for three years in Shiloh college, served in the Mexican War as a lieutenant of volunteers, graduated from the law department of Louisville university in 1851 and practised law with success. He entered politics as a Douglas Democrat. In 1858 and 1860 he was elected to the national house of representatives. Though unattached and unenlisted, he fought at Bull Run, and then returned to Washington, resigned his seat and entered the Union army as colonel of a regiment of volunteers, which he organized. He was regarded as one of the ablest officers who entered the army from civil life. In Grant's campaigns terminating in the capture of Vicksburg he rose to the rank of major-general of volunteers; in 1863 he was placed in command of an army corps, and after the death of McPherson he was in command of the army of the Tennessee at the battle of Atlanta. When the war closed, Logan resumed his political career as a Republican and was a member of the national house of representatives from 1867 to 1871, and of the U.S. senate from 1871 until 1877 and again from 1879 until his death. He was always a violent partisan and was identified with the radical wing of the Republican party. His war record and his large personal following, especially in the Grand Army of the Republic, contributed to his nomination for vice-president in 1884 on the ticket with James G. Blaine, but he was not elected. His impetuous oratory, popular on the platform, was less adapted to the halls of legislation. When commander-in-chief of the Grand Army of the Republic in 1868–71, he successfully urged the observance of Memorial or Decoration day. He died at Washington, D.C., on Dec. 26, 1886.

LOGAN, SIR WILLIAM EDMOND (1798–1875), Canadian geologist, was born in Montreal on April 20, 1798, of Scottish parents. He was educated partly in Montreal and at the high school and University of Edinburgh, where Robert Jameson excited his interest in geology. In 1831 he took charge of a colliery and copper-smelting works in Swansea. In 1840 Logan brought before the Geological society of London his paper "On the character of the beds of clay lying immediately below the coal seams of South Wales, and on the occurrence of coal boulders in the Pennant Grit of that district." He pointed out that each coal seam rests on an underclay with rootlets of *Stigmaria,* and expressed his opinion that the underclay was the old soil in which grew the plants from which the coal was formed. To confirm this observation he visited America in 1841 and examined the coal fields of Pennsylvania and Nova Scotia, where he found the underclay almost invariably present beneath the seams of coal. In 1842 he took charge of the newly established geological survey in Canada, and continued as director until 1869. Logan was elected a fellow of the Royal society in 1851.

Logan died at Castle Malgwyn, Pembrokeshire, on June 22, 1875.

LOGAN, a city of Utah, U.S., and seat of Cache county, is a college community and a distribution and marketing centre, on the Logan river, 80 mi. N. of Salt Lake City. Logan, with its many trees and gardens, is laid out at the mouth of scenic Logan canyon on terraces of prehistoric Lake Bonneville. It has an elevation of 4.535 ft. above sea level, with nearby Wasatch mountain peaks towering more than 5.000 ft. higher.

The city takes its name from the river, named for Ephraim Logan, a trapper of the 1820s. Believing Cache valley too cold for agriculture, Mormon colonizers did not arrive until 1855–56, and it was 1859 before Logan itself was founded; the city was incorporated in 1866. Grains and sugar beets nere found to grow well, and subsequently dairying and stockbreeding thrived. A gray, twin-towered temple. completed in 1884, made Logan a Mormon religious centre. Utah State university, formerly the state agricultural college (founded 1888) has profoundly influenced the community. The Utah Northern railroad, built to Logan in 18'73 and to Montana in 1877–81. was later incorporated into the Union Pacific system.

For comparative population figures *see* table in UTAH: *Population.* (D. L. M.)

LOGANBERRY (LOGAN BLACKBERRY). This well-known fruit originated as a hybrid between the wild blackberry (*Rubus ursinus*) of the Pacific coast and the red raspberry. The fruit was raised from seed in 1881 in the garden of Judge J. H. Logan at Santa Cruz, Calif. It is grown commercially in large quantities, especially in Oregon and Washington and in England and Tasmania. The Logan is a vigorous, nearly trailing, blackberry-like plant with three- to five-foliate leaves, prickly canes and deep wine-red, tart, high-flavoured berries that separate from the stem as do the blackberries. The fruit is canned, frozen for preserve or pie stock, or made into wine. The Phenomenal, originated by Luther Burbank, is very similar to the Logan, but bears slightly larger fruit. The Young (Youngberry), Boysen (Boysenberry), Pacific and Cascade are related berries that have the high aroma and flavour of the Logan and of the native blackberry. Research by M. B. Crane and P. T. Thomas in England and Waldo and Darrow in the U.S. department of agriculture indicates that the Logan probably originated as a hybrid of an octoploid blackberry fertilized with diploid pollen of a red raspberry. Hybrids of this kind are similar in appearance to the Logan. L. H. Bailey proposed the species name R. *loganobaccus* for this cultivated blackberry. *See* also DEWBERRY. (J. R. MAG.)

LOGANIACEAE, a family of dicotyledonous plants including herbs, vines, shrubs and trees, chiefly tropical but with some representatives in temperate regions. About 33 genera and 700 species are recognized. The largest and most important genus is *Strychnos* in the tropics of both hemispheres, the seeds of various species, but especially those of *S. nux vomica,* yielding the drug strychnine (*q.v.*). Many species of *Buddleia* and one of *Gelsemium,* the yellow jessamine of the southeastern United States, are cultivated for ornamental purposes. (E. D. ML.)

LOGANSPORT, principal town and seat of Cass county, north-central Indiana, U.S., 70 mi. N.N.W. of Indianapolis, at the confluence of the Wabash and Eel rivers. It is a trading centre for an agricultural area comprising Cass, Carroll, Pulaski, Fulton, Miami and White counties, and an important shipping point for livestock and grain.

Manufactures include air-operated and hydraulic laboursaving equipment, die castings, electronic and electrical controls, automobile and airplane parts, metal stampings, screw products, hardwood lumber, fishing tackle, fire-fighting apparatus, mechanical rubber goods, metal springs and women's foundation garments.

Two of Logansport's public utilities, water and electricity, are municipally owned. A large state mental hospital is located there.

Title to the land was acquired by treaty in 1826 from the Miami and Pottawatomie Indians. The town was platted in 1828 and named after a Shawnee chief, the so-called Captain Logan (d. 1812), who was evidently an ally of the Americans in the War of 1812. It was incorporated as a town in 1831 and as a city in 1838.

For comparative population figures *see* table in INDIANA: *Population.* (WI. BA.)

LOGAR, a river and valley of Afghanistan. The Logar river drains a wide tract of country, rising in the southern slopes of the Sanglakh range and receiving affluents from the Kharwar hills, northeast of Ghazni. It joins the Kabul river a few miles below the city of Kabul. The Logar valley, which is watered by its southern affluents, is rich and beautiful, about 40 mi. long by 12 mi. wide, and highly irrigated throughout. Lying in the vicinity of the capital, the district contributes largely to its food supply.

LOGARITHMIC DECREMENT is the measure of the rate of decay of any exponentially damped oscillation. It is the Naperian logarithm of the ratio of the first to the second of two successive current amplitudes in the same direction. The logarithmic decrement can also be considered as a constant of a simple radio circuit, being π times the product of the resistance by the square root of the ratio of the capacity to the inductance of the circuit. Measurement of logarithmic decrement is of great importance since it makes possible the determination of the equivalent resistance of the circuits under consideration, and also gives information concerning the lengths of the wave trains. The value of the sum of the decrements of two circuits may be obtained from their resonance curve.

LOGARITHMS. By shortening processes of computation, logarithms have doubled the working speed of astronomers and engineers and others working with masses of mathematical data. The explanation of this highly practical branch of mathematics begins most conveniently with the exponential expression b^l which represents some number n, so that we may write $n = b^l$. In the elementary theory we assume b, n, 1 to be real numbers, b and n positive, and b greater than unity. If we know b and the exponent l, we may compute n. For example, if $b = 10$, $l = 3$, then $n = b^2 = 103 = 1{,}000$. If any two of the three numbers b, 1, n are given, the third may be computed. To develop the elementary theory of logarithms we assume the number n and the base b to be given; then the exponent 1 may be found. For the case under consideration (when b and n are both positive and b is greater than unity), the actual existence of one and only one real value 1 can be established by the modern theories of irrational numbers, such as that of J. W. Dedekind. For, if we make a "cut" of all ordered real numbers by placing in one class every number α for which $b^\alpha \leqq n$, and in the other class every number β for which $b^\beta > n$, then if N is the number defined by the "cut," we must have $b^N = n$, for the reason that every other assumption leads to an evident contradiction. That is, if we assume that $b^N < n$, then another number b^{N_1} exists which lies between b^N and n, and there are numbers in the first class greater than N, which is contrary to assumption. A similar result is reached if we assume that $b^N > n$.

The number l is called the logarithm of the number n to the base b, in which case n is sometimes called the antilogarithm of l. From a knowledge of the properties of the expression b^2 it becomes evident that certain values of the base b are more convenient than others. Thus, b is selected to be positive, because a negative b would produce undesired fluctuations in the signs of n, when l takes successively the values 1, 2, 3, 4, . . . , while for $l = \frac{1}{2}$, $\frac{1}{4}$, . . . the n would be an imaginary number. It is evident also that $b = 1$ would place limitations upon the possible values of n corresponding to the real exponents 1, since $1^l = 1$. Accordingly, when the base is unity, 1 is the only real number having a real logarithm. If b lies between 0 and 1, then l decreases as n increases, a relation that is workable in practice, though not particularly desirable. Hence we assume, as was done above, that b is positive and greater than 1.

Of all possible values greater than 1 which might be chosen as the base, two have been selected, which yield two systems of logarithms. One value is $b = 10$, used in the common logarithms, chosen because of certain practical advantages that accrue from a base which is the same as the scale of our number system. Common logarithms have also been called Briggsian logarithms, after Henry Briggs (*q.v.*). The other value taken for the base is 2.718 . . . ; it is usually represented by the letter e, and belongs to a type of irrational numbers called transcendental numbers. The logarithms having the base e are called natural logarithms, or sometimes, less appropriately, hyperbolic or Naperian logarithms. The base 10 yields logarithms that are most convenient for the purposes of computation; the base 2.718 . . . yields logarithms which lead to simpler formulas in higher analysis than other systems, and are therefore the most "natural" ones to use.

General Properties. — According to the definition of logarithms given above, *logarithms are exponents*, and therefore are endowed with the properties of exponents, viz.,

$$b^{l+l_1} = b^l \cdot b^{l_1}, \quad b^{l-l_1} = b^l / b^{l_1}, \quad b^{ll_1} = (b^l)^{l_1} \tag{1}$$

where l and l_1 may be positive or negative, rational or irrational real numbers. In the theory of logarithms, if $b^2 = n$, we use the notation $l = \log, n$, and we read this, "1 is the logarithm of n to the base b." As $b^0 = 1$ and $b^1 = b$, it is evident that no matter what value different from zero the base may have, the logarithm of 1 is zero, and the logarithm of the base itself is unity. Writing $b^2 = n$ and $b^{l1} = n_1$, the three exponential formulas (1) translated into the notation of logarithms, become

$$l + l_1 = \log_b nn_1, \quad l - l_1 = \log_b n/n_1, \quad ll_1 = \log_b (n)^{l_1} \tag{2}$$

Substituting log, n for l, log, n_1 for l_1, we have

$$\log_b n + \log_b n_1 = \text{loga}\ nn_1, \quad \log_b n - \text{loga}\ n_1 = \log_b n/n_1, \\ p \log_b n = \log_b (n^p) \tag{3}$$

Stated in words: (1) The logarithm of a product is equal to the sum of the logarithms of the factors; (2) the logarithm of a quotient is equal to the logarithm of the dividend minus the logarithm of the divisor; (3) the logarithm of a power of a number is equal to the product of the exponent and the logarithm of the number itself. *(See* EXPONENT.)

Common Logarithms. — Since $10^0 = 1$ and $10^1 = 10$, the logarithm of 1 is zero and the logarithm of 10 is unity. Any number between 1 and 10 has a common logarithm which lies between 0 and 1. Similarly, since $10^2 = 100$, any number between 10 and 100 has a common logarithm which lies between 1 and 2; and since $103 = 1{,}000$, any number between 100 and 1,000 has a common logarithm which lies between 2 and 3; and so on. Thus the logarithm of 75 is nearly 1.87506. The integral part of the logarithm is called the characteristic; the decimal part is called the mantissa. From the relations just given we obtain the general statement that *the characteristic of the common logarithm of a number greater than* 1 *is one less than the number of integral figures.* Thus, 3768.5 has four integral figures (3, 7, 6 and 8); hence its logarithm has the characteristic 3. From the relations $10^0 = 1$, $10^{-1} = .1$, $10^{-2} = .01$, $10^{-3} = .001$, etc., we obtain a corresponding rule for decimal fractions less than unity, and also the provision that the mantissa shall be positive; namely, the rule that the *characteristic of the common logarithm of a decimal fraction less than unity is negative and is numerically one more than the number of zeros immediately following the decimal point.* Thus, 0.000107 has three zeros immediately following the decimal point and the characteristic of its logarithm is -4. The minus sign is sometimes written above the characteristic, thus $\bar{4}$, to serve as a reminder that it applies only to the characteristic and not to the mantissa. It is simply for convenience that the mantissa, when different from zero, is always taken to be positive. This is accomplished by framing the rules for finding the characteristic. as was done above, so that. when the mantissa is not zero, the characteristic is always the integer immediately below the true value of the logarithm. and the fractional value (the mantissa) must be added to the characteristic to secure the true value of the logarithm. Thus the logarithm of .07 lies between -1 and -2; it might be taken to be -1 and a minus mantissa or -2 and a positive mantissa. The latter course is chosen, for the reason that the computation involving mantissas is simplified by taking them to be always positive.

The great advantage of the common system of logarithms lies in the fact that the mantissa of the same sequence of figures is the same, no matter where the decimal point is placed. Thus, 3.7568 and 375.68 have different characteristics but the same mantissa. This fact is evident from the relation

$$3.7568 \times 100 = 375.68$$

which indicates that the logarithm of 3.7568 is less than that of 375.68 by exactly 2. which is the logarithm of 100. This property of the mantissa and the simple rules for finding the characteristic make it possible to prepare tables of common logarithms in very much more compact form than for other systems. Characteristics are omitted altogether from the tables and are supplied by the computer.

Natural Logarithms. — To show how natural logarithms arise in analysis, we find the derivative of $y = \log_b x$, where b is any positive constant greater than 1. We obtain $y + h = \log_b (x + k)$,

$$h = \log_b (x + k) - \log_b x = \log_b \frac{x + k}{x} = \log_b \left(1 + \frac{k}{x}\right), \text{ and}$$

$$\frac{h}{k} = \frac{1}{x} \cdot \frac{x}{k} \cdot \log_b \left(1 + \frac{k}{x}\right) = \frac{1}{x} \cdot \log_b \left(1 + \frac{k}{x}\right)^{\frac{x}{k}}$$

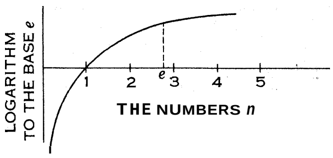
The derivative $\frac{dy}{dx}$ is the limit of $\frac{h}{k}$, as $k \to 0$. Thus we are led to consider the limit of $\left(1 + \frac{1}{n}\right)^n$, where $n = \frac{x}{k}$. This limit can be shown to exist, but the proof, when n may assume any real values, rational or irrational, is somewhat long. It is one of the fundamental limits in mathematics. Expanding $\left(1 + \frac{1}{n}\right)^n$ by the binomial theorem and letting $n \to \infty$, we obtain the rapidly convergent series

$$e = 1 + 1 + \frac{1}{2!} + \frac{1}{3!} + \cdots + \frac{1}{n!} + \cdots = 2.718281828459 \cdots$$

We thus obtain $\frac{dy}{dx} = \frac{1}{x} \log_b e$. If we take the base $b = e$, so that $\log_e e = 1$, this expression reduces to the simpler form $\frac{dy}{dx} = \frac{1}{x}$

The notation $\ln n$ often is used for the natural logarithm of n, since $\log n$ usually stands for the common logarithm of n. To avoid ambiguity the base may be designated, as in $\log_e n$.

From the graph (see fig.) it is evident to the eye that positive numbers less than 1 have negative logarithms. Numbers very close to 0 have negative logarithms whose numerical values are very large. The vertical axis is an asymptote to the curve. These statements are true also for the graphs of common logarithms and of logarithms to any base $b > 1$. It is a curious special property of the graph for natural logarithms that only one of its points has co-ordinates, both of which are rational numbers, namely the point (1, 0). In other words, the equation $l = \log_e n$, or $e^l = n$, can be satisfied by only one set of numbers l and n, of which both are real and rational, namely $n = 1$ and $l = 0$. This unexpected and curious property is rendered even more subtle by the additional fact that in all other sets of values for n and l, at least one of the two numbers is a very special type of irrational, called transcendental. As already stated, the base e is itself a transcendental number. A number is called transcendental when it is not algebraic; *i.e.*, when it cannot be the root of an algebraic equation, $x^m + ax^{m-1} + bx^{m-2} + \ldots + fx + g = 0$, where m is any positive integer and the coefficients a, b, . . . , f, g are all integers. or zero, except that g cannot be zero since that would change the degree of the equation. Algebraic numbers include all integers and rational fractions, and also all irrational numbers which are roots of algebraic equations of the kind here described. The proof that e is transcendental was a notable achievement of the French mathematician Charles Hermite in 1873.



GRAPH OF NATURAL LOGARITHMS
(*see* TEXT FOR EXPLANATION)

If in the figure we imagine all algebraic numbers marked on the n-axis and also on the l-axes, the points so marked are "dense" on each axis; *i.e.*, between any two algebraic numbers, no matter how close they are to each other, there exists at least one other algebraic number, *e.g.*, the arithmetic mean of the two. If in the nl-plane we imagine all points marked which have an algebraic abscissa n and also an algebraic ordinate l, then the entire plane is "densely" covered by these algebraic points. In spite of this fact. the logarithmic curve possesses the extraordinary property of not containing any of these algebraic points, except only $n = 1$ and $l = 0$. With this exception, all points of the curve must have at least one co-ordinate which is an irrational of the transcendental type; the curve finds its way through this complicated maze of points without hitting more than once a point whose coordinates are both algebraic. "How would Pythagoras celebrate such a discovery." exclaims Felix Klein. "if the ordinary irrational seemed to him worthy of a hecatomb!"

Change of Base. — The change of logarithms from one base to another is effected by a formula obtained as follows: If

$$n = b^l = b_1^{l_1}$$

then taking the logarithm to the base b gives

$$l \cdot \log_b b = l_1 \cdot \log_b b_1$$

Since $\log_b b = 1$, we have $l = l_1 \cdot \log_b b_1$, or

$$\log_b n = \log_{b_1} n \cdot \log_b b_1$$

If we take $b = 10$ and $b_1 = e$, we obtain

$$\log_{10} n = \log_e n \cdot \log_{10} e, \text{ where } \log_{10} e = 0.434294481903251 \ldots$$

is a constant factor sometimes called the modulus of the common system of logarithms. For the special case when $n = b$, we obtain $1 = \log_c b \cdot \log_b c$. Suppose that we know the common logarithm of 200 and we wish to compute the natural logarithm of 200. We have from the above

$$\log_e 200 = \log_{10} 200 \div \log_{10} e = 2.30103 \ldots \div 0.43429 \ldots = 5.2983 \ldots$$

the natural logarithm of 200.

Logarithms of Complex Numbers. — If, in the equation $b^l = n$, b is a positive real number and l is either positive or negative, but real, then n must necessarily be positive, for a positive number raised to a power that is real, though either positive or negative, always yields a positive result as its principal value. Under these restrictions a negative number has no logarithm. This limitation causes no embarrassment in computation with logarithms, for we proceed as if all factors were positive. If the number of negative factors is odd, we mark the final result as negative. From the standpoint of theory, however, the failure of the elementary exposition to include the logarithm of negative numbers indicates a lack of generality. It is found that, as soon as we drop the limitation that l shall be real, and permit l to become imaginary or complex. any number n, whether positive or negative or even complex, has not only one logarithm, but an infinite set of them. To establish this fact we make use of two well-known theorems in trigonometry. One theorem states that the periodicity of the sine and cosine functions is $2m\pi$, where m is any integer. The other theorem, due to Roger Cotes and Leonhard Euler, is expressed by the formula

$$e^{i\theta} = \cos\theta + i\sin\theta \tag{4}$$

where $i = \sqrt{-1}$ and θ is any angle measured in radians. Accordingly we obtain

$$e^{i\theta} = \cos\theta + i\sin\theta =$$
$$\cos(\theta + 2m\pi) + i\sin(0 + 2m\pi) = e^{i\theta + 2im\pi}$$

Suppose now that $n = p + iq$, and $l = c + id$, where p, q, c, d are real numbers; then, for simplicity, taking e as the base of the system of logarithms, we obtain

$$p + iq = e^{c+id} = e^c \cdot e^{id} = e^c(\cos d + i\sin d) \tag{5}$$

Equating the real numbers and also the imaginary numbers, we obtain the numerical relations

$$p = e^c \cdot \cos d, \qquad q = e^c \cdot \sin d$$

Allowing for periodicity, we obtain from (5) the more general equation

$$p + iq = e^c[\cos(d + 2m\pi) + i\sin(d + 2m\pi)] = e^{c + i(d\ 2m\pi)} \tag{6}$$

and $$\log,(p + iq) = c + i(d + 2m\pi) \tag{7}$$

If we write $z = p + iq$ and $p = \sqrt{(p^2 + q^2)}$, then log p = c and we obtain formula (7) in the form

$$\log, z = \log, p + i(d + 2m\pi) \tag{8}$$

As formula (7) is a general expression which is true for every integral value of m, we see that the number of logarithms of $z = p + iq$ is infinite. Let us consider some special cases. To find the logarithm of a negative number, say -1, we take $n = -1$, $p = -1, q = 0$, and obtain from formula (6) $c = 0$, and

$$\cos(d + 2m\pi) = -1$$

therefore d = π, and finally from formula (7)

$$\log_e(-1) = i\pi(1 + 2m) = i\pi, 3i\pi, 5i\pi, \text{etc.}$$

That is, the natural logarithm of -1 has, in this more general theory. an infinite number of logarithms, all imaginary. In the case of i, we find

$$\log_e i = i\left(\frac{\pi}{2} + 2m\pi\right) = \frac{i\pi}{2}, \frac{5i\pi}{2}, \frac{9i\pi}{2}, \text{etc.}$$

Similarly, for the logarithm of e, we obtain

$$\log, e = 1 + 2im\pi = 1, 1 + 2i\pi, 1 + 4i\pi, \text{etc.}$$

That is, e has one real logarithm, namely 1; all the others are imaginary. Note that the integer m may also take negative values.

The conclusion reached is that in this more general treatment of logarithmic theory, every number has an infinite set of logarithms which are all imaginary except when the number n is positive, in which case there is one real logarithm to the base e which is the same as the natural logarithm obtained by the more restricted theory.

"Gaussian" Logarithms.——When $\log_{10} a$ and $\log_{10} b$ are known, there is often great need of a process for finding $\log_{10}(a + b)$ and $\log_{10}(a - b)$, without making it necessary to pass from log a and log b to a and b. To achieve this expeditiously the Italian physicist Zecchini Leonelli in 1803 suggested a new type of table. A five-place table of this type was published in 1812 by Karl Friedrich Gauss; hence the name "Gaussian logarithms." Six-place tables of this kind are due to Karl Bremiker, to Siegmund Gundelfinger and to George W. Jones. A seven-place table was brought out by T. Wittstein. Leonelli and Gauss used a table consisting of three columns of figures, which Gauss marked by the letters A, B, C. Gauss lets $A = \log x$, $B = \log\left(1 + \frac{1}{x}\right)$, $C = \log(1 + x)$, where x is a number greater than 1. It is seen that $A + B = C$. The table is arranged according to positive values of A, increasing from 0 up to a point where B vanishes within the desired degree of approximation. Then if $\log(a + b)$ is to be determined from log a and log b, observe that, when $a > b$ and $\frac{a}{b} = x$,

$$\log(a + b) = \log a\left(1 + \frac{b}{a}\right) = \log a\left(1 + \frac{1}{\frac{a}{b}}\right) = \log a + B \tag{9}$$

The computation proceeds as follows: Find A from the equation $\log a - \log b = A$; in the table find the B which corresponds to A; add B to log a.

If $a < b$, simply interchange a and b, and take

$$\log(a + b) = \log b + B$$

To find $\log(a - b)$ from log a and log b, use column B or C, according as $\log a - \log b$ is greater or less than log 2. If it is greater, take $\log a - \log b = B$; here $\frac{a}{b} = 1 + \frac{1}{x}, \frac{1}{x} = \frac{a}{b} - 1$; hence

$$\log(a - b) = \log b\left(\frac{a}{b} - 1\right) = \log b - A \tag{10}$$

In computing, find the A which corresponds in the table to B; subtract A from log b.

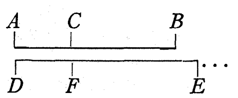
When $\log a - \log b$ is less than log 2, put $\log a - \log b = C$; then $\frac{a}{b} = 1 + x$, $x = \frac{a}{b} - 1$, and

$$\log(a - b) = \log b\left(\frac{a}{b} - 1\right) = \log b + A \tag{11}$$

In the table find the A which corresponds to C; add A to log b.

Since the time of Gauss, logarithmic addition and subtraction tables have been rearranged in several different ways. Some writers increase the number of columns, while others reduce the number of columns to two. No agreement has yet been reached as to what arrangement is the best.

History **of** Logarithms.—Logarithms were invented independently by John Napier, a Scotsman, and by Joost Bürgi, a Swiss. The logarithms which they invented differed from each other and from the common and natural logarithms now in use. Napier's logarithms were published at Edinburgh in 1614 under the title *Mirifici logarithmorum canonis descriptio*. When, in 1620, Biirgi's logarithms appeared at Prague under the title *Arithmetische und Geometrische Progresstabulen*, Napier's logarithms were already known and admired quite generally throughout Europe. To modern readers Napier's logarithms are a great curiosity. because of their singular properties and their strange mode of derivation. His theory and mode of computation are fully set forth in a second book *Mirifici logarithmorum canonis constructio*, which appeared in 1619, two years after his death. This book was translated into English in 1889 by W. R. Macdonald. Napier invoked kinematic notions in the development of his theory. One point moves along the line segment AB with a velocity decreasing so that when at any point C its



velocity is proportional to the remaining distance CB. A second point starts at the same time and with the same initial velocity, moving on the unlimited line DE with uniform velocity. Then, by definition, if C and F are simultaneous positions of the two points. DF is the logarithm of CB. The successive distances DF, taken at equal intervals of time, yield an arithmetical series whose terms are increasing; the corresponding distances CB yield a geometric series whose terms are decreasing. In the translation of these kinematic concepts into numbers, Napier begins by taking the distance $AB = 10^7$, and the distance AC passed over during the first small time-interval equal to 1. Clever devices are employed for the computation of the two series. His object was to simplify trigonometric computation. Hence his book of 1614 is not what is ordinarily called a table of logarithms of numbers, but a table of logarithmic sines which can be used also as a table of the other trigonometric functions. Since sin 90° is of frequent occurrence in computation, he thought it most convenient to take its logarithm to be zero. But sin 90° is equal to the radius of the circle which he assumed to be 10^7. Hence the logarithm of 10^7 was taken to be zero.

It is of interest to develop a formula expressing the relation between Napier's logarithms of 1614 and the modern natural logarithms. If $AB = a = 10^7, DF = x$ and $CB = y$, then $AC = a - y$. The velocity of the point C at any moment is $\frac{d(a-y)}{dt} = y$. Integrating, we obtain $-\log_e y = t + c$, where c is a constant of integration. To determine this constant, assume the initial conditions of motion to be $t = 0$ and $y = a$; substituting these values, $c = -\log_e a$. The uniform motion of the point F on the second line yields $\frac{dx}{dt} = a$ as its velocity. Consequently $x = at$, the constant of integration being zero in this case. Substituting for t and c their values, $-\log_e y = \frac{x}{a} - \log_e a$, observing that $a = 10^7$ and $-\log y = \log \frac{1}{y}$, and remembering that, by Napier's definition of a logarithm, $x =$ Nap. log y, we have

$$\text{Nap. log } y = 10^7 \log_e \frac{10^7}{y} \qquad (12)$$

Assuming the properties of natural logarithms, the various properties of the logarithms of Napier may be deduced from this compact formula. We see that Napier's logarithms increase as the numbers y decrease, that $y = 10^7$ has the logarithm 0, and that a number y larger than 10^7 has a negative logarithm. We see also that, in Napier's system, the logarithm of a product xy of two numbers is not equal to the sum of the logarithms of the numbers x and y. How is it possible to use such numbers in computation? The answer is that, according to the custom of the time, trigonometric computation was carried on by the aid of proportions, such as $\sin A : \sin C = a : c$. An unknown term, sin A, is found by two operations, one a multiplication and the other a division. For these two operations combined, Napier's logarithms give correct results. In other words, in his system the relation holds, $\log \sin A - \log \sin C = \log a - \log c$. Since Napier in 1614 did not take the logarithm of 1 to be 0, his logarithms, unmodified, do not admit *of a* base; *i.e.*, the relation of a number to its logarithm cannot be expressed by the equation $b^l = n$.

Bürgi's Logarithms.—Bürgi's publication of 1620 is, in arrangement, a table of antilogarithms. The logarithms are printed in red and the numbers in black. His explanation of his logarithms was not printed until 1856 (*Archiv für Mathematik und Physik,* vol. xxvi, pp. 316–344, 1856). But Bürgi did not have the concept of a logarithmic base any more than had Napier. Neither of them started out from the relation $b^l = n$. The possibility of defining logarithms as exponents was recognized by John Wallis in 168j and by Johann Bernoulli in 1694, but not until 1742 was a systematic exposition of logarithms based on this idea, by William Jones. Burgi started out with the comparison of arithmetic and geometric series, which indicates clearly that when inventing his logarithms he adopted the point of view taken before him by Michael Stifel and other algebraists for the purpose of illustrating the addition of exponents in multiplication, and the subtraction of exponents in division.

Invention of Common Logarithms.—The invention of the common system of logarithms resulted from the combined efforts of Napier and Henry Briggs. The share taken by each is described by Briggs in his *Arithmetica* logarithmica (1624):

I myself, when expounding this doctrine publicly in London to my auditors in Gresham college, remarked that it would be much more convenient that zero should be kept for the logarithm of the whole sine (as in the Canon *mirificus*) but that the logarithm of the tenth part of the same whole sine, that is to say, 5 degrees 44 minutes and 21 seconds should be 10000000000 And concerning that matter I wrote immediately to the author himself; and as soon as the season of the year and the vacation of my public duties of instruction permitted I journeyed to Edinburgh, where, being most hospitably received by him, I lingered for a whole month. But as we talked over the change in the logarithms he said that he had for some time been of the same opinion and had wished to accomplish it; he had however published those he had already prepared until he could construct more convenient ones, if his affairs and his health would admit of it But he was of the opinion that the change should be effected in this manner, that 0 should be the logarithm of unity and 10000000000 that of the whole sine; which I could not but admit was by far the most convenient. So, rejecting those which I had previously prepared, I began at his exhortation to meditate seriously about the calculation of these logarithms.

This statement contains all the information that has been handed down on the part taken by the two mathematicians in the invention of common logarithms. Briggs's and Napier's suggestions, described in this passage, do not quite yield the common logarithms. If R is the radius, Briggs's suggestion was that $\log R = 0$ and $\log \frac{R}{10} = 10^{10}$. Napier's improved suggestion was $\log 1 = 0$ and $\log R = 10^{10}$. It was a later change, nowhere specifically described, which replaced $\log R = 10^{10}$ by $\log 10 = 1$. Briggs began his computing of tables by extracting the square root of 10 fifty-four times in succession and at each step dividing the logarithm by 2. Thus $\log \sqrt{10} = \log 3.162 \ldots = 0.5$; $\log \sqrt[4]{10} = \log 1.778 \ldots = 0.25$; etc. His publication of 1624 contained the logarithms to 14 places of the numbers 1 to 20,000 and from 90.000 to 100,000. The gap 20.000 to 90,000 was filled up by Adrian Vlacq, a Dutch bookseller then residing in London, who in 1628 published tables from 1 to 100.000. Tables of common logarithms of trigonometric functions were first published by Edmund Gunter in 1620; more extensive ones, computed in part by Briggs and completed by Henry Gellibrand, were published by Vlacq at his own expense. The word "characteristic." as used in the theory of logarithms, first occurred in Briggs's tables of 1624; the word "mantissa" was introduced by John Wallis in his Algebra of 1693.

Origin of Natural *Logarithms.*—Natural logarithms first arose as more or less accidental variations of Napier's original logarithms. Their real significance in analysis was not recognized until later. The earliest natural logarithms occur in the 1618 edition of Edward Wright's translation into English of Napier's *Descriptio,* where in an anonymous appendix, very probably written by William Oughtred, there is a small table containing logarithms of 72 sines. used in a process of interpolation. The latter are natural logarithms with the decimal point omitted. In the 1622 edition of John Speidell's *New* Logarithms there is included a table of logarithms of the numbers 1 – 1.000; except for the omission of the decimal point, these are natural logarithms. The earliest table to appear after the importance of natural logarithms in analysis nas generally understood was published more than a century later, in 1770, by Johann Heinrich Lambert, an Alsatian. He included a seven-place table of natural logarithms of the numbers 1 – 100 in his *Zusätze zu* den Logarithmischen und *Trigonometrischen* Tabellen.

Controversies About Logarithms of Complex *Numbers.*—The history of this subject affords an interesting example of how able intellects may for a long time grope hopelessly in the dark but through persistent effort may finally reach general, consistent and elegant results. In 1712 and 1713 G. W. Leibniz and Johann Bernoulli discussed in their correspondence the question whether negative numbers have logarithms. Leibniz contended that since a positive logarithm corresponds to a number larger than unity and a negative logarithm to a positive number less than unity, the logarithm of -1 was not really true, but imaginary (non-existent); hence the ratio $-1 \div 1$, having no logarithm, is itself imaginary. Bernoulli maintained that -1 has a logarithm, since $dx : x = -dx : -x$, and, integrating, $\log x = \log(-x)$. Thus x and $-x$ have the same logarithm.

A second discussion of this question took place in a correspondence between Johann Bernoulli and Leonhard Euler in the years 1727–31. Euler uncovered the inconsistencies of Bernoulli's conclusion that $\log x = \log(-x)$, and also of views which he himself had entertained. Somewhat later, Euler exchanged letters with Jean d'Alembert on this topic and disproved the latter's contention that $\log(-1) = 0$. About 1747 Euler succeeded in creating a consistent theory of logarithms of negative and complex numbers, but d'Alembert advanced arguments against it—metaphysical, analytical, and geometrical in nature — which shrouded the subject in a dense haze and helped to prolong the controversy to the beginning of the 19th century.

Euler published in 1749 an article De la controverse entre Mrs. Leibnitz et Bernoulli sur les logarithmes, *négatifs* et imaginaires, which gives the modern results that $\log n$ has an infinite number of values, which are all imaginary, except when n is a positive number, in which case one logarithm out of this infinite number is real. These conclusions were so novel and the theory of imaginary numbers in algebra was so little understood that in his day Euler's theory was not understood or generally accepted as valid.

In the early part of the 19th century the general theory of logarithms was elaborated, and Euler's results were confirmed by Martin Ohm, John Graves, John Warren, A. J. H. Vincent, Augustus De Morgan, William R. Hamilton and others.

Methods of Computing *Logarithmic* Tables. — For the computation of logarithms numerous processes were devised by Napier, Briggs, James Gregory, Abraham Sharp and others. Nicolaus Mercator in 1668 derived the infinite series

$$\log(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} +$$

which, though convergent for $-1 < x \leqq 1$, is worthless for practical computation because of its slow convergence. John Wallis in 1695 deduced from it the rapidly convergent series

$$\tfrac{1}{2}\log\frac{1+z}{1-z} = z + \tfrac{1}{3}z^3 + \tfrac{1}{5}z^5 +$$

and G. F. Vega, in his Thesaurus of 1794, let $z = 1/(2y^2 - 1)$ and obtained expressions converging rapidly.

See also ARITHMETIC: *Logarithms;* INTERPOLATION; MATHEMATICAL TABLES; NOMOGRAPHY.

BIBLIOGRAPHY.—For details on the modern technique of logarithmic computation and ior lists of leading publications of logarithmic tables, *see* the *Napier Tercentenary Memorial Volume* (1915). Among other publications of logarithmic tables are: a 10-place table of logarithms of numbers to 100,000 (1910); also an 8-place table to 200,000, and trigonometric tables to every sexagesimal second, by J. Bauschinger and J. Peters; a 14-place table of logarithms of sines and tangents to every 10 sexagesimal seconds, by H. Andoyer (1911). (F. CA.; X.)

LOGAU, FRIEDRICH, FREIHERR VON (1604–1655), German epigrammatist, was born at Brockut near Nimptsch in Silesia in June 1604. He entered the service of the duke of Brieg, and in 1644 was made ducal councilor. He died at Liegnitz on July 24, 1655.

Logau's epigrams, which appeared under the pseudonym "Salomon von Golaw" (an anagram of his real name), show great range and variety of expression. They are contained in two collections: Erstes *Hundert deutscher Reimensprüche* (1638), and *Deutscher Sinnge-dichte* drei *Tausend* (1654). He satirized the court life, the useless bloodshed of the Thirty Years' War, the lack of national pride in the German people and their slavish imitation of the French in customs, dress and speech. He regarded himself as a follower of the poet Martin Opitz, but he did not allow such a tie to influence his independence.

LOGGERHEAD (Caretta caretta), a carnivorous marine turtle inhabiting tropical seas. See TURTLE.

LOGGIA, in architecture. is a room, gallery or hall open to the air on one or more sides, associated particularly with the Mediterranean and near eastern regions, where an open sitting room with protection from the hot sun was desired. Ancient Egyptian houses often had a loggia on their roofs, or an interior loggia facing upon a court. In medieval and Renaissance Italy the loggia was used frequently in conjunction with a public square or piazza. Thus the Loggia dei Lanzi, begun 1376, consists of three gigantic arches dominating one side of the main square of Florence. Another at Florence, the Loggia degli Innocenti, begun in 1419 after the design of Filippo Brunelleschi, marks the first appearance of the Renaissance revival of classic forms. The loggia was also an essential feature of villas and often had outstanding decoration, such as that of Raphael and his assistants in the Villa Farnesina at Rome. (D. R. CN.)

LOGIA, a title used to describe a collection of the sayings of Jesus Christ, and therefore generally applied to the "Sayings of Jesus" discovered in Egypt by B. P. Grenfell and A. S. Hunt. There is some question as to whether the term is rightly used for this purpose. It does not occur in the papyri in this sense. Each "saying" is introduced by the phrase "Jesus says," (legei) and the collection is described in the introductory words of the 1903 series as logoi, not as logia. Some justification for the employment of the term is found in early Christian literature. Several writers speak of the oracles of (or concerning) the Lord. Polycarp, for instance, speaks of "those who pervert the oracles of the Lord" (Philipp. 7), and Papias, as Eusebius relates, wrote a work with the title "Expositions of the Oracles of the Lord." The expression has been variously interpreted. It need mean no more than narratives of (or concerning) the Lord; on the other hand, the phrase is capable of a much more definite meaning, and there are many scholars who hold that it refers to a document which contained a collection of the sayings of Jesus and which is believed to be the source, or the principal source, of the teachings of Jesus found in Matthew and Luke but not in Mark.

"The Sayings." — These fragments, to which the term Logia is also applied, consist of: (1) a papyrus leaf containing seven or eight sayings of Jesus discovered in 1897; (2) a second leaf containing five more sayings discovered in 1903; and (3) two fragments of unknown Gospels, the former published in 1903, the latter in 1907. All these were found among the great mass of papyri acquired by the Egyptian Exploration fund from the ruins of Oxyrhynchus, one of the chief early Christian centres in Egypt, situated about 120 mi. S. of Cairo. The eight sayings discovered in 1897 may be translated as follows:

1. ". . . and then shalt thou see clearly to cast out the mote that is in thy brother's eye."

2. "Jesus saith, Except ye fast to the world, ye shall in no wise find the kingdom of God; and except ye make the sabbath a real sabbath, ye shall not see the Father."

3. "Jesus saith, I stood in the midst of the world and in the flesh was I seen of them, and I found all tnen drunken, and none found I athirst among them, and my soul grieveth over the sons of men, because they are blind in their heart, and see not. . . ."

4. ". . . poverty . . . ."

5. "Jesus saith, Wherever there are two, they are not without God, and wherever there is one alone, I say, I am with him. Raise the stone and there thou shalt find me, cleave the wood and there am I."

6. "Jesus saith, A prophet is not acceptable in his own country, neither doth a physician work cures upon them that know him."

7. "Jesus saith, A city built upon the top of a high hill and stablished can neither fall nor be hid."

8. "Jesus saith, Thou hearest with one ear [but the other ear hast thou closed]."

The "sayings" of 1903 are as follows:

1. "Jesus saith; Let not him who seeks . . . cease until he finds and when he finds he shall be astonished; astonished he shall reach the kingdom and having reached the kingdom he shall rest."

2. "Jesus saith (ye ask? who are those) that draw us (to the kingdom if) the kingdom is in Heaven? . . . the fowls of the air and all beasts that are under the earth or upon the earth and the fishes of the sea (these are they which draw) you and the kingdom of Heaven is within you and whosoever shall know himself shall find it. (Strive therefore?) to know yourselves and ye shall be aware that ye are the sons of the (Almighty?) Father; (and?) ye shall know that ye are in (the city of God?) and ye are (the city?)."

3. "Jesus saith, A man shall not hesitate . . . to ask concerning his place (in the kingdom. Ye shall know) that many that are

first shall be last and the last first and (they shall have eternal life?)."

4. "Jesus saith, Everything that is not before thy face and that which is hidden from thee shall be revealed to thee. For there is nothing hidden nhich shall not be made manifest nor buried which shall not be raised."

5. "His disciples question him and say, How shall we fast and how shall we (pray?) . . . and what (commandment) shall we keep . . . Jesus saith . . . do not . . . of truth . . . blessed is he "

First Gospel Fragment. — The fragment of a lost Gospel which was discovered in 1903 contained originally about 50 lines, but many of them have perished and others are undecipherable. The translation, as far as it can be made out, is as follows:

1–7. "(Take no thought) from morning until even nor from evening until morning either for your food what ye shall eat or for your raiment what ye shall put on." 7–13. "Ye are far better than the lilies which grow but spin not. Having one garment what do ye (lack)? . . ." 13–15. "Who could add to your stature?" 15–16. "He himself will give you your garment." 17–23. "His disciples say unto him, When wilt thou be manifest unto us and when shall we see thee? He saith. When ye shall be stripped and not be ashamed . . ." 41–46. "He said. The key of knowledge ye hid: ye entered not in yourselves, and to them that were entering in, ye opened not."

Second Gospel Fragment. — The second Gospel fragment discovered in 1907 "consists of a single vellum leaf, practically complete except at one of the lower corners and here most of the lacunae admit of a satisfactory solution." The translation is as follows:

". . . before he does wrong makes all manner of subtle excuse. But give heed lest ye also suffer the same things as they: for the evil doers among men receive their reward not among the living only, but also await punishment and much torment. And he took them and brought them into the very place of purification and was walking in the temple. And a certain Pharisee, a chief priest. whose name was Levi. met them and said to the Saviour, Who gave thee leave to walk in this place of purification: and to see these holy vessels when thou hast not washed nor yet have thy disciples bathed their feet? But defiled thou hast walked in this temple, which is a pure place, wherein no other man walks except he has washed himself and changed his garments, neither does he venture to see these holy vessels. And the Saviour straightway stood still with his disciples and answered him, Art thou then. being here in the temple, clean? He saith unto him, I am clean; for I washed in the pool of David and having descended by one staircase, I ascended by another and I put on white and clean garments, and then I came and looked upon these holy vessels. The Saviour answered and said unto him. Woe ye blind, who see not. Thou hast washed in these running waters wherein dogs and swine have been cast night and day and hast cleansed and wiped the outside skin which also the harlots and flute-girls anoint and wash and wipe and beautify for the lust of men; but within they are full of scorpions and all wickedness. But I and my disciples who thou sayest have not bathed have been dipped in the waters of eternal life which come from . . . . But woe unto the . . . ."

Probable Date of the "Sayings." — These documents have naturaliy excited considerable interest and raised many questions. The papyri of the "sayings" date from the 3rd century and most scholars agree that the "sayings" themselves go back to the 2nd. The year A.D. 140 is generally assigned as the *terminus* ad *quem*. There is a considerable diversity of judgment, however, with regard to the value of the collection.

1. Some scholars maintain that the collection goes back to the 1st century and represents one of the earliest attempts to construct an account of the teaching of Jesus. They are therefore disposed to admit to a greater or less extent and with widely varying degrees of confidence the presence of genuine elements in the new matter.

2. Sanday and many others regard the sayings as originating early in the 2nd century and think that, though not "directly dependent on the Canonical Gospels," they have "their origin under conditions of thought which these Gospels had created." The "sayings" must be regarded as expansions of the true tradition, and little value is therefore to be attached to the new material.

With the knowledge at our disposal, it is impossible to reach an assured conclusion between these two views. The real problem, to which no solution has been found, is to account for the new material in the "sayings." There seems to be no motive sufficient to explain the additions that have been made to the text of the Gospels. It cannot be proved that the expansions were made in the interests of any sect or heresy. Unless new discoveries provide the clue, or some reasonable explanation can otherwise be found, there seems to be no reason why the "sayings" should not be regarded as containing material to be taken into account in the critical study of the teaching of Jesus.

Date of the Gospel Fragments. — The 1903 Gospel fragment is so mutilated in many of its parts that it is difficult to decide upon its character and value. It appears to date from before 150, and to be taken from a Gospel which followed more or less closely the version of the teaching of Jesus given by Matthew and Luke. The second Gospel fragment (1907) seems to be of later origin than the documents already mentioned. Grenfell and Hunt date the Gospel, from which it is an excerpt, about 200. There is considerable difficulty with regard to some of the details. The statement that an ordinary Jew was required to wash and change his clothes before visiting the inner court of the temple is quite unsupported by any other evidence. Nothing is known about "the place of purification" nor "the pool of David." Nor does the statement that "the sacred vessels" mere visible from the place where Jesus was standing seem at all probable. But if the inaccuracy of the fragment in this important respect is admitted, the historical character of the whole episode breaks down and it is probably to be regarded as an apocryphal elaboration of Matt. xv, 1–20, and Mark vii, 1–23.

See the *Oxyrhynchus Papyri*, part i (1897), part iv (1904), part v (1908). (H. T. A.; X.)

LOGIC is the systematic study of the structure of propositions and of the general conditions of valid inference by a method which abstracts from the content or *matter* of the propositions and deals only with their logical *form*. This distinction between form and matter is made whenever we distinguish between the logical soundness or validity of a piece of reasoning and the truth of the premisses from which it proceeds, and in this sense is familiar in everyday usage. However, a precise statement of the distinction must be made with reference to a particular language or system of notation, a *formalized language*, which shall avoid the inexactnesses and systematically misleading irregularities of structure and expression that are found in ordinary (colloquial or literary) English and in other natural languages, and shall follow or reproduce the logical form — at the expense, where necessary, of brevity and facility of communication. To adopt a particular formalized language is thus to adopt a particular system or theory of logical analysis. And the formal method may then be characterized by saying that it deals with the objective form of *sentences* which express propositions, and provides in these concrete terms criteria of meaningfulness, of valid inference, and of other notions closely associated with these — among which we mention the notions of logical compatibility, analytic or logical truth, probable inference, and degree of confirmation.

The topics of inductive and probable inference, confirmation, and degree of confirmation belong to *inductive logic*, and are treated in the articles INDUCTION and PROBABILITY. In this article we confine attention to the remaining part of logic, or *deductive logic*. And we also omit treatment of *modal logic*, partly because this branch of deductive logic (though its beginnings go back to Aristotle) is still in a much more unsettled state than the remainder. But works on modal logic and modality are included in the bibliography.

FUNDAMENTALS OF MODERN LOGIC

The Propositional Calculus is, in most developments, the most elementary branch of logic, on which the others are based. It deals with the *sentence connectives*: "and," "or," "if," "not," "if and only if," and others of similar character. And in order to analyze and exhibit the logical properties of the connectives it employs also propositional variables p, q, r, . . . , which are to be thought of as variables replaceable by sentences.

In strictness the sentences by which the propositional variables are replaceable should be sentences of some appropriate formalized language (for instance, one of the functional calculi which are described below, or one of the systems of set theory). But for informal expository purposes we may employ also declarative sentences of the English language. Thus, with $\supset$ as notation for "if . . . then," the expression $p \supset q$ of propositional calculus may be thought of as having (by substitution for p and q) such instances as the following: "If you are not satisfied, we will refund your money," "If there are any survivors of the disaster, they are in need of immediate help," "If Vidkun Quisling was a patriot, then n-butyl mercaptan is a perfume."

Of the various systems of notation which are in use, me here adopt a particular one for purposes of exposition. We shall use the sign $\sim$ to denote negation ("$\sim p$" to mean "not p"), the sign $\supset$ to denote the *conditional* ("$p \supset q$" to mean "if p then q" or "not both p and not q"), the sign $|$ to denote non-conjunction ("$p|q$" to mean '(not both p and q"), juxtaposition or a dot to denote conjunction ("pq" or "$p \cdot q$" to mean "p and q"), the sign $\equiv$ to denote the biconditional ("$p \equiv$ q" to mean "p if and only if q"), the sign v to denote inclusive disjunction ("$p \vee q$" to mean "p or q or both"), the sign $\not\equiv$ to denote exclusive disjunction ("$p \not\equiv q$" to mean "p or q but not both^x).—As the word "or" is am-biguous in ordinary English usage between inclusive disjunction and exclusive disjunction, the two signs v and $\not\equiv$ are provided for the two meanings of the word. The signs $\supset$ and $\equiv$ may often conveniently be read as "implies" (or "implies that") and "is equivalent to" respectively; but these readings must be employed with a certain caution not to misunderstand them, since the terms implication and equivalence in ordinary usage often suggest that there is some relationship between the logical forms of the propositions or the sentences involved, whereas the truth of $p \supset$ q and of $p \equiv$ q (upon substitution of particular sentences for p and q) requires no such relationship. The connective $\supset$ is also said to stand for material implication, distinguished from formal implication (defined below) and strict implication (a notion of modal logic). Similarly, $\equiv$ is said to stand for material equivalence.

There are various ways in which some of the sentence connectives named above can be defined in terms of others. If the sign of non-conjunction (*Sheffer's* stroke) is taken as primitive, all the other connectives can be defined from this one. Also, if the signs of negation and inclusive disjunction are taken as primitive, all the others can be defined in terms of these; likewise if the signs of negation and conjunction are taken as primitive. But because of its special role in the rule of *modus* ponens and in the deduction theorem (see below), we here prefer to include $\supset$ as one of the primitive connectives. Therefore we take $\sim$ and $\supset$ as primitive, and define the remaining connectives as follows:

$$[\mathrm{A}|\mathrm{B}] \rightarrow [\mathrm{A} \supset \sim\mathbf{B}] \qquad [\mathrm{A} \equiv \mathrm{B}] \rightarrow [[\mathrm{A} \supset \mathrm{B}][\mathrm{B} \supset \mathbf{A}]]$$
$$[\mathbf{AB}] \rightarrow \sim[\mathrm{A}|\mathbf{B}] \qquad [\mathbf{A} \vee \mathbf{B}] \rightarrow [\sim\mathrm{A}\ \mathbf{3}\ \mathbf{B}]$$
$$[\mathrm{A} \cdot \mathrm{B}] \rightarrow \sim[\mathrm{A}|\mathrm{B}] \qquad [\mathbf{A} \not\equiv \mathbf{B}] \rightarrow \text{--}[\mathbf{A} \equiv \mathbf{B}]$$

Here the bold capital letters stand for arbitrary well-formed *formulas* of the propositional calculus (in the technical sense defined below)—or, when appropriate, for arbitrary well-formed formulas of some more extensive formalized language containing the propositional calculus as a part. And the arrow is to be read "is defined as," or "is an abbreviation for."

To formulate the propositional calculus explicitly, we first list the primitive symbols. These are the two connectives $\sim$ $\supset$, the two brackets [ ], and an infinite list of propositional variables p, q, 7, s, p_1, q_1, r_1, s_1, p_2, $\cdot \ldots$ Any finite sequence of the primitive symbols is a formula. But as some formulas are evidently not meaningful, we define a subclass, the well-formed *formulas*, by the following *formation* rules: i. A propositional variable standing alone is a well-formed formula. ii. If A is a well-formed formula, $\sim\mathbf{A}$ is a well-formed formula, iii. If A and B are well-formed formulas, [A $\supset$ **B**] is a well-formed formula.

Hereafter the bold capital letters shall stand for well-formed formulas of the propositional calculus—or later also well-formed formulas of other calculi or formalized languages—and the condition of well-formedness shall be understood without explicit repetition in every case.

In writing well-formed formulas we may abbreviate them by means of the definitions listed above; for instance, $[pq]$ is to be understood as an abbreviation of $\sim[p \supset \sim q]$, and [p $\equiv$ [p v q]] is to be understood as an abbreviation of [[p $\supset$ $[\sim p \supset q]][[\sim p \supset q] \supset p]]$, *i.e.*, as an abbreviation of $\sim[[p \supset [\sim p \supset q]] \supset \sim[[\sim p \supset q] \supset p]]$. Also well-formed formulas may be abbreviated by omission of brackets, in accordance with the three following conventions: (1) A bold dot is used to indicate that the scope of an omitted pair of brackets extends from the point where the dot appears, forward to the end of the formula; for example, $p \supset \centerdot\, q \supset \centerdot\, r \supset s$ is an abbreviation of [p $\supset$ [q $\supset$ [r $\supset$ s]]]. *(2)* In restoring omitted brackets, and so far as not otherwise indicated by bold dots, the scope of a pair of brackets belonging to a conditional, a biconditional, or an exclusive disjunction is to be made wider than the scope of a pair of brackets belonging to an inclusive disjunction or a non-conjunction, and the latter in turn wider than the Scope of a pair of brackets belonging to a conjunction; for example, $\sim p$ v q $\sim r$ > pq v rs is an abbreviation of $[[\sim p \vee [q \sim r]] \supset [[pq] \vee [rs]]]$, *i.e.*, of $[[\sim\sim p \supset \sim[q \supset \sim\sim r]]\ \mathbf{3}\ [\sim\sim[p\ \mathbf{3} \sim q] \supset \sim[r \supset \sim s]]]$. **(3)** Where neither of the two preceding conventions applies, brackets are restored in accordance with the convention of association to the left; for example, $p \supset$ [q $\supset$ r] $\supset \sim s \supset \centerdot\, p \supset q \supset r$ is an abbreviation of $[[[p \supset [q \supset r]] \supset \sim s] \supset [[p\ \mathbf{3}\ q] \supset r]]$.

It must be understood that these abbreviations are not an actual part of the formalized language—the propositional calculus, or better, the particular formulation of propositional calculus which we are here stating. *E.g.*, the formalized language expresses the inclusive disjunction of p and q by $[\sim p \supset q]$, and it is merely a device for our typographical convenience in writing about the formalized language, serving the purposes of brevity and perspicuity, that we sometimes abbreviate this as $[p \vee q]$, or as p v q. Especially, the rules of inference stated below are to be applied to the well-formed formulas themselves, and not to their abbreviations.

As axioms of the propositional calculus we take the three following:

1. $p \supset q \supset \centerdot\, q \supset r \supset \centerdot\, p \supset r$
2. $\sim p \supset p \supset p$
3. $p \supset \centerdot \sim p \supset q$

The assertion of the axioms is of course meant in the sense that they hold for any p, q, and r whatever. These particular axioms are due to Jan Łukasiewicz; they represent only one of many possible choices of axioms from which the same theorems follow by means of the two rules of inference below. Convenient verbal readings of the axioms, in which advantage is taken of the two readings of >, are as follows: 1. If p implies q, if q implies r, then p implies r. 2. If not-p implies p, then p. 3. p implies that, if not-p, then q.—Axiom 1 expresses the transitive law of material implication, and 2, the law of Clavius.

The rules of inference are the two following: I. Rule of substitution. From A, if B is any well-formed formula and b is a propositional variable, to infer the result of substituting B for b throughout A. II. Rule of *modus* ponens. From [A $\supset$ B], and A, to infer B.—In an application of I, we call A the premiss, and the result of the substitution the conclusion. In an application of II, [A $\supset$ B] is the major premiss, A is the minor premiss, and B is the conclusion.

A theorem of the propositional calculus is obtained from the axioms by a succession of applications of the rules of inference. Or more explicitly, a proof of a theorem is a finite sequence of well-formed formulas, of which the last one is the theorem in question, and each of which either is an axiom or is inferred from earlier formulas in the sequence by one of the two rules of inference; and a theorem is then any well-formed formula of which there is a proof.

For example, a proof may be constructed as follows, of the theorem $p \supset$ p (the *reflexive* law of material implication). Axiom 1 is first taken as premiss for an application of the rule of substitution. The substitution of $\sim p$ > p for q gives p > $[\sim p > p]$ $\supset \centerdot \sim p \supset p \supset r \supset \centerdot\, p \supset$ r, and from this by substitution of p for r (another application of the rule of substitution) is inferred $p \supset [\sim p \supset p] \supset \centerdot \sim p \supset p \supset p \supset \centerdot\, p \supset p$. This last is to be the major premiss in an application of *modus* ponens. Axiom 3 is the source of the minor premiss $p \supset \centerdot \sim p \supset p$ (obtained by substituting p for q). Hence by *modus* ponens is inferred $\sim p \supset p \supset p$ $\supset \centerdot\, p \supset p$. Axiom 2 is then taken as minor premiss, and by another application of *modus* ponens is inferred $p \supset p$.

Other theorems are the following, which may be proved in the order named (though the proofs are generally not as easy as the example just given): $p \supset . q \supset p$ (law of *affirmation of* the consequent), $\sim q \supset \sim p \supset . p \supset q$ (converse law of *contraposition*), $\sim p \supset . p \supset q$ (law *of* denial *of the* antecedent), $p \supset q \supset p \supset p$ (*Peirce's law*), $p \supset [p \supset q] \supset . p \supset q$, $p \supset . p \supset q \supset q$ (*law of* assertion), $p \supset [q \supset r] \supset . q \supset [p \supset r]$ (law *of commutation*), $q \supset r \supset . p \supset q \supset . p \supset r$, $p \supset [q \supset r] \supset . p \supset q \supset . p \supset r$ (*self-distributive* law *of* material implication), $\sim\sim p \supset p$ (law *of* double negation), $p \supset \sim\sim p$ (converse law *of* double negation), $p \supset q \supset . \sim q \supset \sim p$ (law *of* contraposition), $p \supset q \supset . p \supset \sim q \supset \sim p$ (law *of reductio* ad absurdum), $\sim . p \sim p$ (law *of* contradiction), $p \vee \sim p$ (law *of* excluded middle), $pq \supset r \supset . p \supset . q \supset r$ (*law* of exportation), $p \supset [q \supset r] \supset . pq \supset r$ (law *of* importation), $[p \supset q][p \supset r] \supset . p \supset qr$ (law of composition), $\sim[pq] \equiv \sim p \vee \sim q$ and $\sim[p \vee q] \equiv \sim p \sim q$ (De Morgan's *laws*), $[p \supset q] \vee [q \supset p]$.

The last theorem in the foregoing list is sometimes spoken of as one of the "paradoxes" of material implication. It is not a paradox in the sense of an antinomy and is not inconsistent with important uses of $\supset$ as expressing an implication relation. But it shows a divergence of the meaning of $\supset$ from some of the various meanings of the words "if then" in ordinary usage, and especially from their familiar but not very definite meaning in conditions contrary to *fact*. (To illustrate the latter we quote the conditional sentence, "If Vidkun Quisling had been a patriot, then *n*-butyl mercaptan would be a perfume," which must be distinguished from the corresponding sentence with a simple condition, quoted above, and indeed is clearly false.)

We shall speak of a valid *inference of* the propositional *calculus* not only within the propositional calculus itself but also within a more extensive formalized language containing the propositional calculus as a part. Namely a substitution instance of a theorem of the propositional calculus is any well-formed formula (of the more extensive formalized language) which results from a theorem of the propositional calculus by substituting specific well-formed formulas (of the more extensive language) for one or more of the propositional variables. And an inference from hypotheses $\mathbf{A}_1$, $\mathbf{A}_2$, . . . , $\mathbf{A}_n$ to a conclusion B is called a valid inference of the propositional calculus if B can be obtained from the hypotheses $\mathbf{A}_1$, $\mathbf{A}_2$, . . . , $\mathbf{A}_n$, together with any number of additional premisses which are either theorems of the propositional calculus or substitution instances of theorems of the propositional calculus, by a succession of applications *of* the *rule of modus* ponens only.

Within the propositional calculus itself, if the inference from $\mathbf{A}_1$, $\mathbf{A}_2$, . . . , $\mathbf{A}_n$ to $\mathbf{B}$ is a valid inference of the propositional calculus, it can be shown that $\mathbf{A}_1 \supset . \mathbf{A}_2 \supset . \ldots \mathbf{A}_n \supset \mathbf{B}$ must then be a theorem of the propositional calculus. This general result, which is not a theorem *of* the propositional calculus but a theorem about the propositional calculus, is known as the deduction theorem. We shall see below that it can be extended to other more extensive formalized languages.— It is in the sense that the rule of *modus ponens* and the deduction theorem are both fulfilled that we are able to think of and use $\supset$ as expressing an implication relation (in spite of the so-called paradoxes of material implication).

It is convenient to use such words as "theorem," "proof," "premiss," "conclusion" both for propositions, in whatever language expressed, and for formulas expressing propositions in some fixed formalized language. However, theorems about a particular formalized language are distinguished from theorems of the language by calling the former *metatheorems.* The deduction theorem is, *e.g.*, a metatheorem of the propositional calculus, in contrast with, say, Peirce's law, which is a theorem of the propositional calculus. The metatheorems of a formalized language are said to belong to the metatheory of the language: and though we shall here treat the metatheory informally, it may itself be organized as a formalized language, which is then called a meta-language of the first language as object language. (See METATHEORY; SEMANTICS IN LOGIC.)

We go on to explain some additional metatheorems of the propositional calculus.

The two primitive connectives (hence all connectives definable from them) denote truth-functions: *i.e.*, the truth-value (truth or falsehood) of $\sim p$ and of $p \supset q$ is uniquely determined by the truth-values of p and q. In fact the truth-value of $\sim p$ is falsehood when the truth-value of p is truth, and truth when the truth-value of p is falsehood. And (corresponding to the four theorems $p \supset . q \supset . p \supset q$, $p \supset . \sim q \supset \sim . p \supset q$, $\sim p \supset . q \supset . p \supset q$, $\sim p \supset . \sim q \supset . p \supset q$) the truth-value of $p \supset q$ is falsehood when the truth-value of p is truth and the truth-value of q is falsehood, and the truth-value of $p \supset q$ is truth in each of the three remaining cases. These determinations of the truth-value of $\sim p$ and of $p \supset q$ in terms of the truth-values of p and q, by using (say) 0 for truth and 1 for falsehood, may conveniently be displayed in the form of tables, which are then called truth-tables of negation and material implication.

The truth-tables enable us, given a well-formed formula of the propositional calculus and an assignment of a truth-value to each of its variables, to reckon out by a mechanical process the truth-value of the entire formula. (For example, if the values of p and q are both 1, the value of $p \supset q$ is 0, hence the value of $p \supset q \supset p$ is 1, hence the value of Peirce's law $p \supset q \supset p \supset p$ is 0.) If, for all possible assignments of truth-values to the variables, the calculated truth-value of the entire formula is 0, or truth, the formula is said to be a tautology. The test whether a well-formed formula is a tautology is effective, since in any particular case the total number of different assignments of truth-values to the variables is finite, and the calculation of the truth-value of the entire formula can be carried out separately for each assignment of truth-values to the variables.

Now it may be verified that the three axioms, 1–3, given above are tautologies, and that the two rules of inference preserve tautologies in the sense that if the premiss or premisses are tautologies the conclusion must be a tautology. Hence every theorem of the propositional calculus is a tautology. By a more difficult argument it may be shown that every tautology is a theorem. Hence the truth-table test for tautologies (just described) can be used to decide, for any given well-formed formula of the propositional calculus, whether it is a theorem. This is a solution of the *decision* problem of the propositional calculus.

As corollaries of the solution of the decision problem, it follows that the propositional calculus is consistent in the sense that $\mathbf{A}$ and $\sim\mathbf{A}$ cannot both be theorems, and complete in the sense that if $\mathbf{A}$ is not a theorem the addition of A as an extra axiom would result in inconsistency. By a different method it may be shown that the three axioms and the two rules of inference are independent in the sense that completeness is lost if any one of them is omitted.

In one sense the solution of the decision problem renders unnecessary the statement of axioms and rules of inference of the propositional calculus. For we might instead merely stipulate that every tautology shall be a theorem. However, this summary procedure provides no analysis of the logical relationships of the theorems among themselves, and no method by which to trace the consequences of a particular law of the propositional calculus or to formulate the situation which results when particular laws are rejected.

An example of the last is provided by the intuitionistic school of mathematics (see MATHEMATICS, FOUNDATIONS OF), which rejects the law of excluded middle and some other related laws of negation. To formulate the propositional calculus of mathematical intuitionism we may modify our above formulation as follows. Axiom 2 is replaced by the weaker axiom $p \supset \sim p \supset \sim p$, and there are then added the two further axioms. $p \supset . q \supset p$, $p \supset [p \supset q] \supset . p \supset q$. These axioms suffice for the intuitionistic laws of implication and negation. But as the definitions of conjunction and inclusive disjunction, given above, no longer serve to yield the characteristic properties of these connectives, it is necessary to introduce these two connectives as additional primitives, and to add also the axioms: $pq \supset p$, $pq \supset q$, $p \supset . q \supset pq$, $p \supset p \vee q$, $q \supset p \vee q$, $p \supset r \supset . q \supset r \supset . p \vee q \supset r$. Then finally, after this last addition, the axiom $p \supset . q \supset p$ may be dropped as not independent: in fact we can prove the theorem $p \supset . p \supset . q \supset p$ using only the axioms $p \supset . q \supset pq$, $pq \supset p$, and the transitive law, and then $p \supset \centerdot q \supset p$ follows by the axiom $p \supset [p \supset q] \supset \centerdot p \supset q$.

Using this formulation of the intuitionistic propositional calculus we can show that not only the law of excluded middle is not a theorem, but also the law of Clavius, the converse law of contraposition, Peirce's law, and the law of double negation fail; but the introduction of any one of these as an added axiom would restore all the others as theorems. The "paradox" $[p \supset q] \vee [q \supset p]$ is still a consequence in the form $\sim[p \supset q] \supset \centerdot q \supset p$, but not in the form containing the disjunction sign.

A Logistic System, or Calculus, is the purely formal part of a formalized language, taken in abstraction from any meaning or interpretation.

A logistic system is determined by giving its vocabulary, or list of primitive symbols, defining certain finite sequences of the primitive symbols to be well-formed *formulas*, listing certain well-formed formulas as axioms, and finally, stating rules of inference, by means of which a well-formed formula may on given conditions be inferred (as conclusion) from a set of one or more well-formed formulas (as premisses). A theorem of the logistic system is then defined to be a well-formed formula of which there is a proof, *i.e.*, a finite sequence of well-formed formulas each of which is either an axiom or inferred from earlier formulas in the sequence by one of the rules of inference, the last formula in the sequence being the theorem.

It is usually required that the set of rules of inference shall be effective, in the sense that there shall be a definite procedure or test by which, whenever a particular proposed conclusion from given premisses is before us, we can always actually decide whether the proposed inference is correctly made in accordance with one of the rules of inference; further that the set of axioms shall be effective, in the sense that there shall be a test by which, whenever a particular well-formed formula is before us, we can always decide whether it is an axiom (this requirement is satisfied when the axioms are a finite list which has been written out in full, but may also be satisfied in some cases of an infinite set of axioms). For these two requirements it will generally be necessary that the definition of well-formedness shall also be effective, in the sense that there shall be a test by which, whenever a particular formula is before us, we can always decide whether it is well-formed or not.

The reason for these requirements lies in the nature of the notion of a proof—as it is commonly understood, or as it is needed for the purposes of deductive logic (and, as a special case, in connection with mathematical proof). Namely it is a part of the notion of proof that a proof shall carry final conviction of the theorem proved (*i.e.*, of course, for any one who admits the axioms and rules of inference on which the proof is based). But without the requirements of effectiveness, it might happen that some one confronted with a proof of a theorem (and admitting the axioms and rules of inference) might nevertheless continue to doubt the theorem, because of doubt that the alleged proof actually is a proof in accordance with the axioms and rules. In such a case the proposer of the proof might fairly be asked to give a supplementary proof that it is a proof—and for purposes of deductive logic, this supplementary proof ought then to be treated as part of the whole proof, and included with it when the process of proof is formalized by the logistic method.

Though in the light of the requirements just explained, the notion of being a proof, in a particular logistic system, must be effective, it is clear that in general the notion of being a theorem may not be effective. For a well-formed formula is established as a theorem if a proof of it is found, but the failure of a particular investigator to find a proof may not necessarily mean that there is no proof to be found. It may indeed be possible in particular cases, by special methods, to establish as a metatheorem that a certain well-formed formula is not a theorem. But this is not to say that there is a general test by which it is always possible, whenever a well-formed formula is given, to decide effectively whether or not it is a theorem.

Such a general effective test, by which to recognize any arbitrary given well-formed formula of a particular logistic system as being or not being a theorem, is called a decision procedure for the particular system. And the problem to find a decision procedure for a logistic system is called the decision problem of the system. As a particular example, we have seen (above) a solution of the decision problem of the full propositional calculus—or, as this particular logistic system is often called because of the character of the decision procedure, the two-valued propositional calculus. There exist also decision procedures for the intuitionistic propositional calculus, but none of them is as simple as that for the two-valued calculus. On the other hand there are logistic systems for which there is no solution of the decision problem, not merely in the sense that none has been found, but in the sense that it has been established as a metatheorem that none can exist; examples of such systems (which will be discussed below) are the pure functional calculus of first order and of all higher orders—but the singulary functional calculi of first and second orders (obtained from the corresponding pure functional calculi by omitting all functional variables which are more than singulary) do have decision procedures.

As already indicated, the two-valued propositional calculus, the intuitionistic propositional calculus, and other systems to be introduced below may be considered as examples of logistic systems. Each is namely a logistic system if regarded as determined by its vocabulary, its *formation* rules (defining the well-formed formulas of the particular system), its axioms, and its rules of inference, in abstraction from any meaning or interpretation. The logistic system becomes a formalized language if suitable meanings are given to its well-formed formulas, as is done informally in this article, and as may be done more accurately by providing definitions of truth and of satisfaction in the manner outlined in the article SEMANTICS IN LOGIC—or if sense as well as denotation is to be provided for (see the same article), then by *rules* of sense, which are similar in character to the rules that compose the step-by-step definition of satisfaction, but which deal directly with the sense.

In general, if a logistic system has any sound interpretation, *i.e.*, any non-trivial way of giving meanings to its well-formed formulas in conformity with the formation rules, axioms, and rules of inference, it will have many such. Thus the same logistic system is common to many different formalized languages, and the results (theorems and metatheorems) for the logistic system hold equally for all the formalized languages, with appropriate changes of interpretation.—The point may be illustrated by the case of the pure functional calculus of first order (which we now go on to treat), each different domain of individuals providing a different sound interpretation and hence a different formalized language.

The Functional Calculus of First Order has, besides the notations of the propositional calculus (propositional variables and sentence connectives), also notations for propositional functions and the *quantifiers*.

To explain these new notations and their meanings we return to the notion of a sentence, which we have already employed in explaining the use of propositional variables.

A propositional form is an expression which is like a sentence except that it contains a number of variables, of any kinds, at places at which a corresponding sentence must contain fixed names or terms (constants)—the difference being that a sentence may be said simply to be true, or false, but a propositional form must rather be said to be true, or to be false, for some system of values of its variables. To turn to elementary mathematics for examples, "$49 + 36 = 85$" and "$59 + 36 = 85$" are sentences, the first one true and the second one false. But "$x + 36 = 85$" is a singulary propositional form, the adjective singulary indicating that there is one variable of which values are to be considered. It may not be said to be true, or to be false, but rather it is true for the value 49 of x, and false for the value 59 of x; or in a different terminology (see SEMANTICS IN LOGIC), "$x + 36 = 85$" is satisfied by the value 49 of x, and by no other value of x. Similarly "$x^2 + y^2 = 85$" is a binary propositional form, which is true for (satisfied by) the pair of values 7, 6 of x, y; also true for the values 6, 7 of x, y; also true for the values

2, 9 of x, y; but false for the values 5, 8 of x, y. Even "$x + y - x = y$"—being a binary propositional form rather than a sentence—must not be said just to be true, but to be true *for* all values of x, y.

In the foregoing examples the variables are numerical variables, *i.e.*, variables whose values are numbers. As examples of propositional forms containing variables of other kinds we may cite the quaternary form, "The distance from P to Q is less than the distance from R to S," in which the values of the variables P, Q, R, S are points; and the singulary form, "If x is a man, then x is mortal," in which the values of x are, say, concrete material things.

As an extreme case, and as a matter of terminological convenience, it is usual to consider a sentence as being a kind of a propositional form, namely a propositional form in which the number of variables is 0 (or more correctly, as we shall see below, in which the number of free variables is 0).

As *universal quantifier* we shall use the notation consisting of a variable between parentheses; *e.g.*, if the variable is x, the notation is (x). The meaning is roughly indicated by saying that the universal quantifier corresponds to such English words as "all," "every", or better indicated by saying that if a universal quantifier with some particular variable, say x, is prefixed to a singulary propositional form whose variable is x, the resulting expression is a sentence, which is a true sentence if and only if the propositional form is true for all values of x. For example, "(x) [if x is a man, then x is mortal]" is a sentence (of a certain ill-defined language which we here use for temporary illustrative purposes only, a half-formalized version of English); and in fact, on the best available evidence, it is a true sentence. Again, "$(x)\ [x + 36 = 85]$" is a false sentence. However, a universal quantifier may be prefixed also, with analogous meaning, to a propositional form which is more than singulary—or even, as a quite special but nevertheless allowable case, to a sentence. For example, "$(y)\ [x^2 + y^2 = 85]$" is a singulary propositional form; and since, as it happens, this singulary form is false for all values of x, the sentence "$(x)\sim(y)[x^2 + y^2 = 85]$" is true. Again "$(y)\ [x + y - x = y]$" is a singulary propositional form, true for all values of x; and hence "$(x)(y)[x + y - x = y]$" is a true sentence. And again "$(x)[49 + 36 = 85]$" is a true sentence, because "$49 + 36 = 85$" is a true sentence.

As *existential quantifier* we shall use the sign $\exists$ followed by a variable, with parentheses enclosing both. The meaning corresponds roughly to that of the English word "some" (in the sense "at least one") or of the phrase "there is a." And if an existential quantifier with, say, the variable x is prefixed to a singulary propositional form whose variable is x, the resulting expression is a sentence, which is true if and only if the propositional form is true for at least one value of x. The usage is otherwise similar to that of the universal quantifier, as a few examples will suffice to illustrate. If the meaning of the numerical variables x, y is such that they include the negative as well as the positive numbers among their values, "$(\exists y)[x + y = 85]$" is a singulary propositional form which is true for all values of x, and therefore "$(x)(\exists y)[x + y = 85]$" is a true sentence. Also "$(\exists x)(\exists y)[x + y = 85]$" is true. But "$(\exists y)(x)[x + y = 85]$" is a false sentence, as there is no one number y such that $x + y$ is always 8; for every number x. On the other hand, "$(\exists y)(x)[x \times y = 0]$" is true, as there is one number y, namely 0, such that $x \times y$ is always 0.

When a quantifier with a particular variable is prefixed to a propositional form, all occurrences of that variable in the resulting expression, including the occurrence of the variable in the quantifier itself, are said to be *bound* occurrences of the variable. Other occurrences of a variable, not bound, are called *free* occurrences. It is not excluded that a propositional form may contain both bound and free occurrences of the same variable; in fact, if A is a propositional form containing free occurrences of a certain variable, and B contains bound occurrences of that variable, then $[A \supset B]$ and $[B \supset A]$ each contain both bound and free occurrences of the variable. The variables which have bound occurrences in a given propositional form are called the bound variables of the form, and those which have free occurrences in it are called its *free variables*.

Having these last definitions, we must now go back and make the following amendment to our first account of propositional forms as it was given above The variables of which values are to be considered in a propositional form are only the free variables of the form. And the form is said to be true or to be false for some system of values of its free variables (or in the other terminology, to be satisfied or not satisfied by a system of values of its free variables). A propositional form is singulary if it has just one free variable, *binary* if it has just two different free variables, and so on, regardless of the number of bound variables. A sentence has no free variables; but it may have any number of bound variables, since the presence of bound variables does not prevent the sentence from expressing a particular proposition (making a particular statement or assertion).

For purposes of introductory exposition, we may describe a *propositional function* as obtained by abstraction from a propositional form. A binary propositional form, for instance, determines an association of a truth-value with each system—*i.e.*, each pair—of values of its free variables, since for each such pair of values the propositional form is either true or false. And if this scheme of association of truth-values with pairs of things is taken as an abstract correspondence, independent of its expression in any particular language or of any particular notation for it, we have a binary propositional function. If, say, F is a binary propositional function thus obtained from a binary propositional form, and a, b is a pair of things of appropriate kind, we use the notation $F(a, b)$ to express that truth is associated with the pair a, b in the abstract correspondence; hence we have that $F(a, b)$ if and only if the propositional form is true for the system of values a, b of its free variables.

Similarly, if F is a singulary propositional function obtained by abstraction from a singulary propositional form, we have that $F(a)$—or, as we shall say in words, that F holds of the argument a—if and only if the propositional form is true for the value a of its free variable. And generally, if F is an n-ary propositional function obtained by abstraction from an n-ary propositional form, we have that $F(a_1, a_2, \cdots, a_n)$—or in words, that F holds *among* the *arguments* $a_1, a_2, \ldots, a_n$—if and only if the propositional form is true for the system of values $a_1, a_2, \cdots, a_n$ of its free variables.

A propositional function obtained by abstraction from a propositional form must not be identified with the latter, since in fact different propositional forms may well sometimes determine the same scheme of association of truth-values with ordered sets of n arguments, that is, the same propositional function. A propositional form must also not be used as a name of the corresponding propositional function, since the propositional function is a fixed particular thing, of which no expression containing free variables may serve as name; but the propositional form with an abstraction operator prefixed (see ABSTRACT AND ABSTRACTION) is rather to be used as a name of the propositional function, where the abstraction operator, like the quantifiers, has the effect of changing free variables to bound variables. For example, if A is a singulary propositional form with free variable x, then $\hat{x}\mathbf{A}$ or $\lambda x\mathbf{A}$ (we shall here use the latter) is a name of the singulary propositional function obtained from A by abstraction.

Moreover, propositional functions must not be limited to those obtained or obtainable from propositional forms by abstraction, especially if only propositional forms belonging to one particular (formalized or other) language are considered. But abstractly, any scheme of the sort described (*i.e.*, by which truth-values are made to correspond to ordered sets of n arguments) is a propositional function, however it may have come to be known, or even if the particular propositional function never comes to be known.

It should be added that the term "propositional function" is used with various meanings and shades of meaning by different writers, the terminology being not yet fixed. Sometimes "propositional function" is used to mean what we here call a propositional form, or in a way that involves confusion between this and one of the more abstract meanings.

But as the term has just been explained, and as it will be used in this article, a singulary propositional function may be identified with a class or set, and a binary propositional function may be identified with a (binary) relation. Thus the notation "$F(a)$" may be read not only as "F holds of the argument a" but also as "a belongs to the class F"; and "$F(a, b)$" may be read as "the relation F holds between a and b" or "a bears the relation F to b."

In the functional calculus of first order, the arguments of the propositional functions considered are taken as belonging to a fixed domain, the domain of individuals. Any well-defined class of things may be chosen as the domain of individuals, subject to the one restriction that it shall not be empty, *i.e.*, that there shall be some individuals. (And we shall here use the term domain *of* individuals to mean a domain that is not empty.) But a definite domain of individuals must be fixed upon in order to have an interpretation of the calculus and thus a particular formalized language.

Individual constants are symbols used as names of particular individuals. Individual *variables* are variables which have individuals as values, and which are therefore under appropriate circumstances replaceable by individual constants, in the same sense in which propositional variables (see above) are replaceable by sentences. Likewise, n-ary *functional* constants (or n-ary predicates, as they are also called) are symbols used to denote particular n-ary propositional functions. And n-ary *functional* variab'es are variables which have n-ary propositional functions as values, and which are therefore under appropriate circumstances replaceable by n-ary functional constants.

In our present formulation of functional calculus of first order we shall use as individual variables the letters x, y, z, t, u, v, w, x_1, y_1, z_1, t_1, u_1, v_1, w_1, x_2, . . . ; we shall use as propositional variables the same which were used in the propositional calculus; as singulary functional variables, F^1, G^1, H^1, F^1_1, G^1_1, H^1_1, F^1_2, . . . ; as binary functional variables F^2, G^2, H^2, F^2_1, . . . ; and so on for ternary functional variables, quaternary functional variables, ... The superscripts 1, 2, 3, . . . upon the functional variables, distinguishing them as singulary, binary, ternary, . . ., are necessary in principle, especially in connection with the semantics of the language, in order to avoid using the very same symbol with two or more different meanings. But in practice, and as an abbreviation, the superscript may usually be omitted as being uniquely determined by the context.

The *alphabetic* order of the individual variables is the order in which they were just listed, *i.e.*, x, y, z, t, u, and so on. Likewise in the case of the functional variables of each kind, the alphabetic order is that in which they were just listed.

The name *functional ca'culus of* first *order* is applied to any one of many (different but closely related) logistic systems, which differ only in regard to the list of primitive symbols. All of these systems include as primitive symbols a sufficient list of sentence connectives and quantifiers, and also the notation which was explained above (consisting of parentheses and commas) for the holding of a propositional function, among certain arguments or of a certain argument. The individual variables are, further, always among the primitive symbols. And the remaining primitive symbols must belong to one of the categories of propositional variables, functional variables, individual constants, or functional constants.

The *pure functional* calculus *of first* order has all the propositional variables and functional variables as primitive symbols, and no individual constants or functional constants. An applied functional calculus of first order contains individual constants or functional constants or both, among its primitive symbols. A simple applied functional calculus of first order is an applied functional calculus of first order in which there are no propositional or functional variables among the primitive symbols.

As primitive connectives and quantifiers for functional calculus of first order we shall here use the signs of negation and material implication. and the universal quantifier. However, as in the case of the propositional calculus, other choices are possible. (And in fact the article SEMANTICS IN **LOGIC** makes use of negation, inclusive disjunction, and universal quantification as primitive.)

The well-formed formulas are defined by formation rules, which we here state in such a form that they can be used equally for any of the different functional calculi of first order: i_0. A propositional variable standing alone is a well-formed formula. i_1. If f is a singulary functional variable or a singulary functional constant, and x is an individual variable or an individual constant, then $\mathbf{f}(\mathbf{x})$ is a well-formed formula. i_n. If f is an n-ary functional variable or an n-ary functional constant, and $\mathbf{x}_1$, $\mathbf{x}_2$, . . . , $\mathbf{x}_n$ are individual variables or individual constants or both, not necessarily all different, then $\mathbf{f}(\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_n)$ is a well-formed formula. ii. If A is a well-formed formula, $\sim\mathbf{A}$ is a well-formed formula. iii. If $\mathbf{A}$ and B are well-formed formulas, $[\mathbf{A} \supset \mathbf{B}]$ is a well-formed formula. iv. If $\mathbf{A}$ is a well-formed formula, and x is an individual variable, then $(\mathbf{x})\mathbf{A}$ is a well-formed formula.

Every well-formed formula in a functional calculus of first order is a propositional form or a sentence, as in the case of the propositional calculus and other formalized languages which we shall consider in this article. However, there are many important cases (not here treated) in which the well-formed formulas include formulas that are not propositional forms or sentences but, *e.g.*, names of propositional functions, or of numbers, or of concrete material things. And indeed it would not be unnatural, in the case of the functional calculi of first order, to take the individual constants, individual variables, functional constants, and functional variables to be well-formed formulas when they stand alone — although the standard convention, in this particular case, is rather that which is given by the formation rules above.

In abbreviating well-formed formulas of functional calculus of first order, we omit superscripts upon functional variables (as already described), we use the same conventions regarding omission of brackets which were explained above in connection with the propositional calculus, we use the same definitions (of $[\mathbf{A} \mid \mathbf{B}]$ etc.), also the definition of the existential quantifier,

$$(\exists \mathbf{x})\mathbf{A} \rightarrow \sim(\mathbf{x})\sim\mathbf{A},$$

where $\mathbf{x}$ is an individual variable, also further the following definitions:

$$\begin{aligned}
&[\mathbf{A} \supset_{\mathbf{x}} \mathbf{B}] \rightarrow (\mathbf{x})[\mathbf{A} \supset \mathbf{B}]\\
&[\mathbf{A} \equiv_{\mathbf{x}} \mathbf{B}] \rightarrow (\mathbf{x})[\mathbf{A} \equiv \mathbf{B}]\\
&[\mathbf{A} \wedge_{\mathbf{x}} \mathbf{B}] \rightarrow (\exists \mathbf{x})[\mathbf{AB}]\\
&[\mathbf{A} \supset_{\mathbf{xy}} \mathbf{B}] \rightarrow (\mathbf{x})(\mathbf{y})[\mathbf{A} \supset \mathbf{B}]\\
&[\mathbf{A} \equiv_{\mathbf{xy}} \mathbf{B}] \rightarrow (\mathbf{x})(\mathbf{y})[\mathbf{A} \equiv \mathbf{B}]\\
&[\mathbf{A} \wedge_{\mathbf{xy}} \mathbf{B}] \rightarrow (\exists \mathbf{x})(\exists \mathbf{y})[\mathbf{AB}]
\end{aligned}$$

and likewise with three or more subscripts x, y, $\mathbf{z}$, etc., where the subscripts x, y, $\mathbf{z}$, . . . must be individual variables and all different in each case.

The relation between propositional functions that is expressed, in accordance with the above definitions, by the sign $\supset$ followed by one or more individual variables as subscripts is called *formal* implication (the standard term, though the adjective "formal" has here a rather different meaning from that which we have given to it elsewhere). For example, in the case of singulary propositional functions, $F(x) \supset_x G(x)$ (*i.e.*, the well-formed formula which is thus abbreviated) is said to express that F formally implies G, or in different words, that $F(x)$ formally implies $G(x)$ with respect to x; and in the case of binary propositional functions, $F(x, y) \supset_{xy} G(x, y)$ expresses that F formally implies G, or that $F(x, y)$ formally implies $G(x, y)$ with respect to x and y.— In similar fashion the sign $\equiv$ followed by individual variables as subscripts is said to express the relation of *formal* equivalence between propositional functions.

Now by including rules of substitution among the rules of inference, it is possible to make a formulation of the pure functional calculus of first order in which the number of axioms is finite. But because of rather complicated explanations which would be necessary in connection with one of the substitution rules in particular (that for functional variables) we here prefer a formulation without rules of substitution and with an infinite number of axioms. The infinite set of axioms is then given by means of five axiom schemata, which we shall state. And this procedure has *the further advantage that the same five axiom schemata (though not the same infinite set of axioms) are sufficient for any one of the other first-order functional calculi, as well as for the pure calculus.*

The first three of the axiom schemata are as follows:

1. $\mathbf{A} \supset \mathbf{B} \supset . \mathbf{B} \supset \mathbf{C} \supset . \mathbf{A} \supset \mathbf{C}$
2. $\sim\mathbf{A} \supset \mathbf{A} \supset \mathbf{A}$
3. $\mathbf{A} \supset . \sim\mathbf{A} \supset \mathbf{B}$

The first axiom schema means, e.g., that if **A**, **B**, **C** *are any well-formed formulas of the first-order functional calculus under consideration (possibly all three different, or possibly some of them the same), then* $A \supset B \supset . B \supset C \supset . A \supset C$ *is an axiom. In the case of the pure first-order functional calculus, two of the axioms which are instances of the first axiom schema are, for instance,* $p \supset q \supset . q \supset r \supset . p \supset r$ *and* $\sim q \supset [F(x) \supset G(x)] \supset . F(x) \supset G(x) \supset (x)H(x, y) \supset . \sim q \supset (x)H(x, y)$.

The fourth axiom schema is the following:

4. $A \supset_x B \supset . A \supset (x)\mathbf{B}$, *provided that x is an individual variable which is not a free variable of A.*

In order to state the fifth axiom schema, it is necessary first to explain another metatheoretic notation. In using bold capital letters to stand for well-formed formulas, we shall sometimes add after the letter an indication of one of the free variables it may contain, providing by this device a convenient notation for the process of substituting one free variable for another. For example, if we use Ax to stand for a well-formed formula which has or may have x as a free variable, then Ay shall stand for the well-formed formula obtained from Ax by substituting y for all free occurrences of x in Ax—provided, however, that if any of the free occurrences of x in Ax are in a well-formed part of Ax of the form (y)C, then Ay shall be obtained from Ax by first substituting **z** *for all bound occurrences of y in Ax and then substituting y for all free occurrences of x in Ax,* **z** *being the first individual variable in alphabetic order that does not occur in Ax. In the special case that* **A**x *does not actually contain x as a free variable, Ay is the same as Ax. And the same notation may be used also for substitution of a constant for a free variable, so that, e.g., if a is any individual constant, Aa stands for the result of substituting a for all free occurrences of x in Ax.*

Employing this notation, we state the fifth axiom schema:

5. $(\mathbf{x})\mathbf{Ax} \supset Ay$, *where x is an individual variable, Ax is a well-formed formula which may have* **x** *as a free variable, and* **y** *is an individual variable or an individual constant.*

To use the case of the pure functional calculus of first order for illustration, following are some examples of instances of axiom schema 5, which are therefore axioms:

$$(x)F(x) \supset F(y)$$
$$(y)F(y) \supset F(y)$$
$$(y)F(x, y) \supset F(x, x)$$
$$(x)(y)F(x, y) \supset (z)F(y, z)$$
$$(z)[F(z) \supset G(z)] \supset . F(x) \supset G(x)$$
$$(z)[F(x) \supset G(x)] \supset . F(x) \supset G(x)$$

To complete the formulation of first-order functional calculus as a logistic system (whether the pure first-order functional calculus or one of the others), it remains only to state the rules of inference. These are the two following: II. *Rule of modus ponens. From* $A \supset B$ *and A, to infer B.* III. *Rule of generalization. From A, if x is any individual variable, to infer* $(\mathbf{x})\mathbf{A}$.

In an application of the rule of generalization, the variable **x** *is said to be generalized upon.*

Where $\mathbf{A}_1, \mathbf{A}_2, \ldots, A,$, *B are well-formed formulas of one of the functional calculi of first order, we say that the inference from the hypotheses* $\mathbf{A}_1, \mathbf{A}_2, \cdots, A,$ *to the conclusion B is a valid inference of first-order functional calculus if B can be obtained from the hypotheses* $\mathbf{A}_1, \mathbf{A}_2, \cdots, A,$ *, together with the axioms of the particular functional calculus of first order, by a succession of applications of the two rules of inference, modus ponens and generalization, subject to the restriction that no variable shall be generalized upon which is a free variable of any of the hypotheses* $\mathbf{A}_1, \mathbf{A}_2, \ldots, A,$. *(The distinction which is made here between "hypotheses" and "premisses" may be ignored only if the hypotheses are without free variables.)*

For example, from the single hypothesis $F(x)$ *there is a valid inference to the conclusion* $(y) . \sim F(x) \supset F(y)$, *namely by taking as major premiss the axiom* $F(x) \supset . \sim F(x) \supset F(y)$, *which is an instance of axiom schema* **3**, *and applying modus ponens, and then generalizing upon y. On the other hand there is no valid inference from the hypothesis* $F(x)$ *to the conclusion* $(x)F(x)$, *and indeed it is informally evident that the definition ought not to allow this as a valid inference—i.e., from the hypothesis that a particular individual x belongs to the class F, it does not in general follow that all individuals belong to the class F.*

There is not space to treat in detail particular theorems and valid inferences of first-order functional calculus. But some of the simplest of the latter will be mentioned below in the discussion of traditional logic. And we list here the following important metatheorems (omitting their proofs, with one exception):

The Deduction Theorem.—If there is a valid inference (of first-order functional calculus) from the hypotheses $\mathbf{A}_1, \mathbf{A}_2, \cdots, A,$ *to the conclusion B, there is a valid inference also from the hypotheses* $\mathbf{A}_1, \mathbf{A}_2, \ldots, \mathbf{A}_{n-1}$ *to the conclusion* $A, \supset B$. *Hence if there is a valid inference from the hypotheses* $\mathbf{A}_1, \mathbf{A}_2, \ldots, A,$ *to the conclusion B, then* $\mathbf{A}_1 \supset . \mathbf{A}_2 \supset . \ldots A, \supset B$ *is a theorem. And, as a special case, if there is a valid inference from the single hypothesis A to the conclusion B, then* $A \supset B$ *is a theorem.*

Tautologies.—Every tautologous well-formed formula is a theorem, i.e., every well-formed formula which is a tautology of the propositional calculus or is obtained from such a tautology by substitutions for the propositional variables.

Substitutivity of Equivalence.—If $\mathbf{M} \equiv N$ *is a theorem, if A is a theorem, and if B is obtained from A by replacing M by N at one or more places (not necessarily at all occurrences of M in A), then B is a theorem.*

Reduction to Prenex Normal Form.—There is an effective procedure by which, given a well-formed formula A of a first-order functional calculus, there may be found a well-formed formula B of the same first-order functional calculus, such that $A \equiv B$ *is a theorem, and B is in prenex normal form—i.e., B consists of a quantifier-free well-formed part, called the matrix, and of a preceding part which is called the prefix and which consists of a number of universal and existential quantifiers prefixed to the matrix, subject to the condition that the variables occurring in the quantifiers in the prefix shall be all different and shall all occur also in the matrix. (As special cases, the quantifiers constituting the prefix may be all universal, or they may be all existential, or the prefix may even be null so that B consists entirely of the quantifier-free matrix.)*

Consistency.—A and $\sim\mathbf{A}$ *cannot both be theorems of a first-order functional calculus. The proof of this is by considering, for any well-formed formula of first-order functional calculus, a corresponding well-formed formula of the propositional calculus which is obtained as follows. From the given formula of first-order functional calculus, first delete (universal) quantifiers, so as to obtain a quantifier-free formula, then replace every propositional variable and every well-formed part of the form* $\mathbf{f}(\mathbf{x})$ *or* $\mathbf{f}(\mathbf{x}_1, \mathbf{x}_2, \ldots, \mathbf{x}_n)$*—cf. the formation rules* i_0, i_1, i_n—each *by the propositional variable p. (For example, if the given formula is* $(x)(y)F(x, y, z) \supset . p \supset q \supset (\exists z)G(z)$, *the deletion of quantifiers yields* $F(x, y, z) \supset . p \supset q \supset \sim\sim G(z)$, *and hence the corresponding formula of the propositional calculus is* $p \supset . p \supset p \supset \sim\sim p$.) *As the reader may verify, every axiom of first-order functional calculus has the property that the corresponding formula of the propositional calculus is a tautology; moreover, the rules of inference preserve this property, i.e.,* if *in an application of one of the rules of inference the premiss or premisses have this property, the conclusion must have it also; hence every theorem has this property. But A and* $\sim\mathbf{A}$ *cannot both have this property (indeed, of the two corresponding formulas of the propositional calculus, the second one is obtained from the first by prefixing the sign* $\sim$, *so that not both can be tautologies). Hence not both A and* $\sim\mathbf{A}$ *can be theorems.*

The Metatheory of the Pure Functional Calculus **of** *First Order contains many results of greater depth than the elementary* *fundamentals which have been discussed above. Only a few of these* will be briefly *indicated here.*

A well-formed *formula is said to be satisfiable in a particular non-empty* domain *if,* when *that domain is taken as the domain of individuals, the formula is satisfied by at least one system of values* of *its free variable? which has individuals (of the domain in question) as values of the individual variables, n-ary propositional functions as values of the n-ary functional variables, and truth-values as values of the propositional variables. Similarly a well-formed formula is said to be valid in a particular* non-*empty domain if, when that domain is taken as the domain of* individuals, *the formula is satisfied by every such system of values of its free variables.* A *well-formed formula is said to be satisfiable if it is satisfiable in some non-empty domain, calid if* it *is valid in every non-empty domain. Evidently, A is satisfiable in a particular domain if and only if $\sim\mathbf{A}$ is not valid in that domain, and A is satisfiable if and only if $\sim\mathbf{A}$* is *not valid.*

The validity of a well-formed *formula in a domain of individuals depends only on the number of individuals in the domain. And in fact* well-formed *formulas (i.e., of the pure functional calculus of first order) can be classified as follows: there are those which are valid in no domain of individuals; for every positive integer n, there are those which are valid in domains of not more than n individuals but not valid in larger domains; there are well-formed formulas which are valid in every finite domain of individuals but not valid in an infinite domain; and there are the valid* well-formed *formulas. It can be shown that every* well-*formed formula belongs to one of these classes.—As examples we cite $(\exists x)(y) \centerdot [F(x, y) \supset F(y, x)] \vee [F(x, x) \equiv F(y, y)]$,* valid *in domains of not more than three individuals, but not in larger domains, and $(\exists x)(y)(\exists z) \centerdot F(z, x) \supset F(z, y) \supset \centerdot F(x, y) \supset F(x, x)$, valid in all finite domains of individuals, but not in infinite domains.*

The above statement includes the following theorem of Leopold Loewenheim: *If a well-formed formula is valid in the domain of positive integers (i.e., when the positive integers 1, 2, 3, ... are taken as the* individuals), *it is valid. As a corollary, or as another form of the metatheorem, if a well-formed formula is satisfiable, it is satisfiable in the domain of positive integers.*

It can be shown that every theorem of the pure functional calculus of first order is valid (since the axioms are valid and the rules of inference preserve validity). The converse of this is the completeness (meta)theorem *of Kurt Goedel: Every valid well-formed formula is a theorem.*

A class of well-formed formulas (finite or infinite in number) is said to be consistent if it does not contain formulas $\mathbf{A}_1$, $\mathbf{A}_2$, .., A, from which as hypotheses there is a valid inference to a conclusion B and also to $\sim\mathbf{B}$. A *class of* well-formed *formulas is said to be simultaneously satisfiable in a* particular *non-empty domain if, when that domain is taken as the domain of individuals, the formulas are simultaneously satisfied by at least one system of values of the free variables. And a class of well-formed formulas is said to be simultaneously satisfiable if it is simultaneously satisfiable in some non-empty domain.*

According to an extension of Loewenheim's theorem by Thoralf Skolem, if a class of well-formed formulas is simultaneously satisfiable, it is simultaneously satisfiable in the domain of positive integers. And according to a closely related meta*theorem due to Goedel, if a class of well-formed formulas is consistent, it is simultaneously satisfiable.*

TRADITIONAL LOGIC

The name traditional logic is given to that part of the ancient and mediaeval logic which survived the decline of scholasticism and long remained with *little change as a traditionally important part of philosophy. Though historically an independent doctrine, with a viewpoint and method that differ from the logistic* method *explained above, it can be exhibited as a part of modern logic, and this is the course which we shall follow here. In doing this it is necessary to make certain changes (as noted below), of which some remove uncertainties or correct confusions of the traditional doctrine, and others, though not required from the point of view of traditional logic itself, are desirable in order to incorporate it into the body of modern logic and to give it its proper place in relation to the remainder.*

Categorical Propositions are propositions of the traditional subject-predicate form, having a subject S and a predicate P. The four forms—All *S* is *P*, *No S* is *P*, *Some S* is *P*, *Some S* is *not P—are traditionally designated by the letters A, E, I, O respectively. Examples are: All men are mortal (A), All men die (A), No man can serve two masters (E), Some prime numbers are odd (I),* **A** *large island is in the bay (I), All that glitters is not gold (O). Propositions of the forms A and I are called affirmative; E and* **O**, *negative; A and E, universal; I and* **O**, *particular.*

The subject and predicate of a categorical proposition are together called the terms of the proposition. Thus in the third example above, the terms are the subject, man, and the predicate, able to serve two *masters.*

In writing categorical propositions in logistic form we shall use functional constants s *and* p *to stand for the subject and predicate, so that the four forms appear as follows: $\mathbf{s}(x) \supset_x \mathbf{p}(x)$, $\mathbf{s}(x) \supset_x \sim\mathbf{p}(x)$, $\mathbf{s}(x) \wedge_x \mathbf{p}(x)$, $\mathbf{s}(x) \wedge_x \sim\mathbf{p}(x)$.*

This manner of representing the categorical propositions is not faithful in all particulars to the traditional account. But among various possibilities it seems to be on the whole the best, and we *shall employ it here, noting the four following points of divergence:*

1. We have defined the notations $\supset_x$ and $\wedge_x$ in terms of the universal quantifier and the two *primitive connectives $\sim$ and $\supset$, whereas the traditional account might be thought to be more closely reproduced if $\supset_x$ and $\wedge_x$ were primitive notations.*

2. The traditional account associates the negation in E and O with the copula, that is, with the words "is" or "is not" that join the subject and predicate, whereas here we *prefix the sign $\sim$ to the subformula $\mathbf{p}(x)$.—*In *regard to 1 and 2 it would be possible to reproduce the traditional account more closely by using four primitive notations A, , E_x, I_x, O_x, where $[\mathbf{s}(x)\ A_x\ \mathbf{p}(x)]$, $[\mathbf{s}(x)\ E_x\ \mathbf{p}(x)]$, $[\mathbf{s}(x)\ I_x\ \mathbf{p}(x)]$, $[\mathbf{s}(x)\ O_x\ \mathbf{p}(x)]$ are to have the meanings of $\mathbf{s}(x) >, \mathbf{p}(x)$, $\mathbf{s}(x) >, \sim\mathbf{p}(x)$, s (~∧)x $\mathbf{p}(x)$, $\mathbf{s}(x) \wedge_x \sim\mathbf{p}(x)$ respectively (and the usual quantifiers and sentence connectives could then be defined in terms of these). But it seems preferable not to complicate the formulation of first-order functional calculus in this way.*

3. *The traditional account includes also, under A and E, propositions expressed in the forms $\mathbf{p}(\mathbf{a})$ and $\sim\mathbf{p}(\mathbf{a})$ respectively, where a is an individual constant. For example, "Socrates is mortal" is considered as expressing an A proposition, and "Socrates is not mortal," an E proposition, the subject being the singular term, Socrates. These singular propositions, as they are called, mill be ignored in our account of opposition and immediate inference, but will appear in connection* with *the categorical syllogism as giving special forms (called singular forms) of certain syllogisms.*

4. Some aspects of the traditional account require that A and E be represented as we have here, others that they be represented by the conjunctions $(\exists x)\mathbf{s}(x) \centerdot \mathbf{s}(x) \supset_x \mathbf{p}(x)$ and $(\exists x)\mathbf{s}(x) \centerdot \mathbf{s}(x) \supset_x \sim\mathbf{p}(x)$ respectively. The problem of choosing between these two *interpretations (or finding a satisfactory third alternative) is known as the problem of existential import of categorical propositions. In our account below we shall meet the difficulty by introducing $(\exists x)\mathbf{s}(x)$ as a separate premiss at those places where it is required.*

Opposition, Immediate Inference.— According to the square **of** *opposition, if the subject and predicate are fixed, A and O (i.e., $\mathbf{s}(x) \supset_x \mathbf{p}(x)$ and $\mathbf{s}(x) \wedge_x \sim\mathbf{p}(x)$) are contradictory, E and I are contradictory, A and E are contrary, I and O are subcontrary, A and I are subaltern, E and O are subaltern. The* two *propositions of a contradictory pair cannot be both true and cannot be both false. Under the premiss $(\exists x)\mathbf{s}(x)$, the contrary pair, A, E, cannot be both true, the subcontrary pair, I, O, cannot be both false, and each of* the *propositions A and E has its subaltern proposition as a consequence.*

Simple conversion of a categorical proposition consists in interchanging the subject and predicate. Thus the converses of $\mathbf{s}(x) \supset_x \mathbf{p}(x)$, $\mathbf{s}(x) \supset_x \sim\mathbf{p}(x)$, $\mathbf{s}(x) \wedge_x \mathbf{p}(x)$, and $\mathbf{s}(x) \wedge_x \sim\mathbf{p}(x)$

are respectively $\mathbf{p}(x) \supset_x \mathbf{s}(x)$, $\mathbf{p}(x) \supset_x \sim\mathbf{s}(x)$, $\mathbf{p}(x) \wedge_x \mathbf{s}(x)$, and $\mathbf{p}(x) \wedge_x \sim\mathbf{s}(x)$. Simple conversion is a generally valid inference only in the case of **E** and **I.**

Obversion of a categorical proposition is effected by replacing p by a functional constant $\mathbf{q}$ which denotes the negation of the propositional function (the complement of the class) that is denoted by $\mathbf{p}$, and at the same time inserting $\sim$ if not already present or deleting it if present. In terms of the abstraction operator, the functional constant q is $\lambda x\sim\mathbf{p}(x)$. Thus the obverse of $\mathbf{s}(x) \supset_x \mathbf{p}(x)$ is $\mathbf{s}(x) \supset_x \sim\mathbf{q}(x)$ (the obverse of *All men are mortal* is *No men are immortal)*. Similarly, the obverse of $\mathbf{s}(x) \supset_x \sim\mathbf{p}(x)$ is $\mathbf{s}(x) \supset_x \mathbf{q}(x)$, the obverse of $\mathbf{s}(x)$ *A,* $\mathbf{p}(x)$ is $\mathbf{s}(x)$ *A,* $\sim\mathbf{q}(x)$, and that of $\mathbf{s}(x)$ *A,* $\sim\mathbf{p}(x)$ is $\mathbf{s}(x) \wedge_x \mathbf{q}(x)$.

The name ('immediateinference" is given to certain inferences from one categorical proposition as premiss to another as conclusion, all of them being valid inferences either of first-order functional calculus or of an extended calculus embracing the abstraction operator A. The immediate inferences include obversion of *A*, E, **I**, *O*, simple conversion of E, I, and subalternation of *A*, E—of which subalternation requires the additional premiss $(\exists x)\mathbf{s}(x)$. Other immediate inferences may be obtained by means of sequences of these; e.g., given that all men are mortal we may take the obverse of the converse of the obverse and so infer that all immortals are non-men (called by some the contrapositive, by others the obverted contrapositive).

Conversion *per accidens*, or *by limitation*, of a proposition *A* may be described as consisting of subalternation followed by simple conversion. Thus from the premisses $\mathbf{s}(x) \supset_x \mathbf{p}(x)$ and $(\exists x)\ \mathbf{s}(x)$ it yields the conclusion $\mathbf{p}(x)$ *A,* $\mathbf{s}(x)$. Conversion *per accidens* of *E* is also possible, by a simple conversion followed by subalternation.

Categorical Syllogism. — The name "categorical syllogism" is given to certain valid inferences of first-order functional calculus which involve as premisses two categorical propositions having a term in common — the *middle term*. Using functional constants *s*, m, p to stand for the *minor term*, the middle term, and the *major term* respectively, we give the traditional classification into figures and moods. In each case we give the *major premiss* first, the *minor premiss* immediately after it, and the conclusion last; in some cases we give a third (existential) premiss which is suppressed in the traditional account. Where in consequence of the admission of singular propositions (as noted above) two different forms of valid inference appear under the same figure and mood, we give the singular forms in a separate list.

First Figure

Barbara: $\mathbf{m}(x) \supset_x \mathbf{p}(x)$, $\mathbf{s}(x) \supset_x \mathbf{m}(x)$; $\mathbf{s}(x) \supset_x \mathbf{p}(x)$.
Celarent: $\mathbf{m}(x) \supset_x \sim\mathbf{p}(x)$, $\mathbf{s}(x) \supset_x \mathbf{m}(x)$; $\mathbf{s}(x) \supset_x \sim\mathbf{p}(x)$.
Darii: $\mathbf{m}(x) \supset_x \mathbf{p}(x)$, $\mathbf{s}(x)$ *A,* $\mathbf{m}(x)$; $\mathbf{s}(x) \wedge_x \mathbf{p}(x)$.
Ferio: $\mathbf{m}(x) \supset_x \sim\mathbf{p}(x)$, $\mathbf{s}(x) \wedge_x \mathbf{m}(x)$; $\mathbf{s}(x) \wedge_x \sim\mathbf{p}(x)$.

Second Figure

Cesare: $\mathbf{p}(x) \supset_x \sim\mathbf{m}(x)$, $\mathbf{s}(x) \supset_x \mathbf{m}(x)$; $\mathbf{s}(x) \supset_x \sim\mathbf{p}(x)$.
Camestres: $\mathbf{p}(x) \supset_x \mathbf{m}(x)$, $\mathbf{s}(x) \supset_x \sim\mathbf{m}(x)$; $\mathbf{s}(x) \supset_x \sim\mathbf{p}(x)$.
Festino: $\mathbf{p}(x) \supset_x \sim\mathbf{m}(x)$, $\mathbf{s}(x) \wedge_x \mathbf{m}(x)$; $\mathbf{s}(x)$ *A,* $\sim\mathbf{p}(x)$.
Baroco: $\mathbf{p}(x) \supset_x \mathbf{m}(x)$, $\mathbf{s}(x)$ *A,* $\sim\mathbf{m}(x)$; $\mathbf{s}(x)$ *A* $\sim\mathbf{p}(x)$.

Third Figure

Darapti: $\mathbf{m}(x) \supset_x \mathbf{p}(x)$, $\mathbf{m}(x) \supset_x \mathbf{s}(x)$, $(\exists x)\mathbf{m}(x)$; $\mathbf{s}(x)$ *A,* $\mathbf{p}(x)$.
Disamis: $\mathbf{m}(x)$ *A,* $\mathbf{p}(x)$, $\mathbf{m}(x) \supset_x \mathbf{s}(x)$; $\mathbf{s}(x)$ *A,* $\mathbf{p}(x)$.
Dstisi: $\mathbf{m}(x) \supset_x \mathbf{p}(x)$, $\mathbf{m}(x) \wedge_x \mathbf{s}(x)$; $\mathbf{s}(x) \wedge_x \mathbf{p}(x)$.
Felapton: $\mathbf{m}(x) \supset_x \sim\mathbf{p}(x)$, $\mathbf{m}(x) \supset_x \mathbf{s}(x)$, $(\exists x)\mathbf{m}(x)$; $\mathbf{s}(x)$ *A,* $\sim\mathbf{p}(x)$.
Bocardo: $\mathbf{m}(x) \wedge_x \sim\mathbf{p}(x)$, $\mathbf{m}(x) \supset_x \mathbf{s}(x)$; $\mathbf{s}(x) \wedge_x \sim\mathbf{p}(x)$.
Feriso (or Ferison): $\mathbf{m}(x) \supset_x \sim\mathbf{p}(x)$, $\mathbf{m}(x)$ *A,* $\mathbf{s}(x)$; $\mathbf{s}(x)$ *A,* $\sim\mathbf{p}(x)$.

Fourth Figure

Bamalip (or Bramantip): $\mathbf{p}(x) \supset_x \mathbf{m}(x)$, $\mathbf{m}(x) \supset_x \mathbf{s}(x)$, $(3x)\mathbf{p}(x)$; $\mathbf{s}(x)$ *A,* $\mathbf{p}(x)$.
Calemes (or Camenes): $\mathbf{p}(x) \supset_x \mathbf{m}(x)$, $\mathbf{m}(x) \supset_x \sim\mathbf{s}(x)$; $\mathbf{s}(x) \supset_x \sim\mathbf{p}(x)$.
Dimatis (or Dimaris): $\mathbf{p}(x)$ *A,* $\mathbf{m}(x)$, $\mathbf{m}(x) \supset_x \mathbf{s}(x)$; $\mathbf{s}(x) \wedge_x \mathbf{p}(x)$.
Fesapo: $\mathbf{p}(x) \supset_x \sim\mathbf{m}(x)$, $\mathbf{m}(x) \supset_x \mathbf{s}(x)$, $(\exists x)\mathbf{m}(x)$; $\mathbf{s}(x)$ *A,* $\sim\mathbf{p}(x)$.
Fresison: $\mathbf{p}(x) \supset_x \sim\mathbf{m}(x)$, $\mathbf{m}(x)$ *A,* $\mathbf{s}(x)$; $\mathbf{s}(x)$ *A,* $\sim\mathbf{p}(x)$.

Singular Forms

Barbara: $\mathbf{m}(x) \supset_x \mathbf{p}(x)$, $\mathbf{m}(\mathbf{a})$; $\mathbf{p}(\mathbf{a})$.
Celarent: $\mathbf{m}(x) \supset_x \sim\mathbf{p}(x)$, $\mathbf{m}(\mathbf{a})$; $\sim\mathbf{p}(\mathbf{a})$.
Cesare: $\mathbf{p}(x) \supset_x \sim\mathbf{m}(x)$, $\mathbf{m}(\mathbf{a})$; $\sim\mathbf{p}(\mathbf{a})$.
Camestres: $\mathbf{p}(x)$ **3,** $\mathbf{m}(x)$, $\sim\mathbf{m}(\mathbf{a})$; $\sim\mathbf{p}(\mathbf{a})$.
Darapti: $\mathbf{p}(\mathbf{a})$, $\mathbf{s}(\mathbf{a})$; $\mathbf{s}(x)$ *A,* $\mathbf{p}(x)$.
Felapton: $\sim\mathbf{p}(\mathbf{a})$, $\mathbf{s}(\mathbf{a})$; $\mathbf{s}(x) \wedge_x \sim\mathbf{p}(x)$.

The last two singular forms, in which the middle term is singular, are classed separately as the *expository* syllogism.

Some add the five so-called weakened moods, Barbari, Celaront, Cesaro, Camestros, Calemos, to be obtained by subalternation of the conclusion from Barbara, Celarent, Cesare, Camestres, Calemes respectively. The five moods of the fourth figure are sometimes classed instead as indirect moods of the first figure, the major and minor premisses being interchanged, and the names being then given as Baralipton, Celantes, Dabitis, Fapesmo, Frisesomorum.

The names of the moods have a mnemonic significance, in which the first three vowels indicate whether the major premiss, minor premiss, and conclusion, in order, are A, E, I, or *O*, and some of the consonants indicate the traditional reductions of the other moods to the four direct moods of the first figure *(see* Logic, History of).

Hypothetical Syllogism, Disjunctive Syllogism, Dilemma. — Besides the categorical syllogism, the traditional logic treats also a number of other kinds of *mediate* inference (*i.e.*, inference from two or more premisses), including especially the *hypothetical syllogism* (or conditional syllogism), the *disjunctive syllogism*, and the *dilemma*. All of these can be exhibited as valid inferences of the propositional calculus, and we shall give them here in this fdrm.

In particular, we shall render the words "if" or "if. . then," as used in stating the traditional hypothetical (or conditional) propositions, by the sign $\supset$ of material implication, although this is certainly contrary to the intention of traditional writers. In the Port-Royal Logic, for example, the contradictory negative of **If** *you eat of the forbidden fruit you will die* is given as *Although you eat of the forbidden fruit you will not die*— whereas if material implication were intended, the contradictory should be rather, *You will eat of the forbidden fruit and you will not die.* Yet in the same work it is explained that a conditional proposition may be true although both parts of it (both the antecedent and the consequent) are false, provided only that the consequence is correctly drawn. By this it is not meant that the consequent must follow logically from the antecedent, but, as is clear from the discussion and the examples given, that the consequent must follow from the antecedent together nith known truths which are taken into consideration. However, this account overlooks that, if two propositions are both false, it is always possible to infer one from the other by means of appropriately chosen truths, which may then be supposed to be knomn and taken into consideration. It is in this way that the traditional account leads to material implication as the best means of representing it consistently within a more complete theory. An alternative amendment of the traditional account indeed suggests itself, by seeking a satisfactory logistic theory of an implication connective which shall reproduce more closely the ordinary usage of "if . . then" in future conditions and conditions contrary to fact, but this has never been successfully carried out. (Compare the discussion of material implication in the first part of this article.)

There is also a question whether the word "or," as used in stating the traditional disjunctive propositions, shall be understood as denoting inclusive disjunction or exclusive disjunction. Here the traditional logic is more explicitly inconsistent — since, although most of the inferences are valid inferences under either interpretation of the word "or," one of them, the *modus ponendo tollens*, is valid only for exclusive disjunction, and the two complex dilemmas are valid only for inclusive disjunction. We shall use exclusive disjunction in *modus ponendo tollens*, but inclusive disjunction elsewhere.

In each entry in the following table the major premiss is given first, or the two major premisses in the case of the dilemmas, then the minor premiss, then the conclusion.

Hypothetical Syllogism

Modus ponens: $A \supset B$. A; B.
Modus tollens: $A \supset B$, $\sim B$; $\sim\mathbf{A}$.

Disjunctive Syllogism

Modus tollendo ponens: $A \vee B$, $\sim\mathbf{A}$; B.
Modus tollendo ponens: $\mathbf{A} \vee B$, $\sim\mathbf{B}$; $\mathbf{A}$.

Modus ponendo *tollens:* $\mathbf{A} \mid \mathbf{B}, \mathbf{A}; \sim\mathbf{B}$.
Modus ponendo *tollens:* $\mathbf{A} \mid \mathbf{B}, \mathbf{B}; \sim\mathbf{A}$.

Dilemma

Simple constructive dilemma: $A \supset C, B \supset C, A \vee B; C$.
Simple destructive dilemma: $A \supset B, A \supset C, \sim B \vee \sim C; \sim A$.
Complex constructive dilemma: $A \supset B, C \supset D, A \vee C; B \vee D$.
Complex destructive dilemma: $A \supset B, C \supset D, \sim B \vee \sim D; \sim A \vee \sim C$.

The inferences from $A \supset B$ and $C \supset A$ to $C \supset B$, and from $A \supset B$ and $C \supset \sim B$ to $C \supset \sim A$ are sometimes added as pure hypothetical syllogisms, and the above simpler forms of the hypothetical syllogism are then distinguished as mixed hypothetical. Some older works, including the Port-Royal Logic, add a copulative syllogism, with major premiss $\overline{} \centerdot AB$, minor premiss A and conclusion $\sim B$, or minor premiss B and conclusion $\sim A$.

TYPE THEORY AND SET THEORY

In the functional calculus of first order there is provision only for individuals as arguments of propositional functions, and it is only individual variables which may be bound by quantifiers. Since the domain of individuals is fixed in advance, and since the classes and relations (and propositional functions generally) which are values of the functional variables are not among the individuals of the fixed domain, this imposes a limitation upon what can be expressed in the notation of the calculus. Indeed it may be thought that the propositions of logic have a character of universal generality which demands for its expression the use of variables of unrestricted range, whose values are not confined to a fixed domain but may he either individuals or classes or relations or anything else whatever. And just this was maintained in particular by Gottlob Frege.

However, the uncritical attempt to introduce such variables of unrestricted range leads to a system which is inconsistent, if besides the variahles of unrestricted range, say x, y, z, x_1, ..., we employ also the usual sentence connectives and quantifiers, and a notation, say $\epsilon(x, y_1, y_2, \ldots, y_n)$, to mean that x is an n-ary propositional *function* and holds among the arguments y_1, y_2, ..., y_n, and adopt what seem to be the natural and obvious axioms and rules of inference. Namely in such a system the antinomy of Bertrand Russell or that of C. Burali-Forti (see ANTINOMY) can be reproduced formally, *i.e.*, in the form of proofs of contradictory theorems of the system. And in fact the significance of these antinomies lies less in their informal statement in words than in their influence upon the construction of logistic systems, through the possibility of their logistic formalization.

In order to obtain a system more comprehensive than functional calculus of first order without falling into antinomy, there are two directions which have been followed. One of these, the direction of type theory, avoids altogether the use of variables of unrestricted range, and introduces instead many different kinds of variables with different restricted ranges. The other, the direction of set theory, has variables of unrestricted range, but imposes restrictions in regard to the existence of sets determined by given conditions. (The word "set" is here used to mean a class which can belong to another class as a member of it, since some forms of set theory admit also classes which are not sets; but outside the context of set theory the words "class" and "set" are generally used synonymously.)

As typical of the two directions we shall describe briefly the simple theory of types, and a form of set theory which is based on the system proposed by Ernst Zermelo in 1908.

The Simple Theory of Types can be described as obtained from the pure functional calculus of first order by successive additions to it.

The first step is to modify the formation rule iv to provide that $(x)\mathbf{A}$ shall be well formed when x is a propositional or functional variable as well as when x is an individual variable. The resulting system is the pure *functional* calculus *of second* order, if suitable axioms and rules of inference are provided (which will not be stated here, but are similar to those for functional calculus of first ortler).

Then functional variables of various higher types are adjoined. Namely if $c_1, c_2, \ldots, c_n$ are non-negative integers, then $(c_1, c_2, \ldots, c_n)$ is a type, and an infinite list of variables of this type is provided: $F^{(c_1, c_2, \cdots, c_n)}$, $G^{(c_1, c_2, \cdots, c_n)}$, ... A formation rule provides that, if f is of type $(c_1, c_2, \ldots, c_n)$, then $f(x_1, x_2, \ldots, x_n)$ is well-formed on condition that each variable x_i is of the type indicated by the corresponding integer c_i, *i.e.*, that x_i is an individual variable if c_i is 0, x_i is a propositional variable if c_i is 1, and x_i is an m-ary functional variable of lower type (one of the variables F^m, G^m, H^m, F^m_1, ...) if c_i is $m + 1$. The values of the variables of type $(c_1, c_2, \ldots, c_n)$ are propositional functions of the kind which is indicated by this formation rule. And the resulting system, if the new variables of higher types occur only as free variables, and if again suitable axioms and rules of inference are provided, is the *pure functional* calculus of third order. Upon further modifying the formation rule iv, to allow the new variables of higher types to occur also as bound variables, the *pure functional calculus of fourth* order is obtained.

Then the next step is to adjoin functional variables of still higher types; *e.g.*, one of these new types is $(0, (2, 3), (3))$, and if f is a variable of this type, then $f(x_1, x_2, x_3)$ is well-formed on condition that x_1 is an individual variable, x_2 is a variable of type $(2, 3)$, and x_3 is a variable of type (3).

In this way, by successive adiunctious of functional variables of higher and higher types—with appropriate changes, at each stage, in the formation rules, axioms, and rules of inference—the pure functional calculi of all finite orders are obtained. The logistic system which embraces all of these in a single system is the pure functional *calculus* of *order* ω.

A notation $=$, to express that two things are the same or identical, may be introduced by definition:

$$x = y \rightarrow (F^e) \centerdot F^e(x) \supset F^e(y),$$

where x and y arr variable? of the same type, and where the particular letter F is used, with type superscript e so chosen as to make $F^e(x)$ and $F^e(y)$ well-formed.

Finally, to the axioms of the pure functional calculus of order ω, there are added one special axiom, the axiom *of infinity*, and two special axiom schemata, which provide the axioms *of* extensionality and the *axioms* of choice.

The axiom of infinity is to the effect that the number of individuals is infinite. There are many ways in which an axiom having this as a consequence may be formulated in the notation of the system, of which the following (based on an idea of Kurt Schuette) is perhaps the briefest:

$$(\exists F)(x)(\exists y)(z) \centerdot \sim F(x, x)\ F(x, y) \centerdot F(z, x) \supset F(z, y)$$

The axioms of extensionality are that two n-ary propositional functions are identical if they hold among exactly the same ordered sets of n arguments:

$$f(x, y, \ldots, u) \equiv_{xy\ldots u} g(x, y, \ldots, u) \supset f = g,$$

where $x, y, \ldots, u$ is any ordered set of n different variables (which may be of various types, the same or different, n being any positive integer), and where f and g are variables of such type as to make $f(x, y, \ldots, u)$ and $g(x, y, \ldots, u)$ well-formed.

The axioms of choice, or multiplicative axioms as they are also called, are:

$$c(f)c(g) \supset_{fg} [f(x)g(x) \supset_x f = g] \supset (\exists h) \centerdot$$
$$c(f) \supset_f \centerdot f(z) \supset_z (\exists y) \centerdot f(x)h(x) \equiv_x x = y,$$

where c, f, g, h, x, y, z are variables which must be no two the same, and of such types that the formula is well-formed.

For the simple theory of types without axiom of infinity a proof of consistency is possible which is similar to that given above for the functional calculus of first order, and which, although more complicated, employs only methods of essentially the same elementary character. On the other hand it is a consequence of Goedel's incompleteness theorem (see the explanation below) that any proof of consistency of the system with axiom of infinity cannot be of such elementary character, but must employ methods of proof that in some sense surpass anything available in the simple theory of types itself.

The Set Theory of **Zermelo** can be described as obtained by adjoining atIditional axioms to a simple applied functional calculus of first order which has one binary functional constant ϵ and one individual constant Λ. The constant ϵ denotes the relation of membership in a set, so that $\epsilon(x, y)$ may be read as "x belongs to the set y" or "y is a set and x is a member of y." The constant Λ denotes the empty set (the set which has no members). The individual variables may in this theory be regarded as variables of unrestricted range, in the sense that the theory assumes the existence of no entities (sets or others) that cannot be values of the individual variables.

In writing well-formed formulas we shall abbreviate $\epsilon(\mathbf{x}, y)$ as $\mathbf{x}\epsilon y$; *i.e.*, to state it as a definition: $\mathbf{x}\epsilon y \rightarrow \epsilon(\mathbf{x}, y)$.

The notation $=$ may be introduced by a definition analogous to that given above in connection with the simple theory of types: $x = y \rightarrow x\epsilon z \supset_z y\epsilon z$. A notation $\subset$, to express that one set is a part of (a subset of) another, may be introduced by a similar definition: $\mathbf{x} \subset \mathbf{y} \rightarrow z\epsilon x \supset_z z\epsilon y$. In both cases z is to be chosen as the first individual variable (in alphabetic order) which is different from both x and y.

To provide for the notion of an ordered pair, a notation $\{x, y, z\}$ may be introduced to express that z is the ordered pair of x and y: $\{x, y, z\} \rightarrow u\epsilon z \equiv_u \blacksquare [v\epsilon u \equiv_v v = x] \vee \blacksquare v\epsilon u \equiv_v \blacksquare v = \mathbf{x} \vee \mathbf{v} = \mathbf{y}$, where $\mathbf{u}$ and $\mathbf{v}$ are to be chosen as the first two individual variables different from x, y, and z. Relations may then be dealt with in the theory by understanding a relation to be a set of ordered pairs.

The axioms of the theory are those of the functional calculus of first order, and in addition the following axioms and axiom schemata:

Axiom of extensionality: $zex \supset \blacksquare z\epsilon x \equiv_z z\epsilon y \supset x = y$.

Axiom of the empty set: $\sim x\epsilon\Lambda$.

Axiom of pairing: $(3t) \blacksquare zet \equiv_z \blacksquare z = x \vee z = y$.

Axiom of summation of sets: $(3t) \blacksquare z\epsilon t \equiv_z (\exists y) \blacksquare z\epsilon y \cdot y\epsilon x$.

Axiom of the set of subsets: $(3t) \blacksquare zet \equiv_z z \subset x$.

Axioms of subset formation: $(\exists t) \blacksquare z\epsilon t \equiv_z \blacksquare z\epsilon x \cdot \mathbf{A}z$, where $\mathbf{A}z$ is a well-formed formula which may have z as a free variable but does not have t as a free variable.

Axiom of choice: $y\epsilon x \cdot z\epsilon x \supset_{yz} [u\epsilon y \cdot u\epsilon z \supset_u y = z] \, 3 \, (\exists t) \blacksquare y\epsilon x \supset_y \blacksquare$ WE)! $\supset_w (3v) \blacksquare u\epsilon y \cdot u\epsilon t \equiv_u u = v$.

Axiom of infinity: $(\exists t) \blacksquare \Lambda\epsilon t \blacksquare x\epsilon t \supset_x (\exists y) \blacksquare y\epsilon t \blacksquare z\epsilon y \equiv_z \blacksquare z\epsilon x \vee z = x$.

Axioms of replacement: $y\epsilon x \supset_y (3u)[\mathbf{A}yz \equiv_z z = u] \supset (\exists t) \blacksquare z\epsilon t \equiv_z (\exists y) \blacksquare y\epsilon x \cdot \mathbf{A}yz$, where $\mathbf{A}yz$ is a well-formed formula which may have y and z as free variables but does not have t or u as a free variable.

Axioms of excluded infinite regress: $(3x)\mathbf{A}x \supset (3x) \blacksquare \mathbf{A}x \blacksquare y\epsilon x \supset_y \sim\mathbf{A}y$, where $\mathbf{A}x$ is a well-formed formula which may have x as a free variable but does not have y as a free variable.

The way in which the theory seeks to avoid antinomy may be seen in particular in connection with the axioms of subset iormation. An uncritical formulation might well have included the stronger axiom schema $(\exists t) \blacksquare z\epsilon t \equiv_z \mathbf{A}z$, providing for the existence of a set t of those things z (sets and others) which satisfy an arbitrary given condition $\mathbf{A}z$. But this axiom schema would lead directly to the Russell antinomy, upon taking $\mathbf{A}z$ to be $\sim z\epsilon z$. The weaker schema actually used (the axioms of subset formation) provides only for the existence of a set t of those things z which belong to a previously given set x and satisfy the condition $\mathbf{A}z$. This is not known to lead to antinomy; but $\sim(\exists t) \blacksquare z\epsilon t \equiv_z \sim z\epsilon z$ is a theorem.

Concerning the history of these axioms for set theory, see the paragraph about Zermelo in the article LOGIC. HISTORY OF. The axioms of replacement and of excluded infinite regress are additions to the original axiom system of Zermelo. and are sometimes omitted, as although they are independent and for some purposes important, there are also many purposes for which they are not needed. On the other hand, if the axioms of replacement are retained in the form in which we have here stated them, they have the effect of rendering the axioms of subset formation non-independent; *i.e.,* the axioms of subset formation may then be omitted from the list on the ground that they can be proved as theorems by using the axioms of replacement.

An extension of the Zermelo set theory which is due to John von Neumann and Paul Bernays (see the paper of Bernays cited in the bibliography) adds, to the sets of the Zermelo theory, also classes which are not sets, *i.e.,* which cannot be members of other classes or sets. And for every condition $\mathbf{A}z$ expressed in the notation of the Zermelo theory there is a class of those elements z which satisfy Az—where an element is a set or anything capable of being a member of a set. (In particular there is, according to this extended theory, a class of elements z such that $\sim z\epsilon z$, but not a set of such elements.)

Two other, different, systems of set theory are treated by W. V. Quine, one in his paper cited in the bibliography, and the other in the 1951 edition of his book. The latter, due jointly to Quine and Hao Wang, is related to Quine's system of 1937. These are not forms of the Zermelo theory but seek to exclude the antinomies by different means.

Goedel's Incompleteness Theorem.— In contrast with the completeness theorem for the pure functional calculus of first order, all known systems of type theory or set theory which are of sufficient strength to provide a logical foundation of mathematics are incomplete. We state this incompleteness theorem, due to Goedel, in the slightly stronger form which was given to it by Barkley Rosser. On the hypothesis that the system in question—it may be in particular either the simple theory of types or any of the systems of set theory mentioned above—is consistent, there is a well-formed formula A which is a sentence (hence without free variables) such that neither $\mathbf{A}$ nor $\sim\mathbf{A}$ is a theorem.

The proof of the metatheorem proceeds by constructing a particular well-formed formula $\mathbf{A}$, and then showing that, ii the system is consistent, A cannot be a theorem, and $\sim\mathbf{A}$ cannot be a theorem. However, it can also be shown that, if the system is consistent, the proposition expressed by A is true. More accurately, me can show, by means that are formalizable in the system itself, "If the system is consistent, then ______," filling the blank with a statement of the proposition that is expressed by A. Hence the further metatheorem follows that the consistency of the system cannot be proved by means that are formalizable in the system itself. (This brief statement oi the matter is incomplete, and some essential explanations which are here omitted will be found in the article MATHEMATICS, FOUNDATIONS OF.)

Both the incompleteness theorem and the further theorem about the possibility of a consistency proof have the striking feature that they hold not only for a particular system but for any arbitrary extension of it that may be obtained by adjoining additional axioms or rules of inference or both, provided only that the requirement is satisfied that the axioms and rules of inierence shall be effective (as described in the first part of this article, in explaining the notion of a logistic system). Having a particular system, which we suppose consistent, and having constructed the sentence A which is then true but not a theorem. we may indeed strengthen the system by adding A to it as an axiom. But the resulting stronger system is still incomplete: in it a particular sentence B may again be constructed by the same method, and it may be shown on the hypothesis of consistency that neither B nor $\sim$B is a theorem, and that the proposition expressed by B is true.

LOGIC, HISTORY OF. In this article the history of logic is presented as follows:

I. Ancient Logic
  1. Aristotle
  2. Theophrastus
  3. Stoics and Megarians
  4. The Last Period

II. Logic in India
  1. Origins
  2. The Old Nyaya (Pracina-nyaya)
  3. The New Nyaya (Nyavya-nyaya)

III. Scholastic Logic
  1. Period of the "Old Logic" (Ars Vetus)
  2. Period of the "New Logic" (Ars Nova)
  3. Rise of Terministic Logic
  4. Classical Period of Scholastic Logic
  5. Decline of Scholastic Logic

I. ANCIENT LOGIC

1. Aristotle.—The history of ancient logic begins with Aristotle. This is not to say that until Aristotle's time no one mas capable of reasoning correctly. The works of Plato are full of interesting arguments, valid and invalid, and, indeed, the same may be said for nearly all of ancient literature—whether written by philosophers, mathematicians, scientists, historians, grammarians or even by poets—both before and after the discovery of the syllogism. However, in determining the scope of a history of logic, one should not fail to distinguish sharply between the use of logical principles, which may be attributed to anyone who reasons, and the *mention and study* of such principles. Only the latter is specifically the business of logic and accordingly is relevant to its history. It is true that the logician himself, like any other theorist, will have to construct arguments and proofs concerning his subject matter. Nevertheless, it is important even in his case to distinguish between the principles he mentions and those he uses. Thus. for instance, when Aristotle proves his various assertions about the syllogism he often argues in accord with inference patterns which are clearly not syllogistic and which, since he never discusses them explicitly, cannot be considered a part of his logic.

Most of Aristotle's contributions to logic are found in a group of treatises known in later times under the title *Organon* and consisting of the *Categories*, *De Interpretatione*, the *Analytics*, the *Topics*, and the *Sophistical Refutations*. These treatises also contain much that lies outside the field of logic. All of them are written in the abbreviated, notebook style which is typical of the entire Aristotelian corpus, and they abound in textual difficulties. The authenticity of the first two is open to doubt, and the order in which the various works were written is unknown. Yet despite such problems and obscurities one cannot fail to be impressed by the sure and masterful way in which Aristotle sets forth his remarkable discoveries in logic. Most of the relevant material is found in the *Prior Analytics* and the *De Interpretatione* (*Peri-hermenias*), and we shall therefore restrict ourselves to a quite summary treatment of the remaining portions of the *Organon*.

The *Categories* begins with a division of linguistic expressions into simple and composite. Examples of the composite are "A man runs," "A man wins"; of the simple, "man." "ox." "runs," and "wins." Xristotle then states that every simple expression means one of the following: substance. quantity. quality, relation, place. time, position, state, action, affection: and he devotes the remainder of the treatise to a discussion of these categories. Most of what is included is not directly relevant to the history of logic. but there are a few passages which bear upon the question of interpreting the important idiom "is predicated of." in terms of which syllogisms are typically stated by Aristotle. Unfortunately, the evidence afforded by these passages tends only to confirm what we gather from the *Analytics,* namely, that Xristotle was not fully clear whether he was speaking of a relation between a thing and a word, or between two things, or between two words. The difficulty is well illustrated by his statement of the one logical principle mentioned in the *Categories:*

> Whenever one thing is predicated of another as of a subject, everything said of what is predicated will also be said of the subject; for example, man is predicated of some particular man, and animal of man; thus animal will be predicated of the particular man also.

The *De Interpretatione* continues the classification of linguistic expressions and sets forth some elementary logical relations among declarative sentences of the simplest types. Sentences, as well as the nouns and verbs of which they are composed, are defined as certain species of significant sounds. Observing that some of them, *e.g.,* prayers, are neither true nor false, Xristotle dismisses these as "belonging to the study of rhetoric or poetry" and restricts the discussion to declarative sentences. These are divided into simple and composite: the simple either affirms or denies something of something. while the composite results from conjoining simples. Further restricting the subject to simple sentences, Aristotle divides them into eight groups, explaining as follows: Some things are universal. he says, and some are particular. By "universal" he means what is of such a nature as to be predicated of many things; by "particular." what is not of such a nature; thus Man is a universal. and Callias is a particular. Now some of our (simple declarative) sentences concern a universal as subject, and others concern a particular. For example. the positive and negative sentences "Socrates is white," "Socrates is not white" both concern a particular. viz., Socrates. Of those which have a universal subject, several kinds are distinguished. Such sentences as "Every man is white" and "No man is white," later known respectively as *A*- and *E-propositions,* are said to be of a universal character and about a universal subject. The words "every" and "no" are the marks of the universal character, and in these examples Man is the universal subject. There are two kinds of sentences which are not of a universal character but are nevertheless about a universal subject. First we have such sentences as "Some man is white" and "Xot every man is white." later called **I**- and *O-propositions,* and described in the *Prior Analytics* as "particular" sentences. In addition there are sentences like "Man is white" and "Man is not white," called "indefinite" in the *Prior Analytics.*

An affirmation and a denial which have the same subject and predicate, but one of which is of a universal character while the other is not, are called "contradictories" by Aristotle. Thus, "Every man is n-hite" and "Not every man is white" are contradictories, as are "No man is white" and "Some man is white." Of a pair of contradictories, exactly one must be true. An affirmation and denial which have the same subject and predicate and each of which is of a universal character are called "contraries." It is not possible for both members of a pair of contraries to he true, hut it can happen that both of their contradictories are true. In other words. contraries may be simultaneously false. This is the case, for example, with the contraries "Every man is white" and "No man is white." In the centuries after Xristotle these relationships were presented schematically by means of the well-known Square of Opposition. which first appears in Apuleius' commentary on *De Interpretatione.*

The remainder of the treatise consists of an unsystematized miscellany of observations. some interesting. some obscure and confused. There is a discussion purporting to show that if one member of every pair of contradictory sentences is true and the other is false, then everything happens by necessity and nothing by chance. The argument is unclear. hut it appears to rest in part upon a confusion between true sentences like "Necessarily. if 'Snow is white' is true. then snow is white" and their more idiomatic (as also in Greek) but strictly false counterparts. "If 'Snow is white' is true, then necessarily snow is white." On another subject. Aristotle makes the interesting point that the word "is" has a different sense in "Homer is" from what it has in "Homer is a poet," and that the former of these sentences does not follow from the latter. In still another place he notices that some predicates will combine in a way in which others will not: thus. from "Socrates is two-footed" and "Socrates is a man" we can deduce correctly "Socrates is a two-footed man"; whereas from "He is good" and "He is a shoemaker" it would be incorrect to infer "He is a good shoemaker." This is reminiscent of the Platonic example: "He (a dog) is yours and he is a father. Therefore, he is your father." The core of Aristotle's logic is in the first seven chapters of Book I of the *Prior dnalytics*. There. within the space of a very few pages, is set forth the theory of the syllogism, an intellectual discovery that was of unequaled magnitude for its time and which dominated the science of logic for 2,000 years.

Aristotle first describes the kinds of sentences which may be components of syllogisms. The classification is somewhat different from that given in *De Interpretatione*. Every premiss and conclusion. he says, affirms or denies something of something and thus is positive or negative. It will also be universal, particular, or indefinite. A universal sentence asserts that something belongs to all or none of something else; a particular sentence asserts that something belongs to some or not to some or not to all of something else; an indefinite sentence merely asserts, neither in general nor in particular, that something belongs or does not belong to something else, *e.g.*, that pleasure is not good. Strictly speaking, the foregoing is an account only of assertoric premisses; there are also problematic premisses, to the effect that something *may* belong to something else; and apodictic premisses, which state that something *must* belong to something else. These also are divided into six kinds, in the same way in which the assertoric premisses are so divided. It will be noticed that no mention is made of sentences with particular subjects (in later terminology, singular sentences, or singular propositions). They are entirely ignored in the *Prior Analytics*, and consequently the ancient and familiar example of a syllogism:

All men are mortal.
Socrates is a man.
Therefore, Socrates is mortal.

is quite un-Aristotelian. Furthermore. the indefinite sentences, too, are very nearly ignored by Aristotle. According to Alexander, the reason is that they are "equivalent" to particular sentences.

In preparation for his deductive exposition of the syllogistic Aristotle states the laws of conversion. The universal negative sentence converts into a universal negative; *e.g.*, if no pleasure is good. then no good will be pleasure. The universal and particular affirmative sentences convert! but into particular affirmatives; *e.g.*, if every pleasure is good, then some good is pleasure, and if some pleasure is good, then again some good is pleasure. The particular negative does not convert, since, for example, it does not follow that if some animal is not a man, then some man is not an animal. Using variables Aristotle states these laws in a general way and demonstrates them by procedures known as *ekthesis* and *reductio ad impossibile:*

First, then, let the premiss AB be a universal negative. If *A* belongs to no B, then *B* will not belong to any *A*. For if it belonged to some A—for instance, to C—then it would not be true that A belonged to no B, for *C* is one of the B's. And if *A* belongs to all B, then B mill belong to some *A*. For if it belonged to no *A*, *A* would belong to no *B*, whereas it was assumed to belong to all B. And likewise if the premiss is particular. For if A belongs to some B, then necessarily B belongs to some A, since if it belonged to none, *A* mould belong to no B. On the other hand, if A does not belong to some *B*, it is not necessary that *B* should not belong to some *A*; for example, let *B* be Animal and *A* be Man. For Man does not belong to every Animal, but Animal does belong to every Man.

The Aristotelian definition of "syllogism" is as follows: a syllogism is discourse in which, certain things being posited, something else follows necessarily from their being so. However. his definition is far too wide, applying to nearly all valid arguments, and it does not agree with his own practice. A much better idea of what is meant by "syllogism" may be derived from an examination of the syllogistic formulas actually set forth. The following literal translations will serve this purpose and will illustrate the methods of reduction. Important words which do not occur in Aristotle's abbreviated statements but which seem to be required by the sense and syntax are enclosed within parentheses. The scholastic names for the moods are due to Peter of Spain.

Barbara. For if *A* (is predicated) of all *B* and *B* of all *C*, it is necessary for *A* to be predicated of all *C*. (*An. Pr.* I, 25 b 37)

Celarent. Likewise, if A (is predicated) of no *B* but *B* of all *C*, (it is necessary) that *A* will belong to no *C*. (25 b 40)

Darii. Let *A* belong to all B, anti B to some *C*. Then if "predicated of all" means what was said at the beginning, it is necessary for *A* to belong to some *C*. (26 a 23)

Ferio. And if A belongs to no *B*, but B to some *C*, it is necessary that *A* does not belong to some *C*. (26 a 25)

Cesare. Let *M* be predicated of no *N* but of all *O*. Then, since the negative converts, *N* will belong to no *M*. But M was assumed (to belong) to all *O*; so that *N* (will belong) to no *O*; for this has been shown previously. (27 a j)

Camestres. Again, if *M* (belongs) to all *N* but to no *O*, neither will *N* belong to any *O*. For if *M* (belongs) to no *O*, then *O* (belongs) to no M; but *M* belonged to all *N*; therefore, *O* will belong to no *N*; for the first figure has been produced again. And since the negative converts, *N* will belong to no *O*. (27 a 9)

Festino. For if *M* belongs to no *N* but to some *O*, it is necessary for *N* not to belong to some *O*. For since the negative converts, *N* will belong to no *M*. But *M* was assumed to belong to some *O*, so that *N* will not belong to some *O*; for a syllogism in the first figure is obtained. (27 a 32)

Baroco. Again, if *M* belongs to all *N* but not to some *O*, it is necessary for *N* not to belong to some *O*. For if it belongs to all, and *M* is also predicated of all *N*, it is necessary for *M* to belong to all *O*. But it was assumed not to belong to some. (27 a 36)

Darapti. Whenever both *P* and R belong to all *S*, (it is true) that *P* will of necessity belong to some *R*. For since the affirmative converts, *S* will belong to some R, so that since P (belongs) to all *S*, and *S* to some *R*, it is necessary for *P* to belong to some R. For a syllogism in the first figure is produced. It is also possible to make the proof *per impossibile* and by *ekthesis*. For if both belong to all *S*, then if one of the *S*'s, *e.g.*, *N*, is taken, both *P* and *R* will belong to this, so that *P* will belong to some R. (28 a 17)

Felapton. And if *R* belongs to all *S*, but *P* to none, there will be a syllogism that of necessity P will not belong to some R. The same type of proof (mill work) by converting the *RS* premiss. It might also be shown *per impossibile*, as in the previous cases. (28 a 26)

Disamis. For if *R* (belongs) to all *S* and P to some, it is necessary ior P to belong to some R. For since the affirmative converts, *S* will belong to some P, so that since *R* (belongs) to all S, and *S* to some P, R will belong to some P. So that P (will belong) to some R. (28 b 7)

Datisi. Again, if *R* belongs to some *S* and *P* to all, it is necessary for *P* to belong to some R. For the same method of demonstration (will work). And it is also possible to demonstrate it both per *impossibile* and by *ekthesis*, just as in the previous cases. (28 b 11)

Bocardo. For if *R* (belongs) to all *S* and P does not belong to some, it is necessary for *P* not to belong to some *R*. For if to all, and R (belongs) to all *S*, P will also belong to all *S*. But it did not so belong. It is also proved without reduction, if one of the *S*'s to which *P* does not belong is taken. (28 b 17)

Ferison. For if P (belongs) to no *S*, but R belongs to some *S*, P will not belong to some *R*. For the first figure will be produced again when the *RS* premiss is converted. (28 b 33)

Fesapo and *Fresison*, premisses in reversed order. . . . such as, if *A* (belongs) to all *B* or to some, but B to no C. For when the premisses are converted it is necessary for *C* not to belong to some *A*. Likewise in the other figures: a syllogism always results from conversion of the premisses. (29 a 23)

There is some question as to how these formulas should be interpreted. Traditionally, "Aristotelian" syllogisms have been presented as arguments and not as conditional sentences. The well-known example of a syllogism in Barbara has the form of an argument consisting of two premisses and a conclusion:

All men are mortal.
All Greeks are men.
Therefore, all Greeks are mortal.

As J. Lukasiewicz emphasized, this cannot be obtained by substituting terms for variables in the Aristotelian formula. The difficulty is not only that Aristotle uses expressions like "*A* is predicated of all *B*" or "*A* belongs to all *B*" instead of "All *B* is *A*"; more important, nearly all of the Aristotelian formulas have the form of conditional sentences, and the word "therefore" almost never occurs. Thus, their instances cannot be arguments — at least, not of the usual type. On the other hand, however, Lukasiewicz himself is not very convincing when he argues that the "true" syllogisms are generalized conditionals; on this hypothesis Barbara, for example, would be:

For every *A*, *B*, *C*, if *A* is predicated of all B and B is predicated of all C, then A is predicated of all C.

It will be noticed that some of the Aristotelian statements approximate this form, but that others do not. Aristotle's formulations of Darii and Cesare are not conditionals, and his statement of Felapton is clearly metalinguistic. Further, the sense of the word "necessarily," which occurs in nearly every one of the formulas, is not adequately represented by the prefix "For every A, B, C." Anyway, there is no evidence that Aristotle ever used quantifiers; he seems rather to have thought of variables simply as letters standing in place of terms. Further, a number of passages seem to indicate that, for Aristotle, the syllogisms are *instances* of the formulas containing variables and do not themselves contain variables. All of these obstacles stand in the way of accepting Lukasiewicz' interpretation.

Another, and closely related, difficulty concerns the question whether terms are classes or the names of classes. There are many places in which it appears that Aristotle regards terms as constituents of sentences. the latter being clearly regarded as significant sounds. But there are equally many places where he seems to be thinking of them as classes. Thus, he says "for one thing to be included as a whole in another, and for the other to be predicated of all of the one, are the same." Probably the truth is simply that Aristotle did not honour our much-valued distinctions between the use and mention of linguistic expressions and between arguments and conditional sentences. In asking whether he "really" meant syllogisms to be arguments or conditionals, and whether he "really" meant his logic to concern classes or names, we may be asking questions to which there are no appropriate answers.

The moods of the syllogism are grouped into three figures. Aristotle says that if we want to prove syllogistically that A belongs (or does not belong) to B, we have to take something common in relation to both, and this can be done in three ways: by predicating either A of C and C of B, or C of both. or both of C. "These," he continues, "are the figures of which we have spoken, and it is clear that every syllogism must be in one of these figures." Accordingly. Barbara, Celarent, Darii. and Ferio belong to the first figure; Cesare. Camestres. Festino, and Baroco to the second; and Darapti, Felapton, Disamis. Datisi, Bocardo, and Ferison to the third. There has been much discussion as to why Aristotle did not anticipate his followers in mentioning a fourth figure: *i.e.,* why he did not consider the possibility of proving A of B by predicating C of A and B of C. Numerous answers, none completely convincing, have been given. In any case, it is probable that Aristotle did recognize the existence of such syllogisms. For he allows interchange of the premisses of a syllogism and says that the result of converting the conclusion of a syllogism is again a syllogism; applying these operations to Barbara. Celarent. and Darii we obtain the moods Bramantip, Camenes, and Dimaris of the fourth figure. The remaining valid moods in this figure, Fesapo and Fresison, are given explicitly, although with their premisses in reversed order.

As I. M. Bochenski observed. "the assertoric syllogism is probably the most important discovery in all the history of formal logic, for it is not only the first formal theory with variables, but it is also the first axiomatic system ever constructed." (I. M. Bochenski, *Ancient Formal Logic*, North-Holland Publishing Company. 1951.) Aristotle axiomatizes his syllogistic in several ways. In the first of these he chooses as axioms the syllogisms of the first figure. They are said to be "perfect," *i.e.,* intuitively evident. He then proves the validity of the syllogisms in the second and third figures by reducing them to syllogisms of the first figure. The reductions are of two sorts: direct reduction and *rcductio ad impossibile.* Direct reductions are made by converting one or more premisses of the syllogism to be proved, reversing their order if necessary, and then deriving the desired conclusion (or its converse) by means of the syllogism to which reduction is made. By this procedure Aristotle reduces Cesarc and Camestres to Celnrent; Festino. Felapton, and Ferison to Ferio; Darapti, Disamis, and Datisi to Darii. (*See* the translations above.) The other method proceeds as follows: from one of the premisses and the contradictory of the conclusion of the syllogism to be proved, one derives (using the syllogism to which reduction is being made) the contradictory of the other premiss, thus establishing that the conclusion follows from the premisses. Aristotle uses this method to reduce Baroco and Bocardo to Barbara. Then! after reducing all of the moods to those of the first figure, he further states that Barbara and Celarent alone would suffice as axioms. He proves this by showing how to reduce Darii and Ferio to syllogisms of the second figure and by reminding us that all syllogisms of the second figure are reducible to Barbara and Celarent. (We are told that Festino may be proved by a *reductio* ad *impossibile* to Celarent, as well as by a direct reduction to Ferio.) Elsewhere he observes that the moods of any of the three figures will serve equally well as axioms.

Aristotle arrives at the valid moods by a process of elimination. To show that there is no valid syllogism of a given type, he always produces a counter-example. He does this in a particularly expeditious manner, managing to deal with several possibilities at a time. We quote and explain a typical example.

> But if M is predicated of all N and O, there will not be a syllogism. Terms for the affirmative relation are substance, animal, man; for the negative relation substance, animal, number.

This is a condensed argument to show that in the second figure there is no valid mood of the form "If M is predicated of all N and O, then . . . ." It makes tacit use of the fact that any substitution of terms for variables which converts the premisses of a valid mood into true sentences will also convert the conclusion into a true sentence. Now suppose there were a valid mood with the indicated premisses and a negative conclusion. Then any substitution of terms for variables which makes the premisses true will also make this negative conclusion true. and will tlierefore make false the universal affirmative formula "N is predicated of all O," which is the contradictory of the particular negative and the contrary of the universal negative. But, as a matter of fact, substitution of the terms "substance," "animal," and "man" for "M," "N," and "O," respectively, makes the premisses and this universal zffirmative formula true. Therefore. there is no valid mood with the indicated premisses and a negative conclusion. Analogously, since substitution of the terms "substance," "animal," and "number" makes the premisses and the universal negative formula "N is predicated of no O" true, there cannot be an affirmative conclusion. Therefore, there is no valid mood of the type under consideration. Often Aristotle does even better than this, dealing simultaneously with two pairs of premisses and thus eliminating eight possibilities at once.

After sifting out the valid moods of the syllogism Aristotle proceeds to make certain general remarks about them. He notices that in every syllogism at least one of the premisses must be affirmative and at least one must be universal. He points out further that a universal conclusion occurs only when both premisses. are universal. while a particular conclusion may follow from premisses which are both universal or one of which is particular. Also, at least one of the premisses must be like the conclusion in being affirmative or negative. Many other less interesting points are made, such as that only Barbara has a universal affirmative conclusion.

We have confined our attention to the assertoric syllogism, *i.e.,* to such syllogisms as contain only assertoric components. Actually much the greater portion of *Prior Analytics* I is devoted to modal syllogisms, which contain problematic or apodictic premisses or both. Aristotle develops the theory of such syllogisms in a manner similar to that used for the assertoric syllogism. However, his treatment is incomplete and contains many errors; and the already complex subject is further complicated by the fact that he uses the modal operators "necessary" and "possible" in a number of different senses. some of which are very difficult to grasp. His contribution to modal logic is undoubtedly important, but a great deal of work remains to be done before it can be regarded as well understood.

The remainder of the *Prior Analytics* and all of the *Posterior Analytics* are devoted primarily to subjects which are not relevant to logic as presently conceived. The same is true of the *Topics* and the *Sophistical Refutations.* In the *Posterior Analytics* Aristotle investigates the nature of scientific knowledge. The *Topics* attempts to lay down rules for arguing dialectically, *i.e.*, for establishing desired conclusions syllogistically from generally accepted premisses, and the Sophistical *Refutations* consists of a laborious discussion of fallacious arguments. Yet throughout these works there occur incidental remarks mhich, as Bochenski has shown, reveal that Xristotle was aware of many non-syllogistic laws of logic, including examples from what would now be described as the theory of identity and the calculi of predicates, relations, and propositions. Indeed, the science of logic has very few branches of which the beginnings, albeit sometimes faint, cannot be found somewhere in his writings.

2. Theophrastus.—Theophrastus, Aristotle's successor as head of the Peripatetic school, was evidently a logician of tonsiderable ability. Unfortunately, we possess only a few fragments of his logical works, and in many of these his name is linked with that of his successor, Eudemos. These fragments, however, suffice to show that his work consisted mainly in the development and correction of Aristotelian doctrine. We know but few details. To the first figure of the assertoric syllogism he added five moods which, when the order of their premisses is reversed, are seen to be precisely the five moods of the fourth figure. (Lukasiewicz conjectures that he was led to do this by defining the first figure as that in which the middle term is the subject of one premiss and the predicate of the other.) He expressly identified the indefinite sentences with the particular. He objected. for some reason or other, to Aristotle's use of "A does not belong to some *B*" and "Not: A belongs to all *B*" as synonymous. Further, it may be conjectured that he used something like the Euler diagrams for the syllogism, since he paraphrases "No *S* is *P*" as "S is separate from P."

However, Theophrastus' most significant contributions were in the field of modal logic, where, according to Bochenski, he made two major changes: (1) the interpretation of "possible" as "not self-contradictory" instead of "contingent"; (2) the affirmation and consistent application of the principle that the conclusion always follows the weaker premiss. It is also likely that his investigations into hypothetical syllogisms anticipated, to some extent, the Stoic logic of propositions.

3. Stoics and Megarians.—In many respects ancient logic reached its zenith in the writings of the Stoic and Megarian logicians. The Megarian school was founded by Euclid. one of the followers of Socrates. Among his pupils were Eubulides, to whom the Liar paradox is ascribed: Ichthyas. the successor of Euclid as head of the school; and Thrasymachus of Corinth. the teacher of Stilpo. The best-known pupil of Stilpo was Zeno (c. 350–260 B.C.), founder of Stoicism. Zeno's successors were Cleanthes and Chrysippus, the latter of whom was the most productive logician of the school. ("If there had been no Chrysippus. there would have been no Stoa"; "If there is any logic in heaven, it is the logic of Chrysippus.") Another important branch of the Megarian school consisted of Eubulides, Apollonius Cronus. Diodorus Cronus. and Philo. Unfortunately, the writings of all these men have been lost, and it is therefore necessary for us to depend upon fragments quoted by later authors. The best of our sources are Sextus Empiricus and Diogenes Laërtius, although we also get bits of information from Cicero, Gellius, Galen, Boethius, Apuleius, Alexander and the other Greek commentators, Origen, Proclus, Stobaeus, Epictetus, Seneca and a few others. Of these, only Epictetus and Seneca were favourably inclined toward Stoicism, and they were not interested in logic. The result is that our knowledge of the Stoic-Megarian logic has to be obtained principally from persons nho were trying to show that it was of no value.

Nevertheless, the picture which can be pieced together from these fragmentary sources is one of a relatively sophisticated and formalized logic quite different from that introduced by Aristotle. It is a logic of propositions. nhile the syllogistic is a logic of classes or terms: *i.e.*, the values of the Stoic variables are propositions; those of the Aristotelian variables are terms or classes. Further, it is a logic of valid inference schemas, while the Aristotelian formulas are usually propositional forms of conditional type. Stoic-Negarian logic is very modern in a number of important respects. The usual sentence connectives are interpreted truth-functionally, as is customary nowadays, and various possibilities of defining them in terms of one another are noticed. Arguments are sharply distinguished from the corresponding conditional propositions. The inference schemas which make up the calculus are never confused with the meta-rules for their reduction to one another. The whole logic is conceived in terms of a semantic distinction very similar to G. Frege's distinction between the sense and the denotation of linguistic expressions. In general, it is drawn upon lines very familiar to modern students of the subject.

Stoic semantics rests upon a fundamental distinction among three things: (1) the linguistic sign or sound, *e.g.*, the name "Dion." (2) the existent object denoted by the sign, which in this example would be Dion himself, and (3) the meaning of the sign. The first two of these three things are always bodies. say the Stoics, but the third factor is not a body. It is what Greeks but not Barbarians are able to grasp when they hear Greek words spoken. The technical term for these meanings or senses is "Lekta." On the Stoic view, it is with Lekta, and not with the linguistic expressions thereof. that logic is concerned.

The Lekta are classified in great detail. First, they are divided into deficient and complete. The deficient Lekta are subjects and predicates, a subject being the sense of a proper or class name, while a predicate is the sense of a verb. Complete Lekta are propositions, questions. imperatives. oaths, salutations: etc. Of course, the interest of logic is confined to propositions. which are defined as complete Lekta which are assertoric. They are elsewhere differentiated from other complete Lekta by the property of being true or false. A proposition is the sense of a declarative sentence; if atomic (see below) it is somehow composed of the subject and predicate nhich are the senses of the components of the sentence.

Propositions are divided into atomic and molecular. An atomic proposition is composed of subject and predicate without the help of a logical connective. A molecular proposition always contains at least one connective and consists either of two occurrences of a single proposition (as in "If it is day, then it is day") or of different propositions (*e.g.*, "If it is day, then it is light"). Atomic propositions are either definite (*e.g.*, "This man is walking"), indefinite (*e.g.*, "Somebody is walking"), or intermediate (*e.g.*, "Socrates is walking"). Types of molecular proposition include the negation, conditional, conjunction, disjunction, and several others. The negation of a proposition is said to be formed by prefixing "not," and emphasis was placed upon "prefix." (What this spatial terminology can mean when applied to propositions, as contrasted with sentences, is not explained.) Thus, they said, the correct negation of "It is day and it is night" is "Not both: it is day and it is night." which is of course quite ditierent from "It is day and it is not night." A conditional proposition is one that is formed from two occurrences of a single proposition or from different propositions by means of the connective "if" (*e.g.*, "If it is day, then it is light"). The part immediately following the "if" is the antecedent, and the other part is the consequent, even when the conditional is stated backwards. *e.g.*, "It is light if it is day." A conjunction is a molecular proposition compounded by means of the connective "and." *e.g.*, "It is day and it is light." Similarly, the parts of a disjunction are joined by "or," *e.g.*, "It is day or it is light."

There was a great controversy among the Stoics and Megarians about the meanings of conditionals. Callimachus reports, "Even the crows on the rooftops are discussing the question as to mhich conditionals are true." Sextus states and illustrates the four main proposals. He arranges these from the weakest (material implication) to the strongest, at each step cleverly producing an example which is true in all the preceding senses but false in the sense at hand.

For Philo says that a true conditional is one which does not have a true antecedent and a false consequent; *e.g.*, when it is day and I am conversing, "If it is day, then I am conversing"; but Diodorus defines it as one which neither is nor ever was capable of having a true antecedent and a false consequent. According to him, the conditional just mentioned seems to be false, since when it is day and I have become silent, it will have a true antecedent and a false consequent; but the following conditional seems true: "If atomic elements of things do not exist, then atomic elements of things do exist," since it will always have the false antecedent. "Atomic elements of things do not exist," and the true consequent, "Atomic elements of things do exist."

And those who introduce "connection" or "coherence" say that a conditional holds whenever the denial of its consequent is incompatible with its antecedent; so that, according to them, the above-mentioned conditionals do not hold, but the following is true: "If it is day, then it is day." And those who judge by "suggestion" declare that a conditional is true if its consequent is in effect included in its antecedent. According to these, "If it is day, then it is day" and every repeated conditional probably will be false, for it is impossible for a thing to be included in itself.

It will be noticed that Philo has defined what is now called "material implication." This definition seems to have been the one which found the greatest favour with the Stoics. It occurs in many of the fragments. sometimes even in what amounts to truth-table form:

Since, then, there are four possible combinations oi the parts of a conditional—true antecedent and true consequent, false antecedent and false consequent, ialse and true, or conversely true and false—they say that in the first three cases the conditional is true (*i.e.*, if the antecedent is true and the consequent is true, it is true; if false and false, it again is true; likewise, for false and true); but in one case only is it false, namely, whenever the antecedent is true and the consequent is false.

The view of Diodorus is not as clear as that of Philo, but from his definition of the "possible" as "that which either is or will be true" we can determine that a conditional holds in the Diodorean sense if and only if it holds *at all* times in the Philonian sense. For example. "If it is day, then it is light" holds in the Diodorean sense provided that for every value of t the propositional form "If it is day at time t, then it is light at time t" is a true Philonian conditional. The third sense mentioned in Sextus' list is what is now called "strict implication"; the fourth is nowhere taken up again.

Two basic types of disjunction were recognized by the Stoics: exclusive and inclusive. Exclusive disjunction was most used, and it is the only type of disjunction involved in the Stoic calculus of propositions. An exclusive disjunction is true if and only if exactly one of the disjuncts is true! *e.g.,* "It is day or it is night." For inclusive disjunction we possess no clear truth-functional definition, but there are illuminating examples, such as "Socrates is walking or Socrates is conversing." There seem also to have been non-truth-functional definitions: according to one of which a disjunction is not true unless the disjuncts are incompatible. As to conjunction, the case is simpler. A conjunction is true if and only if both parts are true. A negation is true if and only if what is negated is not true.

Chrysippus, in reference to the statement "If anyone is born under the Dog Star, then he will not drown in the sea," recommends that it be expressed as follows: "Not both: someone is born under the Dog Star and he will drown in the sea." thus showing that he knew how to express material implication by means of negation and conjunction. There is also some evidence that the Stoics knew how to define exclusive disjunction in terms of negation and equivalence.

As with Aristotle's syllogistic, however, the most interesting aspect of the Stoic logic of propositions is its arrangement into a deductive theory. The elements of the Stoic theory are arguments: not propositions, where an argument is regarded as a system of propositions containing premisses and a conclusion. Arguments of five types are taken as basic, and all others are declared provable in terms of these. The basic types are represented by the following five schemas:

I. If the first, then the second.
The first.
Therefore, the second.

II. If the first, then the second.
Not the second.
Therefore, not the first.

III. Not both the first and the second.
The first.
Therefore, not the second.

IV. The first or the second.
The first.
Therefore, not the second.

V. The first or the second.
Kot the first.
Therefore, the second.

For an example of a proof in the system, consider the following schema:

1. If both the first and the second, then the third.
2. Not the third.
3. The first.

Therefore, not the second.

The Stoic proof given by Sextus makes use of the following meta-rule: "If we have premisses which yield a conclusion, then we have in effect also the conclusion among the premisses, even if it is not explicitly stated." From 1 and 2, by a basic argument of type II, we get

4. Not both the first and the second.

which. according to the meta-rule, can now be considered as one of the premisses. From 3 and 4 we then obtain the conclusion by a basic argument of type III.

We know that there were four meta-rules by means of which such proofs were to be carried out. Unfortunately, we possess only two (or possibly three) of these rules. The first was "If from two propositions a third is deduced, then either of the two together with the denial of the conclusion yields the denial of the other," and the third was "If from two propositions a third is deduced and there are propositions from which one of the premisses may be deduced, then the other premiss together with these propositions will yield the conclusion." Perhaps the rule used in the example above is another version of this one. The Stoics seemed to think that their system was complete, *i.e.*, that every valid argument in the calculus could be reduced to a chain of arguments of the five basic types. Without knowing all four of the meta-rules we are not in a position to evaluate this claim.

Examples of Stoic proofs are very few in number. However, numerous arguments are mentioned and schematized without proof. For instance, there is the schema

Either the first or the second or the third.
Kot the first.
Not the second.
Therefore, the third.

Chrysippus said that even dogs make use of this sort of argument. For when a dog is chasing some animal and comes to the junction of three paths, if he sniffs first at the two paths down which the animal did not run, he will rush off down the third path without stopping to smell. Another schema is

If the first, then the second.
If the first, then not the second.
Therefore, not the first.

A Stoic example of an argument of this type is

If you know that you are dead, then you are dead.
If you know that you are dead, then you are not dead.
Therefore, you do not know that you are dead.

The Stoic and Megarian logicians, like logicians of all times, were greatly interested in paradoxes, the most famous of which was the Liar. This important antinomy was the subject of much writing in antiquity, including perhaps 28 books by Chrysippus alone. In fact. there is an ancient epitaph which says that Philetas of Cos died from spending his nights thinking about it. The Liar appears in several forms. Alexander gives "The man who says 'I am lying' is both telling the truth and lying." Cicero's version is "If you say that you are lying and tell the truth. then you are lying." Gellius asks, "When I am lying and say that I am lying, am I lying or telling the truth?" A closely related paradox, often called "the Epimenides." first appears in the Apostle Paul's *Epistle* to *Titus*. Paul there reminds Titus that even the Cretan prophet (identified by commentators as Epimenides) said that all Cretans were liars, gluttons. and evil beasts. He adds that what Epimenides said was true! No clear solution to any of these formulations is to be found in extant ancient literature.

4. The **Last** Period.—The history of ancient logic after Chrysippus is a subject still awaiting exploration in the second half of the 20th century. In the imperfect state of knowledge it appears that there were no logicians worthy of being mentioned in the same breath with Aristotle, Diodorus and Chrysippus. The period was not a creative one, new problems and methods being entirely

lacking, and what literature there was consisted primarily of commentaries and compendiums. In this connection, the contemporaries Galen and Apuleius (c. A.D. 150), whose handbooks are extant, deserve mention. Among the commentators, Alexander of Aphrodisias, a Peripatetic of the 3rd century A.D., was clearly a competent logician. His commentary on the *Organon* remains down to the present as perhaps the best exegetical account of this work. Of the later Greek commentators on Aristotle, Simplicius must be listed as one of the few who wrote intelligently about matters of logic. Martianus Capella, author of a Latin handbook of great importance for the transmission of ancient logic to later times, should also be mentioned.

Anicius Manlius Severinus Boethius (c. A.D. 480–524), the last Roman philosopher, was not a very good logician but is nevertheless highly important because of his influence on the middle ages. He wrote a number of books on logic, including De Syllogismo Hypothetico, De Syllogismo Categorico, and the commentaries on De *Interpretatione*. In these works we find Aristotelian logic presented in a terminology and manner now known as "traditional." Thus, the syllogisms are stated as arguments and not in conditional form. The Square of Opposition appears in its usual form, and many other details of classical logic occur for the first time in Boethius.

In the De Syllogismo Hypothetico we find a number of formulas best interpreted as theorems or rules of the propositional calculus. Some of them appear to be absurdly erroneous, but Van den Driessche has shown that Boethius occasionally used "if" in the sense of material equivalence. In the light of this explanation, such formulas as

If not-a, then b implies c: but
b implies c; therefore, not-a.

are seen to be valid, after all.

With Boethius, ancient logic comes to a close.

II. LOGIC IN INDIA

1. Origins.—The origins of formal logic in India lie in exegesis and debate. By perhaps the 4th century B.C. the school of exegetes or interpreters of Vedic texts (mimamsa) began to furnish technical terms and a few basic concepts that were to be used later in logic. Actual logical operations are first found in the patterns of debate, called in some schools nyaya, which crystallize about the 2nd century B.C. The opening argument of the Buddhist *Kathavatthu* of this period falls into such a formal pattern. It contains a refutation that may be summarized thus:

If my first statement (a) was true, then you should consent to my second (b). You are wrong to say that a is true but b is not true. If b is not true, then a is not true. You are wrong to say that a is true but b is not true.

This is certainly an approach to propositional logic, as Stanislaus Schayer has pointed out. But it is consistent with the practical nature of such texts that while logical operations are actually performed no general rules are yet given for their performance.

These patterns of debate were often very lengthy, their form being chosen for psychological or rhetorical effect. According to the Jain author Bhadrabahu (1st century B.C.) the best pattern is one of ten members, which he lists as follows: (1) general thesis, (2) particular thesis, (3) general reason, (4) particular reason, (5) counter-argument, (6) denial of the counter-argument, (7) example, (8) doubting the example, (9) laying the doubt, (10) conclusion. It is from such a pattern as this that the classical Indian syllogism, likewise called nyaya, arises.

2. The Old **Nyaya (Pracina-nyaya)**.—The major school of Indian logic takes its name from the syllogism. The oldest writings of the school, the Nyayasutras, may go back to the time of Christ but acquired additions perhaps as late as A.D. 200. The early period of the school is characterized by intense and beneficial argument between orthodox (Hindu) and Buddhist logicians. Important contributions to logic were also made by the physicists (vaiseshika) in the early period and from the 5th century onward by the Jains.

The classical Indian syllogism is found in the earliest Nyaya texts. It consists of five members and shows clearly its origin from a pattern such as Bhadrabahu's (see above). It has become a syllogism by the expansion of the "example" to include a statement of universal concomitance or pervasion (*vyapti*). In the following example the particular argument is directed against the exegetes, who claimed that the word of the Veda is eternal.

1. Thesis: Word (is) non-eternal,
2. Reason: because (it possesses) the property of being produced.
3. Example: What possess(es) the property of being produced (is) seen to be non-eternal, as a pot. What possess(es) the property of not being produced (is) seen to be eternal, as the soul.
4. Application: It (viz., word) (is) like this (viz., possesses the property of being produced).
5. Conclusion: Therefore, word (is) non-eternal.

The original of the above contains no finite verb. According to commentators the last three members only are assertions. In the first two the terms are simply brought together without anything yet being asserted of the truth or falsity of the collocation.

This syllogism contains three parts (ansa) or terms. (1) The paksha (field), viz., the subject of thesis and conclusion. It is called a field because the other two parts occur (vartete) in it. In the above example paksha = word. (2) The hetu (reason proper). In the example hrtu = the property of being produced. (3) The sadhya (that which is to be proved). The early Nyaya argues about just what the sadhya is, *e.g.*, whether in the above example it is "the non-eternality of word" or "word-as-non-eternal" or, what was finally agreed on, simply "non-eternality."

This analysis shows how the classical Indian syllogism differs both from those of Aristotle, the terms of which are classes, and from the formulas of propositional logic. The paksha is normally a single individual; hetu and sadhya are regularly properties, expressible in Sanskrit by an abstract noun. The translation of the third member as "$F(x) \supset_x G(x)$" may refer to the same facts in a given instance as the Indian original, but the facts are not arranged in the Indian way. The letter F refers by an indissoluble expression to two notions which are quite distinct to the Indian logician: the hetu and the relation by which the *hetu* occurs. In the later development of Nyaya either of these notions may be qualified independently of the other.

The Buddhist Vasubandhu (4th century A.D.) distinguishes between inference for others (pararthanumana, *i.e.*, formal debate), which requires the presence of all five members, and inference for oneself (*svarthanumana*), which requires only the first three. The syllogisms of later textbooks are regularly given in the three-membered form. Prasastapada the physicist and the Buddhist Dinnaga (both c. A.D. 400) give systematic lists of fallacies.

Dinnaga is the first to give a "wheel of reasons" (hetucakra), that is, a systematic list of possible hetus. His list is based on the distribution of the hetu with respect to the *sapaksa* (objects other than the paksha but like it in being loci of the sadhya) and the vipaksa (objects other than the *paksha* and unlike it in not being loci of the sadhya). There are nine possible distributions, as the hetu may occur in all, part of, or none of either of these areas.

This wheel of reasons is vastly increased by Lddyotakara (c. A.D. 600) of the orthodox Nyaya, who gives 176 possible hetus. The increase is occasioned in the first instance by the addition of cases where sapaksha, vipaksha, or both simply do not exist. Thus, as an example of the third type: "Everything is eternal, because it (is) an object of knowledge." Other refinements of Uddyotakara are to distinguish cases where the *hetu* occurs in all, part, or none of the paksha itself, where the hetu is complex, *e.g.*, "Word (is) non-eternal, because while it (is) nameable it (is) an object of knowledge," etc.

The Buddhist Dharmakirti (7th century) propounds a further division of *hetus* into: (1) Those which possess a common nature with the sadhya, *e.g.*, "This is a tree, because it is a *Simsapa* (tree)." (2) Those which are an effect of the sadhya, *e.g.*, "This hill possesses fire because it possesses smoke." (3) Those which are cases of nonperception, *e.g.*, "There are no Simsapas here, because we perceive no trees." It is of this third class, which includes inferences from negative premisses and inferences leading to negative results, that Dharmakirti's analysis is most elaborate. He lists 11 varieties.

The Old Nyaya is summed up from an orthodox standpoint by Vacaspati Misra, who wrote his Nyayasucinibandha in A.D. 976. The date A.D. 841, given in many books, is due to an error in identifying the era.

3. The New Nyaya (Navya-nyaya).—Udayana (11th century) and others were instrumental in altering the Nyaya to the form which it assumes in the hands of Gangesa (14th century according to the evidence adduced by Dinescandra Bhattacaryya). Gangesa for the first time expressly refers to his school as the New Nyaya. In the centuries which followed, other schools also contributed to logic, notably the pluralistic Vedanta of south India (*e.g.*, Jayatirtha and Vyasatirtha), the neogrammarians (*e.g.*, Nagesa Bhatta), and the Jains. The following account is limited to the New Nyaya since its contributions appear to be the most important.

The chief innovations of the New Nyaya are three: a new method of universalization, rendered possible by the concept of limitation (avacchedakata); the discovery of a number of laws similar to the theorems of propositional logic; a new interest in the definition of relations and the use of these relations in operations of considerable complexity.

The method of universalization springs from a dissatisfaction which had always been felt with quantifiers. "All things which possess smoke possess fire" had troubled even the old logicians and for more reasons than one. There was the formal difficulty of binders. Mountain fire does not occur in a kitchen nor kitchen fire on a mountain. Deeper than this was a problem of knowledge. Even if interpreted without cross-connection. such statements refer to facts which the Naiyayikas claim are impossible to be known except by inference. And inference cannot serve as the basis for inference. What we perceive, say the Naiyayikas, are the generic principles (jati or vibhajakopadhi) that reside in the individual manifestations with which the senses come in contact. If a universal statement is to serve as the basis of inference, it should be phrased in accordance with the facts presented by perception. The New Nyaya method of so phrasing statements appears clumsy in English translation and can best be shown by a graduated example.

For "All that possesses smoke possesses fire" let us first substitute the equivalent expression "No case of smoke occurs in what is not a locus of fire." And for this let us substitute again: ('The absence of smoke which occurs in the locus of a generic absence of fire is a generic absence." The terms to be universalized are now (a) generic absence of fire and (b) generic absence (of smoke). Absence a is said to be such that its counterpositiveness (*pratiyogita*, the nature of the thing which it denies) is limited (*avacchinna*) by fireness (*vahnitvavacchinna-pratiyogitanirupitabhava*). That is to say, we are denying not this or that case of fire but any case you choose of an entity inhered in by fireness. Absence b is said to be an absence whose counterpositiveness is limited by smokeness.

Notice that in these substitutions, which sound so clumsy in English, the Sanskrit expression is a single compound word. The literal rendering of *vahnitvavacchinna-pratiyogitanirupitabhava* would be fireness-limited-counterpositiveness-described-absence. It is this syntactical peculiarity which allows the New Nyaya to operate with such terms somewhat as the modern logician operates with the symbols p and q or F and G where these symbols stand for whole propositions or functions. Accordingly, we find in the New Nyaya definitions of conjunction, disjunction, and implication which cover the facts referred to by sentence connectives as well as class connectives. One must bear in mind, however, that a translation of these definitions into logistic notation is never an exact one. The New Nyaya units are never precisely propositions or classes; they are the referenda of abstract nouns. New Nyaya techniques are parallel in many respects to those of modern logic: thus, where the western mathematician or logician speaks of a class of classes the Naiyayika speaks of the abstra-ct of an abstract; but parallel lines do not actually meet.

This New Nyaya method of universalizing by abstraction offers a quite satisfactory substitute for quantification so long as the number of terms and length of operations is not too great. Limits are imposed by human memory and corporeal breath but these limits are fairly wide. In formal debate Naiyayikas of the present day will use words that run to 300–400 syllables and take more than a minute each to pronounce.

As counterpositiveness is limited by an abstract determining the nature of the entity denied, so are causeness, effectness, etc.,' limited by abstracts which determine or show the precise selection of things caused or effected. A further step is taken by the technique of relational limitors. The counterpositiveness of absence limited by fireness is said to be limited also by the relation contact when we deny the presence of fire in a locus such as hearth, by a relation objectivity if we deny that fire is an object of knowledge, by identity if we deny that fire is water, etc. In this way the New Nyaya comes to investigate the relations between entities, and by simplifying all complex relations into chains of relations of two terms each, it is able to analyze situations of considerable complexity.

The New Nyaya reaches its height of analytical power with Raghunatha Siromani (c. 1475–*c.* 1550). This philosopher is as famous for the innovations he introduced in metaphysics, where he overthrew Nyaya tradition for a system much closer to Vedanta, as he is for his logic. Raghunatha constructs definitions of concomitance and pervasion (*vyapti*) that will fit cases of compound and complex *hetu* and sadhya. In his analysis of relations he comes on a discovery of the true nature of number. It is typical of his school that he does not distinguish abstracts or classes (*e.g.*, pairs, triples) from the corresponding cardinal numbers (*e.g.*, 2, 3). He distinguishes the relation by which twoness is connected with the components of pairs (the relation of inherence) from the relation by which twoness is connected with the pairs as abstracts. The latter relation, called *paryapti* (which may be translated literally by coining the phrase "circumtaining relation"), corresponds to what Frege in 19th-century Europe expressed by saying that a number belongs to a concept; it represents in another form Frege's insight that, *e.g.*, the number 2 should be attached to the concept, satellite of Mars, rather than to the concrete physical objects, Deimos and Phobos.

The creativeness of the New Nyaya, like that of all schools of Indian philosophy, declines from the beginning of the 18th century, but competent Naiyayikas and a few brilliant ones are still to he found in Benares, Calcutta, Mysore and in the district of Nadia in Bengal, the birthplace of Raghunatha.

III. HISTORY OF SCHOLASTIC LOGIC

Medieval scholastic logic is characterized by its dependence on classical tradition, by its use of the Latin language and by the influence of Christian theology. While tradition and the Latin language had a more direct bearing on its formation and development, theology influenced it rather indirectly, partly by demanding a well-developed logic for the discussion of theological questions, partly by positing a few logical and semantical problems of its oun; for example, the problem of the truth or falsity of propositions concerning future contingent facts, or the problem of formality of logical discourse in terms of the divine Persons of the Holy Trinity. The Latin language. however, was of far greater importance than theology in the development of medieval logic. Essentially and entirely, the logic of the schoolmen was based on a "natural" language which, with the help of the grammarians (mostly Priscian and his medieval disciples like Elyas), was analyzed, reduced to rules and adapted to the needs of logic. Consequently the language of scholastic logic is richer, or rather more complicated and more involved in the subject matter, than the artificial languages of modern logic. But above any other factor, it mas tradition that guided the development of scholastic logic.

Primarily through Boethius and Apuleius, the early schoolmen believed themselves in uninterrupted contact with ancient logic; what they actually had. however, was but a fragment of the whole. It was only toward the end of the 12th century that the total body of Aristotelian logic became known; and at the same time the Arabian philosophers—notably Averroes, the great commentator on Aristotle—became available to the schoolmen, while elements of Stoic logic still continued, transmitted primarily from Cicero through Botthius and Apuleius.

By way of summary, it can be said that scholastic logic began to develop in the 12th century, reached maturity in the 14th and 1jth centuries, and declined rapidly from the 16th to the 18th centuries It is impossible to fill this bare outline with complete details. Modern scholars, thanks to the pioneer work of Jan Lukasiewicz, were at mid-20th century, only on the verge of bringing to light the highly developed logic of the 14th and 15th centuries—a logic that up to a few decades before had been completely lost.

1. Period of the **"Old** Logic" (**Ars** Vetus).—Fragments of ancient logic were transmitted to the scholastics through the works of the church fathers primarily St. Augustine The main sources, however, were Porphyry's *Isagoge,* or *Introduction to the Categories of Aristotle,* and the *Categories* and *Perihernzenias (De Interpretatione)* of Aristotle

Later, when other logical treatises of Aristotle became known, these three works were grouped together under the title of *Ars Vetus* (Old Logic), while the neuly discovered works were called *Ars Nova* (New Logic).

Another part of the logical heritage from antiquity was Cicero's *Topics,* to which must be added the commentaries of Boethius on the norks included in the *Ars Vetus,* his *Introduction to the Categorzcal Syllogism,* his treatises *On Topical Differences* and *On Hypothetical Syllogisms* and a few minor works, together with the *Perihermenias* of Apuleius of Madauros who also treated the categorical syllogism.

Thus the logicians of the early middle ages—thanks to Cassiodorus and the Benedictine monks who preserved what they could of ancient learning—had at their disposal a classification of terms; a theory of definition and division; an analysis of sentences; the truth and falsity both of simple categorical sentences and of modal sentences and a theory of their oppositions. a theory of the categorical syllogism and of the hypothetical (mostly conditional) syllogism; and a theory of dialectical or topical inferences. Through Cicero, Boethius, and Apuleius, fragments of Stoic logic were also available to the early scholastics, and Apuleius provided the additional help of a primitive systematization of logic The most conspicuous deficiency of early medieval logic, measured according to the standard of Aristotelian logic. was the lack of any treatment of the modal syllogisms and of any theory of demonstration.

The history of logic from the end of the ancient world up to the 11th century can be summarized in the one main fact that this partial legacy from antiquity was at least tenaciously preserved and slowly and thoroughly absorbed.

The real development of scholastic logic began with Peter Abelard (1079–1142) and his school. Although contemporary writers speak much of the great activity in logic during this time, and although many logical tracts are still extant in manuscript, little is actually known about the logic of the period, Abelard's *Glosses to Porphyry,* the *Categories* and *Perihermenias* are the only complete texts edited, and they deal more with semantical and philosophical problems (universals) than with logic. His *Dialectica,* substantial parts of which were published by Cousin, seems completely dependent on Boethius and Apuleius for its logic; in fact it amounts to little more than a systematization of the Boethian legacy.

There are five parts: (I) On the Parts of Speech *(Oratio),* On the Predicables, On the *Categories,* and On the Content of *Perihernzenias;* (II) On Categorical Propositions and Syllogisms, or the *Prior Analytics;* (III) Topics; (IV) On Hypothetical Propositions and Syllogisms, or the *Posterior Analytics* (!); and (V) On Divisions and Definitions.

It may be remarked in passing that Abelard was quite aware that it was his logic and his daring application of it to theological problems rather than the scandal of his private affairs that brought him into conflict with St. Bernard (*Odiosum me reddit mundo logica*).

John of Salisbury, a disciple of Abelard, and a great admirer of the *Topics* or *Dialectics,* gives in his *Metalogicon (Et quia logicae suscepi patrocinium, Metalogicon inscriptus est liber;* ed. by Clemens C. I. Web, p. 3, Oxonii 1929) many details about the enormous activity in logic that was then going on. He mentions Adam of Little Bridge *(de Ponte Parvo),* an Englishman named after the place where he taught in Paris, who also wrote a textbook, an *Ars dialectica* or *Ars discernendi.* He tells a remarkable story about one of Adam's disciples, William of Soissons, who apparently composed a *machina,* a calculus of logic. According to John of Salisbury, this man learned from Adam of Little Bridge certain quite remarkable consequential rules for the proof of which he used his "machine"; for instance: From one impossible (sentence?) every impossible follows. Although John refuses to accept this, it nevertheless seems to be the forerunner of the later scholastic consequential rule: From an impossible anything follows.

There were about 12 handbooks of logic in use at this time, but they seem to have been more or less of the same type. In any case none of them gained general recognition, and none is accessible to us in printed form.

2. Period of the "New Logic" (**Ars** Nova).—Around 1zoo, according to Alexander Neckam (d. 1217), the school at the Little Bridge in Paris required the reading of the *Ars Vetus,* and in addition, Aristotle's *Topics, Sophistical Refutations* and the two *Analytic~*these last constituting the *Ars* Nova. From then on the scholastics had at their disposal the entire *Organon* of Aristotle. They immediately began the work of assimilation, and it can be safely stated that around the middle of the 13th century the whole of Aristotelian logic had been completely absorbed and was being extensively used by the schoolmen, notably also by the theologians.

The process of assimilating the *Organon* was greatly helped by the influx of oriental literature into the Latin occident. Long before the scholastics became acquainted with the whole of the *Organon,* the Arabians, through the help of the Syrians, had absorbed Aristotelian logic. It is said that al-Farabi (d. 950), "the Second Philosopher" (Aristotle being "the First Philosopher," Xvicenna, "the Third"), directed his attention largely toward the logic of Aristotle and introduced it into the culture of Islam. He overcame the violent reaction of the Islamic theologians and paved the way for "the Third Philosopher," Avicenna (Ibn Sina, d. 1037 in Persia). The part of Avicenna's *Logic* that was translated into Latin toward the end of the 12th century is but an insignificant fragment of his well-developed treatise. His complete original work never directly reached the scholastics, and like the entire "hellenizing Arabian philosophy," as M. Horten calls it, remained foreign to orthodox Arabian philosophy and theology. Most important, as far as scholastic logic is concerned, was the work of Averroës (Ibn-Rushd, d. 1198 in Spain). His excellent and faithful commentaries — the scholastics used to call him simply "the Commentator" — for which he in turn exploited the earlier Greek commentaries — appeared in the first half of the 13th century at Paris and Oxford.

As far as logic is concerned, it seems that the influence of the Jewish philosophers on the scholastics was nil or at most negligible. Even the classical definition of truth as conformity of thought with reality (adequatio rei et intellectus), which Thomas Aquinas attributed to Isaac Israeli, is actually not to be found at all in Israeli's Book of Definitions. The formula is of Arabian origin.

Thus, through acquaintance with the culture of the east, the schoolmen obtained access to a wealth of material which they used extensively and well. But parallel to this opening up of sources from Arabian philosophy went the direct contact with the Greek sources of Aristotle and his commentators. Thus the revival of the ancient Aristotelian logic was complete. This abundance of newly acquired material was brought together in the voluminous work of Albertus Magnus. He wrote no sum of logic, to be sure, but he paraphrased the whole *Organon* of Aristotle, including also the additions made by Boethius, by drawing from the Arabian sources. How far he went independently beyond this scope is difficult to say at present. His logic: as far as syllogistics and the modal logic is concerned, is essentially that of the Aristotelian commentators.

Several near-contemporaries of Albertus Magnus also made important contributions to the development of logic. Robert Grosseteste (d. 1253), bishop of Lincoln, wrote a commentary to the Posterior Analytics which had great influence and was widely used. St. Thomas Aquinas (d. 1274) wrote an important commentary to Perihermenias, making use of the translations from the Greek furnished by William of Moerbeke. One of his followers, Giles of Rome (d. 1316), composed valuable commentaries to all the works of the *Organon*. Robert Kilwardby (d. 1279), the fellow Dominican and opponent of St. Thomas, also produced commentaries to logical writings, as did Duns Scotus (d. 1308) and the so-called Averroists such as Boethius of Dacia (c. 1285).

It is not easy to state just how far these logicians went beyond the matter they had at hand. Clearly, their commentaries did not simply repeat or explain, but sifted and developed as well. The confusing state of the Aristotelian logic of modalities, which was keenly felt by some logicians, was to a certain extent overcome by the distinction of Theophrastus' sensus divisus or the modality of the thing, and the sensus *compositus*, or the modality of the dictum. A similar advance can be noted in syllogistics in general. From Averroës the schoolmen learned to enumerate all possible combinations in each figure and to eliminate the invalid moods. Beyond this, nothing definite can be said until further research has been completed.

It is worthy of note, however, that these commentaries to the classical treatises strictly followed the line of development presented in the treatises themselves, taking little or no cognizance of the current of Terministic logic that finally absorbed the Aristotelian. This is true even of those commentaries written by logicians who also wrote original tracts completely in line with Terminism.

3. Rise of Terministic Logic. — Genuine scholastic logic did not originate from the revival of Aristotelian logic, but rather had its roots in earlier tradition, inaugurated by Boethius and Apuleius and developed by Abelard and his successors in constant contact with grammar. It was the logic of speech (scientia *sermocinalis*), in differentiation from, though not in opposition to, the logic of second intentions. This was the logic that remained basic not only in the sense that it was obligatory for beginners, but also in the sense that it was the starting point for an enormous and original productivity in logic. This logic of the Terminists or Summulists took definite shape, as far as is kno n at present, toward the middle of the 13th century, and was given its classical form by Petrus Hispanus (Peter of Spain, later Pope John XXI, d. 12 77), whose famous textbook remained in use until the 17th century. Terminism was developed primarily by the artists (philosophers) rather than by the theologians, who were relatively late in taking the leading part in it; there are, however, traces of Terministic logic in all the great theologians of the 13th century, beginning with Alexander of Hales (d. 1245).

Terministic logic led its own life, was in constant contact with the logic of the commentators, and was confined neither to the Realists nor to the so-called Nominalists, for it was indifferent to metaphysical implications.

Of the numerous summulae composed during the 13th century, only two have been printed in modern times — those of William of Shyreswood (d. after 1267) and Peter of Spain — and a few others have been described. Their relation to Apuleius is evident from the fact that all of them start with a discussion of propositions (Perihermenias) and include compound propositions. Their indebtedness to the grammarians is obvious from the introduction of semantical problems; their character as textbooks is likewise evident from the introduction of mnemonic verses, some of which have survived up to the present (for instance, Barbara celarent), and the discussion of sophismata. The pattern of these textbooks for beginners is essentially the same. They open with a tract on propositions, then deal with terms (at least with the five predicable~of Porphyry), then with the categorical syllogism, followed by topical rules and ending with fallacies. However, within this framework and sometimes scattered throughout, as in Peter's *Summulae,* there is found a group of additional tracts which constitute the most important contribution of the Summulists. They were called in the middle ages the Parva Logicalia, or the tracts on the properties of terms. These properties are the semantical relations of terms in the context of propositions: suppositio, *copu*latio, appellatio, ampliatio, and restrictio, to which are added *distributio* and the corresponding properties of relative terms. *Sup*positio is the use of a term that stands for something in a proposition. According to the older, Realist, logicians, a term signifies that for which it is instituted by convention, that is, for a concept or for a nature; but it stands for (*supponit*) that for which it is actually used in a proposition. Hence suppositio is the most general property of a term. The predicate term calls for (appellat-appellatio) verification for the time indicated by the tense of the verb; the verb itself and true adjectives have copulatio (binding) ; a term may be restricted (restrictio) in its scope by the tense of the verb or by the adjectives, or enlarged (*am*pliatio) in a similar way, and may be distributed (distributio) by quantifiers, and refer back to another term when it is a relative pronoun. Thus in the sentence: "Every white man was an animal," the terms "white" and "was" have copulatio; "animal" has *suppositio,* for it stands for the nature "animality" in every man; and it also has appellatio, since it calls for existing men, but only according to the form of the verb — that is, at some past time it must have been true to say: "This white," pointing at a man who is now or was white, "is an animal." The term "man" is restricted by the adjective "white" to stand for fewer individuals than it is able to stand for alone, and the term "white man" is distributed for every individual man who is white.

Of all these properties, it was suppositio that received the fullest treatment and the most extensive development. The *supposita* (individuals in a broad sense) for which a term can stand are, according to the Realists, either individuals, or the nature signified by the term. or the term itself. In the first case it is called personal suppositio, in the second, simple suppositio, and in the third, material suppositio. The first two apply to terms in use, the latter to terms in mention. Further distinctions are made, such as common suppositio (of a common term) and discrete (of a singular term or its equivalent) ; natural suppositio (the standing of a common term for anything it can stand for), and accidental *sup*positio (the standing of a common term for that which the context requires). Accidental suppositio is either simple or personal, and personal *suppositio* is further subdivided into confused and distributive (when a term stands for every individual), determinate (when a term stands for at least one individual), and confused only (when a term is bound or "immobilized" by the essence signified by another term).

It is obvious that semantical and intensional considerations prevailed among the Summulists, although the foundation for an extensional interpretation was laid and to a certain extent developed. It remained for the following period to develop this fully.

The Summulists' interest in semantical relations also led them to study the syncategorematic terms as distinct from the categorematic, which distinction probably goes back to the Stoics. While categorematic terms have a definite object that they signify by convention, syncategorematic terms (*e.g.,* the conjunctions "and," "or," "if-then," etc., the signs of negation and predication such as "no" and "is," etc., the quantifiers "every," "none," "some," etc.) have signification only with categorematic terms, but not alone. This led the Summulists already to understand them as logical operators or functors (*officiales*), and thus they advanced from a semantical to a syntactical interpretation of them. The great interest of the Summulists in these terms is apparent from the fact that they treated them extensively in several independent tracts, and also by the fact that they gave considerable attention to another type of logical literature, the Sophismata, which dealt mainly with the same matter. Sophismata (which seem to have originated in the school of Abelard) are not always false arguments; they are rather ambiguous sentences that owe their ambiguity precisely to the syncategorematic terms contained in them. In the medieval texts they are always treated in the same manner; the positio of the sophisma (one sentence) is followed by the *probatur* (it is proved) etc.. and the improbatur (it is disproved) etc., and terminated by the *solutio* of the probatur or of the *im*probatur or of both. The study of such tracts was an excellent means of obtaining practice and skill in the application of logical rules.

It may be well to add here that for the same reason—for practice in logic—the so-called Obligatio was introduced and developed. Obligatio has almost the same meaning as axiomatics in the modern sense, for the Respondens binds himself to the acceptance of a proposition and its consequences, and has to guard against the contradictions in the original sentence (the positio or petitio) or its opposite (the depositio), and in the consequences assuming pertinent or impertinent sentences. One kind, the impositio, deals with the use of symbols (for propositions or terms) and its limitations.

4. Classical Period of Scholastic Logic.—The classical period of scholastic logic which began, roughly speaking, *c.* 1300, achieved the synthesis of the entire Aristotelian logic with the Terministic logic and systematized that synthesis on the basis of consequential rules. It is impossible to mention the names of all those who deserve credit for this splendid accomplishment, but at least a few of the greatest among them require some comment.

It is becoming more apparent, as research progresses, that the main impetus of the new movement came from Oxford—or in any case from England—with Roger Bacon (d. after 1292) as a forerunner. Sutton, perhaps the Dominican Thomas Sutton (c. 1300), composed a tract on consequential rules which was quoted and commented on later by Albert of Saxony. Judging from Albert's comments, the tract was marked by a high degree of formality. The two outstanding men of this period, however, were the so-called Nominalist, William Ockham (Occam), and the Realist, Walter Burley. They had immediate followers among equally great logicians, partly at Oxford, where the Mertonians (William Heytesbury; Richard Swineshead, "the Calculator," who mas highly praised by Leibniz; John Dumbleton; Ralph Strode; and Richard Ferabrich) held sway; and partly at Paris, where Jean Buridan and Albert of Saxony were leaders.

Ockham (c. 1300–1349) composed three sums of logic, two of which are still unedited. The first and longest is known as the Summa Logicae. It is written not for beginners, but for theological students, and as such is a work of maturity. In the spirit of the Terminists. Ockham arranges the entire *Organon* of Aristotle into three parts: (I) On Terms; (II) On Propositions; (III) On Argumentation (the syllogism in general, the demonstrative syllogism, the Topical rules the fallacies). To the first section are added the Parva naturalia; to the second. a discussion of compound propositions; to the third, after the Topical rules, a tract on Obligatio is added. Ockham gives only brief mention to hypothetical syllogisms, but he treats in *extenso* of modal syllogisms and mixed syllogisms in a manner that leads far beyond Aristotle. Although he formulates the general consequential rules in the section dealing with the Topical rules, he speaks of them in all three parts of the *Summa,* clearly implying that he considers them the basis of syllogistics.

The step that made Ockham's implication explicit was taken by Walter Burley (c. 1275–1345), a staunch adversary of Ockham in many respects but one with him in the purely formal treatment of logic. The bulk of his De puritate *artis* logicae was written after Ockham's Summa. As far as is known, this is the first work in the history of logic that places the consequential rules first and reduces syllogistics to a subdivision thereof.

Of the continental logicians, one of the most important was Jean Buridan (c. 1295–1366), who rewrote the *Summulae* of Petrus Hispanus, revising the theory of suppositio and putting it before the treatment of syllogistics, and adding a tract on demonstration.

Buridan's disciple, Albert of Saxony (c. 1316–go), rector of the University of Paris and afterward of the newly founded University of Vienna, and later archbishop of Halberstadt, integrated in his Perutilis *Logica* Burley's concept of logic (whom he often quoted in his other works). with Buridan's improvement. into the system of William of Ockham. Thus was finally completed a system of scholastic logic which would seem to be unsurpassed by that of any other schoolman. This highly condensed and nevertheless complete logic contains six tracts. The first deals with terms; the second, with *suppositio* (adding many rules) ; the third, with propositions; the fourth, with consequential rules; the fifth, with fallacies; the sixth, with *Insolubilia* (insolvables, antinomies) and *obligatio.* In the first three tracts. Albert follows Ockham closely as to arrangement and content. though the second part is much better organized and considerably extended. The fourth tract, however, combines the thought of Ockham, Burley and Buridan, welding together in an ingenious system (and in this order) the general consequential rules of simple categorical propositions, of modal propositions, the consequential rules of categorical, hypothetical, modal and mixed syllogisms and the topical consequential rules. Again syllogistics is subordinated to a general theory of consequential rules.

In this work, as in all the others of the period and of subsequent periods, it is characteristic that the theory of consequential rules is treated as of primary importance. Two other dominant characteristics are a mainly extensional interpretation of the theory of suppositio in combination with a perfect sense for the formality of logic.

This character of the formality of logic is clearly and succinctly expressed by Albert. following Burley. The syncategorematic elements of discourse are the form; they are the skeleton of logical discourse and are clearly understood as being the constants on which the formal validity of inferences rests. The categorematic terms are understood as the material elements; variables are used for them and the rule of uniform substitution applied. Thus the inference: "A man is running, therefore an animal is running," is not valid. For the substitution made in: "If a is b, then c is b," not by alman, *b*/running, *c*/animal (which would yield the true inference), but by *a*/man, *b*/running cltree, will make it a false inference. However, the inference, "If a is *b*, then what is b is a," is formally valid It is also expressly stated that the position of terms or propositions belongs to the form. Hence it is not the same to say: "Socmtes ab homine *differt*" ("Socrates differs from a man") and "Socrates *differt* ab homine" ("Socrates differs from man"). The former is true and the latter false. To be "formally true," "logically true" and "universally true" are interchangeable expressions. Since the syncategorematic terms as the syntactical constants of logical discourse are fixed by definition, though not by a definition of a thing (quid rei) but of the meaning of the term (*quid* nominis), because there is nothing corresponding to them in the object world, the famous and much misunderstood distinction between that which is true because of the expression (de *virtute* sermonis) and that which is true according to the intention of the author, calls for a rigorous analysis of ordinary speech and its reduction to exact language. In fact, it was one of the main tasks of scholastic logicians to codify laws for the complicated Latin language in order to make it a vehicle for valid inferences.

The negation of terms (yielding infinite nouns and verbs), of simple and modal categorical propositions, and of compound propositions (called hypothetical), is consistently carried through. The contradictory opposite of an expression or a sentence is always obtained by adding the sign of negation to the term itself or to the principal element of the proposition. In the latter case, this is either the verb or the modality or the main statement-connective. Lacking adequate symbolism—only term and proposition variables are used—the scholastics scrupulously insisted that the sign of negation must precede that which it is supposed to deny. Hence, a typical negation of a conditional sentence would be: "Non, si a est b, b est c."

It was partly through this device for negation and partly because of their interpretation of the "vel," the "or-conjunction," that the schoolmen, long before Augustus De Morgan, formulated the laws that bear his name. It seems that England discovered them, just as it rediscovered them; for Ockham and Burley are both in complete and perfect command of them as understood by modern logicians—that is, as applying to unanalyzed propositions. According to Burley. the negation of: "a et *b*" ("a" and "*b*" being proposition variables) is "non: a et *b*," and this is equivalent to: "non a vel non b"; and the negation of: "a vel *b*" is "non: a vel b," and this is equivalent to: "non a et non b."

In a surprisingly extensive form, the conditional propositions and inferences between them were studied during this period and developed into a whole system. Sometimes they were united in tracts usually entitled: De Consequentiis, of which the earliest seems to be that of Thomas (?) Sutton. Others were written by Ralph Strode and Jean Buridan—at least there is a printed text attributed to him. These tracts contain the basic theses or laws of modern propositional calculus and some of the theory of quantification, but they are not formulated as laws or theses—though sometimes used as such—but are rather formulated in a metalanguage and as rules for inferences, using as names for variables or substitutions for them "antecedent" and "consequent."

The term "consequence" can be equated with "conditional proposition," though some logicians restrict it to mean logically, that is formally, valid inference. The *officialis* or operator "*si*" (if-then) is understood sometimes in the Diodorean, sometimes in the Philonian, sense; in the latter sense definitely by John of Cornwall (Pseudo-Scotus), most probably also by Ockham. Lately Ernest A. Moody devoted a special study to consequential rules and formulated more than 60 of them, corresponding to the rules given by the scholastics, and corresponding also to theses of the propositional calculus in *Principia Mathematica* and in C. I. Lewis's system of strict implication (Lewis and Langford, *Symboiic* Logic). If to these are added the modal consequences, the number goes far beyond 100, and if the syllogistic consequences of all forms are added, the number goes far beyond 1,000.

Though all the classical scholastic logicians speak of syllogistical consequences, at least one of them was aware that a syllogism in the form received from the Aristotelian commentators is not a consequence, that is, not a conditional proposition, but a juxtaposition of categorical propositions. And since as such a syllogism is neither true nor false, the denial of the conclusion of a syllogism does not infer the denial of the premisses. In order to make the rule: "From the denial of the consequent follows the denial of the antecedent" applicable to syllogisms, we must transform them into compound conditional propositions of which either the antecedent or the consequent is composed of two categorical propositions joined by the connective "and."

The theory of consequential rules deeply penetrates the entire theory of suppositio. The definition of various forms and subdivisions of suppositio are given by formal consequences which are called "descent." The scholastics made use of four different quantifiers which are defined as follows: The universal quantifier ("every") allows the descent from a common term to copulative propositions in which the common term is particularized (*singularizatio*), and all individuals are enumerated for which the common term stands. In a similar way the particular quantifier ("some") allows the descent to a disjunctive proposition, the collective quantifier ("all") to one proposition, in which the term is singularized and its elements joined by "and"; the disjunct or confused quantifier to one categorical proposition in which the term is singularized and its elements joined by "or." For example: "Every man is an animal" is equivalent to: "This man is an animal, and that man is an animal:" and so on for every individual man that is an animal. "Some man is an animal" is equivalent to: "This man is an animal or that man is an animal, etc." "All Apostles are twelve" is equivalent to: "This Apostle and that Apostle and so on for all the Apostles, are twelve." "Every man is an animal:" is equivalent to: "Every man is this or that or that, etc., animal." Later scholastics also studied the relations between the various quantifiers.

During this period, and certainly beginning with Ockham, a semantical definition of truth and falsity on the basis of the theory of suppositio was elaborated. In its simplified form it runs: "A proposition is true if subject and predicate stand for the same or do not stand for the same as is denoted by that (affirmative or negative) proposition." Hence the proposition: "A man is white" is true if, and only if, there is a thing of which it can be said that this is a man and this same is white.

The theory of suppositio also solves the problem of the so-called existential import. Hardly any of the scholastics understood a categorical universal affirmative proposition as equivalent to a conditional proposition, although they understood the latter as a consequence from the former. A scholastic universal proposition is simply invested with existential import and in order to make the conclusio ad subalternatam valid, it is not necessary to add an existential proposition. Later scholastic logicians added a conditional to the descent, for instance: "Every man is an animal, therefore this man, if he exists, is an animal, etc." Or they added the so-called constantia, that is, the proposition: "and these are all . . ." However, since the scholastics were keenly aware of the problem and moulded their theory of suppositio accordingly—which theory varied, for the Realists admitted the existence of universal things and the Nominalists denied it—and since many admitted the suppositio naturalis which was often understood as being of necessary matter, they paid attention to the problem of the conversion of propositions, and were extremely cautious about the conversion by contraposition and in the use of infinite terms (that is terms like "not-man," "not-stone").

The various and varied discussions of the logical antinomies can only be hinted at here. No more than passing mention can be made even of Raimon Lull (c. 1232–1315), whose Ars Magna and his method of combination (mixtiones) so deeply influenced Leibniz, for there is no authentic interpretation of the work of this challenging thinker who was both mystic and logician.

5. Decline of Scholastic Logic.—Toward the end of the 14th century, the decline of scholastic logic set in. The ravages of Black Death, the wars between France and England, the western schism, all acted unfavourably on the scientific culture of the late middle ages. Yet it is remarkable that especially scholastic logic managed for more than a century to maintain its high standard. Its worst enemies arose from the ranks of the Humanists who preferred classical style, poetry, and rhetoric to the rigour of the "barbaric" Latin of scholastic logic. Nevertheless it was Italy, the centre of Humanism, that produced the best logicians of the period. Paul of Venice (d. 1429), an alleged Averroist but certainly of the school of the Nominalists, composed a *Logica* Magna and Parva. The former is a truly monumental work, not only in regard to its size, but in the thoroughness of its formal treatment of logic as well. Paul admits only simple conversion as formally valid, applies quantification also to material suppositio, and has a most interesting discussion of the semantical antinomies. A more succinct and highly systematized logic, composed entirely in the form of theses, was produced by his disciple, Paulus Pergulensis (d. 1451).

During this time many commentaries were written, mostly on the *Summulae* of Petrus Hispanus, or on Buridan (for example, the very important commentary of Dorp). Some writers also commented on the Logica Parva of Paul of Venice, and on a few others of lesser importance. These commentaries are of value for historical notes. It seems that the Realists; during this period, confined their activities to writing commentaries, although toward the turn of the 1 jth century they began to produce original tracts, largely based on the revised order of the *Summulae* of Petrus Hispanus. Of the Scotists, mention should be made of the commentaries of Johannes Magistri (c. 1400), of Johannes de Monte (c. 1450) and especially of Petrus Tartaretus (rector at Paris. 1490), who also composed an excellent little tract on the Descent. Of the Thomistic tradition, the logic of St. Vincent Ferrer (written 1372) merits attention, and the more extensive work of Chrysostom Javellus (d. 1538), both of which continue the realistic Terminist logic.

Under the impact of the Reformation and the new philosophies, the so-called Nominalistic logic, and in general the extremely formalized logic of the 14th and 1 jth centuries, disappeared from the scene. With the Counter Reformation, toward the end of the 16th century, a kind of scholastic renaissance took place, but it disregarded much of the former achievement, going back primarily to the philosophy of St. Thomas and Duns Scotus. Johannes a Sancto Thoma (1589–1644) composed a logical tract that has dra n some attention from modern scholars; and the works of Silvester Maurus, S.J. (1619–87), and Bartholomew Mastrius, O.F.M. Conv. (1602–73), have also won the notice of recent writers.

The 17th century saw the complete disintegration of scholastic logic. Subsequent degeneration was so rapid that by the middle of the 18th century it was dead to all practical purposes.

See also the separate articles on many of the logicians mentioned in this section.

IV. MODERN LOGIC

In this section we outline the development of deductive logic from the 16th to the middle of the 20th century. The history of inductive logic is treated in the articles INDUCTION; PROBABILITY; and SCIENTIFIC METHOD.

1. Ramée.—Pierre de la Ramée, or Petrus Ramus, whose anti-Aristotelian position was widely influential. is perhaps the first of the post-scholastic logicians who deserves mention here. One of the earliest noteworthy works on logic in a modern language is his *Dialectique* of 1555, though other works are in the traditional Latin. His *Dialecticae Libri Duo* of 1 j j6, long used as standard (John Milton's *Artis* Logicae *Plenior Institutio*, 1672. is. e.g ,but a revised edition of it). has a much modified and abbreviated version of the older logic, omitting the immediate inferences altogether and greatly simplifying the rules of the categorical syllogism. In an altered classification into moods or kinds, a special place is provided for syllogisms having two singular premisses, including not only the two moods of the expository syllogism (see LOGIC) but inferences involving a singular predicate, such as: Octavius is heir of Caesar, I am Octavius, therefore I am heir of Caesar; Judas that wrote the Epistle was the brother of James, Judas Iscariot was not the brother of James, therefore Judas Iscariot was not the Judas that wrote the Epistle.

Propositions with singular predicates had been treated by Ockham, Pseudo-Scotus, and other scholastics—as well as the expository syllogism, by some as confined to the third figure, so that the singular middle term occurs only as subject, but by others as admitting moods also in other figures. And indeed Pseudo-Scotus already maintained that syllogisms with singular premisses should be brought into the Aristotelian form by rereading in the following way: Everything which is Octavius is heir of Caesar, everything which is I is Octavius, therefore everything which is I is heir of Caesar. The Ramistic treatment of these singular inferences as non-Aristotelian was later countered on similar grounds by Thomas Spencer (*The* Art of Logick delivered in *the* precepts *of Aristotle and Ramus*, London, 1628) and, more sharply, by the mathematician John Wallis (*q.v.*) in his Cambridge thesis of 1639, published in 1643, and in his *Institutio Logicae* of 1687. Wallis reached the conclusion that singular propositions are to be assimilated to universal propositions for purposes of the syllogism, on the ground that the predicate of a singular proposition and of a universal proposition are alike predicated of all, of the whole rather than a part of the subject. Following, not necessarily Wallis, but earlier writers generally, the authors of the Port-Royal Logic (see below) give a similar account of singular propositions, so that it is said that all propositions can be reduced to the four forms *A*, E, I, *O*. And this remained the generally accepted doctrine until the traditional point of view was superseded by the development of modern logic in the 19th and 20th centuries.

2. Jungius.—Joachim Jungius, in his Logica *Hamburgensis* of 1638, brought forward and discussed a number of forms of inference that are not reducible to the traditional immediate inferences and syllogisms. Relations especially are involved in these, and if widespread attention and study had been given to the matter, the logic of relations might have been developed two centuries in advance of the actual event. But Jungius remained without important influence. except upon Leibniz, and his contributions to logic were ignored by his successors or (*e.g.*, by Wallis) dismissed as reducible to the tradiiional doctrine.

One of these forms of inference which Jungius considers is that of the so-called oblique *inferences*, which had already been treated by Aristotle. An example is: The square of an even number is even, 6 is an even number, therefore the square of 6 is even. The significance of this, as it appeared in the light of much later developments, may be seen by attempting to reduce to traditional syllogistic form as follows: Every even number has an even number as square, 6 is an even number, therefore 6 has an even number as square. In this way the conclusion has 6 as its subject. And if we wish then to infer, in another syllogism, that 36 is the square of 6 and therefore 36 is even, we must first transform the conclusion so that it will have as its subject, the square of 6. The inference which is missing from the traditional catalogue of forms is the immediate inference (if we wish to call it that) from the proposition, 6 has an even number as square, to the proposition, the square of 6 is an even number.

To make the issue clearer we may put the inferences into modern notation, using e (~)to mean that x is even, and s (~y,) t mean that the square of x is y. The first inference is then from the premisses $e(x) \supset_x . s(x, y) \supset_y e(y)$ and e(6) to the conclusion $s(6, y) \supset_y e(y)$, and the second inference then uses the additional premiss $s(6, 36)$ to draw the conclusion $e(36)$. Relational inferences of this sort—here illustrated in a case so simple as to be almost trivial—are as a matter of fact essential to nearly all important mathematical reasoning.

Other examples of Jungian relational inferences are the following. A circle is a figure, therefore who draws a circle draws a figure: $c(x)$ >, $f(x)$, therefore $c(x)$ A, $d(x, ?)$ >, . $f(x)$ A, $d(x, y)$. A reptile is an animal, therefore Who created every animal created every reptile: $r(x) \supset_x a(x)$, therefore $a(x) \supset_x C(x, y) \supset_y . r(x) \supset_x C(x, y)$. David is the father of Solomon! therefore Solomon is the son of David; *i.e.*, upon supplying a tacit premiss, $F(x, y) \supset_{xy} s(y, x)$, F (S, D). therefore $s(D, S)$. (This last had been considered also by Galen.)

3. Geulincx.—Arnold Geulincx published in 1662 Logica *Fundamentis Suis*, a *quibus hactenus collapsa fuerat, Restituta*. Though the title indicates the author's intention to restore neglected fundamentals, this is not just a reproduction of the scholastic logic but an original work. Following are some points of special interest. The doctrine of *suppositio*, largely ignored by other logicians of the period, is here reproduced in altered terminology and with some alteration in content; the possibility of using the same term with different kinds of *suppositio* is treated as being (with a suitable exception to allow for syllogistic inferencej a form of equivocacy, and the device is mentioned in particular of underlining in manuscript or using a distinct style of type in print, to distinguish "grammatical" (*i.e.*, material) *suppositio* and "logical" (*i.e.,* simple) *suppositio* from others. It is argued that negation may be applied only to propositions, and not to terms. Detailed rules (not new except in viewpoint) are given for the reduction of negations, including what are now known as the De Morgan laws of the propositional calculus, the law of double negation, and such reductions as that of not all not to some, *i.e.,* of $\sim(x)\sim$ to $(\exists x)$. Treatment of the categorical syllogism is brief but adequate, and is supplemented by mention of the inference known as the antisyllogism (example: Peter is not an animal, therefore either Peter is not a man or some man is not an animal). What would now be called valid inferences of the propositional calculus are especially well handled, in spite of the handicap of doing it entirely in words, without the aid of special symbols other than the use of capital letters to stand for propositions. Disjunction is explained clearly as inclusive, and *modus ponendo tollens* is rejected (in contrast with the uncritical acceptance of this inference by Ramus and by the Port-Royal Logic). The copulative syllogism (see LOGIC) is treated by use of the appropriate De Morgan lam to reduce it to *modus tollendo ponens*. No reduction of the negation is given in the case of conditional propositions, but negations of such propositions are considered, and the following inferences are allowed: from $\sim . A \supset B$ to $\sim . \sim B \supset \sim A$; from $B \supset C$ and $\sim . A \supset C$ to $\sim . A \supset B$; from $A > B$ and $\sim . A \supset C$ to $\sim . B \supset C$; from $A \sim B$ to $\sim . A \supset B$.

Geulincx considers at one point the inference: Every white man is white, every white man is a man, therefore some man is white. He notes that the premisses are necessary, but the conclusion contingent. And he rejects the inference on the ground that the word "white" is used equivocally—in the conclusion to refer to the present time, and in the premisses absolutely, *i.e.,* without reference to time—so that the syllogism has four terms. The weakness of this is that there are still only three terms in the premisses, and on the traditional doctrine a conclusion should follow in Darapti. But it remained for Leibniz some decades later to give more serious consideration to the problem of existential import.

4. Port-Royal Logic.—Port-Royal Logic or *La Logique* ou *l'Art* de Penser, the original title, was written by Antoine Arnauld and Pierre Nicole, possibly with the collaboration of some others, and was first published in 1662. It was, like Ramus, long and widely used (both Latin and English translations appeared in England) and though the authors follow Ramus in the fourfold division of logic into idea, judgment, reasoning and method, they restore the Aristotelian-scholastic treatment of opposition, conversion and the categorical syllogism.

An important original contribution of the Port-Royal Logic is the distinction between comprehension and extension—of ideas, as the authors say—or of concepts, or of terms, as is more usually said by later writers. The comprehension of a concept consists namely of all those attributes which are contained in it and cannot be removed from it without destroying it—as, *e.g.,* the authors say, the idea (concept) of a triangle contains extension, figure, three sides, three angles, the equality of the sum of these three angles to two right angles, etc. And the extension of a concept consists of the subjects to which it extends, or of what were traditionally called the inferiors of a general term—so that, *e.g.,* the extension of the concept of a triangle consists of all the different species of triangles: isosceles, right, obtuse, etc. This distinction was widely adopted by later writers and became a standard part of the traditional logic. Along with Mill's connotation and denotation of names it may be thought of as a forerunner of Frege's distinction of sense and denotation (see SEMANTICS IN LOGIC; CONNOTATION; and DENOTATION).

The Port-Royal Logic also contains the first publication of the ideas of Blaise Pascal (*q.v.*) about the nature of definition. Namely it was Pascal who first observed that every demonstrative science must begin, not only with unproved propositions (see AXIOM, and POSTULATE) but also with undefined terms, or termes *primitifs* as they are called in the Port-Royal Logic. Pascal also restricts definitions in mathematics to nominal definitions, *définitions* de nom, which consist merely in the giving of a name to something which has been clearly designated in terms completely known; the use and purpose of such definitions is the abbreviation of discourse; they are entirely free, and never subject to being contradicted; and, as Pascal wrote in a letter to Le Pailleur, one may equally well define something impossible as something actual. These ideas were taken up by the authors of the Port-Royal Logic, who lay great emphasis on the need for careful definition as a means of avoiding confusion of thought. However they retain also the notion of a real definition, or *définition* de chose, as a proposition which explains the nature of a thing by means of its essential attributes, and which is therefore capable of being confirmed or disputed. And the idea, which arose much later, that primitive terms and axioms (or postulates) are, like nominal definitions, arbitrary, is not to be found in the Port-Royal Logic; on the contrary the authors demand, following Pascal, that primitive terms shall be completely known, and axioms completely evident.

5. **Saccheri.**—Giovanni Girolamo Saccheri's Logica *Demonstrativa* of 1697 and 1701 also requires mention, though the author is (deservedly) better known for the partial anticipation of non-Euclidean geometry in his Euclides *Vindicatus* of 1733 (see GEOMETRY). The Logica provides a treatment of the traditional logic in the form of a series of demonstrations based on postulates and definitions, in the manner of works on geometry. Two points are emphasized which afterward played an important role in the Euclides Vindieatus, namely: (1) the law of Clavius (see LOGIC) and the associated method of proving a proposition by showing it to be a consequence of its own negation; and (2) the distinction between nominal definitions and real definitions, on the basis that the former merely state the meaning of a term, whereas the latter carry also the assertion of existence.

(1) is the consequentia mirabilis of 17th-century scholastic writers. Geronimo Cardano (*q.v.*) writes in his De *Proportionibus* of the striking character of this method of proof, which he thought to be his own discovery. Knowledge of the method came to Saccheri through Christopher Clavius. by whose name the law is sometimes known, and who, in commentaries on Euclid and on Theodosius, points to its use by Euclid, by Theodosius, and by Cardano. But Saccheri was the first to exploit this method of proof systematically—in his Logica and in Euclides Vindicatus.

Significant in (2) is that definitions are always of terminology, and real definitions are distinguished from nominal by the added demonstration or assumption of existence. Otherwise Saccheri had been anticipated by Pascal and in the Port-Royal Logic, in regard to the nature of nominal definitions and the fallacy of misusing a nominal definition in the role of a real definition. (But Saccheri, in his Latin terminology and in his notion of nominal definition, is evidently following Ockham and other scholastics rather than Pascal.)

6. **Leibniz.**—Gottfried Wilhelm von Leibniz (Leibnitz) (*q.v.*) brought forward already in a work published in his youth (*Dissertatio* de Arte Combinatoria, 1666) the project of constructing a universal exact system of notation, a symbolic language, in which all concepts would be so analyzed into their ultimate constituents, by the notation itself, that it would be the means for a fundamental knowledge of all things. This project of a lingua characterica *universalis* was partly based on the ideas of Lull, to whom Leibniz refers. Leibniz continued to advocate it throughout his life, later adding as an important part the project of a calculus ratiocinator, or calculus of reasoning. And though the total program of Leibniz, as just described, is no doubt not even theoretically fulfillable, the calculus ratiocinator remains an important forerunner of the logistic method in logic.

Leibniz's contributions to logic remained largely unpublished during his lifetime. The most important waited publication much more than a century. But Raspe's Oeuvres Phzlosophiques de Leibniz, published in 1765, contains a purely descriptive paper about the lingua characterica universalis, a paper which treats the difficulty concerning existential import, and the Nouveaux *Essais* sur *l'Entendement Humain.*

In the paper on existential import, Leibniz is led to hold that all four of the categorical forms A, E, I, *O* are to be understood on the basis of a tacit presupposition that the terms which enter are existent (are not empty). This Leibnizian solution of the difficulty has often been adopted since; and if class variables are used to formulate the traditional logic of categorical propositions, the solution may be put in the form of restricting the range of values of the variables to non-empty classes. There is, however, the objection that this seriously reduces the applicability of the traditional logic, as it may be impracticable to ascertain in advance that all terms are existent, and syllogistic reasoning may serve a substantial purpose even in cases in which it is possible or probable that some of the terms are empty.

In a passage in the *Nouveaux* Essais, Leibniz discusses the relational inferences of Jungius, correctly remarking that they cannot be reduced to any traditional syllogism except by a *changement* des termes which renders the total process of inference asyllogistic (see above).

The same work also contains a statement of the law of identity in the form, "A is *A*," or "All *A* is *A*." This law must not be credited exclusively to Leibniz—since Leibniz refers to its use by Ramus to treat the Aristotelian conversions as special cases of categorical syllogisms—and since indeed this possibility was known in the 13th century, and there is mention already by Boethius of uhat John Locke (in 1690) called "identical propositions." But it was Leibniz uho first ascribed to the law of identity a special status as a "primitive truth of reason."

In many of his works Leibniz seems to overestimate the importance of one or both of the laws of contradiction and identity. In the Nouveaux *Essais* Leibniz avoids saying that these laws are alone a sufficient basis for the whole of logic, and even may be thought to imply the contrary. But elsewhere he is less cautious, especially in writings that were not intended for publication. Thus in *Réflexions* sur *l'Essai* de *l'Entendement Humain* de *Mr.* Locke (published with Locke's letters in 1708) and in the reply to the first letter of S. Clarke (published in 1717 after Leibniz's death) it is said that the law of contradiction, so stated as to include the law of identity, suffices to demonstrate either all truths independent of experience or all principles of mathematics. It would seem that Leibniz at times really hoped that all necessary truths might be demonstrably reduced to these very simple ones—though indeed with the aid of certain principles of inference, especially the syllogism in Barbara (cf. the letter quoted by J. E. Erdmann, vol. 1, p. 81). But some of his successors made the idea into an unsupported and almost meaningless item of doctrine—see THOUGHT, LAWS OF.

Leibniz's actual attempts at the construction of a calculus ratiocinator were made in the period from 1679 to 1690 and are published, some in Erdmann's Opera *Philosophica* (vol. 1, 1840) and C. I. Gerhardt's *Philosophische Schriften* (vol. 7, 1890), the remainder in L. A. Couturat's *Opuscules* et Fragments *Inédits* (1903). These show beginnings from which the modern treatment of logic might well have developed. But their content remained unknown for 150 years, and historically only the generalities of Leibniz's program exerted any influence.

In the century following Leibniz there were many attempts at a logical calculus, of which the most widely known and discussed were those of Gottfried Ploucquet (in 1763) and of Johann Heinrich Lambert (*q.v.*) (in 1767, and in a number of fragments published in Lamberts *Logische* und *Philosophische Abhandlungen*, vol. 1, 1782). Lambert's are noteworthy as containing some beginnings of a logic of relations. But none of the attempts produced a satisfactory calculus, and the main trend of opinion was against this direction.

7. Euler.—Leonhard Euler (*q.v.*), in his Lettres *à* une *princesse d'Allemagne* (vol. 2, 1770), illustrated his treatment of the categorical syllogism by using the interiors of three circles to represent the minor term. the middle term and the major term. Thus $\mathbf{s}(x) \supset_x \mathbf{m}(x)$ is pictured by showing the circle for $\mathbf{s}$ entirely within that for m, and $\mathbf{s}(x) \supset_x \sim\mathbf{m}(x)$ by showing the two circles as non-overlapping, etc. This method of visually checking the validity of syllogisms was brought into general use through its adoption by Euler. and came to be known as the *Euler diagram,* though the device did not originate with Euler. Such circle diagrams had been employed in special cases by Johann Christoph Sturm (*Universalia Euclidea,* 1661); and they were used by Leibniz to treat the categorical syllogisms systematically, in a fragment not published until 1903; but their first systematic use for this purpose in a published treatise seems to have been by Johann Christian Lange (*Nucleus* Logicae Weisianne, 1712).

8. **Kant.**—Immanuel Kant (q v.) contributed little to logic. Indeed it was his opinion that logic had made no important step either forward or backward since Aristotle, and seemed to all appearance to be finished and complete (Kritik der *reinen Vernunft,* preface to 2nd ed., 1787). But his influence was great because of his reputation in other fields. In particular the general acceptance of the term, analytic, for propositions that are true on logical grounds alone is traceable to Kant, although Kant's own definition of the term would restrict it to a narrow subclass of such propositions, and although the term, analytic, and its opposite, synthetic, had been used already by Christian August Crusius in 1747. The now familiar contention that "existence is not a predicate" is due to Kant, who used it (op. *cit.*) as an objection against the so-called ontological proof of the existence of God; but a satisfactory positive analysis of the notion of existence had to await the introduction of the quantifiers by Frege and Mitchell.

9. **Hegel.**—Georg Wilhelm Friedrich Hegel (*q.v.*), in *Wissenschaft* der Logik (1812–16), denounces the Leibnizian project of a universal symbolic language as shallow and senseless, and singles out for special attack Ploucquet's recommendation of his calculus as making possible the mechanical performance of logical inference without danger of error if the rules of the calculus are followed. Hegel is similarly critical of the Euler diagrams, and even of the long-established formal treatment of the syllogism as it appeared in the traditional logic of his day. It is not without some justice that he reproaches the latter with being in an ossified and contemptible state. But Hegel represents, as an extreme example, the tendency which long prevailed to hold logic itself in low esteem and to devote the greater part of a work on logic to other subjects, especially to topics in epistemology and metaphysics that bear upon the traditional logic or are suggested by it.

10. **Bolzano.**—Bernard Bolzano's *Wissenschaftslehre* of 1837 contains many original contributions of which the importance was long overlooked, and its proper place in the history of logic came to be seen only in the light of much later developments. In this brief account we confine attention to a single point, Bolzano's treatment of the notion of analyticity.

Bolzano introduces notions of analyticity in a wider and in a narrower sense; but of these only the latter is free from serious objection, and will be described here. It will be convenient to state Bolzano's definition with respect to a formalized language, though it must be remembered that Bolzano did not have this means available, and such restatement of his definition gives it an appearance of greater rigour than was possible for Bolzano himself. We may take this language to be the set theory of Zermelo (see LOGIC), with a large number of individual constants added, corresponding to the words of various kinds that appear in an English dictionary, so that the language becomes (theoretically) usable for purposes of ordinary discourse as well as for expressing propositions of pure logic and of mathematics. Also we state the definition as for an analytically true sentence, although Bolzano deals rather with the proposition ("Satz an sich") expressed by a sentence; and we employ the terminology explained in the article LOGIC, instead of Bolzano's own. From any sentence let a corresponding propositional form be obtained by replacing every extra-logical constant (Bolzano says extra-logical concept) by a variable, two or more occurrences of the same constant being replaced always by the same variable, and different constants by different variables. A sentence is then analytically true (in the narrower sense) if either: (1) the corresponding propositional form is true for all values of the variables; or (2) the sentence can be reduced to one satisfying condition (1), by a series of steps which consist in replacing an occurrence of an individual constant by a synonymous constant or a well-formed part by a synonymous well-formed part.

This definition is not without its difficulties. In particular no explication is offered of the notions of synonymy and of being true for all values of the variables (or satisfied by all values of the variables—*see* SEMANTICS IN LOGIC), but these notions are taken for granted; indeed the notion of synonymy is not explicitly present at all, but is implicit in the treatment of propositions rather than sentences, and its role is indicated only by some examples. Bolzano himself calls attention to the possibility of dispute as to which constants, or concepts, shall be recognized as logical and which as extra-logical (though in the case of the particular language which we have here selected for the purpose of illustration, it might be possible so to control the vocabulary of added individual constants that all constants but A and ϵ would be clearly extra-logical). In spite of such difficulties, Bolzano must be credited with having proposed the first definition of a distinction between analytic and synthetic propositions that deserves serious consideration from the point of view of its logical adequacy.

A minor point is that Bolzano completed Kant's classification of propositions into analytic (analytically true) and synthetic by adding a third category of the analytically false.

11. Mill.—John Stuart Mill's A *System* of Logic, Ratiocinative and *Inductive* (1843) is remembered for its contributions to inductive logic, which are outside the scope of this article, and for its introduction of the distinction of CONNOTATION and DENOTATION, which is treated in the articles of those titles.

12. Algebra of Logic.—The algebra of logic had its beginning in publications of George Boole (*q.v.*) and Augustus De Morgan (*q.v.*) which appeared simultaneously in 1847. There are two main divisions.—The algebra of classes has three basic operations, the logical sum (or union) $F + G$ of two classes F and G, the logical product (or intersection) FG of F and G, and the complement F' of a class F. In the notation introduced in the article LOGIC, $F + G$ may be explained as meaning $\lambda x[F(x) \vee G(x)]$, FG as meaning $\lambda x[F(x)G(x)]$, and F' as meaning $\lambda x{\sim}F(x)$. The notation 0 was used for the empty class; and 1 for the universal class, *i.e.*, the class which coincides with the domain of individuals so that all individuals belong to it. And equations and inequalities were written. such as $G + H = F' + G'$ to mean that the logical sum of G and H is the same as the logical sum of the complements of F and G, or $FG \neq 0$ to mean that the logical product of F and G is not empty, or $F \leqq G$ to mean that F is contained in G in the sense that all individuals belonging to F belong also to G.—The algebra of relations has six basic operations, the logical sum $F + G$ of two relations F and G, the logical product FG, the contrary F' (or $-F$), the relative sum $F \dagger G$, the relative product $F;G$, and the converse F. These may be explained as meaning respectively $\lambda x\lambda y[F(x, y) \vee G(x, y)]$, $\lambda x\lambda y[F(x, y)G(x, y)]$, $\lambda x\lambda y{\sim}F(x, y)$, $\lambda x\lambda y(z)[F(x,z) \vee G(z,y)]$, $\lambda x\lambda y(\exists z)[F(x,z)G(z,y)]$, $\lambda x\lambda yF(y,x)$. The notation 0 was used for the empty relation. 1 for the universal relation, 0' for the relation of diversity (which holds between x and y if and only if x and y are different individuals), 1' for the relation of identity. And again equations and inequalities may be written.

The three basic operations of the algebra of classes, and the six basic operations of the algebra of relations, obey laws which are of much the same kind as familiar laws of the algebra of numbers (and in part coincide with them). By using these a formal algebra or calculus of classes may be set up, and an algebra of relations. These were the first successful calculi of logic. As treated by 19th-century writers, neither is yet a logistic system in the sense of modern logic, but a calculus in a less rigorous sense.

Various notations were used by different writers. And when the two algebras mere incorporated into Principia Matlzematica (see below) as parts of the logistic system of that work, the authors, partly following Giuseppe Peano, changed the old notations completely. In the algebra of classes the logical sum, logical product; and complement are expressed by $F \cup G$, $F \cap G$, and $-F$ respectively, and the notations 0, 1, $\leqq$ are changed to Λ, V, $\subset$ respectively. In the algebra of relations the same notations are used with a dot added, as $F \mathbin{\dot\cup} G$, etc.

The method of Boole, in 1847 and in 1854, is not an algebra of classes in the sense described above, but an application of ordinary numerical algebra to the logic of classes—as is possible if the logical sum of F and G is written as $F + G - FG$, and the complement of F is written as $1 - F$. Yet Boole was able to obtain in this way the essential results of the algebra of classes, and indeed worked them out more fully than De Morgan. In De Morgan's Formal Logic of 1847 are, however, some beginnings of the algebra of classes in the more proper sense, including in particular the De Morgan laws $(FG)' = F' + G'$, $(F + G)' = F'G'$ (it was only later that De Morgan's name came to be applied also to the analogous laws of the propositional calculus). From these beginnings the algebra of classes developed into its classical form through contributions by William Stanley Jevons (*q.v.*) (Pure Logic, 1864, and later works), Charles Sanders Peirce (in a series of papers beginning in 1867), Ernst Schroeder (Der Operationskreis des Logikkalkuls, 1877), John Venn (*Symbolic* Logic, 1881), and Platon Poretsky (in papers published in the period from 1884 to 1908).

The algebra of relations had its beginnings in publications by De Morgan (Syllabus of a Proposed System of Logic, 1860, and a paper in the Transactions *of* the Cambridge Philosophical Society, vol. 10, 1864) and received its major development at the hands of Peirce (in papers beginning in 1870) and Schroeder (in Algebra der Logik, vol. 3, 1895).

The standard reference work on the algebra of logic is Schroeder's three-volume Algebra der Logik (1890–1905). However, Schroeder's axiomatic basis of the algebra is deficient, and should be replaced, in the case of the algebra of classes by E. V. Huntington's (Transactions of the American Mathematical Society, vol. 5, pp. 288-309, 1904), and in the case of the algebra of relations by Tarski's (The Journal of Symbolic Logic, vol. 6, pp. 73-89, 1941).

There is a sense in which the algebra of logic has also a third division, the algebra of propositions, though not always clearly distinguished from the algebra of classes. Boole had already considered the alternative of interpreting the variables of his algebra as propositional variables instead of class variables. But the first true calculus of propositions appears in papers of Hugh MacColl, beginning in 1877; and in particular it was MacColl who rediscovered the so-called De Morgan laws of the propositional calculus (known already to the scholastics). The second volume of Schroeder's Algebra has a combined algebra of classes and propositions.

13. **Peirce.**—Charles Sanders Peirce (*q.v.*), besides the matters already mentioned, has the credit of having taken the first steps in many things which afterward became important in the development of logic. These include the first definition of the notion of simple order (1881); the first treatment of the propositional calculus as a calculus of two truth-values (1885); the definition of = (1885) which is given above in the article LOGIC (though this had been partly anticipated by Leibniz's informal definition, "Things are identical of which one can be substituted for the other with preservation of truth"); and the definition of finiteness (1885) which would be expressed in modern notation as follows: G is a finite class if $(F) \mathbin{.} F(x, y)F(x, z) \supset_{xyz} y = z \mathbin{:\supset:} F(x, z)F(y, z) \supset_{xyz} x = y \supset \mathbin{.} G(x) \supset_x (\exists z)[G(z)F(x, z)] \supset \mathbin{.} G(z) \supset_z (\exists x)[G(x) F(x, z)]$. Peirce also initiated in 1881 the method of treating the foundations of arithmetic which was afterward developed by (Julius Wilhelm) Richard Dedekind (Was sind und was *sollen* die *Zahlen?*, 1888) and Giuseppe Peano (Arithmetices Principia, 1889).

The *Insolubilia* were discussed by Peirce (1869, 1901) with direct reference to the medieval sources. It is quite possibly through Peirce that the Liar first came to the attention of Bertrand Russell, but it required the independent discovery of Richard's antinomy (see below) to make clear the importance of what are now known as the semantical antinomies or paradoxes.

In a paper of 1880, in treating the categorical syllogism, Peirce says that traditionally the affirmative (categorical) propositions imply that their subjects are existent, while the negative ones do not; but he will assume rather that particulzr propositions imply the subjects existent, universal propositions not. Indeed this change of the convention about existential import is strongly indicated from the point of view of the algebra of classes; it was implicit in a short note published by Arthur Cayley in 1871, but was first made explicit from this point of view by Peirce, and by Venn in 1881. It is true that under the changed convention, certain traditional inferences (*e.g.*, conversion per *accidens,* syllogism in Darapti) require an added existential premiss to validate them. But the convention which Peirce describes as the older one also renders some of the immediate inferences invalid without an added existential premiss, those namely (including contraposition) that involve obversion of a negative proposition.

14. Brentano.—Franz Brentano in his *Psychologie vom Empirischen Standpunkte* of 1874, made it a part of his psychology of judgment that every proposition can be reduced to an (affirmative or negative) existential proposition, so that, *e.g.,* "Some man is ill" and "All men are mortal" are said to have the same sense as "An ill man is" and "An immortal man is not" respectively. In modern notation the four categorical forms *A*, E, I, *O* thus become $\sim(\exists x) \,.\, s(x) \sim P(x)$, $\sim(\exists x) \,.\, s(x) P(x)$, $(\exists x) \,.\, s(x) P(x)$, $(\exists x) \,.\, s(x) \sim P(x)$. Hence quite independently of the algebra of logic (to which he was opposed) Brentano arrived at the same doctrine of existential import which was later introduced by Peirce as described above, and at the same modification of the traditional logic. including rejection of the syllogisms in Darapti, etc. But Brentano seems to defend his own revision of the traditional rules as the only right one, whereas Peirce sees more clearly that it is a matter of choosing the convention under which the formal treatment of logic can proceed most eiriciently.

An exposition of Brentano's logical innovations was published by J. P. N. Land in the first volume of the British periodical *Mind* in 1876. And a detailed treatment of immediate inference and the syllogism from Brentano's point of view is in Franz Hillebrand's Die *Neuen Theorien der Kategorischen Schluesse* of 1891.

15. **Frege.**—Gottlob Frege is the founder of modern logic in a sense in which neither Leibniz nor De Morgan and Boole can be so considered, and as such is unquestionably the greatest logician of modern times. The essential steps in the introduction of the logistic method were taken in his *Begriffsschrift* of 1879. In the same work there appear for the first time the propositional calculus in its modern (logistic) form, the notion of a propositional function, the use of quantifiers and the logical analysis of proof by mathematical induction in terms of the notion of a hereditary property—or hereditary class, as we shall here prefer to say.

This last was important in Frege's definition of an inductive cardinal number, and thus provided the basis for the derivation of arithmetic from logic which was described and defended in his *Grundlagen* der *Arithmetik* (1884) and carried through rigorously in the first volume of his *Grundgesetze* der *Arithmetik* (1893). To state the definition in the slightly modified form in which it was later used by A. 9. Whitehead and Bertrand Russell in *Principia Mathematica,* let us call two classes *G* and H similar if there is a one-to-one correspondence between them, *i.e.,* if $(\exists F) \,.\, F(x, y)F(x, z) \supset_{xyz} y = z \,.\, F(x, z)F(y, z) \supset_{xyz} x = y \,.\, G(x) \supset_x (\exists z)[H(z)F(x, z)] \,.\, H(z) \supset_z (3x)[G(x)F(x, z)]$. As the cardinal number of a class G, we might think to take the concept. or property, of similarity to *G*. But if a property is understood (as usual) in intension. this has the defect that the cardinal numbers of two different but similar classes will not be actually identical. Hence we are led to take the corresponding extension. *i.e.*, to define the cardinal number of *G* as the class of classes which are similar to *G*. The cardinal number of *H* is successor of the cardinal number of G if, for some class H, similar to H, $(3y) \,.\, H_1(y) \,.\, G(x) \equiv_x \,.\, H_1(x) \sim x = y$; a class of cardinal numbers is hereditary if all successors of cardinal numbers belonging to it also belong to it; the cardinal number of the empty class Λ is the number 0; and the inductive cardinal numbers (the non-negative integers) are those which belong to every hereditary class to which o belongs.

From an antinomy due to Georg Cantor, concerning the question of the greatest (infinite) cardinal number. Russell extracted the simpler antinomy which is now known by Russell's name (*see* ANTINOMY), and communicated it to Frege in 1902. As the antinomy can be put into the form of a demonstration of contradictory theorems from Frege's logical axioms, Frege felt that one of the foundations of his construction had been shattered. Indeed it must have seemed to Frege and his contemporaries that his great work was a failure. For although Frege's axioms can be amended to remove the inconsistency—and Frege himself made some suggestions in this direction in the Appendix to the second volume of his *Grundgesetze* der Arithmetik (1903)—it must then seem that the axioms have been artificially designed for a purpose. and it is less easy to maintain that they have been taken once for all from a realm of eternal truth. It is only in the perspective of time that we are able to see that Frege's positive contributions far outweigh the inconsistency of the particular system in which they were embodied.

Independently of Frege, the use of quantifiers was suggested also by O. H. Mitchell, to whom the idea is credited by Peirce in his paper of 1885.

Other important contributions of Frege are the distinction of sense and denotation (see SEMANTICS IN LOGIC), and the device of systematically employing quotation marks to distinguish the mention of a term, expression or symbol from its use. The latter distinction is in a sense obvious, and was already recognized among the medieval distinctions of *suppositiones;* yet failure to observe it has been the source of much confusion, in Frege's day and since.

16. Venn.—John Venn, besides contributions already mentioned! introduced in 1880 the *Venn diagram.* This is a modification of the Euler diagram (see above) in which the three circles are so drawn as to overlap in all possible ways, thus dividing their plane into eight regions; and to represent the given premisses, some of these regions are shaded as a sign that the classes they stand for are known to be empty. and others are marked with a star as a sign of non-emptiness. If an inference is to be dealt with (not necessarily syllogistic) that involves n basic classes, n > 3, the corresponding regions may be drawn as ellipses or other more complicated shape, instead of circles, and so placed as to divide their plane into 2^n regions; and then the same process of shading and starring is followed.

17. **Peano.**—Giuseppe Peano is important for his influence on Russell, and for his contribution in devising a scheme of logical notation which is more convenient than those of Peirce: Schroeder and Frege, and much of which (through its adoption by Russell) is still in use. Peano's postulates for arithmetic (see POSTULATE) are due to Dedekind in all but the point of view of taking them as postulates. His *Formulaire* de *mathématiques,* written with the aid of collaborators and published in five "volumes" (or editions) from 1894 to 1908, is intended as a compendium of mathematics; developed from its postulational beginnings with the aid of Peano's logical notation. His treatment of logic had begun to go beyond the algebra of logic but he did not yet have the logistic method.

18. **Burali-Forti.**—Cesare Burali-Forti stumbled upon the antinomy which now bears his name (*see* ANTINOMY), in a paper of 1897 in which he seems to have been not aware that he had revealed antinomy at all.

This antinomy and that of the greatest cardinal number were known already to Cantor but had not been published, and it was through Burali-Forti's paper that there first came to general attention the threat to the foundations of mathematics that is constituted by the antinomies.

19. **Russell.**—Bertrand Russell (*q.v.*) adopted Frege's thesis that arithmetic is a branch of logic, in the sense that all the terms of arithmetic can be defined with the aid of logical terms only (see the brief statement above as to how, in part. this is to be done), and all the theorems of arithmetic can be proved from logical axioms only. And the same thesis was extended by Russell to the whole of mathematics—a doctrine which later came to be known as *logicism.* The project of carrying this out is the subject of Russell's *The* Principles *of Mathematics* (1903). The theory of types as a means of avoiding the inconsistency of such a system as Frege's, though the idea of it was discussed in the *Principles,* was first put into satisfactory form by Russell in a paper of 1908, and on this basis the detailed logicistic development of a large part of mathematics is in the three volumes of Whitehead and

Russell's Principia *Mathematica* (1910–13). Thus Whitehead and Russell succeeded where Frege failed. But the theory of types compels the use of the axiom of infinity—which plays no role in Frege's work—and some have objected that this is not properly an axiom of logic.

The type theory of Principia is the so-called ramified theory of types (concerning which see MATHEMATICS, FOUNDATIONS OF). The reduction of this to the simple theory of types was mentioned by Leon Chwistek in 1921; independently of Chwistek, it was advocated more seriously by F. P. Ramsey in 1926. and thence came into general use through its adoption by Rudolf Carnap (Abriss der Logistik, 1929) and Kurt Goedel (1931).

Another major contribution of Russell is the device (1905) by which descriptive phrases such as "the 32nd president of the U.S.A." may be eliminated if desired (see SEMANTICS IN LOGIC). A technical improvement of Russell's device, important especially when it is employed in a formalized language, was introduced by W. V. Quine in 1940.

20. Zermelo.—Ernst Zermelo stated the axiom of choice in 1904—the use of which in mathematical reasoning had previously been tacit and unrecognized. The first formulation of axioms for set theory was by Zermelo in 1908. Zermelo's axioms involve, however, an unexplained notion of a "definite property." Different proposals for overcoming this difficulty were made by A. A. Fraenkel and Thoralf Skolem in 1922 and 1923, of which Skolem's has the advantage that it leads more directly to logistic formalization of Zermelo's verbally stated axioms. The axioms of set theory as given in the article LOGIC are obtained from those of Zermelo by Skolem's method, with addition of the axioms of replacement, due to Fraenkel, and the axioms of excluded infinite regress due to John von Neumann (later introduced independently also by Zermelo).

21. Richard.—Jules Richard published in 1905 the antinomy now known by his name. Semantical paradoxes related to Richard's were afterward proposed by various other authors, including the paradox of Kurt Grelling in 1908 (see SEMANTICS IN LOGIC).

22. Hilbert.—David Hilbert's contributions to logic arose from his work in the foundations of mathematics (see MATHEMATICS, FOUNDATIONS OF). Important among them are the program of proof theory and in particular of a metatheoretic consistency proof, dating from 1905, and in connection with this the sharp distinction between object language and meta-language (in Hilbert's terminology, between mathematics and metamathematics). *Grundlagen* der *Mathematik* (1934, 1939), a comprehensive treatise of modern logic containing Hilbert's ideas in their final form: was written in collaboration with Paul Bernays, to whom the detailed content of the work is largely due.

23. Brouwer.—Luitzen Egbertus Jan Brouwer is the founder of mathematical intuitionism (see MATHEMATICS, FOUNDATIONS OF; and THOUGHT; LAWS OF). His publications in this field began with his dissertation in 1907 and a paper on the law of excluded middle in 1908 and extended through 1954. The logistic formalization of intuitionism is, however, due to Arend Heyting (1930) and others.

24. Lewis.—Clarence Irving Lewis was led by the "paradoxes" of material implication (see LOGIC) to seek a notion of implication, strict implication, which shall correspond rather to the relation of logical consequence in the sense that, if $<$ is the sign of strict implication, and if **A** and B are any sentences. **A** $<$ **B** shall be true if and only if **B** is a logical consequence of **A.** Lewis's publications about the matter begin in 1912. But the first satisfactory formulation of a propositional calculus with strict implication was in 1920. The book of Lewis and C. H. Langford, *Symbolic*. Logic (1932), treating the subject at length, has become a classic in the field of modal logic, and the starting point of many more recent investigations.

25. Lowenheim.—Leopold Loewenheim in a paper of 1915 proved the theorem which is now known as Loewenheim's theorem (see LOGIC): and several other important results in the metatheory of the functional calculus of first order.

26. Skolem.—Thoralf Skolem, besides the contribution to set theory already mentioned, gave a new and better proof of Loewenheim's theorem, established the extension of this theorem which is stated in the article LOGIC. contributed results connected with the decision problem of the functional calculus of first order (some of which were later important in the proof of Goedel's completeness theorem), and discovered also the following metatheorem, that no set of postulates. finite in number or enumerably infinite. expressible in the notation of a simple applied functional calculus of first order can be adequate for arithmetic in the sense of characterizing completely the system of non-negative integers.

27. Post.—Emil L. Post's dissertation of 1920, published in 1921, contains the first comprehensive metatheoretic treatment of a logistic formalization of the two-valued propositional calculus. including proofs of consistency and completeness; also the first formulation of a many-valued propositional calculus from a point of view which is abstract in the sense of being concerned with the form of the calculus independently of any particular interpretation.

28. Lukasiewicz.—Jan Lukasiewicz, in a paper of 1920, introduced a three-valued propositional calculus based on Aristotle's doctrine of future contingents (see THOUGHT, LAWS OF). This was later generalized to an analogous n-valued propositional calculus, different from that of Post. Much important nork is also due to Lukasiewicz in the two-valued propositional calculus, and in the history of logic.

29. Tarski.—Alfred Tarski contributed extensively to two-valued and many-valued propositional calculus, taking his departure from the work of Lukasiewicz. However, his most noteworthy contributions. beginning in 1930, are to the general metatheory of logistic systems, a domain in nhich many important new ideas are due to him. Especially semantics, in the sense of the metatheoretic treatment of notions related to those of meaning and truth, is the creation of Tarski (see SEMANTICS IN LOGIC). Much of the more recent work of Tarski has been in the boundary region between logic and mathematics, or has applied methods and results of modern logic to special branches of mathematics.

30. Carnap.—Rudolf Carnap, in his Der *logische Aufbau* der *Welt* (1928), Testability and *Meaning* (1936–37) and many other publications, was a pioneer in the systematic application of the methods of modern logic in epistemology and philosophy of science—making in this a contribution to philosophic method which in the eyes of many exceeds in importance his support of a particular philosophical outlook (that of logical positivism, *q.v.*). Carnap's contributions to the study of the metatheory of logistic systems begin in his Logische Syntax der *Sprache* (1934, published, 1937, in English with some additions as *The* Logical *Syntax* of *Language*). In a paper of 1935, somewhat later than Tarski but independently (and in a different terminologyj, Carnap introduced the idea of syntactical definitions of the semantical notions of truth and satisfaction, and in particular was the first to make such definitions for the full simple theory of types, as distinguished from a functional calculus of finite order. And concerning Carnap's contributions to intensional semantics, see SEMANTICS IN LOGIC.

31. Herbrand.—Jacques Herbrand in his short life—he was killed in a mountain-climbing accident in 1931 at the age of 23—made extensive contributions to Hilbertian proof theory and to the metatheory of the functional calculus of first order. The most important of these cannot be stated here. But the deduction theorem of first-order functional calculus should be mentioned as Herbrand's.

32. Goedel.—Kurt Goedel proved the completeness theorem of the pure functional calculus of first order (1930), and the famous incompleteness theorem (1931). For statements of these, see LOGIC and (especially for the latter) MATHEMATICS, FOUNDATIONS OF.

The bearing of the incompleteness theorem on Hilbert's program of a metatheoretic consistency proof for mathematics is obvious: but more far-reaching is the consequence that no single logistic system, satisfying certain very general conditions, can tenably claim to embrace only logical truth *and* the whole of logical truth (if indeed the latter phrase has a meaning at all).

Also due to Goedel (1940) is the metatheorein that if the system of set theory with omission of the axiom of choice (see LOGIC) is consistent, it remains so upon addition of the axiom of choice or an axiom expressing the generalized continuum hypothesis or both. (For a statement of the continuum hypothesis *see* MATHEMATICS, FOUNDATIONS OF.) As Goedel pointed out. his result is applicable alike to various forms of set theory and to type theory.

C.)

LOGICAL POSITIVISM, a philosophical doctrine first formulated in Vienna in the 1920s, according to which scientific knowledge is the only kind of factual knowledge and all traditional metaphysical doctrines are to be rejected as meaningless. The school differs from earlier empiricists and positivists (David Hume. Ernst Mach) in holding that the ultimate basis of knowledge rests upon public experimental verification rather than upon personal experience. It differs from Auguste Comte and J. S. Mill in holding that metaphysical doctrines are not false but meaningless—that the "great unanswerable questions" about substance, causality, freedom and God, are unanswerable just because they are not genuine questions at all. This last is a thesis about language, not about nature, and is based upon a general account of meaning and of meaninglessness. All genuine philosophy (according to the Vienna group) is a critique of language; and (according to some of its leading members) its result is to show the unity of science—that all genuine knowledge about nature can be expressed in a single language common to all the sciences. Philosophy is not a theory but an activity. The proper task of philosophers is linguistic—unless we add that it is their business also to persuade men to adopt a "scientific" attitude to moral and political questions.

The Vienna circle, which launched its first manifesto in 1929, had its origin in discussions among physicists and mathematicians before World War *I*. The general conclusion was reached that the empiricism of Mill and Mach was inadequate since it failed to explain mathematical and logical truths, or to account satisfactorily for the apparently *a priori* element in natural science. In 1922, Hans Hahn at Vienna university laid before his students the *Tractatus Logico-Philosophicus* of Ludwig Wittgenstein, published in the previous year. This work introduced a new general theory of meaning derived in part from the logical inquiries of Giuseppe Peano, Gottlob Frege, Bertrand Russell and A. N. Whitehead. *It* gave the Vienna group its logical foundation and drew in the philosophers hloritz Schlick. Rudolf Carnap, Friedrich Waismann, Otto Neurath and (at Berlin) Hans Reichenbach and Walter Dubislav. The group conducted its campaign in the journal *Erkenntnis* (Leipzig, 1931–40) and, after most of the members of the group had moved to the United States, in an elaborate *International Encyclopedia of Unified Science* (Chicago, 1938 *et seq.)*, published with the help of Charles Morris and other U.S associates. Carnap at Chicago, Reichenbach in California. Philipp Frank at Harvard, Waismann in England and many others, continued the work of the school in a series of systematic works and a stream of papers and monographs. In the meantime disciples had been found in many other countries: in Poland. among the mathematical logicians; and in England, where A. J. Ayer's *Language, Truth and Logic* (London, New York. 1936; rev. ed., 1946) provided an excellent introduction to the views of the group. In England, however, the direct influence of Ludwig Wittgenstein proved very much more powerful. Wittgenstein had come to England from Austria before World War I and had spent some time at Cambridge, discussing logic with Bertrand Russell. The *Tractatus Logico-Philosophicus* expresses and generalizes the conclusions that he had reached upon philosophical questions. In 1929 Wittgenstein returned to Cambridge and taught and worked there (with a few intermissions) until his retirement in 1947. During this later period Wittgenstein himself subjected the doctrines of the *Tractatus* to fundamental criticism and produced what was in effect a new account of philosophy. The later philosophy was disseminated by his students (and by copies of his own informal notes) and profoundly affected the course of English philosophical thought. His *Philosophical Investigations* (Ger. text with Eng. trans., Oxford, New York, 1953) appeared posthumously. While the name "logical positivism" is commonly applied to Wittgenstein's later philosophy as well as to the *Tractatus,* it is certain that a wide gulf separates it from the philosophy which the Vienna circle based in part upon the *Tractatus*.

Characteristic Views of the Vienna Circle.—The following views may be regarded as characteristic of the Vienna school:

Philosophy as a Critique of Language.—It is evident that some of the great philosophers (Locke, Spinoza) explicitly undertook the criticism of language, but it has generally been held that this was not their chief task. Philosophers have usually attempted to assert a view about the world; to state not only the limits of the possible, but also the nature of being or of the universe as we know it. Wittgenstein's *Tractatus* attempted to show that reality *as* a *whole* cannot be described and that the limits of the possible (or "of what can be said") are *shown* in the language as a whole. But what is shown in the language as a whole cannot itself be *said* in language. According to the Vienna school the traditional metaphysical philosophies purport to ask the questions that cannot be answered (*e.g.,* Can one really know material substances?). Here, although experimental evidence may seem to be relevant. it always proves to be beside the point. Metaphysical statements have no verification: metaphysical questions are *Scheinprobleme*. There are of course many questions which philosophers have asked (*e.g.,* about the physiology of perception) which concern particular matters of fact. These however belong to science and not to philosophy. The sole remaining task of philosophy is the analysis and clarification of language. This involves an account of "meaningful" and "meaningless." "true" and "false," "valid inference," etc. as these terms are applied to contingent and to necessary statements—to the propositions of science and history and to the theorems of logic and mathematics. An understanding of such matters will enable us to show how a given metaphysical question arose and why it is meaningless. It is characteristic of the Vienna group, as of the *Tmctatus*, that particular metaphysical puzzles are to be settled by reference to a general theory about language.

The Doctrine of Tautology.—This doctrine derives from the *Tractatus*. The only necessary propositions are those which are true by definition; which are so framed that they cannot be denied without inconsistency. Thus "All men are rational" is held to assert with regard to *anything* that either it is a man or it is not rational. But this follows from our actual use (or one actual use) of "man" and "rational." The necessary proposition cannot but be true since it asserts every possible state of affairs: it is true which-so-ever of its constituents are true and true which-so-ever of its constituents are false. There is a sense therefore in which all necessary propositions say the same thing—that is, *nothing at all.* And the Vienna group held that in general any necessary truth is derivable from some rule of language: its only necessity is its being prescribed by rule in a certain system. This was most easy to show in the case of mathematics, hut some attempt has been made to codify the physical sciences and even branches of biology. With regard to nontechnical necessary propositions (*e.g.,* "Whatever has a beginning in time must have a cause"; and "The same surface cannot be red'all over and blue all over at the same time") it mas recognized that our ordinary language is not itself capable of exact formulation as a calculus: but attempts were made to construct an artificial language in which all necessary statements could be demonstrated by appeal to formulas (*e.g.,* Carnap's *Der logische Aufbau der Welt*, Berlin. 1928).

The Verification Principle.—The fundamental purpose of language is the making of statements about the world. The earlier works of the logical positivists distinguish sharply between "atomic propositions," each of which refers to a single atomic fact, and derivative propositions or hypotheses, which assert some truth-functional combination of atomic facts (*e.g.*, a disjunction of two such facts, a conjunction of a set of such facts). An atomic statement is true if it corresponds to an atomic fact (by which was originally meant a simple observation); a hypothesis is true if the atomic propositions that it asserts are true and the atomic propositions that it denies are false. "The meaning of a statement is the method of its verification" (Waismann). The verification test does not require actual verification but only verifiability in principle, nor is complete verification envisaged in most cases: in all cases it must be possible to collect experimental evidence which determines the truth or falsity of some of the atomic propositions involved (*i.e.*, which tells for or against the hypothesis). The verification test excludes a hypothesis which asserts every possible combination of its atomic constituents: such a "hypothesis" is in fact a tautology or necessary statement. The same test excludes a hypothesis which denies every possible combination: such a "hypothesis" is excluded as being a contradiction or nonsense. But the test also excludes "hypotheses" which do not mean (*i.e.*, from which one cannot validly infer) any set of atomic statements. For where this is the case no evidence is available by which its truth or falsity can be shown. For example, Berkeley argued that the assertion of material substance is nonsensical, since it cannot be "cashed" in any statements about. ideas of sense: whereas the assertion that "a tree exists in the park" or "I have two hands" can be so "cashed."

Form and *Content*.—The earlier writers (especially Moritz Schlick;) were perplexed by the metaphysical problem of how it is possible to communicate at all if our genuine statements are really about our own experiences. How can I be sure, for example, that another person verifies my statement by reference to the same kind of experience as I do? Schlick attempted to avoid the difficulty by his doctrine of form and content: what we communicate by language is not experience but knowledge, and knowledge is the form of which experience is the content. This very difficult doctrine evidently refers to two striking facts about our common use of language: (1) users of a given language employ a common syntax and a common set of definitions: and (2) they also (generally speaking) apply descriptive words on the same occasions even when their experiences come to them through different senses (sight. touch, etc.). This, it is commonly held, one can know without beginning to know what experiences lead people to make use of the language. Schlick maintained that we understand what a man means (in the only sense in which meaning can be communicated; see also SEMANTICS IN LOGIC) if we know (1) the syntactical connections of his words with related expressions in the language (especially if we know *the* definition of his terms in terms which are simple or indefinable); and (2) if we know how he uses the simple terms (*i.e.*, on what occasions he would apply them). This communicable meaning is called form: for a given person, no doubt. it is the form of his own experience-content: but while it is nonsense to speak of community of experience, it is not nonsense to speak of community of structure.

Protocol-Statements. — The doctrine of form and content failed to satisfy. Carnap argued that the question of the relation of an expression to experience (or content) is either meaningless or tan be translated into a question about the relation of one expression (or type of expression) to another. Thus a question about how an empirical proposition is to be verified (or what it means) ought to be tackled by showing its connection not with experiences. but with statements of a peculiar and fundamental kind. the so-called *Protokollsätze*. Such statements would be described by other philosophers as an observer's account of what he actually perceives at a given moment: Carnap describes them by specifying the kinds of expression that can occur in them. Then the last word about the meaning of an empirical proposition is given in showing the kinds or classes of protocol-statements which (if they were made) would logically entail the truth or probability of the statement. This is also the last word about its truth, since, according to the theory, it makes no sense to add "provided that the protocol-statements were made truly." For the protocol-statements have to be taken as indubitable: science rests upon the reports actually made by observers. And Carnap improved the occasion by putting forward the general thesis that statements or questions about the relation of language to experience (which belong to the "material mode of speech") are always a source of metaphysical muddle and can always be replaced by statements or questions about the rules connecting one type of expression with another — statements in the "formal mode of speech." From this, Carnap passed later to the development of a hierarchy of languages.

Physicalism.—The doctrine of protocol-statements was subsequently modified. In the first place, the attempt to show the one-sided dependence of all empirical statements upon some set of protocol-statements came to be regarded as a quaint metaphysical survival: Neurath argued that real language knows no vocabulary of direct experience and that the reports which are actually employed in verifying empirical statements are framed in ordinary language. Second, protocol-statements are not indubitable: not only may we have to select between conflicting reports, we may also decide to reject a report rather than modify an empirical theory or generalization. Neurath preferred to view protocol-statements in the same sort of way as the indications of thermometers or measuring rods: that a thermometer records a high temperature and that an observer says he is getting very hot are both facts (if they are facts) about the physical world and expressed in "physical-object-language"; and either may need correction. Science is possible (it was agreed) because in fact the reports of different observers in the same circumstances do in general agree. and because reports made by the same or different observers upon the evidence of different senses (sight, touch. etc.) also in general correspond. Logical positivists (or many of them) thus passed easily from a quasi-phenomenalistic philosophy to a quasi-materialistic philosophy, and from a correspondence theory of truth to a coherence theory — modified in some cases by the introduction of arbitrary or conventional choice.

The Emotive View of Ethical *Expression*.—Having delivered philosophers and scientists from "the misery of metaphysics," the group proceeded to demolish all kinds of philosophical morality—except possibly their own. So-called statements about what things are right or good cannot be verified (in the manner explained above) and are therefore without meaning. They are simply expressions of attitudes and ought not to be regarded as conveying knowledge or even opinion. The characteristic value words may serve to move or to persuade: they cannot serve to convince us of facts, since they are indefinable in factual terms. This view, reminiscent of Hume, had already been put forward in England by C. K. Ogden and I. A. Richards (The *Meaning* of Meaning, 1922): it was more or less generally adopted by the Vienna group and their English and American disciples, although Schlick (Fragen der Ethik, 1930) argued at length for a typical hedonistic utilitarianism. The "logic" or methodology of persuasive argument was fully examined by Charles Stevenson (Ethics *and Language,* 1945) more from the point of view of the Cambridge analytical school than from that of the Vienna group.

Particular Doctrines of **Wittgenstein.**—In the foregoing account of the Vienna group emphasis has been put on Wittgenstein's *Tractatus Logico-Philosophicus;* undoubtedly the general doctrine of tautology and the doctrine that philosophy is analysis of language are to be found in the *Tractatus*. Two other doctrines to be found there received less attention from the Vienna group: (1) the account of how a simple statement means a simple fact — the "relation of representation" — and the general doctrine of how communication is possible by means of different kinds of signs; and (2) the doctrine that tautologies do not say, but only show, the structure of language — that the characteristic structure of language cannot be said in language. Wittgenstein admits a use for the tautological principles of formal logic — while asserting provocatively that contradictions would have served the same purpose—but is prepared to dismiss as nonsense all those philosophical statements in which the structure of language is elucidated or its limits traced. This self-denying ordinance was not taken seriously by the Vienna group, who attempted to circumvent it by the introduction of the "formal mode of speech" and the hierarchy of languages.

In his later discussions and in the Investigations, Wittgenstein denounced all attempts to build systems of philosophy — even negative systems: he declined to offer any general theory of meaning and was particularly mistrustful of theories which take mathematics or natural science as the ideal. It is possible to trace in his later writings analogues of logical positivist principles: for example, that philosophy is a critique of language. But the doctrines are only analogues, and no conclusion can be reached about his views from a study of the writings of the Vienna circle.

Logical positivism in the United States has found allies among the pragmatists and (naturally enough) among the logicians and scientists. The philosophy of Wittgenstein has been associated with the Cambridge school of G. E. Moore (the defense of common sense and of ordinary language) and has a very wide following in England. See also biographies of philosophers referred to above.

BIBLIOGRAPHY.—Reference should be made to the works mentioned above, especially to those of A. J. Ayer and to the volumes of *Erkenntnis* (1931–40); also to the periodicals *Journal of Philosoplzy, Philosophy of Science, Analysis, Mind* and *Australasian Journal of Philosophy. See* also two short works by R. Carnap, *The Unity of Science,* Eng. trans. (1934), and *Philosophy and Logical Syntax* (1935), as well as his massive *Logical Syntax of Language* (1937). M. Schlick, *Gesammelte Aufsätze* (1938), is of importance. Philipp Frank, *Modern Science and Its Philosophy* (1949), gives a history of the movement. *See* further J. R. Weinberg, *An Examination of Logical Positivism* (1936); and L. S. Stebbing, "Logical Positivism and Analysis," *Proceedings of the British Academy,* vol. xix. Gilbert Ryle, *The Concept of Mind* (1949), and John Wisdom, *Other Minds* (1952), show in contrasted ways the influence of Wittgenstein's later thought. (K. W. B.)

LOGISTICS. In U.S. military administration, a term loosely applied to a wide range of noncombatant activities, especially those connected with supply, transportation, construction and the care and evacuation of sick and wounded. In a nonmilitary sense, long archaic, logistics was the Greek science of computation (from logistikos, '(skilled in calculating"); it is also a branch of logic closely related to mathematics. The military application of the word has little currency outside the United States. and even there its widespread use hardly antedates World War II. Its nearest counterpart in British military terminology is "administration," an even broader term embracing all military activities not directly associated with strategy (*q.v.*) and tactics (*q.v.*). Though still defined in this sense in American military dictionaries, "administration" has been largely replaced by "logistics" in ordinary military usage in the U.S.; when used, "administration" generally has the layman's meaning of "management."

This article is divided into the following sections:

I. CHANGING USES OF THE WORD

In its military sense, the word "logistics" has been used so loosely, and in such a variety of specific and general applications, as to defy precise definition. For some writers in the late 18th and early 19th centuries it appears to have conveyed such disparate meanings as "strategy" and "philosophy of war." For others in the same period it had come to signify military staff work in general.

1. Jomini.—The first serious effort to define the word with some precision and to fix the place of logistics in the science of war was made by Baron Antoine Henri Jomini (*q.v.*), the celebrated student of Napoleon's campaigns and foremost authority on the military art in the first half of the 19th century. In his Precis de l'art de la guerre, published in 1836, Jomini divided the art of war into five branches — strategy, grand tactics, logistics, engineering and minor tactics. Logistics, the third branch, he defined as "the practical art of moving armies," by which he meant not merely the mechanics of transportation, but the staff work, administrative arrangements and even reconnaissance and intelligence involved in moving and sustaining organized military forces. Engineering, defined as the art of fortification, did not include, in Jomini's scheme, nontactical types of construction (building of roads, cantonments, etc.), which presumably came under the heading of logistics. Jomini thought of logistics, in fact, as comprising virtually all military activity, apart from combat and the planning of combat. involved in "the execution of the combinations of strategy and tactics."

In particular, Jomini associated logistics with the work of the military staff. According to him, the word had been derived from the title of the *maréchal* (or major *général*) des *logis* in French armies of the late 17th and 18th centuries, who, like their Prussian counterpart, the *quartiermeister,* had originally been charged with routine administrative arrangements for marches, encampments and troop quarters (*logis*). With the growing complexity of military administration in the 18th century, the more gifted of these officials (like Pierre Joseph de Bourcet, from whose campaign plans Napoleon later profited) had become the equivalent of chiefs of staff to the high-born and often inept commanders of the day, and had developed an efficient staff system along the lines of the modern general (or "capital") staff. Since Jomini's time! other writers have traced the origin of "logistics" to the title of the logista, an administrative official in Roman and Byzantine armies. The Greek word logistikos, mentioned above, also has an obvious functional relationship to it. Whatever the origin of the word, Jomini saw logistics as the central function of the commander's staff, which in his own time had come to play a crucial role in translating the commander's ideas and will into concrete action. Generalship, he insisted, was inseparable from good staff work, and a good general must also be a good logistician. For future generals Jomini left an engaging picture of Napoleon, his own logistician, sprawled on the floor, marking off with a pair of dividers on the map the marches of the several corps that were to converge on tomorrow's objective.

Despite the enormous influence of Jomini's writings on military thought during the long middle span of the 19th century, the word "logistics" gained only a limited currency in French (la logistique) and in English as a rather academic term used occasionally by the learned. German writers, including Jomini's great contemporary Karl von Clausewitz, used it not at all. Jomini's broad conception of the term was generally forgotten; in military parlance its meaning came to be restricted to supply, transportation and quartering of troops. In the 1880s Adm. A. T. Mahan introduced it into U.S. naval usage, and in the decade or so before World War I the navy's concern with the economic foundations of its expansion began to broaden the connotation of the word to include for the first time the processes of industrial mobilization and the functions of a wartime economy in supporting military operations, spheres of activity that in Jomini's day had seemed little related to the conduct of war.

2. Thorpe.—This broader conception of logistics was reflected in a little book published in 1917 by an obscure marine corps officer, George Cyrus Thorpe, under the title Pure Logistics. Thorpe argued that the whole sphere of mar-making fell naturallv into three subdivisions. strategy. tactics and logistics, and that since the first two by common understanding were concerned with the actual conduct of war by the fighting forces, the logical function of logistics was to provide all the means, human and material, for the conduct of war. It therefore embraced, Thorpe insisted, not merely the traditional functions of supply and transportation in the field, but also war finance, ship construction, munitions manufacture and other aspects of war economics.

Thorpe's conception of logistics did not win immediate acceptance, however, either in his own service or in the U.S. army, which also became involved in economic mobilization during World War I and was responsible during the 1920s and 1930s for planning for industrial mobilization in a future war. At the army's general services school at Fort Leavenworth, Kan., logistics was defined as late as 1926 in traditional terms as "that part of the military art which embraces the details necessary to the movement and supply of troops in military operations."

3. World War 11.—The word "logistics" came into sudden vogue in the U.S. during World War II at a time when paradoxically it had almost disappeared from military use in Europe. With wide usage came further confusion of meaning. The army service forces, comprising most of the army's supply and service agencies in the United States, defined logistics (largely in terms of its own functions) to include virtually all aspects of administration except training. During the war and after, in all the military services, the logistics label was attached indiscriminately to numerous staff and operating agencies exercisinp a variety of functions in the field of administration, and the army created several types of "logistical" field commands. Official definitions changed from year to year, and differed among the services. Army dictionaries belatedly recognized the term for the first time in 1944, in the traditional narrow sense; field service regulations did not follow suit until 1949. The navy, by contrast, before 1950 had embraced a conception of the term as broad as that propounded by Thorpe in 1917, even defining a separate sphere of "civil" logistics to cover industrial mobilization for war.

4. Postwar Definitions.— In 1948 the three unified military services agreed on an official definition that listed virtually all military activities dealing with the provision and a'dministration of matkriel, personnel and facilities. Two years later they added to the list training and welfare activities, and also the phrase "acquisition or furnishing of services." These additions seemed to give logistics a scope as broad as that of military administration itself, and marked the high point in the development of official interservice definitions of the word. After 1950 the trend was back toward narrower, more traditional conceptions. As defined in 19j8, logistics still included all aspects of transportation; the acquisition, construction and operation of military facilities; the entire range of matkriel functions. from design and procurement through distribution and final disposition; and services (still unspecified). But of the once long list of personnel functions only hospitalization and evacuation remained.

Official definitions have scarcely affected usage, which remains stubbornly inconsistent and loose. In its narrowest application, logistics may mean simply military supply and transportation. At the other extreme, it may comprehend the provision in the broadest sense of men and matkriel for military operations, including all the planning, administration and services therein involved. and reaching far back into the mobilization of the nation's economic resources for war. As one epigrammatic definition puts it. logistics is often likened to "the military element in the nation's economy and the economic element in its military operations."

Not all the specialists whose skills are thus blanketed consider themselves logisticians; however. To the radio operator or electronics technician, to the nuclear physicist or public information officer, to the personnel administrator, to the file clerk, even to the military engineer. logistics is likely to appear as a vague conglomeration of activities somewhere outside his own area of specialization. Most of the military specialists whose duties bring them in contact with or even within sound of combat feel a strong aversion to the label of logistics because of its traditional noncombatant connotations. The word belongs, in fact, primarily to the vocabulary of the staff planner, for whom it serves as a convenient symbol to apply to whatever combination of noncombatant activities happens to be under consideration at the moment. Even in the language of staff planning, where "logistics" has become a familiar and overworked word, it is likely to be paired with a more precisely definable one, producing such locutions as "logistics and administration," or, inexplicably, "logistics and supply." Rarely in working military parlance does the occasion arise to use the word in its broadest sense. Where logistics stops and something else begins is, in fact, a question of serious concern only to the military theorist and the writer of official definitions.

II. ELEMENTS OF LOGISTICS

Viewed historically and analytically, logistics consists of four principal elements. *Supply* and *transportation* form the hard core, the primary functions by which armed forces are enabled to exist and to perform their essential tasks of moving and fighting. In addition, men and matériel alike depend for effective performance on a variety of *services,* such as repair and maintenance of weapons and equipment. The fourth element, closely related to services. is *administration,* considered in its general meaning as the function of organizing, coordinating and managing military activities.

1. Supply. — Supply is the function of providing the material needs of military forces. (It does not include the provision of men, which ordinarily is not considered an aspect of logistics.) In a narrow sense, supply refers only to distribution and the related function of storage. Broadly construed, it covers all stages in the life of an item of supply or equipment except its actual use or consumption; it includes design and development. manufacture, procurement, storage, distribution, salvage and final disposition. With these go such services as testing, maintenance, repair, packing and packaging. warehousing and veterinary service. Supply is also a planning-administrative process, paralleling the physical processes listed above and including such activities as contracting, pricing, scheduling. allocation and control of raw materials, components, and facilities, industrial relations, conservation, inspection, stock control, administering of supply policies and procedures, requisitioning and the processing of requisitions. All these functions and processes fall into four broad phases: (1) production. in its non-technical sense, including all steps in the creation of finished items of matériel; (2) procurement or acquisition of finished items by the military authorities from producing agencies; (3) distribution through the channels of supply; and (4) dominating the whole, the balancing of supply and demand, *i.e.*, the determination of requirements and assets, and the scheduling of objectives in production and distribution.

While the character of military supply has varied with the changing technology of warfare, it has always had the basic aim of providing military forces the essential material means that enable them to live (food, water, clothing, shelter and medical supplies), to move (vehicles and transport animals, fuel and forage) and to fight (weapons, defensive armament and materials, other combat equipment and the expendables of fire or missile power). In all three categories are items such as clothing, vehicles and weapons, that are used repeatedly, and therefore need only be replaced when lost, destroyed or worn out; and materials such as food, fuel and ammunition: that are expended or consumed, and therefore must be continuously or periodically resupplied. From these characteristics are derived the classifications of *initial issue, replacement* and *resupply.* Other more technical classifications are used in various countries and services. The U.S. army uses five main classifications: (1) subsistence and forage; (2) equipment and other items issued to organizations and individuals on the basis of allowance tables; (3) fuels; (4) equipment and materials of irregular issue; and (j) ammunition. The British army recognizes two broad classes: (1) supplies, which include all the expendables except ammunition; and (2) stores, which include ammunition and military hardware in general.

2. Food, Forage and Fuel. — Historically, food and forage made up most of the bulk and weight of supply requirements until the 20th century, when with mechanization and the growth of air power forage largely yielded to fuel. The demand for food is unremitting and undeferrable; since man himself, as a consumer of food, has changed little or not at all, it is the one constant of logistics. While a man can live without food for as long as five weeks, he becomes militarily useless long before that limit is reached; if deprived of water he succumbs in four or five days. A man's daily ration makes a small package—the U.S army ration in World War II weighed only six pounds—but an army of 50,000 men may consume in one month as much as 4,000 tons of food.

Animals require much more: the standard grain and hay ration in the U.S. army in the 19th century was about 25 lb., and the daily forage for a corps of 10,000 cavalry weighed as much as the food for 50,000 men. Forage requirements tended, moreover, to be self-generating, since the animals needed to transport it also had to be fed. The number of animals accompanying armies varied widely. Napoleon described as an ideal, which he himself failed to attain, a supply train of no more than 500 wagons in an army of 40.000 men; with a corps of 7,000 cavalry, this would amount to about 10.000 animals. Northern armies in the Civil War, whose transport was probably more lavish than the historical average, commonly numbered half as many animals as soldiers. A force of 50,000 men thus might consume more than 300 tons of forage daily. This was more than twice the weight of gasoline that an equivalent force of three World War II infantry divisions, using motor vehicles exclusively, needed to operate for the same length of time In the latter case, moreover, fuel requirements diminished markedly when an army was not moving, uhile the premechanized force had to feed its animals whether moving or not. The expendables of movement in the 20th century, however. include fuel for rail and water transport as well as for motor vehicles and in addition the immense fuel requirements of modern air power. In World War II fuel and food made up more than half the total resupply and replacement needs of U.S. forces (not including fuel for transoceanic shipment), and almost 80% of their resupply of expendables. Food amounted to only 8% and 12%, respectively.

3. Ammunition and Equipment.—Before the advent of mechanization, complex weapons and massive firepower in the late 19th and 20th centuries, equipment replacement and ammunition resupply needs were relatively small. Missile power, in the ages before the invention of gunpowder, was limited by the difficulty of bringing large supplies of missiles to the battlefield. Much depended, in a protracted battle, on the speed with which spent arrows and javelins could be gathered up and turned against their original owners; the ancient slinger (effectively employed by Hannibal against the Romans) had an important advantage over the bowman in using a projectile that was both more portable and more readily obtainable.

For five centuries after the invention of gunpowder the provision of ammunition was not a major logistical problem. Not until the use of field artillery on a large scale in the 18th century, and the development of quick-firing shoulder arms in the 19th, did ammunition begin to constitute a substantial proportion of resupply needs. As late as 1864, in the Atlanta campaign of the American Civil War, Gen. William T. Sherman's average daily ammunition requirements amounted to only one pound per man, as against three pounds for rations; Confederate forces, according to their chief of ordnance. expended on the average only half a cartridge per man per day.

The immense increase of firepower in the 20th century upset the historic ratios. In World War II the average ammunition requirements of C.S. forces overseas amounted to 14% of their total resupply and replacement needs, and 21% of their expendables. Earlier, in World War I, and again in the Korean war ammunition expenditures were higher. Replacement requirements also climbed in the 20th century, particularly in the lavishly equipped U.S. army, but only moderately as compared with the smelling tonnages of expendable supplies. Replacement of equipment and miscellaneous non-expendables for U.S. forces in World War II absorbed only 13% of their total resupply and replacement requirements.

4. **Transportation.**—While strictly speaking a logistical service, transportation is usually considered an independent function of logistics because of the vital importance of movement (both of materiel and personnel) as a basic function of military forces. In the distribution phase of supply, transportation is, of course, the dominant element. (See TRANSPORT, MILITARY.)

For 5.000 or 6,000 years of organized warfare, before the development of steam propulsion and the internal combustion engine, armies depended for mobility on two sources of energy: the muscles of men and animals. and the force of the wind. On land they used men and animals to haul and to carry; on water they used oar-driven or sail-propelled vessels. Among these various modes the balance of advantage and disadvantage was often delicate. involving numerous variables. Movement by water was exposed to the hazards of storm and the vagaries of mind. Transports mere vulnerable to attack by enemy warships; they were also limited in their carrying capacity, and expensive to hire or buy. Large overseas expeditions could be undertaken only by comparatively wealthy states. unless, as in the case of the Scandinavian rovers of the 8th and 9th centuries, the warriors were themselves mariners and seafaring was rooted in the economy. Only rarely was a force transported over water powerful enough to overcome a strong land-based foe—as the Persian invaders of Greece learned at Marathon in 490 B.C.—and its subsequent support was likely to be precarious.

On the other hand, armies have usually been able to move faster by water' than by land. The natural roadway of the sea offers less friction and fewer obstacles to movement over its surface than even good roads, and military history contains few examples of good roads. In the 19th and 20th centuries construction of larger ships and the development of steam and other forms of propulsion made water travel largely independent of wind and weather, and made it possible to transport and sustain overseas larger forces than ever before. On land technological change mas also under way. More and better roads were built, particularly in Europe and the United States, and the railroad. after the mid-19th century. enabled whole armies for the first time to move long distances more rapidly than a man could walk. Motor vehicles and more road building in the 20th century extended the conquest of rough terrain. The airplane. finally, freed military movement, for relatively small forces and limited amounts of materiel, from bondage to earth altogether. Yet the costs of mobility on land—in equipment, materials and energy—were high and military movements, except by small forces with little impedimenta. were still confined to narrou ribbons of rail and road constructed in advance. In large parts of the world these were largely lacking. and the technology of military movement was still primitive. Even in the mid-20th century, in short, movement by water retained the advantages inherent in its nonresistant medium.

On land. the soldier himself has always been the basic and indispensable burden carrier. As a matter of simple logistical economy, he represents large available carrying capacity at no extra cost His equivalent, in an army of 50,000 men. would be 1.250 wagons drawn by 7,500 horses or mules; a difference of only five pounds in his individual load could add or subtract a requirement for 125 wagons and 750 animals. Since the days of the Roman legionary, the soldier's load has averaged. until recently, from 55 to 60 lb. Exceptions were few and conspicuous. Oliver Cromwell reduced the load of his New Model army to less than 40 lb. per man; the troops of revolutionary France endured physical discomfort and developed foraging into a system in order to discard most of the personal impedimenta that had burdened the typical 18th century soldier; "Stonewall" Jackson's foot cavalry in the Civil War carried only musket. ammunition, a blanket or rubber sheet, a frying pan. a few personal necessities and on occasion three days' rations. The ratio between armament and vital needs in the soldier's load has varied widely, but the modern soldier has tended to relegate most of his food to vehicle transport, while carrying a heavier burden of weapons and ammunition. Recent research has discredited the traditional practice of using augmented training loads to develop endurance, and has emphasized the necessity of reducing comhat loads to a minimum, since fear and fatigue both drain muscular power. In most armies following World War II the soldier's load was drastically reduced, in the C.S. army to about 40 lb.

Before the age of steam, armies supplemented the soldier's carrying capacity both with additional manpower and with animal power. Each had its advantages, but the balance was fairly even. A team of six horses ate about as much as 40 or 50 men, but the men could carry more on their backs than the horses could haul, and considerably more than the horses could carry. Men could negotiate rougher terrain, and they required less care. On the other hand, when men were used as carriers their loads had to be distributed in small packages, and men proved less efficient than animals when teamed to haul heavy and bulky loads. (The one-man cart, an ancient means of conveyance, was used to good effect by the Koreans and Chinese in the Korean war and has a significant role in the logistics of the Chinese and Soviet armies.) The horse and mule, besides, have less strength and stamina, though more agility than the ox, which through the ages has been the primary beast of burden. As a mount for the warrior, making the most of its speed and height. the horse has served a more useful function, and one with logistical aspects as well, since mounted troops, whether they fought as infantry or cavalry, could move rapidly for short distances. With such rare exceptions, however, as the far-ranging cavalry armies of the Mongols in the 13th and 14th centuries. large cavalry forces were shackled, like infantry, to their slow-moving transport and to their bases. In general, animal transport has predominated in the military experience of the Western world, where manpower has usually been scarce! while in the orient, where manpower is plentiful, men have been used even more than animals as military beasts of burden. Both forms of transportation continue to be used in the mid-20th century, wherever mechanical transport is insufficient or breaks down or runs out of fuel. In the Korean war the porter with his A-frame probably carried more tonnage than was carried by any other mode of land transport.

5. Services and Administration.— This is the shadow land where logistics merges into areas of military activity to which usage has generally not accorded the name. History and the activities themselves unfortunately recognize no line of functional demarcation that might suggest a distinction between logistical and nonlogistical services and administration. Even the ancient distinction between combat-related and noncombatant activities has grown fuzzy in modern warfare, where so many specialized and unviolent skills (artillery fire direction, for example) may enter into the process of killing.

Services may be defined as activities designed to enable personnel or matériel to perform their appropriate functions more effectively; administration may be defined as the managing and ordering (as opposed to the actual performance) of a function or process—hence also the operation of an organization or installation. Since services themselves must be administered, both purposes are usually combined in the same activity.

The list of military services and administrative activities in modern warfare is long. Those associated with supply have already been mentioned. Transportation, itself a service: involves a subordinate service, stowage of freight, as well as the administering of troop and freight movements, control of traffic and documenting of shipments. Seven other major service-administrative areas can be discerned: (1) communications; (2) the construction, repair and maintenance of facilities (housing, depots, railroads. etc.), including operation of utilities and leasing and disposal of real property; (3) personnel services (medical, spiritual, legal, personal, informational: recreational) and administration (recruitment, induction, classification, assignment, maintenance of records, separation); (4) dissemination of public information; (5) finance and fiscal management; (6) military justice and discipline; and (7) military government. Administration itself, finally, has its own related service: the study and development of improved methods of management.

Even though not all these activities fall within the sphere of logistics by current usage and definitions. they may be referred to collectively, for present purposes, as "logistical services." Most of them are of recent origin, reflecting both the complex technology of modern warfare and the institutional complexity of modern society. Over the long run of military history, the logistical services considered necessary to keep soldiers. animals and equipment in fighting trim were generally of a rudimentary sort. From the earliest times, however, they posed a serious logistical problem. First, they added to armies and their lines of communications substantial, sometimes immense, numbers of people whose primary business was not to fight and who, if not properly organized, often impeded fighting. The soldier seldom possessed the technical skills required to perform any but the simplest logistical services; in some ages. as a member of the warrior class, he was even prohibited by social prerogative from performing them. The classic accompaniment of armies, consequently, has been its long train of noncombatants, often far outnumbering the fighting men.

Logistical services also added to the baggage of armies a growing burden of specialized equipment, tools and materials required for performance of the services. Services tended to generate more services: service equipment itself had to be serviced, sometimes by additional equipment manned by additional technicians, and service personnel themselves required services. Logistical services thus meant more people to be fed, clothed and sheltered, and more people and baggage to be transported. This is the problem of what the British call the "administrative tail"; it is as old as military history.

III. POWER VERSUS MOVEMENT

The potential effectiveness of a military force lies in three attributes—*power*, mobility and *range*—*i.e.*, the ability to fight, to move freely and rapidly and to move far. Each depends on physical ingredients that must be provided and transported, and on logistical services that also place a burden on supply and transportation. Since logistical capabilities are almost always limited, power, mobility and range must compete for the available supply, transportation and services. This competition over the ages has tended to focus on transportation, which for an army in the field almost invariably determined the amount and kind of supplies that could be made available, as well as the scale of services that could be provided. at the time and place needed. Given a fixed amount of transport, the amount of supplies and services it can deliver to a force in the field depends in the main on the distance it must travel in performing these functions. Three methods have been used, in combination and with varying emphasis: (1) self-containment, in which all that the force needs is carried along with it; (2) local supply. in which supplies and services are obtained from sources nearby or along the route of march; and (3) supply from bases, in which supplies are brought as needed from more distant sources.

1. Self-containment.— The idea of complete independence from external sources of supply has always exerted a powerful fascination. For many a commander plagued by supply troubles the hard-hitting, fast-moving, streamlined, self-contained "flying column" was a glittering ideal, which somehow never quite materialized. Self-containment in equipment, service personnel and even ammunition or missiles was the historical rule until the great expansion of fire power and of replacement requirements in the last century. Even in the 20th century, replacement of equipment and resupply of ammunition has normally been intermittent rather than continuous. Few military forces have been able to operate for long without frequent resupply of food, forage and fuel. The disintegration of the French army after its defeat at Blenheim in 1704, and of Napoleon's Grande Armée in the retreat from Moscow in 1812, resulted largely from exhaustion of accompanying supplies and inability to subsist on the countryside.

By its nature, self-containment is the least economical of all methods of supply. The available transportation is fully loaded only once at the beginning of the movement, and serves thereafter as a rolling warehouse, which is steadily depleted as the force eats into its food and fuel or forage. Thus only a fraction of the available capacity is put to use. Self-containment, in fact, offers few advantages other than that of moving by an unpromising. possibly unguarded route. without delays or detours to replenish supplies. Hannibal gained this advantage when he crossed the Alps into northern Italy in 218 B.C., circumventing the Romans barring the easier coastal route—but in doing so he lost almost half his entire force. Gen. John Burgoyne's invasion of New York from Canada in 1777 with a virtually self-contained force bogged down in hostile country and ended in disaster at Saratoga. In general, self-containment requires the sacrifice of both fighting power and range of movement in a striving for mobility which may itself be defeated by the sheer weight of the expendable supplies that must be carried.

2. Local Supply.—Until modern times, supply from local sources (including captured stores) in the regions where armies operated was the most common method of resupplying food and forage and of providing labour and other simple services. In fertile country, an army could usually meet at least a large part of its immense cumulative demand for the major expendables, at low cost in transportation and without sacrificing power or range. When efficiently organized to reduce delays and diversions, local supply even permitted a high degree of mobility. Normally. however, an army living off the country tended to straggle and to load itself down with loot. If it moved too slowly or was pinned down by the enemy, it might sweep the region bare and starve. In winter or in desert mountains local supply offered meager fare. And a hostile population, as Napoleon discovered in Russia and in Spain, could bring disaster to an army that had to scrounge for its food.

Yet, even when the troops could be fed by other means. the animals usually had to shift for themselves: for the burden of transporting forage any considerable distance could be prohibitive. Local supply of forage was in fact almost universal throughout the centuries before the advent of mechanized transport. Moreover, cattle driven along with an army could transform forage into food for the troops—a supply technique as ancient as Biblical times and still common in the late 19th century. Unwieldy and slow-moving though it was, the accompanying herd had the great merit of transporting itself! and unlike the wagon train it dwindled as it was consumed. It was the forage requirement, far more than the problem of food supply, that served. as a general rule until recent times. to confine large-scale military operations to relatively settled. fertile regions and to the months of the growing seasons.

When mechanical transport replaced animals. one of the great continuities of military history was broken. Mechanized armies can operate in winter and desert areas as long as they have fuel. But when that is gone, they grind to a halt. for empty gasoline tanks cannot be replenished from fields and pastures. Mechanization closed the door to both self-containment and local supply as practicable logistical systems. Until power can be packaged in capsules or, like forage, gathered along the route of march, the door is likely to remain closed.

3. Supply From Bases.—The alternative to self-containment and local supply is continuous or periodic resupply and replacement from stores amassed in advance at accessible points. Each of these. or all together. constitute a supply "base," a term also applied to a whole area embracing an army's sources of supply. In the past, supply from bases oifered two main advantages over local supply: (1) bases were relatively secure from attack, and (2) they could be stocked with any desired quantity of war material. On the other hand. supply from bases involved, and still involves, three serious disadvantages. First. the movement of supplies over the routes. or iines of communications joining them to the army, may itself be interrupted or cut off by the enemy. and these supply lines, because of their length, are exceptionally difficult to defend. Second, an army shackled to its bases lacks flexibility and moves slowly, primarily because of the administrative friction and inertia involved in organizing a regular flow of supply from base to army. Finally, the transportation costs of maintaining the flow of supply even over short distances are heavy. These costs rise geometrically as the distance between army and base increases, since in order to deliver a load of supplies each vehicle must travel to the base and return, and additional food, forage and fuel must be carried for the personnel, animals and vehicles engaged in the movement. This geometrical increase in expendable requirements for moving up supplies over a lengthening gap between a base and an advancing army progressively encroaches upon and eventually cancels out the capacity to deliver supplies to the army, regardless of the amount of transport used. With animal-drawn transport. the point of no return is reached very quickly. General William T. Sherman, looking back over his experience in the American Civil War, concluded that an army thus supplied could not operate effectively more than 100 mi., or about five days' march from its base.

With mechanized transport, the theoretical operating radius is greatly extended. The U.S. army truck-and-trailer used in World War II, with $3\frac{1}{2}$ times the capacity of a Civil War-type army wagon. could travel as far on 100 lb. (13.3 gal.) of fuel as the horse- or mule-drawn wagon could travel on 750 lb. of forage. Thus, whereas in the Civil War as much as 75% of the transport used to sustain an army operating 100 mi. from its nearest base might have to be assigned to carry forage for the animals hauling the supplies, only 3% of the trucks used to supply a World War II army operating at the same range were needed to carry their own fuel. In both cases, the ultimate limit on the operating range of armies mas theoretically absolute. In practice, armies using animal-drawn transport could evade the limitation by resorting to local sources for part of their forage, while for the modern mechanized army the ultimate limit was so great—perhaps 3.000 mi.—that it never became operative.

IV. LOGISTICAL SYSTEMS BEFORE 1850

The combination of local supply for food and forage and of self-containment in hardware and services appears often in ancient history as the logistical basis for operations by forces of moderate size. Three of these operations are familiar to every schoolboy—the 4,000-mi. march of Xenophon's Ten Thousand, the even longer campaign of Alexander the Great from Macedonia to the Indus arid Hannibal's campaigns in Italy. The larger armies of ancient times —like that of Xerxes in the invasion of Greece in 480 B.C.—seem to have been supplied by depots and magazines along their routes of march. The Roman legion combined all three methods of supply into a marvelously flexible system. The legion's ability to march fast and far owed much to superb roads and to an efficiently organized supply train; which included mobile repair shops and a service corps of engineers, artificers. armourers and other technicians. Supplies were requisitioned from local authorities and stored in fortified depots; labour arid animals were drafted as required. At need, the legion could carry in its train and on the backs of its soldiers up to 30 days' supply of provisions. In the first Punic War a Roman army marched an average of 16 mi. a day for four weeks.

One of the most efficient logistical systems ever known was that of the Mongol cavalry armies of the 13th century. It rested mainly on self-containment and local supply; supplemented by bases. In normal movements the Mongol armies divided into several corps and spread widely over the country, accompanied by trains of baggage carts. pack animals and herds of cattle. Routes and camp sites were carefully selected for accessibility to good grazing and food crops; food and forage were stored in advance along the routes of march. On entering enemy country, the army abandoned its baggage and herds, divided into widely separated columns and converged upon the unprepared foe at great speed from several directions. In one such approach march a Mongol army covered 180 mi, in three days. Commissariat: remount and transport services were carefully organized. The tough and seasoned Mongol warrior could subsist almost indefinitely on dried meat and kurds. supplemented by occasional game: when in straits, he might drain a little blood from a vein in his mount's neck. The Mongol pony, bred on the steppe, could dig for forage through a light snow. Every man had a string of ponies; baggage was held to a minimum; equipment was standardized and light.

In the early 17th century Gustavus Adolphus of Sweden and Maurice of Nassau restored to European warfare a mobility not seen since the days of the Roman legion, mainly by careful organization of supply. The Swedish armies were based on pre-stocked magazines. but they also had compact supply trains with well-organized services, a flexible tactical organization and light, standardized artillery. An important feature of Gustavian logistics was a system of orderly requisitioning that contrasted with the indiscriminate looting and devastation characteristic of the warfare of the day.

The forinalized warfare of the 18th century was based on an elaborate and ritualistic system of logistics that sacrificed both range and mobility. This was the period of the rolling magazine. and of intricate systems of fortified depots and defended lines of communications. The growing size of armies, increasing use of artillery and greater attention to the creature comforts of a mercenary soldiery, all combined to place heavier burdens on transport. The retinues of baggage and servants accompanying higher officers assumed monumental proportions. At the same time. a widespread revulsion against the depredations and inhumanity of the religious wars in the preceding period brought sharp curbs on looting and other abuses; local supply took the form of carefully regulated requisitioning administered through municipal and provincial authorities under terms often defined by treaty. Since soldiers were expensive, there was a tendency to avoid battles (which, when they occurred, were bloody), and campaigns tended to degenerate into sluggish maneuvers with the primary aim of threatening or defending bases and lines of communications. War became an appendage of logistics in which, as Frederick the Great remarked, "the masterpiece of a successful general is to starve his enemy."

The era of the French Revolution and the Napoleonic domination of Europe (1789–1815) brought back both mobility and range to European military operations, along with an immense increase in the size of armies and the destructiveness of narfare. Logistics became simpler and in many respects cruder. French armies. operating on the principle that "war must support war." largely abandoned the rolling magazine, the elaborate system of supporting depots of the preceding period and even the requisition system. Baggage trains were pared down to the essential needs of fighting power and mobility. The soldier was often heavily burdened with weapons, ammunition and necessities formerly carried by the train; his greatcoat, for example, now served as his tent. Even so, he marched faster and farther (partly by virtue of an accelerated march cadence) than his opponents and predecessors. The system leaned heavily on the willingness of the patriotic citizen soldier (who in a few years became a veteran) to scrounge for himself, to do without and to suffer and die for lack of the rudiments of medical care. Napoleon himself avowedly counted on a brief campaign climaxed by a resounding victory to solve most of his logistical problems. The system, such as it was, tended to degenerate. Baggage trains grew larger; in the invasion of Russia in 1812 they were unable to keep up with the pace of advance and left the troops dependent upon a devastated countryside. In Spain too the logistics of local supply and self-containment broke down.

V. LOGISTICS IN THE INDUSTRIAL ERA (1850–1950)

1. The Revolution in Warfare.— Between 1850 and 1950 the conditions and methods of logistics were transformed by a revolution in warfare more fundamental than any that had occurred in the preceding 6,000 years. The revolution had four facets: (1) the mobilization of mass armies; (2) a revolution in weapons that vastly increased firepower; (3) an economic revolution that provided the physical means needed to feed. munition and transport mass armies; and (4) a revolution in the techniques of management and organization, which enabled nations to mobilize their economic and human resources and to coordinate their use in a war effort often referred to, in the 20th century, as total.

These interrelated developments did not occur all at once. Armies of unprecedented size had appeared in the latter years of the Napoleonic wars. But for almost a century after 1815, the world saw no similar mobilization of military manpower except in the American Civil War. Meanwhile. however, the rapid growth of populations (in Europe, from 188,000,000 in 1800 to more than 550,000,000 in 1950) was creating a virtually unlimited reservoir of manpower. By the latter part of the 19th century most nations were building up large standing armies backed by even larger reserves, and the great 20th-century wars saw the mobilization by each major power of armies numbering many millions.

The revolution in weapons had also started earlier! with a series of inventions and scientific developments dating at least back to the latter part of the 18th century. Its impact upon armaments. in the form of weapons in widespread use, was not felt until about the middle of the 19th century. The rifled percussion musket, rifled and breech-loading artillery, heavy ordnance of very large calibres and steam-propelled and armoured warships were all coming into general use in the 1850s and 1860s. The details of the technological revolution, which proceeded with gathering momentum thereafter, cannot be summarized here. Each successive conflict brought forth a fresh crop of new and deadly weapons, but it remained for mass armies in the 20th-century world wars to realize the full potentiality for destruction that the new technology embodied.

By the mid-19th century the industrial revolution had already given a number of industrialized nations—especially Great Britain, France and the United States—the capacity to produce munitions, food, transport and many other items in quantities no commissary or quartermaster had ever dreamed of. In the American Civil War, the abundant munitions output of the still budding and only partially mobilized industrial economy of the Northern states dimly suggested the latent capabilities that might have been realized. But in general the wars of the 19th century hardly scratched the surface of the immense war-making potential already in being. The generally limited character of all the conflicts between 1815 and 1914 can probably be attributed to the distribution of pomer and the nature of the international rivalries in this period. But even had these factors not tended to limit war objectives and to curb the mobilization of latent military power, it may be doubted whether managerial knowledge and techniques then in existence would have sufficed to carry out such a mobilization. It was, in fact, only in the crucible of World War I at the cost of colossal blunders and waste of effort that these techniques began to be learned.

Thus the full implications of the revolution in warfare were not revealed until the 20th century. Long before 1914, however, new instruments and techniques of logistics had begun to emerge.

2. Transportation and Communication.— The railroad, the steamship and the telegraph had a profound impact on logistical method during the last half of the 19th century. From the Crimean War on, telegraphic communication was an indispensable tool of command, intelligence and operational coordination. particularly in controlling rail traffic. In the 20th century it yielded to more efficient forms of electronic communication—the telephone, radio, radar, television and telephotography.

Railroads spread rapidly over western and central Europe and the eastern United States between 1830 and 1860. They were used. mainly for troop movements, in the suppression of the central European revolutions of 1848–49, on a considerable scale in the Italian War of 1859, and extensively in the American Civil War, where they also demonstrated their capacity for long hauls of bulky freight in sustaining the forward movement of armies. One of the revelations in this conflict was the speed with which torn up or blown up track could be repaired, and this remained true even after rail lines and junctions became prime targets for air bombardment in the 20th century.

In Europe, from 1859 on, the railroads shaped the war plans of all the general staffs, the central feature of which was the rapid mobilization and concentration of troops on a threatened frontier at the outbreak of war. In most countries railroad building was planned with this end in view. Germany's strategic rail net in the centre of Europe enabled her to exploit to the full the advantage of interior lines. In 1870 she was able to concentrate 350,000 troops. 150,000 horses and 6,000 pieces of artillery on the French border in 21 days. and her recognized efficiency in mobilizing influenced the war plans of all the European powers in 1914. In both world wars Germany's railroads enabled her to shift troops rapidly between the Russian and the western fronts.

In the 19th century, steam propulsion and iron ship construction also introduced new logistical capabilities into warfare—the latter by breaking down earlier limitations on the size of seagoing ships. the former by freeing sea-borne transportation from the vagaries of the wind. Steamships moved troops and supplies in support of overseas operations in the Mexican War of 1846–48 and on a much larger scale in the Crimean War of 1854–56; river steamboats played an indispensable logistical role in the American Civil War.

The complement of the railroad was the powered vehicle that could travel on ordinary roads and even unprepared surfaces, within the operating zones of armies, forward of railhead. This was a 20th-century development, a combination of the internal combustion engine, the pneumatic tire and the endless track. Motor transport was first used on a large scale in World War I, along with animal-drawn transport, and in World War II it became, next to the railroad. the dominant means of land movement. Another innovation was the pipeline, used to move water in the Palestine campaign of World War I, and extensively in World War II to move oil and gasoline to storage points close to the combat zones. More revolutionary was the development of air transportation. In World War II, units as large as a division were carried in one movement by air over and behind enemy lines, and resupplied by the same means. Cargo aircraft maintained an air lift for more than three years from bases in India across the Himalayas into China; during the last eight months of operation it averaged more than 50,000 tons per month—an air line of communications for a whole theatre of operations. But the fuel costs of such an operation were exorbitant. Despite the development of gigantic cargo aircraft, air transportation remained primarily a means of emergency movement when speed was an overriding consideration.

3. The Growth in Quantity.—The most conspicuous logistical phenomenon of the great 20th-century wars was the enormous quantity of matériel used and consumed. One cause was the growth of firepower. which was partly a matter of increased rapidity of fire of individual weapons, partly a higher ratio of weapons to men—both multiplied by the vast numbers of men now mobilized. A Civil War infantry division of 3,000 to 5,000 men had an artillery complement of up to 24 pieces; its World War II counterpart, numbering about 15,000 men; had 328 artillery pieces all capable of firing heavier projectiles far more rapidly. A World War II armoured division had an armament of nearly 1,000 pieces of artillery. Twentieth-century infantrymen, moreover, were armed with semiautomatic and automatic weapons instead of the single-shot muzzle-loaders used by most troops in the Civil War.

The upward curve of firepower was reflected in the immense amounts of ammunition required in large-scale operations. Artillery fire in the Franco-German War, and in the Russo-Japanese War, for example, showed a marked increase over that in the Civil War. But World War I unleashed a firepower whose existence had hardly been hinted at in the previous conflicts. In this holocaust British and French forces expended during one average month more than twice as much artillery ammunition as did the Union forces during the entire four years of the American Civil War, and in the seven-days battle of the Somme in 1916 British artillery fired about 4,000,000 rounds, or roughly 125 times as many as the Union artillery in the three-days battle of Gettysburg. In World War II the U.S. procured only about 4 times as many small arms as it had in the Civil War, but 43 times as much small-arms ammunition. The Confederacy fought through the four years of the Civil War on something like 5 000 or 6.000 tons of gunpowder; American factories in one average month during World War I turned out almost four times this quantity of smokeless powder. Again, in one year of World War II; 7,000,000 tons of steel went into the manufacture of tanks and trucks for the U.S. army, 4,000,000 tons into artillery ammunition, 1,000,000 tons into artillery and 1 500,000 tons into small arms—as contrasted nith less than 1 000 000 tons of pig iron used by the entire economy of the northern states during one year of the Civil War. To the ammunition expenditures in the 20th-century world wars were added, moreover. the immense tonnages of explosives used in air bombardment. It must be remembered, finally, that ammunition and explosives remained a relatively small item among the military expendables; the neight of fuel and food was perhaps four times as great.

With growth in quantity went a parallel growth in the complexity of military equipment. The U.S. army in World War II used some 60 major types of artillery above .60 calibre, from the 20-mm. automatic aircraft cannon to the 16-in. coast artillery gun. For 20 difierent calibres of cannon there were some 270 types and sizes of shells. The list of military items procured for U.S. army ground forces added up to almost 900,000, and each end item contained many separate parts; fire control instruments for some anti-aircraft guns contained as many as 25,000 precision-made parts. To convert and expand a nation's peacetime industry to the production of such an arsenal posed staggering technical problems. Manufacturers of automobiles, refrigerators, soap, soft drinks, bed springs, toys, shirts and microscopes had to learn how to make guns, gun carriages, recoil mechanisms and ammunition.

4. The Determination of Requirements.—To design and manufacture a weapon in quantity took from 18 months to two years or more, the so-called "lead time" of logistical planning. The operation in which the iveapon was used was rarely planned in detail more than six months in advance. From this circumstance was derived the central problem of logistical planning: how to predict, without operational plans, what would be needed to carry on a war, in time to produce and make the matériel available when needed. In World War II the U.S army developed elaborate administrative processes for accomplishing this feat, involving hundreds of statisticians and technical experts, electrical computing machinery and an army of clerical personnel.

Fundamentally the method ivas simple. Instead of "guestimating" the needs of all possible future operations not yet planned or conceived, requirements were calculated item by item for the army as a ivhole. on the basis of general expectations as to its composition, rate of expansion and overseas deployment, and the areas where it would operate. Requirements were grouped under the following headings: (1) initial equipment for each soldier and troop unit that the army expected to mobilize; (2) replacement equipment to cover expected losses in use and in combat, as indicated by analysis of past experience; (3) consumption and expenditure requirements for expendable supplies, also based on past experience: and (4) distribution requirements for both equipment and supplies needed to "fill the pipeline" in the army's world-wide system of supply (*i.e.*, quantities stocked in depots, in transit, and iost in transit), and thus ensure ready availability when and where needed. Reserves were also provided to cover unforeseen needs, and specific bills of requirements added for planned operations and for certain projects (*e.g.*, the reconstruction of a port) that could be foreseen. In general, the aim of the system was to provide a diversified fund of war material of all kinds. from which. it was hoped, specific needs could be met as they arose. The British in World War II used a somewhat different method which emphasized the calculation of requirements for forces in each theatre of operation.

5. The System of Staged Resupply.—Long before mechanization relegated local supply to a minor role in the support of modern armies, growing supply requirements had made armies dependent on more or less continuous resupply from bases. The *étappen* system of the Prussian army in 1866 was essentially a modification of the rolling magazine of the 18th century. Behind each army corps trailed a series of supply trains. shuttling continuously between the advancing troops and the nearest magazines in the rear. The magazines were repeatedly moved forward to keep within one or two days' march of the advance. and were in turn replenished by a lengthening chain of magazines extending back as far as the railhead. Only a small train accompanied the troops, carrying a basic load of ammunition, rations and baggage; each soldier carried three days' emergency rations. The system was geared to a steady, slow advance on a rigid schedule and a predetermined route, and the individual soldier was still heavily laden. Yet no alternative method seemed possible, since in 1366 and again in 1870–71 Prussian forces were able to obtain no more than a third of their supplies locally.

Staged; continuous resupply became the basic logistical system for all armies in the industrial era. and for large, well-equipped forces sustained reliance on self-containment and local supply virtually disappeared. Accompanying loads were limited mainly to fighting equipment and a small reserve of fuel and ammunition, and soldiers carried a day or two of emergency rations. The administrative "tail" of magazines and shuttling transport stretching far back to the army's sources of supply became a regular feature of modern land warfare. In World War II, supplies moving to U.S. armies overseas normally passed through seven or eight major stages, besides numerous intervening ones: from a depot in the U.S. to a port of embarkation, to an overseas port, to a rear-area depot and perhaps to an intermediate or advanced depot, to a regulating station, to an army-area supply point, to a division or regimental supply point and finally to the troops.

Under this system, even though it was frequently described as a "pipeline," supplies never flowed continuously from ultimate source to consumer. The object was to stock reserves of material as far forward as safe and practicable, making possible regular supply of food and fuel, and immediate provision of ammunition, replacement equipment and services when needed. Before any major operation, large reserves had to be accumulated close behind the front; the build-up of American war matériel in the British Isles preceding the Normandy invasion of 1944 went on continuously over a period of two years, and involved the shipment of 16,000,000 tons of cargo across the Atlantic from the Cnited States. In essence, the system strove to convert supply from bases into an approximation of local supply, by moving the bases close to the troops.

Behind the armies: in the continental European theatre in World War II, spread the rear-area administrative zone, a vast complex of depots. traffic regulating points, railway marshalling yards, troop cantonments and rest areas, repair shops, artillery and tank parks. oil and gasoline storage tanks, airfields and headquarters—through which ran the lines of supply stretching back to ultimate sources. In the Pacific: the administrative zone covered vast reaches of water, and most of the bases were on islands. Communication and movement in this theatre depended largely on shipping, supplemented by aircraft, and one of the major logistical problems was moving forward bases and reserves as the fighting forces advanced. Late in the mar, supply ships often sailed all the way from the U.S. west coast, bypassing intermediate bases, to forward areas where they were held as floating warehouses until their cargoes were exhausted.

The system of staged resupply gave modern armies considerable range of movement and sustained offensive power, but it crippled their mobility. The natural habitat of the system was the creeping or sealed front of World War I, though many offensives on the western front bogged down, after gaining a few miles, through failure of supplies to keep up with the advance. World War II brought back maneuver and rapid movement. but mobile forces remained tied to their bases; they could move only so far and so long as their supplies could be carried to them. Both the capabilities and limitations of the system were dramatically demonstrated when the U.S. 3rd army plunged across France in the summer of 1944, only to halt after four weeks because the racing armoured spearheads had outrun the capacity of their methodically shuttling transport. Even though used on a lavish scale, motor vehicles could not keep them supplied with the immense quantities of fuel required.

One of the striking lessons of World War II, often obscured by the tactical achievements of air power and mechanized armour, was the great power that modern logistics gave to the defense. In 1943 and 1944 the ratio of superiority enjoyed by Germany's enemies in output of combat munitions was about $2\frac{1}{2}$ to 1; the whole apparatus of Germany's war economy was subjected to relentless attack from the air, and had in addition to make good the enormous losses of material resulting from a succession of military defeats. Yet Germany was able, for about two years, to hold its own, primarily because its waning logistical strength could be concentrated on sustaining the firepower of forces that were stationary or were retiring slowly toward their bases, instead of on the immensely expensive effort required to support a rapid forward movement.

6. Logistical Specialization. — For many centuries the soldier was a fighting man and nothing else; he depended on civilians to provide the services that enabled him to live, move and fight. Even the more technical combat and combat-related skills, such as fortification, siegecraft and the service of artillery, were traditionally civilian. After the mid-19th century, with the rather sudden growth in the technical complexity of warfare, the military profession faced the problem of assimilating a growing number and variety of specialized noncombatant skills. Many of the uniformed logistical services date from this period; examples are the British army's transport corps (later Royal army service corps), hospital corps, and ordnance corps and the U.S. army's signal corps. In the American Civil War the Union army formed a railway construction corps, largely civilian in composition and operation but under military control. Prussia a little later created a railway section in the great general staff and a combined military-civilian organization for controlling and operating the railroads in time of war.

Not until the 20th century, however, did organized military units performing specialized logistical services begin to appear in large numbers in the field. By the end of World War II, what was called "service support" comprised some 45% of the total strength of the U.S. army. Only three out of every ten soldiers had combat functions, and even within the ranks of a combat division, one man out of four fell into the noncombatant category. Even so the specialized services that the military profession succeeded in assimilating were only a small fraction of those on which the combat soldier depended. Throughout the vast administrative zones behind combat areas and in the national base, armies of civilian workers and specialists manned depots, arsenals, factories, communications centres; ports and the other apparatus of a modern society at war. Military establishments employed a growing number of civilian administrators, scientists, management and public relations experts and other specialists. Within the profession itself, the actual incorporation of specialized skills mas limited, in the main, to those directly related (or exposed) to combat, such as the operating and servicing of military equipment, though even here the profession had no monopoly. Soldiers also served as administrators and supervisors over civilian specialists with whose skills they had only a nodding acquaintance. On the whole, the fighting man at mid-20th century belonged to a shrinking minority in a profession made up largely of administrators and noncombatant specialists.

LOGISTICS IN THE NUCLEAR AGE

The dropping of the first atomic bombs in August 1945 and the subsequent emergence of nuclear and thermonuclear weapons systems employing long-range missiles as well as manned aircraft inaugurated a new era in warfare, which promised to demand radical changes in logistics and logistical systems as well. But the new weapons were not immediately used in war; the limited conflicts of the 1950s employed, in the main, the weapons and logistical methods of World War II.

1. Korean War. — The major conflict in this period, the war in Korea (1950–53), was reminiscent in many ways of the positional warfare in Italy in World War II. For U.S. forces, the near-disastrous retreat to the Pusan perimeter at the outset of the war recalled the tragedy of Bataan early in 1942. In many other respects, the war seemed an extension of World War 11—even to the stocks of munitions left over from that conflict without which the UN operations of the first year could hardly have been supported. Late in the war, American forces began to use new model trucks, but they represented no new departure in design. Weapons were also mostly World War II models, in some cases improved versions.

UN forces had an excellent base in nearby Japan, whose factories made a major contribution by rebuilding American World War II matériel. Both Japan and South Korea's major port of entry, Pusan, were free from Communist air attack throughout the mar. Chinese bases north of the Yalu enjoyed a similarly immunity from UN air raids. This curious circumstance greatly simplified the supply problems of UN forces, enabling them to funnel through Pusan supply tonnages comparable to those handled by the largest ports in World War II, and to concentrate depots and other installations in the Pusan area to a degree that would have been suicidal without complete air superiority.

The expenditure of artillery ammunition by UN forces at times soared above the highest levels attained in World War II, and the available supply often fell dangerously low. Output of ammunition in the U.S. was meager, owing to the long lead time needed to reach quantity production and to the expectation that the war would not last long. Actual shortages on the firing line were primarily a result of inadequate transportation facilities in Korea. UN forces also suffered at the beginning of the winter of 1950-51 for lack of winter clothing which had not been moved forward soon enough. The numbers of service troops never seemed to be adequate, although they were considerably greater than was normal in World War II, and were supplemented by large numbers of Korean labourers — more than 150,000 in the fall of 1951. Korean porters made a major contribution to the UN transport service in rugged terrain which trucks could not negotiate.

Communist supply lines, though heavily bombarded by UN air forces, functioned remarkably well; troops and supplies mere moved by night. local labour and transportation were used extensively and the Chinese soldier proved, as he had often done during World War II, that he could endure an incredible amount of privation, subsist on very little food and still fight well. The Communist logistical system, technically primitive, enabled the Communist forces to mount heavy offensives, but they could not be sustained for more than three or four days. On the U S side, the most brilliant logistical exploit was the "amphibious operation in reverse" by which the X corps was evacuated from Hungnam in Dec. 1950. In a period of two weeks, under constant enemy attacks, some 105,000 troops, 98,000 Korean civilians, 17,500 vehicles and 350,000 tons of cargo were loaded in 193 vessels.

By World War II standards, the Korean war was a limited conflict (except for the two Korean belligerents, on whose soil it was fought). It involved only a partial. or "creeping" economic mobilization in the U.S., the major UN participant, and a modest mobilization of reserve manpower. Yet this was no small war. During the three years that it lasted, about 37,200,000 measurement tons of cargo were poured into the South Korean ports, or more than three-fourths of the amount shipped to U.S. army forces in all the Pacific theatres from Dec. 1941 to Xug. 1945. And the combined UN forces reached a peak strength of almost 1,000,000 men. of whom more than a third consisted of U.S. and other non-Korean contingents. Communist forces were considerably larger.

(See also KOREAN WAR.)

2. Management. — Logisticians were much concerned in the post-World War II period with improvements in management aimed at greater economy and efficiency. This was no new trend, for World War II had seen a major effort, especially in the service forces and air forces of the U.S. army, to bring order and reasonable economy into operations which, because of their unprecedented magnitude, tended to breed waste and duplication. In the postwar years the slashing of military appropriations, the increasing cost of military hardware in a period of rapid technological change and growing international tensions all combined to put heavy pressure on the armed services to squeeze more military strength from the defense dollar — to get, as the saying went, "more bang for a buck."

To a considerable extent, the methods adopted to improve management in logistics were those used in the business world, though in many cases they had actually developed, and in some cases had their origin, in the military establishments. Civilian management firms, hired to survey these establishments, gave a strong impetus to the organization of logistical activities along "functional!' line , as opposed to the traditional organization by commodity groups with headquarters of the general-staff type--though the attempt to do so was successfully resisted in many quarters. Under the unified military establishment in the U.S., all activities were grouped into major and subsidiary "programs," with orderly schedules of objectives which were continuously matched against performance. Unification also spurred efforts to break down the uneconomical compartmentation of logistical activities under each armed service. Large groups of related functions (*e.g.,* military transportation by land, water or air, or procurement of subsistence, clothing or medical supplies) were placed under the control of one of the armed services or a single interservice agency. In overseas commands certain logistical activities were also "unified" for all three services.

In the technology of logistical administration, an innovation of revolutionary implications was the introduction of completely automatic electronic data processing machinery. Applied to such large-scale operations as the processing of supply requisitions and control of inventories, this development held promise of reducing to small proportions the factor of time in many areas of logistical activity, of centralizing control to an unprecedented degree and of slashing administrative manpower requirements.

Another significant development was "operations research" or "operations evaluation," a form of scientific study and investigation which used advanced mathematical techniques in the analysis of repetitive operations, particularly those involving the use and performance of military hardware, with a view to developing more efficient methods and procedures.

Operations research was applied to many areas of military and business operations, but proved especially productive in the analysis of logistical activities.

3. Logistics in Nuclear War. — For logisticians, however, the fundamental dilemma posed by the "quantum jump" in weapons technology after World War II was the absence of any comparable development in the apparatus or methodology of logistics. No technical innovation perfected and applied during this period, in transportation, supply or administration had an impact upon the conduct of war remotely comparable to that produced in the 19th and early 20th centuries by the railroad, the telegraph, the internal combustion engine or mass production. On the other hand, the new weapons, with their immense destructiveness and range, threatened to sweep away every vestige of the logistics developed to meet the demands of the industrial era. None of the elaborate apparatus of rear-area administration, lines of communications or even sources of supply required in the two world wars of the 20th century seemed likely to survive the firepower that could now be brought to bear against it, and no effective defense against this firepower had yet appeared.

The problem was. indeed, under attack from many angles. New logistical doctrine stressed dispersion, and much study went into the determination of how small a concentration of personnel or structures constituted a "profitable target." In the future war, the communications zone would be wide and deep; installations would be small. widely dispersed, duplicated on a large scale to avoid irretrievable loss, and, as far as possible mobile; depot stocks would be mixed instead of specialized; automatic data processing machinery would permit rapid supply action by remote control; a variety of small, mobile cargo carriers would be available, combining the functions of storage and movement, and capable of travelling on any terrain; cargo would also be carried by helicopter and aircraft that could use water runways; "roll-on-roll-off" seagoing and submersible carriers would discharge their cargoes rapidly on small beaches and immediately put out to sea; all movements of troops and cargo would be spread among numerous alternate routes.

Combat units, small, mobile, lean, stripped down to the bare essentials of equipment and services, would resupply themselves from small dispersed magazines, or be resupplied by aircraft and fast-moving supply columns.

Yet all this, by 1960, was still hardly more than a planner's vision. At best. it held promise of reducing to some degree the inherent vulnerability of the surface-bound installations and transport on which military forces in the foreseeable future were likely to depend for most of their logistical support. Dispersion and duplication were enemies of economy and efficiency, and the more advanced new means of movement, storage and handling were expensive, intricate and difficult to produce in quantity. The net effect could only be to increase the costs of logistical support and to diminish the yield in delivered supplies and services.

The central problem of logistics in the nuclear era, as before, was one of weight and bulk — the historic barriers to mobility and range, and the primary causes of vulnerability to the new firepower. With substantial reductions in weight and bulk of impedimenta and supplies, the pace of supply movements would quicken, armies could thin out the density of their rear-area installations and lines of communications, and the self-contained, hard-hitting "flying column" might return to warfare. Some promise of a real breakthrough in this area was offered by the application of atomic energy to transportation. Atomic-powered vehicles, whether on land, on the sea, under water or in the air, would consume virtually no fuel, and in World War II fuel had accounted for from two-thirds to three-fourths of the weight of all supply requirements. The first atomic-powered submarines and surface vessels appeared in the 1950s, and nuclear submarines, by the end of the period, had become a regular component of the U.S. navy. A further reduction of transportation requirements was inherent, too, in the new weapons themselves, which replaced many times their own weight and bulk in the older types of explosives and delivery instruments.

The growing range of firepower, moreover, involved a corresponding diminution of the distances over which the ingredients of firepower and logistical support had to be transported. Intercontinental missiles and bombers, based in a nation's home territory, theoretically could eliminate altogether the need for advanced air and missile bases, along with the defending forces, lines of communications and administrative establishments that supported them. By 1960 all the major powers had to reckon with the possibility that the sources of logistical support might, in any case, be wiped out, and lines of communication rendered inoperable by the initial strikes and counterstrikes of an all-out nuclear war. In such a case, the ensuing "broken-backed" conflict, if hostilities continued at all, would have to be waged by surviving farces in being with whatever weapons, supplies and transport remained. It could readily be envisaged that warfare under these circumstances might eventually revert to more primitive pre-industrial forms.

Logistical planners still had to reckon, however, with the probability of limited wars, with or without nuclear weapons, and with such present realities as limited budgets and interservice competition for funds and priorities. Development of new tools for logistics lagged behind the development of new weapons. The motor vehicles, ships, railroads and air transports in general use by 1960 were not significantly different from those used in World War II. Despite plans for dispersion, mobility and automated supply procedures, military forces remained dependent on the system of staged resupply from bases, elaborate service support and ponderous administration that had characterized the logistics of the industrial era.

LOGOGRAM AND SYLLABARY. Under this heading are included systems of writing that utilize logograms, or signs for words, and syllabograms, or signs for the syllabic components of words. (For systems of writing that utilize letters or signs for the smallest elements of language, namely phonemes, *see* ALPHABET.)

The systems of writing that utilize logograms and syllabograms may be divided into two classes: (1) logosyllabic writing, which utilizes in about equal measure signs both for words and for syllables; and (2) the syllabic writing, which either contains only signs for syllables or utilizes syllabic signs more than logographic signs.

Logosyllabic Systems.—This term includes full systems of writing, which represent actual units of language, such as words and syllables. They are to be distinguished sharply from primitive systems, which express vaguely defined ideas or meanings. The latter are called pictographic, ideographic or semasiographic systems and are forerunners of writing. (*See* WRITING; PICTOGRAPHY.)

Full systems of writing originated in the vast mass of land extending from the eastern shores of the Mediterranean sea to the western Pacific. In this large area seven original systems of writing developed. all of which could claim independent origin: (1) Sumerian in Mesopotamia. 3100 B.C.–A.D. 50; (2) proto-Elamite in Elam, 3000–2200 B.C.; (3) proto-Indic in the Indus valley, c. 2200 B.C.; (4) Chinese in China, 1300 B.C.–present; (5) Egyptian in Egypt. 3000 B.C.–A.D. 400; (6) Cretan in Crete and Greece, 2000–1200 B.C.; and (7) Hittite in Anatolia and Syria, 1500–700 B.C.

New systems of writing come to light from time to time through the efforts of excavators. The proto-Armenian inscriptions, which have been discovered in great numbers in Armenia, are too little known to warrant their addition to the list. The undeciphered Phaistos and Byblos writings are most likely syllabic and thus fall under the classification of syllabic writings. The mysterious Easter Island inscriptions, on which much effort has been spent by many imaginative minds, probably represent pictorial concoctions for magical purposes. Finally, the Amerindian systems of the Mayas and the Aztecs do not represent full writing, since even in their most advanced stages they never attained the level of development characteristic of even the earliest phases of the seven systems.

Sumerian System.—The home of cuneiform writing was in Mesopotamia. in the basin of the Tigris and Euphrates rivers. The term cuneiform means literally "wedge form," from Latin *cuneus*, "wedge." plus *forma*, "form," and ones its origin to the medgelike appearance of the little strokes. The decipherment of cuneiform was initiated in the first half of the 19th century by Georg Friedrich Grotefend and Henry Creswicke Rawlinson; by the end of the century it was possible to read with relative ease the various forms of cuneiform in which many languages of the ancient near east were written. Chief among these were Sumerian, spoken in southern Mesopotamia by a people of disputed ethnic and linguistic affiliation. and Akkadian. a Semitic language spoken in all of Mesopotamia, which included two main dialects. Babylonian and Assyrian. Toward the end of the 3rd millennium B.C. the Sumerian language died out, giving way to Akkadian.

Throughout its history the material par excellence of Mesopotamian writing was clay. As the rounded forms of pictures could not easily be incised on clay with a stylus, the signs acquired an angular form consisting of a few separate strokes of the stylus. The natural pressure of the stylus on one of its corners produced the appearance of wedges. Cuneiform was later used on other materials, such as stone and metal.

The Mesopotamian cuneiform system included about 600 logograms, out of which about 100–150 signs, depending on time and area, were used syllabically. The normal Mesopotamian syllabic writing contained signs of the type *ta*, *tu*, *tam*, *tum*. At no time did any of the Mesopotamian syllabaries contain signs for all the possible syllables in the languages for which they were used. The attempt to express linguistic forms with the fewest possible signs resulted in various economizing measures. No Mesopotamian system distinguished between voiced, voiceless and emphatic consonants in the case of signs ending in a consonant. Thus, the sign IG had the value ig, ik and iq, just as the sign TAG might have stood for *tag*, *tak* and *taq*. In addition, some older systems. such as Old Akkadian and Old Assyrian, did not even distinguish the quality of the consonant in signs beginning with a consonant. Thus, in these systems the sign GX had the value of *ga*, *ka* and *qa*. In all cuneiform systems many signs ending in i might stand also for those ending in *e*, as in the sign LI with the values *li* and *le*. Syllables which were not represented by a sign in the syllabary might be represented by signs with similar consonants, as, for instance, in expressing the syllable rin with the sign which had a normal value *rim.* When there were no signs with similar consonants. a syllable was written in Sumerian in a way not paralleled in any other syllabic system; the syllable ml, for which no separate sign existed, was written as *ra-al,* while in other known syllabic systems this syllable would be written *ra-l(a)*. ra-lie) or the like. (See also SUMERIAN LANGUAGE; AKKADIAN LANGUAGE.)

Egyptian System.—The name of the hieroglyphic writing of the Egyptians is derived from the Greek *hieroglyphika* gvammata and owes its origin to the belief that it was used chiefly by the Egyptians for sacred purposes (*hieros*, "sacred," *glyphein,* "to incise"). By 1822 the hieroglyphic writing was successfully deciphered by the Frenchman Jean François Champollion. chiefly on the basis of comparison with the Greek inscription on the Rosetta stone (*q.v.*). The hieroglyphic form of writing, used chiefly for public display purposes. was not the writing of everyday practical life. For such purposes the Egyptians developed two forms of cursive writing, first the hieratic and then the demotic. The Egyptian system consisted of about 700 signs, of which about 100 were used syllabically. The syllabary consisted of about 24 signs, each with an initial consonant plus any vowel, such as the sign m^x with the values m^a, m^i, m^e, m^u and $m^{(x)}$, and of about 80 signs, each with two consonants plus any vowel(s), such as the sign t^xm^x with the values t^am^a, t^im^i, t^em^e, t^um^u, t^am^i, t^em^i, $t^am^{(a)}$, $t^em^{(e)}$, $t^{(a)}m^a$, etc. This characterization of the Egyptian nonlogographic writing as consisting of signs expressing one or two consonants plus any vowel is in disagreement with the views of many Egyptologists. who say it is simply consonantal or even alphabetic. (See I. J. Gelb, *A* Study of *Writing,* pp. 76–81 [1952].) (*See* EGYPTIAN LANGUAGE; HIEROGLYPHS.)

Hittite System.—The decipherment of the Hittite hieroglyphic writing was achieved in the 1930s through the combined efforts of several scholars. Knowledge of Hittite has not reached the level of Sumerian or Egyptian. The term hieroglyphic was taken over from Egyptian writing. and it simply implies that Hittite writing, like Egyptian, was picture writing; it does not imply that the Hittite hieroglyphic system was borrowed from the Egyptian hieroglyphic or that it was in any way related to it. Hittite hieroglyphic writing was in use from about 1500 to 700 B.C. in a large area extending from central Anatolia to northern Syria. Its language was related to, but by no means identical with, cuneiform Hittite, a language preserved in the cuneiform writing borrowed from Mesopotamia. Both of these languages and writings were used simultaneously in the Hittite empire, but while cuneiform Hittite was limited to the area around Bogazkoy. the capital of the empire, and died out soon after 1200 B.C., hieroglyphic Hittite was used throughout the empire and continued as a living tongue up to about 700 B.C. Hittite writing consisted of about 450 signs, of which about 60 were used syllabically. The syllabic signs were of the type ta, ti, te, *tu,* each representing a syllable beginning with a consonant and ending in a different vowel. (See HITTITES.)

Chinese System.—Of the four main systems of writing. Chinese is the only one which did not have to be deciphered in modern times; because knowledge of it was passed from generation to generation, Chinese writing made its appearance about the middle of the 2nd millennium B.C.. during the Shang dynasty. as a fully developed phonetic system. In its outer form the writing has changed greatly during its long history, but the inner characteristics of the oldest inscriptions hardly differ from those of recent times. The oldest Chinese inscriptions are the oracle texts on animal bones and tortoise shells, and some short texts on bronze vessels, weapons, pottery and jade. The signs in the Shang period were limited in number, no more than about 2.500, and in the majority of them the pictorial character is still clearly recognizable. But the signs developed a linear form, and in later writings it is impossible to recognize the pictures they originally represented.

Chinese writing does not have a full syllabary comparable to the syllabaries in the other three (major) systems. As the words of the Chinese language are regularly expressed by word signs, it is only in writing foreign words and names that the necessity arose to use word signs in a syllabic function. Thus; "Jesus" is written as Yeh-su, "English" as *Ying-chi-li,* "French" as *Fa-lan-hsi,* "telephone" as te-li-feng. There are no set word signs for certain syllables, as there are in the near eastern systems; for example, "Jesus" might also be written Ya-su; "telephone," te-lu-fung. The characteristic tendency of Chinese toward abbreviation may be noted in the use of *Ying* for "English" (besides *Ying-kuo-jen* for "Englishman." that is, "English-country-man"), Fa for "French" (besides *Fa-kuo-jen*) or Lo for "Roosevelt" (besides *Lo-ssu-fu*). Frequently words spelled out syllabically acquired a logographic spelling; for example, the above-mentioned te-li-feng, "telephone," is now usually written as *tien-hua,* "electricity talks." Chinese writing is said to consist of about 50 000 signs, of which an unspecified number are used in a syllabic function This extraordinary development of Chinese logography constitutes a unique phenomenon in the history of writing. (See CHINESE LANGUAGE.)

Proio-Elamite, **Proto-Indic** and Cretan Systems.—All these systems are either completely or largely undeciphered. The proto-Elamite writing first dppeared at Susa. the capital of ancient Elam. and can be dated roughly to the so-called Jemdet-Nasr period after 3000 B.C. The earliest examples are found on several hundred clay tablets, perhaps business records Not even one of the several hundred signs can be read certainly. Some number signs and the existence of a decimal system have been determined with some assurance. A more developed form of proto-Elamite writing, also undeciphered, occurs on about a dozen stone inscriptions from the Old Akkadian period around 2200 B.C. The later type of writing consisted of a very limited number of signs (only 55 have been discovered) differing greatly in form from those of the previous period.

Seals with peculiar signs, which have aroused intense interest throughout the world, have been found sporadically during the 20th century at various sites in the Indus valley. In 1924 the archaeological department of the government of India undertook the first systematic excavation of the ancient sites today called Harappa and Mohenjo-Daro, and a considerable number of texts were discovered. More inscriptional material of the same nature was uncovered at Chanhu-Daro. At these sites cultures of great antiquity were unearthed. about which, strangely enough, Indic tradition says nothing. The still undeciphered writing consists of about 250 signs found on short seal inscriptions, pottery and copper tablets. The relative chronology of this proto-Indic writing was established by comparative stratigraphy with the help of Mesopotamian finds. The writing made its appearance in the second half of the 3rd millennium B.C. and, after a few centuries, disappeared as suddenly as it had appeared.

The origin and development of the Cretan writing are best illustrated by the epigraphic finds made at the beginning of the 20th century by Sir Arthur Evans at Knossos, in Crete. Other sites in Crete (Mallia, Hagia Triada) and in Greece (Mycenae, Orchomenus. Pylos, Thebes. Tiryns), as well as in the Aegean islands, have yielded epigraphic material that supplements the knowledge derived from the Knossos material.

The tuo major classes of Cretan writing are the Hieroglyphic and Linear. The undeciphered Hieroglyphic A and B are probably of the standard logosyllabic type. Linear B is predominantly syllabic, as is the still undeciphered Linear A system. (See MINOAN LINEAR SCRIPTS.)

Syllabic Systems.—Four syllabic systems developed from the logosyllabic systems discussed above: the cuneiform syllabaries from the Mesopotamian cuneiform; the West Semitic syllabaries from the Egyptian; the Aegean syllabaries from the Cretan; and the Japanese syllabary from the Chinese.

Cuneiform Syllabaries.—Mainly during the 2nd millennium B.C. the cuneiform writing of the Sumerians and Akkadians was borroned by many peoples surrounding Mesopotamia. such as the Elamites of Iran, the Hurrians of northern Mesopotamia and Syria, the Hittites of Anatolia and the Urartaeans of Armenia. Only the Hittites took over the Mesopotamian logosyllabic system in approximately the form it had at its original home. All others simplified their cuneiform writings considerably by limiting their systems to syllabic signs plus a small number of logograms for the most common nouns.

West Semitic Syllabaries.—In contrast to the East Semitic group of languages, represented only by Akkadian, all other Semitic languages, such as Phoenician, Hebrew, Aramaic, Arabic and Ethiopic, belong to the West Semitic group. This linguistic grouping is paralleled by a grouping based on graphic considerations. The Akkadians used cuneiform writing, while all other Semites used writing that was first developed on the Egyptian model in the middle of the 2nd millennium B.C. in the Syro-Palestinian area and reached its climax about 1000 B.C. in the Phoenician writing of Byblos, from which it spread to the surrounding West Semitic peoples.

All the West Semitic writings used a limited number of syllabic signs, 22 to 30. each of which expressed an initial consonant plus an inherent but unindicated vowel. With the development of separate vocalic signs in the first centuries A.D., the originally syllabic signs of the West Semitic writings became alphabetic, and the West Semitic writings became alphabets. (See also SEMITIC LANGUAGES.)

Aegean Syllabaries. — Under the syllabic writings of the Aegean area can be included the still undeciphered Cypro-Minoan and the deciphered Cypriote syllabaries of the island of Cyprus, the undeciphered syllabary of the disk of Phaistos in Crete and the undeciphered syllabary on about ten stone and metal inscriptions from Byblos.

The number of syllabic signs used in the Aegean systems varies from 56 to 90, and the signs are regularly of the type ta, te, ti, *tu*, to, that is, an initial consonant plus a different vowel. The difference between voiced, voiceless and aspirated consonants is not indicated in the writing. This type of syllabic sign is found in the Cretan, as well as in the hieroglyphic Hittite, writings discussed above.

Japanese Syllabary. — After a few centuries of cultural and commercial contact between China and Japan, the Chinese system of writing seems to have made its appearance in Japan in the 5th century A.D. The Chinese word signs were simply taken over by the Japanese and read not with their Chinese values but in Japanese. Thus, for example, the Chinese word sign *nan*, "south," was read in Japanese as *minami*, "south." The Chinese writing may have been well suited to a monosyllabic and isolating language in which grammatical forms are normally expressed by syntactical position rather than by special formatives. However, such writing was not suited to Japanese, which is polysyllabic and agglutinative and expresses grammatical forms by means of special formatives. Therefore, some of the Chinese word signs soon came to be employed as syllabic signs expressing the grammatical formatives of the Japanese language. Originally, the choice of the syllabic signs was unsystematic, and it was not until about the 9th century that a stable syllabary with 47 signs was developed, each expressing a consonant plus a vowel, with the difference in voice being fully indicated. In introducing a full syllabary the Japanese have never given up the logographic apparatus borrowed from Chinese, which they use along with their syllabary. See JAPANESE LANGUAGE.

Writings of Modern Primitive Societies. — Several systems. such as those of the Cherokees and Alaska Eskimos in America and of the Vai and Bamum Negroes in Africa, were developed in modern times under the influence of white men. Starting as a primitive logography, they passed through a logosyllabic stage. ending with syllabaries consisting of 85 (Cherokee) to 226 (Vai) signs.

LOGOGRAPHI, in Greek logographoi, writers of logoi or compositions of any sort, especially in prose. In Attic Greek the word signifies "professional speech writers"; in modern usage (since G. F. Creuzer. Die *historische Kunst* der *Griechen* in *ihrer* Entstchung und Fortbildung, 1803) it refers to pre-Herodotean writers of chronicles, from the doubtfully historical Cadmus of Miletus (*q.v.*) to Pherecydes. All these make extensive use of mythology, but their attempts at systematization and criticism are primitive. Their dialect is Ionic. Mention may be made of the following: Hecataeus of Miletus (*q.v.*); Acusilaus of Argos, who paraphrased in prose (correcting the tradition where it seemed necessary) the genealogical works of Hesiod; Charon of Lampsacus (c. 450), author of histories of Persia, Libya, and Ethiopia, of annals of his native town, and of the chronicles of Lacedaemonian kings; Xanthus of Sardis in Lydia (*c.* 450), author of a history of Lydia; Hellanicus of Lesbos (*q.v.*); Hippys and Glaucus, both of Rhegium, the first the author of histories of Italy and Sicily, the second of a treatise on ancient poets and musicians; and Damastes of Sigeum, author of genealogies of the combatants before Troy (an ethnographic and statistical list), and of short treatises on poets, sophists and geographical subjects. The work of Stesimbrotus of Thasos "On Themistocles, Thucydides and Pericles," though belonging to the same period, did not belong to the same category. It was really a political pamphlet, the first known of its kind, directed against the democratic imperialism of Athens.

LOGOS, a common term in ancient philosophy and theology. It expresses the idea of an immanent reason in the world, and, under various modifications, is met with in Indian, Egyptian and Persian systems of thought. But the idea was developed mainly in Hellenic and Hebrew philosophy, and the term is significant in the Gospel of St. John in the New Testament.

THE HELLENE LOGOS

To the Greek mind, which saw in the world a *kosmos* ("ordered whole"), it was natural to regard the world as the product of reason, and reason as the ruling principle in the world. So a Logos doctrine was more or less prominent from the dawn of Hellenic thought to its eclipse. It rises in the realm of physical speculation, passes over into the territory of ethics and religion and makes its way through three well-defined stages. These are marked off by the names of Heraclitus of Ephesus, the Stoics and Philo.

Heraclitus.—The idea of Logos acquires its first importance in the theories of Heraclitus (6th century B C), who, trying to account for the aesthetic order of the visible universe, broke away to some extent from the purely physical conceptions of his predecessors and discerned at work in the cosmic process a logos analogous to the reasoning power in man On the one hand the Logos is identified with gnome and connected with dike, which latter seems to have the function of correcting deviations from the eternal law that rules in things. On the other hand it is not positively distinguished either from the ethereal fire, or from the *heim armene* and the ananke according to which all things occur. Heraclitus holds that nothing material can be thought of without this Logos, but he does not conceive the Logos itself to be immaterial Whether it is regarded as in any sense possessed of intelligence and consciousness is a question variously answered. But there is most to say for the negative. This Logos is not one above the world or prior to it, but in the world and inseparable from it. Man's soul is a part of it. It is relation, therefore, as Friedrich Schleiermacher expresses it, or reason, not speech or word. And it is objective, not subjective, reason. Like a law of nature, objective in the world. it gives order and regularity to the movement of things and makes the system rational.

The failure of Heraclitus to free himself entirely from the physical hypotheses of earlier times prevented his speculation from influencing his successors. With Anaxagoras a conception entered which gradually triumphed over that of Heraclitus, namely, the conception of a supreme, intellectual principle, not identified with the world but independent of it. This however was *nous*, not Logos. In the Platonic and Aristotelian systems too the theory of ideas involved an absolute separation between the material world and the world of higher reality, and though the term Logos is found the conception is vague.

With Plato the term selected for the expression of the principle to which the order visible in the universe is due is *nous* or *sophia,* not logos. It is in the pseudo-Platonic *Epinomis* that logos appears as a synonym for *nous.* In Aristotle again, the principle which sets all nature under the rule of thought, and directs it toward a rational end, is *nous,* or the divine spirit itself; while logos is a term with many senses, used as more or less identical with a number of phrases, hou *heneka* ("final cause"), energeia, *entelecheia,* ousia, eidos, *morphe,* etc.

The Stoics.—In the reaction from Platonic dualism, however, the Logos doctrine reappears in great breadth and is a capital element in the system of the Stoics (*q.v.*). With their teleological views of the world they naturally predicated an active principle pervading it and determining it. This operative principle is called both Logos and God. It is conceived of as material and is described in terms used equally of nature and of God. There is at the same time. the special doctrine of the logos *spermatikos,* the seminal Logos, or the law of generation in the world, the principle of the active reason working in dead matter. This parts into logoi *spermatikoi,* which are akin, not to the Platonic ideas, but rather to the "material" logoi of Aristotle. In man too there is a Logos which is his characteristic possession, and which is *endiathetos,* as long as it is a thought resident within his breast, but *prophorikos* when it is expressed as a word. This distinction between Logos as ratio (reason) and Logos as oratio (oratory), so much used subsequently by Philo and the Christian fathers, had been so far anticipated by Aristotle's distinction between the "outside" logos and the logos "in the soul." It forms the point of attachment by which the Logos doctrine connected itself with Christianity. The Logos of the Stoics is a reason in the world gifted with intelligence, and analogous to the reason in man.

(X.)

THE LOGOS IN JUDAISM AND CHRISTIANITY

The problem of the Logos in the New Testament is that the fourth evangelist, in opening his Gospel with the statement, "In the beginning was the Word" (Logos), is undoubtedly recalling the opening words of Genesis, "In the beginning God created the heaven and the earth, ... And God said . . . ." but, in using the Logos absolutely to denote a divine hypostasis, is employing the term in a manner which is without parallel in the Bible and cannot be derived directly from the Old Testament.

The Hebrew Logos.—In the Old Testament "the word of the Lord" is another way of saying "God speaks," and means any communication of God to man, especially through a prophet (II Sam. xxiii, 2). "The word of the Lord came to . . ." can stand at the head of a prophetic book. In Hebrew thought the word carried with it the idea of activity and power. The word does not describe or comment, but effects what it utters (Isa. lv, 10–11). It judges, destroys and delivers (Jer. v, 14; Ps. cvii, 20). It is thought of as having a quasi-independent existence and an inherent power, especially in blessing and cursing (Zech. v, 3–4).

Alongside the word in the prophets, which is occasional, appears later the word in the Law, which is authoritative for all Israel for all time (Deut. xxx. 11 ff.). Later still the activity of the word in revelation is extended to cover the work of creation (Ps. xxxiii, 9). Subsequently Judaism sought to avoid anthropomorphism and stressed the transcendence of God over His creation, but maintained His contact with the world and His activity in creation and revelation by postulating divine agents, Wisdom, Word and Torah (Law). In the successive stages of the Wisdom literature a doctrine of Wisdom (grammatically feminine in gender) is developed. She has some sort of independent existence, is the divine artificer and draws men to God (Prov. viii, 14 ff.); she is identified with her supreme manifestation among the nations, namely the Torah possessed by Israel (Ecclus. xxiv, 7–23); and she is herself the presence of God, is before all light and is identified with the word of God (Wisdom of Solomon vii, 22–30, ix, 1–2, xviii, 15). The identification of Wisdom with Torah was particularly the work of the rabbis, who speak of the Law in personal terms as divine and pre-existent with God, as light and life and as the source of truth. It is possible to parallel most of the statements about the Logos in the Johannine prologue with almost identical statements made either about Wisdom in the Wisdom literature or about the Torah in the rabbinic writings. While these agencies are to a greater or lesser degree personified, Jewish thought stopped short of hypostatization, and they are not conceived as independent metaphysical entities. The Johannine Logos is such an entity and would therefore appear to have its origin in a wider sphere than the Old Testament or orthodox Judaism. Its introduction in the prologue without explanation indicates that readers were expected to be familiar with it and that it had a considerable currency. Such a currency would correspond with the philosophical eclecticism and religious syncretism of the period.

Philo and Hellenistic Religion.—A notable example of such syncretism from the Jewish side was the Alexandrian Jew Philo (*q.v.*). He was not an original thinker but a compiler and. to judge from signs that he has incorporated material from predecessors in the same field. is the sole survivor of a widespread Jewish "philosophy" centred on, but not confined to, Alexandria. It aimed at converting the Greek world by presenting Judaism as the true philosophy by means of an allegorical and speculative interpretation of the Old Testament. (See JEWISH PHILOSOPHY.)

In Philo's voluminous works the term Logos occurs about 1,300 times, but it is impossible to harmonize the bewildering variety of his statements about the Logos into a single and consistent doctrine. At times he is dependent on Stoicism (*e.g.,* for such concepts as "the seminal Logos" and the "immanent and expressed Logos") but, unlike the more consistent type of Stoicism, differentiates the Logos from God as His work or image (De *specialibus* legibus, i, 81). He is dependent on Platonism when he identifies the Logos with the *kosmos* noefos or intellectual universe as a model for creation, or with the *topos* ("place") of the ideas considered as expressions of the mind of God. In general, Philo's Logos is a cosmological principle and, despite its frequency, hardly plays a living part in his theology, being an accommodation to Greek thought with the purpose of distinguishing between God as existing in Himself and God as acting toward the cosmos. Although he speaks of it in personal terms (*e.g.,* as first-born son), the Logos can hardly be said to be personified, except where, in exposition of Old Testament texts, it is identified with figures such as Aaron and Melchizedek. The Logos is divine but not God, is with God, is light (De *somniis,* i, 75), water (De posteritate *Caini,* 127), manna (Legum allegoriae, iii, 172 ff.) and shepherd (De *agricultura,* 51). Thus there is a close similarity of symbolism between Philo and the fourth evangelist, and they move in the same world of thought; but a comparison of their writings makes any direct dependence highly improbable. Philo speaks generally of "the divine Logos" or "the Logos of God" rather than of "the Logos" absolutely.

The evidence of syncretistic religion outside Hellenistic Judaism is difficult to assess. being found in, or deduced from, sources which are widely different in character and of disputed date (*e.g.,* the *Hermetica* and the Mandaean literature), are generally later than the 1st century A.D. and may in some cases be Christian or have been exposed to Christian or to Jewish influence. Moreover, fresh material, as it becomes available, tends to modify previous judgments. Thus the view that the Aramaic *memra* ("word") in the Targums on the Old Testament provides no parallel to the Johannine Logos is certainly correct, since the *memra* in the Targums is not a divine hypostasis but a theological device for avoiding the mention of the divine name; yet the "Gospel of Truth" discovered in the Jung codex contains elaborate speculation on the divine name as a divine hypostasis, which may go back to a 1st-century Judaism of a more heterodox kind than that of the Targums. Second-century Gnostic systems exhibit a mythological figure under various guises: such as Son of God, Image of God, *Nous, Anthropos,* among which is Logos. This figure has a cosmological function as mediator between the unknowable God and the world, brings gnosis to men and, in some cases, rescues men from a hostile world. The fourth Gospel has this element of emphasis on the function of Logos as Saviour in common with such systems, as well as a general similarity of language and ideas, but lacks their speculation or polemic on the origin of the world or of darkness, and is not likely to be dependent on them. In Gnosticism Logos is one among many aeons, while the Johannine Logos is the one and only mediator.

The New Testament. — The affinities of the fourth Gospel may thus be various, but the clearest allusions are to Genesis, Wisdom and the Torah. Such polemic as there is in the prologue concerns the relation between the Logos and the Torah. This is evident from the conjunction of the statements that the incarnate Logos was "full of grace and truth" and that "the law was given by Moses, but grace and truth came by Jesus Christ" (i, 14–17). The character and functions of the Torah as pre-existent with God. as the source of life and the illumination of men, are transferred to Jesus. and thereby the Logos is for the first time fully personified. The term Logos will then owe less to current philosophical and religious speculation than to Christian theological reflection upon the person of Christ. The same path was trodden by other New Testament writers to the point where they might well have used the term itself. For St. Paul the Gospel is the word of God, which is also the word of Christ (II Cor. ii, 17; Col. iii. 16), which is Christ Himself, in whom the fullness of the Godhead dwells (Col. i, 25–27, ii, 9) and who is the agent of creation (I Cor. viii, 6). In the Epistle to the Hebrews Jesus, who qualifies by an earthly career for an eternal priesthood, is presented as the author and sustainer of the universe and as the image of God (Heb. i, 1–4); and the author of the Apocalypse (Rev. xix, 13) identifies the exalted Christ with the Word of God, which elsewhere in his book means the revelation of God through Christ. The fourth Gospel represents the climax of such theological reflection. In this Gospel outside the prologue *logos* is used of individual statements made by Jesus (ii, 19–22); these are not, however. sporadic statements, but constitute together a single *logos* or message, which conveys truth and eternal life (v, 24, viii, 31, 43) and which is itself the *logos* of God (xiv, 24, xvii, 14). Further, for the evangelist this *logos* is not simply that which Jesus proclaims, but is inseparable from His person; He is the content of His own message and is Himself the light, life and truth which He gives. Thus the identification of Jesus with the Logos is a short and almost inevitable step and will have been taken, not by way of applying current metaphysical thought to the Gospel, but in order to present in its widest cosmic significance—no doubt by means of a term which would be widely recognized—the person of Christ as Son of God and revealer of the Father.

Although the title Logos is confined to the prologue this does not imply that the prologue is an afterthought loosely attached to the Gospel, since what is predicated of the Logos in the prologue, viz., that he is pre-existent, life, light, is rejected by his own and gives grace and truth to those who receive him. is predicated of Jesus in the Gospel.

The Early Church. — The Logos doctrine which played a major, and in some respects an unfortunate, role in the earliest attempts of the primitive church to state Trinitarian belief mas not a further development of the thought of the fourth Gospel but represents an importation from current philosophical thought and terminology. This was due to the apologists, whose aim in the face of a hostile world was to make the divinity of Christ intelligible to that world, to claim the world for Christ as its creator and to set forth Christianity as superior to, or the heir to, all that was best in pagan philosophy. Christ as the pre-existent Logos (1) reveals the Father to men and is the subject of the Old Testament manifestations of God; (2) is the divine reason in which the whole human race shares, so that Socrates and others who lived with reason were Christians before Christ; and (3) is the divine will and word by which the worlds were framed. Theophilus borrows the Stoic terms "immanent" and "expressed" Logos to denote Christ first as pre-existent with God before creation and then as uttered or generated for the purpose of creation; and the same idea is present in Athenagoras.

The apologists tended to start with Christ as a cosmological figure rather than as the revealer of the Father or as redeemer, and it was impossible for them to avoid an impersonal conception of Him as an attribute or function of God, or as a thought in the mind of God, which acquired self-expression and personality only in being uttered for the purpose of creation. They therefore inevitably subordinated him to God. Justin describes the Logos as flame derived from fire and as "numerically another thing." Subordination was carried further by Origen, who starts from a Greek philosophical conception of God as passionless and incomprehensible and, in attempting to do justice to such passages of Scripture as "the Father that sent me is greater than I," differentiates God as "cause" from the Logos as "caused" and calls the latter "a creature." although this was mitigated by his doctrine that the Son is eternally generated by the Father. Arianism pushed one side of Origen's thought to extremes and, working almost exclusively with the pagan idea of God as the immutable absolute and concentrating entirely on the cosmic function of the Logos, declared that since the Logos was susceptible of suffering he could not be God and that there was a time when he did not exist. Meanwhile there was another doctrine of the Logos in the church which was eventually able to escape the dangers of subordinationism. The Logos does not appear to have figured greatly in Gnosticism until Basilides, Valentinus and Heracleon, who were under Christian influence. It was possibly in opposition to their systems that St. Irenaeus and Tertullian developed a doctrine which started from Christ as the Son who reveals the Father through incarnation and redemption and used the term Logos for the more limited purpose of relating Christ as Son to the universe as its creator. It was this tradition in Athanasius and his followers which, when combined with Origen's doctrine of the eternal generation of the Son, led to the defeat of Arianism and ultimately to the conclusion that the scriptural and specifically Christian understanding of the Godhead was better expressed in terms of the relation of an eternally begotten Son to the Father than in terms of the relation of a pre-existent Logos to God.

LOGOTHETE, originally the title of a variety of administrative officials in the Byzantine empire; *e.g.,* the official who was practically the equivalent of the modern postmaster general; and the logothete of the military chest. Gibbon defines the great logothete as "the supreme guardian of the laws and revenues" who "is compared with the chancellor of the Latin monarchies." From the eastern empire the title was borrowed by the west, though it only became firmly established in Sicily. where the *logotheta* occupied the position of chancellor elsewhere, his office being equal if not superior to that of the *magnus cancellarius.*

LOGROÑO, an inland province of northern Spain, the smallest of the eight provinces formed in 1833 out of Old Castile; bounded north by Burgos, Álava and Navarre, west by Burgos, south by Soria and east by Navarre and Saragossa. Pop. (1950) 231,010; area, 1.946 sq.mi. The portion skirting the Ebro forms a spacious and for the most part fertile undulating plain, called La Rioja. In the west the Cerro de San Lorenzo. the culminating point of the Sierra de la Demanda, rises 7,421 ft., and in the south the Pico de Urbion reaches 7,310 ft. The products of the province are chiefly cereals, good oil and wine (especially in the Rioja), fruit, silk. flax and honey. Large tracts of country are covered with vines and olive groves. Iron and argentiferous lead are mined in small quantities. A railway along the right bank of the Ebro connects the province with Saragossa. and from Miranda there is railway communication with Madrid, Bilbao and France. Besides Logrofio and Calahorra (*qq.v.*) the only municipalities with over 6,000 inhabitants are Haro (8,594) and Alfaro (8,097).

LOGROÑO, the capital of the Spanish province of Logrofio, on the right bank of the Ebro river and on the Saragossa-Miranda de Ebro railway. Pop. (1950) 50,080 (mun). The district was in ancient times inhabited by the Berones or Verones of Strabo and Pliny. and their Varia is identified with the modern suburb of the city of Logroiio now known as Varea. Logrofio nas named by the Romans Juliobriga and afterward Lucronius. It was unsuccessfully besieged by the French in 1521, and occupied by them from 1808 to 1813. Nationalists captured it during the civil war of 1936–39.

Logroño is an ancient walled town, finely situated on a hill 1,204 ft. high. Its bridge of 12 arches across the Ebro was built in 1138, but has frequently been restored. The crooked but picturesque alleys of the older quarters are in striking contrast with the broad avenues and squares laid out in modern times. Commercial centre of the fertile plain of the Rioja, Logroño has an important trade in wine.

LOGROSCINO (or Lo Groscino), **NICOLA** (1700?–1763?), Italian musical composer, who is remembered for his comic operas, mas born at Naples and was a pupil of Francesco Durante. In 1738 he collaborated with Leonardo Leo and others in the hasty production of *Demetrio;* in the autumn of the same year he produced *L'Inganno per inganno,* the first of a long series of successful comic operas.

He went to Palermo, probably in 1747, as a teacher of counterpoint; as an opera composer he is last heard of in 1760, and is supposed to have died about 1763.

LOGUE, MICHAEL (1840–1924), Irish ecclesiastic, was born at Kilmacrenan, County Donegal, on Oct. 1, 1840. He was appointed professor of theology and belles-lettres at the Irish college in Paris, where he was ordained a priest in 1866. He became bishop of Raphoe in 1879, archbishop of Armagh in 1887 and in 1893 was raised to the cardinalate. During World War I he deprecated participation by the clergy in Sinn Fein agitations, but in 1918 opposed conscription on moral grounds. In 1919 and 1921 he rigorously denounced campaigns against the police and the military, at the same time criticizing severely the policy and methods of the British government. He died at Armagh on Nov. 19. 1924.

LOGWOOD, a dyestuff for fabrics made from fibres of vegetable origin. Logwood comes into commerce in blocks which are hard and dense and possess a brown-red colour. It was imported into Europe soon after the discovery of South America, and mas cultivated in Jamaica from 171j. Logwood is the heartwood of the *Haematoxylon campechianum* (family Leguminosae), a tree distinguished by its peculiar ribbed appearance. It has been largely employed for the production of black and compound shades on woolen material, mainly in conjunction with a chromium mordant, and for the black dyeing of silk.

"Logwood extract." obtained by lixiviating the freshly cut wood with water and evaporating the solution *in vacuo,* and manufactured in the neighbourhood of the plantations, was exported for dyeing purposes.

Logwood contains the colouring principle haematoxylin, $C_{16}H_{14}O_6 \cdot 3H_2O$, which was first isolated by M. E. Chevreul in 1810. This, which is not a dyestuff, when oxidized readily passes into hematein, $C_{16}H_{12}O_6$, the true colouring matter. Such an oxidizing process has been applied to logwood extract, and the so-called hematein paste is a product of this character. Unaged extracts can, however, also be employed for dyeing when an oxidizing mordant is employed. The constitution of haematoxylin and hematein was elucidated by W. H. Perkins, R. Robinson and their pupils. (A. G. P.)

LOHENGRIN, the knight of the swan, hero of the German version of a legend widely known in literature from the middle ages onward. The legend assumes different forms in different literatures. but the common framework, the oldest part of which probably derives from the fairy tale "The Seven Swans," is the story of a mysterious knight who arrives in a boat drawn by a swan to protect a noble lady in distress, defeats her enemy and marries her, forbidding her, however, to ask his origin or his name; she later forgets her promise, and he leaves her, never to return.

The original home of the legend is unknown. The earliest known reference to it occurs in the 12th-century history of the crusades by William of Tyre, the source of the French version. In this *Roman du chevalier au cygne,* one of the *chansons de geste* (*q.v.*) based on the first crusade, the knight of the swan is called Hell-as. He is the son of King Oriant of Lillefort, and the story of his brothers' metamorphosis into swans and his own escape from this fate follows the tale of the seven swans persecuted by a wicked grandmother. Helyas marries Beatrix of Bouillon in circumstances parallel to those in which Lohengrin marries Elsa of Brabant *(see* below). Their grandson, Godfrey, becomes ruler of Jerusalem: and from this historical event stems the adaptation of the whole story to the glorification of the house of Bouillon.

In English, a late 14th-century alliterative romance, *Chevalere Assigne,* retells the first part of the *Roman du chcvalicr au cygne* and takes over the explanation that one of the knight's brothers did not regain human shape but remained a swan, accompanying his brother Enyas (the "Chevalere Assigne") on his travels. The same story is told in the opening of *Helyas— Knyght of the Swanne,* a prose romance adapted from the French by Robert Copland in 1512, which relates the history of the knight, his brother the swan and his marriage into the Bouillon family.

The German story first appears at the end of Wolfram von Eschenbach's epic *Parzival* (c. 1210). Elsa, a young princess of Brabant, refuses all offers of marriage, saying that she will only give herself to a man sent by God. From the temple of the Holy Grail arrives a knight in a boat pulled by a swan, and he is hailed by the princess as her God-sent husband. He marries her. but makes her promise that she will not ask his name or origin. She pledges her word but some years later asks the forbidden question. The swan returns, and the knight goes back to the Grail castle. His name was Loherangrin, the son of Parzival. king of the Grail.

The story is expanded into an epic of some 760 strophes in the anonymous Middle High German *Lohengrin.* This was the main source used by Wagner for his opera. The opening is in a Thuringian dialect but most of the poem is the work of a Bavarian poet who gives the story a historical context in the age of the German king Henry the Fowler (876?–936) and elaborates the realistic content at the expense of the romantic legend. *Lohengrin,* composed between 127j and 1290, is related to the contemporary poem known as the *Wartburgkrieg:* here the story is put into the mouth of Wolfram von Eschenbach who is made to recite it during the famous singers' contest at the Wartburg, seat of the Thuringian landgraves: certain gaps in the story of the *Wartburgkrieg* can be filled from passages in *Lohengrin;* and the ten-line stanza known as *Klingsors Schwarzer Ton* is common to both morks. Other medieval German versions of the story, which ultimately rest on the same passage from Wolfram's *Parzival,* include Konrad von Wiirzburg's *Schwanritter* (based on a French model) and the anonymous 15th-century epic *Lorengel,* which still uses *Klingsors Schwarzer Ton.*

Through its alignment with a specific historical period, its integration into the Wartburg story and its association with the Holy Grail and thence with the Xrthurian legend, the Lohengrin story has become part of German popular tradition. In particular it has become linked with the town of Cleves, whose rulers took the swan as their crest, and where the *Schwanenturm* on the castle and a statue of the knight and his swan perpetuate its memory.

See R. Jaffray, *The Two Knights of the Swan* (1910); *R.* Heinrichs, *Die Lohengrindichtung und ihre Deutung* (1905). Both contain details of text editions and further critical studies. (Rd. J. T.)

LOIN, that part of an animal lying between the upper part of the hipbone and the last of the false ribs on either side of the backbone; hence the butcher's term for a piece of meat cut from that part of the body. The upper part of a loin of beef is known as the "surloin," commonly corrupted into "sirloin." In the plural the word is a term for the lower part of the human body at the junction with the legs. It is more or less synonymous with flank, or that portion of the body bounded by the lower ribs, the backbone and the pelvis.

LOIRE, a department of central France, made up in 1793 of the old district of Forez and portions of Beaujolais and Lyonnais, all formerly included in the province of Lyonnais. Population (1954) 654,482. Area 1,853 sq.mi. It is bounded north by the department of Saône-et-Loire, east by those of RhBne and Isère, south by Ardèche and Haute-Loire and west by Puy-de-Dôme and Allier. From 1790 to 1793 it constituted, along with that of RhBne, a single department (Rhône-et-Loire). The Loire river rises in the department of Haute Loire to the south but traverses the department of Loire from south to north, and that department reaches west to the Mts. du Forez and east to the hills edging the Rhône valley, going beyond these to reach that river just south of Vienne. The valley floor in the south is the basin of Forez, an ancient lake floored by Tertiary strata, and the Loire, after subsequently passing through narrow defiles, enters the smaller basin of Roanne, also an old lake basin similarly floored. The hill frame is mainly formed of Archaean and Carboniferous rocks set in north-east to south-west lines to form the Mt. Pilat (4,705 ft.), Mts. du Lyonnais, Mts. du Beaujolais and Mts. du Charolais on the east, and the Mts. du Forez (Pierre sur Haute, 5,381 ft.) on the west. The climate on the heights is cold and healthy, it is unwholesome in the marshy plain of Forez, mild in the valley of the Rhône. The annual rainfall varies from 39 to 48 in. on the Forez mountains, but only reaches 20 to 24 in. in the vicinity of Montbrison. The plains of Forez and Roanne produce wheat and rye, and some oats, barley and colza. The vine is cultivated in the valley of the Rhône, on the lower slopes of the Forez mountains and on the hills west of the plain of Roanne. The forests of Mt. Pilat and the Forez chain yield good-sized pines and wood for mining purposes. The so-called Lyon chestnuts are to a large extent obtained from Forez; the woods and pasture lands of Mt. Pilat yield medicinal plants, such as mint. The pasture lands of the plain and mountains of Forez support live stock, notably the famous Charolais oxen. Poultry-rearing and bee-keeping are considerable industries. The department is rich in mineral springs, the waters of St. Galmier, Sail-sous-Couzan, St. Romain-le-Puy and St. Alban being largely exported. The chief wealth of the department lies in the coal deposits of the basin of St. Étienne (*q.v.*), the second in importance in France; quarrying is also active. Metal-working industries are centred in the south-east of the department, where are the great manufacturing towns of St. Étienne, Rive-de-Gier, St. Chamond and Firminy. At St. Étienne there is a national factory of arms, in which as many as 10,000 were employed; it makes cycles, motorcars, dynamos and accessories for electric lighting, apparatus for making acetylene gas, locks, edge-tools, common cutlery, chain cables for the mines, files, rails, etc. The glass industry is carried on at Rive-de-Gier and St. Galmier. St. Étienne and St. Chamond are centres for the fabrication of silk ribbons, elastic ribbons and laces, and the dressing of raw silks. The arrondissement of Roanne manufactures cotton stuffs, muslins and the like. That of Montbrison produces table linen. The department has numerous dye-works, flour-mills, paper works, tanyards, brickworks, silk-spinning works and hat factories. It is served by the P.L.M railway, Roanne being the junction of important lines from Paris to Lyon and St. Btienne. Within the department the Loire is hardly used for commercial navigation; there are canals from Roanne to Digoin (13 mi. in the department), and from Givors to Rive-de-Gier (7 mi.) and the Rhone (7 mi.).

Loire comprises three arrondissements—St. Étienne, Montbrison and Roanne—with 32 cantons and 338 communes. It is in the region of the XIII army corps (Clermont-Ferrand) and the *diocèse* and *académie* (educational division) of Lyon, where also is its court of appeal. St. Étienne is the capital, other leading towns being Roanne, Montbrison, Rive-de-Gier, St. Chamond, Firminy and Le Chambon. St. Bonnet-le-Château, besides old houses, has a church of the 15th and 16th centuries, containing paintings of the 15th century; St. Rambert and St. Romain-le-Puy have priory churches of the 11th century; and at Charlieu there are remains of a Benedictine abbey founded in the 9th century, including a porch decorated with fine Romanesque carving, old houses, etc.

LOIRE, the longest river of France, rising at 4,500 ft. in the recent volcanic peak of Gerbier de Jonc on the central plateau, and flowing north and west to the Atlantic. After a course of 18 m. it follows a picturesque channel along the foot of the basaltic rocks of Le Puy district, through narrow gorges and small plains. At Vorey, it is joined by the Arzon (left) and becomes navigable for rafts. The north-westerly direction of the Loire and its affluent the Allier is due to a tilting of the central plateau of France in Tertiary times so that the river valleys are filled with Tertiary deposits, on to which the Loire flows after passing the gorges of St. Victor. It again penetrates the hills of Carboniferous rocks before reaching the plain of Roanne. In this course it is joined by a large number of streams, the most important being the Coise (right), the Lignon du Nord and the Aix (left). Below Roanne the Loire is accompanied by a canal to Digoin (35 m.), thence by the so-called "lateral canal of the Loire" to Briare (122 m.).

At Digoin the Loire receives the Arroux, and gives off the canal du Centre (which utilizes the valley of the Bourbince) to Chalon-sur-Saône. Before reaching Nevers the Loire passes off the central plateau and on to the Jurassic rocks which form the rim of the Paris basin, over which rocks it flows in a northerly direction. Just beyond Nevers it is joined by the Allier (left); this river rises 30 m. S.W. of the Loire and follows an almost parallel course. Above Nevers the Loire is joined by the Aron (right), along which a canal proceeds northward, and below the confluence of the Allier gives off the canal du Berry to Bourges. Near Sancerre the river leaves the Jurassic rocks and has worn a valley through the Cretaceous uplands. At Briare it gives off a canal northward to the Seine. Between Gien and Blois the river flows in a wide arc across the Tertiary rocks of the Paris basin, passing Orléans, whence the canal d'Orléans, following the river Cens, communicates with the Briare canal. Passing Blois the Loire receives (right) the Cisse, and, after passing Tours, the three important left-hand tributaries of the Cher, Indre and the Vienne. Below Saumur it is frequently divided by long sandy islands fringed with osiers and willows; while upon arriving at Les Ponts-de-Cé (south of Angers) it is split into several distinct branches and studded with islands. At Angers it passes off the Cretaceous and on to the Palaeozoic and Archaean rocks of the Armorican massif.

The principal tributaries are: left, the Thouet at Saumur, the Layon and the Evre; right: the Authion, and, most important tributary of all, the Maine, formed by the junction of the rivers Mayenne, Sarthe and Loir. It receives the Erdre (right) at Nantes and the Sèvre-Nantaise (left), and farther on the canalized Achenau (left) and the navigable Etier de Méan (right) near St. Nazaire. Below Nantes, between which point and La Martinière (below Pellerin) the channel is embanked, the river is known as the Loire Maritime and widens out between marshy shores, passing Paimboeuf on the left and finally St. Nazaire, where it is $1\frac{1}{2}$ m. broad. The length of the channel of the Loire is about 625 m A lateral canal, known as the Maritime canal of the Loire, between Le Carnet and La Martinière enables large ships to ascend to Nantes. It is $9\frac{1}{2}$ m long, and $19\frac{1}{2}$ (capable of being increased to 24) ft. deep. At each end is a lock 405 ft. long by 59 ft. wide. The canal de Nantes à Brest connects this city with Brest.

The Loire is navigable only in a very limited sense. During the drought of summer thin and feeble streams thread their way between the sandbanks of the channel; while at other times a stupendous flood submerges wide reaches of land. When the flood waters of two or more tributaries arrive serious inundations result. Attempts to control the river began at a very early date, and in the middle ages the bed between Orléans and Angers was enclosed by dykes 10 to 13 ft. high. In 1783 a double line of dykes 23 ft. high was completed from Bec d'Allier downwards. In modern times embankments, aided by dredging operations extending over a large number of years, have ensured a depth of 18 ft. in the channel between La Martinière and Nantes Several towns have constructed special works to defend themselves against the floods; Tours, the most exposed of all, being surrounded by a circular dyke; and in the upper Loire reservoirs have been constructed to store flood waters.

LOIRE-INFÉRIEURE, a maritime department of France, made up in 1790 of a portion of Brittany on the right and of the district of Retz on the left of the Loire, and bounded west by the ocean, north by Morbihan and Ille-et-Vilaine, east by Maine-et-Loire and south by Vendée. Pop. (1936) 659,428. Area 2.695 sq.mi. The department consists of flat land on each side of the estuary of the Loire, and its suriace is varied oniy by the presence of weak ribs running west-north-west and east-south-east and continuing those of Brittany; the northernmost one, on the borders of Ille-et-Vilaine, reaches 377 ft., the *Sillon* *de Bretagne* stretching on the right bank of the estuary from Nantes towards the Vilaine hardly exceeds 250 ft. Seaward from the *Sillon,* and behind St. Nazaire, are peat-bogs including Grande Brikre which recently supplied old trees for joiners' work; near the coast are large salt-marshes, with Guérande as a salt-refining centre. The district south of the Loire lies equally low; its most salient feature is the lake of Grandlieu, covering 27 sq m., and surrounded by low and marshy ground, but so shallow (6½ ft. at most) that drainage would be comparatively easy. Canals are an important feature of the department, and the Nantes to Brest canal uses the Erdre up to within four m. of Nort, where it crosses to a tributary of the Vilaine. The south side of the Loire estuary has been canalized from Le Pellerin to Paimboeuf, and vessels drawing over 21 ft. can reach Nantes The climate is equable and drier than that of Brittany. At Nantes the mean annual temperature is 54·7°, the annual rainfall being 25.6 inches.

Horse, mule and cattle raising prospers. Good butter and cheese are produced. Poultry also is reared, and there is a good deal of bee-keeping. Much wheat, oats, buckwheat, potatoes and root-crops are grown, also leguminous plants, especially near Nantes. Vines and cider apples are grown. The woods are of oak in the interior and pine on the coast. Some iron is extracted in the department. North-west of Ancenis coal is obtained The granite of the sea-coast and of the Loire up to Nantes is quarried. Steam-engines are built for the navy at Indret, below Nantes; the forges of Basse-Indre are famous for their iron; and large quantities of lead are smelted at Coueron. There are considerable foundries at Nantes, Chantenay and St. Nazaire, and shipbuilding yards at Nantes and St. Nazaire. Pickles and preserved meats are prepared at Nantes, sardines cured at Le Croisic, which is the centre of the fishing industry, and in the neighbouring *communes,and sugar, brushes, macaroni and similar foods, soap and chemicals are made at Nantes, and paper, sugar and soap at Chantenay. The department is served by State railways, the Orleans company and the Western company. The department is divided into the three arrondissements of Nantes, Châteaubriant and St. Nazaire. There are 46 cantons and 220 communes. The appeal court is at Rennes, where is also the centre of the *académie* (educational division), to which it belongs. It is in the region of the XI army corps (Loire. Inf.) (Nantes), and forms the bishopric of Nantes under the archbishop of Tours.

The principal places are Nantes, the capital, St. Nazaire and Chbteaubriant. On the west coast the town of Batz, and neighbouring villages, are inhabited by a small community with a distinct costume and dialect, claiming descent from a Saxon or Scandinavian stock. Guérande has well-preserved ramparts and 15th century pates, a church dating from the 12th to the 16th centuries and other old buildings. At St. Philbert-de-Grandlieu there is a church with portions belonging to the beginning of the 11th century. Cisson has a 13th century castle and a market-hall built of wood. There are many megalithic monuments in the department.

LOIRET, a department of central France, made up of the three districts of the ancient province of Orléanais—Orléanais proper, Gâtinais, and Dunois. It is bounded north by Seine-et-Oise, north-east by Seine-et-Marne, east by Yonne. south by Nièvre and Cher, south-west and west by Loir-et-Cher and north-west by Eure-et-Loir. Area, 2,630 sq mi. Pop. (1936) 343,865. The department is a plain drained by the Loire from east to west, receiving the Loiret in the west on its left bank; this stream is only a few miles long, but so large that it is supposed to be an underground branch of the Loire. Towards the north the drainage is to the Seine by the Essonne and the Loing. The Sologne *(see* LOIR-ET-CHER) and the Beauce *(see* EURE-ET-LOIR) extend into the department on the south-west and north-west respectively. In the east is La Gâtine (capital Montargis), a region of wildernesses producing saffron and honey. The historic forest north of Orléans is slowly giving place to arable land. The lateral canal of the Loire from Roanne stops at Briare, from which town the *canal de Briare* connects with the Seine by the Loing valley, which is joined by the Orléans canal below Montargis The mean temperature is a little above that of Paris; the rainfall varies from 18·5 in. in the exposed Beauce to 27·5 in. in the well-wooded Sologne. Hailstorms cause destruction in the Loire valley and the neighbouring regions.

Sheep, cattle, horses, pigs, poultry, especially geese, and bees are reared. The chief cereals are wheat and oats, rye, barley, meslin, buckwheat; potatoes, beetroot, colza and forage plants and vines are grown, largely for vinegar. The woods consist of oak, elm, birch and pine; fruit trees thrive in the department, and Orleans is a great centre of nursery gardens. Gien is an important centre for the manufacture of faience. Porcelain buttons and beads are made at Briare. There are iron and copper foundries, which make agricultural and other implements. There are wool-spinning and wool manufacture carried on. The two arrondissements are those of Orleans and Montargis, with 31 cantons and 349 communes. The department forms part of the *académie* (educational division) of Paris. It forms also the bishopric of Orléans under the archbishops of Paris. It is in the military region of the Xth Army Corps (Orléans); and has its court of appeal at Orléans. The churches of Cléry (15th century), of Ferrières (13th and 14th centuries) of Puiseaux (12th and 13th centuries) and Meung (12th century) are interesting. At Germigny-des-Prés there is a church built originally at the beginning of the 9th century and rebuilt in the 19th century, on the old plan and to some extent with the old materials. Yèvre-le-Châtel has an interesting 13th century chbteau, and Sully-sur-Loire the fine mediaeval château rebuilt at the beginning of the 17th century by Maximilien de Béthune, duke of Sully, the famous minister of Henry IV. There are remains of a Gallo-Roman town (perhaps the ancient *Vellaunodunum)* at Trigukres and of a Roman amphitheatre near Montbouy.

LOIR-ET-CHER, a department of central France, formed in 1790 from a small portion of Touraine, the Perche, but chiefly from the Dunois, Vendômois and Blésois, portions of Orléanais. It is bounded N. by Eure-et-Loir, N.E. by Loiret, S.E. by Cher, S. by Indre, S.W. by Indre-et-Loire and N.W. by Sarthe. Pop. (1936) 240,908. Area, 2,479 sq.mi. The department stretches from the river Cher in the south through the one-time marshy Sologne, now largely drained, and across the Loire to the south-east corner of the hills of Perche, rising in the department to 840 ft., and draining to the Loir which flows westwards to join the Maine above Angers. Between Loir and Loire is the southern part of the Beauce *(see* EURE-ET-LOIR). In the tufa walls here and there in the valleys of Cher and Loir dwellings have been excavated, as at Les Roches in the Loir valley. The Sologne is famous for hunting and fishing. The Loire and, with the help of the Berry canal, the Cher are navigable. The climate is temperate and mild, though that of the Beauce tends to dryness and that of the Sologne to dampness. The mean annual temperature is between 52° and 53°. The department is primarily agricultural. The northern region of the department yields abundant wheat and oats, besides rye and potatoes. Vines thrive on the valley slopes, the vineyards falling into four groups—those of the Cher, which yield fine red wines, the Sologne, the Blésois and the Vendômois. In the valleys fruit-trees and nursery gardens are numerous; the asparagus of Romorantin and Vendôme is well-known. The Sologne supplies pine and birch for fuel, and there are extensive forests around Blois and on both sides of the Loir. There is good pasture in the valleys. Sheep are the chief stock; the Perche breed of horses is famous for lightness and strength. Formerly the speciality of Loir-et-Cher was the production of gun-flints. Stone-quarries are numerous. The chief industries are cloth-manufacture, leather-dressing, glove-making, lime-burning, the manufacture of "sabots" and boots and shoes, hosiery and linen goods. The department is served chiefly by the Orléans railway.

The arrondissements are those of Blois, Romorantin and Vendôme, with 24 cantons and 297 communes. Loir-et-Cher forms part of the educational division (académie) of Paris. Its court of appeal and the headquarters of the Xth army corps, to the regions of which it belongs, are at Orléans. Blois, the capital, the seat of a bishop under the archbishop of Paris, Vendôme, Romorantin and Chambord are the chief towns. In addition to those of Blois and Chambord there are numerous fine chbteaux in the department, of which that of Montrichard, with its 11th-century dungeon, that of Chaumont (15th and 16th centuries), and that of Cheverny (17th century) in the late Renaissance style are the most important. Those at St. Aignan, Lassay, Lavardin and Cellettes may also be mentioned. Churches wholly or in part Romanesque architecture were built at Faverolles, Selles-sur-Cher, St. Aignan and Suèvres. In the village of Trôo, close to ancient tumuli, was built a 12th-century church, and other surviving remains include those of a lazar house of the Romanesque period. There are several megaliths in the department.

LOISY, ALFRED FIRMIN (1857–1940), French Catholic theologian, was born at Ambrières in French Lorraine of peasant parents. The boy was sent into the ecclesiastical schools of St. Dizier, without any intention of a clerical career; but he decided for the priesthood, and in 1874 entered the Grand Séminaire of Chblons-sur-Marne. He was ordained priest in 1879. After being curé successively of two villages in that diocese, Loisy went in May 1881, to study and take a theological degree, to the Institut Catholique in Paris, where he ultimately became professor. He was dismissed from his professorship in 1893 in consequence of an article on "La Question biblique et I'inspiration des Ecritures" contributed by him to his bi-monthly review, *L'Enseignement biblique*. The promulgation of the papal bull *Providentissirnus Deus* by Leo XIII led him to discontinue the review. Meanwhile he had brought his *Les évangiles synoptiques* down to the confession of Peter. Loisy then became chaplain to a Dominican convent and a girls' school at Neuilly, but he soon resigned these appointments to continue his critical work in seclusion at Bellevue. A paper on "La Religion d'Israël" *(Revue du clerge' français,* Oct. 1900) was condemned by Archbishop Richard and by the pope. Loisy then began to lecture on biblical criticism at the École des Hautes Études Pratiques. Meanwhile he made a European reputation by his *L'Évangile et l'église* (1902, Eng. trans., 1903), which was a Catholic answer to Adolph von Harnack's *Wesen des Christentums.* The book was condemned by the archbishop, but Leo XIII declined to condemn the *Etudes évangéliques,* which appeared about the same time. But after the accession of Pius X, both these books, mith *Autour d'un petit livre* (1903) and *Le Quatrième Évangile* (1903), were placed on the Index. Loisy made a partial submission, which was regarded as unsatisfactory at Rome; he retired first to Dreux, then to his home in Lorraine.

But in 1908 he published the now completed *Les Évangiles synoptiques,* embodying the results of the "higher criticism" followed by *Simples Réflexions sur le décret Lamentabili et sur l'encyclique Pascendi.* The Holy Office pronounced the major excommunication on Loisy on March 7, 1908. From 1909 to 1932 Loisy was professor of church history at the Collège de France. His works include *L'Évangile selon Saint Marc* (1912); *Les mystères païens et le mystère chrétien* (1914); *Les actes des Apôtres* (1920); *L'Apocalypse de Jean* (1923). Loisy died June 1, 1940.

The Loisy controversy attracted great attention throughout Europe, and the literature is extensive. *See* Loisy's own *Autour d'un petit livre* (1903); A. Houtin, *La Question biblique au XIX^e Siècle* (1902); C. A. Briggs and F. von Hügel, *The Papal Commission and the Pentateuch* (1907).

LOJA (formerly written *Loxa),* a town of southern Spain, in the province of Granada, on the Granada-Algeciras railway. Pop. (1950) 30,056 (mun.). Loja, which has sometimes been identified mith the ancient *Ilipula*, or with the *Lacibi (Lacibis)* of Pliny and Ptolemy, first emerges in the Arab chronicles of 890. It was taken by Ferdinand III in 1226, but was soon afterward abandoned, and was not finally recaptured until 1486. The narrow and irregular streets of Loja wind up the sides of a steep hill surmounted by a Moorish citadel; many of the older buildings. including a fine Moorish bridge, were destroyed by an earthquake in 1884, although two churches of the early 16th century remained intact. An iron bridge spans the Genil river. which flows past the town on the north. Local products consist chiefly of coarse woolens. silk. paper. leather and salt.

LOKEREN, an important industrial town of Belgium between Ghent and Xntwerp (in East Flanders on the Durme). Pop. (1955 est.) 25,985. It lies at the southern point of the district called Waesland. It is sometimes called the "Garden of Belgium." The clayey-gravel nature of the soil and the dampness of the atmosphere are favourable to the cultivation of flax. Root crops have been grown there with great success since the 18th century. Industries include the spinning of wool, flax and hemp, and the manufacture of linen, canvas, etc.

LOKOIYA: *see* LOATUKO.

LOLLARDS, in late medieval England, a name given to holders of certain religious tenets deriving from the teachings of John Wycliffe (*q.v.*). The term comes from Middle Dutch *lollaerd*, "a mumbler" or "mutterer"; it had been applied before Wyclifie's time to the Flemish Beghards and other continental groups suspected of combining pious pretensions with heretical belief. As early as 1382 it was used in an anti-Wycliffite sermon by the Irish Cistercian Henry Crump, while in 1387 the bishop of Worcester, Henry Wakefield, gave it official currency in a mandate against five heretics.

Early History.—The earliest Lollard group consisted of the Oxford scholars who showed allegiance to Wycliffe's doctrines *c.* 1380; they were headed by Nicholas Hereford of Queen's college, to whom is attributed the first Lollard translation of the Scriptures. His associate Philip Repingdon, an Augustinian canon of St. Mary-in-the-Fields, probably carried the movement to Leicester. where by 1382 William Swinderby led a group of lay adherents and went forth to preach in neighbouring towns. Though Wycliffe himself was still writing at Lutterworth, no solid evidence supports the tradition that he personally sent out "poor preachers." In Nov. 1382 Archbishop William Courtenay assembled convocation at Oxford and there forced the academic Lollards into submission. Repingdon conformed with enthusiasm and ultimately, as bishop of Lincoln, became an active persecutor. Hereford was excommunicated, fled to Rome and appealed in vain against his sentence; arrested on his return, he recanted and by 1393 had also become a champion of orthodox belief. In 1390–92 Swinderby was still being pursued by authority and sheltered by sympathizers in the Welsh marches. At this stage the prime agent was Wycliffe's former secretary John Purvey, who probably compiled the second translation of the Bible, one far more attractive and idiomatic than that by Hereford. Despite Courtenay's apparent triumph, the sect continued to multiply among townsmen, merchants, gentry and even among the lower clergy. Several knights of the royal household gave their support, while vociferous partisans, concerned especially to disendow the church, emerged in the house of commons.

Lollard Beliefs.—The most complete statement of early Lollard teaching appears in the *Twelve Conclusions,* drawn up, originally in English, to be pressed upon the parliament of 1395. They began by stating that the church in England had become subservient to her "stepmother the great Church of Rome." The present priesthood was not the one ordained by Christ, while the Roman ritual of ordination had no warrant in Scripture. Clerical celibacy occasioned unnatural lust, while the "feigned miracle" of transubstantiation led men into idolatry. The hallowing of wine, bread, altars, vestments and so forth was related to necromancy. Prelates should not be temporal judges and rulers, for no man can serve two masters. The *Conclusions* also condemned special prayers for the dead, pilgrimages and offerings to images; they declared confession to a priest unnecessary to salvation. Warfare was "express contrarious to the New Testament, the which is a law of grace and full of mercy." Vo s of chastity by nuns led to the horrors of abortion and child murder. Finally, the multitude of unnecessary arts and crafts pursued in the church encouraged "waste, curiosity and disguising."

Though no particular manifesto ever commanded general adherence, the *Twelve Conclusions* cover all the main Lollard doctrines except two: that the prime duty of priests is to preach, and that all men should enjoy free access to the vernacular Scriptures. The movement's obvious attraction lay in this last provision and in its argument that the wealth, pride, ritualism and coercive powers of the church stood at variance with the recorded practices of Christ and the apostles. Its weaknesses sprang from bibliolatry and the vagaries of uninstructed private judgment. Though modern knowledge of Lollard extremist fundamentalism derives largely from such hostile writers as Bishop Reginald Pecock and Thomas Netter, the movement inevitably acquired a fringe of cranks. From its early days it also tended to discard the scholastic subtleties of Wycliffe, who probably wrote few or none of the popular tracts in English formerly attributed to him.

Fluctuations During the 15th Century.—The personal opinions and political needs of the Lancastrian kings induced them from the first to support the bishops in a campaign to obliterate the heresy. In March 1401 Archbishop Thomas Arundel forced Purvey into submission and induced convocation to condemn William Sawtre (Sawtrey), who was in fact burned a few days before parliament passed the statute *De haeretico comburendo*. This measure stipulated that a heretic convicted by the spiritual court and refusing to recant, or relapsing after recantation, must be handed over to the civil power and suffer burning. The persecution, though reinforced in 1407 by Arundel's new purge at Oxford, failed to stifle Lollardy or to abash the boldness of its supporters in parliament. In 1410 these latter openly sought to modify the law of heresy, to dispossess the church and to endow the crown, together with many new earls, knights, esquires, universities and hospitals, from the spoils. Foremost among the lay converts mas the distinguished soldier Sir John Oldcastle (*q.v.*), who was indicted in March 1413 for maintaining Lollard preachers and opinions. Arraigned before Arundel, he denied transubstantiation and the confessional. In October he escaped from the Tower of London and proceeded to organize a great march upon London by Lollards from many parts of the kingdom. On Jan. 9–10, 1414, Henry V assembled troops in St. Giles's fields and dispersed the rebels with little fighting. Though the elusive Oldcastle avoided arrest and execution until 1417. his rising resulted in a roundup of leaders and suspects so complete as to shatter the overt political influence of Lollardy. Driven underground, it operated henceforth chiefly among tradesmen and artisans, supported by a few clerical adherents. Between 1424 and 1430 over 100 Lollards were arraigned in the diocese of Norwich, while cases also proved common in Somerset and in parts of the diocese of Lincoln. Early in the century Scottish Lollards were being persecuted by the inquisitor Laurence of Lindores, yet the sect persisted there until the Reformation.

In the spring of 1431 a fresh Lollard plot came to light; its ramifications proved surprisingly extensive, and it aimed at no less than the overthrow of the government and the disendowment of the church. The subsequent decline in the number of prosecutions may indicate merely a slackening of official pressure. Despite a few martyrs, Lollardy was neither demonstrative nor heroic; it flourished upon quiet evasion, and most of its adherents submitted tamely when brought into the ecclesiastical courts. In 1455 Reginald Pecock issued his *Repressor* of *Overmuch Wijting [Blaming] of the Clergy,* a powerful attack upon Lollard beliefs and especially upon their misuse of biblical texts. His analysis indicates that the emphases of Lollardy had not substantially altered since the time of the *Twelve Conclusions.*

Lollardy and the Reformation.—There can be little doubt that a Lollard revival began about 1500. Much of the detailed evidence comes from John Foxe, *Acts and Monuments* (1563), yet it is highly circumstantial and finds support elsewhere. In the London diocese, especially in Essex, Bishop Richard Fitzjames prosecuted about 50 Lollards in 1510 and about as many again in 1518. In Dec. 1514 the murder of the Lollard merchant Richard Hunne in the episcopal prison at St. Paul's immensely intensified anticlerical feeling in the city. Between 1527 and 1532 the bishops Cuthbert Tunstall and John Stokesley caused at least 218 heretics to abjure in that diocese; with few exceptions these heresies remained purely Lollard. Another major focus lay in the Chilterns, especially around Amersham and Buckingham, where in 1506–07 about 45 cases were presented to Bishop William Smyth of Lincoln. In 1521 Bishop John Longland occasioned in that area 50 abjurations and 5 burnings, and he continued active for another decade. The region was connected through a number of scattered communities in the Thames valley with others in Berkshire, Wiltshire and the Cotswolds. At Newbury about 140 heretics are said to have abjured together sometime during the early years of the century. Yet another centre lay in the Kentish clothing towns of Tenterden, Cranbrook and Benenden, where in 1511 about 46 Lollards were denounced to Archbishop William Warham, 5 being burned, the rest abjuring. Between these various areas active liaison existed; for example, Thomas Man, burned at Smithfield in 1518, had moved about instructing communities in East Anglia, the Chilterns. the Thames valley and Newbury.

Before 1530 the old Lollard and the new Protestant forces had begun to merge. Early Lutheran missionaries, like Robert Barnes, sold William Tyndale's New Testament to Lollard communities. When the writings of Luther began to enter England, Bishop Tunstall wrote to Erasmus, "it is no question of pernicious novelty; it is only that new arms are being added to the great band of Wycliffite heretics." The list of proscribed doctrines compiled by convocation in 1536 still retained a high proportion of characteristically Lollard beliefs, and even the conservative north was affected by the revival. Research into the archives of the diocese of York revealed proceedings against about 32 heretics under Henry VIII and against 45 others during the reign of Mary I. The uneducated majority of these offenders evinced neither Lutheran nor Zwinglian beliefs. Both before and after the advent of continental Protestantism, they attacked, on a Lollard basis, saint worship, images, relics. holy bread, holy water. sacred buildings and objects, and, above all, the doctrines of confession and transubstantiation. Nearly all these cases fail to appear in the actual registers of the archbishops of York but emerge from day-to-day court books, which in most other dioceses have been lost for that period. Hence it is not possible to estimate accurately the scope of the movement or even the number of trials. Yet this resurgence of an inveterate Lollardy, however negative and confused, undoubtedly amplified those complex undercurrents of dissent and anticlericalism that disturbed English society under Henry VIII. Late Lollardy coloured proletarian criticism of the church outside as well as inside the small Lollard communities; it facilitated the spread of Lutheranism, predisposed opinion in favour of the king's anticlerical legislation and, since it persisted beyond mid-century, may have helped create the psychological bases of popular nonconformity.

LOLO: *see* Yi.

LOMAS DE ZAMORA, Argentine city and important suburb of greater Buenos Aires, located 10 mi. directly south of the federal district. Pop. (1960) 275,219. Its name and origin date from the end of the 16th century, when several of the low hills in the region were given in a grant to a Spaniard named Zamora who accompanied Juan de Garay in the second and permanent founding of Buenos Aires. The town developed as a residential area and with the growth of Buenos Aires merged into the suburban area of greater Buenos Aires. After 1940 it became a major industrial area with chemical, electrical and cement factories. (Js. R. S.)

LOMBARD, PETER (Petrus Lombardus) (*c.* 1100–1160). theologian and bishop, best known as "Master of the Sentences" *(Magister Sententiarum),* was born about 1100. Little is known of his life. After early schooling at Bologna he went to France to study first at Rheims, then at Paris. From 1136 to 1150 he taught theology in the cathedral school of Notre Dame. He was present at the Council of Rheims in 1148. In 1159 he was named bishop of Paris. He died in 1160. Besides the *Books of Sentences* (*sententiarum libri IV*), Peter Lombard wrote commentaries on Holy Scripture, sermons and letters. No special importance attaches to these writings. The *Sentences,* however, established his reputation and subsequent fame.

This work, written between 1148 and 1151, is a collection of teachings of the church Fathers (sententiae *Patrum*), plus some opinions of medieval masters, arranged as a systematic treatise on sacred doctrine. Lombard takes due cognizance, throughout, of the role of reason in theology. His work marks the culminating point of a long tradition of theological pedagogy, and until the 16th century it was the official textbook of theology in the universities. Hundreds of scholars wrote commentaries on it (180 in England alone).

The contents of the Books of Sentences are as follows: book I deals with God, the Trinity, providence, predestination, evil; book II with angels, demons, the Fall, grace, sin; book III with the incarnation, the redemption, virtues, the Ten Commandments; book IV with the sacraments in general, the seven sacraments in particular, the four last things (death, judgment, hell, heaven).

The author shows originality in choosing and arranging his texts, in utilizing various currents of thought, in avoiding the extremes of both dialecticians and authoritarians, and above all in crystallizing the theology of the sacraments. He asserted that there are seven sacraments and that a sacrament is not merely a "visible sign of invisible grace" but also the "cause of the grace it signifies."

Peter Lombard's teachings encountered opposition during his lifetime and after his death. Later theologians rejected a number of his views. One opinion he held was officially censured, an opinion derived from Abelard's teaching that, in Christ, God is not man, but has humanity. This formula smacked of "christological nihilism" (a term applied to the heresy of adoptionism, according to which the Man, Christ, was not God's true Son, but his adopted son), and in 1177 Pope Alexander III condemned this error.

Notwithstanding, Peter Lombard was never regarded as unorthodox. Efforts to have his works condemned were unsuccessful. The fourth Lateran council (1215) even prefaced a profession of faith with the words "We believe with Peter Lombard. . ."

Peter Lombard's collected works may be found in J. P. Migne, Patrologia *Latina,* vol. 191 and 192. The best edition of the Books *of* Sentences (no English translation), is that by the Franciscans at Quaracchi, Libri quattuor *sententiarum,* 2 vol. (1916).

LOMBARD, a village in Du Page county, northeast Illinois, U.S., 21 mi. W. of the Chicago "loop," is located on gently rolling terrain at an altitude of 700–750 ft. It was named for Joseph Lombard, a Chicagoan, who platted the site in 1868. Incorporated as a village in 1869, it is still classified as such, even though it has a population of about 20.000.

Known as the "lilac village," Lombard has six parks, covering more than 100 ac Lilacia park, bequeathed by Col. William Plum who collected lilacs as a hobby, has notable varieties of these flowering trees and shrubs. Lombard was one of the first communities in Illinois to give women the right to vote.

Lombard is mainly a residential suburb of Chicago and has little local industry.

For comparative population figures see table in ILLINOIS: *Population.* (D. A. Pr.)

LOMBARD LEAGUE. The attempt of the emperor Frederick I to re-establish imperial power in Italy led to a coalition, formed in March 1167, between the cities of Cremona, Mantua, Bergamo and Brescia. This league was soon joined by other cities. among which were Milan. Parma. Padua, Verona. Piacenza and Bologna, and the allies began to build a fortress near the confluence of the Tanaro and the Bormida, which. in honour of Pope Alexander III, was called Alessandria. During the absence of Frederick from Italy from 1168 to 1174, the relations between the pope and the league became closer, and Alexander became the leader of the alliance. The decisive struggle began when Frederick attacked Xlessandria in 1174, but the historical importance of the war is due to the defeat inflicted on the emperor by the league at Legnano. May 29,1176. The peace of Constance (June 25, 1183), which ended the struggle, left only a shadowy authority to the emperor in Italy. In 1226 the league was renewed against the emperor Frederick II and was one of the principal forces opposed to the Hohenstaufen thenceforward until their final overthrow.

LOMBARD0 (or LOMBARDI), the name given to a family of Lombard origin uho practised in Venice in the 1jth and 16th centuries as sculptors and architects, and who were largely responsible for the formation of the Venetian Renaissance style. Its most notable members were Pietro Lombardo *(c.* 143j–151j) and his sons Tullio (*c* 14j5–1532) and Antonio (c 1458–1516). The son of Tullio Lombardo, Sante (1504–1560), also practised as an architect.

PIETRO LOMBARDO was born at Carona about 1435, and is first heard of in Padua, where he was active in 1464–67. There he executed the Roselli monument in S. Antonio (1467) and the Casa Olzignani. About 1467 he transferred his studio to Venice, where he worked for the remainder of his life, producing a long succession of buildings and sepulchral monuments. The Roselli tomb derives from Florentine humanist monuments, and the earliest of his buildings in Venice, the church of S. Giobbe (after 1470) is also markedly Tuscan in character. Thereafter he developed a more individual architectural style, of which the first evidence is found in the church of Sta. Maria dei Miracoli (completed 1489). With its harmonious proportions and rich marble incrustation, this is one of the most distinguished Venetian churches of the early Renaissance.

In sculpture Pietro Lombardo also worked his way forward from the Niccolb Marcello (d. 147j) monument in SS. Giovanni e Paolo to the more complex and more typically Venetian Pietro Mocenigo monument in the same church (1476–81). In 1482 he executed the tomb of Dante for Ravenna and in 148j began work on his most distinguished monument, the Zanetti tomb in the cathedral at Treviso, where the carving was in large part carried out by his sons. From 1498 until his death in June 1515 he served as *capomaestro* of the ducal palace in Venice.

TULLIO LOMBARDO, the elder of Pietro's sons, was born in Venice, probably about 1455. He is mentioned with his brother Antonio by the humanist Collaccio in 147j, and assisted his father in work on the Pietro Mocenigo monument in SS. Giovanni e Paolo. The figure sculpture in his most important work, the Vendramin monument from Sta. Maria dei Servi, now in SS. Giovanni e Paolo, is the peak of Venetian classicism; a beautiful figure of Adam from this tomb is now in the Metropolitan museum, New York. In 1525 he executed his best-known work, the recumbent figure of Guidarello Guidarelli at Ravenna. His last dated work is the Bellati monument in the cathedral at Feltre (1528). Tullio was also active as an architect, designing the Cappella dell'Argento for the cathedral at Ravenna (1515) and the cathedral at Belluno (1517) and working in this capacity at Mantua (1527). He died on Nov. 17, 1532.

ANTONIO LOMBARDO, the younger of Pietro's sons, seems to have been born about 1458 and was already active by 1475. He assisted his father and brother in Sta. Maria dei Miracoli, on the Zanetti and Vendramin monuments, and on the façade of the Scuola di S. Marco (for the reliefs on which he and Tullio were jointly responsible). In 1501 he received the commission for two reliefs for the chapel of St. Anthony in S. Antonio at Padua, only one of which was completed (1505). This reveals Antonio as a more restrained and in some respects more sensitive sculptor than his brother Tullio. Between 1504 and 1506 he worked on the tomb and chapel of Cardinal Zen (d. 1501) in St. Mark's, Venice. This was the first major work in bronze executed by a Venetian sculptor and was completed by Paolo Savin.

In 1j06 Antonio Lombardo transferred his workshop to Ferrara, where he was employed by the Este and where he is last mentioned in 1516. There he was responsible for the carving of the celebrated Camerini d'Alabastro (alabaster chambers) in the Castello, which were decorated with mythological and other reliefs. An important group of carvings from this complex is in the Hermitage at Leningrad.

(J. W. P.-H.)

LOMBARDS or LANGOBARDI, a Suevic people who appear to have inhabited the lower basin of the Elbe and whose name is believed to survive in the modern Bardengau to the south of Hamburg. They are first mentioned in connection with the year A.D. 5, when they were defeated by the Romans under Tiberius, afterward emperor. In A.D. 9, however, after the destruction of Varus' army, the Romans gave up their attempt to extend their frontier to the Elbe. At first, nith most of the Suevic tribes they nere subject to the hegemony of Maroboduus, king of the Marcomanni, but they revolted from him in his war with Arminius, chief of the Cherusci, in the year 17. We again hear of their interference in the dynastic strife of the Cherusci some time after the year 47. From this time they are not mentioned until the year 165, when a force of Langobardi, in alliance with the Marcomanni, was defeated by the Romans, apparently on the Danubian frontier. It has been inferred from this incident that the Langobardi had already moved southward, but the force mentioned may very well have been sent from the old home of the tribe, as the various Suevic peoples seem generally to have preserved some form of political union. From this time onward we hear no more of them until the end of the 5th century.

Shortly before this time the Langobardi appear to have taken possession of the territories formerly occupied by the Rugii whom Odoacer had overthrown in 487, a region which probably included the present province of Lower Austria. At this time they were subject to Rodulf, king of the Heruli, who, however, took up arms against them. The result was the total defeat of the Heruli by the Langobardi under their king Tato and the death of Rodulf at some date between 493 and 508. By this time the Langobardi are said to have adopted Christianity in its Arian form. Tato was subsequently killed by his nephew Waccho. The latter reigned for 30 years, though frequent attempts were made by Ildichis, a son or grandson of Tato, to recover the throne. Waccho is said to have conquered the Suabi, possibly the Bavarians, and he was also involved in strife nith the Gepidae, with nhom Ildichis had taken refuge. He was succeeded by his youthful son Walthari, who reigned only seven years under the guardianship of a certain Audoin On Walthari's death (about 546?) Audoin succeeded. He also aas involved in hostilities uith the Gepidae. In these quarrels both nations aimed at obtaining the support of the emperor Justinian, who, in pursuance of his policy of playing off one against the other, invited the Langobardi into Noricum and Pannonia, where they now settled.

A large force of Lombards under Audoin fought on the imperial side at the battle of the Apennines against the Ostrogothic king Totila in 553, but the assistance of Justinian, though often promised, had no effect on the relations of the two nations, which were settled for the moment after a series of truces by the victory of the Langobardi, probably in 554. The resulting peace was sealed by the murder of Ildichis and Ustrogotthus, and the Langobardi seem to have continued inactive until the death of Audoin, perhaps in 565, and the accession of his son Alboin. It mas about this time that the Avars entered Europe, and with them Alboin is said to have made an alliance against the Gepidae under their new king Cunimund. The Avars did not take part in the final battle. in which the Langobardi xere victorious. Alboin, who had slain Cunimund in the battle, took Rosamund, daughter of the dead king. to be his wife. In 568 Alboin and the Langobardi, in accordance nith a compact made with Baian, recorded by Meander, abandoned their old homes to the Avars and passed southnard into Italy, mhere they were destined to found a new and mighty kingdom (F. G. M. B.)

The Lombard Kingdom in Italy.—Alboin's reign in Italy was brief. In 572, according to Lombard tradition, he fell a victim to the revenge of his nife Rosamund, the daughter of the king of the Gepidae, whose skull Alboin had turned into a drinking cup. But in these few years the Lombards had established themselves in the north of Italy, from mhere in the next decade they frequently raided Frankish territory beyond the Alps. Chiefs were placed, or placed themselves, first in the border cities, like Friuli and Trent, which commanded the northeastern passes, and then in other principal places; and this arrangement became characteristic of the Lombard settlement. Its principal seat was the rich plain watered by the Po and its affluents, which was in future to receive its name from them; but their power extended across the Apennines into Liguria and Tuscany, and then southward to Spoleto and Benevento. Ticinum (Pavia), the one place which had obstinately resisted Alboin, became the seat of their kings.

Alboin was succeeded by a Lombard noble named Cleph who reigned for only 18 months. For the next ten years (574–584) no noble was able to obtain recognition as king. In the latter year, threatened by a Frankish invasion, the Lombards chose as king Authari, the son of Cleph, to whom is principally due the consolidation of Lombard power in Italy. Under him the independence of the dukes was reduced and something was done toward their transformation into royal officers. The dukedoms of the northern marches, Trent and Friuli, with the dukedom of Turin, long retained the independence natural to a border government in early times. Benevento, in the south, with its neighbour Spoleto, threatened at one time to be a separate principality, and to the last resisted the full claims of royal authority at Pavia.

The kingdom of the Lombards lasted from Alboin (568) to Desiderius (774), but it was never complete in point of territory. Throughout the greater part of this period there were three capitals in Italy—the Lombard Pavia; the Latin Rome; the Greek Raven,,. It was, moreover, long before the Lombards became amalgamated with the Italian population, and the process was far from complete when the kingdom came to an end. The Lombards were profoundly influenced by Italian civilization. They ultimately accepted Catholic Christianity, and they allowed the subject Italian population to live under Roman law; their charters are full of formulas derived from the phraseology of the Roman private deed. Nevertheless throughout this period the Lombards were essentially aliens in Italy. They threatened the independence of the papacy. and it was hostile. The new element they introduced into the Italian complex of races was never strong enough to dominate Italy as the Franks dominated northern Gaul.

Authari married Theodelinda, a daughter of Garibald, duke of the Bavarians. She played an important part in Lombard history as the mediator between the Lombards and the Catholic Church. Authari died shortly after his marriage (591), but Theodelinda had so won the Lombard chiefs that they bid her as queen choose the one among them whom she would have for her husband and for king. She chose Agilulf, duke of Turin (592–615), who remained an Arian but was favourably disposed both to peace and to the Catholic Church. The Arian and Catholic bishops went on for a time side by side; but the Lombard kings and clergy gradually yielded to the influences around them. Gregory the Great recognized that the empire could never expel the Lombards, and tried to promote peace between the Italians and Agilulf. Under these conditions the pope and the king of the Lombards naturally became the two real powers in the north and centre of Italy.

Agilulf was followed, after two unimportant reigns, by his son-in-law, the husband of Theodelinda's daughter, King Rothari (636–652), the first Lombard king to issue a body of law in his own name. From Rothari (d. 652) to Liutprand (712–744) the Lombard kings strove to enlarge their boundaries, and contended with the aristocracy of dukes inherent in the original organization of the nation. Their old enemies the Franks and the Slavs or Huns, ever ready to break in on the northeast, and sometimes called in by mutinous and traitorous dukes of Friuli and Trent, were constant and serious dangers. By the popes they were always looked upon with dislike and jealousy; with the Greek empire there mas chronic war. In the last phase of the kingdom it produced two rulers of unusual ability. Liutprand, who destroyed the independence of the great southern duchies, Benevento and Spoleto, and Aistulf who threatened Rome itself. Their success led directly to the events which brought the Lombard kingdom to an end. The popes, thoroughly alarmed, and hopeless of aid from the east, turned to the family which was rising into power among the Franks of the west, the mayors of the palace of Austrasia. Pope Gregory

III applied in vain to Charles Martel. But with his successors Pippin and Charles the popes were more successful. In return for the transfer by the pope of the Frankish crown from the decayed line of Clovis to his own, Pippin crossed the Alps, defeated Aistulf and gave to the pope the lands won by the Lombards from the empire, Ravenna and the Pentapolis (754–756).

Finally. invited by Pope Adrian I, Pippin's son Charlemagne once more descended into Italy. As the Lombard kingdom began, so it ended, with a siege of Pavia. Desiderius. the last king. became a prisoner (774), and the Lombard power perished. Charlemagne, with the title of king of the Franks and Lombards, became master of Italy.

For the subsequent history see the article ITALY. For the Lombard league see the articles under that title and COMMUNE: Mediaeval. See also T. Hodgkin. Italy and Her Invaders, vol. v and vi, 2nd ed. (1916) and bibliography in V. Chevalier, *Répertoire* des Sources *Historiques* du Moyen Age (1905). (R. W. C.; X.)

LOMBARD'S KOP, BATTLE OF: see SOUTH AFRICAN WAR, 1899–1902.

LOMBARDY, a region of northern Italy, bordered north by Switzerland, west by Piedmont, south by Emilia and east by the Veneto and Trentino-Alto Adige. It covers an area of 9,191 sq.mi. and is the fourth largest region of Italy.

Physical Features. — Physically, it may be divided into three zones: a northern, mountainous zone; a median, hilly zone; and a southern, flat zone. The northern zone is divided into the Alpine and pre-Alpine zones. The Alpine zone, where crystalline rocks prevail, comprises part of the Lepontine and the Retiche Alps, the Orobie Alps, the Ortles and the Adamello. In the Bernina it reaches a height of 13,304 ft. and has many glaciers. The pre-Alpine zone. mostly calcareous, though also dolomitic, attains less elevated heights, although it occasionally rises above the 8,000-ft. line, but it is particularly beautiful at some of its massifs, such as the Grigne. The hilly zone, partly composed of a morainic material with some morainic amphitheatres, is gently undulating. The alluvial plain, sloping northwest-southeast. is divided into high and low areas; the former has a gravelly soil, poor in superficial water; the latter. nith plentiful moisture content, is separated from the former by the "spring line." where the waters, hidden in the subsoil at the higher level, gush out.

Lombardy has many rivers, all tributaries of the Po. The principal are the Ticino; the Adda, with its affluents the Brembo and Serio; the Oglio, with its affluents the Mella and the Chiese; and the Mincio. The Valtellina, and the valleys Brembana, Seriaria, Camonica, Trompia and Sabbia, traversed by these rivers, are among the most beautiful in Italy. Lombardy has many Alpine, pre-Alpine and inframorainic lakes: part of Lake Maggiore and Lake Lugano, both shared with Switzerland; Lakes Como and Varese; the Lakes of the Brianza (Pusiano, Annone, Alserio, Segrino); Lake Iseo; Lake Idro; and Lake Garda, the largest Italian lake.

The climate, though in the main continental, is variable, because of great differences of height and the presence of large water areas; it is most continental on the lower plain at Milan, Pavia and Cremona. The rainfall, not less than 24 in. annually in the area near the Po, reaches 80 in. in the mountainous regions.

Population.—Lombardy has a larger population than any other Italian region. In 1951 it had a population of 6,566,154, which had increased to an estimated 6,721,767 by Dec. 31, 1954. Of the total population of Italy, therefore, 14% lived in Lombardy, which covers only 6.9% of the total area, with a density of 276 inhabitants per square kilometre, only surpassed in Campania and Liguria. The density is greatest in the pre-Alpine zone and on the plains, which accounts for the intense economic, agricultural and industrial development of the region.

A table giving area and population of the various provinces will be found in the article ITALY.

Agriculture, Industry, Communications. — Agriculture, especially in the plains, is industrialized, and high productivity is achieved by scientific use of fertilizers and by irrigation. Grasslands, where grass is mown up to eight times a year in the *marcite* (flooded meadows), cereal growing (rice, wheat and maize) and sugar-beet cultivation are characteristic of the low plains; the higher plains grow cereals, green vegetables, fruit trees and mulberries. The hilly zone has fruit and chestnut trees; the climate and soil around the lakes are specially suitable for olive trees and limes; in the pre-Alpine zone vines grow at altitudes as high as 2,400 ft above sea level; and on the Alps there is excellent grazing. In the alpine hamlets cattle breeding is scientifically practised and there is a livestock production of 1,700,000 head, of which half are milk producing; there are 500.000 pigs and 100.000 sheep, bred for wool and meat. Honey is another important product. Lombardy ranks third, after Veneto and Friuli, for production of silk cocoons.

A national park, of about 350 sq.mi., for the preservation of the indigenous fauna, was set up at Stelvio in 1935.

The development of industry began earlier in Lombardy than in any other Italian region; metal. paper, textile and leather industries were started at a remote date. Despite the necessity for importing many raw materials (metal, cotton, etc.) the great modern industries (engineering, metallurgical, electrical, chemical, textile, etc.) and flourishing crafts include 16% of all Italian firms and employ 25.2% of the working population. Installed motive power — electricity and methane gas—is 30% of the total production. The state draws from Lombardy 25.7% of its revenue; Lombardian savings constitute 20% of the national total.

There are excellent road and rail communications, the latter radiating from Milan (pop., 1951, 1,260,609). Other towns with over 100.000 estimated population are Brescia and Bergamo.

For the history of Lombardy, see LOMBARDS and ITALY. (A C.)

LOMBOK, one of the Lesser Sunda Islands, Indonesia, lies due east of Java, with the island of Bali between it and the Javanese coast, the Lombok strait separating it from Bali. Lombok has an area of 1,825 sq.mi It is very mountainous, being divided for nearly its whole length by two mountain chains, separated by a valley, which slopes upward, gradually, in terrace formation, and is broken in the centre by a ridge of low hills. The southern chain, which runs from southeast to south-southwest. does not exceed 1,000 ft., but the northern chain, beginning with Gunong Wangsit, 11½ mi. N. of Ampenam, rises eventually to 12,224 ft. in Gunong Rinjeng or Rinjani (the Peak of Lombok) one of the highest volcanoes of the Malay archipelago. Lower peaks flank the mountain, united by a plateau 7,200 ft. in height, and containing a fine lake, Danu (Segara Anak). Of the many small rivers none is navigable. The coast is very bold in places, with cliffs rising precipitously from the sea, but there are good anchorages in bays on the west and east coasts.

The flora includes, among the palms usual to the tropics, a great palm, a species of Corypha, which is a striking feature of the plains, and several Australian forms. The fauna comprises monkeys (*Macacus* cynomolgus), deer and wild pigs and many beautiful birds, large green pigeons, eight kinds of kingfishers, a ground thrush (Pztta concinna), grass-green doves, little crimson and black flower peckers, large black cuckoos, king crows, golden orioles and fine jungle cocks, and dragon flies abound.

For the scientist, Lombok possesses particularly great interest, in that it is the most westerly point of a former Australian or Pacific continent which must have broken up before Java, Sumatra, Bali, etc., were separated from Asia, and probably before the extreme southeastern portion of Asia was raised above the waters of the ocean.

Lombok strait, which has depths exceeding 600 fathoms, marks the edge of the Asian continental shelf. Alfred Wallace (1823–1913) (*q.v.*) drew a line from the strait northward, between Celebes and Borneo, and then passing eastward, between the Sangir Islands and Mindanao, into the Pacific ocean, to denote the frontier between the Asian and the Australian regions, which has been known since as the Wallace line. It is supported by the fact that there are marked differences between the flora and fauna of Bali and Lombok, the barbets, fruit thrushes, and woodpeckers of the former being practically unknown in the latter, while the cockatoos, honeysuckers and mound builders (Megapodidae), of Lombok are equally foreign to Bali.

Later observations, however, established that some intermingling of species is taking place.

The population of Lombok (1957 est.) was 1,252,157, composed largely of Sasaks, the indigenous inhabitants of the island, of Malayan origin and akin to the indigenous population of the neighbouring island of Sumbawa, with some Balinese who confine themselves mostly to the northwest. The Sasaks, who are Muslim, built villages and houses after the Balinese pattern, and followed customs resembling those of the Balinese under whose domination they came. Sasaks use the Balinese script for writing, and their literature consists of Javanese and Malayan translations. Clothes and mats are woven, and there are workers in gold, silver and iron. The people also cultivate rice and coffee.

Mataram, the chief town and trade centre, is a short distance inland from Ampenam, the chief port of Lombok, which is on the western coast; the port of Labuan Hadji is on the east coast.

As early as 1640 Lombok was regarded by the sultan of Macassar as being under his rule, and when his power was shattered by the Dutch in 1667–68, a Sumbawa chief, signatory to the Bongay contract, endeavoured to impose his sovereignty on the island, in which the Dutch assisted, peacefully. Civil war in Sumbawa left Lombok the prey of first pirate adventurers from Macassar and later of the Balinese who planted colonies in north Lombok and set about establishing their rule. Balinese intervention commenced about 1692, and eventually the Balinese succeeded in establishing four kingdoms in Lombok: Mataram, Karang Asem, Pagasangen, and Pagutan.

In 1843 Mataram entered into a contract with the Dutch, agreeing to acknowledge Karang Asem in Bali as the suzerain power. In 1849 the Dutch were at war with Karang Asem and Klungklung in Bali, and were assisted by Mataram, which, as a reward, was given Karang Asem (Bali), as a fief. But in 1872, Mataram refused to send its regular embassy to Batavia and, in 1891, interfered in the domestic politics of Bali.

At the same time it cruelly oppressed the Sasak population of Lombok, so that the latter made ineffectual attempts to throw off the Balinese yoke, finally invoking Dutch aid. This was given, and in 1894, after one expedition had met with disaster, a second was successful in overthrowing the government of Mataram. Lombok was made a division of the residency of Bali and Lombok, under an assistant resident at Ampenam, and was divided into two districts, East and West Lombok; a third district, Central Lombok, was created in 1898, the capitals of the three districts being at Mataram, Praja and Sisi. During World War II Lombok was occupied by the Japanese. It became part of the republic of Indonesia after the war. (E. E. L.)

LOMBROSO, CESARE (1836–1909), Italian criminologist, whose interests centred on the relation between mental and physical disorders, was born on Nov. 18, 1836, at Verona. He studied at Padua, Vienna and Paris, and in 1862 became professor of psychiatry at Pavia, then director of the lunatic asylum at Pesaro and later professor of forensic medicine and of psychiatry at Turin, where he eventually filled the chair of criminal anthropology.

He held that the criminal population exhibits a higher percentage of physical and mental anomalies than noncriminals; and that these anomalies are due partly to degeneration, partly to atavism, or reversion to a primitive evolutionary stage. He contended that criminals can be identified by certain "stigmata" or physical characteristics. Although most of Lombroso's theories were discredited, he worked in a practical way for a more humane and constructive treatment of convicts. *(See* CRIMINOLOGY.)

His *Crime, Its Causes and Remedies* was translated by Henry P. Horton (1911). Lombroso died at Turin on Oct. 19, 1909.

See also T. L. Ferrero, *Criminal Man According to the Classification of Cesare Lombroso* (1911); M. E. Paul (trans.), *C. Lombroso, a Modern Man of Science* (1911).

LOMÉNIE DE BRIENNE, ÉTIENNE CHARLES DE (1727–1794), French politician and ecclesiastic, was born at Paris on Oct. 9, 1727, of a Limousin family, dating from the 15th century. After a brilliant career as a student he entered the church. In 1752 he was appointed grand vicar to the archbishop of Rouen, in 1762 bishop of Condom, and in 1763 archbishop of Toulouse.

In 1770 he became an academician. He was on three occasions the head of the *bureau de jurisdiction* at the general assembly of the clergy; he addressed to Turgot a number of *mémoires* on political and social questions, one of them, treating of pauperism, being especially remarkable. As president of the assembly of notables (1787) he attacked the fiscal policy of Calonne, whom he succeeded as head of the *conseil des finances* on May 1, 1787. He made the *parlement* register edicts dealing with internal free trade, the establishment of provincial assemblies and the redemption of the *corvée*. To crush opposition to the stamp duty and the proposed new general land tax the *parlement* was exiled to Troyes (Aug. 15, 1787), and only returned to Paris on its agreement to an alternative plan prolonging for two years the tax of the two *vingtièmes* (a direct tax on income). But a further attempt to force the *parlement* to register an edict for raising a loan of 120,000,000 livres met with determined opposition.

The struggle of the *parlement* against the incapacity of Brienne ended on May 8 on its consenting to an edict for its own abolition; but with the proviso that the states-general should be summoned to remedy the disorders of the state. Brienne, who had been made archbishop of Sens, now had to face almost universal opposition; he was forced to suspend the *Cour plénière* which had been set up to take the place of the *parlernent,* and himself to promise that the states-general should be summoned. On Aug. 29, he had to retire, leaving the treasury empty. On Dec. 15 following, he was made a cardinal, and spent two years in Italy. After the outbreak of the Revolution he returned to France, and took the oath of the civil constitution of the clergy in 1790 *(see* FRENCH REVOLUTION).

He was repudiated by the pope, and in 1791 had to give up the biretta at the command of Pius VI. Both his past and present conduct made him an object of suspicion to the revolutionaries; he was arrested at Sens on Nov. 9, 1793, and died in prison, on Feb. 16, 1794.

The chief works published by Brienne are: *Oraison funèbre du Dauphin (1766)*; *Compte-rendu au roi* (1788); *Le Conciliateur,* in collaboration with Turgot (Rome, Paris, 1754). *See* also J. Perrin, *Le Cardinal Loménie de Brienne . . . épisodes de la Rdvolution* (Sens, 1896).

LOMOND, LOCH, the largest and most beautiful of Scottish lakes, situated in the counties of Stirling and Dunbarton. It is about 24 mi. long; its width varies from 5 mi. toward the south end to $\frac{1}{3}$ mi. at the north; the greatest depth is 623 ft. It is only 23 ft. above sea level. It contains 30 islands, the largest of which is Inchmurrin, with the ruins of Lennox castle, and 24 of which form an archipelago at the widest part of the loch. From the west the loch receives the Inveruglas (where is the powerhouse of a hydroelectric scheme), Douglas, Luss, Finlas and Fruin rivers. In the south it discharges through the Leven to the Clyde. From the east it receives the Endrick, the Blair, the Cashell and the Arklet. From the north it receives the Falloch. The narrow northern end of the loch lies between Ben Vorlich on the west and Beinn a Choin and Stob-an Fhainne on the east, but Ben Lomond (3,192 ft.), on the east but farther south, dominates the landscape. A good road follows the western shore and another leads from the Trossachs to the eastern shore at Inversnaid.

LOMONÓSOV, MIKHAIL VASILIEVICH *(c.* 1711–1765). Russian poet and man of science, was born in the village of Denisovka (the name of which was afterwards changed in honour of the poet), situated on an island not far from Kholmogorî, in the government of Archangel. His father, a fisherman, took the boy into his trade at the age of ten, but he had a passion for learning, and made his way to Moscow when he was 17. There he obtained admission into the Zaikonospasski school, and in 1734 he was sent from Moscow to St. Petersburg (now Leningrad). There he was chosen as one of the young Russians sent to complete their education in foreign countries. He studied metallurgy at Marburg; he also began to write poetry, imitating German authors, among whom he is said to have especially admired Günther. His Ode *on the Taking of Khotin from the Turks* was composed in 1739. On his return to Russia he was made professor of chemistry in the university of St Petersburg;

he ultimately became rector, and in 1764 secretary of state. He died in 1765.

In the history of Russian letters he is above all important as the man who reformed the Russian language and helped to make it an effective literary medium by his Rhetoric, his Russian *Grammar*, and his essay *On the Use* of *Sacred* Books in the *Russian* Tongue. His task was to find a middle course between the complicated Slavonic language used in the church services, with its elaborate syntax derived from Greek, and spoken Russian. Not only did he fix the literary language, but he wrote magnificent verse which had an enduring effect on later Russian poetry.

LONDON, JACK (JOHN GRIFFITH LONDON) (1876–1916), U.S. novelist. was born at San Francisco, Calif.. on Jan. 12. 1876. He soon moved to Oakland, Calif., where, as he recounts in his autobiographical *John* Barleycorn (1913), he quit school at 14 to escape poverty and gain adventure. In his sloop he explored San Francisco bay, alternately stealing oysters and working for the law, as told in Tales *of* the Fish Patrol (1905); he roamed as far as Japan as a sailor on a sealing cruise; and he saw much of the United States as a member of Kelly's Industrial army (a protest group, born of the panic of 1893, that originated in California and staged a march on Washington) and later as a railroad tramp, riding the rods as described in The *Road* (1907). Observation of depression conditions, fortified by a prison term for vagrancy, turned him in 1894 to Marxian socialism. a doctrine he supported for most of the rest of his life. Rebelling against becoming "a work beast," he crammed high school into one year, took a semester's work at the University of California, and energetically set out to write, supporting himself with odd jobs as narrated in *Martin* Eden (1909).

A winter in the Klondike during the gold rush of 1897 gave London his real start as a writer and supplied him with material for much of his best fiction. Combining his experience with ideas concerning evolution absorbed from Darwin and Spencer, and narrative techniques learned principally from Kipling, he gained a wide audience with his first book, *The Son* of the *Wolf* (1900). During the remainder of his short life he produced steadily. completing 50 books in 17 years. As his writing rested partly on reportorial elements. he constantly sought new scenes and experiences; thus, he lived in the London slums to get material for The People of *the* Abyss (1903); he served as a correspondent in the Russo-Japanese War; and he sailed a ketch to the South Pacific, telling of his adventures in The *Cruise* of the *Snark* (1911) and using the locale in many stories. In 1910 he settled on a large ranch near Glen Ellen, Calif.. where he experimented with farming techniques and built his grandiose "Wolf House," which burned before completion. He died at his ranch on Nov. 22, 1916.

Though his writing was uneven. London produced a number of forceful novels and short stories. Besides those mentioned above. the following are outstanding: *The* Call of the *Wild* (1903). *White* Fang (1906) and *Burning Daylight* (1910), in which he dramatized in turn atavism, adaptability and the appeal of the wilderness; and The Sea-Wolf (1904), The Iron Heel (1907) and *The* Valley of the *Moon* (1913), in which he combined adventure with theories about the Nietzschean superman, the future of socialism and the plight of the city worker. respectively. An enthusiast for social progress, he reflected the hopes, conflicts and frustrations of his period.

LONDON, a city of Ontario, Can., the seat of Middlesex county, is 115 mi. S.W. of Toronto, at the forks of the Thames river, 21 mi. N. of Lake Erie and midway between Lakes Ontario and St. Clair. Pop. (1961) 166,818; metropolitan area 178,409. London is a financial, ecclesiastical, medical. educational, military and manufacturing centre; its coat of arms incorporates a locomotive, attesting the continuing importance of transportation in the economy of the city. It is served by all major Canadian railroads and has rail service to Chicago, Ill., and to Detroit, Mich.; there are also excellent highways and a municipal airport.

The name London was first applied to the site when it was chosen, in 1792, for the capital of Upper Canada, but the plan was not acted upon, and there were no buildings until 1826, when the first settlement was made. London was incorporated as a village in 1840, as a town in 1848 and as a city in 1855. This rapid growth was due to its interlake position, its early development as a transportation centre and the excellence of the surrounding land. In 1840 Dundas street, a plank and gravel road, from near Hamilton, was extended to London. and in 1853 the first railroad, the Great Western (now the Canadian National Railways main line), arrived. Thereafter the city grew steadily as a manufacturing, distributing and financial centre. In the 1960s there were over 500 diversified manufacturing industries producing a wide range of goods, including breakfast cereals, biscuits, beer, wine, flour, brass and steel goods, abrasives, diesel locomotives, refrigerators, textiles, hosiery and boxes. There were also printing and lithographing industries.

London is the seat of the Anglican diocese of Huron and the Roman Catholic diocese of London. The University of Western Ontario, with its affiliated medical school, is located there.

(G. FN.)

LONDON, the capital and largest city of the United Kingdom and the centre of the Commonwealth of Nations, is the largest port and industrial town in England. Its ancient heart is the City; a county corporate with an area of 677 ac. and a resident population of 4.771 in 1961. The county of London (excluding the City) consists of 28 metropolitan boroughs and covers an area of 115.9 sq.mi. with a population of 3,190.343 in 1961. Together, the City and the county of London make up the administrative county of London, with a population in 1961 of 3,195,114 and an area of 117 sq.mi., around which is a ring of suburbs conterminous with the Metropolitan Police district. The whole of this area, known as Greater London, covers 721.6 sq.mi. and had a population of 8,171,902 in 1961; it includes the county of Middlesex and parts of Essex, Kent, Surrey and Hertfordshire. The 28 metropolitan boroughs, each of which is noticed in a separate article, are:

1. *North* of *the Thames*.—The following, commencing on the west. lie on the river: Hammersmith, Fulham, Chelsea, Westminster (the City). Stepney and Poplar; north of these, and adjoining the northern boundary, are: Kensington, Paddington, Hampstead, St. Pancras, Islington, Stoke Newington and Hackney; and between these two groups are St. Marylebone, Holborn, Finsbury, Shoreditch and Bethnal Green.

2. *South* of the *Thames*.—Wandsworth, Battersea. Lambeth, Southwark, Bermondsey, Deptford. Greenwich and Woolwich (these touching the river and two small parts of Woolwich being on its north bank). Camberwell and Lewisham.

Geographical Situation.— London is situated in the London basin. which is drained by the lower Thames. The basin is formed by a downfold in the chalk, which underlies all the area between the North Downs and the Chilterns. This downfold is floored with very thick deposits of London clay, an impervious, sticky, water-holding deposit, upon which are scattered remnants of later coverings of sands and gravels.

The general relief of the land is low, the ground rarely rising above 400 ft. There are, nevertheless, two outstanding features. These are, first, the flood plain of the Thames, about 3 mi. wide, rising gently from the river to about 25 ft. (ordnance datum), covered with gravel and alluvial deposits. among which river silt, fine sand and peat predominate. Largely because of the shrinkage of the previously water-logged peat and silt, which took place as a result of embanking and the consequent drying out of these softer elements. the gravels lie generally several feet above the level of the alluvium. Here and there the drop from one to the other can be distinguished in the low relief. Both gravel and silt, however, lie mainly below the level of high tide today, and but for the embankments would be more or less submerged at every high tide and would revert to marshland; the gravels in the neighbourhood of the Thames are saturated with water every time the tide rises.

The second feature consists of two low, undulating plateaus rising above the flood plain to north and south in a couple of usually well-marked terraces covered with gravel. The rise of the southern plateau is continuous with that of the North Downs beyond London. except in the southwest, where a broad, gravel-floored valley, once, possibly, occupied by a precursor of the river Mole, links the Thames at Kingston with the Wandle valley at Merton and isolates the hills of Richmond and Wimbledon. On the north the land rises steadily to the hills of Hampstead and Highgate, and beyond to Finchley and Hendon, but drops steeply to the broad trench of the Lea valley in the east, and more gently to the broad clay valley of the Brent in the northwest. The lower terrace of the plateau, known as the Taplow terrace, lies between 50 and 100 ft. above sea level and drops somewhat steeply to the flood plain 25 ft. or so below. It may be easily distinguished in the steep descent from the Strand to the Embankment, or from Upper and Lower Thames street to the river, or in the drop from St. Giles's to Charing Cross. Above this terrace a higher one may be distinguished, generally referred to as Boyn hill terrace. It lies between 100 and 150 ft. above sea level; gravels which represent its floor form the greater heights of Richmond hill and Putney common and cap the spur of Islington hill.

The Thames winds in broad, tidal meanders between the edges of the flood plain, cutting now into the northern, now into the southern rim. Before its regulation and confinement between embankments. backwaters and ancient channels surrounded many sandy islands along its course. The names of some of them are perpetuated in the districts of Battersea, Bermondsey and Chelsea. A group of such islets filled the angle that the river makes at Lambeth, the most northerly being the famous Thorney, on which the Abbey of St. Peter (the predecessor of Westminster abbey) was founded. The broad, shallow course of the Thames as it crossed the flood plain from Lambeth toward Charing Cross was probably a fordable reach in Roman times, and there has been much conjecture as to the probability of the crossing of the Roman road in the neighbourhood of Westminster (or even of Lambeth) bridge. before its diversion to pass through the City. The northern section of the Watling street seems to trend toward a crossing there. and rhe alignment of the road along the edge of the Tyburn valley could be laid out from the high ground west of the Darent, south of the Thames, near the known end of the southern section of the street. But the remains of Roman occupation are so few at Westminster that it is unlikely that the Watling street ever crossed the Thames by ford or ferry there.

Just below Westminster and Whitehall the river takes a sharp bend to the east and flows for a couple of miles at the foot of the Taplow terrace, leaving a great stretch of reclaimed marsh to the south, occupied now by Lambeth, Southwark, Bermondsey and Rotherhithe. As a result of the set of the current against the northern shore in this reach, the river is deeper and narrower than at Westminster or—farther downstream—at the Isle of Dogs, where it is relatively broad and shallow. Across the brink of the gravel terrace which there directly overlooks the Thames, several small tributary valleys have been trenched, cutting the terrace into low hills which drop abruptly about 40 or 50 ft. to the river, and slope steeply to the side valleys that separate them.

Two of these small hills appear to have formed the site of the earliest London. which, according to one widely held theory, began its existence with the construction of a bridge across the Thames by the Romans. The selection of the site by the Romans would be based on the practicability of an approach and crossing as far downstream as possible. As regards approach there is no place on the north bank except this stretch between the Tower of London and Waterloo bridge where the 50-ft. contou- line approaches the river, until Staines is reached. This steep bank washed by relatively deep water would facilitate approach from the north and by river, but the crossing of the flood plain from the south must always have presented difficulties. It is this great expanse of marshland south of the City that lends support to a theory that London arose, not as a river crossing, but as the river port of Verulamium (St. Albans) with which it communicated by the ridgeways between Colne and Lea and by the two tributaries themselves. The Thames and the flood plain have afforded ample evidence that the river was a highway from earliest times, and that it formed a line of communication with the continent and the numerous small riverside settlements long before the Roman invasion. The steep edge which the two hills present to the deep river at London and to the stream valleys that isolate them, must have made defense of the site relatively easy. The gravel that covers the hills provided London's earliest water-supply, for the banks of the small tributaries oozed with springs. Many of these were important throughout mediaeval times and their names are still household words—St. Bride's well, Clerkenwell, St. Clement's well and Holywell, for instance; the Roman bath in Strand lane is still fed by water percolating through the gravels. Apart from ease of access and capability of defense, other physical conditions conducive to settlement would be the abundance of food and building materials. Fish, including salmon, was plentiful in the Thames; game, as well as timber—invaluable both for constructional purposes and as fuel—flourished in the great forest of Middlesex, behind, while the Taplow terrace was covered with brick earth which provided a light, rich soil as well as material for brickmaking.

The later growth and development of London was strongly influenced by the distribution of the terrace gravels. Settlement only advanced into the flood plain where embankments provided protection from flooding or where small hummocks of gravelly material caused a slightly greater elevation. Outside London it was the Taplow gravels and the Upper Tertiary and Drift gravels remaining in scattered fragments on the London clay that determined the settlement in villages. Apart from the bridgehead at Southwark, it was not until water could be brought from a distance and distributed widely in pipes, and until scientific drainage and sewerage were introduced, that settlement of any density was possible on the flood plain or on the London clay; even today large areas of the latter and of the alluvial marshland remain untenanted. Apart from the Thames gravel terraces, which have played so important a part in the site and expansion of London, and the small patches of gravel that provided sites for villages in the low-lying clay valley of the Brent, the sands and gravels of the London basin, where they cover large areas, have not been conducive to settlement, for they provided but poor soil. Much of the land became common grazing land and has been preserved as open common, for it is to these sandy and gravelly patches that London owes many of the high open spaces which are such an asset to the modern metropolis.

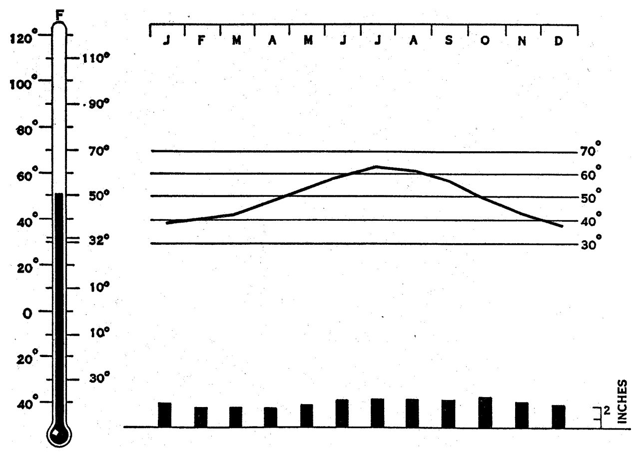

FIG. I.—WEATHER GRAPH OF LONDON. THERMOMETER SHOWS NORMAL ANNUAL MEAN TEMPERATURE; THE CURVE, MONTHLY MEAN TEMPERATURE AND THE COLUMNS. NORMAL MONTHLY PRECIPITATION

Climate.—The climate of London is equable and the weather variable because of the steady indraught of warm moisture-laden winds from the Atlantic and the frequent passage of cyclones, whose southern quadrants usually cross the London basin. Prevailing winds are from the southwest. As a result of the shelter afforded by the Chilterns and the North downs, and occasional inclusion within continental climatic influences in winter, London has a smaller rainfall than the Wealden or Chiltern areas. It

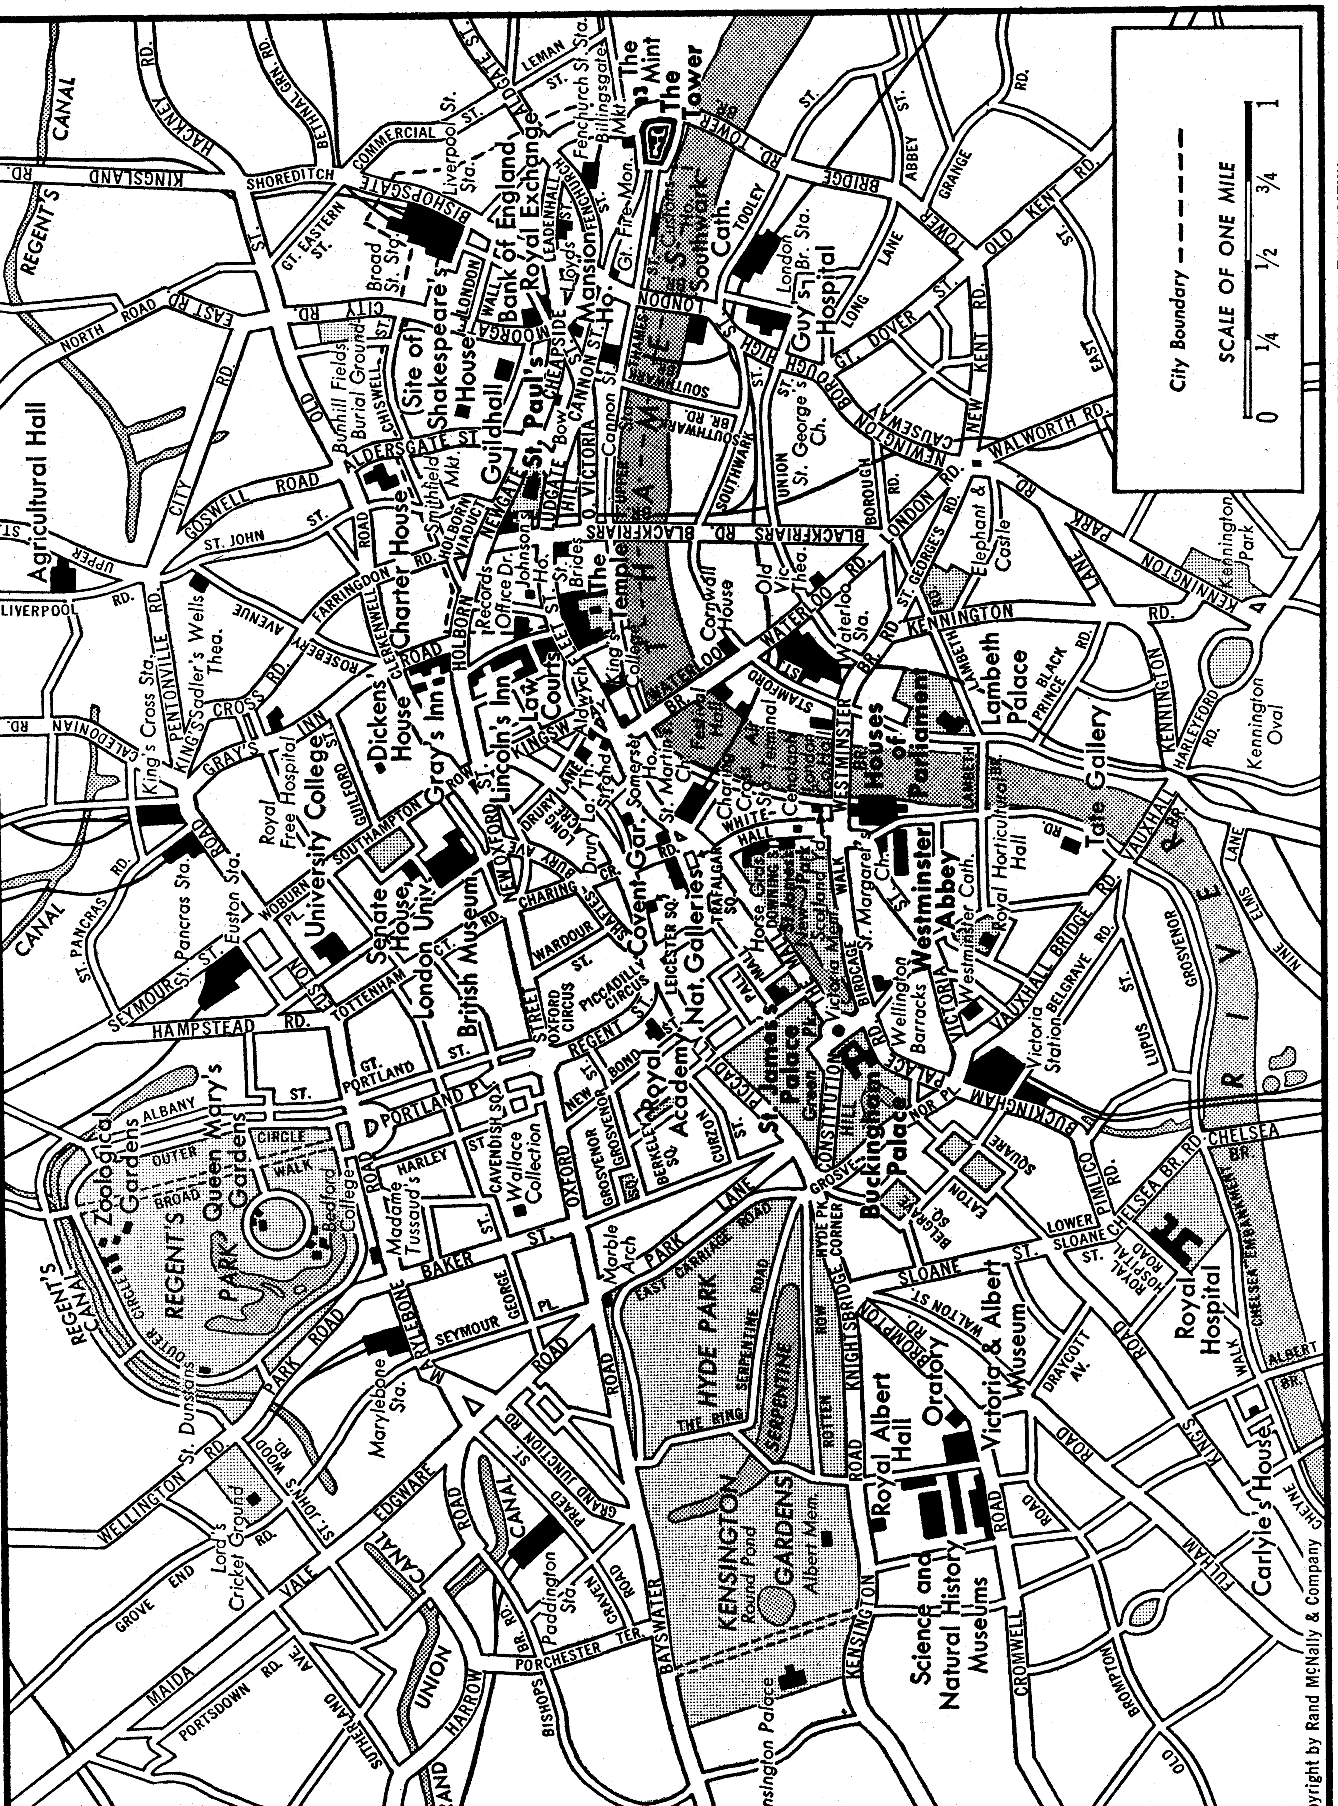

FIG. 2.—MAP OF THE MAIN DISTRICTS OF LONDON SHOWING LOCATION OF PRINCIPAL STREETS, RAILWAY STATIONS AND BUILDINGS, AND BOUNDARY OF THE "CITY"

has also a greater range of temperature and would experience more sunshine but for the pall of smoke that sometimes shuts out the sky in the winter half of the year. The mean annual temperature is 50° F.; the mean annual rainfall is about 23½ in. (H. OR.)

London's Lost Rivers.—Four northern tributaries of the Thames helped to form the physical site of London, and two of them determined the situation of the first town of which there is reliable historical record. From east to west these tributaries are the Walbrook, the Fleet, the Tyburn and the Westbourne. They are all lost rivers in the sense that none of them reaches the Thames above ground, and there are streets or thoroughfares named after all except Tyburn, that sinister name having been lost when the Marble arch moved to its present site in 1851.

The Walbrook rose in the marshy ground near Finsbury circus, pierced the Roman wall through a culvert, received one or more feeders in the region of the Mansion house and became a tidal stream slightly west of the streets named Walbrook and Dowgate. There can be no doubt of the antiquity of the name (the earliest mention of Walbroke street is in a charter of Henry III, 1236) nor of its early importance for shipping; the small vessels of the day were sailed or warped up it as far as Bucklersbury. Moreover the banks of the Walbrook were a favourite site for the houses of well-to-do Romans or romanized Britons.

Nevertheless excavation in 1953 showed that the mapping of an estuary with a wide mouth in the *Roman London* volume published by the Royal Commission on Historical Monuments has little relation to the ascertained facts. The Walbrook had three bridges across it; by John Stow's time (c. 1525–1605) it had become choked up and was hardly discernible. Today its valley is marked by a slight dip in Cannon street near the station.

The Fleet now flows into the Thames through two large sewers to be seen under Blackfriars bridge at low tide. It comes from the Highgate ponds. Stow's identification of the upper part of the stream as the River of Wells, mentioned in a charter of William I, is doubtful; its course is not. The stream flowed through Kentish Town. Camden Town and Somers Town to Battle bridge (subsequently King's Cross) and then through a deep channel in the gravel under what is now Holborn viaduct, Farringdon street and New Bridge street to the Thames. The tidal portion only was known as the Fleet (Flete ditch, 1278; Fleote, 1311; with other forms). Three bridges crossed this tidal part; and Seacoal lane, near Holborn viaduct, preserves the memory of wharves and shipping (first mentioned 1228). One of these bridges was Fletebrigge, crossing the stream at Ludgate circus. It gave its name to the modern Fleet street (Fletestrete, 1274).

The Tyburn—a Saxon name at least as old as the reign of King Edgar, whose charter to the monks of St. Peter, Westminster, calls it Theoburnan—gave its name to the gallows at Tyburn Tree (see TYBURN). At present the stream provides the beautiful stretch of water in Regent's park. Its source was in Hampstead near Swiss Cottage, and it flowed west of Primrose hill to Regent's park, took the course followed still by Marylebone lane (hence the latter's windings) and crossed Piccadilly near Half Moon street (where a dip can still be seen). Thence it flowed across the Green park and to the Thames (this stretch is now in a sewer) a little west of Vauxhall bridge. This little stream formed the marsh now drained and covered by Buckingham palace.

The Westbourne, Kilburn or Bayswater brook collected its waters from tributaries on the southern and western flanks of Hampstead hill. Kilburn High road follows part of its course, after which it diverged southwestward, crossed the Bayswater road at Marlborough gate; its bed formed the course which was widened into the Serpentine in the 1730s by order of Queen Caroline. The stream flowed under the Knight's bridge. where the highway was often flooded. and gave London another modern name. Pipes still carry the water across Sloane square station and can be seen from the platforms. From there the waters formed a marshy area near Ebury bridge.

A succession of streams enters the Thames from the south of London and drains an area between Deptford and Croydon. The Ravensbourne, Effra and the Wandle are the best-known, and their waters supply ponds or ornamental waters at Catford, Dulwich and south Wimbledon; only one of them, however. the Effra, qualifies as a "lost river" by reason of a partially underground course.

Thames Embankments.—The Victoria embankment, from Blackfriars bridge to Westminster and commonly known as "the Embankment," was opened in 1870 by the prince of Wales (later Edward VII). It had taken six years to construct, and 373 ac. of mud was reclaimed for public gardens, a roadway 100 ft. wide and the District railway underneath. The project originally arose from the necessities of main drainage; it was found that an embankment would cost no more than to run the pipes along the foreshore; accordingly these are installed behind the river wall. Before the embankment was made, the river front was disfigured by dilapidated buildings and offensive mudbanks. The Chelsea embankment, a mile long and providing for a roadway of 70 ft., also accommodates main drainage; it reclaimed 9½ ac. of foreshore. This embankment, which runs from west of Chelsea bridge to Battersea bridge, was opened by the duke and duchess of Edinburgh in May 1874. Together the Victoria and Chelsea embankments—with Grosvenor road, constructed at the same time—provide a continuous riverside communication (broken only between Lambeth bridge and Westminster) of about 4½ mi. The Albert embankment. on the south side opposite the houses of parliament, was opened in Nov. 1869 and had its origin in the need for flood prevention; 8½ ac. of foreshore was reclaimed and on this St. Thomas's hospital was built and a 70-ft. promenade constructed. A fourth embankment in front of the County Hall was opened in 1910. In 1951 this was extended to Waterloo bridge, and gardens were laid out on land denuded of buildings during World War II.

Bridges and Tunnels.—From Roman times until the 18th' century London bridge was the only bridge across the river Below London bridge (1) and on the seaward side of the Pool are now (2) the Tower bridge, completed in 1894. Upriver, within the county of London, are (3) Southwark bridge, the old "Iron bridge," begun in 181j, being replaced by the existing bridge, opened in 1921; its northern approach mas damaged in World War II; (4) Blackfriars bridge, opened in 1769, rebuilt between 1865 and 1869 and widened 1907–09 for tramways; (j) Waterloo bridge. opened 1942 replacing a celebrated bridge erected by John Rennie in 1817; (6) Westminster bridge, erected between 1854 and 1862 to replace a bridge, built between 1739 and 1750, which had become unsafe; (7) Lambeth bridge. opened 1932, replacing a suspension bridge of 1862; (8) Vauxhall bridge, opened 1906, replacing one built just before the battle of Waterloo; (9) Chelsea bridge, opened 1937. replacing a bridge of 1858; (10) Albert bridge, opened 1873, an ugly iron structure; (11) Battersea bridge, opened 1890 and replacing a picturesque timber bridge of 1773 renowned as the subject of a James Whistler picture; (12) Wandsworth bridge, opened 1873 and reconstructed between 1936 and 1940; (13) Putney bridge, 1884–86, widened in 1933, replacing a wooden toll bridge of 1729; (14) Hammersmith bridge, opened 1887 and repaired 1952, replacing a previous suspension bridge of 1827, the first of its kind across the Thames. All these are bridges carrying all kinds of traffic. To them must be added a 1jth, the Hungerford footbridge on the eastern side of Charing Cross railway bridge.

The Thames tunnel, opened 1843, between Shadwell and Rotherhithe, was an attraction to early Victorian Londoners nith its shops and stalls. and it was used as the starting-point of a walk into Kent by east London pedestrians. The tunnel never paid its way and now carries the electric railway service between Whitechapel and New Cross. The London County council (L.C.C.) maintains the Woolwich Free ferry (opened March 1889) and the following tunnels: Blackwall. opened 1897, 6 200 ft. long; Greenwich (foot passengers only) opened 1902, 1.21; ft. long; Rotherhithe, opened 1908, 6,833 ft. long; Woolwich (foot passengers) opened 1y12, 1,6jj ft. long. The L.C C. also controls more than 1.600 wharves and is responsible for flood precautions.

Central **London.**—No such expression is in use officially, but the postal districts W. (West), W.C. (West Central), E. (East)

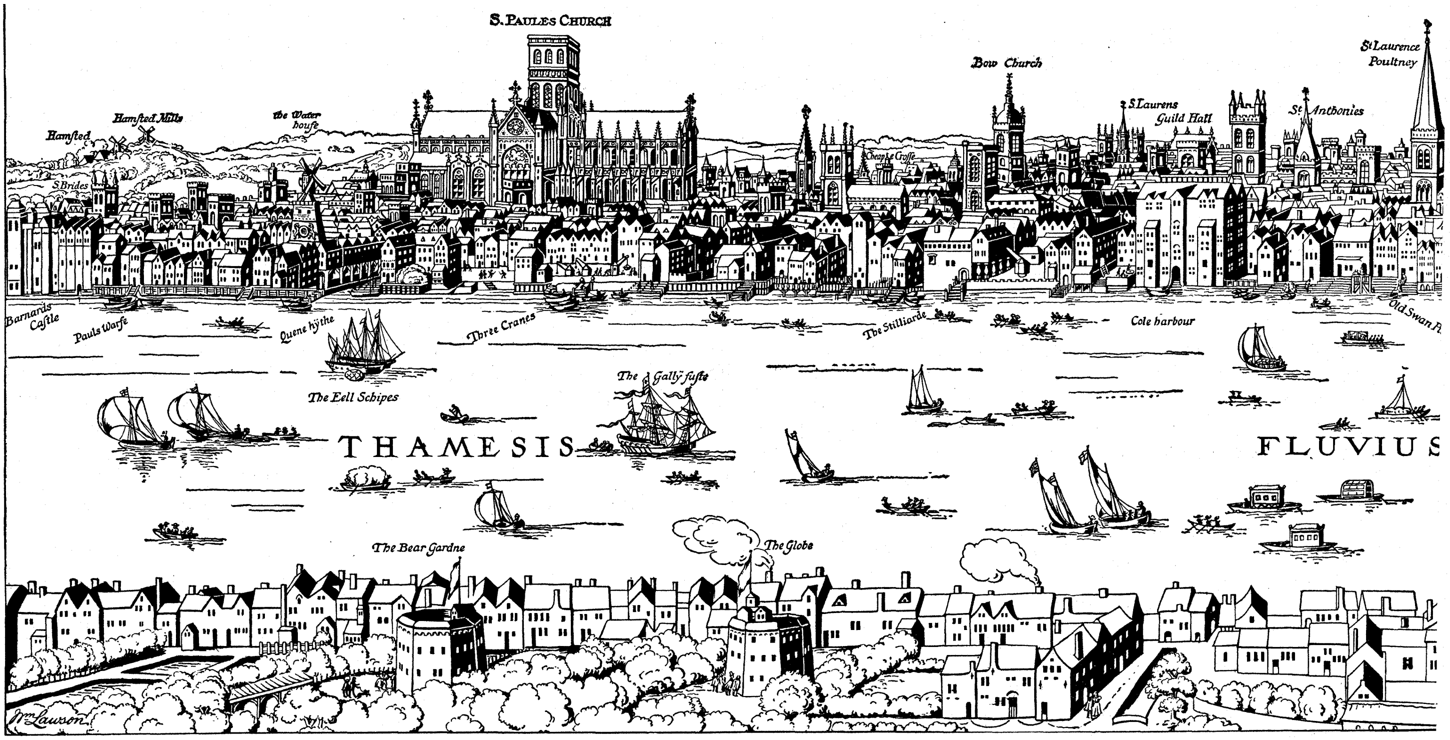

FIG. 3.— VIEW OF LONDON IN THE 17TH CENTURY. FROM THE SURREY SIDE OF THE THAMES, AFTER A DRAWING BY A CONTEMPORARY ARTIST, THE HIGHEST CHURCH IN EUROPE. BEING 520 FT. TO THE TOP OF THE STEEPLE. and E.C. (East Central) define the central area, though they exclude the region south of the river. The southwest postal district by exception groups a suburban district on the south'side with Westminster and much of what is known loosely as the West End. After 1955 Charing Cross was taken as the nodal point of modern London.

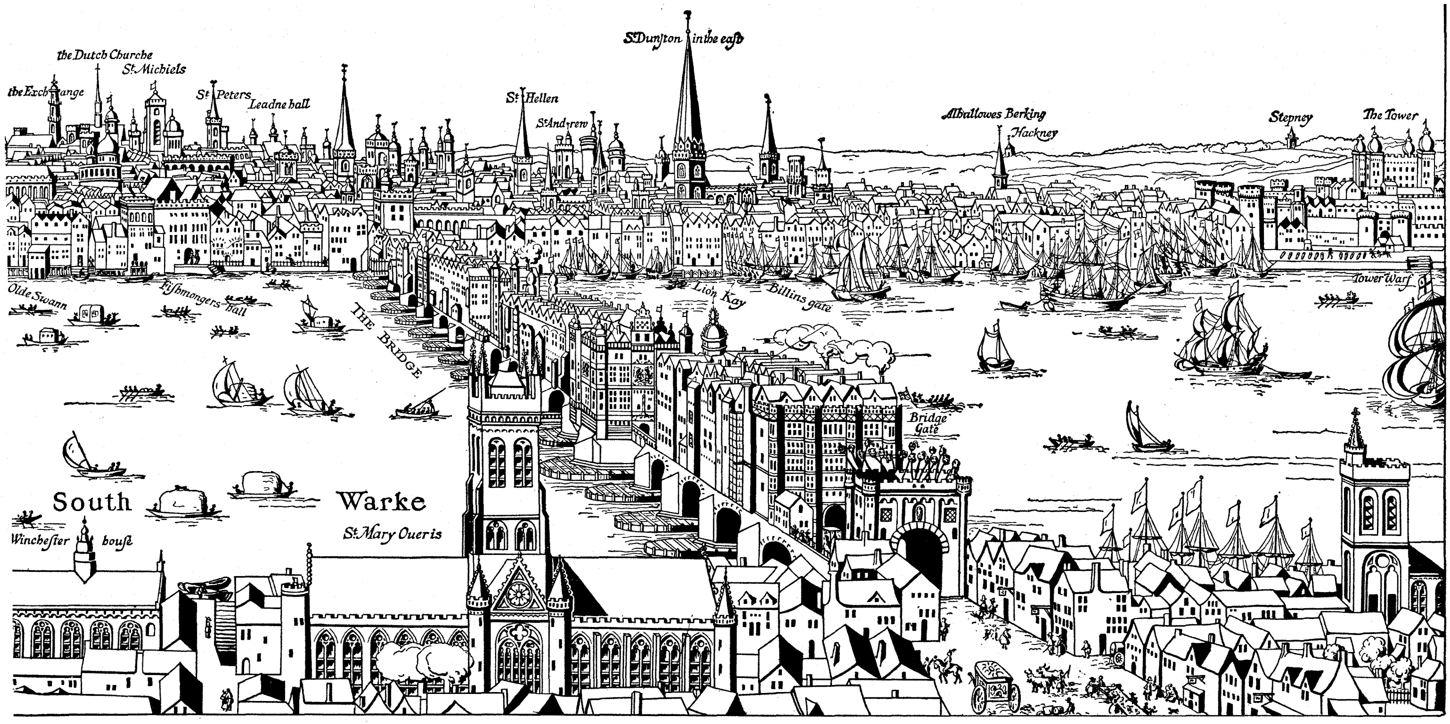
The City.—The antiquity of the City of London forms the background, but the background only, of a vigorous modern life. Within the small area between Temple Bar and Aldgate there are concentrated the Bank of England, the stock exchange! royal exchange, the Mansion house, the head offices of banks, financial houses and insurance offices, shipping companies, wholesale markets, Lloyds, the Baltic, the Wool, Iron and Steel and Coal exchanges, the general post office, telephone and cable headquarters, and the newspaper press and its accessories, the international news agencies and offices of overseas journals. The ratable value of the City in 1949 was £6,344,046 (it had been £507,372 in 1801); and the profits assessed to income tax of firms or persons carrying on business in the City was assessed in 1947–48 at £347,313,000. This was about one-sixth of the total for the United Kingdom. The day population was estimated at 500,000 in 1939 but may well be double that figure. At night the City is quieter than many villages. In 1951 the resident population was only 5,324. In 1563 it was 93,000; in 1801, 128,000; and in 1851, 129,000. By 1871 it had shrunk to 74,000 and has decreased ever since.

The Port of London.—From the earliest times the prosperity, and even the existence, of London depended upon its water-borne trade. This was carried on, however, mith no other docking facilities than were afforded by the two creeks of the Walbrook and the Fleet and two small havens of early construction at Billingsgate and Queenhithe. Billingsgate was mentioned in the De *Institutiones* Lundonie of King Aethelred II; Queenhithe appears under its older name of Etheredshyde in a charter of King Alfred; it became Queenhithe after its grant by Henry I to his wife, Queen Adelaide of Louvain. The Walbrook was used by vessels as far as Bucklersbury up to the 15th century; but it gradually filled up and its course was hardly to be seen at the end of the 16th. The Fleet was navigable to Seacoal lane (which tells its own story), first mentioned in 1287, but silted up, like the Walbrook. Its clearance and conversion into the New canal under William and Mary gave it only a brief renewal of life.

In 1661 the first dock was built at Blackwall and in 1700 the Howland Great Wet dock at Rotherhithe; but the modern system of docks was started only in 1802 with the West India dock, the first to be enclosed. There followed the London dock in 1805, the East India company's dock at Blackwall in 1806, the Surrey Commercial docks between 1807 and 1876, St. Katharine's (1825–28), Millwall (1868), the Royal Victoria (1855) and Royal Albert (1880). In 1886 the first Tilbury dock mas made, extending the port of London nearer the sea. Finally the Port of London authority (P.L.A.) came into existence in 1909, took over the old docks and embarked on a program of construction of which the King George V dock (opened 1921) is the largest. The group of Royal docks at Woolwich make up the largest expanse of impounded water in the world. The P.L.A. controls 69 mi. of river from Teddington lock to the sea. It is not necessary to visit the docks to see the port of London at work. Large vessels are unladen in the Pool of London, providing a continual spectacle; and another viewpoint is from the terrace in front of the Tower.

East London.—Londoners live in a metropolis which has extended in an ill-defined way. The unifying link is the Thames, and the complementary masses are the vague area of the West End and the East End belon London bridge. Unlike the West End, the East End has a precise frontier; it begins at Aldgate Pump. The two regions speak the same language, if with differing accents, and obey the same laws; to a large extent they are unknown to one another. They have the river in common. and without the river and all it means the West End would wither and decay. They differ in that the East End knows the Thames to carry the life and labour on its tides; the West does not.

This other London must be sought in such places as the Whitechapel road, in the ceaseless activity, curiosity and courage of the



VISCHER. ON THE LEFT IS SHOWN "OLD ST. PAUL'S," BUILT DURING THE 12TH AND 13TH CENTURIES AND DESTROYED BY FIRE IN 1666. IT WAS PRIEST. PETER OF COLE CHURCH; BEGUN IN 1176 AND FINISHED IN 1209, AFTER THE ARCHITECT'S DEATH. BY THREE LONDON MERCHANTS. THE HEADS OF CRIMINALS. IN THE 18TH CENTURY THE HOUSES WERE REMOVED. AND IN 1825 THE PRESENT BRIDGE WAS BEGUN

pavement, and the noise and vulgarity wherein resides the essence of the Cockney. Many Jewish, as well as Cockney. faces are to be seen in the Whitechapel road. East London has its Chinatown at Limehouse, and there is a Scandinavian quarter across the river at Rotherhithe. A blended odour hangs over East London. Such a name as Pickle Herring wharf gives a hint, picturesque but inadequate. The blend contains the individual odours of wooden packing cases and damp straw packing, tea, cheese, butter, bacon, rum and spices, vinegar and hot humanity, the shifting scents of ebbing and flowing tides. So with the names and the mingling of past and present: the Isle of Dogs, Bugsby's reach, Galleon's reach. Wapping Old Stairs, and the public houses, the Prospect of Whitby, the Artichoke Tavern and the Town of Ramsgate (where the mob caught Judge Jeffreys).

The West End. — Fashion began to move west from the City as early as the reign of Henry III, who gave the manor of Savoy (now the names of a royal chapel, a theatre and a hotel) to Peter of Savoy, who had married his niece Eleanor of Provence. By 1573 houses of bishops and nobility were continuous on both sides of the Strand, the bridle path along the bank of the river. Henry VIII had begun to demolish the leper hospital on the site of St. James's palace in the year he married Anne Boleyn (1533); and he had almost immediately moved to York house (which became Whitehall palace) on the fall of Thomas Wolsey in 1529. This was the origin of what became known as the West End—an indeterminate region focused on the court. The day of its splendour began after the Restoration, when Charles II walked with his courtiers, his ladies and his spaniels in Birdcage walk. In the 18th century Buckingham house in St. James's park was acquired by Queen Charlotte and was known as "the Queen's house" for some time afterward. The house became Buckingham palace after it had been reconstructed between 1825 and 1836. William IV disliked living in it, and the *Times* of the day criticized its unhealthy situation; but it became the London home of Queen Victoria and the prince consort and has since been the centre of the public life of the sovereign. The main front toward the Mall was refaced in 1912.

The West End embraces the four royal parks: St. James's, Green park, Hyde park and Kensington gardens (275 ac.)—a continuous stretch of lawn, trees, ornamental waters and laid-out gardens — which includes Kensington palace, where Queen Victoria was born. It includes Pall Mall and the clubs, Piccadilly and Piccadilly circus, Regent street, Mayfair, Park lane (no longer the home of multimillionaires but a place of luxury hotels); the houses of parliament and Westminster abbey and most of the great public art collections. Many of the large department stores are in the West End, and such streets as Bond street. Savile row, Regent street and Oxford street have an attraction of their own. Of the squares, big and little, some are highly fashionable, some going down in the world and being invaded by commerce, some with no social pretensions whatever, but all are beautiful, with matured and graceful trees and a general absence of the artificial. The eastern outpost of the West End may be taken as St. Martin-in-the-Fields, Trafalgar square, "the parish church of London" and the pioneer of broadcast services. When Charing was a village, St. Martin's stood among green meadows.

Soho, a cosmopolitan area with many restaurants and provision shops and peopled by Italians, Greeks, Cypriots and other foreigners, lies between Regent street and Charing Cross road and is bounded on the north by Oxford street. East of Piccadilly and particularly in Shaftesbury avenue and the Strand are most of the London theatres.

The Shopping Area. — Bargains are to be found in London, as in Paris and other great cities, in the byways rather than the highways; and part of the collector's pleasure lies in collecting little out-of-the-way shops. London contains some of the most famous shops in the world. The goods displayed are of good quality and any luxury or necessity for any climate or mode of life can be obtained somewhere in London. The chief shopping centres are in Bond street (a name which is almost a trademark for quality goods); in St. James's street and the Haymarket (with hatters and wine merchants dating from the 18th century); Jermyn street. Sackville street and Burlington arcade (for men's high-quality clothing); Piccadilly circus, Piccadilly and Regent street (with shops as well-known as the streets themselves); Victoria street. Knightsbridge, Sloane square and Brompton road. Westward of Oxford circus the region of large stores begins. These are matched or rivalled in Kensington High street and Queensway (formerly Queen's road). Bayswater.

William Whiteley (*q.v.*) was the pioneer of the universal store, Born near Wakefield. Yorks., in 1831, he was a draper's assistant there for four years and then for nine years in London. In 1863 he opened a small draper's shop in Westbourne grove; by 1876 he had 15 shops and 2.000 people working for him. He claimed that he could satisfy any demand and is said to have been tested by a request for an elephant. He came through the test. John Barker (later knighted) established an equally successful business in High street. Kensington, and before his death in 1914 saw it grow to a vast concern with several subsidiary shops. Harrod's. in Brompton road, grew out of a tiny grocery shop belonging in 1849 to Philip Henry Burden. Harry Gordon Selfridge established a well-known Oxford street store in 1909 with 130 departments. The suburbs of London and the East End also contain many thriving large stores and the multiple shop is to be seen nearly everywhere. In 1952 there were 111,742 retail shops in Greater London, representing 132.8 per 10.000 persons.

The Suburbs. — The spread of London westward from the City has already been noticed. The suburbs were a later and continuing development. encouraged and made possible first by the railway building of the 19th century, and later by the "tubes," the bus and electrified train services. Thus was created Greater London, covering a radius of about 16 mi. from Charing Cross. Of the population of Greater London (8,346,137 in 1951) a large number travel to their work in inner London every day. They sleep in "dormitory London." but their lives are concerned for five or six days a week with London proper.

In mediaeval London the word "suburb" was a synonym for "liberty." denoting a privileged area exempt from outside jurisdiction. Such were at first the outlying areas not included in the City walls; and the suburb par excellence was the district between Ludgate and Temple Bar. A charter of Edward III made a grant of land *apud* Flete *in Suburbio London.* Beyond "the suburb" were the villages swallowed up later by the insatiable appetite of the growing capital. A map of 1782 shows such villages as Islington, Hoxton, Stratford-le-Bow. Deptford, Camberwell, Newington, Battersea, Chelsea, Brompton and Paddington as separated from London; while a little farther out Kensal Green, Hampstead. Highgate, Kentish Town. Holloway, Lewisham, Dulwich, Clapham, Kensington and Hammersmith were in open country. Some of these, such as Dulwich, Hampstead and Highgate, still conserved something of their village atmosphere in the 1950s. Newer residential districts farther out and especially where there was an old village nucleus, possess attractive parks; and a notable permanent increase of bright flower beds was fostered by the festival year of 1951 and the coronation of 1953. Some of the suburban centres have grown up into the adult dignity of boroughs with mayors and corporations.

HISTORY

Conjecture and legend have built up a story of the origins of London which will not bear the scrutiny of history or archaeology. Much new material was brought to light about Roman London after World War II; but no structural evidence of a pre-Roman London was produced. The piles of early dwellings in such places as the bed of the Walbrook stream cannot be attributed to a "Celtic capital." A deep excavation made there in 1949 for a new building went down to the blackened piles supporting successive levels of London through 19 centuries. Its history became visible in three layers of burnt ashes representing the sack of London by Boudicca (Boadicea), a fire in Roman times and the Great Fire of London in 1666. On top of all were the rubble and ashes of World War II. The earliest traces of occupation were Roman, of the 1st century A.D. In another part of the City, just outside the Roman town hall near Cripplegate, postwar excavation showed that there had been occupation by a nomad community with primitive habits. It was tempting to guess, in the company of earlier historians, that these had been early London "lake-dwellers." the possible precursors of Celtic inhabitants: did they not live in a swampy region, their dwellings hardly raised above the surface of a region still known as Moorgate? But archaeology showed that they were squatters with gypsy habits and hardly earlier than the Norman conquest.

History is silent also. There are no relevant Celtic documents. The name alone is Celtic beyond dispute. But its earliest recorded form is the latinized *Londinium,* and the few references to it in classical literature relate to the years of Roman conquest or dominance. It has been asserted without any supporting evidence that the Celtic kingdom of Cunobelin or Cymbeline — which had its capital first at Verulamium and afterward at Colchester — possessed a port of entry on the Walbrook creek. Roman writers knew nothing of it. They might not have cared had they known. Archaeology does not admit such fictions, however picturesque.

Roman London. — With the Roman conquest historians are on firm ground. The unquestioned history of London begins with the Claudian conquest of A.D. 43. not with Julius Caesar's raids of 55 and 54 B.C. Caesar crossed the Thames somewhere below London, and he does not even mention it. The Claudian invasion was begun by Aulus Plautius, and the plain dictates of strategy determined the choice of the site of London as an advanced base for the subjugation of the island. His armies marched from four Kentish ports to Canterbury and from there along an ancient trackway which he converted into the first great military road. It cannot be doubted that the Thames was bridged in this advance; Roman generals and engineers had dealt with a far more formidable obstacle in the Rhine.

London's story thus began with the formation of a camp, which developed into a fort and then into a fortified town. It was already a busy port in A.D. 61 when it was put to fire and sword in the terrible vengeance of Boudicca, the legions having gone too far northwestward and left their rear exposed. Boudicca's rebellion provides the first recorded mention of London. There is none as yet of its walls or buildings. The excavations of 1950 and subsequent years however revealed portions of a substantial early fort covering 11 ac. This occupied an area within the later Wall south of Cripplegate. The fort was protected by a ditch and drawbridge; and modern and mediaeval streets within its area corresponded roughly with the pattern of a Roman "grid." The interest of this discovery — dated by finds and other evidence to the decade A.D. 70–80—is that it was constructed before the wall (which is not bonded into it) and while the conquest was still proceeding. The discovery seems to account first for an unexplained twist of the wall southwestward near the church of St. Anne and St. Agnes; and secondly for the enclosure within Roman London of an area remote from the main centre of Roman urban life between the Walbrook and London bridge.

Careful excavation there and elsewhere in the City became possible after extensive damage by fire and bombing had been done in World War II. Large areas were denuded of buildings and remained accessible to archaeologists as late as 1954. Earlier digging had proved the existence of a municipal centre on the site of the present Leadenhall market. An extensive range of buildings had been identified grouped around a forum. with a basilica or town hall, other public buildings, shops and commanding monuments, including the head of a colossal bronze statue of the emperor Hadrian (117–138). Elsewhere in the City have been found from time to time tessellated floors. hypocausts, decorated walls and other attributes of luxurious living. London, however, never became a capital in Roman times. In recognition of its wealth and importance it was officially renamed Augusta; but it reverted to London under various forms.

One monument has survived all changes. London Wall is still the name of a street. Modern street names recall the approximate if not the identical points where Roman roads pierced the wall—as Aldgate, Bishopsgate, Moorgate, Cripplegate, Aldersgate, Newgate and a doubtful Ludgate. The course of the wall is known from the Tower, where the remains of a bastion can be seen just southeast of the keep, to a point behind Stationers' hall. There and in other places fragments or sections can be seen above ground, though the visible masonry is often mediaeval or even later. Traces of hurried rebuilding near Aldersgate are taken with some plausibility as signifying raids of the Picts and Scots in the 4th century. A Roman galley, recovered from the Thames mud under County hall near Westminster bridge, preserves a memory of sea fights and perhaps of that between Allectus and Carausius in A.D. 293.

In 1954 an unsuspected Mithraeum, or temple of Mithras, believed to have been built about A.D. 150, was discovered in the course of a contractor's excavations for the foundations of a new building, about 1j ft. below the modern ground level on the west side of Walbrook (the street) but on the east side of the new course of the Walbrook stream or creek as determined by this excavation. The temple measured 60 ft. by 25 ft.; it had a projecting western apse and an entry from the east down steps in part remaining. The building was divided into a nave and aisles by two rows of columns, seven on each side, of which the bases remained. On the chord of the raised apse were two blocks of stone representing altars. The malls, built of squared stones and bonding tiles, stood shoulder-high. A timber-lined well was found, suggesting ritual lustrations, and other cult objects were a stone holy-water stoup and parts of two massive stone lavers. Among the sculptures discovered on the site, the most important was a head, and later a bust fitting into it, attributed to Mithra or Mithras. Other sculptures may have represented Serapis, the Ptolemaic god-of-all-purposes absorbed into the Mithraic cult, and various Graeco-Roman deities and temple attendants. The Mithraeum went out of use at some unknown date not much later than the end of the 4th century. Earlier in that century there had been a rehabilitation of pagan worship under Julian the Apostate; and it was thought that the temple might have been destroyed and its statuary hidden from Christian iconoclasts in the time of Constantine. It was found possible to arrange for its piecemeal removal and re-erection on a nearby site.

Rome rallied against barbarian onsets from the north and across the seas and established the forts of the Saxon Shore, some of which are still standing. But near the end of the 4th century rebellion became almost continuous; and the year 410, when the emperor Honorius recalled the legions, has been taken as the end of the occupation and thus of intercourse between London and the civilized outer world that had lasted almost four centuries.

Dark-age London. — London is hidden in the mist which settles on the whole island from the severing of the formal link with Rome to the coming of St. Augustine and his Latin monks. Little more can be discerned from the historical record than that London was the chief town of the East Saxons at the beginning of the 7th century and that its first bishop, Mellitus, built a church in honour of St. Paul on the highest ground within the city.

But what had happened since the departure of the legions? Did the urban life of the romanized British continue, with diminished resources. yet in substantial and often luxurious houses, with access to the sea and protection from the wild men of the north by a solid town wall? Was London deserted with the decline of trade and industry and the buildings left to decay? Or did their owners, as in many parts of the island, surrender to pillage, fire and murder if they could not escape? No firm answer can be given. Modern scholarship will not sustain the claim to a continuous city life; still less will it support the association of mediaeval London institutions with their Roman equivalents. The lord mayor bears a French title, while the sheriffs are Anglo-Saxon; the livery companies have no relation to anything known of Roman London. In fact it was administered by a procurator, responsible directly to the emperor.

The wall is the only link during the dark ages between Roman and Saxon London. Except in the instance already described of the newly discovered fort near Cripplegate, the Roman street plan cannot be reconciled with the mediaeval netaork of streets and courts. The line of Watling street and Bucklersbury may represent a road from the Roman bridgehead to Newgate, deflected from its direct course by St. Paul's. What is now Holborn and Oxford street is named Watling street on a pre-Conquest charter and was evidently recognized as a continuation of the road which emerged at Newgate (the only proved Roman exit). But Watling street is a Saxon name; all that can be said of it is that it seems to have been applied to well-made Roman roads still fit to use in Saxon times. These were London's only highways worth the name until the 18th century; and even in a derelict London one or two of them may have survived as through routes. When houses appear and can be plotted on a map, from the evidence of will and charters, they are found to bear little relation to any system of streets. They were placed irregularly, obliquely and often athwart the roadway.

Saxons and Danes. — The conquest of Britain by the Teutonic tribes of whom one, the Angles, ultimately gave its name to England, was a major event; its details are few and obscure. Modern historians permit us to accept Hengest (Hengist) and Horsa as real persons and the date of their landing on the Kentish coast as 449. But the record in the *Anglo-Saxon Chronicle* comes from a narrative compiled in more than one monastery, often long after the events described. Some of the dates are manifest guesswork. The mythical background provides an ancestor for the West Saxon kings in the heathen god Woden. The *Chronicle*, however. becomes factual and contemporary in the reign of Alfred and by Alfred's direction. This does not dispose of the fact that records of the conquest in the 5th and 6th centuries were meagre in the 8th and remained so.

The conversion of London to Christianity was precarious and premature. King Sebert of the East Saxons, under whom Mellitus had set up his London bishopric, was nephew of King Aethelbert of Kent, "lord over all the English races as far as the boundary of the flood Humber" (Bede). On Aethelbert's death Kent relapsed into heathenism; Sebert died at the same time; his sons refused to accept Christianity and Mellitus was banished. Two other bishops are named; but the stubborn paganism of the Londoners frustrated the attempt to found the first bishopric. Bede, writing in the 8th century, mentions London as the mart of many people coming by land and sea: but its possession passed to and fro between contending overlords until Ecgbert, king of Wessex, "conquered the kingdom of the Mercians and all that was south of the Humber."

A new epoch, for England and for London, begins with Ecgbert's grandson Alfred, who came to the throne in the thick of the fighting with the Danes. After his victory at Edington (878) a peace was arranged which restored Wessex to him and confined the Danes to the Danelagh in the east of England.

A new invasion took place in 884, the Norsemen being supported by the Danes of the Danelagh. Alfred beat them off by land and sea, pushed the frontier back in Essex and occupied London. Bishop Asser, in his contemporary biography, says that in 886 Alfred "after the burnings of cities and the slaughter of peoples, honourably restored the city of London and made it habitable," afterward entrusting it to the care of his son-in-la Aethelred, ealdorman of Mercia. The bishop adds that afterward all the Angles and Saxons who had been dispersed or were in captivity among the pagans turned of their own accord to submit themselves to the lordship of the king.

London was thus not yet the capital. It was a strong place and henceforth a rallying place outside the Danelagh. The capital was Winchester. London for the time being was a southeastern outpost of Mercia. The distinction between Mercia and Wessex (the only Saxon kingdoms which stood erect against the Scandinavian onslaughts) tended to break down with the relationship of their rulers and their common share in the task of reconquering the England of Ecgbert. The recovery of London implied the political unity of Alfred's kingdom, if Asser's record of submission to Alfred may be taken as more than a local affair between London and the Danelagh. From this day, since the London defenses aere never penetrated, the future capital became identified with its destiny. Excavations in 1952 near the London wall, behind the disused churchyard of St. Alphage, yielded evidence of continuous repairs above the Roman core. Both there and in other parts of the wall brought to light by bomb and spade the lower levels may safely be attributed to Alfred's initiative.

The 10th century. after Alfred's death, is in part a steady advance and consolidation of English conquests, in part a renewal of raids by the Norsemen. Remains of an important earthwork can be seen at Witham, Essex, raised soon after 911 as an obstacle to the Danish advance. London held firm, in spite of its siege by Olaf Tryggvesson and Sweyn Forkbeard with 94 ships in 994. An Icelandic saga relates how the long ships, unable to get past the bridge, were at last lashed together and carried forward by the force of the tide to break it down.

London was besieged by Canute in the short reign of Edmund Ironside. Canute cut a channel round the southern end of London bridge and blockaded the town. Edmund Ironside defeated a Danish army at Otford, near Sevenoaks, in Kent. but was afterward overwhelmed in battle in Essex on a site believed to have been Ashingdon. Peace was made on the basis of allotting Wessex to Edmund and the rest of the country to Canute. The men of London, now Canute's subjects, had to buy peace from the Danish army for a large ransom. Edmund died in Nov. 1016, and the men of Wessex submitted to Canute.

London was becoming a national capital in fact though not in name in the 11th century. Edward the Confessor was elected there by popular acclamation in 1042 after the failure of the Danish male line. London's growing importance is shown by meetings there of the witan, the old English council, eight times between 934 and 1055.

Harold II was elected king in London the day after the death of Edward the Confessor and reigned for nine months. The threat of invasion hung over the realm until Harold met, first the Norwegian assault of Harald Haardraade near York; and secondly the Norman host at battle near Hastings, in 1066. Duke William's victory was the end of the Anglo-Saxon era.

London after the Conquest. — Hastings was a decisive battle, but William had not conquered England until he had secured London. All the English leaders were not involved in the defeat at Hastings. William made a circuitous march on the city, burned Southmark and had half encircled London when Archbishop Stigand, leader of the aetheling's party, went to William at Wallingford and submitted to him. William received the Englishmen's oath of fealty at Berkhamstead, where London was represented by the city magnates. He was crowned king at Westminster in the midst of a tumult, never repeated in the case of his successors. Six months later, though the whole of England was not yet in his hands, he was able to leave for Normandy. He had not misjudged the importance of London.

William's charter greeted "all the burgesses within London, French and English, friendly," and promised the observance of the laws of King Edward the Confessor's day. The charter was addressed to William, bishop, and to Gosfrith, portreeve; it recognized. that is, a joint ecclesiastical and secular jurisdiction, or rather two jurisdictions side by side. William built the White Tower within, and partly upon, the Roman wall. A period of peace and increasing prosperity was interrupted but not brought to an end by a fire which in 1687-destroyed St. Paul's and a large part of the city.

William II (Rufus) strengthened the tower and built the great hall at Westminster. From the reign of Henry I, London assumed the character of a political capital; it obtained from Henry a charter of liberties, and in 1135 the citizens asserted their right to choose a new king on the death of the old. They refused to recognize Henry's daughter Matilda as queen, obtained the release of Stephen and finally drove her from the kingdom.

FROM THE MIDDLE AGES TO THE FIRE

London Under the Plantagenets. — The story of London between the Angevin monarchs and the Tudors is at the centre of national events. Pretenders to the crown had to secure the support of London, notably in the Wars of the Roses; and its money was required for the wars to conquer France, as under Edward III, Henry V and Henry VI. Its turbulent apprentices gave constant occupation to the city authorities; but they provided a ready-made defense force against an outside enemy.

The revolt under Wat Tyler (*q.v.*) in 1381, when the red dagger first appeared on the Corporation arms, and that of John (Jack) Cade (*q.v.*) in 1450, as later that of Sir Thomas Wyat against Queen Mary I in 1554, marked the relative ease with which rebellion was nipped in the bud during this period if the crown had the citizens' support.

The importance for London of the mediaeval centuries lies however elsewhere: in the assertion of the independence of the City, subject to fealty to the sovereign, in the creation of the mayoralty, in the rise of the guilds and in the growth of the great religious houses. The portreeve is the earliest official known to the documents. As mentioned above. he was addressed by name by William the Conqueror. This pre-Norman functionary, who had equivalents in several English as well as French cities, was one of a group of aldermen, who were territorial magnates whose estates gave their names to wards still existing. John Stow describes them as the knightengild. The idea of a commune or self-governing community forming a miniature republic was not English but French, as was the title of *maire* adopted for its head. London obtained its commune or self-governing corporation from John, acting as regent for his brother Richard I during his absence. On Oct. 8, 1191, John acknowledged the right of the citizens to combine in a sworn association, to take an oath to preserve the City and its liberties and to be obedient to its officers. This is taken as the recognition of the citizens as a corporation bound by corporate oath and replacing the looser association of wards, sokes and liberties. It is generally agreed that the mayoralty was established in connection with the granting of the commune. The precise date is uncertain. Henry FitzAilwin of Londonstone was the first mayor. He is mentioned without that title in Nov. 1191, as well as in later charters; but the oath of the commune in 1193 bound the citizens to accept the decisions of the mayor and others associated with him. The reasonable assumption is that the mayoralty dates from the year before, 1192. Its authority has never since been in dispute, and from the beginning of the 13th century the mayoralty is continuous through good and bad times. The dignity is supported by sheriffs and aldermen (these titles are Saxon), and by the livery companies (*q.v.*), whose power grew up with the growth of trade.

Trade called for a new bridge of stone, and in 1176 Peter of Colechurch began the new London bridge, which lasted until 1832. The Hanseatic merchants were settled on the banks of the Thames in 1157. Vessels drew up at the little ports of Billingsgate and Queenhithe (both of pre-Conquest origin) but also at wharves on both sides of the river. Close to the southern end of London bridge, St. Mary Overie (now Southwark cathedral) represented the importance of the ferry. By the 15th century the Thames side had assumed the picturesque appearance it bore in old prints up to the Great Fire of 1666. Great London merchants, such as Richard Whittington and John Pountney, had their homes (which were also their warehouses) near the river. The scene was dominated by the great spire of old St. Paul's (520 ft. high), with the silhouette of spires and towers below. This skyline survived the Great Fire and even to a large extent the bombing of World War II. For though the Reformation destroyed the religious houses the people clung to their parish churches, many of which were rebuilt through the genius of Sir Christopher Wren.

Late mediaeval London cannot be conceived without the great convents and priories which followed the coming of the friars in the 13th century. Blackfriars is still the name of a district. a bridge and a railway station. One formless mass of masonry is all that remains of the famous Dominican house, in the great hall of which the divorce proceedings of Henry VIII and Queen Catherine were heard. (Two Blackfriars playhouses, from 1576 to 1584 and from 1596 to 1655, were later set up there.) The Greyfriars, or Franciscans, had their church from 1306 on the north side of Newgate, on the site afterward occupied by Christ's hospital and Christ church. The Whitefriars, or Carmelites, from 1241 were on the south side of Fleet street between Bridewell and the Temple. Their conventual buildings ran down to the Thames, with a garden and a millhouse where Tudor street is now.

Other communities occupied the priory of St. Bartholomew (of which a noble fragment remains); the Charterhouse, or Carthusian priory of the Salutation, and the priory of St. John Clerkenwell (of which the gate still stands); the collegiate church of St. Martin-le-Grand; the Austin Friars, Old Broad street; and the priory of Holy Trinity, Aldgate, with the priory of Benedictine nuns in St. Helen's Bishopsgate. St. Helen's contains famous monuments in a mediaeval setting which dates from the 12th to the 15th century.

Tudor and Early Stuart London. — The modern history of England begins with the Tudors. The Reformation was the most permanent and is still the most controversial part of Henry VIII's legacy to the future. This involved the destruction of lovely buildings and venerable institutions. Moreover, his marriages left the succession in dispute long after his death. London was the spectator, or accomplice, in many evil deeds of this period. Tower hill was the scene of the execution of Queen Anne Boleyn (1536), of Margaret, countess of Salisbury (1541), of Queen Catherine Howard (1542), of Sir Thomas More and Bishop John Fisher (1535) and many others, including subsequently Lady Jane Grey (1554) and Robert Devereux, earl of Essex (1601). "The fires of Smithfield," chiefly executions of Protestants under Queen Mary, were the counterpart of the scaffold of her father. The victims burned there were altogether 43; a tablet on the wall of St. Bartholomew's hospital names John Bradford, John Rogers and John Philpot.

The spoils of the church were distributed for the most part to a new aristocracy. The sites of the convents were cut up into little streets and courts; new slums appeared in their place, with a great increase of the danger of fire. In Blackfriars what had been the prior's garden became the narrow Friar street. Holy Trinity priory, Aldgate, between Duke street and Leadenhall, possessed in the 15th century "a great garden," a second garden south of the convent church, a churchyard and a garden behind St. Katherine Cree church. Whitefriars had a Great Friars gate and a Little Friars gate on the south side of Fleet street, and its gardens stretched to the river. Bouverie street now cuts the convent lands in two. Some few fragments were spared. St. Bartholomew's hospital was refounded by Henry VIII after the destruction of the priory (except the nave of the church which was retained for parochial use). Henry also refounded St. Thomas's hospital in Southwark; and Edward VI gave his father's derelict Bridewell palace, with an endowment, for a hospital in the old sense of a refuge for the poor and infirm. London was swarming with beggars, cripples and an underworld hitherto dependent on the monasteries.

The livery companies also obtained halls. Edward VI converted the Greyfriars into Christ's hospital, for the maintenance and education of poor children; and the Charterhouse, though by no royal generosity, became in 1611 the home of 80 old pensioners and 40 boys. There had been a grim ending to the life of the convent. The Greyfriars had found it possible to assent to the act of succession but they could not bring themselves to swear that Henry was the head of the church. So resolving in their chapter house, they knew their doom: to be dragged on hurdles to Tyburn, there to be hanged and disembowelled.

Elizabethan London sprang from such a soil. Controversy was far from dead, and the axe had not yet finished its work; but a new spirit was stirring. About 1586 William Shakespeare came as a young man from Stratford to Blackfriars, where his first work, *Venus and Adonis*, was published in 1593. He was soon to be known as an actor and as a playwright. His career is closely associated with two theatres of which he was at one time joint proprietor — the Globe at Bankside and the Playhouse at Blackfriars. Both were outside the jurisdiction of the corporation of London. which was rigidly puritanical. Playhouse yard, just behind the *Times* office, preserves the memory of the entrance to the Blackfriars playhouse; the theatre itself is believed to have been on the site now occupied by a private house. That of the Globe is identified in the London County council *Survey of London;* it is shown in Wencel Hollar's bird's eye view of London as nearly opposite the quay of "Blackfreyars."

Jacobean London differed little from that of Elizabeth. Hollar's bird's eye view, just mentioned, was published in Amsterdam in 1647 but it was derived from sketches made just before the Great Rebellion. It shows many-gabled houses crowded together as in a mediaeval German city, but for the most part covered with tiles. Before war broke out, there had been some rebuilding and a beginning of planning. Inigo Jones erected the first Renaissance building in London in the church of St. Paul, Covent Garden, for James I, to whom is also due the New River company, providing the first supply of pure water.

The Great Rebellion left relatively few traces in the City. The centre of the drama was Westminster where Charles I met his parliament, his accusers and his death. The City was a parliamentary island, already with strong puritanical leanings, to be confirmed when Charles went in person in 1642 to Guildhall to demand the surrender of the five members of parliament accused of treason. Throughout the war a minority at least of the citizens was believed to stand behind the king; but London had the money, the men and the means of arming them. There was a moment after Edge Hill when swift decision might have changed the course of events. Charles had marched to Brentford but found parliamentary troops drawn up at Turnham Green. After a reconnaissance he retired to Reading and Oxford. London saw him no more until it flocked to the final scene at Whitehall on the cold morning of Jan. 30, 1649.

The Great Plague and the Great Fire. — "Late into December nights of the year 1664 London citizens sat up to watch a new blazing star, with 'mighty talk' thereupon" (Walter George Bell, *The Great Fire of London,* [London, 1951]). This was one of the portents (for in March a yet brighter comet was seen in London) that went before the Great Plague of London. Plague had been intermittent since the reign of James I; there had even been a "Great Plague" in 1625. That of 1665 was merely the worst. unexampled in its sudden spread and deadly effects.

The Great Plague began in St. Giles-in-the-Fields; the districts that suffered worst were Stepney, Shoreditch, the Borough, Bishopsgate, Aldgate, Whitechapel, Cripplegate and Clerkenwell. both sides of the Fleet ditch, both sides of Holborn and the crowded streets around Westminster abbey. The peak of 7,000 deaths in a single day was reached in September; after this the numbers declined to 500 in December and never rose above 300 a day thereafter. A return made to Charles II on Dec. 19 by the Company of Parish Clerks gave "the total of all the burials this year 97,306. Whereof, of the Plague 68,596."

The Great Fire followed before the plague had completely disappeared. Samuel Pepys, who had been to and fro during the plague, describes the beginning of the fire as seen by one of his maids from his house in Seething lane, near the Tower. at three o'clock in the morning of Sept. 2, 1666. It had started in Pudding lane near London bridge and seemed then a small affair. It was not arrested until practically the whole area of the city had been burned out; and the flames had spread beyond to the Temple and Holborn.

London within the wall was still a mediaeval city in appearance and much besides. when the fire broke out. Some rebuilding had taken place under James I and in the early years of Charles I; little under the Commonviealth; the main aspect was that now popularly recognized as "Elizabethan." Few of these timbered houses survive, and almost none in the actual fire area. The streets were almost impassable to wheeled traffic and would long ago have had to be widened, had not the Thames been the great highway. Nowhere did the timber-framed houses crowd more closely than by the river, where the outbreak began.

In Pudding lane — a dark, cobbled, narrow street sloping steeply to the Thames — John Farynor, the king's baker, had gone to bed at 10 o'clock after his day's trading was done. At 2 A.M. his man was roused by a choking sensation and found the house full of smoke. The baker, his wife, daughter and his man escaped over the roofs. The maid remained and became the first victim of the fire. Such was the origin of the fire in the opinion of Walter Bell, who wrote the standard work on the subject. At the time popular opinion demanded a culprit and fixed on papists and Frenchmen. The monument recorded from 1681 to 1685 and again from 1689 to 1830 the "perpetual remembrance of that most dreadful burning of this Protestant city, begun and carried on by ye Popish faction."

The fire spread slowly at first. A strong wind was blowing from the northeast. By eight o'clock London bridge and the houses on it were blazing. Live flakes were carried on the wind and the fire began to creep back from the river. That night all London saw such a glare as it had never known. The first day had carried the frontier of flame nearly to Queenhithe, on the river bank, and northward to Cannon street and East Cheap. On the afternoon of the second day the fire was raging about the Royal exchange, Lombard street and Cornhill, among the dwellings and shops of rich brokers and merchants. On the third day Guildhall was burning, the custom house and the Royal exchange were destroyed, and fire broke out on the roof of St. Paul's. The wind fell during the night, and the fire was out except for patches of flame on the fourth day. Its limit was in the Temple, where James, duke of York, had been put in command of soldiers and seamen.

The record on the north side of the monument states that the fire consumed 89 churches, 13,200 houses and 400 streets.

GROWTH OF THE MODERN CITY

Later Stuart London. — The Augustan age in English literature has long been recognized; but it was only after the upheaval of World Wars I and II that the architecture of Queen Anne's reign was fully appreciated. English baroque came to be compared with that of the Lon Countries, of Germany, of France and of Italy and to survive the comparison. Sir Christopher Wren (*q.v.*) actually began the rebuilding of St. Paul's cathedral under Charles II; it was finished in 1710, under Queen Anne. Wren's series of rebuilt City churches was completed under George I. The Great Fire destroyed or seriously damaged 87 out of the 101 churches in the City. Wren rebuilt or superintended the rebuilding of 51, as well as St. Andrew's, Holborn (not destroyed by the fire).

These churches formed a group unmatched for variety and attractiveness; among the most notable of Wren's towers and spires are reckoned St. Mary-le-Bow, Cheapside; St. Bride's, Fleet street; St. Vedast, Foster lane; and St. Michael, Paternoster Royal. Work began on these new churches in 1670; by 1687 the bodies of the earlier buildings and the lower stages of the towers were mostly completed; 17 were started in 1670, and 1700 saw them nearly finished.

Forty-four halls of City livery companies (*q.v.*) were also destroyed in the Great Fire. These did not form a group, as did the churches; they were scattered about the City, though they tended to concentrate near the river. After Guildhall they were the most important of the secular buildings. The earliest was the 14th-century Barbers' hall, near Cripplegate; the Merchant Taylors' hall, Threadneedle street, had a 15th-century hall and an earlier crypt; the Mercers' hall, Cheapside, had a private chapel which had formed part of the pre-Reformation hospital church of St. Thomas of Acon. Most of these buildings were restored or rebuilt soon after the fire. It has been claimed that some of them were designed by Wren. No evidence exists for this assertion. The companies employed their own surveyors; and these men, unknown outside the companies' records, designed some noble rooms and accessories. The wood carving of this period is seen at its best in St. Paul's; the City companies found other craftsmen, less well-known and not under royal patronage, to execute work which has never since been equalled.

The social quality of London was altering during the Restoration period and the earlier years of the 18th century. Fashion began to move out of the City under the influence of the court. Covent Garden and Lincoln's Inn fields were already fashionable under the first Stuarts; royalists returning with Charles II built themselves houses farther west; by the end of the reign wit and fashion had begun to follow the court toward Whitehall.

Hanoverians and the Regency. — The sturdy independent life of the City did not come to an end with its desertion by the aristocracy. Prosperous merchants and tradesmen alike lived over their warehouses and shops. Kings, ministers and parliaments had to look to the City of London or take the consequences. The declaration of allegiance to the prince of Orange, afterward William III, had been drawn up at Guildhall by the lords spiritual and temporal. The City supported "Wilkes and liberty" against parliament from 1769 onward and joined with him in challenging the right of parliament to prohibit the reporting of debates. The Gordon riots of June 1780 were the most formidable rising that the capital had known since Jack Cade and Wat Tyler. No police force existed. Soldiers had to be called in to prevent the spread of arson and mob terrorism, inspired by religious bigotry.

The sedan chair had come into use under Queen Anne. and it remained the most popular means of conveyance throughout the 18th century. Conveyance to Westminster was by river. This was safer, cleaner, quicker and pleasanter than to pass through ill-lit streets, cobbled, filthy, evil-smelling, undrained; with no footpaths and no protection for foot passengers except the iron posts along which Dr. Johnson felt his way. This was nevertheless the London of which James Boswell left such memories. Samuel Johnson wrote his *Dictionary* in Gough square; Oliver Goldsmith was living in the Temple; David Garrick after his marriage lived in Southhampton street, Strand; and Joshua Reynolds lived in Leicester square. The classical age of English portrait and landscape painting was soon to begin.

Georgian architecture came into being in quiet squares and streets, or in individual houses. Its merits were not to be recognized—it was indeed despised—until the 20th century was well on. For the most in brick, it was plain and austere, its decoration confined to a doorway or to a cornice; its beauty resided in its harmonious proportions. Display was reserved for the inside. Good portraits, good wine, good silver, good music and good company might be met there. The furniture had elegance and comfort.

The Regency introduced stucco to London—partly for reasons of economy during the Napoleonic Wars. Regent street and Carlton House terrace were the best-known examples until the Regent street quadrant wss rebuilt in Edwardian-Palladian between World Wars I and II. The regent himself impressed a vivid personality and a restless spirit of innovation on the society as well as the London of his day.

Victorian London. — London changed during the long reign of Queen Victoria from an insanitary, overcrowded and tortuous city to a spacious capital (outside the ancient City) which remained substantially unchanged until large areas of it were destroyed in World War II. A writer in the *Times* of July 28, 1853, said: "It does not take a very old man to remember when there was neither a gas-lamp, nor a cab, nor an omnibus, nor a steam-vessel, nor a plate-glass window, in a city of which these things are now essential ingredients." London at the beginning of the reign had only one railway terminus (Euston, line opened 1838), no underground or tubes, only the old palace of Westminster for the houses of parliament, no Trafalgar square, no Embankment, no Victoria street (Westminster) or Queen Victoria street (City), no Holborn viaduct or New Oxford street. Human rabbit warrens occupied the immediate region of Westminster abbey, St. Giles's circus and the sites of the later Aldwych and Kingsway. In the course of clearing these areas new slums were created by overcrowding elsewhere; but main arteries were driven through London from east to west. The Aldwych scheme was completed in 1905, soon after Queen Victoria's death; when she came to the throne the neighbourhood of Trafalgar square was known as Porridge Island, the National gallery was being built on what had been the king's mews, and behind it were barracks. Nelson's column, begun in 1840, did not receive its figure until 1843. Even the idea of a noble open space seemed ludicrous to contemporary opinion. The *Times* wrote of "this ill-fated square" and derided the lanterns of the National gallery as "pepper castors."

The Crystal palace (opened by Queen Victoria on May 1, 1851, in Hyde park) had also to undergo a fire of criticism in the press and in both houses of parliament. Popular criticism had changed into popular enthusiasm by the opening day of the Great exhibition, and the queen wrote of it in her journal: "This day is one of the greatest and most glorious days of our lives." The exhibition was an overwhelming success from the day of its opening to "the sad solemnity of the closing" (so described by Lord John Russell) on Oct. 11. It remained in the memory of Londoners long after the Crystal palace had been re-erected at Sydenham (1854); it left as permanent memorials the creation of a cultural and educational centre in South Kensington on an estate purchased out of its profits by the foresight of Prince Albert. The re-erected Crystal palace at Sydenham was burned down on Nov. 30, 1936.

World Wars I and II.—Edwardian London appears in retrospect as a prolongation of the Victorian scene; at the time a new reign seemed to inaugurate a new age. King Edward opened parliament in state to the delight of Londoners and brought back the colour and pageantry so long forgotten. The new Admiralty arch opened a dignified entrance to the processional way along the Mall; while Buckingham palace was refronted and a colossal statue of Queen Victoria erected. The statuary and architecture of the reign have not escaped criticism; they stamped it with an unmistakable signature needing no such identification as had been supplied by the word "Albert" to the Albert memorial.

The clouds of war were already beginning to gather when George V came to the throne in May 1910. When they dispersed in 1918, throne and people had been united more closely than ever before. World War I broke on a London unfamiliar with war, unprepared and incredulous. In April 1915 air raids on London became frequent, and Zeppelin attacks followed, causing a maximum of alarm; by the end of the war the Zeppelin had been superseded finally by the aeroplane; anti-aircraft defense had been developed, and London had shown its stout heart. A total of 355 incendiary and 567 explosive bombs was dropped in the City, killing 670 people, injuring 1,962 and causing damage estimated at £2,042,000.

World War II drew a red scar across the face of London. Figures give no indication of the facts in terms of human suffering except by comparison with those of World War I. Between 1939 and 1945 about 30,000 people lost their lives in air raids in London; more than 50,000 were injured. In the fierce attacks between Sept. 1940 and July 1941 between 45,000 and 50,000 bombs, excluding incendiaries, were dropped in the London region. Bombing continued for 57 nights between Sept. 7 and Nov. 2, 1940. What was justly called the second Great Fire of London occurred on the night of Dec. 29–30, when 1,500 fires were started. One night in September more than 40 fires were blazing on the Thames or in the docks. On another night Charing Cross bridge was damaged, all except one line; and on this suburban traffic ran again next morning. The damage to Westminster abbey and to the houses of parliament was done in a raid of May 10–11, 1941. Finally, after a long lull. the V-I, flying bomb, or "doodle-bug" as Cockneys called it. started a new series of air raids, more terrifying than the earlier ones, on June 13, 1944. The rocket, or V-2, followed on Sept. 8 (the first fell at Chiswick) and continued until March 1945 (the last at Smithfield, Stepney and Tottenham Court road). The London victims of the two V-weapons were 8.938 killed and 24,504 injured.

When World War II came to an end, the map of London showed wide areas of nearly complete destruction. In the City little was left standing between Cheapside and the Barbican. North of St. Paul's, Paternoster row had disappeared and almost every building as far as Newgate street. East of St. Paul's was another area of desolation extending from Cheapside to Upper Thames street. From the back of the Mansion house destruction had spread on both sides of the Walbrook to the Thames between Southwark bridge and London bridge. Another blitzed area lay round Fenchurch Street station and much of the area of Holborn circus, Gray's Inn road and Theobald's road was flattened.

St. Paul's cathedral was in continual danger from incendiaries but escaped save for the piercing of the choir rood and damage to the altar by a high-explosive bomb. The Temple church was badly damaged. calling for drastic restoration. The Middle Temple hall was badly damaged but the roof and screens—among the most precious survivals of later Gothic woodwork—were carefully restored to their original design. Ruin overtook many of Wren's most notable churches. These included St. Bride's, Fleet street; Bow church or St. Mary-le-Bow; St. Mildred, Bread street; St. Stephen, Coleman street; St. Alban, Wood street; St. Mary Aldermanbury; St. Augustine, near the east end of St. Paul's cathedral; St. Lawrence Jewry, near Guildhall; St. Nicholas Cole abbey; St. Swithin, opposite Cannon Street station and embodying London Stone; St. Vedast, Foster lane; and Christ church. Newgate street.

The steeples of many of these churches had escaped damage or were capable of restoration. Ultimately almost all were rescued for the future, though some are to be used for general rather than parochial purposes. Worship was carried on continuously in all cases, either in a vestry, a tower or a neighbouring church.

Treasures lost during World War II included many of the halls of the livery companies (*q.v.*). These were little known to the public but their interiors represented Restoration woodwork at its best; they contained notable portraits, and some of them incorporated mediaeval crypts or other early features. Of these halls 19 were completely destroyed or burned out; 11 were damaged less severely; only 2 remained substantially unharmed.

Excavation and Rebuilding.—The London Roman and Medieval Excavation council, formed while the war was still in progress. pursued patient research at many points in the City before rebuilding began. Part of the rebuilding plans provided for the permanent preservation of the wall near St. Alphage's church as an open space. Little churchyards belonging to churches never rebuilt after the Great Fire also found their place in rebuilding plans. Controversy delayed the building of the extension of the Bank of England east of St. Paul's; and the elaborate scheme for new alternative roads and bold planning to give better views of the cathedral was held up, despite increasing traffic problems. London's outdoor statues had been taken away for safety or had been protected on their sites: Charles I returned to his place at the junction of Charing Cross and Trafalgar square in 1946; Eros was poised again on his pedestal in Piccadilly in 1952.

Important changes on the south bank of the Thames were made in connection with a Festival of Britain held in 1951 to mark the centenary of the Great exhibition. A permanent memorial remained in the Festival hall, which was criticized for its frontage to the river but quickly became popular as a concert hall. Gardens were also laid out in part of the bombed area between the County hall and Waterloo bridge. Part became a helicopter station in 1954 and threatened the project of a continuous embankment and gardens from Westminster to Blackfriars bridge. River services were restarted in 1951 upstream to Kew and downstream to Greenwich and Gravesend. A new addition to the Embankment gardens was made in front of a huge new block of government offices west of Horse Guards avenue. In 1953 the coronation of Queen Elizabeth II brought unprecedented crowds into London; 30,000 people were counted outside Buckingham palace one night. In subsequent years permanent congestion of the streets seemed to threaten the continued life of historic London. (W. T. H.)

ARCHITECTURE

There is no definite evidence of a settlement on the site of the City of London before the Roman occupation. The Romans chose a site at the lowest point where the Thames could most easily be bridged. After the sack of London in A.D. 61 the walls were added and, though much rebuilt, they survived until the 18th century. Parts which include Roman work can still be seen at Tower hill, Monkwell street (east of Aldersgate street). St. Giles, Cripplegate, and the general post office. It seems that the City contained more stone and brick buildings at the end of the 1st century A.D. than at any other time until after the Great Fire. A hypocaust remains beneath the coal exchange, and there are mosaic pavements inside the Bank of England. Of the 330 ac. within the walls, only the eastern half appears to have been occupied by the Romans. There was also a small settlement at Thorney Island, where Watling street met the Thames at a ford—the nucleus of the present Westminster.

It is clear from early records that the City grew in strength and importance during the Saxon period. The predominance of early church dedications round the site of St. Paul's cathedral suggests that this western part of the space within the walls was the first to be used. During World War II Saxon work was uncovered at the church of All Hallows Barking-by-the-Tower A late Saxon rood panel remains at St. Dunstan's church, Stepney. King Canute made Westminster the site of a royal palace, thus initiating its separate existence as a court centre. Place names indicate considerable Danish influence in and around the City, (*e.g*, St. Clement Danes church, Strand). Immediately before the Norman conquest an impressive church was built at Westminster for Edward the Confessor, of which the Chapel of the Pyx and the monk's dormitory undercroft remain.

The Norman invasion resulted in major building activity in London, of which much is left. The Tower of London is outstanding, and contains the White Tower, an early Norman hall keep begun in 1078, with the well-preserved apsidal chapel of St. John projecting at its southeast corner. Many merchants' houses were built on vaulted stone crypts: houses surviving at Lincoln show the type. The wave of prosperity in the 12th century led to extensive rebuilding of churches in stone. Of these, the choir of St. Bartholomew the Great, Smithfield, founded in 1123 (nave completed in the 13th century) and containing the founder's tomb, still stands. The rotunda of Temple church (consecrated 1185) remains, though injured by restoration and bombing; and the crypts of St. John of Jerusalem, Clerkenwell (1140–85), and St. Mary-le-Bow (c. 1090) can still be seen.

Life in mediaeval London revolved round the central market area of Cheapside. The city government is traditionally associated with this area, in which stood the halls of the city companies and where Guildhall remains with much important mediaeval work (new roof by Sir G. G. Scott finished in 1954). As trade increased, much of the foreshore was reclaimed, the space within the walls was built over, and extramural building along the river bank began. The network of narrow streets which remains shows how overcrowded the City was; some idea of its appearance can be gained from study of the mediaeval streets of Chester and York, and in London itself from the timbered front of Staple inn, Holborn (late 16th century, but much rebuilt, latterly in 1950). About a quarter of the City was occupied by religious houses and their holdings. There were 106 churches, serving so dense a population that the present Bank of England covers the sites of two parishes. Records indicate continual rebuilding in City churches in the late middle ages, but much was lost in the Great Fire of 1666. Surviving mediaeval churches are St. Etheldreda, Ely place, Holborn (the only largely complete pre-Reformation church in England occupied by the Roman communion), built about 1300 as the private chapel of the bishop of Ely; Lambeth palace chapel (c. 1230) with undercroft (c. 1200); and, in the City, St. Helen, Bishopsgate (with Perpendicular arcade), St. Ethelburga, Bishopsgate (with early 15th century arcade), St. Giles, Cripplegate (14th century, rebuilt 1545; damaged by bombing), St. Andrew Undershaft (rebuilt 1532) and the Savoy chapel, Strand (1505 *et* seq.).

Mediaeval Westminster, on the other hand, centred round the ceremonial of court and abbey. Until the late 18th century the river was the chief means of transport, and the chain of great houses of the nobility along the Strand linked the City with Westminster. In Westminster some of the finest mediaeval architecture of London can be seen. Westminster hall was completed in 1097, but modified in 1380–1402 when the fine hammer-beam roof (designed 1380) was added—one of the earliest remaining in England. Westminster abbey was rebuilt for Henry III between 1245 and 1269; the eastern part, the north and south transepts and five bays of the nave are of this period. The cloister court (1245–50; 1344–70) and the chapter house (c. 1245–53; heavily restored by Sir George Gilbert Scott in the mid-19th century) are fine works; much of the monastic buildings of the mid-14th century remain. The rest of the nave was built between 1350 and 1420. At the extreme east end, Henry VII's chapel (1503–19) has a magnificent fan vault with pendants.

Southwark cathedral. though much restored (nave wholly 19th century), contains interesting 13th-century work (retrochoir, chancel, etc.). Several other mediaeval churches outside the City still stand. The best preserved is St. Margaret's, Westminster, a fine Perpendicular parish church. St. Mary, Stratford-le-Bow (Poplar), retains much 14th century work; good mediaeval west towers survive at the parish churches of Fulham (heavily restored), Lambeth and Putney (heavily restored). Two fine secular buildings can be seen: Crosby hall (1466–75), which was removed from the City and rebuilt in Chelsea in 1910, and Eltham hall, Woolwich, a splendid great hall of the late 15th century.

By 1600 most of the monastic property in and around London was occupied by laymen. Some churches were put to parochial use. After the dissolution of the monasteries the population of London increased, and the City began to assume its present-day pattern of life; streets grew up outside the walls. Brick came into wide use as a building material. The brick gateway of St. James's palace and some parts of Lambeth palace are of the late 16th century. What is now known as the St. John's institute, at Hackney, is a well-preserved early 16th century manor house. The Charterhouse. Finsbury, retains much 16th century work and some earlier fragments. The remnants of Well hall, Eltham, contain a range of brick buildings of 1568. The front of Sir Paul Pindar's Bishopsgate house, of about 1624, is preserved in the Victoria and Albert museum. Charlton house near Greenwich (1607) is a well-preserved Jacohean mansion (and with the demolition of Holland house in 1953–54, the only Jacobean house of first importance in London); number 17 Fleet street retains a Jacobean room ("Prince Henry's room"; 1610–11); the George inn, Southwark, has a galleried innyard of 1676, continuing the earlier mediaeval tradition; and Cromwell house, Highgate, of about 1637–40, has a fine staircase.

The 17th century saw the rise of the architect as an individual, and this century, which included the working lives of Inigo Jones and Sir Christopher Wren, gave to London some of its finest buildings. Inigo Jones initiated the use of a carefully worked-out classicism, which remained the dominant form in London architecture until the Gothic revival. He worked in the court circle and built, in the manner of Andrea Palladio, the Queen's house, Greenwich (1616–19; 1629–37) and the Banqueting hall, Whitehall (1619–22). Inigo Jones also designed Covent Garden piazza (begun 1630). Of the Lincoln's Inn fields scheme, begun about 1638 under the inspiration of Covent Garden, Lindsay house (possibly by Nicholas Stone) remains. The typical 18th-century London square derives from these two schemes. John Webb carried on in Jones's tradition and began work at Greenwich on a royal palace; his work comprises the eastern part of what is now called King Charles's block (1663–67) and the palace was continued, as the Royal Naval hospital, mainly by Sir Christopher Wren. The extramural expansion of London that had begun on a large scale in the Elizabethan age continued unchecked. At this time the speculative builder made his appearance. Noteworthy work of the period survives in the chapel of Lincoln's inn (1617–23; restored), built in an interesting revived Gothic style; a fine house, Ashburnham house (before 1662), remains in Westminster.

The Great Fire of London, 1666, destroyed four-fifths of the City. In the rebuilding the earlier street plan was followed in the main. In the interests of fire prevention, private houses were now built in brick and stone. Among the lost mediaeval works were most of the halls of the city companies. They were rebuilt in brick and stone on similar lines to the private houses. World War II again destroyed most of them; Skinners' hall and Vintners' hall still stand, with interesting woodwork, and Apothecaries' hall, which retains its courtyard, is valuable as an example of the former appearance of many City houses.

Before World War II, the 32 surviving examples of parish churches rebuilt, using the mediaeval ruins as foundations, under the supervision of Sir Christopher Wren formed an unrivalled group of works in the English Baroque style. The beautifully varied steeples formerly gave great charm to the City skyline. In many cases steeples have survived, including the two finest. St. Bride's, Fleet street (1702), and St. Mary-le-Bow (1683). The only churches to have survived the bombing intact are St. Benet, Paul's Wharf (1677–85); St. James, Garlickhithe (1674–87); St. Magnus the Martyr, London Bridge (1676–1705); St. Margaret Pattens (completed 1689); and St. Mary at Hill (1672–77); though some of the damaged churches were being restored in the 1950s. The major ecclesiastical monument of the City, St.

Paul's cathedral (1675–1710), a fine and characteristic work of Wren, is almost undamaged and still dominates the City. Other buildings by Wren in London are Greenwich observatory (1675–76), parts of the Royal Naval hospital. Greenwich (1696–1705); Chelsea Royal hospital (1682–92); and almost certainly Morden college, Blackheath (founded 1695); also work at Kensington palace (1690–1704).

In the early 18th century, the rapid growth of London continued. Gray's inn, Lincoln's inn, Inner Temple and Middle Temple were almost entirely rebuilt and retain the distinctive character of the period in spite of further modification and wartime damage. The squares, the most distinctive unit of Georgian town building, can be seen in the areas east and west of the City. Between 1710 and 1730 a number of fine churches built to serve these regions brought to prominence a new generation of architects following in the footsteps of Wren. Worthy of note are: St. Mary-le-Strand (1714–17) and St. Martin-in-the-Fields (1721–26), both by James Gibbs; St. Mary Woolnoth (1716–27), St. George, Bloomsbury (1720–30), and Christ Church, Spitalfields (1723–29), all by Nicholas Hawksmoor; and St. George, Hanover square (1712–24), by John James. In the City, the Mansion house was built in 1739–53 by George Dance the Elder on the site of a market. This was the first of the group of grandiose buildings marking the centre of activity in the City. Subsequent rebuilding there was in the same spirit. The ancient hospitals of London were rebuilt and several new ones constructed on the outskirts. Work by James Gibbs is to be seen at St. Bartholomew's hospital (begun 1730). William Kent designed the Horse Guards building before his death in 1748; it was executed by John Vardy, 1751–58.

In the second half of the 18th century the outward expansion of London was not as rapid, but some rebuilding was done, and several notable buildings resulted. Stylistically a move was made away from the earlier Palladianism. Robert Adam, probably the best-known 18th century architect, designed an important scheme. the Adelphi (begun 1768). of which the Royal Society of Arts building (1772–74) survives. Kenwood house. Highgate (1767–68), is a fine example of a large Adam country house. Adam's admiralty screen (1760) sets off Thomas Ripley's belatedly Wrenian admiralty building (1722–26). Robert Adam designed extremely graceful façades and delightfully varied interiors for his town houses, of which Chandos house, Chandos street, Cavendish square (1771), and 20 Portman square (1775–77), now the University of London Courtauld Institute of Art, remain in a good state of preservation. Adam's contemporary. Sir William Chambers, designed the first part of Somerset house (begun 1776), which survives in its riverside setting, with the arcaded terrace to the river front and a triumphal entrance on the Strand.

Sir John Soane's work is far more personal and daring than earlier architecture. The Bank of England (1792–1833) was his major work. The screen wall survives relatively unaltered, also some of the interior, though overshadowed by the rebuilding of 1925–39. Interesting work by him can also be seen in his own house (1812–14), number 13 Lincoln's Inn Fields (now Soane museum), and in the Dulwich art gallery and mausoleum (1811–14; destroyed 1944 but rebuilt from the original plans).

In the latter part of the 18th century important building projects were carried out on the great estates in the northwest of London. The most striking and best preserved is on crown land, the Regent's park-Regent street scheme (1811–23), designed by John Nash. The best surviving work is in the undamaged part of Park crescent. Portland place had already been laid out by Robert Adam's younger brother James, but very little is left. In 1821 St. James's park was redesigned on "picturesque" principles and Carlton House terrace was laid out. This scheme was meant to include Buckingham palace; and the Marble arch (1828, later moved to its present site at the top of Park lane) was intended for the park façade of the palace. Hyde park was laid out at the same time, and Decimus Burton designed (182; et seq.) the lodges to it, the excellent Ionic screen at Hyde Park corner and the Roman triumphal arch into Constitution hill, now somewhat dwarfed by the Quadriga placed on top in 1912. Three buildings of the early 19th century dedicated to learning can be compared: University college (1827–29) and the National gallery (1832–38), both by William Wilkins; and the British Museum (1823–47) by Robert Smirke. St. Pancras parish church (1818–22) by H. W. Inwood (with his father William Inwood) can be taken as a typical example of the church design of the period, with its antiquarian copying of classical details. Two interesting late Georgian theatre exteriors survive: Drury lane (1811), by Benjamin Dean Wyatt; and the Haymarket (1820–21), by John Nash.

In the 19th century London increased dramatically in area, and the administrative centre was largely, rebuilt. Early 19th century work is distinguished by the use of stucco, but brick returned to general use later. The new railway system called for a new type of building in the shape of the great termini. These display an interesting early use of cast iron and glass. The earliest, Euston (1839–40), by P. Hardwick, has a massive Doric entrance portico. King's Cross (1851–52) by L. Cubitt has a forthright brick faqade. The iron and glass train hall at Paddington (1854) is by the great engineer I. K. Brunel. Finally, there is Sir Gilbert Scott's St. Pancras station (1868–74): his complex Romantic Gothic exterior contrasts with the admirable train shed in glass and iron (1868) by W. H. Barlow. The use of iron frameworks became general. Buildings were made taller and the exteriors became ever more varied. All types of earlier architecture were copied. In the club houses of St. James's, as in the City warehouses, Italian Renaissance palaces were taken as models in the 1830s. In the early 1850s the copying of every kind of Gothic architecture began. For some time both styles were in use. The outstanding examples of Victorian Gothic in London are: the houses of parliament (1837–57) by Sir Charles Barry, assisted by A. W. N. Pugin; the Law courts, Strand (1874–82) by G. E. Street; the Albert memorial (1863–72) by Sir George Gilbert Scott; and Tower bridge (1886–94) by Sir John Wolfe-Barry and Sir Horace Jones.

During this century, particularly under Bishop Charles James Blomfield (bishop 1828–57), many new churches had to be provided for the ever growing metropolis. The most remarkable are those of William Butterfield (*e.g.*, All Saints', Margaret street, begun 1849), stridently original and wholly at variance with time-honoured standards of beauty. Pugin designed the Roman Catholic cathedral of St. George Southwark (1841, much damaged in World War II) and Scott rebuilt St. Mary Abbots', Kensington (1869–79), closer to mediaeval models. Other leading London church architects were G. E. Street (St. Mary Magdalene, Paddington, 1868–78), J. L. Pearson (St. Augustine. Kilburn, 1870–80) and G. F. Bodley (St. Michael, Camden Town, 1876–81). The great revival of domestic architecture and design, beginning in the 1860s under William Morris' leadership, is also well displayed in London, mainly in houses in Hampstead, Kensington and Chelsea—by now centres of artists and artistic people—designed by Philip Webb, Richard Norman Shaw, C. F. A. Voysey and their followers.

Throughout the 19th and the 20th centuries blocks of dwellings for working-class tenants were constructed. One of the earliest (of 1849) remains in Streatham street, Bloomsbury. In the late 19th and early 20th centuries a restated English Baroque was evolved and used on a number of monumental buildings. several of which are still on the river front. Examples are New Scotland Yard (1891) by Richard Norman Shaw, and County hall (1912–22) by R. Knott. Regent street and Piccadilly circus were redesigned in this style in the early 20th century and Bush house and the buildings of Kingsway continued this trend into the 1920s. Sir Aston Webb, a leading architect of the early 20th century, designed the Victoria and Albert museum (built 1899–1909) and the Buckingham palace main faqade (1913). Westminster cathedral (1895 *et* seq.) by J. F. Bentley is a fine neo-Byzantine building in red and white brick, with a tall campanile.

In the second and third decades of the 20th century enormous buildings in an unadorned, massively simple style were built. Outstanding examples are the Port of London Authority building, Tower hill (1922); Imperial Chemical house, Millbank (1929–36), by Sir. F. Baines; London Transport Executive headquarters, Westminster (1928–29), by Charles Holden; Broadcasting house (1930–31) by Val Myer; and the University of London senate house (1933 et seq.) by Holden.

But in the early 1930s a new trend appeared, under contemporary French and German influence (Walter Gropius and Eric Mendelsohn. the leading German architects were in London in the mid-1930s as political refugees and designed houses in Chelsea). Buildings were constructed of reinforced concrete, with much use of cantilever construction to permit larger unbroken window areas, and without the masking screens of decoration hitherto considered indispensable; for example, Sassoon House flats, Camberwell (1932), by E. Maxwell Fry; Simpson's store, Piccadilly (1936), by J. Emberton; Peter Jones's store, Sloane square (1936), by W. Crabtree and Sir Charles Reilly; the two Highpoint blocks of flats. Highgate (1936 and 1938), by B. Lubetkin and Tecton; and the Pioneer health centre, Peckham (1934–35), by Sir Owen Williams. Battersea power station (1933) by Sir Giles Gilbert Scott, is an impressive functional design in brick.

Postwar building continued in this style. Among outstanding works are Westminster Council flats, Ranelagh road (1946), by Powell and Moya; and the Royal Festival hall, South Bank (opened 1951), by R. H. Matthew and J. L. Martin. (K. Mn.)

POPULATION

The following table gives comparisons between certain census returns for Greater London and its chief component parts, namely, the City, the administrative county and Outer London (*i.e.*, the zone outside the county boundary but inside Greater London). All the figures before those of 1921 are adjusted to these areas.

Year	City	County	Outer London	Greater London
1841	123,563	1,825,714	286,067	2,235,344
1881	50,569	3,779,728	936,364	4,766,661
1921	13,709	4,484,523	2,995,678	7,480,201
1931	10,996	4,397,003	3,806,939	8,203,942
1951	5,324	3,347,982	4,997,801	8,346,137

In the above table it will be npticed that the population of Greater London has been increasing steadily and that since 1921 a decline in the population of the administrative county has been added to the long decline in that of the City. The increase in the whole London area since 1921 has taken place, therefore, entirely outside the county boundary, and of this increase the most striking feature is the rapid growth of Outer London. There have been two distinct population movements, one outward from the centre and one inward from the provinces.

As the population of London has been increasing, so has its character been changing. For centuries London has been one of the greatest seaports of the world and a great centre of commerce, but never before had it been a centre of manufacturing industry in the way it was becoming up to the outbreak of World War II; and a great part of the new development was in the outer ring.

One effect of this trend was to raise the proportion of the population born outside the area. through immigration that was to a great extent industrial in character. The peak of the immigration was in the 1930s and the proportion of "natives" was expected to rise again by the 1950s as those who had settled in London had locally born families. According to the sample analysis of the 1951 census, nearly three-quarters of the residents in the Greater London registration district were born in the London and south-eastern region. The numbers (in thousands) from other parts were as follows:

Rest of England	1,25j	Commonwealth	89
Wales	164	Colonies and protectorates	38
Scotland	142	Foreign	301 (of whom 120 were aliens)
Northern Ireland	38		
Eire	169		

GOVERNMENT

The Municipal Corporations act (1835) did not affect London. This was not so much a deliberate omission as that the commissioners on whose reports the act was based were baffled by the problems of the metropolis and failed to reach a definite conclusion about its future. The City of London, unlike other large towns, did not expand as the built-up area developed. It remained, as it still remains. within its historic "square mile" with little change from the middle ages. The rest of London was governed by the inhabitants of each parish in vestry assembled, save that in some instances parishes had elected select vestries under the provisions of the Vestries act, 1831. In neither case had the vestry powers of town management. To meet the needs of particular localities, commissioners or trustees having such powers had been from time to time created by local acts. In 1855 these local acts numbered 250. administered by not less than 300 bodies either self-elected, or elected for life, or both, and therefore in no degree responsible to the ratepayers. There were two bodies having jurisdiction over the whole metropolis except the City, namely, the officers appointed under the Metropolitan Building act of 1844, and the metropolitan commissioners of sewers. appointed under the Commissioners of Sewers act, 1848. Neither was responsible to the ratepayers.

Metropolitan Board of Works.—To remedy this chaotic state of affairs, the Metropolis Management act, 1855, was passed. Under that act a vestry elected by the ratepayers of the parish was established for each parish in the metropolis outside the City. The vestries for larger parishes became the local authorities; smaller parishes were grouped under district boards. A central body, the Metropolitan Board of Works, having jurisdiction over the whole metropolis (including the City) was also established, the members of which were elected by the common council of the City, the vestries and district boards and the previously established local board of Woolwich (*q.v.*). The board had a salaried chairman. The area of the metropolis for local government purposes was for the first time defined. Different areas were considered, including the police district, but that finally chosen was the district used by the registrar general for bills of mortality. The subsequent county of London was still virtually the same area in 1954. The Metropolitan Board of Works was given certain powers of supervision over the vestries and district boards, became the authority for main drainage and for the administration of the Building acts and subsequently had many additional powers and duties conferred on it. It completed the main drainage scheme; made a number of street improvements; constructed the Thames embankment; acquired 30 parks including Hampstead heath; and established the London Fire brigade. But like some of the vestries it also acquired an unfortunate reputation for corruption, which hastened its abolition when the general reform of county government in England began.

London County Council.—By the Local Government act (1888) a directly elected county council was established to administer the same metropolitan area as had been constituted in 1855. It took over the administrative powers of the justices of the peace as well as the functions of the Metropolitan Board of Works. By the Education (London) act (1903) the London County council took over the elementary education duties of the London School board. The Local Government act (1929) brought the transfer to it in 1930 of the poor law functions of the 25 boards of guardians, the Metropolitan Asylums board, the four boards of district school managers and the Central (Unemployed) body. Maternity and child welfare powers were transferred from the metropolitan boroughs under the National Health Service act (1946).

The act of 1888 left the vestries and the City unaffected. Over the next ten years there were several abortive bills to reform London government. Controversy raged between the "unifiers," who wished to amalgamate the City and the county council into a central corporation. and the "tenifiers," who wished to place local government in the hands of ten separate boroughs. In 1897 Kensington and Westminster petitioned to be created boroughs by the grant of charters under the Municipal Corporation acts. Instead the London Government act (1899) was passed. This interfered with neither the L.C.C. nor the City but kept fairly close to the structure adopted for the rest of the country in 1894. For the 40-odd vestries and district boards were substituted not 10 but 28 boroughs, each with a mayor and aldermen but with very much the same powers as the bodies which they succeeded.

In 1955 the London County council had 126 councillors, each parliamentary constituency returning 3 representatives. These councillors elect a chairman, who need not be already a member, and 21 aldermen. Councillors are elected every three years, the first postwar election being in March 1946. Aldermen hold office for six years, one half being elected by each new council. By convention the vice-chairman is chosen from the majority party and the deputy chairman from the minority. The standing orders also provide for a "leader of the council" and "leader of the opposition" who are entitled to attend and to speak but not to vote at the meeting of any committee or subcommittee of which they are not members.

For the first year of its life the council met at the City's Guildhall. It then moved into the premises of the Metropolitan Board of Works in Spring gardens, now known as Old County hall. The present County hall on the south bank of the Thames was opened in 1922. An annex including a conference hall was completed in 1933 and further office accommodations finished during World War II.

Corporation of the City of London. — The legislation of 1855, 1888 and 1899 left the government of the small area of the City in the hands of an unreformed corporation. Here the mediaeval system, in spite of any anomalies with respect to modem conditions. has resisted reform, and no other municipal body shares the traditions and peculiar dignity of the City corporation. This consists of a lord mayor, 25 aldermen and 206 (to be reduced to 159 by St. Thomas' day, 1959) common councilmen, forming the court of common council, which is the principal administrative body. The election of common councilmen, whose institution dates from the reign of Edward I, takes place annually, the electors being the ratepayers divided among the 25 wards of the City. An alderman (q v) of each ward (save that the wards of Cripplegate Within and Without share one) is elected for life. The lord mayor is now elected by the court of aldermen from two aldermen nominated in the court of common hall by the livery, an electorate drawn from the members of the ancient trade guilds or livery companies (*q.v.*), which, through their control over the several trades or manufactures, had formerly an influence over the government of the city which from the time of Edward III was paramount.

Metropolitan Borough Councils. — The metropolitan borough councils are elected every three years in May of the year after the county council elections. The councillors elect the aldermen who hold office for six years and are in the proportion of one to every six councillors. Councils vary in size; the tendency being to reduce the size when there is a reorganization. In 1954, 11 of the 28 boroughs had 60 councillors and 10 aldermen; the smallest had 30 councillors and 5 aldermen. Some wards return as many as nine councillors but the tendency is to standardize representation at three councillors for each ward.

Each borough has a mayor elected by the council. He need not be a member before he is elected but must be qualified to be one. Most councils also elect a deputy mayor from among their members. Each borough has its town hall. Some are modem buildings. but many are the old vestry halls, which have survived, with or without additional buildings, to meet expanding needs.

As an instrument for negotiation with central government departments and with the county council and for discussion of common problems, the borough councils established in 1912 a standing joint committee. This is made up of three representatives of the City and of each borough council, one of whom is usually the town clerk. It is assisted in its deliberations by advisory bodies of chief officers from the boroughs. In addition to its consultative work, the committee manages a union catalogue for all the public libraries in the county and provides an organization and methods service for those boroughs who wish to use it.

The 19th century provides a rich bibliography of royal commissions, select committees and abortive bills concerned with the reorganization of London government and its relation to the City. In the 20th century the more pressing problem has seemed to be the relation of the administrative county to the built-up areas beyond and the possibility of a unified local government for Greater London. A royal commission under the chairmanship of Viscount Ullswater sat from 1921 to 1923. The majority report was content to leave the structure as it was and proposed a London and home counties advisory committee to secure some common action. One minority report suggested a division of an area within ten miles of Charing Cross into county boroughs with a regional authority for some common services. Another proposed a directly elected Greater London council.

In 1945 a committee under the chairmanship of the marquess of Reading was established to examine London government within the county and the division of powers between the L.C.C. and the borough councils but dissolved without reporting.

The county of London was omitted from the reference to the Local Government Boundary commission which reported in 1947. The report excluded from consideration the Greater London area on the ground that it could not be treated independently of the future of the county itself. In 1949 a departmental committee under Clement Davies, set up to advise on machinery to implement the Greater London plan, pointed to the need for a regional authority and an "entirely new alignment of regional, county and local functions" and recommended reference to a Local Government commission.

The Central Government. — Apart from its control of the police, the central government has no greater administrative functions in the metropolis than in the rest of the country. The greater part of London was in 1954 in the standard administrative region V, London and southeastern. The ministry of housing and local government has a separate London region for the built-up metropolitan area.

The metropolitan police force was established by Sir Robert Peel in 1829. It is under the direction of a commissioner who is appointed by the crown and acts under the authority of the home secretary. Half the cost of the force is met out of central government funds and the other half by way of precepts levied on the borough and district councils. In addition to the ordinary police, operating in 22 divisions, there is a body of Thames river police and specialist services at headquarters in New Scotland Yard, available for consultation by provincial forces. The City of London force was established in 1839 and is under the direction of a commissioner appointed by the Common council.

As elsewhere, prison commissioners control the London prisons. All are used as local general prisons with additional special features. Brixton has accommodation for civil prisoners, Pentonville a small part reserved for recalcitrant prisoners. Wandsworth serves as an allocation centre for corrective trainees; Wormwood Scrubs as a corrective training and a young persons' prison as well as a reception centre for Borstal. Holloway is a women's prison. Feltham in Middlesex is a closed Borstal for boys and Latchmere house near Richmond a reception centre.

London has the judicial machinery of the rest of the country with certain peculiar features of its own. The principal courts for the trial of criminal cases are the central criminal court and the courts of quarter sessions. The central criminal court, taking the place of the provincial assizes, was established by an act of 1834 and sits at the Old Bailey, under a high court judge and two full-time judges, the recorder of the City of London and the common serjeant. It serves the counties of London and Middlesex and parts of Essex, Kent, Surrey and Hertford. The remaining parts of Greater London come within the southeastern circuit. London quarter sessions are held at Newington causeway.

In the administrative county, except for the northern part of Hampstead, the main courts of summary jurisdiction are the 12 metropolitan police courts, presided over by stipendiary magistrates. The chief magistrate's court is at Bow street. There are also stipendiary magistrates at West Ham and East Ham. In the City, the courts of summary jurisdiction are at the City of London justice rooms at the Mansion house, where the lord mayor or one of the aldermen sits and at the Guildhall where the aldermen sit in rotation. In the remaining parts of London, summary jurisdiction is exercised by the petty sessional courts of justices of the peace, who have concurrent jurisdiction where there is a stipendiary magistrate. The old petty sessional divisions were revised in 1953 and are now within the county of London.

Juvenile courts within the metropolitan police court area are in an exceptional position in that they are controlled by the home office. The home secretary appoints from among the London justices a panel of magistrates who sit in six courts, one for every two police court districts. The London Probation service is also under the control of the home secretary, advised by a committee of metropolitan magistrates and juvenile court justices.

The county court districts in London bear no relation to any local government areas. The mayor's and City of London court covers the City. Some districts are wholly within the county, some within the remaining part of Greater London and some fall partly within and partly outside London. The coroners' districts include one for the City and two franchise districts for the Tower liberty and the Queen's household. With these exceptions, the London coroners are appointed by the councils of the respective counties or county boroughs.

Parliamentary Representation.— The administrative county returns 42 members to parliament. The rest of Greater London is spread over about 50 constituencies. One metropolitan borough, Wandsworth, returns four members; three return three; five, two; and 14, one each. The cities of London and Westminster together return one member as do Shoreditch and Finsbury. Hackney returns one and one in conjunction with Stoke Newington; St. Pancras one and one with Holborn. Barons court is shared by Fulham and Hammersmith.

Finance, Rating, **etc.**—Before 1899 the duties of overseers in London had been performed by most diverse bodies. In that year the new borough councils were constituted in every case the overseers within their respective boroughs, except that the town clerk of each borough performs the duties of an overseer with respect to the registration of electors Again, with regard to rates. there were till 1899 three or four different rates leviable in each parish. These are now consolidated into a single rate, called the general rate. Every precept sent by an authority in London for the purpose of obtaining money which has ultimately to be raised out of a rate within a borough is sent to the council of the borough. The metropolitan borough councils make one general rate, which includes the amount necessary to meet their own expenditure, as well as to meet the demands of the county council and the metropolitan police. The total amount of rates raised in 1951–52 was £47,173,075, representing an average rate of 17*s.* 9*d.* in the pound (calculated on the basis of the net produce of a rate of a penny in the pound). Of this one-third was retained locally by the City corporation and the metropolitan borough councils.

The total expenditure of the local authorities, within the county, in 1951–52 was £109,683,703 when payments included twice had been deducted. This expenditure was divided mainly among the following bodies: London County council, £59,369,584; metropolitan police (proportion), £9,639,146; City of London corporation, £3,369,659; metropolitan borough councils, £32,114,983. Of the county council expenditure £27,625,832 went to educational services; £7,994,828 to housing; £6,015,965 to the metropolitan water board (proportion). Of the total expenditure of the boroughs, £5,041,652 went to highways and £4,605,810 to housing. From this gross expenditure £31,420,835 representing fees, rents and other receipts had to be deducted before reaching the amount to be met out of public funds. For example, nearly two-thirds of the expenditure on housing was met out of rents.

For certain services such as education and housing the central government makes a specific grant in aid. The total grants payable in this year were £27,171,650 or 24.8% of the gross expenditure. In addition to the grants in aid of specific services London received before 1929 the revenue from certain assigned taxes. Between 1929 and 1948 a block grant was paid to London in common with other local authorities, the amount being calculated according to a formula designed to take into account the comparative needs of different areas. After the Local Government act of 1948 the county of Essex and the county boroughs of East and West Ham were the only areas in Greater London to share in the new equalization grant. Instead of a central government grant, the administrative county introduced a new scheme for equalizing the rate burden.

This had long been a difficult and contentious question. A first step was taken by the establishment of the Metropolitan Common Poor fund in 1867; in 1894 an equalization rate of 6*d.* was levied over the county and distributed as a capitation grant. After World War I the situation became more acute, particularly with the growth of unemployment. It was brought to a head in 1921 by the refusal of the Poplar Borough council to pay the county precept, as a result of which the mayor and most of the council, George Lansbury among them, were committed to prison for contempt of court. In 1929 it was eased by the transfer of poor relief to the L.C.C. which meant that it was financed out of the general county precept. But there remained wide disparities between boroughs of high ratable value, such as Westminster and St. Marylebone, and those such as Poplar and Bethnal Green.

The purpose of the 1948 scheme was in broad terms to bring the ratable value per head of the poorer boroughs up to the average for the county. For the purpose of these calculations the population was weighted by the proportion that the net annual value bore to the ratable value. a weighting which took into account the effects of industrial derating. In order to bring a subnormal borough up to the average, additional ratable value had to be credited ta it. The rate in the pound payable on this credited ratable value was the amount of the grant paid out of the county funds.

Ecclesiastical Areas and Denominations.— The diocese of London founded in 314, covers the cities of London and Westminster, the county of Middlesex and the boroughs of the county of London north of the Thames. In the diocese are the bishoprics suffragan of Fulham, Kensington, Stepney and Willesden. The bishopric of Southwark was created in 1904, hdving been previously a bishopric suffragan in the diocese of Rochester. It contains the bishoprics suffragan of Woolwich and Kingston-upon-Thames. Greater London is also included in the dioceses of Chelmsford, Rochester, Canterbury, St. Albans and Guildford. Westminster is the seat of the Roman Catholic archbishopric in England, and Southwark and Brentwood are bishoprics. London is divided into six Methodist districts: north, northeast, northwest and south, southeast, southwest. The diocesan cathedrals in the county are St. Paul's and St. Saviour's, Southwark. The Roman Catholic cathedrals are Westminster and St. George's, Southwark. In 1903 the Wesleyans acquired the site of the Royal aquarium, near Westminster abbey, for the erection of a central hall. The Great Synagogue of the Jews is in Aldgate. The headquarters of the Salvation Army are in Queen Victoria street. City. There are numerous foreign churches, among which may be mentioned the French Protestant church in Soho square; the Greek church of St. Sophia, Moscow road, Bayswater; the German Evangelical church in hlontpelier place, Brompton road; and the Dutch Protestant church in Austin Friars.

PUBLIC HEALTH

London has separate health legislation from that of the rest of the country, the principal statute being the Public Health (London) act (1936). Public health bye-laws for London are made by the L.C.C. although in many cases administered by the metropolitan boroughs.

Sanitation.— Drainage is shared between the county and the metropolitan borough councils. The first act providing for a commission of sewers in London dates from 1531. Various works of a more or less imperfect character were carried out, such as the bridging over in 1637 of the River Fleet, which as early as 1307 had become inaccessible to shipping through the accumulation of filth. Scavengers were employed in early times, and sewage was received into wells and pumped into the kennels (channels) of the streets. A system of main drainage was inaugurated by the commissioners of sewers in 1849, but their work proceeded very slowly. It was carried on more effectively by the hletropolitan Board of Works (1856–88), and was transferred in 1889 to the newly created London County council, which completed and improved the system, covering the county of London, Willesden, Tottenham, Wood Green, West Ham, Brent area (Willesden), Leyton, Walthamstow, Ilford. Barking and Penge and parts of Acton, Croydon, Beckenham, Hornsey and East Ham. There are actually two distinct systems, north and south of the Thames, having separate outfall works on the north and south banks of the river. The sludge is taken out to sea by boat and the remainder discharged into the river. The borough councils provide and maintain the local street sewers, which discharge into the county trunk seners. The system takes both sew-age and rainwater, being supplemented by storm relief sewers which discharge storm water into the Thames. Outside the London drainage area, the borough and district councils are responsible, though there are a number of centralized disposal works administered by joint boards and committees. The collection and disposal of house refuse is the responsibility of the borough councils. Controlled dumping to reclaim waste land is the most common method of disposal.

The City of London is the port health authority. The City and the metropolitan boroughs undertake sanitary inspection and the inspection of food, slaughterhouses, offensive trades and rodent destruction, and the provision of baths and washhouses.

Cemeteries.—The cemeteries of London have developed from the old burial grounds of the different parishes. There are between 300 and 400 disused grounds, some of which are now open spaces. Most of the cemeteries now in use were opened in the 19th century. particularly in the 1850s, after the passing of the Burial act (1852). As these are filled, new ones have to be opened outside the county boundaries. The Brompton cemetery is the property of the government. Several are privately owned including the large Kensal Green cemetery. Most of the metropolitan boroughs have adopted the Burial act and provide municipal cemeteries inside or outside the county. The first crematorium in Greater London was opened in 1902 at Golders Green. The City opened one at Ilford in 1904. Metropolitan boroughs followed suit in the 1930s.

Hospitals.—The present hospital service in London represents a confluence of two very diverse channels. Most of London's best-known teaching hospitals were not under public management before 1948, such as St. Bartholomew's, the oldest, founded by Rahere in 1123, St. Thomas' (1200), Guy's (1724), St. George's (1733), St. Mary's (1845) and the London hospital (1740). At the end of 1936 there were 107 voluntary hospitals in the London county area, containing 15,443 beds. Some control over them was exercised by the King Edward's Hospital fund through its power to give or withhold grants.

Poor law hospitals go back to 1601 but the whole position was reorganized after the Poor Law Amendment act (1834), which created the unions and boards of guardians. In 1867 the Metropolitan Asylums board (M.A.B.) was established. This comprised some members appointed by the guardians and some nominated by the central government. Sickness of a general character was treated in the poor law infirmaries. The M.A.B. provided specialist hospitals for infectious diseases, tuberculosis and some other diseases. Mental hospitals were divided. Some came to the L.C.C. through the justices; some were established by the M.A B.

The 25 boards of guardians within the county and the M.A.B. were abolished by the Local Government act (1929) and in April 1930, 77 hospitals as well as 5 mental hospitals were transferred to the L.C.C. By 1948 the council maintained 100 hospitals with about 70.000 beds. On July 5 of that year, under the National Health Service act (1946) these were transferred to the regional hospital boards 'nhich also took over the voluntary hospitals, except for the teaching institutions which were nationalized under separate management. After 1948 the, county of London ceased to exist as a unit of hospital administration. There are four metropolitan hospital regions with regional boards, fanning radially from the Marble arch, but these stretch far beyond the boundaries of Greater London. In addition to these boards. there are governing bodies for 12 London undergraduate teaching hospitals and 14 graduate.

Maternity and child welfare became the responsibility of the metropolitan boroughs in 1918, though some councils continued to use the services of voluntary bodies. Ante- and post-natal clinics were provided with domiciliary supervision by health visitors. Before 1939 some boroughs provided lying-in hospitals in addition to the general L.C.C. and voluntary hospitals. Home helps were introduced as well as day nurseries, which were greatly increased during World War II. By the 1946 act these functions all passed to the L.C.C. Midwives came under the authority of the L.C.C. in 1936, as a municipal service. For the years 1896–1900 the death rate in London for babies under one year was 162 per 1,000 births. By 1938 it had fallen to 57. In 1953 it was 24. No borough in 1953 had an infantile mortality rate greater than 39.

The other branches of the national health service are under the London Executive council which covers the administrative county. The rest of Greater London comes under the executive councils of the appropriate counties and county boroughs.

WELFARE

London had the rudiments of a welfare system before the Poor Law Amendment act (1834). Under acts of 1647 and 1662 a Corporation of the Poor was established and by 1732 there were 45 workhouses in London. The act of 1834 set up boards of guardians for different parishes; these were joined in 1867 by the Metropolitan Asylums board. In the same year began the Metropolitan Common Poor fund which was the first attempt to spread the burden of maintaining the poor more evenly over the county. Subsequent legislation and administrative changes developed and modified the system.

Since 1948 responsibility for helping those without resources and those whose means, including national insurance benefits, were inadequate was placed on the National Assistance board (N.A.B.). Welfare, apart from financial assistance, remained with the county councils, who also received wider powers to care for children deprived of normal home life.

The N.A.B. followed the ministry of national insurance in dividing the standard London and southeastern region into two. The inner London region covers the counties of London and Middlesex with a small piece of Hertfordshire; the outer London region covers western Essex, Surrey, Kent and Sussex. Within these regions there are areas of which 26 are within the administrative county. For each county in the two regions there is an advisory committee; for London there are two, one for each side of the Thames. The county councils provide welfare homes and, on behalf of the N.A.B., manage reception centres in place of the old casual wards. Some of the homes are adapted from old institutions, others are smaller private houses taken over in order to provide smaller units. The L.C.C. has three lodging houses for men who, without being destitute, have no permanent home. There are also 11 hostels available for employed persons. A new and special problem is provided by those who, while not necessarily in financial difficulties, are unable to obtain housing accommodation. For them. accommodation is provided by the L.C.C. in homeless family units and in rest centres. There are four reception centres in the administrative county. The biggest of these, in Camberwell, accommodated (Dec. 1953) an average of j61 persons a night or a little more than one-quarter of those so accommodated in Great Britain.

In Nov. 1953 there were in the administrative county 8,719 deprived children in the care of the L.C.C. This was 11.3 per thousand of the population under 18 years. Of them 22% were boarded out. In Middlesex 5, and in Surrey 4.4 per thousand of the population under 18 were in care.

Voluntary Agencies.—The special social problems of a great urban area have led in London to the development of voluntary work parallel with that of the official system. In addition to the big national bodies, London has had its own organizations, which have grown up out of the spasmodic religious and philanthropic work of the 18th and early 19th centuries. In 1869 the Charity Organization society was founded to provide systematic help for those in need, working through branches spread through the county. Octavia Hill (*q.v.*) began her pioneer work in housing management in 1867 by acquiring houses in St. Marylebone. Later in the century came the settlements, of which the best known are Toynbee hall (1884) in Stepney, Oxford house in Bethnal Green and Cambridge house in Camberwell. In 189j the first hospital almoner began work at the Royal Free hospital. By 19j3 the Annual Charities Register and Digest gave particulars of 3,000 voluntary organizations available for citizens of the metropolitan area.

After World War II and the growth of publicly provided welfare services, the work of voluntary organizations moved away from various forms of material assistance to problems of personal adjustment, such as marital disharmony and behaviour problems in children. In 1946 this difference in emphasis was marked by the change of name of the Charity Organization society to the Family Welfare association. Family service units specializing in helping "problem families" established units in Stepney, Kensington and Islington. There was also a growth in specialist organizations. particularly for the care of the aged and the physically handicapped, such as spastics and paraplegics. The co-ordination of voluntary social work and the furtherance of community organizations is the special concern of the London Council of Social Service. In 1953 in Greater London there were 27 local councils of social service of which 5 were within the county.

PUBLIC UTILITIES

Electricity. — The Metropolitan Board of Works and the commissioners of sewers in the City began experiments with electric light. which was introduced in 1881 at the Royal Exchange and neighbourhood. At the close of the 19th and the beginning of the 20th century a large number of electric light companies came into existence, and some of the metropolitan borough councils and local authorities within Greater London also undertook the supply.

Under the Electricity Supply act of 1926, the London and Home Counties Joint Electrical authority, composed of representatives of the county councils and the electrical undertakings, was formed and made responsible for the supply over an area of 1,841 sq.mi., stretching from Guildford to Gravesend and from Hertford to Reigate. Since 1948 the London Electricity board has served an area of 253 sq.mi. This is the smallest of the country's distribution areas but has the largest population.

Gas. — From 1416, citizens were obliged to hang out candles between certain hours on dark nights to illuminate the streets. An act of parliament enforced this in 1661; in 1684 Edward Heming, the inventor of oil lamps, obtained a licence to supply public lights; and in 1736 the corporation took the matter in hand, levying a rate. Gaslighting was introduced on one side of Pall Mall in 1809, though it is said that Golden Lane Brewery and portions of Beech and Whitecross streets were lit by gas in 1807. In 1810 the Gas Light and Coke company received a charter and developed gaslighting in 'Clrestminster. Since 1948 the gas industry has been nationalized and managed by area boards.

Water Supply. — In the 12th century London was supplied with water from local streams and wells, of which Holy well, Clerk's well (Clerkenwell) and St. Clement's well, near St. Clement's Inn, were examples. In 1236 the magistrates purchased the liberty to convey the waters of the Tyburn from Paddington to the City by leaden pipes, and a great conduit was erected in West Cheap in 1285. Other conduits were subsequently built (cf. Conduit street off Bond street, Lamb's Conduit street, Bloomsbury); and water was also supplied by the company of water-bearers in leathern panniers borne by horses. In 1582 Peter Moris, a Dutchman, erected a forcer on an arch of London bridge. which he rented for 10*s.* per annum for 500 years. His works succeeded and increased and continued in his family till 1701, when a company took over the lease. Other forcers had been set up, and in 1609, on an act of 1605, Sir Hugh Myddelton undertook the task of supplying reservoirs at Clerkenwell through the New river from springs near Ware, Hertfordshire; and these were opened in 1613.

In 1630 a scheme to bring water from Hoddesdon on the Lea was promoted by aid of a lottery licensed by Charles I. The Chelsea Water company opened its supply from the Thhmes in 1721; the Lambeth waterworks were erected in 1783; the Vauxhall company was established in 1805, the West Middlesex, near Hammersmith, and the East London on the river Lea in 1806, the Kent on the Ravensbourne (Deptford) in 1810, the Grand Junction in 1811, and the Southwark (which amalgamated with the Vauxhall) in 1822.

In 1902 the Metropolis Water act constituted the Metropolitan Water board to purchase and carry on the undertakings of the eight then existing companies, and of certain local authorities. It consists of 66 members, appointed by the London county council (14), the City of London (2), the City of Westminster (2), the other metropolitan boroughs (27), the county councils of Middlesex, Hertfordshire, Essex, Kent and Surrey, the borough of West Ham, various groups of other boroughs and urban districts, and the Thames and the Lea Conservancies. June 24, 1904, was the date fixed on which control passed to the board, and by 1943 it was the largest water company in the world. It serves an area of 540 sq.mi. (42 mi. from north to south and 34 mi. from east to west). Roughly 60% of the water supplied by the board is taken from the Thames, next in importance being the Lea and New rivers. Water is regularly taken at the Laleham intake, 15 mi. above Teddington weir and intermittently from the Staines intake 4 mi. further upstream. The average amount of water supplied daily by the board was 49 gal. per head in 1952, and in 1953 there were 8.500 mi. of water pipes.

Fire Prevention. — In 1833 the fire insurance companies united to form a small fire brigade, the London Fire Engine establishment. Previously fire protection had been given by separate insurance brigades and by engines provided by parishes. In 1866, after the great Tooley street fire of 1861 had shown its inadequacy in relation to London's fire risks, it was taken over by the Metropolitan Board of Works, which also took over the fire escape stations that had been maintained since 1836 by the Society for the Protection of Life from Fire. In 1888 the Metropolitan Board of Works was superseded by the London County council. The last manual engine was used in 1899, and from 1906 the internal combustion engine was standard on all new London Fire brigade appliances. The brigade had been built up by two famous firemen, James Braidwood, the chief of the establishment. killed at the Tooley street fire, and Eyre Massey Shaw, chief officer from 1861 to 1891. It gained a great reputation for efficiency and courage. A number of other brigades were maintained alongside it by the local authorities of the Greater London area.

Under the Fire Services act (1947) the national fire service formed in World War II came to an end in 1948, and fire brigades became once again a local authority responsibility, but now of counties and county boroughs only. Greater London is therefore served by the brigades of the London County council. the county boroughs of Croydon, East Ham, West Ham and the counties included in the area; all of these have arrangements for mutual assistance when needed.

The London Fire Engine establishment began with about 80 men; in 1888 when the county Council took over, there were 581, and in 1952 there were 2,134.

The London Fire brigade has normally available 58 motor pump escapes, which combine a pump and a 50-ft. escape in one appliance, and 51 motor pumps. Most of these are fitted with water tanks and hose reels. The brigade also has 16 mechanical turntable ladders, 3 fireboats and a number of specialized vehicles such as emergency tenders and a breakdown truck for special tasks. The brigade's cost is met from the county rates, after government grant and a contribution from the fire insurance companies have been credited. These companies also maintain a separate salvage corps.

HOUSING AND TOWN PLANNING

Responsibility for providing municipal housing for the county of London is shared by the county council and the metropolitan boroughs. The L.C.C. alone has power to build outside its own area.

The L.C.C. inherited its housing powers from the Metropolitan Board of Works, and the boroughs took over the public health duties of the vestries. Until World War I they were mainly concerned with clearing unhealthy areas, providing accommodation for people displaced by highway and similar improvements as well as building a little additional housing. After the first government housing subsidy in 1919 there began a new stage of striving to meet the shortage left by the war. Until 1934 the main emphasis was on additional housing. This was the period of the develop-

ment of great out-county estates such as Becontree (Essex, 2,784 ac.), St. Helier (Surrey, 825 ac.) and Watling (Middlesex, 386 ac.). After 1934 the state subsidy was confined to dwellings used for families displaced by slum clearance and in 1935 it was extended to housing required to abate overcrowding. More emphasis was placed on rehousing on cleared slum sites. and in most cases that meant the building of blocks of flats. World War II not only suspended all housing opeiations but caused serious damage. It was estimated that of approximately 790,000 dwellings in the county about 270,000 suffered war damage. Slum clearance was only slowly resumed. In addition to the repair of war-damaged property and the building of new permanent dwellings, nearly 8,000 prefabricated temporary houses were provided, and large houses were requisitioned for conversion into emergency accommodations for the homeless. At the end of 1951 there were 37,419 of these requisitioned properties, many of them accommodating several families. This record does not give a complete picture. Between the wars municipal housing accounted for some 42% of the total provision of houses in the administrative county and 15% in the rest of Greater London. From 1945 to 1953 the proportion in the administrative county was 92%. Some of the effect of these housing efforts could be seen from the change in the census between 1931 and 1951. The proportion of persons living more than two to a room fell from 13% to 2.5%. But there are three boroughs in which the proportion is more than 4%, or twice the proportion for England and Wales as a whole.

Town planning legislation began in 1909, but until the Town and Country Planning act (1932) there was little power to control built-up areas. By this act the L.C.C. became the planning authority for the county; the City and the borough and district councils in Greater London exercised the same powers. Some of these authorities at various dates combined to form joint planning committees. Those that were in the London traffic area (within a radius of about 25 mi. from Charing Cross) formed in 1937 a standing conference on London regional planning to make recommendations on planning matters of common concern. The L.C C. began to prepare a scheme to cover the whole of its area except the City. In 1935 was launched the Green Belt scheme, designed to acquire and preserve areas of recreational and agricultural land on the outskirts of London. Much of the green belt goes beyond Greater London. It is a joint undertaking in which the cost is shared by the L.C.C. and the other county councils concerned. In 1943 a County of London plan was prepared by Sir Patrick Abercrombie and J. H. Forshaw and adopted in principle by the County council. A plan for the City was completed in 1944 but not approved by the minister of town and country planning. A subsequent plan was prepared by Sir William Holford and C. H. Holden. In 1945 Sir Patrick Abercrombie published on behalf of the standing conference the Greater London plan, which covered a much wider area than that normally regarded as Greater London. It dealt with a population (1938) of 6,250,000 and an area of 2,600 sq.mi. controlled by 143 planning authorities. The plan, which was complementary to the county plan, was accepted in 1946 with some modifications by the Advisory Committee for London Regional Planning representative of the planning authorities concerned. In 1947 a new Town and Country Planning act made the county and county borough councils the planning authorities and charged them with the duty of submitting to the minister a development plan for their area. The plan for London was approved in 195j.

An important feature of any attempt to plan London is the problem of overspill. When a congested area in London is redeveloped, it is not usually possible to rehouse on the site the same number of people as has been displaced. The Abercrombie plans estimated that between 1,000,000 and 1,250,000 people would have to be decentralized. of whom 618,000 would be from the administrative county. If the "London sprawl" and the long journey to work were not to be further extended, this would require planned settlement with industrial and other employment to accompany them. The first method of achieving this was to build new towns under government direction through the New Towns act (1946). Of the first new towns, eight were associated with the London region: Hemel Hempstead, Stevenage, Hatfield and Welwyn in Hertfordshire, Harlow and Basildon in Essex, Crawley in Sussex and Bracknell in Berkshire. In many of these cases development took the form of expansion of existing towns. The Town Development act (1952) provided an alternative way of expanding towns to accommodate overspill by agreement between local authorities of receiving and expanding areas.

By 1952–53 permanent municipal housing available for the county amounted to 205,242 dwellings. Of these 148,510 were provided by the L.C.C. (78,690 outside the county) and 56,732 by the City and metropolitan boroughs. Large postwar L.C.C. estates are St. Paul's Cray (Kent), 570 ac.; Oxhey (Herts.), 925 ac.; and Headstone Lane (Middlesex), 153 ac. Debden and Hainault estates in Essex and Sheerwater in Surrey we're still being developed in 1954.

Before 1919 about one-third of L.C.C. dwellings were cottages. In both the interwar and post–1945 periods the proportions were reversed, about one-third being in flats.

COMMUNICATIONS

This section deals with the main forms of transport in London.

Railways. — Despite national operation on a regional basis, London remains the principal focal point of the British railway system. Each region of British Railways has more than one terminal station in London--excepting the Scottish and North Eastern regions. The London Midland region operates from Euston and St. Pancras stations; the Southern from Waterloo, Victoria, Charing Cross and London Bridge stations, as well as several smaller terminals mainly concerned with suburban traffic. The Eastern region is responsible for King's Cross, Liverpool Street and Fenchurch Street, and the Western for Paddington and Marylebone.

Continental services are operated from Victoria, Liverpool Street and Waterloo, and services to Scotland from Euston, King's Cross and St. Pancras. Comparative figures of the number of passengers handled daily at the principal London terminals show Waterloo as having the largest turnover (200.000) followed by London Bridge (175,000), Victoria (140,000), Liverpool Street (125,000), Charing Cross (120,000) and Paddington (70,000). The last-named station deals principally with long-distance passengers and has little suburban traffic comparable with that at the other main London termini.

Airports. — London airport (Heath Row) was first licensed as a civil aerodrome in 1930, to a private company, and Gatwick in 1934. Northolt was largely used for civil aviation from 1946. From London airport services were operated to all parts of the world while Northolt handled about 2,000,000 passengers in 1953, out of 3,500,000 served by U.K. airports. London airport handled 1,200 000 passengers, 17,000 short tons of freight and 6.200 short tons of mail. It was proposed to develop Gatwick as the main alternate to London airport and Northolt was closed. On the plan's completion there would be three operational airports — London, Gatwick and Blackbushe.

Trams. — The first regular tramcar service in London began in Kennington road on May 1, 1870, and was follom-ed a week later by another from Whitechapel to Bow church. Electric traction appeared in 1905 but because of the fact that the streets in a large area of central London could not accommodate tram-lines along with other traffic over any great distance, there were never very many lines in the central area, though quite an extensive service existed in northern, western and eastern outskirts of the city and south of the Thames. Tram operation ceased on July 5, 1952, having at its greatest extent covered some 350 mi. of track.

Taxicabs. — At the end of 1950 there were 6,799 licensed cabs in London, but economic difficulties in the trade (*i.e.,* cost of new vehicles and of maintenance, coupled with increases in the duty on gasoline) had reduced the number to 5,209 by July 1954.

Traffic Congestion. — Attention was focused on the traffic problem as early as 1903, when a royal commission mas appointed to consider the question of transport in London. As a result of its recommendations a large and extensive program of arterial road works (mainly outside the county) was undertaken after

World War I. Nevertheless in 1951 the position in inner London had become so acute that the London and Home Counties Traffic Advisory committee issued a special report on traffic congestion. They reported that no major improvement to the roads in inner London had been made since 1905, when Kingsway and Aldwych were completed and recommended a boulevard scheme for Hyde park; the construction of slip roads on the northwest and southeast corners of St. Giles's circus to enable roundabout working to be instituted; the widening of the Strand between George Court and Charing Cross station; the widening of Euston road between Albany street and Gower street; and the construction of a roundabout at Hampstead road. It was also proposed that Tottenham Court road should be widened between Whitfield street and north of St. Giles's circus.

Some idea of the volume of traffic may be obtained from the police traffic census of July 1952 which showed that in the 12 hours from 8 A.M. to 8 P.M. the traffic volume of Hyde park corner was 77,013 vehicles, Trafalgar square 64,700, Marble arch 52,055, and Piccadilly circus 47,354.

The Traffic committee found that the largest contributory cause of congestion was the parked vehicle; a further serious cause was lack of road space at certain major intersections to allow free movement, particularly for turning vehicles. A working party on car parks set up by the minister of transport in 1951 recommended the provision of a number of garages under London squares, coupled with experiments in unilateral waiting and the use of parking meters at authorized street car parks.

PORT AND COMMERCE

The forces which led to the development of the Port of London arose primarily from its geographical and physical advantages. It is situated on a broad deep tidal river with a current sufficient to keep up a natural scour which maintains the channel, yet not so fast as to prevent the safe navigation of the largest vessels. But it is to the enormous expansion of British colonies and possessions that the port owes its prosperity.

The total value of the imports of all classes of merchandise from overseas in 1951 was £1,304,826,881, representing 33.4% of the total for Great Britain. The value of goods imported for transshipment under bond was £119,365,484. London also has the largest coastwise trade of any port in Britain, the principal commodity being coal.

The net registered tonnage of shipping (merchandise) entering and leaving the port in the year ending March 31, 1954, was:

	Foreign	*Coastwise*	*Transshipments*
Imports	18,449,780	20,494,826	1,757,324
Exports	5,936,815	3,009,486	

The total net registered tonnage of vessels that arrived and departed with cargoes and in ballast from and to British and foreign countries and coastwise, excluding naval vessels, in the same period, was 68,550,917.

The industrialization of outer London in the west and northwest increased rapidly between World Wars I and II and included many highly mechanized industries such as aircraft factories, motor-vehicle factories and electrical concerns; there were also many other ventures directed toward extensive overseas trade as well as to the home market. As a result of this industrial expansion and because of the size of London itself and its supremacy as a market for all kinds of consumer goods, the control of overseas trade gradually became concentrated in London to the exclusion of other ports in the country.

Port Administration. — Until the establishment in 1909 of the Port of London authority, the administration of the port had been largely in the hands of free competition between the dock companies and river wharfingers. The authority began its career by assuming the functions of the Thames Conservancy in the lower river and those of the old private companies in the docks and was charged with the duty of improving accommodation in the port.

The authority has a board of 28 members. Seventeen are elected by the ship owners, merchants, wharfingers and owners of river craft. One member is elected by the wharfingers in their own interests, and the remainder are appointed by the L.C.C. (4), the City corporation (2). Trinity House (1), the admiralty (1) and the ministry of transport and civil aviation (2). The authority's jurisdiction over the river extends from Teddington lock down to an imaginary line drawn from Warden point in Kent to Havengore creek in Essex. This line is 50 mi. below London bridge and 69 mi. from Teddington lock. On this part of the river, the authority is the conservator. It controls the licensing of all erections on the river banks. the regulation of the navigation of the river, the prevention of pollution and the licensing of lightermen and their craft. The control of the lighting and buoying of the river as well as of pilotage is in the hands of Trinity House. In the docks, the authority, as the successor to the dock companies, furnishes every class of accommodation, except storage for mineral oils and explosives. At the upper docks the authority undertakes the discharging of ships, whereas at the lower docks ship owners discharge their own ships, the only exception being bulk grain for which the authority provides floating elevators and carries out the work with its own staff. The actual loading of ships is not performed by the authority, its only service to export goods being the handling of such cargo as passes over the dock quays. The most important functions of the authority in the docks are connected with operations on goods stored in its warehouses and intended for sale in the wholesale markets of the City. In 1951 the tonnages of goods received by the authority for warehousing, immediate delivery or export were: imports 1,846,291 tons; exports 1,950,625 tons. The largest lock is Tilbury main entrance lock which has a length of 994 ft. and a width of 110 ft. The length of dock quays under the authority's jurisdiction is about 36 mi.

EDUCATION AND RECREATION

Education. — The British and Foreign School society (1808) and the National society (1811), together with the Ragged Schools union (1844), were the only special organizations providing for the education of the poor until 1870, but in that year, when the London School board was created. more than half the child population of London had no school to attend. Under the Education (London) act, 1903, which was passed in pursuance of the system, put into operation by the Education act. 1902, of bringing general education within the scope of municipal government, the board's activities were transferred (1904) to the County council, which at the same time was given the responsibility of maintaining the voluntary schools.

Organized higher technical education was slower in coming and did not get under way until the formation in 1893 of the Technical Education board under the county council which was, therefore, from the first the authority for such education. During its 11 years' existence it did much to improve matters, partly through grants to existing voluntary technical institutions and partly through conducting centres itself. There were also established the Central School of Arts and the London Day Training college (since 1932 the Institute of Education), besides many science lecture rooms, laboratories and workshops, while a scheme of scholarships to link elementary and secondary education was set up.

Provision for the foundation of polytechnics was made under the City of London Parochial Charities act, 1883, the model institution being that of Quintin Hogg, which had been opened in Regent street the previous year. In 1880 the City and Guilds of London institute had been formed for the advancement of technical education.

Under the Education act, 1944, elementary education ceased to be an operative term. The educational process was divided into primary, secondary and further education and the council was called upon to provide sufficient education throughout these stages. Free secondary education had to be available for all children of the appropriate age. The draft development plan was submitted to the minister of education in 1947. It estimated the number of pupils to be provided for as follows: nursery (2–5), 54,000 (one-half the age group); primary (5–12), 216,000; secondary (12–18), 160,000 (with compulsory attendance to 15; an additional 30,000 if compulsory age is raised to 16).

The development plan provided for 103 comprehensive high school units, each catering for all the children in its area of the appropriate age group. Of these, 67 would be county schools, the other 36 would be made up of voluntary schools and county complements. There would also be 21 Church of England, 42 Roman Catholic and 2 Jewish secondary schools. A further 2,500 places would be taken up in independent and direct grant schools. Nursery schools would require 1,350 units of 40 pupils, some of which would be in nursery classes in primary schools. Primary schools would average about 700 pupils. About one-fifth of the places would be in voluntary schools.

The council was required by the 1944 act to consider the provision of boarding education in appropriate cases. Two methods of doing so were adopted at first: to pay for places in existing boarding schools; and to provide new schools. By 1952 the council had become in whole or in part responsible for 572 children in boarding schools not maintained by it. One selective county boarding school was provided at Woolverstone hall in Suffolk. Entry was at the age of 11 or over.

Special Services.—The educational system also makes provision for handicapped children. In 1953 there were 8,278 London children receiving care of this kind. In addition to 14 schools for the blind, partially sighted and deaf, there were open air schools, 20 schools for the physically handicapped, 32 for the educationally subnormal, 5 schools for children presenting behaviour problems through psychological maladjustment and 6 hospital schools. For other children there were speech clinics, child guidance clinics and other specialist treatment.

Further Education.—In the year ended July 31, 1953, there were approximately 55,000 students, spending 10,000,000 student hours at evening institutes. These included vocational and general recreational classes for all ages.

More advanced technical education was provided in colleges and polytechnics. The student hours were provided about equally by the aided polytechnics and the council's technical and commercial colleges. There were 47 institutions of this kind of which 18 were aided and 29 maintained. The total number of students was about 144,000, some of whom attended full-time, some for a few days in the week and others in the evenings.

The University of London (see LONDON UNIVERSITY) which began in 1836 as purely an examining body is now a federation of a number of colleges and medical schools. It receives grants from local authorities as well as from central government funds. There are five national colleges of technology which receive direct grants from the central government.

Teachers.—The L.C.C. maintains six training colleges with places for 341 men and 1,067 women. These are not confined to London citizens many of whom go outside the county for their training. There are also 13 voluntary training colleges in the county.

In 1952–53 in London's primary and secondary schools there were 6,251 men and 9,657 women. Another 803 full-time teachers and 8,040 part-time were engaged in maintained institutions of further education.

Cost of the Education Service.—The gross expenditure of the L.C.C. education service in 1952–53 was £29,846,307. The cost per head in primary schools was £33 2s. 11*d.*, in secondary £56 0*s.* 11*d.* Of the gross expenditure 41.7% was absorbed by teachers' salaries and 4.3% by administration and inspection.

Public Schools.—In early times the priories and other religious houses generally had grammar schools attached to them. Those at St. Peter's, Westminster, and St. Paul's attained a fame which has survived, while other similar foundations lapsed, such as St. Anthony's (Threadneedle street, City), at which Sir Thomas More, Archbishop Whitgiit and many other men of eminence received education. Certain of the schools were re-endowed aiter the dissolution of the monasteries. St. Peter's college or Westminster school (see WESTMINSTER) is unique among English public schools of the highest rank in maintaining its original situation in London. Other early metropolitan foundations have been moved in accordance with modern tendencies either into the country or to sites aloof from the heart of London. Thus Charterhouse school, part oi the foundation of Sir Thomas Sutton (1611), was moved (1872) from Finsbury to Godalming, Surrey; St. Paul's school (1509) has occupied modern buildings at Hammersmith since 1884, and Christ's hospital (1553) has been at Horsham, Sussex, since 1902.

Of other schools, Merchant Taylors' was founded by the company of that name in 1561, and occupied the premises vacated by Charterhouse school from 1875 to 1933, when it moved to Sandy Lodge, near Rickmansworth. The Mercers' school, Holborn, originally attached to the hospital of St. Thomas of Acon, was refounded in 1447. It was taken over by the Mercers' company in 1542 and was transierred to Barnard's Inn in 1894. The City of London school (1442), refounded in Milk street, Cheapside, by the City corporation in 183j. occupies modern buildings on the Victoria embankment. Dulwich rollege originates in a licence granted in 1619 to Edward Alleyn to found a coilege in Dulwich. St. Olave's and St. Saviour's Grammar school received its charter in 1561 arid since 1896 has been in new buildings in Bermondsey.

Museums, Art Galleries, Libraries.—In the British Museum, London possesses one of the most celebrated collections in the world; originated in 1753 by the purchase of Sir Hans Sloane's collection and library by the government. The great building in Bloomsbury (1828–52) with its massive Ionic portico houses the collections of antiquities, coins, books, manuscripts and drawings and contains the reading rooms for the use of readers. The natural history branch was removed to a building at South Kensington (the Natural History museum) in 1881, where the zoological, botanical and mineralogical exhibits are kept.

Near the natural history branch is the Victoria and Albert museum for which an extension of buildings was begun in 1899. Here are collections of pictures and drawings, including the Raphael cartoons, objects of art of every description, including Japanese, Chinese and Persian collections, and an Indian section. The Science museum, nearby, has divisions of industrial and mechanical engineering, transport in all its branches and scientific instruments. In the vicinity also is the fine building of the Imperial institute, founded in 1887 as an exhibition to illustrate the resources oi all parts of the empire and as an institution for the furtherance of imperial intercourse. The London museum in Kensington palace illustrates the antiquities and history of London.

Other museums are Sir John Soane's collection in Lincoln's inn fields and the Museum of Practical Geology, South Kensington, while the scientific societies have libraries and in some cases collections of a specialized character. Among permanent art collections the first place is taken by the National gallery in Trafalgar square. This magnificent collection was originated in 1824, and the building dates from 1838 but has been more than once enlarged. The building of the National Portrait gallery, adjoining it, dates from 1896, but the nucleus of the collection was formed in 1858. The generosity of Sir Henry Tate provided the gallery, commonly named aiter him, by the Thames near Vauxhall bridge, which contains the national collection ot British art. The Wallace collection of paintings and objects of art, in Hertford house, Manchester square, was bequeathed to the nation by the widow of Sir Richard Wallace in 1897. Of the periodical art exhibitions that of the Royal academy is most noteworthy. It is held annually at Burlington house from the first Monday in May to the first Monday in August. There are many art galleries in and about Bond street and Piccadilly, Regent street and Pall Mall. A saiety, health and welfare museum was opened in Horseferry road by the home office in 1927. The Imperial War museum in Lambeth road was founded in 1917. The National Maritime museum is at Greenwich and the Royal Cnited Service museum in Whitehall.

The London County council administers the Horniman museum at Forest Hill, Lewisham, and the Geffrye museum in Shoreditch. The City corporation maintains the fine Guildhall library and museum. The principal library is at the British Museum with its newspaper annex at Colindale. The London library is a private lending library in St. James's square. The specialized libraries of the learned societies and of the university are oiten available for students. All the metropolitan boroughs adopted the public libraries act and provide services covering lending, reierence and juvenile sections.

Theatres and Places of Entertainment.—The principal London theatres and music halls lie between Piccadilly and Temple Bar, and High Holborn and Victoria street, the majority being in Shaftesbury avenue, the Haymarket, the neighbourhood of Charing Cross and the Strand. The Covent Garden and Sadler's Wells theatres are the principal homes of opera and ballet. The main concert hall is the Royal Festival hall (capacity 3,261) on the south bank, erected in 1951 as part of the Festival of Britain, but concerts are also given in the Royal Albert hall (capacity 7,000) along with boxing, wrestling and other large-scale functions. The Wigmore hall is devoted chiefly to recitals and chamber music. Among other popular places oi entertainment may be mentioned the Earl's Court exhibition, rebuilt 1936–37 and covering about 19 ac. It has iceskating and, with Olympia hall, Hammersmith road, is used for such purposes as military tournaments, motor-car shows, "ideal home" exhibitions and the like; the celebrated waxwork exhibition of Madame Tussaud in Marylebone road, burned in 1925, was restored and again damaged in World War II; and the Agricultural hall, Islington, where agricultural and other exhibitions are held. The gardens of the Zoological Society of London are in Regent's park and at Whipsnade (Redfords.). Theatres, music halls, concert halls, cinematograph theatres and so forth are licensed by the County council, except that the licence for stage plays is granted by the lord chamberlain under the Theatres act, 1843. The council provides for inspection of places of entertainment in respect of precautions against fire, structural safety, etc. The principal clubs are in and about Piccadilly and Pall Mall *(see* CLUBS).

Permitted times of opening for premises licensed to sell alcoholic refreshments are fixed by each petty sessional division. In total they amount in the county on weekdays to nine hours between 11 A.M. and 11 P.M., with a break of at least two hours after noon; on Sundays to five hours, not more than two between noon and 3 P.M. and not more than three between 6 P.M. and 10 P.M.

Parks. — St. James's park, Green park, Hyde park and Kensington gardens (which, with Regent's park, Richmond, Bushey and Greenwich parks and Kew gardens, are royal parks) stretch in an irregular belt for nearly 3 mi. between Whitehall and Kensington. St. James's park was transformed from marshy land into a deer park, bowling green and tennis court by Henry VIII, extended and laid out as a pleasure garden by Charles II and rearranged according to the designs of John Nash in 1827–29. Its lake, the broad Mall leading up to Buckingham palace, and the proximity of the government buildings in Whitehall, combine to beautify it. St. James's park is continued between the Mall and Piccadilly by the Green park. Hyde park, to the west, belonged originally to the manor of Hyde, which was attached to Westminster abbey, but was taken by Henry VIII on the dissolution of the monasteries. Two of its gateways are noteworthy, namely that at Hyde Park corner at the southeast and the Marble arch at the northeast. The first was built in 1828 from designs of Decimus Burton and comprises three arches with a frieze above the central arch copied from that of the Parthenon at Athens, now in the British Museum. The Marble arch was intended as a monument to Horatio Nelson; it was erected by John Nash in 1828 in front of Buckingham palace and was moved to its present site, in 1851. In 1908 this corner of the park was cut to give additional accommodation for the heavy traffic between Oxford street, Edgware road and Park lane, and the Marble arch was left isolated. Hyde park and Kensington gardens between them contain a lake 1,500 yd. in length, known in its park portion as the Serpentine and in the gardens portion as the Long Water; from the bridge which marks the division one of the finest prospects in London is seen, including the distant towers of Westminster and, on the north bank of the Serpentine, the bird sanctuary with Jacob Epstein's "Rima" memorial to W. H. Hudson. In the 17th and 18th centuries this park was a favourite duelling ground, and in the present day it is not infrequently the scene of political and other popular demonstrations (as is also Trafalgar square), while the neighbourhood of Marble arch is the resort of orators on social and religious topics. Kensington gardens were originally attached to Kensington palace, but were subsequently much extended; they are specially favoured by children, for the famous Round pond is located there, and in 1912 Sir George Frampton's statue of "Peter Pan" was placed there. They were magnificently timbered, containing plantations of rare shrubs and flowering trees. Regent's park, mainly in the borough of Marylebone, owes its preservation to George IV, who, when regent, intended to build a palace there and had the park laid out by John Nash in 1812. The other most notable open spaces wholly or partly within the county are: Hampstead heath in the northwest, a high-lying tract, preserved to a great extent in its natural state, which, with the adjoining Parliament hill, Ken wood and Golders Hill park, covers about 850 ac.; and in the southwest Wimbledon common and Putney heath (together 1,200 ac.) and the royal demesne of Richmond park (2,358 ac.), which from its higher parts commands a wonderful view up the rich valley of the Thames. The east, south and north are not lacking in open spaces, the chief of which are Victoria park (217 ac.), in the northeast; Greenwich park (188 ac.), Blackheath (267 ac.) and Woolwich commons in the southeast; and Battersea park (200 ac.) and Wandsworth (183 ac.) and Tooting Bec (217 ac.) commons in the south; but there is an extensive inner area where at most only small gardens and squares break the continuity of buildings and where, in some cases, old churchyards serve as public grounds. The proportion of open space in the administrative county is less than two acres per thousand of the population. Outside the county, the L.C.C. owns Hainault, and the City Epping forest in Essex.

Sports Grounds. — Among many sports grounds, the two best-known cricket grounds are Lord's, near Regent's park (M.C.C.—Marylebone Cricket club—and Middlesex county matches, Oxford *v.* Cambridge university matches, Eton *v.* Harrow school matches, etc.), and the Oval in Kennington (Surrey county matches, etc.). At these two grounds there also take place any "test" matches played in London by teams representing England against overseas sides. International Rugby football matches (among others) are played at Twickenham; and the final ties of the English association football cup at Wembley stadium. Athletic meetings take place at the White City (Hammersmith) and the lawn tennis championships at Wimbledon (Surrey). In Greater London are several horse racing courses, including Epsom, the home of the Derby. (J. E. ML.)

LONDON, CONFERENCES OF. Many important international conferences have been held in London during the 19th and 20th centuries. The first, in June 1814, was the outcome of the visit of the Allied sovereigns to the prince regent after the downfall of Napoleon, the opportunity being used to effect some of the settlements agreed upon in the first treaty of Paris, notably the conditions attached to the erection of the kingdom of the United Netherlands. From 1815 onward, too, diplomatists of the Allies accredited to Great Britain formed a conference in London for the purpose of discussing measures for the suppression of the slave trade and of the Barbary pirates.

Greece. — In 1827 a conference met in London to attempt to settle the affairs of Greece. This conference (the first international gathering to be usually thus described) met on July 12, 1827, and sat till 1832. It was attended only by the representatives of the three powers which had signed the treaty of London (July 6, 1827); *i.e.,* France. Great Britain and Russia. The treaty of London of May 7, 1832, however, which established the kingdom of Greece, with Prince Otto of Bavaria as king, was signed also by Baron de Cetto on behalf of the king of Bavaria.

Belgium. — In 1830, while this conference was still in session, the insurrection of the Belgians against the king of the Netherlands led to the summoning of another conference in London, which first met on Nov. 4, 1830, there being in all 70 sessions. After the independence of Belgium had been recognized and Leopold of Coburg had been elected king (June 4, 1831) a Belgian plenipotentiary was also admitted. On Oct. 1, 1832, Austria, Prussia and Russia having refused to agree to the French proposal to coerce the Dutch king into accepting the 24 articles embodied in the treaty of Nov. 15, 1831, the conference virtually broke up, the further proceedings being conducted by the representatives of France and Great Britain. These ended on May 21, 1833, with the signature of a convention between the two powers and the Netherlands, providing for the nonrenewal of hostilities and freedom of navigation on the Scheldt and Meuse. Thus matters remained till 1839 when, the king of the Netherlands having at last consented to recognize the inevitable. the plenipotentiaries of all the five powers met in London to sign with those of the Netherlands, on April 7–19, a treaty to which the 24 articles of Nov. 15, 1831. were annexed (see BELGIUM).

Schleswig-Holstein and Luxembourg. — In 1848 the war between Prussia and Denmark over the Schleswig-Holstein question (*q.v.*) led to the assembling of an international conference in London. It met after the pressure of the powers had forced Prussia to conclude the truce of Malmö (Aug. 26) and resulted in the peace signed at Berlin on July 2. 1850, which left the main problems unsolved. By the protocol signed on May 8, 1852. the conference settled the succession to the Danish throne and the duchies of Schleswig and Holstein on Christian of Gliicksburg.

In 1864, during the war between the two great German powers and Denmark, Great Britain invited the signatories of the protocol of 1852 to a conference in London, with a view to a settlement. The conference met on April 25, immediately after the storming of the Diippel lines; but, as a result of Bismarck's diplomacy, it broke up on June 25 without having effected anything.

In 1867 an important international conference met in London, at the instance of the king of the Netherlands, to deal with the situation in regard to Luxembourg created by the war of 1866 and the consequent dissolution of the old German confederation. The conference consisted primarily of the representatives of the states signatory of the treaty of 1839, by which the status of the grand duchy of Luxembourg had been determined (*i.e.,* Austria, Belgium, France, Great Britain, Holland-Luxembourg, Prussia and Russia). but on the motion of Lord Stanley, who presided, the Italian ambassador was also invited to assist. The conference resulted in the treaty of London of May 11, 1867, by the terms of which the Prussian troops, which had garrisoned the city of Luxembourg since 1815, were to be withdrawn and the fortress demolished. On the motion of the Prussian plenipotentiary, Count Bernstorff, the signatories guaranteed Luxembourg's neutrality.

Russia. — In 1871, during the Franco-German War, the denunciation by Russia of the Black sea clauses of the treaty of Paris of 1856 led to the assembling of a conference in London, in order to regularize the situation thus created by a revision of the treaty of 1856, so far as regarded the neutralization of the Black sea, the straits of the Dardanelles and Bosporus, and the navigation of the Danube. The conference, which sat from January to March and was attended by the representatives of North Germany. Austria-Hungary, Great Britain, Italy, Russia and Turkey, while revising the treaty in accordance with Russia's wishes, asserted the principle of the inviolability of treaties (see TREATIES).

Treaty of Berlin. — In 1883 a conference sat in London (Feb. 8–March 10) to consider the execution of articles 54 and 55 of the treaty of Berlin of July 13, 1878, concerning the navigation of the Danube (*q.v.*). It was attended by representatives of all the powers which had signed the Berlin treaty and those of the other riverain states (*i.e.,* Serbia and Rumania) which had not signed the treaty were invited to attend but without a deliberative voice. Bulgaria, as a vassal state, was represented by the Turkish delegate. Rumania refused to accept these conditions, but the Serbian plenipotentiary attended the sessions.

Egypt. — In 1885 a conference between the great powers and Turkey was held in London to deal with the situation arising out of the financial crisis in Egypt. The result was the signature in March of what is known as the London convention, the terms of which were embodied in a khedivial decree and, with some modifications, remained for 20 years the organic law governing the administration of the finances of Egypt (see EGYPT: *History*).

Naval Conference. — In 1908, at the invitation of the British government an international naval conference met in London to attempt a settlement of those questions regarding contraband, blockade, etc., which had been raised at the second Hague conference. The conference met on Dec. 4, 1908 and continued in session until Feb. 26, 1909, the outcome of its labours being the Declaration of London. This declaration was never ratified.

The Balkans. — In 1912 and 1913 conferences were held in London to arrange terms of peace between Turkey and the allied Balkan states, Bulgaria, Greece, Montenegro and Serbia. The conference, which was attended by representatives of the belligerent states, was opened on Dec. 16, 1912, by the British foreign secretary but was suspended without result on Jan. 6. It met again on May 30, 1913, the outcome being the treaty of London signed on the same day. The conference was dissolved on June 9, and its work was rendered abortive by the outbreak, immediately afterward, of the Second Balkan War (see BALKAN WARS).

Conferences After World War I.—In 1921–22 four conferences of Allied statesmen were held in London, to adjust matters arising out of the peace treaties which ended World War I. The first met from Feb. 21 to March 14, 1921, and carried on alternately two sets of negotiations, one with the Athens, Constantinople and Angora governments on the near eastern question (see TURKEY), the other with Germany on the subject of reparations. The result in both cases was failure. The conference was hardly over before the Greeks launched a new offensive against the Turkish Nationalists, while the unacceptable German counterproposals led, early in March, to fresh sanctions being taken against Germany (occupation of Diisseldorf, etc.).

On April 29 the Allied leaders met again in London, having before them the Reparations commission's estimate of Germany's total liability. They made this the basis of a schedule of payments which was sent to Berlin on May 5, with an ultimatum, and on the 11th the German government accepted the Allies' terms.

In 1922 as a result of the failure of Germany to carry out this agreement, similar conferences of Allied leaders met in London, in August and in December. At each of these R. Poincaré put forward his claim for "productive guarantees" from Germany as a precondition of any moratorium. The British could not agree to such sweeping measures and the conference adjourned on Dec. 11 without agreement being reached (see REPARATIONS).

In Jan. 1930 the United States, France, Italy and Japan, accepting a British invitation, met in London to discuss naval disarmament. By the end of three months general agreement had been secured on the regulation of submarine warfare and a five years' holiday for capital ship construction. The United States, Great Britain and Japan signed, on April 22, a treaty limiting battleship tonnage in the ratios of 10:10:7. France and Italy, opposed respectively to the concept of ratios and the acceptance of any inequality, declined to sign (see DISARMAMENT).

On June 12, 1933, the World Economic conference met in London, with representatives of the U.S. and all the League of Nations states in attendance. Soon after it opened, the announcement by Pres. Franklin D. Roosevelt of his opposition to currency stabilization rendered its proceedings nugatory, and on July 27 it adjourned with nothing accomplished.

Conferences After World War II.—On Jan, 10, 1946, the first part of the first session of the United Nations assembly met in London at the Central hall, Westminster. It was principally notable for the election of Trygve Lie as secretary-general and the bringing into operation of the Security council and the Economic and Social council.

After the failure of the French assembly to accept the European Defense community plan a nine-power conference was hurriedly summoned to meet in London on Sept. 28, 1954. The foreign ministers of Great Britain, the United States, Italy, Belgium, the Netherlands and Canada and the prime ministers of France, the German Federal republic and Luxembourg were present. The agreements which they signed on Oct. 3 provided for the termination of the occupation regime in western Germany, the establishment of an agency to control continental armaments, and the admission of Germany and Italy to the Brussels Treaty organization and of Germany to the Korth Atlantic Treaty organization (*q.v.*). Britain undertook to maintain four divisions on the continent for 44 years and the German Federal Republic pledged itself not to seek German reunification by force.

In 1956 the nationalization ot the Suez canal by the Egyptian government created an urgent problem for all the canal users. At the invitation of Britain. France and the United States a conference of 22 countries met in London during Aug. 16–23. Eighteen countries agreed on a plan to guarantee free use of the canal. This was rejected by Egypt. and a second London conference (Sept. 19–21) proposed the establishment of a canal users association.

The association, imperfectly conceived and inadequately directed, failed to materialize and in October the Israeli attack on Egypt and the Anglo-French armed intervention in Suez gave events an entirely different turn. (W. A. P.; H. G. N.)

LONDONDERRY, EARLS AND MARQUESSES OF. The 1st earl of Londonderry was Thomas Ridgeway (c. 1565–1631), a Devon man, who was treasurer in Ireland from 1606 to 1616 and was engaged in the plantation of Ulster. Ridgeway was knighted in 1600, made a baronet in 1611, Baron Ridgeway in 1616 and earl of Londonderry in 1622. The Ridgeways held the earldom until March 1714, when Robert, the 4th earl. died without sons. In 1726 Robert's son-in-law, Thomas Pitt (c. 1688–1729), son of Thomas Pitt (1653–1726; often called "Diamond Pitt," governor of Fort St. George, Madras. India) and uncle of the great earl of Chatham, was created earl of Londonderry, the earldom again becoming extinct when his younger son Ridgeway, the 3rd earl of this line, died unmarried in Jan. 1765. In 1796 Robert Stewart (1739–1821), of Mount Stewart, County Down, was made earl of Londonderry in the Irish peerage. He had been created Baron Londonderry in 1789 and Viscount Castlereagh in 1795; in 1816 he was advanced to the rank of marquess of Londonderry. His son, the 2nd marquess, who succeeded in 1821, was styled Viscount Castlereagh from 1796 to 1821, and is better known by that title (*see* LONDONDERRY, ROBERT STEWART. 2ND MARQUESS).

He was succeeded by his half brother Charles William Stewart Vane (*q.v.*), who in 1819 married as his second wife the daughter and heiress of Sir Harry Vane-Tempest and consequently took the name of Vane instead of that of Stewart. He was succeeded by his son by his first wife, Frederick William Robert Stewart, the 4th marquess (1805–72), who was M.P. for County Down from 1826 to 1852; a lord of the admiralty, 1826–52; and vice-chamberlain of the royal household, 1834–35. He died without issue and was succeeded by his half brother, who in 1854 took the name of Tempest after that of Vane. The 6th marquess (1852–1915) in 1885 added the name Stewart, becoming Vane-Tempest-Stewart. He was M.P. for County Down, 1878–84, and lord lieutenant of Ireland from 1886 to 1889. Chairman of the London School board from 1895 to 1897, he became postmaster general in 1900 and was president of the board of education from 1902 to 1905. His son, Charles Stewart Henry Vane-Tempest-Stewart, the 7th marquess (1878–1949), was M.P. for Maidstone, Kent, from 1906 to 1915, and was undersecretary for air, 1920–21; minister of education for Northern Ireland, 1921–26; first commissioner of works, 1928–29 and again in 1931; secretary of state for air, 1931–35; and lord privy seal and leader of the house of lords in 1935.

LONDONDERRY, CHARLES WILLIAM STEWART (VANE), 3RD MARQUESS OF (1778–1854), British soldier and diplomatist, who served in the peninsular war and took part in the diplomatic affairs of the Napoleonic and post-Napoleonic period. He was the son of the 1st marquess by his second marriage, with the daughter of the 1st Earl Camden, and was born in Dublin on May 18, 1778. He was thus half brother to Lord Castlereagh, the 2nd marquess of Londonderry (*see* LONDONDERRY, ROBERT STEWART). He entered the army and served in the Netherlands (1794), on the Rhine and Danube (1795), in the Irish rebellion (1798) and in Holland (1799), rising to be colonel. He was elected M.P. for Derry and became undersecretary for war under his half brother Lord Castlereagh in 1807. In 1808 he was given a cavalry command in the peninsula, where, in 1809, and in the campaigns of 1810–11 as major general, he served under the duke of Wellington as his adjutant general.

He was at the capture of Ciudad Rodrigo, but at the beginning of 1812 he was invalided home and Wellington refused his request of a cavalry command. Castlereagh then sent him as ambassador and military representative to Prussia, now engaged in the struggle against Napoleon. He was no great diplomatist hut his energy and courage were sometimes most useful. In 1814 he nas made a peer as Baron Stewart, and later in the year was appointed ambassador at Vienna, and was a member of the important congresses which followed, where he sometimes shocked high society by his undiplomatic behaviour. In 1822 Castlereagh's death made him 3rd marquess of Londonderry, and after attending the conference of Verona he resigned. being created Earl Vane (1823). In 1835 he nas appointed by Sir Robert Peel at the suggestion of the duke of Wellington as ambassador to St. Petersburg but criticism in the house of commons forced him to resign at once. After the death of Wellington in 1852, he received the order of the Garter.

He was twice married, first in 1808 to the daughter of the earl of Darnley, and secondly in 1819 to the rich heiress of Sir Harry Vane-Tempest. when he assumed the name of Vane. He was devoted to his half brother. defended his reputation and published 12 volumes of his correspondence as well as books on his own military career and travels. He died in London on March 6, 1854. (C. K. W.)

LONDONDERRY, ROBERT STEWART, 2ND MARQUESS OF (1769–1822), British statesman, better known as VISCOUNT CASTLEREAGH, ranks high among British foreign ministers. He was the eldest son of Robert Stewart of Ballylawn Castle, in Donegal, and Mount Stewart in County Down, an Ulster landowner, of kin to the Galloway Stewarts, who became baron, viscount, earl and marquess in the peerage of Ireland. He was born on June 18, 1769. in the same year as Napoleon and Wellington. His mother, Lady Sarah Seymour, daughter of the marquess of Hertford, died shortly after his birth. He went from Armagh school to St. John's college, Cambridge, where he worked diligently, but illness interfered with his studies. With Lord Downshire, then holding sway over County Down, his father had a standing feud, and he put forward his son, in July 1790, for one of the seats in the Irish parliament. Young Stewart was returned, but at a vast cost to his family, when he was barely 21. He paid two visits to the continent and later was a member of the British house of commons for a short period and attracted the attention of William Pitt. He married Lady Emily Hobart, daughter of the earl of Buckinghamshire. They were devoted to one another throughout their married life. There were no children. From 1796, when his father became an earl, he took the courtesy title of Viscount Castlereagh. When his uncle, Lord Camden, became lord lieutenant, he became keeper of the privy seal in Ireland and acted as chief secretary during, the prolonged absence of Thomas Pelham, afterward earl of Chichester, from March 1798. He succeeded him in Nov. 1798. Castlereagh's conviction was that, in presence of threatened invasion and rebellion, Ireland could only be made safe by union with Great Britain. In Lord Camden, as afterward in Lord Cornwallis, Castlereagh found a congenial chief. In suppressing Lord Edward Fitzgerald's conspiracy, and the rebellion which followed in 1798, Castlereagh's vigilance and firmness were effective. He was then the principal actor in abolishing the separate parliament of his own country and thus incurred the undying hatred of Irish nationalists. Some bribery was used, but Castlereagh, like Pitt, intended Catholic emancipation to follow the union, though no express promise was made to the Catholics. (*See* IRELAND.)

When the Act of Union was carried through the Irish parliament, in the summer of 1800, Castlereagh's official connection with Ireland practically ended. Before the imperial parliament met he urged upon Pitt the measures which he and Cornwallis thought requisite to make the union effective. But the king flatly refused to sanction emancipation, and Pitt and his cabinet made way for Henry Addington's administration. Thereupon Castlereagh resigned, with Cornwallis. He took his seat at Westminster for Down, the constituency he had represented for ten years in Dublin. The leadership of an Irish party was offered to him, but he declined so to limit his political activity. His father accepted, at the duke of Portland's request, an Irish marquessate, on the understanding that in the future he or his heirs might claim the same rank in the imperial legislature; so that Castlereagh was able to sit in the house of commons as marquess in 1821–22.

In 1802, Castlereagh, at Pitt's suggestion, became president of the board of control in the Addington cabinet. He had, though not in office, taken charge of Irish measures under Addington, including the Suppression of Rebellion bill and the temporary Suspension of Habeas Corpus act in 1801, and he continued to advocate Catholic relief, tithe reform, state payment of Catholic and dissenting clergy and "the steady application of authority in support of the laws." To Lord Wellesley's Indian policy he gave a staunch support, warmly recognized by the governor general. On Pitt's return to office (May 1804), Castlereagh retained his post, and, next year, he took over the duties of secretary for war and the colonies. His house became a meeting place of the party, and his influence in parliament grew.

After Pitt's death (1806) his colleagues failed to form a cabinet able to face the combination known as the ministry of "all the talents," and Castlereagh acquiesced in the resignation. But to the foreign policy of the Fox-Grenville ministry and its conduct of the war he was always opposed.

In 1807 Castlereagh returned to the war office under Portland, but grave difficulties arose. The operations to avert the ruin of the coalition at the battle of Friedland (June 1807) came too late. The tsar Alexander believed that England would no longer concern itself with the continental struggle, and Friedland was followed by the treaty of Tilsit which left Great Britain isolated. The seizure of the Danish squadron at Copenhagen and the measures taken to rescue the fleets of Portugal and Sweden from Napoleon crushed a combination as menacing as that defeated at Trafalgar. The expedition to Portugal, though Castlereagh's influence was able only to secure Arthur Wellesley (afterward duke of Wellington) a secondary part at first, soon dwarfed other issues. In the debates on the conyention of Cintra (Aug. 1808), Castlereagh defended Wellesley against parliamentary attacks. Early in 1809, Castlereagh secured his friend's appointment as commander in chief of the second Portuguese expedition. (See also PENINSULAR WAR.)

Disagreement With Canning. — Meanwhile a breach arose between Castlereagh and George Canning, the foreign secretary. Canning was not openly opposed to the Walcheren expedition. Castlereagh's proposal of action in the Netherlands was for a coup de main, under strict conditions of celerity and secrecy, as Antwerp was unable to make any adequate defense. But the expedition, planned at the end of March, did not reach Walcheren till the end of July, 1809; and more time was lost, until sickness in the army necessitated its withdrawal in September. Meanwhile Canning had insisted on the removal of Castlereagh from his office and the prime minister had secretly consented. Public opinion threw the whole blame upon Castlereagh, who then found that some of his colleagues had determined, behind his back, on his removal. Castlereagh held himself justified in sending a challenge to the original author, as he held, of a disloyal intrigue against a colleague. In the subsequent duel Canning was wounded and the rivals simultaneously resigned. Though Wellington's retreat after Talavera had been included, with the disasters of the Corunna and Walcheren campaigns, in the censures on Castlereagh, and though ministers were often depressed and doubtful, Castlereagh never lost faith in Wellington's genius. Lord Wellesley's resignation in 1812, when the Whigs failed to come to terms with the regent, led to Castlereagh's return to office as foreign secretary (March 1812). The assassination of Spencer Perceval (May 1812) soon threw upon him the leadership of the house of commons, and this double burden he continued to bear during the rest of his life.

The Duel With Napoleon. — From March 1812 to July 1822 Castlereagh's biography is, in truth, the history of England. He set himself at once to meet Napoleon's designs in northern Europe, where Russia was preparing for its life-and-death struggle. After the Moscow debacle and Prussia's defection, subsidy treaties were made with Russia and Pruesia. One had previously been made with Sweden, which eventually led to Swedish armies under Bernadotte (Charles XIV John) taking part in the struggle against Napoleon, and one was made with Austria when it abandoned its neutrality after a vain effort at mediation. The result was the battle of Leipzig (Oct. 1813) and the advance of the allies to the Rhine. The allied powers were willing, even after Leipzig, to treat with France on the basis of restoring its "natural frontiers" — the Rhine, Alps and Pyrenees. This step, which would have left Belgium and Antwerp in French possession, was partly due to the lack of skill and personal rivalry of the three British ambassadors to Russia, Prussia and Austria. They had also failed to obtain the treaty of alliance between the four allied powers which Castlereagh had proposed in the autumn, thus taking the first step toward carrying out the policy laid down by Pitt in 1805. The cabinet, therefore, decided to send Castlereagh himself to the continent to maintain British interests in the approaching settlement. The coalition against Napoleon was already showing signs of weakness and division when he arrived at Basle on Jan. 18, 1814. Austria distrusted Russia, while the policy of the tsar was ambiguous and vacillating. Napoleon, on the other hand, was now displaying once more his military genius. Castlereagh succeeded, by frank conversations with Metternich and Alexander in cementing the coalition, and the treaty of Chaumont (March 1, 1814) bound the four powers together in an alliance against France which was to continue after victory had been won. He himself had gone previously to Châtillon where the negotiations nith the marquis de Caulaincourt, Napoleon's foreign minister, were taking place. He insisted on making the return of France to its ancient limits the basis of the peace. When Napoleon refused these terms it uas largely due to Castlereagh's advice and action that the German troops under the reluctant Bernadotte were transferred to the command of the energetic G. L. von Blucher. The latter gained two victories, the allies were able to enter Paris and the treaty of Fontainebleau (April 11, 1814) by which Napoleon was given Elba was made before Castlereagh arrived. Louis XVIII was now restored as Britain had always desired if the French people, as had now happened, showed themselves ready to receive him.

The Reconstruction of Europe.—In the negotiations which led to the first peace of Paris (May 30, 1814) Castiereagh, having secured the inclusion of Belgium in the restored Netherlands, treated France generously, giving back many colonies and seeking no indemnity. The rich Dutch East Indies were also restored to the Netherlands. But, despite efforts at agreement at Paris and during the subsequent visit of the allied sovereigns and statesmen to London, the settlement of the other European frontiers had to be postponed to a congress of all the European powers at Vienna, Talleyrand, Louis XVIII's foreign minister, agreeing in the peace treaties to accept the decisions of the allies. These had hoped to come to an agreement before the congress met. But they failed to do so (see VIENNA, COKGRESS OF) and Castlereagh had to play a principal role in the reconstruction of Europe. His object was the same as that of Pitt—to establish a balance of power so that no state could attack the others with success. He failed in his first plan, which was to combine Prussia and Austria together to resist the absorption of Poland by Russia, but when Prussia joined Russia in order to obtain the whole of Saxony, he was the principal author of the secret treaty with France and Austria (Jan. 3, 1815) and their united front forced a compromise. The result was to bring Prussia to the left bank of the Rhine, while Austria obtained control in Italy, the former thus supporting the restored Netherlands and the latter an enlarged Piedmont, as barriers against France. In the east Alexander retained nearly all of Poland that he claimed, but Castlereagh persuaded him to give back Thorn to Prussia, while Cracow was made a free state. In all these negotiations Castlereagh had the role of mediator and the result was largely due to his diplomatic skill and energy. He even proposed a general guarantee of the new frontiers, in which those of the Ottoman empire were to be included, though later he preferred the alliance to a guarantee of this kind. He also secured a declaration against the slave trade, the principal interest of the British people at this time, and in subsequent years spent much effort in trying to make it effective.

After Wellington had replaced Castlereagh at Vienna Napoleon returned from Elba, a new treaty of alliance had to be made (March 25, 1815) and Britain again took Europe into its pay. After Napoleon had been overthrown at Waterloo and Louis XVIII, largely by the efforts of Castlereagh and Wellington, restored to the throne a second time as a constitutional monarch, Castlereagh negotiated the second peace of Paris (Nov. 20, 1815). It was largely due to him, splendidly supported by the victorious Wellington, that France incurred only a small reduction of territory and a moderate indemnity. An allied army of occupation remained in France for three years, but Castlereagh put his main trust in the treaty of alliance (also signed on Nov. 20, 1815) between the four great powers against French aggression. In this renewal of the treaty of Chaumont, he introduced the device of periodical meetings between the sovereigns and statesmen to resolve differences and maintain peace. This simple idea was confused in the minds of the public with the Holy Alliance, a treaty between the sovereigns engaging them to act as Christians, which Alexander forced the others to adopt and which was subsequently signed by every monarch in Europe except the pope, the sultan and the prince regent of England.

Home Policies.—Castlereagh had to defend the reactionary and unpopular conduct of the British government in a policy of repression of the social unrest caused by the financial and economic problems of the return to peace which culminated in the Peterloo massacre (*q.v.*) and the repressive six acts which attempted to put down political gatherings and to prevent the spread of seditious literature. He thus incurred the savage hatred of the radicals and reformers. The king's attempt to obtain a divorce almost overthrew the Liverpool government in 1820 and it was only finally saved by Castlereagh's influence on the king and his reorganization of the cabinet in 1821 (see GEORGE IV).

The System of the Alliance.—Meanwhile the new system of diplomacy had worked admirably at the conference of Aix-la-Chapelle (*q.v.*; 1818), when the army of occupation was withdrawn and France, after arranging loans to pay its reparations and indemnity, was made a member of the great power conference. A number of other questions were also broadly discussed and some of them were settled. They included that of the relations of Spain to the Latin-American colonies now in revolt. Others concerned the interests of other small powers not represented, but in a protocol of Nov. 15, 1818, often referred to later in the century, the great powers promised that in the future a conference on questions in which other powers were specially interested should only take place at their initiative and with their participation. However when revolutions broke out in Spain and Italy in 1820 Metternich, who had hitherto worked closely with Castlereagh, joined the tsar in an attempt to use the alliance as a means to enable the autocratic states to combine together to repress them. Castlereagh allowed Lord Stewart, the British ambassador at Vienna, to attend the conferences at Troppau and Laibach in which this policy was agreed upon, but he protested, at first secretly and then, when their actions became apparent, in a public state paper of Jan. 21, 1821, against such intervention in the internal affairs of states which was no part of the treaty of alliance and which Britain had, therefore, no obligation to support. He had already in 1818 done so as regards the revolutions in the Spanish colonies whose independence he now prepared to recognize. The revolution in Greece in 1821 brought Castlereagh and Metternich together again and in the autumn of that year after an interview at Hanover they agreed to work together to restrain the tsar from attacking Turkey to help the Greeks. France, which had hitherto taken an intermediate position on the question of suppressing revolutions, now threatened to intervene in Spain. Castlereagh, therefore! prepared to go himself to the next conference, then to be held at Vienna though it was later transferred to Verona, in order to settle in accordance with British interests the three great problems of the eastern question, the Spanish colonies and Spain. He made skilful moves in the summer of 1822 to attain his purpose, making an especial effort to get into close touch with France and arranging to visit Paris on his way to the conference. But he could no longer endure the strain to which he had been subjected for over ten years and his mind gave way. Though his wife and doctor had been warned by Wellington that suicide was possible and took precautions, Castlereagh cut his throat with a small penknife and died immediately (Aug. 12, 1822). With him also died the European alliance though it left behind it the Concert of Europe which was used for the same purpose intermittently throughout the 19th century. Castlereagh died unpopular and misunderstood, but his great achievements have been recognized in recent years.

BIBLIOGRAPHY.—Castlereagh's correspondence and papers were published by his brother and successor (London, 1848–53) in 12 volumes. *See* also Sir Archibald Alison, *Lives of Lord Castlereagh and Sir Charles Stewart*, 3 vol. (London, 1861). For an account of his early life *see* H. M. Hyde, *The Rise of Castlereagh* (London, New York, 1933); and for his diplomacy *see* W. A. Phillips, *The Confederation of Europe* (London, New York, 1920); C. K. Webster, *British Diplomacy, 1813–1815* (London, 1921), *The Foreign Policy of Castlereagh, 1812–1815* (London, New York, 1931), *The Foreign Policy of Castlereagh, 1815–22* (London, New York, 1925). (C. K. W.)

LONDONDERRY, a county of Northern Ireland, bounded by the Atlantic ocean on the north, by the Foyle and the Republic of Ireland on the west, by Antrim and the river Bann on the east, and by Tyrone and the Sperrin mountains on the south. The area is 521,230 ac., or 814 sq.mi. Pop. (1951), exclusive of Londonderry county borough, 105,448. This roughly triangular county has wide areas of mountain and moorland, particularly in the south and centre; but on two sides, east to the Bann valley, and northwest to the Roe valley and the shores of the Foyle, the hills fall away into rich agricultural lowlands.

In the south and east, Old Red Sandstone and Lower Carboniferous Sandstone overlie older rocks, meeting the igneous rocks and intrusive granite of north Tyrone at Slieve Gallion. As in a great part of Antrim, Londonderry contains a wide area of limestone covered by basalt, which rises into scarped hills close to the north coast at Benevenagh. A raised shelf of postglacial clays forms the flat land west of Limavady. The outlet of the Foyle is narrowed by a long sandy spit of raised sea bed, ending in Magilligan point.

In the shiring of Ulster, carried out on the commission of Lord Deputy Perrott in 1585, this county was described as the county of Coleraine and was of smaller extent than at present. The area was O'Neill territory and was the country of the O'Cahans who were subordinate allies of the O'Neills. After the final defeat of Hugh O'Neill, earl of Tyrone, in 1603, and the confiscation of O'Neill territory in 1607, the county of Coleraine was committed to the companies of the City of London to be administered and colonized by them. A special body was set up in 1610 to represent the City of London in the matter, the body which later came to be known as the Honourable The Irish society. A charter in 1613 transformed the area into the new county of Londonderry, adding to it the town and district of Derry, and the barony of Loughinsholin which was formerly part of Tyrone.

The colonization scheme was only a limited success. Many of the planters did not carry out the conditions laid down for them. After a long quarrel the City of London was prosecuted in the court of star chamber and heavily fined for its failures in implementing its undertakings. Its Ulster property was confiscated in 1637. This did much to throw London more decisively on the parliamentarian side in the ensuing Civil War. Parliament later reversed the decision against the City, and the Irish society was restored and received a new charter from Charles II. It has continued to own property and carry out duties in the county up to the present day, though the Irish land acts and other changes have reduced its property to small extent.

Much disturbance of persons and property also occurred in Londonderry at the time of the rising of 1641 and during the war in 1689, when the siege of Londonderry took place.

Although the city of Londonderry is an industrial centre, specializing particularly in the manufacture of shirts, the county is mainly agricultural. Small industries are situated in a number of the towns. The spinning and weaving of linen and the manufacture of milk products and automatic numbering machines go on in Coleraine. Handkerchiefs are made in Kilrea, and corsets at Limavady, which is also the market and administrative centre for the prosperous farming area of the Roe valley. There are fisheries on the Bann and along the north coast, where, at Portstewart, Castlerock, Downhill and several smaller resorts, there is also an active tourist industry. Along the north coast the railway connects Londonderry city with Belfast; and by skilful engineering a main road from Belfast has been carried in a fairly direct line to Londonderry across the mid-Derry mountains by the Glenshane pass. Londonderry (including Londonderry county borough) returns five members to the parliament of Northern Ireland and one to the United Kingdom parliament. (Hu. S.)

LONDONDERRY, a city, county and parliamentary borough, the second city of Northern Ireland. situated on the Foyle, a broad estuary into which flow the rivers Finn, Mourne, Strule, Derg and Deele. The city is 75 mi. W.N.W. of Belfast by road. Pop. (1961) 53,744. Area 3.44 sq.mi.

Derry, the older name of Londonderry. comes from the Gaelic word for an oak nood. At that site Columba established a monastery in the middle of the 6th century. The fortunes of Derry as an ecclesiastical and monastic centre were varied. It was plundered by Scandinavians and is said to have been burned down at least seven times before the year 1200. As a strategic site, Derry was of interest to Anglo-Norman adventurers, being plundered by John de Courcy and finally granted by Richard II to Richard de Burgh, well-known as the Red Earl. It served as a strategic point in the Tudor wars against the native Irish, being destroyed in 1568 by the blowing up of a munition dump. Sir Henry Docwra established a fort at Derry in 1600 as part of a successful plan to enclose Hugh O'Neill, earl of Tyrone. The little town at Docwra's fort was burned down by Sir Cahir O'Doherty of Inishowen in his shortlived insurrection in 1608 Derry was granted in 1613 to the City of London as part of the area to be colonized by the City. (See LONDONDERRY, county.) Derry itself received the name of Londonderry and was given a municipal corporation. The representatives of the Londoners planned a new tonn and built the present city walls. The district suffered much in the rising of 1641 and subsequent fighting. the city being besieged in 1649. It again experienced siege in 1689 when it held out for 105 days against the forces of James II, being defended with great heroism and relieved just before resistance became impossible.

The city stands on a hill. It is surrounded by the city walls. about one mile in circumference. having seven gates and several bastions, but modern buildings extend far beyond the walls and across the Foyle nhich is spanned by Craigavon bridge. The Protestant cathedral, built in 1633, contains many relics of the siege. Other important buildings are St. Eugene's Roman Catholic cathedral (1870), the guildhall, Magee University college (1865), and Foyle college, a school for boys, founded in 1617.

The staple industry of Londonderry is the manufacture of shirts and collars. and there are a good many smaller industries including the manufacture of furniture, small ships, sound-reproducing machines, tire fabrics and various foods. The city returns one member to the parliament of Xorthern Ireland and is merged in the Londonderry county constituency for the purpose of returning one member to the United Kingdom parliament. (Hu. S.)

LONDON PRIDE: see SAXIFRAGE

LONDON UNIVERSITY. Plans for a university in London, Eng., were put forward as early as the 16th and 17th centuries, but it was not until after 1825 that a start was made. By then a rapidly growing urban middle class, in which dissent was strongly represented, was making demands for higher education that the older universities, uhich confined their degrees to members of the Church of England and paid little attention to physics, chemistry and other new branches of learning, could no longer meet in full. At the same time. the state of English medical teaching was arousing public concern.

In 1825 a group of influential dissenters, Whigs and Radicals led by Thomas Campbell, the poet, and Henry Brougham set to work to raise funds for founding a college in London on Scottish and German models to give a broad and wholly nonsectarian education in arts, science and medicine. This college was opened in 1828 as "the London university" in fine classical buildings in Gower street designed by William Wilkins. Church and Tory interests at once responded by founding in 1829 on Church of England principles a rival institution, King's college, which was opened in 1831 in a building adjacent to Somerset house. Strand, designed by Sir Robert Smirke. King's college did not seek university status; but the promoters of "the London university" petitioned the crown for powers to grant both general and medical degrees. This claim aroused widespread opposition, and a compromise was adopted. On Nov. 27, 1836, King William IV granted a charter which established the University of London in the form of a chancellor, and a senate of 36 fellows appointed for life by the crown, to hold examinations and grant degrees in arts, laws and medicine, but without teaching functions. On the same day the Gower street college accepted a charter of incorporation as "London University college." Candidates for examinations were to present certificates of attendance at University college or King's college, but other educational institutions, not necessarily situated in London, could be admitted by the government into connection with the university. But, with no organic link to unite them, the university and the London colleges soon drifted apart, the university developing its examination system primarily for national purposes through a free use of the power to admit provincial and even colonial colleges, while University college and King's college struggled to reach high academic standards unaided by the prestige of full university rank. In 1858 the senate acknowledged the realities of the position by throwing all examinations, except those for medical degrees, open to all candidates irrespective of their place of education. The university thus became, and remained until. the end of the century, a general examining body. As such, it was the first body in England to institute degrees in science (1859) and the first to open its degrees to women (1878). Toward the end of the century a strong agitation developed in favour of a teaching university and two royal commissions reported on the question in 1889 and 1894. The existing system had staunch supporters, who feared the results of placing it under the control of an academic body dominated by local college interests, and a long and at times bitter controversy was ended only in 1898, when the first University of London act became law.

The statutes made under this act, which came into force in 1900, reconstituted the university as a dual-purpose institution. Its governing body. the senate, was composed on its "internal" side of representatives elected by the teachers of certain established London colleges and other educational institutions, grouped in faculties of theology, music, arts, laws, medicine, science, engineering and economics; and on its "external" side of a like number of representatives of the convocation of graduates; a third group of representatives was appointed by the crown in council, the London county council and some other public bodies. The principal colleges received the academic status of "schools of the university" but only University college and King's college had statutory representation in the senate. They and the other schools admitted in 1900 carried on the bulk of the teaching work, and remained legally and financially independent of the senate, whose powers of intervention in their affairs were limited to instituting and appointing the holders of professorships and readerships, recognizing the more junior teachers, regulating the courses of instruction for degrees and periodical inspection. A peculiar feature of the constitution was the recognition of individual teachers, under whom students could follow courses of instruction leading to internal degrees, in a number of educational institutions in London not otherwise connected with the university. The former examining system of the university was placed under an external council controlled by the convocation members of the senate, and statutory precautions were adopted to ensure that the standard and prestige of the external degrees should not suffer.

Progress was at first delayed by mutual distrust between the internal and external parties, and by lack of additional resources for the new responsibilities which public opinion expected the university to undertake. With a view to strengthening it at its centre University college in 1905 and King's college in 1908 surrendered their legal independence and in 1907 and 1910 respectively became incorporated in the university, but this example was not followed by other schools. The emergence of the powerful Imperial College of Science and Technology made the excuse for

the appointment in 1909 of yet another royal commission to review the whole position of the reconstituted university. Its drastic recommendations for replacing the loose federation by a closely articulated unitary organization were suspended by the outbreak of World War I. When in 1924 a governmental committee at length reconsidered the royal commission's report, a much more limited plan of reform was adopted. The principal changes effected in the revised statutes which came into force in 1929 were first, the creation of a new body, the court, with supreme authority in matters of finance which extended over the independent schools in respect of all public grants or benefactions; and secondly, the closer association of the schools with the central body, mainly through statutory representation on the senate, which remained the supreme governing body of the university in all academic matters. The court, with 15 (later 16) members, was composed of those representatives of the crown and the local authorities who had hitherto sat in the senate, together with 8 members appointed by the senate. The representation of other public bodies ceased. The essential features of the reconstitution of 1900—the federal principle and the dual system of internal and external degrees—were preserved. During the first half of the 20th century a great expansion of the teaching university took place. In 1900 there were 18 schools of the university and in 1902–03 it had 2,004 internal students. In 1952–53 it comprised 34 schools (of which 18 were nonmedical and 16 medical) and 10 university institutes, with 646 professors and readers; there were also 1,086 other recognized teachers. The internal students numbered 22,482 of whom 4,215 were in "institutions having recognized teachers" not organically connected with the university. All schools of the university engaged in undergraduate teaching also promote advanced study and research. A significant feature of the modem growth of the university has been the development, in supplementation of the main teaching work carried on in the schools, of central institutes directly administered through committees or councils responsible to the senate.

The external work of the university continued to expand after 1900. While the university still registered many technical college and private students, it was increasingly concerned on its external side with fostering the growth of university colleges (*q.v.*) both in the home country and in the colonial territories of the British commonwealth, providing them with advisory services and an examination and degree system during the period of their growth toward full and independent university status. The number of students registered for external degree and diploma examinations of the university in 1952–53 was 23,803.

The colleges and other institutions of the university are dispersed over a wide area, two (Royal Holloway college, near Staines, and Wye college, near Canterbury) being indeed outside London altogether. From 1836 to 1936 the university headquarters were housed by the government, from 1871 to 1900 in Burlington gardens, and later in part of the Imperial institute building at South Kensington. After 1910 the provision of a new headquarters on a central site became a major issue of policy. It was not, however, until 1927 that the university mas able to acquire, with the aid of a munificent gift of £400,000 from the Rockefeller foundation, a site of $11\frac{1}{2}$ ac. in Bloomsbury close to University college, on which it erected between 1931 and 1937 a monumental senate house and library to the designs of Charles Holden, the cost being met by gifts of more than £1,3013,000 from local authorities, City companies, business firms, banks and private donors. The Institutes of Education and Historical Research and the School of Slavonic and East European studies are in the same building. Space was also found on the site for the School of Oriental Studies, Birkbeck college and the university students' union.

In 1949–51 the university acquired, with the aid of the treasury and the London county council, further property covering $13\frac{1}{2}$ ac. adjoining the original site. It was thus able to establish a "university precinct." (W. D. H.)

LONG, CRAWFORD WILLIAMSON (1815–1878), U.S. physician, who first used ether as an anesthetic in surgery, was born in Danielsville, Ga., on Nov. 1, 1815. He received an A.M. degree from Franklin college, Athens, Ga., in 1835 and then read medicine under George R. Grant at Jefferson, Ga. He matriculated at the medical department of Transylvania university, Lexington, Ky., and later transferred to the University of Pennsylvania, Philadelphia. After his graduation in 1839, he went to New York city to walk the hospitals, then returned to Jefferson, where he soon acquired an extensive practice.

Long's imagination was stirred by the observation that injuries were sustained without pain during "ether frolics." On March 30, 1842, Long painlessly removed a tumour from the neck of James Venable, to whom he administered ether. At first, credit was denied to Long, who, as a rural physician, had no opportunities to test his discovery during major operations and cautiously accumulated data to justify publication in 1849 in the *Southern Medical and Surgical Journal.* In the famous ether controversy Charles T. Jackson. Horace Wells and William T. G. Morton (*q.v.*) each claimed the discovery for himself and applied for a national reward from congress. Long claimed no money; he wanted only recognition of the fact that he discovered and used the anesthetic effect of ether in surgery for the first time. Wells, a Hartford, Conn., dentist, conceived the idea, independently of Long, of anesthesia during "laughing gas parties"; he introduced anesthesia for tooth extractions, using nitrous oxide gas, in 1844. Morton, Wells's friend and onetime partner, in 1846 gave the first public demonstration of ether anesthesia in surgery; but he borrowed the idea from Jackson, a chemist and geologist, whose own claim to priority rests on accidental self-observations without uitnesses.

Long emerges from all the evidence as the discoverer of ether anesthesia in surgery and as a figure justly aloof from the ethically questionable implications of this chapter of medical history. He died at Athens on June 16, 1878.

LONG, HUEY PIERCE (1893–1935), U.S. political leader, u-as born on hug. 30, 1893, at Winnfield, La.. the son of a farmer. After public-school education and incomplete legal training at the University of Oklahoma. Norman, and Tulane university of Louisiana, New Orleans! he became a lawyer in 1915. Politically ambitious, he gained election to the Louisiana Railroad commission at age 25 and continued in that or similar posts for ten years. Winning the governorship in 1928 with heavy support from backwoods districts. he soon became nationally famous for his erratic and picturesque conduct as "the Kingfish," but his real importance lay in: (1) his assertion of a broad, positive role for the previously static state government (*e.g.*, a vast highway program); and (2) his gradual concentration of political power into an executive dictatorship unique in C.S. history. In 1930 he was elected Cnited States senator and as such appealed to a depression-shocked public with his fallacious but tempting Share-the-Wealth program ("every man a king"). Simultaneously harassing the Franklin D. Roosevelt administration and consolidating his absolutism in Louisiana, he was at the height of his power when, in 1935, he was assassinated in the Louisiana capitol by Carl Weiss, the son of one of his political enemies.

His brother EARL K. LONG (1895–1960), who thereafter dominated Louisiana politics, was governor three times (1939–40; 1948–52; 1956–60). Huey Long's son RUSSELL B. LONG (1918–) was elected U.S. senator from Louisiana in 1948 and was reelected in 1950 and 1956. (D. PR.; X.)

LONG, WALTER HUME LONG, 1ST VISCOUNT (1854–1924). English politician, was born at Bath July 13, 1854. Educated at Harrow and Christ Church. Oxford. he entered parliament in 1880 as Conservative member for North Wilts and sat in the house of commons till he was created a peer in 1921, though he changed his constituency several times. In March 1905 Long became chief secretary for Ireland. He was returned to parliament for a Dublin seat in the general election of 1906. In the first coalition ministry. 1915. he was president of the Local Government board and in the second coalition, 1916, colonial secretary. He was first lord of the admiralty, 1919–21, and mas created Viscount Long of Wraxall in 1921. He died Sept. 26, 1924, at Rood Ashton, Wilts.

LONG. A buyer or holder of securities is said to be "long" of the market or "long" of stock if he has more of a particular security than he has contracts to deliver. The longs are usually those who have bought expecting a rise in prices and are commonly included among those known as "bulls" (see STOCK EXCHANGE). The opposite term, "short," is applied to one who has contracted to deliver more of a certain security than he holds. The shorts are principally those who have "sold short" in anticipation of a drop in prices, in which event they will buy at the lower price for delivery. They are often included among those known as "bears."

LONG BEACH, a city of Los Angeles county. Calif., U.S., 20 mi. S. of Los Angeles, on San Pedro bay, is a tourist resort and an important industrial and commercial centre. Catalina Island is 23 mi. off the coast and the Palos Verdes hills lie to the west. The elevation ranges from 14.5 below sea level to 170 ft. above sea level. Long Beach completely surrounds the cities of Signal Hill and Lakewood, and the three cities, along with Catalina, form a unified school district. The site was once a portion of a Spanish land grant given to Manuel Nieto in 1784 which was divided among his five children as ranchos. Two of the latter, Los Xlamitos and Los Cerritos, which included most of modern Long Beach, passed into the hands of Abel Stearns and John Temple in the early 1840s. By 1882 both ranchos had been purchased by the Bixby family. William E. Willmore made the first attempt to found a town in 1882; after securing an option from Jotham Bixby on 4.000 ac.. he organized the American colony, but the plan collapsed in 1884. The Long Beach Land and Water company continued with the project and gave the seven miles of wide strand the name Long Beach. It was first incorporated in 1897.

Until 1921 Long Beach was a seaside resort with a largely transient population. Harbour development was made possible by the acts of 1911 and 1925 by which the state granted to the city the bordering tidelands and submerged lands. Bond issues and revenue from oil and gas provided funds to develop an excellent man-made harbour. The discovery of oil in 1921 at Signal Hill resulted in increased industrial activity and a spectacular leap in population. After 1937 the city was plagued with litigation and legislation over the revenue accruing from the tideland reserves u-here the removal of oil and gas also produced the serious problem of subsidence.

In March 1933, Long Beach suffered a destructive earthquake: after which a widespread building program was inaugurated. During World War II a naval base (now a shipyard) was established there. Douglas Aircraft corporation built and progressively expanded a plant, which at peak production employed 30.000 workers. In nearby Seal Beach and Los Alamitos, a naval ammunition and net depot and air base were opened and continue to operate. A naval hospital was also erected. which became a veterans administration hospital. A modified council-manager form of government. with some aspects of the commission type. was adopted in 1921. Gas and water utilities are municipally owned.

The port of Long Beach has modern facilities, used by about 1,700 ships annually. and can berth 30 vessels at one time. After World War II most of the commerce was with Japan, and the principal export was petroleum. Long Beach and Los Angeles harbours are connected by Cerritos channel: Fisheries are important, and thousands of tons of fish are processed in local canneries. Freeways serve the port and the city. Diversified industries include automobile assembling and the manufacture of oil-drilling equipment. aircraft. soap an. toiletries. chemicals. paints, furniture, clothing, furnaces and heaters. ceramics and glass, paper, plastics, and building and insulation products.

The great inundation of population after World War II produced grave educational problems, and it became necessary to double the capacity of the public schools. Long Beach City college '(established 1927) is one of the largest two-year colleges in the nation; Long Beach State college (1949) has an enrollment of about 10.000. The city supports an art centre, an extensive library system, a symphony orchestra. a municipal band, a light opera association and community playhouses. It also maintains parks, municipal golf courses, a stadium. a marine stadium and the modern marina (1,250 ac.) for private ocean-going craft. The annual "Miss International Beauty" pageant gained international publicity for the city. Pop. (1960) 343,168. (H. P. Jo.)

LONG BEACH, a resort and residential city in Nassau county on Long Island. N.Y., U.S. Henry Hudson's log from the "Half Moon" reported in 1609 a "long glistening bar of exceptionally white sand" off the westerly. southern shore of the island. More than 200 years later the name Long Beach was given to this 7-mi. sand bar approximately 6 mi. from the New Tork city line. The white sandy beach, one of the few on the east coast which faces directly south off the Atlantic ocean, was ideally situated for New York vacationists. In 1880 the Long Beach hotel was constructed. In the early 20th century it was developed into a thriving resort where many prominent citizens maintained summer residences. However, after the 1930s Long Beach attracted an increasing number of permanent residents, so that its character as a community became more suburban. For comparative population figures see table in NEW YORK: Population. (WI. M D.)

LONGBENTON, an urban district (1935) in the Wallsend parliamentary division of Northumberland, Eng., adjoining the northeastern boundary of Newcastle upon Tyne for which it is a residential area. Pop. (1951) 25.066. Area 10.6 sq mi. The church of St. Bartholomew, originally built in the 12th century, stands between Longbenton and Killingworth. Thomas Addison, the physician, was born at Longbenton in 1793 and George Stephenson (*q.v.*) the inventor of the locomotive, was at one time the engineer at Killingworth colliery and his house is still preserved. In the 17th century the Newcastle races were run on Killingworth moor, later known as the district of Forest Hall and West Moor. The knights hospitallers also held land in Killingworth which was granted to them after 1308. Other than agriculture. the principal industry, for about 200 years, has been coal mining.

LONG BRANCH, a city of Monmouth county, N.J., U.S.. is located on the Atlantic coast, 45 mi. S. of New York. For years it uas knonn as one of the oldest summer resorts, but with the growth of the garment and electrical industries in the 20th century, it gradually became an all-year residential community. Fishing and truck farming are also significant. Its name stems from the fact that it borders on the eastern or long branch of the South Shrewsbury river.

The first village was established at West Long Branch, one mile from the shore. The section nearer the beach developed later, when there was a regular line of stages from Philadelphia and a steamboat service from New York. In 1860 the first railroad arrived. In the late 19th and early 20th centuries people visited the resort, including the presidents U. S. Grant, Rutherford B. Hayes. Benjamin Harrison and Woodrow Wilson. Pres James A. Garfield, after he was shot in Washington, D.C., was brought to his Long Branch summer cottage, where he died in 1881. The city was chartered in 1904 and includes the communities of Elberon, North Long Branch and West End. For comparative population figures see table in NEW JERSEY: *Population.* (H. F. WI.)

LONGCHAMP, WILLIAM (d. 1197), chancellor of England and bishop of Ely, entered public life at the close of Henry II's reign as official to the king's son Geoffrey, for the archdeaconry of Rouen. Henry II. nho disliked him, called him the "son of two traitors." He soon deserted Geotirey for Richard, who made him chancellor of the duchy of Aquitaine. As Richard's envoy, in Paris, he defeated Henry II's attempt to make peace with Philip Augustus (1189). On Richard's accession William became chancellor of the kingdom and bishop of Ely. When Richard left England (Dec 1189), he put the tower of London in his hands and chose him to share with Hugh de Puiset, the great bishop of Durham, the office of chief justiciar. William immediately quarrelled with Hugh and by April 1190 had ousted him from office. In June 1190 he received a commission as legate from Pope Celestine.

John returned to England in 1191; he and his adherents were immediately involved in disputes with William. At last (June 1191) Geoffrey, archbishop of York and William's earliest benefactor, was violently arrested by William's subordinates on landing at Dover. They exceeded their orders, which were to prevent the archbishop from entering England until he had sworn fealty to Richard. This outrage was made a pretext lor a general rising against William, whose legatine commission had now expired, and whose power was balanced bv the presence of the archbishop of Rouen. Walter Coutances, uith a commission from the king William shut himself up in the Tower, but he was forced to surrender his castles and expelled from the kingdom. In 1193 he joined Richard in Germany. Richard employed Longchamp in confidential and diplomatic missions in Germany, in France and at Rome. He died in Jan. 1197.

LONG EATON, an urban district in the South East Derbyshire parliamentary division of Derbyshire, Eng., 10 mi. E.S.E. of Derby and 8 mi. S.W. of Nottingham by road, on the Erewash canal between the Erewash and the Trent. Pop. (1951) 28,641. Area 5.6 sq.mi. The church of St. Laurence, with a Norman south aisle, stands in the market place. Trent college, a boys' boarding school, was founded in 1866. Long Eaton is a modern industrial town with straight, wide roads. Formerly a centre of the lace-making trade. among its varied industries now are upholstery and furniture. pianos, elastic goods, food and chemicals.

LONGEVITY, or length of days, is the prolongation of life to or beyond the standard duration. Generally speaking there is a rough correspondence between the bodily bulk and the span of life; thus the imagines of ephemerids or dayflies after an hour or two of "aerial life devoted to love" die, whereas the tortoise may survive for one or even two centuries; but this relation is not absolute, parrots, ravens, and geese live longer than many larger birds and than most mammals (Mitchell); some fish, such as salmon (100 years), carp (150) and pike (200), have a longevity contrasting with the 30 years of horses. Trees are constructed on an entirely different plan from that underlying the complex higher animals, and are thus endowed with a kind of potential immortality. The section of the trunk of a mammoth tree (Sequoia gigantea) in the Natural History Museum, South Kensington, showing 1,335 rings, might have been as many years old.

Death, the termination of life, is avoided in the protozoa by the division of the individual into two, which thus start afresh, so that, as Weismann long ago argued, the organism is immortal. But in the higher grades of the animal kingdom such rejuvenation is impossible, and the processes of senescence and death must be regarded as the penalty to be paid for their higher differentiation; they are dependent for their term of life on an inherited physico-chemical constitution, and are thus. like a clock, set for a definite period. After the time of Aristotle, the vital cycle has been thought to be a multiple of the period of growth; Francis Bacon considered that as a rule animals should live eight times, Flourens five times, as long as they take to reach maturity; in the case of man both Buffon and Flourens, though on rather different grounds, estimated that 100 years is the physiological duration of life, and this has been widely accepted, in spite of the psalmist's "three score years and ten," with perhaps a sorrowful extension to four score.

In more modern times the number of reputed centenarians has been shown by critical enquiry to be much in excess of the real figure, and that the ages popularly ascribed to Henry Jenkins (169), Thomas Parr (152), Katherine, Countess of Desmond (140), and many of the 1,712 centenarians in James Easton's list covering the years A.D. 66 to 1799 cannot be accepted as authentic. Fallacies easily creep in and memories and records fail; thus in the census of 1911 the excess of persons alive over 91 and the deficit of those between 85 and 90 could only be explained by exaggeration of their age by old people.

It is desirable to distinguish clearly between the concept of the life span and that of the average length of life. The former term is best reserved to denote the extreme limit of life characteristic of the species, say a little more than 100 years in the case of man. On the other hand, the term average length of life is applied to a figure computed from a life table; it measures the average number of years lived by the individuals of a large cohort of persons passing from birth to death in accordance with the mortality exhibited in the life table. The average length of life, so defined, is also often spoken of as the expectation of life at birth. Similarly, the average number of years lived beyond a given age, such as age 30 for example, is called the expectation of life at that age. While the life span has probably changed little, if at all, in all historic time, the average length of life has been greatly extended, especially in modern times. So, *e.g.*, the average length of life, as given by the registrar-general for England and Wales in 1838–54, was 39.91 years for males and 41.85 years for females; by 1937, the latest year for which a life table is available (1947), the corresponding figures were 60.18 and 64.40 years. The expectation of life at later ages, that is to say the average after-lifetime; also shows improvement; thus in 1854, males at the age of 60 had an expectation of 13.53 years, females an expectation of 14.34 years. The corresponding figures for 1937 were 14.32 and 16.48 years. In the United States, the expectation of life at birth for both sexes combined in the white population in 1901 was 48.23 for males and 51.08 for females; by 1944, these figures had risen to 63.55 and 68.95 years respectively. The gain has been chiefly in the childhood ages. It is due in large part to the success gained in the treatment, and even more in the prevention, of infectious diseases. The diseases characteristic of middle life and advanced age—the so-called degenerative diseases, especially those associated with hardening of the arteries—have so far yielded little to efforts of control.

Presumably if all were placed under similar environmental circumstances, there would be certain racial differences in longevity. This statement is hardly capable of definite test, since the more outstanding racial differences in different parts of the world cannot be separated from accompanying environmental differences. As to sex differences, in all civilized countries females have a lower mortality than males at most ages of life. Figures for the last census year, 1940, in the United States show that if deaths from causes connected with childbirth are excluded, the difference in favour. of female mortality extends to all ages of life. An interesting observation by Graham Bell, in his analysis of the Hyde genealogy, dealing with 8.972 persons and dating from the 17th century, shows that, in this group at least, the proportion of those living long increased with size of family up to families containing nine and ten children, and then fell in the case of still larger families. It also appeared that the first born lived as long as subsequent children, and that children born between four and eight years after their parents' marriage were on the average longer lived than those born earlier or later.

Heredity.—The two great factors influencing the length of life are heredity and environment in its broadest sense; for obvious reasons it is impossible to disentangle them and ascertain what share each of these two factors contributes. That longevity well beyond the average tends to run in families seems to be well established. To this topic an important contribution has been made by the late Raymond Pearl in a book under joint authorship with his daughter, Ruth DeWitt Pearl, entitled *The Ancestry of the Long-Lived.* A most striking example of apparently hereditary longevity quoted by these authors is that of a group of seven persons, grandparents, parents and son, whose aggregate age at death was no less than 699 years; at that, two of them died by accident. Another significant investigation of inheritance of longevity, conducted on the basis of records of insurance companies by Louis I. Dublin and Herbert Marks, showed very clearly how longevity of parents favourably influences the longevity of offspring.

Inborn vitality may counteract the evil influences of unhealthy environment and bad habits, such as overcrowding in towns and alcoholism, and so explain the occasional longevity of those who have lived in most unfavourable circumstances; *e.g.*, the contrast between two aged brothers, one a confirmed toper, the other a total abstainer. Of the hereditary factors innate vitality of the nervous and the circulatory systems are the most important; the nervous system decides the mental disposition and the reactions of the body as a whole. Cazalis' aphorism "Man is as old as his arteries" expresses the advantage of possessing a circulatory system which does not degenerate readily, harden into the condition of arteriosclerosis, or show an excessive blood pressure; for it is well known that the members of some families tend to die about the age of 60 from apoplexy, heart or kidney disease, the latter being often the result of arterial disease in the kidneys.

Environment.—One way in which environmental conditions affect longevity is through diseases contracted in the course of life. It has been stated that only those who have escaped illness up to the age of 60 years are likely to reach extreme old age, but nearly half of the 824 persons between the ages 80 and 100, analysed by Sir George Humphry, had passed through a severe illness, in many of them an acute infection. An acute illness may be the apparent starting point of old age and senescence, especially if sufficient time for convalescence is not allowed. It has been suggested that the deteriorating influence of malaria on individuals may, by its mass effect, account, in some degree at any rate, for the decadence of Magna, Graecia (W. H. S. Jones). Functional activity, mental and bodily, plays an important part in postponing the advent of morbid old age, and there is more danger of rusting out than of wearing out, provided the body is healthy and the mind free from worry. The advanced ages of many dignitaries of the Church and the bench and of prime ministers, though many of these may be supermen, point to the beneficial influence of long-continued activity. Among painters Giovanni Bellini, Michelangelo, and Sidney Cooper worked up to nearly their death, and Titian was painting with "incomparable steadiness of hand" when cut off by the plague at the age of 99. The same retention of productivity was seen in Voltaire, Littré, Anatole France, Goethe, von Ranke, and Frederick Harrison. The members of the Académie Française are long-lived, and thus doubly justify their title of "the immortals." Retirement, often looked forward to in early life, is a source of danger, as it may bring with it cessation from activity.

The majority of centenarians have been small eaters, and several aphorisms point to the evil, if slow, effect of being a good trencherman, such as Montaigne's "Man does not die, he kills himself" and the forcible proverb "You dig your grave with your teeth." Overfeeding by overworking the resources of the body leads to metabolic disease, such as diabetes mellitus. and to arterial, heart and kidney affections, which are preceded often by long periods of latency during which the individual flatters himself on his vigour, but in which his arterial blood pressure is unduly high. During World War I it was observed that in certain countries the death rate from diabetes was reduced. and this has been attributed to dietary curtailment. Poverty, within limits, is an advantage inasmuch as it removes the dangers of excessive eating, particularly of meat, after the body has reached maturity. The beneficial effects of a meagre dietary were set forth by the noble Venetian Luigi Cornaro (1467–1566), by Metchnikoff, Henry Thompson the surgeon, Hermann Weber, and many others who practised their own precepts. With regard to the influence of alcohol there can be no doubt, as the actuarial reports of life assurance companies amply prove, that excess is harmful.

It is true that Raymond Pearl's statistical enquiry into over 5,000 lives at Baltimore showed that "a moderate use of alcohol does not tend to shorten life." But what constitutes moderation is open to question.

Prolongation of life towards its limits may be healthy or attended by morbid manifestations. Healthy or normal old age is attended by diminution in functional activity which corresponds with the characteristic changes of atrophy and involution in the structure of organs and tissues and of a diminished area of the capillary blood vessels. With the waning of sexual power the mind becomes calmer and more philosophic, so that the limitations of activity are more cheerfully accepted; but fatigue is more readily produced, memory, especially for names, becomes less agile, and will power, like the gait, becomes less certain. The mental outlook is largely determined by that of the individual in the past, happy and kindly, or pessimistic and uncharitable. Often there is a tendency to ego-centricity and to nervous apprehension, as the preacher (Koheleth) in Ecclesiastes said "Fears shall be in the way." It may be pointed out that the glands of internal secretion become old with the rest of the body, not that their atrophy causes old age. For it has been thought that senescence results from failure of the thyroid, and especially of the interstitial cells of the testes, and experiments and operations by Steinach and Voronoff to supplement this want have been followed by dramatic, if temporary, rejuvenation, which in animals at least cannot be explained by suggestion; but that life is thus prolonged as well as being made to burn more brightly remains to be proved in the case of man.

It is hard to draw a sharp line of demarcation between normal old age (senescence), with its limitations due to atrophic changes in the body, on the one hand, and on the other hand the manifestations in the elderly resulting from past infections and diseases (senility). Physiological old age, that is freedom from any pathological change, is agreed to be rare, and it has been said by Terence, Cicero, Sanctorius, and often since that old age is itself a disease.

Eli Metchnikoff attributed the senile accompaniments of advanced years to pathological and preventable causes, especially poisons produced by bacteria in the large intestine, these toxins causing degeneration of the bodily cells which are eaten up by more resistant cells called macrophages; this hypothesis has been much discussed.

That disease may produce the picture of morbid old age prematurely is well established, and in the remarkable but rare condition of progeria this occurs in childhood. The various parts of the body do not all grow old at the same time. but when these changes are much more advanced in a vital organ, especially the brain, than elsewhere, the proper harmony of the system is so disturbed that the condition becomes pathological, and then instead of a happy, healthy and pleasant old age there is the picture of incapacity, pain and misery so that existence becomes a burden to the individual and to his family.

Some diseases are especially prone to attack the aged, though they are not entirely confined to the evening of life. The chief diseases mainly concentrated in later life are diabetes, cancer and the cardiovascular-renal group. This last is closely related to arteriosclerosis which may affect various parts of the body, such as the kidneys, the brain and the heart.

The acute fevers, such as measles, typhoid, scarlet fever and diphtheria, rarely attack the old, probably because immunity has gradually been acquired, but pneumonia and erysipelas are exceptions to this rule, and pneumonia, with but few symptoms, often proves to be the last straw in breaking the feeble thread of existence.

LONGFELLOW, HENRY **WADSWORTH** (1807–1882), the most popular of U.S. poets in the 19th century, was born in Portland, Me., on Feb. 27. On both sides of the family he came from Yorkshire stock. His mother. Zilpah Wadsworth, was the daughter of a general in the American Revolution, who traced his ancestry back to the Plymouth Pilgrims. His paternal ancestor, a blacksmith, settled in Byfield, Mass., in 1680. His early education was in private schools and in the Portland academy. He entered Bowdoin college as a sophomore and graduated in the class of 1825 with Nathaniel Hawthorne. At college he studied unremittingly to fit himself for a literary career. He was attracted especially to Sir Walter Scott's romances and Washington Irving's *The Sketch Book*. While an undergraduate he published verses in national magazines. His father wanted him to enter his law office, but the future poet wrote, "I most eagerly aspire after future eminence in literature." During his junior year he had so deeply impressed a college trustee by the fluency with which he translated an ode of Horace that on graduation he was offered a professorship in modern languages provided that he would first study in Europe.

On the continent he learned French, Spanish and Italian, but refused to settle down to a regimen of scholarship at any university. In 1829 he returned to the U.S. to be a professor and librarian at Bowdoin. There he proved himself an excellent teacher. He wrote and edited textbooks, translated poetry and prose, and wrote essays on French, Spanish and Italian literature.

He felt himself somewhat too isolated at Bowdoin, so when he was offered a professorship at Harvard, with the hint of another opportunity to go abroad, he gladly accepted and set forth for Germany in 183j. Before settling down he visited England, Sweden and the Low Countries. Saddened by the death of his wife in 1835 he ceased his wandering and settled at Heidelberg where he fell under the influence of German Romanticism. The transcendental quality of such poetry as in Novalis' "Hymns to the Night" induced in him an introspective mood.

In Oct. 1836 he sailed for home and returned to Harvard. Meanwhile he had published a book of travel sketches, *Outre-Mer*, vignettes of life in France, Spain and Italy, written under the influence of Irving's *Sketch Book*. He lacked Irving's sense of humour and capacity for creating character and the book did not succeed. In 1839 he published *Voices of the Night*, a volume containing "The Psalm of Life" and "The Light of the Stars"—poems that became immediately popular. Early in the same year he brought out *Hyperion*, a romantic novel idealizing his European travels.

For 18 years he presided successfully over Harvard's modern language program, but his "poetic dreams were shaded by French irregular verbs," and he longed for freedom. The poet in him was kept alive by his work as a translator. In 1841 his *Ballads and Other Poems*, containing "The Wreck of the Hesperus," came out and swept the nation. In 1854 he left teaching and entered upon his long-cherished dream of building "some tower of song with lofty parapet." While this major ambition was maturing he wrote a few *Poems on Slavery* (1842), finished productions which lacked, however, the power of John Greenleaf Whittier's Hebraic denunciations. He was more at home in *Evangeline*, an idyll of Acadia skillfully written in dactylic hexameters, which reached almost every literate home in the U.S.

The Song of Hiawatha, published in 1855, proved another popular success. With Henry Rowe Schoolcraft's two books on the Indian tribes of North America as the base, and the trochaic metrics of the Finnish epic *Kalevala* as his medium, he fashioned one of his most artistic productions. Its appeal was immediate. In 1858 he wrote *The Courtship of Miles Standish* in the "Evangeline" measure. The material is less idyllic than that of the earlier story, but the metrics are enriched by a more varied accent.

The death in 1861 of his second wife, who died of burns after she had accidentally set her dress on fire while sealing packages, deepened his melancholy (cf. "Cross of Snow," 1879). Her death drove him for spiritual relief into translating that "Medieval miracle of song," the *Divine Comedy of Dante Alighieri*, one of the most notable translations of the Florentine to that time. While engaged in this work he wrote six sonnets on Dante which are among his finest productions.

The *Tales of a Wayside Inn*, modeled roughly on the plan of Geoffrey Chaucer's *Canterbury Tales* and published in 1863, reveals his marked narrative gift. The first poem, "Paul Revere's Ride," became a national favorite. He published in 1872 what was intended to be his masterpiece, the *Christus: A Mystery*, a trilogy dealing with the subject of Christianity from its beginning, and followed this trilogy with two fragmentary dramatic poems: "Judas Maccabaeus" and "Michael Angelo." But his genius was not dramatic, as he had demonstrated earlier in *The Spanish Student* (1843), although it should be noted that these neglected later works contain some of his most effective writing.

In the 19th century Longfellow was loved and honoured at home and abroad. Oxford conferred upon him a D.C.L. and Cambridge an LL.D. in 1868. After his death March 24, 1882, a memorial to him was unveiled in Westminster abbey. Some years after his death a violent reaction against his poetry set in. Critics who had put the Romantic movement behind them and who deplored his sometimes heavy-handed didacticism appeared to take pleasure in reducing him to the status of a hearthside rhymer. This harsh dismissal was somewhat unfair. His poetry is still loved by the unpretentious, and such poems as "My Lost Youth" transcend the metrical scaffolding on which they are erected. His poetry rarely touches greatness; he does not produce the "martial music" of John Milton or Homer, but good singing poetry can be found throughout his work.

BIBLIOGRAPHY.—*See* the Riverside edition of Longfellow's *Works* (1886). Still of importance although outdated is the biography of the poet by his brother Samuel Longfellow, *Life of Henry Wadsworth Longfellow with Extracts from His Journals and Correspondence*

(1886), supplemented by his *Final Memorials of Henry Wadsworth Longfellow* (1887). E. C. Wagenknecht's *Longfellow: a Full-Length Portrait* (1955) incorporates much new material hitherto scattered or unpublished. The most thorough account of the formative years is L. R. Thompson's *Young Longfellow (1807–1843)* (1938). H. S. Gorman's *A Victorian American, Henry Wadsworth Longfellow* (1926) has interest as an adversely critical biography. See also *Mrs. Longfellow, Selected Letters and Journals*, ed. by E. C. Wagenknecht (1956).

No comprehensive bibliography of Longfellow exists. Of limited value is L. S. Livingston's *Bibliography of the First Editions in Book Form of the Writings of Henry Wadsworth Longfellow* (1908).

Among special studies may be noted: Iris L. Whitman, *Longfellow and Spain* (1927); J. T. Hatfield, *New Light on Longfellow; with Special Reference to His Relations to Germany* (1933); A. R. Hilen, *Longfellow and Scandinavia* (1947); and C. L. Johnson, *Professor Longfellow of Harvard* (1944). P. Morin's *Les Sources de l'Oeuvre de Henry Wadsworth Longfellow* (1913) is useful but must be supplemented with many subsequent articles. The Introduction to Odell Shepard's edition of *Representative Selections* in the American Writers Series (1934) is valuable, and William Dean Howell's description of his friend in *Literary Friends and Acquaintance* (1900) is of historical interest. Examples of early 20th-century opinion may be found in Paul Elmer More's *Shelburne Essays*, vol. v (1908) and Bliss Perry's *Park-Street Papers* (1908). (WT. S.; X.)

LONGFORD, a county of Ireland, bounded northwest by Leitrim, northeast by Cavan, southeast and south by Westmeath and west by Loughrea and Roscommon. The land area is 257,936 ac., or 403 sq.mi. Pop. (1956) 32,969.

The Silurian axis of Newry reaches the north of the county, where Lough Gowna lies upon it. Anticlinals bring up Old Red Sandstone at Longford town and Ardagh, above the Carboniferous limestone plain, in which Lough Ree forms a characteristic lake, with signs of extension by solution along its shores. Marble of fine quality has been quarried. In the north indications of iron are abundant, and there are also traces of lead, The principal rivers are the Camlin, which rises near Granard and flows past Longford to the Shannon, and the Inny, which enters the county from Westmeath, crosses its southern corner and falls into Lough Ree. Lough Ree is partly included in Longford. The other principal lakes are Derrylough and Loughs Gowna, Drum and Bannow.

The early name of Longford was Annaly or Analé, a principality of the O'Farrells. Then included in Meath, it was granted by Henry II to Hugh de Lacy, who started an English colony. On the division of Meath into two counties in 1543, Annaly was included in Westmeath, but in 1569 it was made shire ground under the name of Longford.

The chief rath is called the Moat of Granard. There are monastic remains at Ardagh, a former bishopric, Longford, Moydow and on several of the islands of Lough Ree. The principal castles are those of Rathcline near Lanesborough, and Ballymahon on the Inny. Oliver Goldsmith spent his early childhood at Pallas, a village near Ballymahon, in this county; and at Edgeworthstown (now called Mostrim) lived the family of Maria Edgeworth.

The climate is moist and cold, and there is much marsh and bog. The soil in the southern districts resting on the limestone is a deep loam well-adapted for pasture, but in the north it is often poor. Oats and potatoes are the principal crops. The railway from Mullingar to Sligo crosses the county by way of the county town of Longford; and the Cavan branch touches the extreme east.

The Royal canal enters the county in the south at Abbeyshrule, and joins the Shannon near Cloondara. The constituency of Longford-Westmeath returns five members to *dail eireann.*

LONGFORD, the county town of County Longford, Ireland, on the Camlin river, 76 mi. W.N.W. of Dublin. Pop. (1956) 3,716. The principal building is St. Mel's Roman Catholic cathedral for the diocese of Ardagh and Clonmacnoise, which includes nearly all Longford, most of Leitrim and parts of Offaly, Nestmeath, Roscommon, Sligo and Cavan. Trade is in grain, butter and bacon. There are corn mills, a spool factory and tanneries. The ancient name of the town was Athfada, and there a monastery is said to have been founded by St. Idus, a disciple of Patrick.

LONGHI, ALESSANDRO (1733–1813), Italian painter, etcher and biographer of Venetian artists. the most important Venetian portrait painter of his day, son of Pietro Longhi (*q.v.*), was born and died at Venice. His father gave him his first training but quite soon put him to study under the Rembrandtesque painter of portraits and fancy subjects, Giuseppe Nogari. In 1759 he was elected a member of the Venetian academy, for which he painted one of his rare subject pictures, the allegorical "Painting and Merit." In 1762 Longhi issued his book *Compendio delle Vite de' Pittori Veneziani Istorici piu rinomati del presente secolo con sui ritratti dal naturale delineati ed indisi,* one of the most important source books for the history of Venetian 18th-century painting. Both portraits and text were printed from plates he etched. In addition, he etched some of his own and some of his father's works. His work is best seen at Venice. (F. J. B. W.)

LONGHI, PIETRO (PIETRO FALCA) (1702–1785), Italian painter of small scenes of Venetian social and domestic life, was the son of a silversmith in whose workshop he received his first training. Later he worked under the Veronese history painter Antonio Balestra, but his one important work of this sort, the monumental ceiling of the "Fall of the Giants," executed in 1734 for the Palazzo Sagredo, was a complete failure. It is likely that it was because of this that he left Venice for a time and studied at Bologna under Giuseppe Maria Crespi. After his return to Venice he devoted himself to painting somewhat in the manner of Nicolas Lancret but more satirical. He also painted occasional portraits. Longhi was also undoubtedly influenced by Dutch *genre* painting, of which there was at least one important collection in Venice at that date. His paintings, like those of Antoine Watteau, were based on carefully observed figure drawings, a large number of which survive. Many of his paintings were engraved. He was elected to the Venetian academy at its foundation in 1756 and died in Venice on May 8, 1785. His works are best seen at Venice, though there are a few in London. (F. J. B. W.; X.)

LONGINUS, CASSIUS (*c.* A.D. 213–273), Greek rhetorician and philosophical critic, surnamed PHILOLOGUS. The origin of his gentile name Cassius is unknown; it can only be conjectured that he adopted it from a Roman patron. He was perhaps a native of Emesa (Homs) in Syria, the birthplace of his uncle Fronto the rhetorician. He studied at Alexandria under Origen the heathen, and taught for 30 years at Athens. Longinus upheld, in opposition to Plotinus, the doctrine that the Platonic ideas existed outside the divine *nous* (*see* NEOPLATONISM). Plotinus, after reading his treatise *On First Principles,* remarked that Longinus might be a scholar, but that he was no philosopher. The reputation which Longinus acquired by his learning was immense; he is described by Porphyry as "the first of critics," and by Eunapius as "a living library and a walking museum" or encyclopaedia.

During a visit to the east he became teacher in Greek, and subsequently chief counsellor in state affairs, to Zenobia, queen of Palmyra. It was by his advice that she endeavoured to regain her independence; Aurelian, however, crushed the attempt, and while Zenobia was led captive to Rome to grace Aurelian's triumph, Longinus paid the forfeit of his life.

Longinus was the author of a large number of works, nearly all of which have perished. Among those mentioned by Suïdas are *Quaestiones Homericae, An Homerus fuerit philosophus, Problemata Homeri et solutiones, Atticorum vocabulorum editiones duae;* the most important of his philological works, *Philological Discourses,* consisting of at least 21 books, is omitted. A considerable fragment of the *De finibus, On the Chief End,* is preserved in the *Life of Plotinus* by Porphyry. Under his name there are also extant Prolegomena to the *Encheiridion* of Hephaestion on metre and the fragment of a treatise on rhetoric inserted in the middle of a similar treatise by Apsines. It gives brief practical hints on invention, arrangement, style, memory and other things useful to the student.

It is as the reputed author of the well-known and remarkable work generally, but inadequately, rendered *On the Sublime* that Longinus is best known. Modern scholars, however, with few exceptions, are agreed that it can not with any certainty be ascribed to him, and that the question of authorship can not be determined.

The alternative author, Dionysius, of the manuscript has been variously identified with the rhetorician and historian Dionysius of Halicarnassus, the Atticist Aelius Dionysius of Halicarnassus, Dionysius Atticus of Pergamum, Dionysius of Miletus. W. R.

Roberts concluded on an unidentified Greek man of letters who probably lived at Rome not more than 30 or 40 years after the birth of Christ. Wilamowitz-Möllendorff also gives his date as about A.D. 40. The rendering On *the* Sublime implies more than is intended by the original Greek ("impressiveness in style," R. C. Jebb). Nothing abnormal, such as is associated with the word "sublime," is the subject of discussion; it is rather a treatise on style. According to the author's own definitions, "sublimity is a certain distinction and excellence in expression," "sublimity consists in elevation," "sublimity is the echo (or expression) of a great soul." The treatise is especially valuable for the numerous quotations from classical authors.

"Its main object is to point out the .essential elements of an impressive style which, avoiding all tumidity, puerility, affectation and bad taste, finds its inspiration in grandeur of thought and intensity of feeling, and its expression in nobility of diction and in skilfully ordered composition" (J. E. Sandys).

A full bibliography of this subject will be found in the edition by W. Rhys Roberts (2nd ed. 1909), with introduction, analysis, translation and appendices. *See* also W. R. Roberts' introduction to *Demetrius on Style* in *Aristotle: the Poetics* (ed. with Eng. trans. by W. Hamilton Fyfe, 1927); F. Marx, *Wiener Studien* (xx, 1898) and F. Kaikel, *Hermes* (xxxiv, 1899), who respectively advocate and reject the claims of Longinus, and J. E. Sandys, *History of Classical Scholarship* (2nd ed. 1906). The number of translations in all the languages of Europe is large, including the famous one by Boileau. A text and translation was published by A. O. Prickard (1907–08).

LONG ISLAND, a fragment of the North American continent extending 118 mi. E.N.E. from the mouth of the Hudson river on the northeastern shore of the United States. It roughly parallels the south shore of Connecticut from which it is separated by Long Island sound (go mi. long) and lies southeast of the mainland of New York state, of which it is a part.

The island is from 12 to 23 mi. wide and has an area of 1,723 sq.mi. The east end is divided into two narrow peninsulas by three bays, Great Peconic, Little Peconic (in which lies Shelter Island) and Gardiners (in which lies Gardiners Island). The northern peninsula, about 25 mi. long, culminates in Orient point; the southern peninsula, about 40 mi. long, ends in Montauk point, the eastern extremity of the island. The north shore of the island is broken in its western half by Flushing bay, Little Neck bay, Manhasset bay, Cold Spring harbor, Huntington bay, Smithtown bay and Port Jefferson. The south shore has Jamaica bay, with many low islands and nearly cut off from the ocean by the narrow spit of Rockaway beach; and the ill-defined Great South bay, which is separated from the Atlantic by the narrow Long beach, Jones beach and Oak Island beach and by the long peninsula called Fire Island or Great South beach. Still farther east is Shinnecock bay, about 10 mi. long and cut off from the ocean by a narrow beach.

Physiography, climate and location have combined to make Long Island one of the richest and most important garden spots in the United States. The hills of glacial moraine and much of the outwash plains of the southern half of the island, covered for centuries with forest mold, offer a rich soil to the husbandman. A mild maritime climate brings the spring earlier and holds the autumn later than in the continental interior at the same latitude.

History.—When the Europeans first settled on Long Island, they found the area occupied by Indians who were generally of Delaware stock and who, according to early accounts, were divided into a number of small groups, loosely called tribes. There were supposedly at least 13 of these major groups and there may have been more. As part of the Atlantic coast line claimed by England, the island was part of the territory originally included under the jurisdiction of the Plymouth company in the early 1600s and later in 1635 its title was presumably conveyed to the earl of Stirling (Sir William Alexander) by Charles I. The earl's agent, James Farret, was sent to the area and conveyed land titles to groups of individuals between 1635 and 1640.

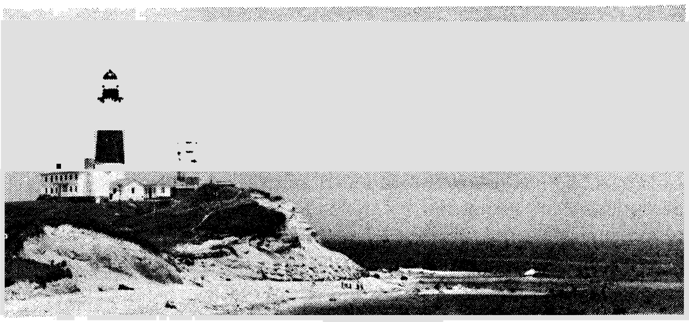
Dutch interest in this part of the new world had been aroused by the voyage of Henry Hudson in 1609 and resulted in the Dutch West India company setting up a trading post on Manhattan Island in 1624. Long Island was part of the territory claimed by the company even though it conflicted with English claims to the same area. There is some evidence of settlement in the extreme western part as early as 1625; certainly Dutch settlers crossed the East river in the mid-1630s and located in what is now Kings county. Breuckelen (Brooklyn), Amersfort (Flatlands), Midwout (Flatbush), and Nieuw Utrecht (New Utrecht) were Dutch communities established under the authority of the company from 1636 to 1660.

In 1640 Englishmen from Lynn, Mass.. under a Stirling patent, attempted to settle near Manhasset bay but were warned anay by Gov. William Kieft of New Netherland, who would not admit the validity of the English claim. Later that year these people settled at Southampton, toward the eastern end of the island; at about the same time a group from New Haven located at Southold, a little to the north. These two settlements together with the Gardiner family on Gardiners Island (1639) were the first English groups on the Long Island scene. Another band of English settlers obtained a patent from Governor Kieft in 1644 to found Hempstead under the Charter of Freedoms and Exemptions. Other English towns, Gravesend (1645), Flushing (1645), Newtown (1655), and Jamaica (1656), were set up in similar fashion with the inhabitants swearing allegiance to the Dutch authorities. By the treaty of Hartford of 1650 between New Netherland and the United Colonies of New England, a demarcation line was drawn from Oyster bay to the ocean, recognizing the island as Dutch to the west and English to the east.

In March 1664 Long Island was part of the area given to the duke of York by Charles II and in August the conquest of New Amsterdam and the Dutch territory was effected. By this time the English settlements in the eastern part of the island had associated themselves generally with either New Haven or Connecticut, the latter making some claim to the Long Island area by its charter of 1662. Besides Southampton and Southold, the eastern towns included East Hampton (1648), Shelter Island (1652), Huntington (1653), Oyster Bay (1653), Brookhaven (1655) and Smithtown (1663).

Long Island, together with Westchester and Staten Island, became known as Yorkshire and was governed by the Duke's Laws promulgated at Hempstead in March 1665. In 1683, Yorkshire was abolished and the county system introduced in the province with Long Island receiving three of the original counties—Suffolk, Queens and Kings. A major political change occurred in 1899, when the three eastern towns of Queens county—Hempstead, North Hempstead and Oyster Bay—formed the new Nassau county and the other towns in Queens became part of New York city. The p[illegible] of the American Revolution saw Long Island a hotbed of [illegible] vity on the [illegible] t of both Loyalist and Patriot, and its coastal area was the scene of raids by privateers and organized military units For the entire period [illegible] f the British [illegible] upati[illegible] of New York city, Long Island was the major source of supplies of wood a[illegible]d food, [illegible] d its western area was continuously occupied [illegible]y detachments of British troops.

Industries.—During the 19th century Long Island was chiefly known for it[illegible] agriculture and its fishing industry. Manufacturing was present in the metropolitan area of King[illegible] cou[illegible]ty and to a certain extent in some th[illegible] regions. Lonr Island agriculture of the 17th and 18th centuries was characterized by the self-sufficient farm. Toward t[illegible] end [illegible] f the 18th century some farmers began selling their surplus crops in New York. Connection with this



BY COURTESY OF NEW YORK STATE DEPARTMENT OF COMMERCE

MONTAUK POINT LIGHTHOUSE AT THE EASTERNMOST TIP OF LONG ISLAND market was made by wagons from the farms at the western end of the island and by small coasting boats from the homesteads of the north shore. Two events in the first half of the 19th century established Long Island agriculture on its modern basis. In 1825, the completion of the Erie canal gave New York city a connection with the continental interior and allowed a swift development which made it the metropolis of North America. In 1844 the Long Island railroad was completed to Greenport. The growth of New Uork and the completion of the railroad caused the general farms to be turned into market gardens, cultivated intensively.

Whaling was the most important maritime industry. So far as Long Island was concerned, the fishery had its origin in the 17th century at East Hampton and Southampton. Early in the 19th century Sag Harbor became the chief Long Island whaling port. The village, dependent almost solely upon whaling, prospered in the golden age of the industry and suffered heavily when whaling swiftly declined after the middle of the century. Throughout most of the 19th century the menhaden fishery flourished along the southern shore and in Peconic bay. Before the end of the 18th century, the blue point oyster bed in Great South bay had been discovered and was being worked, and in 185j New York permitted the leasing of sea bottom. which was not part of a natural bed, for the purpose of establishing oyster farms. Oystering under the new conditions became one of the most important industries, not only of Great South bay, but of Peconic bay and some of the north shore harbors. Throughout the history of the island, deep-sea fishing—for cod, mackerel, bluefish, sea bass, weakfish, etc.—has been the major support of many Long Island families. Fishing for recreation has always been of importance and Long Islanders for many decades have serviced these interests.

In the colonial period, milling of various kinds was carried on in the scattered settlements and some types of primitive manufacturing was engaged in to a limited degree. The chief manufacturing enterprises of the first half of the 19th century were those supplying the needs of the maritime industries. Cooperages and ropewalks characterized Sag Harbor in the whaling days. The building of ships and boats became an important industry at Port Jefferson and other north shore towns located near good timber The development of oystering on a large scale made a new demand for boats and for repair work. More important was the growth of summer colonies on the shores. The making, repairing and storing of pleasure craft during the winter became an important industry. Here and there, as at Patchogue and Sag Harbor, other manufacturing industries sprang up, and, as the years passed, Brooklyn and Queens became two of the most important industrial centres in the United States.

Recreation.—In the first decade of the 19th century Far Rockaway became a watering place for New York's elite. After the Civil War. nith the increase of railroad facilities, Long Island took on an added attraction for the wealthy. Southampton became a second Newport and great estates were built along the north shore For some distance along the south shore eastward from the city of New York, summer hotels were constructed which by the turn of the century were attracting thousands of summer vacationists. Coney Island, pioneer of U.S. amusement parks, has always flourished. while the major recreational achievement in recent years has been the continued development of Jones Beach by the Long Island State Park commission; it attracts millions of visitors each summer.

Population.—An outstanding phenomenon in the latter part of the 20th century was the tremendous upward surge of Long Island's population.

The four counties of the island expanded from 5,237,918 in 1950 to 6,403,852 in 1960. Between 1950 and 1960 Nassau county grew from 672,765 to 1,300,171 while Suffolk showed an increase from 276,129 to 666,784. One reason for this expansion in population was the construction of low-priced, one-family housing units in both Nassau and western Suffolk; a prime example is Levittown, developed after World War II as a private investment.

Transportation.—Long Island is served on both shores and through the central part of the island by the Long Island railroad, which is reputed to carry more commuters than any other railroad in the country. A highly developed and efficient system of parkways is in operation, while Manhattan is connected with Brooklyn and Queens by the Interborough Rapid Transit and Independent subway lines. Bridges connect the western part of the island with Manhattan and the Bronx; there is direct ferry service from north shore points to Connecticut and from the south shore to Staten Island.

With the advent of the airplane in the early decades of the 20th century, Long Island attracted attention because its flat plains presented ideal conditions for the manipulation of aircraft. By the 1920s Roosevelt field (closed in 1951) and Mitchell air force base (deactivated in 1961) had become internationally known. Both LaGuardia field and Idlewild (New York International) airport are on the island and the airplane industry there is regarded as the single most important manufacturing enterprise outside the New York metropolitan limits.

Battle of Long Island, 1776.—The interest of this battle lies in the fact that it was the first engagement in the campaign of 1776 (see AMERICAN REVOLUTION) and was expected in England to be decisive of the contest in the colonies. After the evacuation of Boston (March 1776), Lord Home moved against New York city, which he thought would afford a better base of operations for the future. The Americans undertook its defense although recognizing the difficulties in the case, as the bay and rivers adjoining would enable the British fleet to co-operate effectively with the army. To protect his left flank George Washington was forced to throw a portion of his troops over to the Long Island side of the East river; they fortified themselves there on the site of the present borough of Brooklyn. Lord Howe, who had encamped on Staten Island at the entrance to the harbour, determined to attack this isolated left wing, and on Aug. 22 landed at Gravesend bay, Long Island, with about 20,000 men. The Americans maintained strong outposts in the wooded hills in advance of their fortified lines. On the morning of Aug. 27 Howe, after four days' reconnaissance, attacked these posts with three columns, the left and centre delivering the holding attack, and the right and strongest column turning the enemy's left by a detour. Howe himself, accompanied by Generals (Sir H.) Clinton and Lord Cornmallis, led the turning movement, which came upon the rear of the enemy at the moment when they were engaged with the two other columns. By noon the Americans had been driven back into the Brooklyn lines in considerable confusion, and with the loss of about half their number. This constituted the battle. The completeness of the British victory resulted from the neglect of the Americans in guarding the left of their outposts. Howe has been criticized for not immediately assaulting the American works, which he might have carried on the evening of the battle. In view of the fact that he had only defeated a small portion of the American forces. and that the works were of considerable strength, he decided to make a formal siege, and Washington took advantage of the delay in operations to retreat across the river to New Uork on the night of the 29th. This successful movement repaired to some extent the bad moral effect of the defeat of the 27th in the American camp. In the engagement of Long Island Washington lost 1,200 prisoners, 30 guns, and 400 killed and wounded; of the latter the British lost nearly the same number.

See T. W. Field, "The Battle of Long Island," *Long Island Hist. Soc. Memoirs,* vol. ii (1869); and C. F. Adams, "The Battle of Long Island," *Amer. Hist. Rev., 1*:650–670 (1896). (C. F. A.)

LONG ISLAND SOUND, a semienclosed arm of the Atlantic ocean. lies between Connecticut and the island whose name it bears. Its easterly limits are defined by Long Island's Orient Point, and by Plum Island, Great Gull Island, and Fishers Island. The narrow western gateway is at Throgs Neck, where the waters of the sound meet the swift cross currents of the East river. The sound has a length of 90 mi. (78 nautical mi.), a width of 20 mi. (15 nautical mi.) and an area of 1,180 sq.mi. In Pleistocene time, the sound was deepened by two advances of the great Labrador ice sheet which scoured its crystalline bedrock and left two terminal moraines as a dominant feature of Long Island's topography. There is a maximum depth of 330 ft. near the sound's eastern limits, but elsewhere the water is little more than 100 ft. in depth. The mean tidal range is from less than 3 ft. in the east to more than 6 ft. in the west. The drainage basin of the sound is approximately 13 times its area and the annual volume of fresh water is about 35% of its total. Most of this runoff, chiefly from the Housatonic, Connecticut and Thames rivers, enters the sound's relatively open eastern end and is flushed out rapidly to Block Island sound; its effect on the salinity of the sound as a whole is minima!. As this freshened surface layer moves eastmard it is replaced by a more saline inflow along the bottom. The relatively :hallow waters of the sound are rich in plankton and bottom organisms, which make them favourable for young fish but deter most commercially valuable fish. Except for menhaden, processed for fish meal, the sound does not support an important commercial fishery. The major sports fishing is for weakfish and bluefish. Lobsters, crabs, and clams are caught along the Connecticut shores, and oyster farms are found from Bridgeport eastmard. Long Island sound is an important coastal shipping route. Its shores have many residential communities and yachting centres. (W. Wr.)

LONGITUDE, the angle which the terrestrial meridian from the pole through a point on the earth's surface makes with some standard meridian, commonly that of Greenaich. It is equal to the difference between local time on the standard meridian, and at the place defined, one hour of time corresponding to 15° difference of longitude. Formerly each nation took its own capital or principal observatory as the standard meridian from which longitudes were measured. Another system had a meridian passing through or near the island of Ferro, defined as 20° W. of Paris, as the standard. While the system of counting from the capital of the country is still used for some purposes, the meridian of Greenwich has been used for nautical and international calculations since the Washington Meridian conference of 1884. In astronomy, the longitude of a celestial body is the distance of its projection upon the ecliptic from the vernal equinox, counted in the direction west to east from 0° to 360°.

LONGMANS, a firm of English publishers. The founder. Thomas Longman (1) (1699–17jj), was the son of Ezekiel Longman, a gentleman of Bristol. Thomas was apprenticed in 1716 to John Osborn. a London bookseller. He married Osborn's daughter, and in 1724 purchased the goods of William Taylor, the first publisher of *Robinson Crusoe,* for 52,282 9s. 6d. Taylor's two shops in Paternoster Row were known respectively as the Black Swan and the Ship. Osborn, who afterwards entered into partnership with his son-in-law, held one-sixth of the shares in Ephraim Chambers's *Cyclopaedia of the Arts and Sciences,* and Thomas Longman was one of the six booksellers who undertook the responsibility of Samuel Johnson's *Dictionary.* In 1754 Thomas Longman took his nephew into partnership, the title of the firm becoming T. and T. Longman.

Upon the death of his uncle in 1755, Thomas Longman (2) became sole proprietor. He had three sons. Of these, Thomas Norton Longman (3) succeeded to the business. In 1794 Owen Rees became a partner. and Thomas Brown, who was for many years after 1811 a partner, entered the house as an apprentice. He published the works of Wordsworth, Coleridge, Southey and Scott. In 1324 the title of the firm was changed to Longman, Hurst, Rees, Orme. Brown & Green. In 1814 arrangements were made with Thomas Moore for the publication of *Lalla Rookh,* for which he received £3.000; and when Archibald Constable failed in 1826, Longmans became the proprietors of the *Edinburgh Review.*

Thomas Norton Longman (3) died on Aug. 29, 1842, leaving his two sons. Thomas (4) and William Longman in control. They first published Macaulay's *Lays of Ancient Rome,* which was followed in 1849 by the issue of the first two volumes of his *History of England.* Thomas Langman edited a beautifully illustrated edition of the New Testament, and William Longman wrote a *History of the Three Cathedrals dedicated to St. Paul* (1869) and a work on the *History of the Life and Times of Edward III* (1873). In 1890 they incorporated all the publications of the firm of Rivington, established in 1711.

LONGOMONTANUS (Christian Severin) (1562–1637), Danish astronomer and astrologer, who is best known for his association with Tycho Brahe and for his published expositions of the Tychonic system of the world, was born at Longberg, in Jutland, Den.. on Oct. 4, 1562. He is usually known as Christian Longomontanus, from the latinized form of his birthplace. Educated at. Longberg and at Viborg, he was employed for eight years (1589–97) by Tycho Brahe at Copenhagen, as an assistant. He was appointed rector of the gymnasium at Viborg in 1603, elected professor in the University of Copenhagen in 1605 and promoted to the chair of mathematics in 1607. Longomontanus began the construction of the Copenhagen observatory in 1632, but he died on Oct. 8, 164;. before its completion. (O. J. E.)

LONGSTREET, JAMES (1821–1904), American soldier, lieutenant general in the Confederate army, was born on Jan. 8, 1821, in Edgefield district, S.C., and graduated from West Point in 1842. He was severely wounded in the Mexican war, and received two brevets for gallantry. In 1861, having attained the rank of major, he resigned when his state seceded, and became a brigadier general in the Confederate army. In this rank he fought at the first battle of Bull Run, and at the head of a division in the Peninsular campaign and the Seven Days. This division later became the nucleus of the 1st corps, army of northern Virginia, which was commanded throughout the war by Longstreet, and took part in the second battle of Bull Run, Antietam and Fredericksburg. Most of the corps was absent in North Carolina when the battle of Chancellorsville took place, but Longstreet, now a lieutenant general, returned to Lee in time to take part in the campaign of Gettysburg. In Sept. 1863 he took part in the great battle of Chickamauga. In November he commanded the unsuccessful expedition against Knoxville. In 1864 he rejoined Lee's army in Virginia, and on May 6 arrived upon the field of the Wilderness as the Confederate right had been turned and routed. His attack was a model of impetuosity and skill, and drove the enemy back until their entire force upon that flank was in confusion. At this critical moment, as Longstreet in person. at the head of fresh troops, was pushing the attack in the forest he uas fired upon by mistake by his own men and desperately wounded. This mischance stayed the Confederate assault for two hours, and enabled the enemy to provide effective means to meet it. In Oct. 1864 he resumed command of his corps. which he retained until the surrender, although paralyzed in his right arm.

During the period of Reconstruction, Longstreet's attitude toward the political problem, and the discussion of certain military incidents, notably the responsibility for the Gettysburg failure, brought the general into extreme unpopularity. His admiration for General Grant, and his loyalty to the Republican party accentuated the ill feeling of the southern people. But in time his services in former days were recalled, and he became once more "General Lee's war horse" to his old soldiers and the people of the south.

He held several civil offices, among them that of minister to Turkey under Grant. and that of commissioner of Pacific railways under Presidents McKinley and Roosevelt. In 1896 he published *From Manassas to Appomattox,* and in his later years he prepared an account of Gettysburg, which was published soon after his death, with notes and reminiscences of his whole military career.

Longstreet died at Gainesville. Ga., on Jan. 2, 1904.

See Helen D. Longstreet, *Lee and Longstreet at High Tide* (1904), also Sir F. Maurice, *Statesmen and War* and *Robert E. Lee.*

LONGUEVILLE, ANNE GENEVIEVE, Duchesse de (1619–1679), was the only daughter of Henri de Bourbon, Prince de Condé, and the sister of Louis. the great Condé (*q.v.*). She was the guiding spirit of the first Fronde (*q.v.*) when she brought over Armand, Prince de Conti, her second brother, and her husband to the malcontents, but she failed to attract Condé himself, whose loyalty to the court overthrew the first Fronde.

The second Fronde was largely her work, and in it she played the most prominent part in attracting to the rebels, first Condé and later Turenne. After the war she became more and more Jansenist in opinion.

In her house Antoine Arnauld, Pierre Nicole (*qq.v.*) and De Lane were protected. Her letters to the pope are part of the history of PORT ROYAL (*q.v.*), and as long as she lived the nuns of Port Royal des Champs were left in safety.

As her health failed she hardly ever left the convent of the Carmelites in which she had been educated. On her death in 1679 she was buried with great splendour by her brother Condé, and her heart, as she had directed, was sent to the nuns of Port Royal des Champs.

The chief authority for Madame de Longueville's life is a little book in two volumes by Villefore the Jansenist, published in 1738. Victor Cousin has devoted four volumes to her, which, though immensely diffuse, give a vivid picture of her time. *See* also Sainte-Beuve, *Portraits of Women* (tr. 1891). Her connection with Port Royal should be studied in Arnauld's *Memoirs,* and in the different histories of that institution. *See* also Hugh Noel Williams, *A Princess of Intrigue, Anne Geneviève de Bourbon, Duchesse de Longueville, and her Times* (1908).

LONGUS, Greek romancer, author of *Daphnis and Chloe.* All that can be said about him is that he probably lived at the end of the 2nd or the beginning of the 3rd century A.D. Even the name attributed to the author may be a misreading of the title of the work.

Longus's style is rhetorical, his shepherds and shepherdesses are wholly conventional, but he has imparted human interest to a purely fanciful picture. As an analysis of feeling *Daphnis and Chloe* makes a nearer approach to the modern novel than its chief rival among Greek erotic romances, the *Aethiopica* of Heliodorus, which is remarkable mainly for the ingenious succession of incidents. Daphnis and Chloe, two children found by shepherds, grow up together, nourishing a mutual love which neither suspects. The development of this simple passion forms the chief interest, and the only notable incident is the abduction of Chloe by a pirate. The two lovers eventually discover their parents and marry.

See J. Dunlop, *History of Prose Fiction* (1888), and especially E. Rohde, *Der griechische Roman* (1900). Longus found an incomparable translator in Jacques Amyot, bishop of Auxerre, whose French version, as revised by Paul Louis Courier, is better known than the original. It appeared in 1559, 39 years before the publication of the Greek text at Florence by Columbani. The chief subsequent editions are those by G. Jungermann (1605), J. B. de Villoison (1778, the first standard text with commentary), A. Coraes (Coray) (1802), P. L. Courier (1810, with a newly discovered passage), E. Seiler (1835), R. Hercher (1858), N. Piccolos (1866) and Kiefer (1904), W. D. Lowe (1908). A. J. Pons's edition (1878) of Courier's version contains an exhaustive bibliography. There are English translations by G. Thorneley (1733, reprinted 1893), C. V. Le Grice (1803) ; R. Smith (in Bohn's *Classical Library),* and the rare Elizabethan version by Angel Day from Amyot's translation (ed. J. Jacobs in *Tudor Library,* 1890).

LONGVIEW, a city of eastern Texas, U.S., is the centre of a rapidly growing urban area, 126 mi. E. of Dallas, and the seat of Gregg county. It has a large municipal airport and is the principal city of the east Texas oil field, a region with 20,000 producing wells. There are also numerous gas wells and iron-ore deposits in the vicinity, with a fully integrated steel plant located 30 mi. to the north.

Longview has petroleum refineries, and plants manufacturing oil-field machinery and equipment, chemicals, paper, plastics, agricultural implements, feedstuff, building materials and photographic supplies. The city's industrial growth has reduced the number of farms in the area, but agriculture is still significant, with many small landowners working part time in the industrial plants. It adopted a commission-manager form of municipal government in 15123. For comparative population figures *see* table in TEXAS: *Population.* (N. McG.)

LONGVIEW, a seaport city at the confluence of the Cowlitz and Columbia rivers, in Cowlitz county, Wash., U.S.is about 50 mi. N. of Portland, Ore. Founded in 1922 by R. A. Long, of the Long-Bell Lumber company, on the site of old Monticello, it is one of the world's greatest lumber centres end was the first city of the Pacific northwest to be completely planned with streets, parks and zoned areas. Longview was dedicated in 1923. A large timber company maintains its largest lumber, paper and pulp mills there, drawing raw material from a 500,000-ac. tree farm.

In addition to Longview's lumber and pulp industries, aluminum. paint. concrete pipes, canned goods, dairy products and fisheries are significant. Nearly 600 ships a year call at the city's public port docks. The Longview bridge, which spans the Columbia and connects Washington and Oregon, is one of the longest cantilever bridges (1,200 ft.) in the U.S. Adjoining Longview to the northeast is the older city of Kelso.

On Nov. 25, 1852, a group of residents of northern Oregon territory held a convention at Monticello to petition congress for division of the territory. This led to the creation of Washington territory in 1853.

For comparative population figures *see* table in WASHINGTON: *Population.* (J. M. McC.)

LONICERA: *see* HONEYSUCKLE.

LÖNNROT, ELIAS (1802–1884), Finnish philologist and discoverer of the *Kalevala,* was born at Nyland, Finland, on April 9, 1802. He entered the university of Åbo in 1822, and qualified as a physician.

As early as 1827, he had begun to publish contributions to the study of the ancient Finnish language, and to collect the national ballads and folklore. In 1833 he settled as a doctor in the country district of Kajana, and began to travel throughout Finland and the adjoining Russian provinces, collecting songs and legends. In this way he was able to put together the great epic of Finland, the *Kalevala,* the first edition of which he published in 1835; he continued to add to it, and in 1849 issued a larger and completer text.

Lonnrot also published an important collection (1840) of the *Kanteletar,* or folk songs of ancient Finland, which he had taken down from oral tradition; and the *Proverbs of Finland* (1842). In 1853 Lonnrot succeeded Castrén as lecturer on the Finnish language and literature at the Helsingfors high school; he retired in 1862.

Lonnrot died on March 19, 1884.

LONSDALE, EARLS QF. This English earldom is held by the ancient family of Lowther, which traces its descent to Sir Hugh Lowther, who flourished in the reign of Edward I. Sir Hugh's descendant Sir Richard Lowther (1529–1607) received Mary queen of Scots on her flight into England in 1568, and in the two follo ing years was concerned with his brother Gerard in attempts to release her from captivity. He was sheriff of Cumberland and lord warden of the west marches. Sir Richard's eldest son. Sir Christopher Lonther (d. 1617), was the ancestor of the later Lowthers, and another son, Sir Gerard Lowther (d. 1624), was judge of the common pleas in Ireland.

One of Sir Christopher's descendants was Sir John Lowther, Bart. (d. 1706), the founder of the trade of Whitehaven, and another was John Lowther (1655–1700), who was created Viscount Lonsdale in 1696.

Before this creation John had succeeded his grandfather, another Sir John Lowther (d. 1675), as a baronet. In 1690 he was first lord of the treasury, and he was lord privy seal from March 1699 until his death in July 1700.

James Lowther, 1st earl of Lonsdale (1736–1802), was descended from Sir Christopher Lowther; through his mother, James was a great-grandson of the 1st Viscount Lonsdale. From 1757 to 1784 he was a member of parliament, exercising enormous influence on elections in the north of England on account of his great wealth, and controlling nine seats in the house of commons, where his nominees were known as "Sir James's ninepins." In 1784 Lowther was created earl of Lonsdale and in 1797 Viscount Lowther with an extended remainder.

The earldom became extinct in 1802, but was revived in 1807, and William Lowther (1757–1844), a cousin of James Lowther, was created the 1st earl of Lonsdale after the earldom was revived. He was succeeded by his eldest son. William Lowther II (1787–1872), upon whose death a nephew, Henry Lowther (1818–76), became the 3rd earl. St. George Henry Lowther (1855–82), son of Henry Lowther, and 4th earl, was succeeded by his brother, Hugh Cecil Lowther, 5th earl of Lonsdale. He died on April 13, 1944.

LONSDALE, DAME KATHLEEN (née YARDLEY) (1903–), English crystallographer, who in 1945 was one of the first two women to be elected to the fellowship of the Royal society, was born on Jan. 28, 1903. She was educated at the University of London, where she graduated in physics. From 1922 to 1927 and from 1937 to 1942 she was research assistant to Sir William Henry Bragg (*q.v.*) at University college and the Royal institution, London. Between these two periods, she was Amy Lady Tate scholar in the University of Leeds and then Leverhulme research fellow, and afterward, during 1944–46, Dewar fellow at the Royal institution. In 1947 she was special research fellow, United States federal health service. In 1949 she became professor of chemistry at University college, London. In 1956 she was created Dame of the British Empire and in 1957 was awarded the Royal society's Davy medal in recognition of her distinguished studies in the structure and growth of crystals.

Dame Kathleen Lonsdale's publications include *Structure Factor Tables* (1936), *Crystals and X-Rays* (1949), *International Tables for X-Ray Crystallography* vol. i (1952), and many papers in scientific journals. Her other interests are reflected in *Quakers Visit Russia* (1952), *Removing the Causes of War* (1953) and *Is Peace Possible?* (1957). (D. McK.)

LONSDALE, WILLIAM (1794–1871), English geologist and palaeontologist, born at Bath on Sept. 9, 1794, was educated for the army, and in 1810 was gazetted as ensign in the 4th (King's Own) regiment. He served in the Peninsular War at the battles of Salamanca and Waterloo, for both of which he received medals; and he retired as lieutenant. At his home at Batheaston he collected a series of rocks and fossils which he presented to the Literary and Scientific Institution of Bath. He became the first honorary curator of the natural history department of the museum.

He was assistant secretary and curator of the Geological society of London at Somerset House from 1829 to 1842. In 1829 Lonsdale read before the society an important paper "On the Oolitic District of Bath" (*Trans. Geol. Soc.* ser. 2, vol. iii), the results of a survey begun in 1827; later he was engaged in a survey of the Oolitic strata of Gloucestershire (1832), and he laid down on the one-inch ordnance maps the boundaries of the various geological formations.

He became the highest authority in England on corals, and he described fossil forms from the Tertiary and Cretaceous strata of North America and from the older strata of Britain and Russia.

In 1837 he suggested from a study of the fossils of the South Devon limestones that they would prove to be of an age intermediate between the Carboniferous and Silurian systems. This suggestion was adopted by Sedgwick and Murchison in 1839, and may be regarded as the basis on which they founded the Devonian system.

Lonsdale's paper, "Notes on the Age of the Limestones of South Devonshire" (read 1840), was published in the same volume of the *Transactions of the Geological Society* (ser. 2, vol. v) with Sedgwick and Murchison's famous paper "On the Physical Structure of Devonshire." Lonsdale died at Bristol on Nov. 11, 1871,

LONS-LE-SAUNIER, a town of eastern France, capital of the *dkpartement* of Jura, 76 mi. N.N.E. of Lyons on the P.L.M. railway, on which it is a junction for Chalon-sur-Saône, Dôle, Besançon and Champagnole. Pop. (1954) 13,806. The town is on both sides of the river Vallibre and is surrounded by the vine-clad hills of the western Jura.

Lons-le-Saunier, known as Ledo in the time of the Gauls, was fortified by the Romans, who added the surname Salinarius to the Gallic name. An object of contention owing to the value of its salt, it belonged for a long time during the medieval period to the house of Chalon. It was burned in 1364 by the English, and again in 1637, when it was seized by the duke of Longueville for Louis XIII. It became definitely French in 1674. There the meeting between Ney and Napoleon took place, on the latter's return from Elba in 1815.

The town owes its name to the salt mines of Montmorot, its western suburb, which have been used from early times. The church of St. Désiré (12th and 15th centuries), has a huge Romanesque crypt.

The town is the seat of a prefect and of a court of assizes, and there are tribunals of first instance and of commerce and a chamber of commerce. There are sodio-chlorinated mineral waters. The principal industry of the place is the manufacture of sparkling wines.

LOO, formerly called "Lanterloo" (Fr. *lanturlu,* the refrain of a popular 17th century song), a game of cards, invariably played for a stake. The players may number from five to about nine, each for himself. The pack of 52 cards is used.

In the simplest form of the game, three cards are dealt to each player, and the next is turned for trump. Eldest hand leads, and one-third of the pool goes to the winner of each trick. The pool is formed by antes before each deal, and may be increased by payments for *loo* (failure to win a trick) and fines for irregularities.

Among the features added to this base are found:

1. Turn of a card for trump is deferred until the first time any hand fails to follow suit. The trump then fixed affects the winning of the current and any subsequent tricks.

2. The first pool is a *single,* three counters put in by dealer alone. The players who are looed pay three counters each to the next pool, making it a *double.*

An extra hand called the *miss* is dealt at the right of the next dealer. Each player in turn, eldest hand first, must *pass, stand* or take the miss if it is still available. The player who takes the miss discards his original hand. After the miss is taken, the remaining players must pass or stand. All who pass throw in their cards; all who stand must play. Dealer must take the miss if no other does, playing for himself or "for the pool" (in which case his winnings if any remain in the next pool). The pool is divided, one-third for each trick. Players looed contribute to the next pool. Whenever the pool is cleared, the next deal is a *single,* otherwise the *doubles* continue.

3. The first dealer (eldest hand of those who stand) must lead the ace of trumps if he has it, or the king if the ace was previously turned for trump. The leader is also bound to lead a trump if he has two. Each player must *head* a trick if able, by playing higher in the suit led, by trumping if void of the suit led, or by playing a higher trump than any previously played to the trick.

4. A player dealt a *flush* wins the pool without play. A flush is three trumps.

5. The penalty for loo is to double the current pool. This variant, unlimited loo, has caused some considerable fortunes to change hands.

6. The hand may be five cards instead of three.

7. The turned trump may be taken up by the dealer in place of a discard.

8. *Pam,* the knave of clubs, is always the highest trump. It may be used as a "wild card" to complete a *flush* or a *blaze.* A flush is five trumps; a blaze is five court cards. The holder of either wins the pool without play.

9. Pam may be withheld on a trump lead, and must be withheld if the leader of the trump ace says, "Pam be civil!"

See J. Warren, *Rules for Three Card Loo* (1820); *The Laws of Loo of the Blenheim Club* (London, 1866).

LOOE, a seaport, market town and urban district in the Bodmin parliamentary division of Cornwall, Eng., 18 mi. W. of Plymouth by road. Pop. (1951) 3,833. Area 2.6 sq.mi. It is divided into East and West Looe by the Looe river, which forms the harbour and is crossed by a seven-arched stone bridge. Above the bridge the river also divides into the East and West Looe rivers. The town is so sheltered by the surrounding hills that myrtles, geraniums, fuchsias and other Mediterranean plants flourish at all seasons. Its streets are narrow, steep and winding, with many ancient thick-walled houses. The East Looe beach is sandy while the Hannafore beach, on the other side of the river, is largely rocky. The parish church of St. Mary adjoins the sea front at East Looe. Remains of a Benedictine priory and of a Celtic chapel have been found. The harbourage was probably the original cause of settlement at Looe. At the time of the Domesday survey East Looe was assessed under Pendrym, which was of the king's demesne, and West Looe under Hamelin's manor of Trelowia. In the 14th century the former manor was held by the family of Bodrugan, the latter by that of Dauney. In 1237 Henry Bodrugan received the grant of a market on Fridays and a fair at Michaelmas. A charter of incorporation was granted in 1587 and in 1685 James II provided that there should be a mayor and 11 aldermen, 36 free burgesses, four fairs and a court of piepowder. East Looe was governed under this charter until 1885. West Looe (known also as Porpighan or Porbuan), was constituted a free borough by a charter ratified in 1325. Upon the attainder of the earl of Devon in 1539 the borough fell to the crown and in 1574 a charter of incorporation was granted providing for a mayor and 11 burgesses, also for a market on Wednesdays and two fairs. West Looe continued to be administered under this charter until 1869. Of the markets and fairs only the U'ednesday and Saturday markets and a fair on May 6 remain. Looe was second only to Fowey as a port in the 15th century. It furnished 20 ships for the siege of Calais. A considerable export trade in copper, tin and granite was formerly carried on; the harbour is now used by sailing dinghies and other small craft, and by fishing boats. There are thriving fisheries, the Looe fishermen being particularly expert with the seine on a rocky bottom. Up the West Looe river is a pilchard canning establishment. Looe Island, lying $\frac{1}{2}$ mi. from the beach, is 1 mi. in circumference. It has many legends and is presumed to have been connected with the abbey of Glastonbury.

LOOFAH: *see* LUFFA.

LOOM: *see* WEAVING.

LOON *(DIVER)*, name properly restricted to birds of the family Gaviidae, containing four species of the genus *Gavia* and constituting the order Gaviiformes. Measuring about two to three feet in length, they have thick plumage, which in summer is mainly black or gray above and white below, with spots, streaks or bars of white on the upper parts. With the exception of the red-throated loon, G. *stellata,* distinguished by its rich chestnut throat and foreneck (summer plumage), they lose the bold dorsal pattern in winter. They all have a strong, tapering bill; rather small, pointed wings; and legs placed so far back on the body that walking is virtually impossible. The tarsal bones of the ankles are laterally compressed and the first three toes webbed.

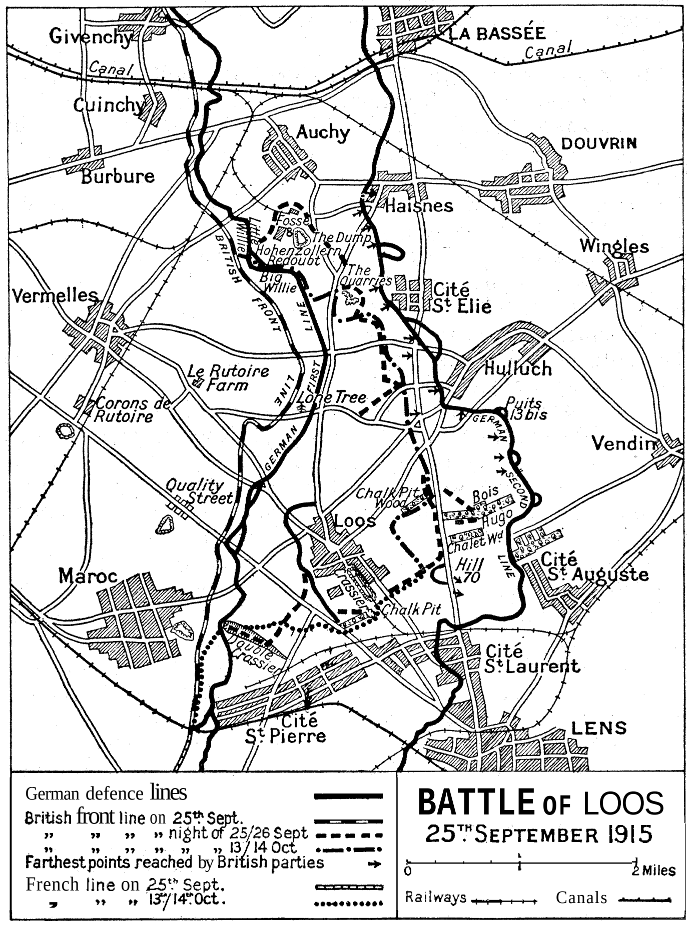
Almost wholly aquatic, divers or loons are capable of swimming long distances beneath water and have been known to dive to depths approaching 200 ft. Usually they are found singly or in pairs but may winter in small flocks. The voice is distinctive, consisting of various guttural notes and very loud quavering calls. They feed mainly on fish, crustaceans and insects. The nest usually is a heap of vegetable matter at the edge of water. The eggs, one to three in number, are olive-brown spotted with darker brown.

H. M. HALLIDAY FROM THE NATIONAL AUDUBON SOCIETY

COMMON LOON OR GREAT NORTHERN DIVER (GAVIA IMMER) IN SUMMER PLUMAGE

The loons are wide ranging: the common loon or great northern diver, G. *immer*, of the northern hemisphere, is the most abundant loon in North America; the arctic loon or black-throated diver, G. *arctica,* is circumpolar in distribution, being commonest in the old world; the yellow-billed loon, G. *adamsii,* is found on arctic coasts from Siberia to northwestern Canada. (E. R. BE.)

LOOS, THE BATTLE OF (Sept. 25–Oct. 19, 1915), is the name given to the actions fought by the British in the Allied offensive in France in the autumn of 1915.



The French Plan.—The plan elaborated by Gen. Joseph Joffre was to attack on both sides the great salient formed by the German front in France: on the right in Champagne with the French 2nd and 4th armies, the main effort; and on the left in Artois with the 10th army. He hoped by these two operations to cut off the German troops in the salient knd get astride their communications. He asked that the British should co-operate by attacking in Artois on the left of the 10th army. Sir John French, therefore, was given definite orders to co-operate with the French. The 1st army under Gen. Sir D. Haig, was selected to carry out the attack. Both Sir John French and Gen. Haig were opposed to attacking in the area between Lens and the La Bassée canal, as Gen. Foch required; for it involved advancing over unfavourable ground, open, but dotted with coal mines and mining villages, while Lens and its suburbs formed one vast industrial town. They suggested an objective further north. This proposal was overruled.

The Employment of Gas.—While the British leaders were doing their best, against their better judgment, to prepare the offensive at a spot not of their own selection and with totally inadequate artillery, the first consignment of chlorine gas arrived, for trial. Its use seemed to promise a chance of surprise and provide a solution of the problem of attack with inadequate means. A sufficient supply of gas was manufactured and preparations were made to employ it. After four days' bombardment, during the later part of which the weather was unsuitable for flying and observation, on Sept. 25 the offensive was begun simultaneously in Champagne (30 French divisions) and Artois (17 French and nine—later 12—British divisions), whilst diversions were made at other parts of the line: by the British near Givenchy, Neuve Chapelle and Hooge; by the Belgians near Nieuport; and by the navy on the coast. On the British front gas and smoke were discharged for 40min. preceding the assault, which took place at 6:30 A.M. The French X. Army did not leave its trenches until 12:45 P.M. and even then the Allied contingents in Artois were not shoulder to shoulder, for between them opposite Lens was left a passive front of 3m. held by a French Territorial division.

The Assault on Sept. 25.—The British assault was made by the 47th (2nd London Territorial), 15th (Scottish, of the New Army) and 1st Divisions of the IV. Corps (Rawlinson), and the 7th, 9th (Scottish, of the New Army) and 2nd Divisions of the I. Corps (Gough). Although the wind was very feeble, and on the front of the 2nd Division unfavourable so that the gas and smoke blew back, considerable success was obtained by the British. The German defences comprised two separate positions (see sketch) disposed on the great rolling plain in which the spurs of the Artois plateau sink down. In spite of insufficient bombardment, the German front line position was overrun from the British right nearly as far as Auchy. The 47th Division reached all its objectives and formed a defensive flank towards Lens; the 15th Division captured Loos, but then lost direction and moved south-east on Hill 70 instead of continuing eastwards; the 1st Division got beyond the Lens-La Bassée road, but, in trying to keep touch with the 15th, became divided, thus creating a gap in its front; the 7th Division advanced beyond the German first line, captured the Quarries, and in places arrived at the German second line, a few men actually entering Hulluch; the 9th Division was even more successful: it overran the Hohenzollern redoubt, a strong independent work in the general line, and its wings, Big and Little Willie, captured Fosse 8 and the Dump, a valuable observatory, and got up to, and in places into, the second line between Cité St. Elie and Haisnes. Only the 2nd Division, in whose area the gas had blown back, made no progress

With this effort the IV. and I. Corps had shot their bolt and fresh troops were required to carry on the attack and break through the second line. Unfortunately Sir John French had kept back near Béthune his general reserve, the XI. Corps (Haking), consisting of the Guards Division, recently formed, and the 21st and 24th Divisions, two New Army divisions, just out from England. No orders for the 21st and 24th Divisions to move from their rendezvous 5 to 8 miles from the battlefield were sent until 9:30 A.M. on the 25th, and it was not until 1:20 P.M. that these divisions were put under Sir D. Haig.

The Attack on Sept. 26.—Already fatigued by a series of night marches to reach Béthune unseen by enemy aeroplanes, and by delays due to the congestion of traffic on the roads behind the battlefield, it was the morning of Sept. 26 before the 21st and 24th Divisions were on the field and ready to move to the attack of the German second line between Bois Hugo and Hulluch. And meantime it had become necessary to use the two leading brigades to patch up the British line. Hill 70 and Hulluch, on the flanks of the attack, were still in enemy hands, renewed attacks having failed to capture them, and soon after 9 A.M. the Germans had recaptured Bois Hugo. In the hours which had elapsed since the original attack, they had recovered from their surprise, brought up reinforcements and strengthened their second line. During the night of the 25th–26th and early morning of the 26th they made counter-attacks on both flanks of the line gained by the British in the first advance and recovered part of the lost ground.

The attack of the four remaining brigades of the two divisions at 11 A.M. against the intact second line was a failure, though some units actually reached the wire entanglement in front of it. Eventually the men, new to war, having done all that was possible, began to stream back. The Guards Division was brought up to fill the gap in the line that their retirement caused, and the 3rd Cavalry Division to stiffen the defence near Loos village. The French X. Army, having no gas, had less success than the British; but its persistent attacks, against the crest of Vimy Ridge by Gen. Foch's orders, caused the Germans to divert the Guard Corps from the British to the French front.

After Sept. 26 the fighting became desultory and degenerated into trench warfare, and on the 30th the French offensives, both in Champagne (where also no success had been achieved) and Artois, were formally stopped in order to prepare for another combined effort. Delays brought about by bad weather, enemy interference with the preparations and enemy counter-attacks, led to postponement after postponement.

The Last Phase.—Finally a renewed French attack in Champagne was made on Nov. 6, a French attack in Artois on Nov. 11, and a British (fresh divisions, the 12th, 28th and 46th having arrived) on the 13th, with no result but heavy casualties. Trench fighting, particularly round the Hohenzollern Redoubt, went on for several days longer, and then both sides settled down to winter conditions. The fighting of the year had but proved that, with the guns and munitions then available, the defence was still stronger than the attack. The British losses in the battle of Loos included three divisional commanders killed (Maj.-Gen. Sir T. Capper, G. H. Thesiger and F. D. V. Wing) and 2,407 officers and 57,985 other ranks killed, wounded and missing, and were probably three times as heavy as those of the enemy.

See *History of the Great War Based on Official Documents*, "Military Operations France and Belgium, 1915," vol. ii. (1928, where there is a bibl.); *Les Armées Françaises dans la Grande Guerre*, tome iii. (1922); M. Schwarte, *Ed., Der grosse Krieg, 1914–1918*, vol. ii. (1921–25). (J. E. E.)

LOOSESTRIFE, the common name of any plant of the genus *Lysimachia* of the family Primulaceae. The Eurasian L. *vulgaris*, an erect plant, 2 to 4 ft. high, is common on river banks in England; the branched stem bears tapering leaves in pairs or whorls, and terminal panicles of rather large deep yellow flowers. L *nemorum*, yellow pimpernel or wood loosestrife, a low-growing plant with slender spreading stem and yellow flowers standing singly in the leaf-axils, is frequent in England. L. *nummularia* is the well known creeping jenny or moneywort, a larger plant with widely creeping stem. pairs of shining leaves and large solitary yellow flowers; it is found on banks of rivers and damp woods, and is a common rockery plant. Purple loosestrife, *Lythrum salicaria*, belongs to a different family, Lythraceae. It is a handsome plant growing 2 to 6 ft high on river banks and ditches with a branched stem bearing whorls of narrow pointed stalkless leaves and ending in tall tapering spikes of beautiful rose-purple flowers. The flowers are trimorphic, that is to say, exist in three forms which differ in the relative length of the styles and stamens and are known as long-styled, mid-styled and short-styled forms; the size and colour of the pollen also differ. These differences are important in the pollination of the flower, making self-fertilization next to impossible. (See POLLINATION.)

LOPE DE VEGA: see VEGA CARPIO, LOPE FELIX DE.

LOPES, FERNÃO (1380?–1460?) (**FERNAM LOPEZ**), the patriarch of Portuguese historians, was appointed keeper of the royal archives, then housed in the castle of St. George in Lisbon, by King John I. in Nov. 1418. He acted as private secretary to the Infantes D. Duarte and D. Fernando, and when the former ascended the throne he charged Lopes, by a letter of March 19, 1434, with the work of "putting into chronicles the stories of the kings of old time as well as the great and lofty actions of the most virtuous king my lord and father" (John I.). King Alphonso V. confirmed him in his post by a letter of June 3, 1449, and in 1454, after 36 years' service in the archives and 20 as chronicler he resigned in favour of Gomes Eannes de Zurara. The modern historian Herculano says, "there is not only history in the chronicles of Fernão Lopes, there is poetry and drama as well; there is the middle age with its faith, its enthusiasm, its love of glory." Lopes has been called the Portuguese Froissart, and that rare gift, the power of making their subjects live, is common to the two writers; indeed, had the former written in a better-known language, there can be little doubt that the general opinion of critics would have confirmed that of Robert Southey, who called Lopes "beyond all comparison the best chronicler of any age or nation." Lopes composed a general chronicle of the kingdom, which almost certainly served as a foundation for the chronicles of Ruy de Pina. Lopes prepared himself for his work by a study of the archives belonging to municipalities, monasteries and churches in Portugal and Spain.

See extant works of Lopes: *Chronica de D. João I* (1644; part 1, ed. B. Freire, 1915); *Chronica de D. Pedro I,* in vol. iv of the *Collecção de Livros Ineditos da Historia Portugueza* (1816); *Chronica de D. Fernando,* in the same volume. (E. P.; A. B.)

LÓPEZ, CARLOS ANTONIO (1792–1862), second dictator of Paraguay, ended his country's isolation, sought to modernize its economy and society, and became deeply involved in international disputes. Born in Asunción on Nov. 4, 1792, López attended the San Carlos seminary, taught there until it was closed by the dictator José Gaspar Rodríguez Francia (*q.v.*), and then became a lawyer. Exiled to his *estancia* in 1837, López returned to his suburban home when Francia died in 1840. The next year he became the principal of two consuls and in 1844 was elected president with dictatorial powers, an office he held until his death on Sept. 10, 1862.

López amassed a large personal fortune and bestowed favours liberally on his family. Imported foreign technicians built a railway, highways, foundries and modern fortifications. López founded Paraguay's first newspaper, encouraged education and relaxed some of Francia's stern laws. Commerce, agriculture and foreign trade, largely monopolized by the state, improved moderately. At first conciliatory, Pres. Juan Manuel de Rosas of Argentina refused to recognize Paraguay's independence and a brief war occurred (1845–46); relations improved when Rosas was overthrown in 1852. Recognition by several countries followed in 1853, but Paraguay's foreign relations were never smooth. Difficulties with the United States almost resulted in war and neighbouring countries remained unfriendly during most of the López regime. (H. G. Wn.)

LÓPEZ, FRANCISCO SOLANO (1827?–1870), dictator of Paraguay and eldest son of Carlos Antonio López (*q.v.*) seized power upon his father's death in 1862. Born near Asunción on July 24, 1826 or 1827, he received an indifferent education but fancied himself without a peer in military science. A brigadier general at 18, he commanded Paraguay's army in the abortive war with Argentina (1845–46). A few years later he headed a diplomatic mission to Europe during which he purchased munitions, engaged foreign artisans, and acquired an Irish mistress, Eliza Lynch. When he became dictator López continued the construction of public buildings and roads and installed the first telegraph system in South America. He devoted most of his time and resources to military preparations until Paraguay had a standing army of more than 60,000, a force López was ready to use to settle boundary and navigation disputes with Brazil and to prevent disruption of the delicate political balance in the La Plata basin. He believed that maintenance of Paraguay's independence and territorial integrity required that he champion nonintervention in Uruguay. On Nov. 12, 1864, less than a month after Brazil intervened in the Uruguayan civil war, López seized a Brazilian merchant vessel and started what became the War of the Triple Alliance. Instead of marching to the aid of his favoured Uruguayan faction, López in December sent an army northward which overran the disputed region of Mato Grosso north of the Río Apa and captured Corumbá. Reinforced with supplies taken in this campaign, López prepared to attack southern Brazil. When Pres. Bartolomé Mitre refused permission to cross Argentine territory, López seized Argentine ships and attacked Corrientes in April 1865. This move brought Brazil, Argentina and Uruguay together in alliance on May 1. López launched a combined river and land attack in July which resulted in disaster. While the allies prepared to invade Paraguay, López concentrated his forces around the famed fortress of Humaitá which finally fell in July 1867. Thereafter López fought a war of movement, gradually falling back to the north of Paraguay where he was killed on March 1, 1870, at the Aquidabán river. López in 1868 executed several hundred prominent Paraguayans whom he accused of conspiring against him. The war, which exterminated more than 300,000 Paraguayans, caused significant changes in demographic and cultural characteristics. Long considered a cruel tyrant, López later was elevated to the pantheon of Paraguayan heroes. (H. G. Wn.)

LÓPEZ DE AYALA, PEDRO (1332–1407), Spanish historian, poet and chancellor of Castile from 1398 until his death (in Calahorra), was born at Vitoria. His most impressive works are the chronicles of the four kings under whom he served. After transferring his allegiance in youth from Peter the Cruel to Henry of Trastámara, he held high office under the latter and his successors John I and Henry III, seeing action against the Black Prince at Nájera (1367) and the Portuguese at the disaster of Aljubarrota (1385), where he was taken prisoner. Ayala has been called the first Castilian humanist because of his translations from Boccaccio and Guido da Colonna. As a poet, he is the last representative of the medieval "clerkly craft," and his *Rimado de Palacio,* written largely in the old *cuaderna vía,* is notable for its blistering satire on contemporary society, sparing the mighty of neither church nor state. The chronicles (of which the standard edition is that of 1779–80) display the same powers of implacable observation and vivid expression as the *Rimado,* but substitute for the *saeva indignatio* of the poem an icily impassive surface objectivity even more effective, thanks to Ayala's shrewd choice of significant detail and incident, in conveying his moral judgments.

Ayala's *Poesías* were edited by A. F. Kuersteiner (1920) for the Hispanic Society of America. (F. S. R.)

LÓPEZ DE MENDOZA, ÍÑIGO, MARQUÉS DE SANTILLANA; *see* SANTILLANA, ÍÑIGO LÓPEZ DE MENDOZA, MARQUÉS DE.

LOP NOR (LOB NOR, Chinese LO-PU-NO-ERH), a lake in Sinkiang Uigur Autonomous Region of China. It lies in the eastern Tarim basin, between the Astin Tagh on the south and the Kuruk Tagh on the north. Ancient Chinese and Greek accounts and maps placed the lake south and east of the great Silk Road station of Lou-lan, at a point about 42° 30′ N. lat. About A.D. 330 the lower Tarim river broke out of its old course, turning southeastward, to establish a new terminal water body rather close to the base of the Astin Tagh, causing the abandonment of Lou-lan as a Silk Road station. No medieval European travelers mentioned this change, and European cartographers continued to place Lop Nor in the classical location. In 1876 the Russian explorer N. Prjevalsky discovered two closely connected lake basins 1° S. of the classical site of Lop Nor, which he regarded as being identical with the classical lake.

Several decades of exploratory search for the lake followed. Explorers and geographers engaged in heated debate over the physical history of the Tarim river and Lop Nor. In 1928 Sven Hedin, who had repeatedly sought to solve the puzzle, found both the lower Tarim river and Lop Nor back in their classical positions, the river having returned to its ancient channel in 1921. Hedin's studies made clear that the precise location of the terminal lake had steadily shifted over the centuries, and that the lake varied both in area (about 946 sq.mi.) and in depth.

See Sven Hedin, *The Wandering Lake* (1940). (J. E. Sr.)

LOQUAT, a subtropical tree (*Eriobotrya japonica*) of the family Rosaceae, related to the apple and other well-known fruit trees of the temperate zone. It is occasionally called, erroneously, Japanese plum and Japanese medlar, but these names are gradually disappearing.

Though its native home is probably central-eastern China, the loquat tree was introduced very early into Japan, where it was much developed horticulturally. Some superior Japanese varieties eventually reached Europe, the Mediterranean basin and a few other regions. The loquat is grown commercially (usually on a rather small scale) in many subtropical regions. It is not adapted to the tropics, except at elevations where the climate is cool.

Ornamental in appearance and rarely more than 30 ft. in height, the evergreen loquat is frequently planted in parks and gardens. The leaves, which are clustered toward the ends of the branches, are thick and stiff, elliptic to lanceolate in form, eight to ten inches long, with coarsely serrate margins. The small fragrant white flowers are arranged in dense terminal panicles. The fruits are borne in large loose clusters; individually they are round. obovoid or pear shaped, one to three inches in length, with juicy, whitish to orange-coloured flesh surrounding three or four large seeds. The flavour is agreeably tart, suggesting that of several other fruits of the same family.

While the loquat is commonly grown from seeds, commercial plantings are usually based on grafted trees of superior varieties, such as Tanaka of Japanese origin. Gold Nugget, Champagne and Early Red of California. Propagation is by shield budding and cleft grafting; loquat seedlings or quince rootstocks grown from cuttings can be used, the latter if a dwarf tree is desired.

When planted in orchard form, the trees are spaced 20 to 25 ft. apart. They grow well on various soils. from sandy loams to clays) and come into bearing at an early age, three or four years.

(W. Po.)

LORAIN, a city of Ohio, U.S., in Lorain county, is a port on the Great Lakes. Its harbour. the lower 3 mi. of the Black river, is on the south shore of Lake Erie! 25 mi. W. of Cleveland and 70 mi. E. of Toledo. The city occupies the level terrain on both sides of the river to and beyond the head of navigation.

In the early 19th century the area was occupied by Indians. Title to the Connecticut Western Reserve district passed to the Connecticut Land company with the signing of the treaty of Fort Industry in 1805. The territory was then surveyed and opened for settlement under the name of Mouth of Black River. The village was first incorporated as Charleston in 1536. It declined in importance and lost its charter after Cleveland was selected as the terminus of the Ohio and Erie canal and when the westward extension of the railroad was routed through Elyria. leaving Charleston's port without rail connections with the interior. When the Poe lock at Sault Sainte Marie, Mich. was opened in 1896 and the Cleveland. Lorain and Wheeling railroad (now the Baltimore and Ohio railroad) to the coal fields of southeastern Ohio was completed in 1872, the coal and iron ore trade was established. The town was rechartered in 1874 as Lorain because the U.S. post office had approved another Ohio town as Charleston.

In 1890 the Johnstown Steel company was located on 3.000 ac. of land at the head of navigation on the Black river. This company mas chiefly responsible for the city's growth. Other manufacturing industries include shipbuilding. power shovels, cranes, bearings, steel stampings, car and truck assembly, railroad shops, gypsum lath and wallboard, and clothing. Coal averages 98% of all water-borne shipments, and iron ore and limestone constitute 95% of total receipts of the port of Lorain. About 50% of the iron ore and limestone are used locally.

Lorain is a cosmopolitan city with large population segments of Puerto Ricans, Hungarians, Poles, Germans, Italians. Czechoslovakians and Slovenians. Five public parks comprising 171 ac. provide recreational facilities. Population (1960) 68.932.

(R. B. Fr.)

LORAN: *see* Navigation.

LORANTHACEAE, the mistletoe family, containing 36 genera and 600 species. All the members of this dicotyledonous family are parasitic plants with green leaves. In the United States the family is represented by about six species of *Phoradendron* (American mistletoe) and some eight species of *Arceuthobium* (pine mistletoe). The only British species is *Viscum album*, the mistletoe (*q.v.*). For a treatment of the genera *see* A. Engler and K. Krause, "Loranthaceae." *Die Natürlichen Pflanzenfamilien,* ed. 2, 16b: 98–203, fig. 48–102 (1935).

LORCA, FEDERICO GARCÍA (1899–1936), Spanish poet. notable for his poems of death, was born on April 15, 1899, in Fuente Vaqueros: Granada, where he spent his early years on his father's farm. His delicate health encouraged in him a contemplative attitude toward life and the characteristic Granadine love of diminutive objects in nature. During his youth in Granada in the intervals of reading the Spanish classical and romantic poets he studied music and came under the influence of Manuel de Falla. He studied law at Granada and Madrid, but that his main interests were literary is evident from the small book *Impresiones y paisajes* which describes a Spanish town. It was at this time that Lorca began to affirm himself as poet and dramatist. His first work was a collection of poems called *Libro de poemas* (1921), which contains images that recall the *greguerías* (humorous metaphors) of Ramon Gómez de la Serna. From the outset Lorca's cult of children's songs was striking. Through them he penetrated into the life of the people and their folklore. In later years he devoted his energies to La Barraca — the vagabond theatre with which he roamed through the towns and villages of Spain.

In 1922 Lorca collaborated with Falla and Ignacio Zuloaga, the painter, in the *Fiesta de cante jondo,* which marked an important epoch in Andalusian folk art and music. In the following year he produced a children's fiesta with an interlude of Cervantes, an Andalusian tale in dialogue and a 13th-century auto sacramental entitled the "Mystery of the Three Wise Men." The music was arranged by Falla. The result of the struggle in him between poetry and music was his masterpiece *Primer romancero gitano* (1928) which won great fame in Spain and South America. In 1931 he published *Poema del cante jondo — a* subtle evocation of the celebrated Andalusian gypsy singers. In these two volumes we find continually in the background the theme of death when discussing the blood feuds of the gypsies, who in Lorca's poems are always heroic dreamers vanquished by reality. Tragedy was implicit in Lorca's genius from the beginning, and the poems of death culminate in the "Lament" on the death of his friend, the bullfighter Sanchez Mejías, in the bull ring. The finest elegy in modern Spanish literature, this is an expressionistic monodrama with phantom voices repeating again and again the fatal phrase A *las cinco de la tarde* ("At five o'clock in the afternoon").

In 1929 Lorca visited New Tork. This marked an important stage in his career for it revived his poetic demon, and the result was *Poeta en Nueva York* and the odes to the king of Harlem and to Walt Whitman in which surrealistic influences appear, and the poet adopts the tone of a seer. On his return to Spain his experiences with his vagabond theatre inspired him to write his two striking gypsy plays *Bodas de sangre* (1933) and the more romantic *Yerma* (1934). When the Spanish civil war broke out in 1936 he was finishing his play *La casa de Bernarda Alba* (1936). Although invited to visit Mexico he decided to remain in Granada. On the outbreak of the civil war some friends invited him to their house to protect him against irresponsible fanatics. According to trustworthy accounts an armed group broke in while his friends were absent, carried him off and murdered him in the outskirts of Granada on Aug. 19, 1936.

Garcia Lorca's complete works were published in Buenos Aires (1938–49); *Poems of F. Garcia Lorca,* with English translation by Stephen Spender and J. L. Gili, R. M. Nadal (ed.), were published in 1939.

Bibliography. — Roy Campbell, *Lorca: An Appreciation of His Poetry* (1952); Dámaso Alonso, *Ensayos sobre poesía española* (1946); Walter Starkie, In *Sara's Tents* (1953). (W. F. Se.)

LORCA, a town of eastern Spain, in Murcia province, on the Sangonera river. Pop. (1950) 71,269 (mun.). Lorca is the Roman Eliocroca (perhaps also the Ilorci of Pliny, *N.H.* iii, 3) and the Moorish Lurka. It was the key of Murcia during the Moorish wars. In 1810 Lorca suffered from the French invasion. There is trade in agricultural products, livestock, and manufactures of woolen stuffs, leather, chemicals and porcelain.

LORD, in its primary sense, the head of a household, the master of those dependent on him for their daily bread; the word frequently occurs in this sense in the Bible, *cf.* Matt. xxiv, 45. As a term implying the ownership of property, "lord" survives in "lord of the manor" and "landlord." The chief applications are due to its use as the equivalent of Lat. *dominus,* Gr. *kyrios* and Fr. *seigneur;* thus in the Old Testament it represents *Yahweh,* Jehovah, and, in the New Testament *kyrios* as a title of Jesus Christ. It is not only a general word for a prince or sovereign, but also the common word for a feudal superior, and particularly for a feudal tenant holding directly of the king, a baron (*q.v.*), hence a peer of the realm, a member of the House of Lords, constituted of the lords temporal and the lords spiritual; this is the chief modern usage. The prefix "lord" is ordinarily used as a less formal alternative to the full title: whether held by right or by courtesy, of marquess, earl or viscount, and is always so used in the case of a baron (which in English usage is generally confined to the holder of a foreign title). Where the name is territorial the "of" is dropped, thus the marquess of A., but Lord A. The younger sons of dukes and marquesses have, by courtesy, the title of Lord prefixed to the Christian and surname, *e.g.,* Lord John Russell. In the case of bishops, the full and formal title of address is the Lord Bishop of A., whether he be a spiritual peer or not. Many high officials of the British Government have the word "lord" prefixed to their titles. (*See* CABINET, THE.) In certain cases the members of a board which has taken the place of an office of State are known as lords commissioners or, shortly, lords of the office in question, *e.g.,* lords of the treasury, civil or naval lords of the admiralty.

For lord lieutenant and lord mayor *see* LIEUTENANT and MAYOR. As the proper form of address, "my lord" is used not only to those members of the nobility to whom the title "Lord" is applicable, and to bishops, but also to all judges of the High Court in England, and of the Scottish and Irish Superior Courts, and to lord mayors and lord provosts (*see* also FORMS OF ADDRESS.)

LORD ADVOCATE, or king's advocate, the principal law-officer of the Crown in Scotland. His business is to act as a public prosecutor, and to plead in all causes that concern the Crown. He is the head of the administration of criminal justice, and thus his functions are of a far more extensive character than those of the English law-officers. He is aided by a solicitor-general and advocates-depute. The office seems to have been established about the beginning of the 16th century. Originally he could only prosecute with the concurrence of a private party; but in the year 1597 he was empowered to do so at his own instance. He has the privilege of pleading in court with his hat on.

LORD CHAMBERLAIN, in England, an important officer of the king's household, to be distinguished from the lord great chamberlain (*q.v.*). He is the second dignitary of the court, and is always a member of the government of the day (before 1782 the office carried cabinet rank), a peer and a privy councillor. He carries a white staff, and wears a golden or jewelled key, typical of the key of the palace, which is supposed to be in his charge, as the ensigns of his office. He is responsible for the necessary arrangements connected with State ceremonies, such as coronations and royal marriages, christenings and funerals; he examines the claims of those who desire to be presented at court; all invitations are sent out in his name by command of the sovereign, and at drawing-rooms and levees he stands next to the sovereign and announces the persons who are approaching the throne. It is also part of his duty to conduct the sovereign to and from his carriage. At one time he discharged some important political functions. The bedchamber, privy chamber and presence chamber, the wardrobe, the housekeeper's room, the guardroom and the chapels royal are in the lord chamberlain's department. He is regarded as chief officer of the royal household, and he has charge of a large number of appointments, such as those of the royal physicians, tradesmen and private attendants of the sovereign.

All theatres in the cities of London and Westminster (except patent theatres), in certain of the London boroughs and in the towns of Windsor and Brighton, are licensed by him and he is also licenser of plays.

The vice-chamberlain of the household is the lord chamberlain's assistant and deputy. He also is one of the ministry, a white-staff officer and the bearer of a key; and he is generally a peer or the son of a peer as well as a privy councillor. Next to the vice-chamberlain comes the groom of the stole, an office only in use during the reign of a king. He has the charge of the vestment called the stole worn by the sovereign on State occasions, In the lord chamberlain's department also are the master, assistant master, marshal of the ceremonies and deputy-marshal of the ceremonies, officers whose special function it is to enforce the observance of the *etiquette* of the court. The reception of foreign potentates and ambassadors is under their particular care, and they assist in the ordering of all entertainments and festivities at the palace. The gentleman usher of the black rod—the black rod which he carries being the ensign of his office—is the principal usher of the court and kingdom. He is one of the original functionaries of the order of the Garter, and is in constant attendance on the House of Lords, from whom, either personally or by his deputy, the yeoman usher of the black rod, it is part of his duty to carry messages and summonses to the House of Commons. There are six lords and six grooms "in waiting" who attend on the sovereign throughout the year and whose terms of attendance are of a fortnight's or three weeks' duration at a time. Usually "extra" lords and grooms in waiting are nominated by the sovereign, who, however, are unpaid and have no regular duties. Among the serjeants-at-arms there are two to whom special duties are assigned: the one attending the speaker in the House of Commons, and the other attending the lord chancellor in the House of Lords, carrying their maces and executing their orders. The comptroller and examiner of accounts, the paymaster of the household, the licenser of plays, the dean and subdean of the chapels royal, the clerk and deputy clerks of the closet, the groom of the robes, the pages of the backstairs, of the chamber and of the presence, the poet laureate, the royal physicians and surgeons, chaplains, painters and sculptors, librarians and musicians, etc., are all under the superintendence of the lord chamberlain of the household.

The queen consort's household is also in the department of the lord chamberlain of the household. It comprises a lord chamberlain, a vice-chamberlain and treasurer, equerry and the various ladies of the royal household, a groom and a clerk of the robes. The ladies of the household are the mistress of the robes, the ladies of the bedchamber, the bedchamber women and the maids of honour. The mistress of the robes in some measure occupies the position of the groom of the stole. She is the only lady of the court who comes into office and goes out with the administration. She is always a duchess, and attends the queen consort at all State ceremonies and entertainments, but is never in permanent residence at the palace. Since the great "bedchamber question" of 1839 the settled practice has been for all the ladies of the court except the mistress of the robes to receive and continue in their appointments independently of the political connections of their husbands, fathers and brothers. The ladies of the bedchamber share the personal attendance on the queen consort throughout the year. Of these there are eight, always peeresses, and each is in waiting for a fortnight or three weeks at a time. But the women of the bedchamber, of whom there are also eight, appear only at court ceremonies and entertainments according to a roster annually issued under the authority of the lord chamberlain of the queen consort. They are usually the daughters of peers or the wives of the sons of peers. The eight maids of honour have the same terms of waiting as the ladies of the bedchamber. They are commonly if not always the daughters or granddaughters of Peers.

LORD CHIEF JUSTICE OF ENGLAND is the head of the king's bench division of the high court of justice and next in rank to the lord chancellor. He is *ex officio* a member of the court of appeal, and is appointed by the Crown on nomination of the prime minister. This title was conferred upon him by the Judicature Act, 1873, by which the court of queen's bench became one of the divisions of the queen's bench division. It may be traced to that of the first minister of the Crown under the Norman and Angevin kings—capitalis *Angliae justiciarius.* He is now the only judicial officer entitled to wear the collar of SS, formerly worn by the chief justices of the three common law courts. His salary is £8,000 a year.

LORD GREAT CHAMBERLAIN, in England, a functionary who must be carefully distinguished from the lord chamberlain; he is one of the great officers of State, whose office dates from Norman times; and the only one who still holds it under a creation of that period. As his name implies, he was specially connected by his duties with the king's chamber (***camera curie);*** but this phrase was also used to denote the king's privy purse, and the chamberlain may be considered as originally the financial officer of the household. But as he was always a great baron, deputies performed his financial work, and his functions became, as they are now, mainly ceremonial, though the emblem of his office is still a key. The office had been held by Robert Malet, son of a leading companion of the Conqueror, but he was forfeited by Henry I., who, in 1133, gave the great chamberlainship to Aubrey de Vere and his heirs, earls of Oxford, who, with some intermissions, held the office till 1779 when it passed to the coheiresses of Lord Willoughby d'Eresby. The office is now vested jointly in Lords Ancaster, Cholmondeley and Carrington.

The lord great chamberlain has charge of the palace of Westminster, especially of the House of Lords, in which he has an office; and when the sovereign opens parliament in person he is responsible for the arrangements. At the opening or closing of the session of parliament by the sovereign in person he disposes of the sword of State to be carried by any peer he may select, and walks himself in the procession on the right of the sword of State, a little before it and next to the sovereign. At coronations he emerges into special importance; he still asserts before the court of claims his archaic right to bring the king his "shirt, stockings and drawers" and to dress him on coronation day and to receive his ancient fees, which include the king's bed and "night robe." He also claims in error to serve the king with water before and after the banquet, which was the function of the "ewry," a distinct office held by the earls of Oxford. At the actual coronation ceremony he takes an active part in investing the king with the royal insignia.

(J. H. R.)

LORD HIGH CHANCELLOR, a British officer of state with three main functions: he presides over the house of lords; he is the head of the judiciary; he is also a minister, a member of the government and of the cabinet, having under his control all the judicial appointments in the country except those reserved to the prime minister, and a great deal of ecclesiastical patronage.

This miscellany of duties and powers are united in one person for reasons that lie deep in history. In England the office of chancellor dates back to St. Edward, the Confessor, who, in making this appointment, followed the model of the Carolingian court. Until the 14th century the chancellor was invariably a priest; he was at once a royal chaplain, the king's secretary in secular matters and keeper of the royal seal. This combination of duties, characteristic of the primitive administrative systems of the early middle ages, has left its imprint on the chancellorship to the present day: as chaplain the chancellor was keeper of the king's conscience, as secretary he was the king's closest confidant in secular matters and as keeper of the seal he played a necessary part in all formal expressions of the king's will. By him and his staff of chaplains the whole secretarial work of the royal household was conducted, the accounts were kept under the justiciar and treasurer, writs were drawn up and sealed and the royal correspondence was carried on. The chancellor was, in fact, as the historian Bishop Stubbs put it, a sort of secretary of state for all departments.

From the 12th century until the early Tudor period the chancellor wielded immense power, especially during an interregnum or the king's absence abroad. Among notable chancellors were Roger (d. 1139), bishop of Salisbury, who organized the exchequer in the reign of Henry I, and Thomas Becket (d. 1170), who held the office before Henry II made him archbishop of Canterbury. In the reign of Richard I, Archbishop Hubert Walter (d. 1205) achieved particular prominence because of the king's prolonged absences. Robert Burnell (d. 1292) was Edward I's most trusted and influential minister, while tenure of the office contributed greatly to the power and self-importance of the cardinals Henry Beaufort (d. 1447) and Thomas Wolsey (d. 1530).

The chancellorship in England developed on different lines from the chancellorship in the Holy Roman empire and, later, the Austrian and the German empires; there the chancellors, as exemplified by Metternich and Bismarck, remained up to modern times the effective heads of government, as is the chancellor in the Federal Republic of Germany (*see* CHANCELLOR). The reason for the difference lies in the development, in England, of the judicial duties of the chancellor. These grew out of the fact that all petitions addressed to the king passed through the chancellor's hands. Already in the reign of Henry II the chancellor was largely employed in judicial work. The office acquired a more definitely judicial character when, in the reign of Edward III, the chancellor's court ceased to follow the king; and the time when, in the middle of this reign, all petitions that were matters of grace were definitely committed to the king may be taken as the start of the equitable jurisdiction of the chancellor (*see* EQUITY). The chancellor's court was the direct precursor of the court of chancery, which, by the Judicature act, 1873, was fused into the high court of justice, the chancery division of which is primarily responsible for that court's equitable jurisdiction. The lord chancellor is the president of the chancery division; he is a member of the court of appeal and, if present, presides over it.

The judicial work of contemporary chancellors is, however, almost exclusively confined to the house of lords and the judicial committee of the privy council (*q.v.*); when the chancellor is present, he presides over both tribunals, though, because of the weight of administrative business, modern chancellors seem to have less time for their judicial duties than had their predecessors before 1939.

The position of the chancellor as speaker or prolocutor of the house of lords dates from the time of the English Norman kings, when the ministers of the royal *curia* (the king's court) formed ex officio a part of the *commune concilium* (the great council) and parliament. The chancellor originally attended with the other officials, and he continued to attend ex officio after they had ceased to do so. The chancellor attends the house of lords by virtue of his office, but he has generally, and since the reign of Queen Anne invariably, been a peer. There have been times when the great seal has been put into commission and other times when its custody has been transferred from the chancellor to a minister with the title of lord keeper of the great seal (*q.v.*). By the Act of Union (1707) of England and Scotland one great seal was appointed to be kept for all public acts; the chancellor's authority thus extends to the whole of the United Kingdom, and the commissions of the peace for Scotland. as well as for England, issue from him. By the Roman Catholic Relief act, 1829, it was enacted that no Roman Catholic was to be appointed lord chancellor or keeper or commissioner of the great seal.

As speaker of the house of lords, the chancellor's powers and duties differ considerably from those of the speaker of the house of commons. He puts the question but has no power to rule upon points of order. Like the speaker of the house of commons, he may take part in debates, and, unlike modern speakers, chancellors frequently do so.

See also MINISTRY. GOVERNMENT. (W. T. Ws.)

LORD HIGH CONSTABLE: *see* CONSTABLE.

LORD HIGH STEWARD. The lord high steward of England, who must not be confused with the lord steward (*q.v.*), ranks as the first of the great officers of State. Appointments to this office are now made only for special occasions, such as the coronation of a sovereign or the trial of a peer by his peers. The history of the officeis noteworthy. The household of the Norman and Angevin kings of England included certain domestics and officials styled dapifers, seneschals or stewards (the prototypes of the lord steward). At coronations, however, and great festivals it became the custom in England and else here to appoint magnates of the first rank to discharge for the occasion these domestic functions. In accordance with this custom Henry II. appointed both Robert II., earl of Leicester, and Hugh Bigod, earl of Norfolk, to be his honorary hereditary stewards; and at the Christmas festival of 1186 the successors in title of these two earls are described as serving the king at the royal banqueting table. Subsequently the earls of Leicester bought out the rights of the earls of Norfolk for ten knights' fees.

The last of these earls of Leicester to inherit the hereditary stewardship was Simon V. de Montfort, upon nhose death his forfeited estates were conferred on his son Edmund of Lancaster, who also obtained a grant of the stewardship, but only for life. Edmund was succeeded by Thomas, earl of Lancaster, who, upon his execution for treason, was succeeded in the earldom by his brother Henry. The subsequent earls and dukes of Lancaster were all recognized as stewards of England, the office apparently being treated as annexed to the earldom, or honour, of Leicester. Strictly speaking, none of the Lancasters after Thomas had any clear title either by grant or otherwise; such title as they had merged in the Crown when Henry IV. usurped the throne. Meanwhile the stewardship had increased in importance. On the accession of Edward III., Henry, earl of Lancaster, as president of the council, had superintended the coronation of the infant king; John of Gaunt did the same for the infant Richard II., and, as part of the duties involved, sat in the White Hall of Westminster to hear and determine the claims to perform coronation services. The claims were made by petition, and included, amongst others, the claim of Thomas of Woodstock to act as constable, the rival claims of John Dymock and Baldwin de Frevile to act as champion, and the claim of the barons of the cinque ports to carry a canopy over the king. Minutes of these proceedings, in which the duke is stated to have sat "as steward of England," were enrolled by his order. This is the origin of what is now called the court of claims. The precedent of Richard II. has been followed on all subsequent occasions, except that in modern times it has been the practice to appoint commissioners instead of a steward to superintend this court. In 1397 John of Gaunt created a notable precedent in support of the steward's claim to be supreme judge in parliament by presiding at the trial of the earl of Arundel and others.

When Henry IV. came to the throne he appointed his young son Thomas, afterwards duke of Clarence, to the office of steward. Clarence held the office until his death. He himself never acted as judge in parliament; but in 1415 he was appointed to preside at the judgment of peers delivered in Southampton against Richard, earl of Cambridge, and Lord Scrope of Masham, who had been previously tried by commissioners of oyer and terminer. No permanent steward was ever again created; but a steward was always appointed for coronations to perform the various ceremonial services associated with the office, and, until the court of claims was entrusted to commissioners, to preside over that court. Also, in the 15th century, it gradually became the custom to appoint a steward pro *hac vice* to preside at the trial, or at the proceedings upon the attainder, of a peer in parliament; and later, to preside over a court, called the court of the lord high steward, for the trial of peers when parliament was not sitting. To assist in establishing the latter court a precedent of 1400 appears to have been deliberately forged. This precedent is reported in the printed *Year-Book* of 1400, first published in 1553; it describes the trial of "the earl of H" for participation in the rebellion of that year, and gives details of procedure. John Holand, earl of Huntingdon, is undoubtedly the earl indicated, but the evidence is conclusive that he was murdered in Essex without any trial. The court of the lord high steward seems to have been first definitely instituted in 1499 for the trial of Edward Plantagenet, earl of Warwick; only two years earlier Lord Audley had been condemned by the court of chivalry, a very different and unpopular tribunal. The Warwick trial was most carefully schemed: the procedure, fundamentally dis-similar to that adopted in 1415, follows exactly the forged precedent; but the constitution of the court was plainly derived from the Southampton case. The record of the trial was consigned to a new repository (commonly but wrongly called the *Baga de Secretis),* which thenceforth became the regular place of custody for important state trials. Latterly, and possibly from its inception, this repository consisted of a closet with three locks, of which the keys were entrusted, one to the chief justice of England, another to the attorney-general and the third to the master of the Crown office, or coroner. Xotwithstanding the irregular origin of the steward's court, for which Henry VII. must be held responsible, the validity of its jurisdiction cannot be questioned. The Warwick proceedings were confirmed by act of parliament, and ever since this court has been fully recognized as part of the English constitution.

For about a century and a half prior to the reign of James I. the criminal jurisdiction of parliament remained in abeyance, and bills of attainder were the vogue. The practice of appointing a steward on these occasions to execute judgment upon a peer was kept up till 1477—when George, duke of Clarence, was attainted—and then dropped. Under the Stuarts the criminal jurisdiction of parliament was again resorted to, and, when the proceedings against a peer were founded on indictment, the appointment of a steward followed as a matter of settled practice. The proper procedure in cases of impeachment had, on the contrary, never been defined. On the impeachment of Strafford the lords themselves appointed Arundel to be high steward. In Danby's case a commission under the great seal was issued in the common form adopted for the court of the .steward; this was recalled, and the rule agreed to by a joint committee of both houses was that a steward for trials of peers upon impeachments was unnecessary. But, as such an office was obviously convenient, the lords petitioned for a steward; and a fresh commission was accordingly issued in an amended form, which recited the petition, and omitted words implying that the appointment was necessary. This precedent has been treated as settling the practice of parliament with regard to impeachments.

Of the proceedings against peers founded upon indictment very few trials antecedent to the revolution took place in parliament. The preference given to the steward's court was largely due to the practice, founded upon the Southampton case, of summoning only a few peers selected by the steward, a practice which made it easy for the king to secure a conviction. This arrangement has been partially abrogated by the Treason Act of William III., which in cases of treason and misprision of treason requires that all peers of parliament shall be summoned 20 days at least before every such trial. The steward's court also differed in certain other particulars from the high court of parliament. For example, it was ruled by Lord Chancellor Jeffreys, as steward at the trial of Lord Delamere, that, in trials of peers which take place during the recess of parliament in the steward's court, the steward is the judge of the court, the court is held before him, his warrant convenes the prisoner to the bar, his summons convenes the peers for the trial, and he is to determine by his sole authority all questions of law that arise in the course of the trial, but that he is to give no vote upon the issue of guilty or not guilty; during a session of parliament, on the contrary, all the peers are both triers and judges, and the steward is only the chairman of the court and gives his vote together with the other lords. Lord Delamere was tried in 1685 in the steward's court; since then all trials of peers have taken place before the lords in parliament. The most recent trial was that of Earl Russell in 1901, when Lord Chancellor Halsbury was made lord high steward. The steward is addressed as "his grace," he has a rod of office, and the commission appointing him is dissolved according to custom by breaking this rod.

A court of claims sat and a steward was appointed for the coronation of Edward VII.; and during the procession in Westminster Abbey the duke of Marlborough, as steward, carried "St. Edward's crown" in front of the bearer of the Bible (the bishop of London), who immediately preceded the king; this function of the steward is of modern origin. The steward's ancient and particular services at coronations are practically obsolete; the full ceremonies, processions from Westminster Hall and banquet in which he figured prominently were abandoned on the accession of William IV.

Coke, *Institutes* (1797); Cobbett and Howell, *State Trials* (1809, *seq.)* ; Sir *M.* Foster, *Crown* Law (1809); J. Hatsell, *Precedents of Proceedings in the House of Commons*, vol. iv. (1818); and S. M. Phillips, *State Trials* (1826). *See* also the various works on *Coronations* for the steward's services on these occasions. (L. W. V.-H.)

LORD HIGH TREASURER, in England, once the third great officer of state. The office was of Norman origin and dated from 1216. The duty of the treasurer originally was to act as keeper of the royal treasure at Winchester, while as officer of the exchequer he sat at Westminster to receive the accounts of the sheriffs, and appoint officers to collect the revenue. From the middle of the reign of Henry III. he became one of the chief officers of the Crown. He took an important part in the equitable jurisdiction of the exchequer, and was now styled lord high treasurer and treasurer of the exchequer. The first office was conferred by delivery of a white staff, the second by patent. On the death of

Lord Salisbury in 1612 the office was put in commission; it was filled from time to time until 1714, when the duke of Shrewsbury resigned it; since that time it has always been in commission. (See GOVERNMENT DEPARTMENTS.) The Scottish treasury was merged with the English by the Act of Union, but the office of lord high treasurer for Ireland was continued until 1816.

LORD HOWE, an island in the southern Pacific ocean, situated in long. 159° 5′ E. and in lat. 31° 36′ S., 436 mi. N.E. of Sydney, Austr. Pop. (1954) 278. The island measures about 5 mi. by 1 mi., is well wooded and rises to 2,830 ft. at the southern end. It is of volcanic origin, and its coral reefs on the western shore are the most southerly known. The island was discovered in 1788 and was settled in 1843 as a dependency of New South Wales, and is now governed by a board of control in Sydney. Although mainly a tourist resort, the island has a rock-melon seed trade. which replaced an earlier palm-seed trade. Lord Howe is also the name of an atoll in the Solomon Islands.

LORD JUSTICE CLERK, in Scotland, the judge next in rank to the lord justice-general. He presides in civil cases in the second division of the court of session, and in the absence of the lord justice-general, presides in criminal cases in the court of justiciary. The justice clerk was originally not a judge at all, but simply clerk and legal assessor of the justice court. In course of time he was raised from the clerk's table to the bench, and by custom presided over the court in the absence of the justice-general. Up to 1672 his position was somewhat anomalous, as it was doubtful whether he was a clerk or a judge, but an act of that year, which suppressed the office of justice-depute, confirmed his position as a judge, forming him, with the justice-general and lords commissioners of justiciary, into the court of justiciary. The lord justice clerk is also one of the officers of State for Scotland, and one of the commissioners for keeping the Scottish regalia.

LORD JUSTICE-GENERAL, the highest judge in Scotland, head of the court of justiciary, called also the lord president, and as such head of the court of session and representative of the sovereign. The office of justice-general was for a considerable time a sinecure post held by one of the Scottish nobility, but by the Court of Session Act, 1830, it was enacted that, at the termination of the existing interest, the office should be united with that of lord president of the court of sessions, who then became presiding judge of the court of justiciary.

LORD KEEPER OF THE GREAT SEAL, in England, formerly a great officer of State. The great seal of England, which is affixed on all solemn occasions to documents expressing the pleasure of the sovereign, was first adopted by Edward the Confessor (see SEALS), and entrusted to a chancellor for keeping. The office of chancellor from the time of Becket onwards varied much in importance; the holder being an ecclesiastic, he was not only engaged in the business of his diocese, but sometimes was away from England. Consequently, it became not unusual to place the personal custody of the great seal in the hands of a keeper; this, too, was the practice followed during a temporary vacancy in the chancellorship. This office gradually developed into *a* permanent appointment, and the lord keeper acquired the right of discharging all the duties connected with the great seal. He was usually, though not necessarily, a peer, and held office during the king's pleasure; he was appointed merely by delivery of the seal, and not. like the chancellor, by patent. His status was definitely fixed (in the case of lord keeper Sir Nicholas Bacon) by an act of Elizabeth, which declared him entitled to the same powers and jurisdiction as the lord chancellor. Subsequently he was generally raised to the chancellorship, and retained the custody of the seal. The last lord keeper was Sir Robert Henley (afterwards Lord Northington), made chancellor on the accession of George III.

LORD PRESIDENT OF THE COUNCIL, in England, one of the great officers of State, and a member of the ministry. It was only in 1679 that the office of lord president became permanent. Previously either the lord chancellor, the lord keeper of the seal, or some particular court official took formal direction of the Privy Council. In the reign of Charles I, a special lord president of the council was appointed, but in the following reign the office was left unfilled. The office was of considerable importance when the powers of the Privy Council, exercised through various committees, were of greater extent than at the present time. (See GOVERNMENT DEPARTMENTS.) The duties of the office are to preside on the infrequent meetings of the Privy Council, and to draw up the minutes of council upon subjects which do not belong to any other department of State. The office is very frequently held in conjunction with other ministerial offices. The lord president is appointed by a declaration made in council by the sovereign. He is invariably a member of the House of Lords, and is included in the cabinet.

LORD PRIVY SEAL, the officer in the British government who has custody of the Privy Seal. See SEALS.

LORDS JUSTICES OF APPEAL: see JUDICIARY AND COURT OFFICERS.

LORDS OF APPEAL IN ORDINARY: see JUDICIARY AND COURT OFFICERS.

LORD STEWARD, in England, an important official of the king's household. He is always a member of the Government, a peer and a privy councillor. Up to 1782 the office was one of considerable political importance and carried cabinet rank. The lord steward receives his appointment from the sovereign in person, and bears a white staff. He is the first dignitary of the court. In the Statutes of *Eltham* he is called "the lord great master," but in the Household Book of Queen Elizabeth "the lord steward," as before and since. He presides at the Board of Green Cloth, a committee of the king's household, charged with the audit of its accounts. The board had also power to punish all offenders within the verge or jurisdiction of the palace. The name is derived from the green-covered table at which the transactions of the board were originally conducted. Under the lord steward are the treasurer and comptroller of the household, usually peers or the sons of peers and privy councillors, who sit at the Board of Green Cloth, carry white staves, and belong to the Ministry. But the duties which in theory belong to the lord steward, treasurer and comptroller of the household are in practice performed by the master of the household, who is a permanent officer and resides in the palace. He is a white-staff officer and a member of the Board of Green Cloth but not of the Ministry, and among other things he presides at the daily dinners of the suite in waiting on the sovereign. In his case history repeats itself. He is not named in the Black Book of Edward IV. or in the Statutes of Henry VIII., and is entered as "master of the household and clerk of the green cloth" in the Household Book of Queen Elizabeth. But he has superseded the lord steward of the household, as the lord steward of the household at one time superseded the lord high steward of England.

In the lord steward's department are the officials of the Board of Green Cloth, the coroner ("coroner of the verge"), and paymaster of the household, and the officers of the almonry. (See ALMONER.) The lord steward had formerly three courts besides the Board of Green Cloth under him. First, the lord steward's court, superseded (1541) by—second—the Marshalsea court, a court of record having jurisdiction, both civil and criminal, within the verge (the area within a radius of 12m. from where the sovereign is resident), and originally held for the purpose of administering justice between the domestic servants of the sovereign, "that they might not be drawn into other courts and their service lost." Its criminal jurisdiction had long fallen into disuse and its civil jurisdiction was abolished in 1849. Third, the palace court, created by letters patent in 1612 and renewed in 1665 with jurisdiction over all personal matters arising between parties within 12m. of Whitehall (the jurisdiction of the Marshalsea court, the City of London and Westminster Hall being excepted). It had no jurisdiction over the sovereign's household, nor were its suitors necessarily of the household. The privilege of practising before the palace court was limited to four counsel. It was abolished in 1849. The lord steward or his deputies formerly administered the oaths to the members of the House of Commons. In certain cases (messages from the sovereign under the sign-manual) "the lords with white staves" are the proper persons to bear communications between the sovereign and the houses of parliament.

May, *A Practical Treatise on the Law . . . and Usage of Parliament* (13th ed., 1921).

LOREBURN, ROBERT THRESHIE REID, 1st Earl (1846–1923), British lawyer and politician, who as lord chancellor was largely responsible for the passage of the Court of Criminal Appeal act (1907), was born at Corfu on April 3, 1846. He was educated at Cheltenham and Balliol college, Oxford, where he won the Ireland scholarship in 1868. He was called to the bar in 1871, and in 1880 entered politics as Liberal M.P. for Hereford. In 1882 he became queen's counsel and represented Dumfries Burghs from 1886 to 1905. In 1894 he became solicitor-general and during 1894–95 was attorney general. On the formation of Campbell-Bannerman's government in 1905, Sir Robert Reid, who had been knighted in 1894, became lord chancellor, and was created Baron Loreburn. In 1912 he resigned on grounds of health. Lord Loreburn, who was created an earl in July 1911, published *Capture at Sea* (1913) and *How the War Came* (1919). He died at Dover on Nov. 30, 1923.

LOREE, LEONOR FRESNEL (1858–1940), American railway president, son of William Mulford Loree, a millwright, was born in Fulton City, Ill., on April 23, 1858. After graduating at Rutgers college in 1877, he entered the service of the Pennsylvania railroad as a rodman. In 1879 he served in the U.S. army engineering corps and in 1881 as civil engineer for the Mexican National railway. Re-entering the employ of the Pennsylvania railroad in 1883, he served in engineering positions of increasing importance until 1889 when he was made a division superintendent, and in 1896 he rose to the position of general manager. In 1901 he was elected to a vice-presidency but resigned in the same year to become president of the Baltimore and Ohio railroad company, an office held until 1904 when he was chosen president of the Rock Island company. In 1907 he was elected president of the Delaware and Hudson company, a position in which he served for more than 30 years. He served also as a director of several other railways and in 1926 was made chairman of the board of the Missouri-Kansas-Texas railroad company. He invented the upper quadrant system of semaphore signaling, now standard on American railways; built the first high-pressure locomotive; and made other improvements. In the effort to consolidate American railways into a limited number of systems in accordance with the policy formulated by Congress in 1920 he took an active and influential part. He also established the first organized railway police force. He wrote *Railroad Freight Transportation* (1922).

LORELEI, the name of a rock with a remarkable echo in the Rhine river near St. Goar. The word is derived from Old High German, *Lur,* connected with modern German *lauern,* "to lurk," "be on the watch for," and equivalent to *Elf* ("goblin") and *Lai* ("a rock"). In the commonest form of the story associated with it the Lorelei is a maiden who threw herself into the Rhine in despair over a faithless lover, and became a siren who lured fishermen to destruction. Clemens Brentano created the legend in its main essentials in his novel *Godwi* (1800–02). In the 19th century it formed the subject of a number of songs and dramatic sketches (listed in H. Seeliger, *Loreleysage in Dichtung und Musik;* 1898). The poem most often set to music was Heinrich Heine's "Ich weiss nicht was soll es bedeuten," of which the settings by Friedrich Silcher (from a folk song) and by Franz Liszt are the most famous.

See R. Elwenzeller-Favre, *Lorelei. Entstchung und Wandlung einer Sage* (1946).

LORENTZ, HENDRIK ANTOON (1853–1928), Dutch physicist, who shared the 1902 Nobel prize for physics with Pieter Zeeman for work on the influence of magnetism on radiation and helped lay the basis for Albert Einstein's special theory of relativity. He was born at Arnheim on July 18, 1853. He studied at Leyden, where he was appointed professor of mathematical physics in 1878. In 1923 he became director of research at the Teyler institute, Haarlem. He remained honorary professor at Leyden, where he gave a weekly lecture on modern physics, which was usually reported for publication by one of the audience.

Lorentz's work in physics was very wide in its scope, but its central aim, it appears, was to arrive at some consistent theory for electricity, magnetism and light. He tried to explain these phenomena by assuming an ether which was at rest and had electrons either at rest or moving in it. A number of phenomena were successfully explained on this electron theory, but it failed to give an explanation of the negative result of the Michelson-Morley experiment (*q.v.*). To overcome this difficulty Lorentz introduced the idea of "local time" in 1895. The connection between this and the Fitzgerald contraction was pointed out by Sir Joseph Larmor, and in 1903 Lorentz extended his work and arrived at the "Lorentz transformation," which helped form the basis (1905) of Einstein's restricted theory of relativity.

Lorentz's earlier investigations were originally published in Dutch in the *Archives Néerlandaises* and consequently were not known to English physicists; Lord Rayleigh and Sir Oliver Lodge were largely responsible for the spread of his ideas in England. His first paper, published in 1875, dealt with the reflection and refraction of light by dielectrics and metals. In 1880 he published a memoir on the relation between the refractive index and the density of a medium. This was the first application of James C. Maxwell's theory to a medium consisting of discrete molecules. Lorentz dealt with optical dispersion and tried to give an explanation on the assumption that it was due to resonant vibrations. This work was continued in his two well known memoirs, *La Théorie électromagnétique de Maxwell et son application aux corps mouvants* (1892) and *Versuch einer Theorie der electrischen und optischen Erscheinungen in bewegten Körpern* (1895). In the latter memoir he deals with the electrodynamic field of a system moving with uniform velocity. Lorentz gave an explanation of the Zeeman effect very soon after it was observed, and predicted polarization effects which were verified later by experiment. He was also the author of a number of papers on gravitation theory, thermodynamics, radiation and kinetic theory. He was chairman of the committee of intellectual co-operation set up by the League of Nations. He died at Haarlem on Feb. 4, 1928.

Bibliography.—Lorentz's works include *Collected Papers* (1934–39); *Lectures on Theoretical Physics* (1927–31); *Problems of Modern Physics* (1927); *The Theory of Electrons* (2nd ed. 1953). *See* G. L. de Haas-Lorentz, *H. A. Lorentz* (1957). (E. Tr.; X.)

LORENZETTI, the name of two brothers, both Italian painters of the Sienese school, active in the first half of the 14th century. Their style combined the harmonious colour and expressive design of Duccio with the monumental realism of Giotto and, in the case of the elder, the dramatic naturalism of Giovanni Pisano. Their art was much imitated in Siena during the third quarter of the 14th century, and many works by close followers are still commonly attributed to one or the other.

Ambrogio Lorenzetti (*c.* 1290–1348), the younger brother, ranks in importance with the greatest Sienese painters, Duccio and Simone Martini. Since neither he nor his brother is mentioned in documents after 1348, it is assumed that both died of the plague that devastated Siena in that year. Only six documented works of Ambrogio, apparently covering a period of merely 13 years, have survived. They include four scenes from the legend of St. Nicholas of Bari in the Uffizi gallery, Florence, which are parts of an altarpiece painted about 1332 in Florence; the wall decorations of 1337–39 in the Sala della Pace in the Palazzo Pubblico, Siena, representing "Good Government," "Effects of Good Government," "Bad Government" and "Effects of Bad Government"; and the signed and dated panels of the "Presentation of Christ in the Temple" (1342) in the Uffizi, and of the "Annunciation" (1344) in the Pinacoteca, Siena. Ambrogio's most important undocumented works are panel paintings of the "Madonna and Child."

It is not known who Ambrogio's teacher was, but his early works indicate that the young painter received his main inspiration from the art of Duccio, his brother Pietro and Giotto. Already at this early period his representations reveal a realistic individualism and an intense occupation with significant composition and form. These characteristics are most evident in the "Allegories" in the Palazzo Pubblico, the most important Sienese fresco decoration. In it we see Ambrogio as an acute observer of the world around him, an empirical explorer of linear and aerial perspective, a student of classical works of art, and a political and moral philosopher. His desire to depict spatial depth convincingly led Ambrogio to an increasingly accurate rendering of space in his paintings and almost to one-point perspective in his last work, the "Annunciation." With his profound interest in perspective and in classical antiquity Ambrogio anticipated the Renaissance.

PIETRO LORENZETTI (*c.* 1280/90–1348), incorrectly called Pietro Laurati by Vasari, apparently was the elder brother of Ambrogio. His earliest certain work, the Madonna polyptych of 1320, an altarpiece in the Pieve at Arezzo, indicates that he studied under Duccio or a close pupil of this master, and that he was influenced by Giotto's solemn and Giovanni Pisano's dramatic representations. These influences are evident also in the somewhat later frescoes of the "Madonna and Child with Saints," and the "Crucifixion, Deposition, Entombment, Descent into Limbo, and Resurrection of Christ" in the left transept of the lower church of S. Francesco, Assisi. In the Madonna painting at Arezzo and in that at Assisi the Virgin and Child are depicted intently gazing at each other, a motif directly derived from Giovanni Pisano's sculpture. In the important altarpiece of 1329 for the Carmine church, Siena, now in the Pinacoteca of that city, the artist chose a less intimate composition for the Virgin and Child, but he compensated for the formal main representation by adding very animated predella scenes, in which spatial depth is skillfully asserted.

During the 1330's Pietro became somewhat influenced by the art of his brother, with whom he produced in 1335 four scenes from the life of the Virgin (destroyed in the 18th century) on the facade of Sta. Maria della Scala, Siena. In Pietro's triptych of the "Nativity of the Virgin" in the Museo dell'Opera del Duomo, Siena (1335–42), the figures have a breadth and composure and the space representation has an originality suggestive of Ambrogio.

LORENZO, FIORENZO DI (*c.* 1445–*c.* 1525), Umbrian painter, a precursor of Pinturicchio, became a member of the guild of painters in Perugia between 1463 and 1469. In 1472 he was elected prior of the guild and his birth is for this reason generally assumed to have taken place about 1445. A signed altarpiece in the Galleria Nazionale dell'Umbria representing SS. Peter and Paul beside a niche with a lunette of the Virgin and Child was painted in 1487. Works conjecturally datable before this time are a triptych from the Confraternità della Giustizia at Perugia and an Adoration of the Shepherds from Monteluce, both in the Perugia gallery, and a triptych in the National gallery, London. The London triptych is related to paintings by Niccolò Alunno at Deruta and by Benozzo Gozzoli at Vienna, and both these artists seem to have exercised a significant, though not necessarily direct, influence on Fiorenzo's early style. The relationship of Fiorenzo di Lorenzo's early works to paintings by Verrocchio is also noteworthy and lends some force to the view that before 1470 he worked in Florence. Documents of 1490, 1491 and 1513 relate to the production of lost works, but the artist's mature development can be traced through frescoes in S. Francesco at Deruta (1478), Monteluce (1491), Monte l'Abate (1491–92) and in the Perugia gallery (from S. Giorgio, 1498). The last reference to Fiorenzo di Lorenzo's activity dates from Feb. 1522 and he was dead by Feb. 14, 1525. After about 1480 the Verrocchiesque elements in Fiorenzo's work become less pronounced and thereafter he develops a typically Umbrian style. An attractive but relatively weak artist, Fiorenzo di Lorenzo was a precursor of Pinturicchio, who was probably a member of his studio during the 1470s. His later work is a pallid reflection of that of Pinturicchio and Perugino.

See W. Bombe, *Geschichte der Peruginer Malerei* (1912); R. van Marle, *The Development of the Italian Schools of Painting*, vol. xiv (1933). (J. W. P.-H.)

LORENZO MONACO (DON LORENZO) (*c.* 1370–*c.* 1425), Italian painter whose work combined the rhythmic, graceful flow of line and decorative feeling of the Sienese school with the Florentine traditions of the followers of Giotto. Lorenzo was born at Siena. He took the vows of the Camaldolese order in 1391 and lived mostly at the monastery of Santa Maria degli Angeli, in Florence. His name as a layman was Piero di Giovanni del Popolo di San Michele de Bisdomini and a painter of that name was entered in the books of the guild of St. Luke at Florence in 1396. Lorenzo was in some respects an innovator in Florence; in his later work he appears to be influenced by the realistic tendency of the early Renaissance. The Uffizi in Florence contains a signed work by the master, "Coronation of the Virgin" with many figures, painted in 1413 for his convent. The National gallery in London has another smaller version of the same subject; one of his most graceful altarpieces is the "Annunciation" in the Bartolini chapel in the church of Sta. Trinita at Florence. His "Madonna and Child with Angels" was acquired by the Metropolitan Museum of Art, New York city. Another late work of the master is the "Adoration of the Magi" in the Uffizi. The master's feeling for decorative composition, his expressive line and his originality come out well in his small predella pieces, as in the three small fragments at the Florence academy, representing the "Nativity," the "Life of a Hermit" and a stormy seascape, and in the two remarkable illuminations in Berlin museums of the "Journey of the Three Kings" and the "Visitation."

LORETO, episcopal see and a noted pilgrimage resort of The Marches, Italy, in Ancona province, 15 mi. S.S.E. of Ancona by rail. It lies on the right bank of the Musone. Pop. (1957 est.) 8,663 (commune).

The town, surrounded by 16th-century walls and bastions, is virtually a long narrow street, lined with shops for the sale of religious objects. The principal buildings in the Piazza della Madonna are the Palazzo Apostolico (containing works of Lorenzo Lotto and Lodovico Carracci and a replica of the tapestries designed by Raphael for the Sistine chapel) and the Basilica of the Holy House or the Santuario della Santa Casa (a late Gothic structure begun in 1468 and continued by Giuliano da Maiano, Giuliano da Sangallo, Bramante and other architects, who altered the original plan, which was again revived in 1886 by Giuseppe Sacconi). The façade of the basilica was completed under Pope Sixtus V; his colossal statue stands in the middle of the entrance steps. Over the main door is a life-size bronze statue of the Virgin and Child by Girolamo Lombardo; the three superb late-16th-century bronze doors are also by Lombardo, his sons and his pupils. The doors of the Santa Casa (*see* below) and the magnificent chandelier over the presbytery are by the same artists. The richly decorated campanile by L. Vanvitelli is 250 ft. high, and the principal bell, presented by Leo X in 1516, weighs eight tons. The interior of the church has mosaics of Domenichino, Guido Reni, Barrocci and C. Maratta. In the old sacristies are frescoes by Melozzo da Forlì and Luca Signorelli. The Treasure room, where precious gifts and a collection of 16th-century majolica are on view, is close by.

The Santa Casa itself is of plain stone, 28 by 12½ ft., and 13½ ft. in height, with a niche containing a small black image of the Virgin and Child, in Lebanon cedar, and richly adorned with jewels. It is enclosed by a lofty marble screen, designed by Bramante, which has four sides representing the Annunciation, the Nativity, the arrival of the Santa Casa at Loreto and the Virgin's Nativity. According to tradition, the Holy House of the Virgin, threatened with destruction by the Turks, was carried from Nazareth by the ministry of angels and deposited (1291), in the first instance, on a hill at Tersatto in Dalmatia, where an alleged appearance of the Virgin and miraculous cures attested its sanctity. Three years later it was similarly transported across the Adriatic to a laurel grove (*lauretum*, whence Loreto) near Recanati and from there removed (1295) to the present hill. Papal Bulls in favour of the shrine were issued. Pope Innocent XII appointed a *missa* cum *officio proprio* for the feast of the Translation of the Holy House (Dec. 10). Benedict XV declared the Madonna di Loreto to be the patron of aviators (1920). The chief festival is held on Sept. 8, the Nativity of Our Lady.

The Fountain of the Madonna, by C. Maderno, in the piazza, and the Fountain of the Galli (cocks) are worthy of note. The Polish War cemetery is nearby. (PO. G.)

LORETO, the largest and most easterly department of Peru, bounded north and northeast by Colombia, northwest by Ecuador, east by Brazil, west by the departments of Amazonas, San Martin, Huánuco and Junin. and south by Cuzco. Area, 184.686 sq mi. Pop. (1958 est.) 433.560. The montafia territory at the time of independence in the early 19th century was a province of the intendencia of Trujillo, under the name of Maynas. Later it became a province of La Libertad, then of Amazonas in 1853, an independent "littoral province," and finally a department. In 1906 the western portion was attached to the new department of San Martin (*q.v.*).

The chief river in the east of the department, the Ucayali, joins the Marañón or upper Amazon at Nauta. Other significant affluents of the Marañón are the Tigre, Pastaza, Morona, Huallaga and Samiria. From Iquitos westwardly ocean steamers ascend to the confluence of the Ucayali with the Marañón. The Marañón is navigable at all seasons for steamers of four to eight feet draft as far as Puerto Limon, a distance of 484 mi. The Huallaga is navigable at all seasons for steamers of the same draft to beyond Turimaguas, about 150 miles. The lower Ucayali is navigable to the confluence of the Pachitea for vessels of six-feet draft.

Iquitos (pop. [1958 est.] 54,286) is the capital of the department and entrepôt for the upper Amazon. It is served by ocean steamers and can be reached from Lima in five days via the Pucallpa highway and the Ucayali river, two days by bus and three days by river steamer.

The department, largely made up of the Amazonian plains, is almost completely forested. The climate is hot and humid with heavy rainfall (103 in.. annually at Iquitos). The average elevation is about 500 ft. above sea level and the greater part of the region is inundated part of the year. Important exports of the department are rubber (the leading export before the East Indian plantations came into production), Brazil nuts, skins and hides, products of oil, medicinal and wax-bearing plants, and hardwoods. Rice, sugar cane, bananas, manioc, tobacco and other tropical products are cultivated there. The population is chiefly Indian and mestizo. (J. L. TR.)

LORIENT, a maritime town of western France, capital of an *arrondissement* in the *département* of Morbihan, on the right bank of the Scorff, at its confluence with the Blavet, 34 mi. W. by N. of Vannes by rail. Pop. (1954) 37,981.

Lorient took the place of Port Louis as the port of the Blavet. The latter stands on the site of an ancient hamlet fortified during the wars of the League and handed over by Philip Emmanuel, duke of Morcoeur, to the Spaniards. After the Treaty of Vervins it was restored to France, and received its name of Port Louis under Richelieu. Some Breton merchants trading with the Indies established themselves first at Port Louis, but in 1628 built their warehouses on the other bank. The Compagnie des Indes Orientales, created in 1664, took possession of these, giving them the name of l'Orient. The importance of the Compagnie des Indes waned after the English conquest of India, and in 1770 its property was ceded to the State. In 1782 the town was purchased by Louis XVI from its owners, the Rohan-Guéméné family. The trade in fresh fish, sardines, oysters and tinned vegetables is important, and the manufacture of basketwork, rope, nets, etc., tin boxes and ice, and the preparation of preserved sardines and vegetables are carried on. The roadstead is the estuary of the Blavet. In the middle of the channel is the granite rock of St. Michel.

LORIMER, GEORGE HORACE (1867–1937), U.S. editor, was born at Louisville, Ky., Oct. 6, 1867. He attended Colby college and Yale university and, after a short time in business in Chicago, became a newspaper reporter and correspondent. In 1897 he was literary editor of the *Saturday Evening Post* and in 1899 became its editor in chief. The remarkable success of this periodical was largely caused by Lorimer's keen appreciation of the public taste, coupled with his ability to meet it. His *Letters From a Self-Made Merchant to His Son* (1902), which attained great popularity, and *Old Gorgon Graham* (1904) are effective expositions of the philosophy of getting on. He continued his editorship of the *Post* until Jan. 1, 1937, and died at Wyncote, Pa., Oct. 22, 1937.

See John Tebbel, *George Horace Lorimer and The Saturday Evening Post* (1948).

LORIMER, JAMES (1818–1890), Scottish jurist and authority on international law, was born at Aberdalgie, Perthshire, on Nov. 4, 1818. and was educated at Edinburgh university. After study abroad he was admitted to the Scottish bar and in 1862 became professor of public law in Edinburgh university, where he taught until his death on Feb. 13, 1890. Against the positivism of contemporary English jurisprudence Lorimer taught a doctrine of natural law founded on divine authority and revealed in conscience and in history; in particular he held that the science of international law should be concerned with the application of this natural law to the relations of nations with one another. Lorimer's system did not prove of permanent value but his writings are memorable for their vigour and for flashes of prophetic insight, notably his draft scheme (1870) for a "permanent congress of nations" and an international court of justice.

His major writings are: *The Institutes of Law* (1872); *The Institutes of the Law of Nations,* 2 vol. (1883–84); *Studies National and International* (1890). (AR. H. C.)

LORIS, the common name for Indo-Malay lemurs (*see* PRIMATES). Their soft fur, huge staring eyes, rudimentary tails and imperfectly developed index-fingers render lorises easy of recognition. The smallest is the slender loris (*Loris tardigradus)* of the forests of Madras and Ceylon, a creature smaller than a squirre!. The slow loris (*Nycticebus coucang)* is a heavier built and larger animal, known for its deliberate and unhurried pace. It ranges from eastern Bengal to Indochina, the Malay peninsula, Java, Borneo and Mindanao.

W SUSCHITZKY

SLOW LORIS (NYCTICEBUS COUCANG), FOUND IN SOUTHEASTERN ASIA

LORIS-MELIKOV, MICHAEL TARIELOVICH, COUNT (1826–1888), Russian statesman, son of an Armenian merchant, was born at Tiflis on Jan. 1, 1826, and educated in St. Petersburg, first in the Lazarev School of Oriental Languages, and afterward in the Guard's Cadet Institute. He joined a hussar regiment, and in 1847 he was sent to the Caucasus, where he spent 20 years. He was governor of the Terek district from 1855 to 1876, and sought to educate the people so as to make possible the transition from military to civil government. In the Russo-Turkish War of 1877–78 he commanded a separate *corps d'armée* on the Turkish frontier in Asia Minor. After taking the fortress of Ardahan, he was repulsed by Mukhtar Pasha at Zevin, but subsequently defeated his opponent at Aladja Dagh, took Kars by storm and laid siege to Erzerum. For these services he received the title of count.

In 1879 he was appointed temporary governor-general of the region of the lower Volga, to combat an outbreak of the plague. He was then transferred to the provinces of central Russia to combat the nihilists and anarchists, who had adopted a policy of terrorism, and had assassinated the governor of Kharkov. He advocated removing the causes of popular discontent, and for this purpose he recommended to the emperor a large scheme of administrative and economic reforms. Alexander II thereupon appointed Loris-Melikov minister of the interior with exceptional powers. The proposed scheme of reforms was never carried out. On the very day in March 1881 that the emperor signed an *ukáz* creating the necessary commissions, he was assassinated; and his successor, Alexander III, adopted a reactionary policy. Loris-Melikov resigned, and lived in retirement until his death (Dec. 22, 1888) at Nice.

LORME, MARION DE (1613–1650). the celebrated French courtesan whom Victor Hugo made the heroine of a drama and who figures also in Alfred de Vigny's novel *Cinq-Mars,* was born in Paris on Oct. 3. 1613. the daughter of Jean de Lon, sieur de Lorme, and Marie Chastelain, and was brought up at the chbteau of Baye, near Champaubert. She was introduced to the life of pleasure by Jacques Vallée, sieur des Barreaux, a *libertin* or free-thinker, who expressed his sincere love for her in passionate verse. She soon left him, however, for the marquis de Cinq-Mars (*q.v.*), Louis XIII's elegant young favourite, whom at one moment she was on the point of marrying. She then set herself up in the fashionable Place Royale (now the Place des Vosges) in Paris, where her salon attracted the most brilliant company of the town. After the execution of Cinq-Mars (1642), she had many lovers: Saint-Evremond; the marquis de Rouville (Hercule Louis); the soldier and poet Isaac Arnauld de Corbeville; the comte de Miossens (César Phébus, later marshal d'Albret); the comte de Coligny (Gaspard de Chatillon). who was converted to Catholicism to please her; the duc d'Enghien (Louis de Bourbon Condé); the duc de Brissac (Louis de Cossé); the comte de Gramont (Philibert); the superintendant of the finances Michel Particelli d'Emery; and even the cardinal de Richelieu himself. Paul Scarron and other poets were among her friends and wrote in praise of her. The marshal de La Meilleraye (Charles de La Porte), Emery's successor as superintendant during the Fronde, began a persecution of her, and she had to leave the Place Royale and go to her mother's house in the rue de Thorigny. Though most of her friends and lovers supported the opposition to Cardinal Mazarin, there is no proof of the story that she was about to be arrested when she died. in poverty, on July 2, 1650. Her body, in a white dress, was laid out as if in state, and the cure of the parish of St. Paul had to intervene to stop this scandal. The 18th-century story that she died a centenarian is without foundation.

See J. Péladan, *Histoire et légende de Marion de Lorme,* 2nd ed. (1927); G. Mongredien, *Marion de Lorme et ses amours (1940).*

(G. Mo.)

LÖRRACH, a town in the *Land* of Baden-Württemberg, Germany, in the Wiese valley, 6 mi. N.E. of Basle. Pop. (1959 est.) 30,146. Lorrach received market rights in 1403, but did not obtain municipal privileges until 1682. Manufactures include calico, cloth, silk, chocolate, cotton, ribbons, hardware and cigars; there is trade in wine, fruit and timber. It is a centre for the transmission of electric power generated from the Rhine near by. There is a fine view from the nearby Schdtzenhaus, 1.378 ft. high. In the neighbourhood also is the castle of Rotteln, formerly the residence of the counts of Hachberg and of the margraves of Baden.

LORRAINE, a former province and a geographical region of France. The name has been applied to the territory covered by the independent duchy of Lorraine and Bar (*see* BAR, COUNTS AND DUKES OF) and the three episcopal lordships of Metz, Toul and Verdun; or, at the end of the 18th century, by the two *généralités* of Nancy and Metz, which were divided at the Revolution into the departments of Meurthe, Meuse, Moselle and Vosges. Bounded north by the Ardennes and the *Massif schisteux rhénan,* east by the Vosges, south by the plateau of Langres and west by the Argonne, and watered by the upper courses of the Meuse and Moselle, Lorraine corresponds to the western slopes of the Vosges and to the easternmost, highest and oldest parts of the *Bassin Parisien;* the alternation of limestone and clay in the sedimentary rocks gives an undulating landscape, where wet plains, lofty *cuestas* and dry plateaus succeed each other from east to west.

The **Origins** of Lorraine.— The name Lotharingia (Lorraine) appears first in the 9th century. Its origins are to be found in the treaty of Verdun (Aug. 843). The northern part of the Francia Media, allotted by this treaty to the emperor Lothair I, corresponds to the kingdom of Lorraine, created by Lothair when he retired in 855 in favour of his second son, Lothair, (825–869), from whom the names of the country are derived. This kingdom lay between Francia Orientalis and Francia Occidentalis and was bounded to the north by the sea between the mouths of the Scheldt and the Ems; on the east by the Rliine from Wesel (with a westward recession, in the neighbourhood of Bingen, that left Worms and Speyer to Germany) as far as its confluence with the Aar, which formed the southern boundary; and on the west, across the Jura. by the Saône (from a point a little south of its confluence with the Doubs), the Ornain, the Meuse and the Scheldt. Thus, that kingdom comprised the countries of the Moselle and the Meuse, with the dioceses of Cologne, Trier, Metz, Toul, Verdun, Liège, Cambrai, Basle, Strasbourg and Besanqon, including territories now divided between the Netherlands, Belgium, France, Germany and Switzerland. Apparently of an absolutely artificial character, it yet corresponded to Austrasia, the old country of the Franks, cradle of the Carolingian house (which sprang from Metz) and main centre of the Carolingian Renaissance. When King Lothair died heirless in 869, his two uncles, Charles the Bald, king of France, and Louis the German, at once tried to seize Lorraine. It was dismembered by the treaty of Mersen (Aug. 8, 870). by which Charles received Toul, Verdun, Mézières and Libge, while Louis had Besanqon, Saint-Die, Metz, Trier, Aachen and Frisia. But in 880 the unity of Lotharingia was restored, when Charles the Bald's grandsons, Louis III of France and Carloman, gave up their share to Louis the Young, king of Germany (son of Louis the German), who ruled Lorraine till 882. Then, from 882 to 887, the emperor Charles the Fat united it with the reconstituted Carolingian empire. After Charles's deposition in 887 Rudolph I, king of Burgundy, tried to conquer Lorraine but succeeded only in detaching (definitively) the province of Besanqon. The main part of Lorraine fell to the German king Arnulf, who in 895 constituted it a distinct kingdom for his bastard Zwentibold. Zwentibold, however, soon became embroiled with the nobles and the bishops and was killed in battle on Aug. 13, 900, the last independent king of Lorraine. The Lotharingian lords then recognized Arnulf's son, the German king Louis the Child, as king; and he retained Lorraine till his death (911). Since he was the last German Carolingian king, Lotharingians refused to recognize his successor, Conrad I, and elected Charles the Simple of France. But Charles was dethroned in 922 by his vassals; and, after an attempt on Lorraine by the new king of France, Rudolph (Raoul), Lorraine fell in 925 to the German king Henry I. There were further attempts on Lorraine by the last French Carolingians; but the year 925 saw the end of the separate kingdom, after which Lorraine was for centuries a German duchy.

Henry I had been supported by Giselbert, son of Reginar (Regnier), count of Hainaut, and rewarded him with the hand of his daughter Gerberga and the title of duke of Lorraine (928). But the German kings of the Saxon house met with serious difficulties from the Lotharingian lords. In 939 Giselbert revolted against Otto I the Great, Henry's son, and appealed to Louis IV d'Outremer, who came to his help but had soon to return to France to oppose a revolt; Giselbert was defeated and killed near Andernach. Otto got himself recognized in the whole of Lorraine, securing it by a treaty with Louis d'Outremer, who married Gerberga. Otto entrusted the duchy to Count Otto (d. 944), son of Ricuin, then to his son-in-law Conrad of Franconia (who revolted and was deposed in 953) and finally, in 954, to his brother Bruno (*q.v.*), archbishop of Cologne. Bruno had to contend against the efforts of King Lothair of France, as well as against the independent spirit of the Lotharingian nobles. To obviate these difficulties he divided Lotharingia into Lower Lorraine and Upper Lorraine (959).

In 959 Upper Lorraine, corresponding to the ecclesiastical province of Trier, had been given to Frederick, count of Bar (d. 978), a member of the house of Ardenne and a relative of the Carolingians, whose cause, however, he deserted, being also the nephew of Otto and brother-in-law of Hugh Capet; but his grandson, Frederick II, died without male heir in 1033. Lotharingia was then restored in favour of Gothelon (Gozelo), count of Verdun and duke of Lower Lorraine (son of Duke Godfrey, d. 1023). At Gothelon's death in 1043, however, his son Godfrey the Bearded received from the emperor Lower Lorraine only, the other son, Gothelon II, obtaining Upper Lorraine. Godfrey attempted to seize Upper Lorraine, but was defeated in 1045; trying again on Gothelon II's death in 1046, he failed likewise and, deprived of his own duchy by the emperor Henry III, had to flee to Italy, recovering Lower Lorraine only in 1065. The latter duchy passed to his son Godfrey the Hunchback (d. 1076), then to the Hunchback's nephew Godfrey of Bouillon (d. 1100), then to Henry, count of Limburg, and then in 1106, to Godfrey, count of Louvain, who was the first hereditary duke of Brabant (*q.v.*), as the dukes of Lower Lorraine came to be called.

Upper Lorraine in the Middle Ages.—From the 11th century the name of Lorraine was restricted to the duchy of Upper Lorraine, which, from 1043, was definitively separated from Lower Lorraine. On Gothelon II's death the emperor Henry III gave it to Adalbert of Alsace, of the family of the counts of Metz. Adalbert was succeeded in 1048 by his nephew Gerard of Châtenois (d. 1069), whose descendants in direct line possessed the duchy until 1431. The growth of feudal lordships had already seriously weakened the power of the dukes, who had, particularly, to face the three powerful episcopal lordships of Metz, Toul and Verdun, the counts of Bar and the counts of Luxembourg; their own demesne was restricted to the country east of the Moselle. The history of Lorraine in the middle ages can be divided into two parts, separated by the great interregnum of the empire (1250–73): before 1250 it was part and parcel of the Holy Roman empire, the dukes generally supporting the emperors while their rivals, the counts of Bar, supported the Guelph party; but after the death of Frederick II, who had come to Lorraine in 1215 and 1227, the German sovereigns ceased to intervene in the country, and the links with an anarchic Germany slackened. The situation of the 10th century was now reversed: the influence of the powerful western neighbour, already strong in the fields of culture and the arts, began to be felt in the political fields also. With the union of Champagne to the French crown (1285), the duke of Lorraine and the count of Bar became vassals of the king of France for a number of fiefs, mostly on the left bank of the Meuse (*e.g.,* the *Barrois mouoant,* 1301); and the king took under his protection several ecclesiastical lordships, including Toul (1289) and Verdun (treaty of *sauvegarde* with Louis *X*, 1315). The dukes fought for France on the battlefields of the Hundred Years' War; and Charles II was made constable of France (1418) and married his daughter and heiress, Isabella, to René of Anjou, duke of Bar (1420). But on Charles's death (1431) his nephew Antony of Vaudemont disputed the succession with René, who was taken prisoner at Bulgnéville (July 2, 1431) and released in 1436 only against a heavy ransom. Henceforth, however, a French house reigned at Nancy, and the duchy of Bar was united to Lorraine (1480). In 1444, called by René, Charles VII came to Lorraine with an army, besieged Metz and restored the rights of the French crown.

But French influence was temporarily checked by the new menace of the Burgundian state, whose growth was hampered by its division into two parts, the Low Countries and Burgundy, with communications necessarily passing through Lorraine. Charles the Bold, who was dreaming of a restored Lotharingia, invaded Lorraine in 1475 but was defeated and killed before Nancy on Jan. 5, 1477. The duchy had preserved its independence, but its situation had become very dangerous, since most of the Burgundian inheritance passed to the Habsburgs, who, in Luxembourg and Franche-Comté, became the neighbours of Lorraine. The country was thus in danger of becoming a battlefield in the struggle between France and the house of Austria.

Lorraine in Modern Times.—René II (d. 1508) and Antony (d. 1544) tried hard and generally succeeded in maintaining a neutral position in the struggle between their two powerful neighbours. By the treaty of Nuremberg (Aug. 26, 1542) Antony prevailed upon the emperor Charles V, who wanted his friendship, to recognize Lorraine as a free and autonomous state, whose duke was sovereign: the last feudal links with the empire were cut. But Francis I of France had already obliged Antony to cede Stenay and allow the free passage of French troops (1541). In 1544 the imperial army invaded France through Lorraine and penetrated to Meaux; and the weakness of the Meuse frontier was evident. The internal and religious struggles within the empire gave the French the opportunity to consolidate that frontier and to strengthen their grasp on Lorraine. By the treaties of Lochau and Chambord (1551–52) the Protestant princes of Germany authorized Henry II to occupy, in the quality of imperial vicar, the cities of Metz, Toul, Verdun and Cambrai. The occupation took place early in 1552. Later in 1552 Charles V laid siege to Metz but was forced to retreat with heavy loss before the energetic resistance of Francis of Guise (who belonged to a branch of the ducal house). France had secured the key strategical position in the heart of Lorraine.

From 1552 to 1624 the truce in the struggle between France and the Habsburgs, as well as the civil wars in France, gave the duchy a long period of peace, troubled only by the devastating passage of German bands on their way to help the French Protestants. The long reign (1545–1608) of Charles III marks the apogee of the duchy of Lorraine. Charles devoted himself to improving the administration of the duchy: he increased the ducal domain, modernized the judiciary and financial institutions and fostered economic development, setting up a salt monopoly and creating new mines and glassworks. To fight Calvinism he established the Jesuits at Pont-à-Mousson and gave over to them the university that he had founded there in 1572. The country was prosperous, and its artistic development was brilliant (J. Callot, Georges de la Tour).

The Thirty Years' War brought this happy period to a brutal end. On the one hand, French policy again became aggressive under Cardinal Richelieu (1624 #.), who wanted a frontier on the Rhine. The French grasp on Metz, Toul and Verdun was strengthened, and from a regime of "protection" they passed to one of annexation (in 1633 a *parlement* was created at Metz, and in 1648 the treaty of Munster recognized officially the possession by France of the three bishoprics, which constituted the *généralité* of Metz). On the other hand, Duke Charles IV (1604–75) abandoned the neutrality of his predecessors and sided against France, intriguing incessantly against Richelieu, until in 1633 Louis XIII invaded Lorraine. Charles spent the rest of his life in exile fighting and intriguing against France but recovered his duchy for two short periods only (1641 and 1663–70). His nephew Charles V (1643–90) never obtained effective possession of the duchy. From' 1633 to 1697 it was almost continuously occupied by the French, who established a *généralité* at Nancy. The annexation of Alsace to France had completed the encirclement of the duchy, which was itself pronounced annexed, in 1683, by the *chambre de réunion* of Metz. But defeats at the end of the 17th century forced the French to make concessions: by the treaty of Ryswick (1697) the duchy was restored to Leopold, Charles V's son (d. 1729), who had however to dismantle all his fortresses and to disband his army. Despite a new French occupation (1702–14), Leopold's reign was a period of economic reconstruction: he attracted thousands of immigrants and fostered commercial and industrial development, particularly the manufacture of cloth, lace, glass and paper. He ordered moreover the compilation of the Code Léopold. But Leopold's son and heir, Francis III, had been betrothed to Maria Theresa of Austria, daughter and heiress of the emperor Charles VI, whom he married in 1736; and France could hardly admit the union of Lorraine with the empire. The War of the Polish Succession offered an opportunity of settling the problem: negotiations opened in 1735 led to the treaty of Vienna (Nov. 18, 1738), whereby Francis, in exchange for Tuscany, ceded his rights on Lorraine and Barrois to Stanislaus Leszczynski, the dethroned king of Poland, after whose death they were to pass to his daughter, Louis XV's queen, and so to France. Stanislaus reigned but did not rule; by the secret treaty of Meudon (1736) he gave up the whole administration to a chancellor, who was in fact a French *intendant,* Chaumont de La Galaizière. Chaumont introduced the French system of taxation and reorganized the administration on a stricter basis. Stanislaus received a yearly subsidy, held a brilliant little court at Lunéville and did a lot of building. At his death (1766) the chancellor became *intendant* and the duchies of Lorraine and Bar were definitively incorporated into the kingdom of France. They formed the *généralité* of Nancy, where a *parlement* was created in 1776.

The Revolution was at first welcomed wholeheartedly by a country in which loyalty toward the monarchy had had no time to grow, and the revolutionary period was rather uneventful except for the Prussian invasion of 1792. Later Lorraine developed a particular blend of liberalism and moderate republicanism with strongly pro-French tendencies. The loss in 1814 and 1815 of the revolutionary conquests on the left bank of the Rhine and of some of Lorraine's land in the Saar was resented, and the German problem came to loom larger and larger in the people's minds. Under the treaty of Frankfurt (*1871*) the whole of Moselle and a part of Meurthe were annexed by Germany. Prince Otto von Bismarck had at first meant to take only the German-speaking districts, but the general staff, for strategic reasons, demanded the annexation of the fortress of Metz and its district (entirely French-speaking). This dismemberment of the country, which lasted from 1871 to 1918 and was repeated from 1940 to 1944 (*see* ALSACE-LORRAINE), together with the heavy physical damage brought upon it, as a borderland, by three great wars, constituted a dominant factor in Lorraine's later history.

On the other hand, industrial development has made Lorraine one of the great industrial centres not only of France but of all Europe. The soil contains the largest iron-ore deposits in Europe (about 40,000,000 tons have been extracted in certain years). The iron and steel industry began to develop under the Second Empire and made great strides on both sides of the new border after 1880, when the Thomas Gilchrist process made possible the extensive use of phosphoric ores. Unfortunately, coking coal has to be imported from the Ruhr, where much ore is sent; so that Lorraine and the Ruhr are competing but complementary. Lorraine has also important cotton, chemical, glass and pottery industries.

LORTZING, GUSTAV ALBERT (1801–1851), German composer, was born at Berlin on Oct. 23, 1801. Both his parents were actors, and when he was 19 he began to play at the theatres of Dusseldorf and Aachen, sometimes also singing in small tenor or baritone parts. His first opera, *Ali Pasclza von Jannina,* appeared in 1824, but his fame as a musician rests chiefly upon the two operas *Der Wildschütz* (1842) and *Czar und Zimmermann* (1837). The latter, although now regarded as one of the masterpieces of German comic opera, was received with little enthusiasm by the public of Leipzig. Subsequent performance in Berlin, however, provoked such a tempest of applause that the opera was soon placed on all the stages of Germany. It was translated into English, French, Swedish: Danish, Dutch, Bohemian, Hungarian and Russian.

Der Wildschütz was based on a comedy of Kotzebue, and was a satire on the unintelligent and exaggerated admiration for the highest beauty in art expressed by the *bourgeois gentilhomme.* Of his other operas it is only necessary to note *Der Pole und sein Kind,* produced shortly after the Polish insurrection of 1831, and *Undine* (1845). Lortzing died at Berlin on Jan. 21, 1851.

LORY, any of some 60 species of small (mostly 4.5 to' 12 in.), brilliantly-coloured (many with bright red) parrots (*q.v.*), with beak less toothed and tongue brush-tipped, constituting the subfamily Loriinae. Some are called lorikeets. Lories are mostly from New Guinea and adjacent islands, though ranging to southeastern Australia, New Caledonia, the Philippines and Marquesas Islands.

They fly swiftly in flocks, have shrill voices and feed mostly on soft fruits and the nectar of flowers, gathered with the bushy tongue. The four or five white eggs are laid in holes in trees. There are about 15 genera. the best known being *Domicella, Trichoglossus, Chalcopsitta, Phigys, Vini* and *Eos.* (G. F. Ss.)

LOS ALAMOS (Spanish meaning "the cottonwoods"), a town of New Mexico, U.S., and seat of Los Alamos county lies 24 air mi. N.W. of Santa Fe, at an elevation of 7.300 ft., on the summit of one of the innumerable mesas comprising the Pajarito plateau, a forested shelf on the eastern slope of the Jemez mountains.

Until 1942 the site was occupied solely by a group of log cabins and stone buildings comprising the Los Alamos Ranch School for Boys. The mesa was selected because of its comparative isolation and natural facilities as the site for the atomic research laboratory then known as the Manhattan project or Project Y which developed the first nuclear-fission or A-bomb. (*See* ATOMIC ENERGY: *The Atomic Bomb.*) After World R'ar II. the Los Alamos Scientific laboratory, operated by the University of California for the Atomic Energy commission, developed the first thermonuclear-fusion or H-bomb. The town's sole reason for existence is the Scientific laboratory. which is one of the greatest atomic research institutions in the world. The laboratory has been expanded to neighbouring South Mesa where it utilizes about 300 buildings and 77 sq.mi. Research includes basic scientific development directed toward industrial uses of atomic energy, health, radiology, organic chemistry and industrial hygiene.

By the 1960s the small complex of makeshift residential quarters for scientists had grown into the modern town of Los Alamos. (For comparative population figures *see* table in NEW MEXICO: *Population.*) In 1949 it was named the seat of Los Alamos county. the state's newest and smallest county (area 108 sq.mi.), created from part of Sandoval county. In Feb. 1957 it was made an "open city" which anyone could visit, although only persons who are employed there can take up permanent residence. The commission-manager form of municipal government was adopted in 1955.

The Bandelier National park is 5 mi. S.. and the Puye pre-Columbian ruins are a few miles north of the town. (FR. W.)

LOS ANGELES. A vast, sprawling metropolis, seat of Los Angeles county, located in southern California, U.S., was, until 1961, the largest city in area (458 sq.mi. in 1960) and the second largest metropolitan centre of the nation. It has an average altitude of about 275 ft., ranging from sea level to 1,692 ft. atop Mt. Hollywood. The geographical setting between the mountains and the sea is attractive; the central commercial district lies several miles from the Pacific ocean on a coastal shelf extending inland to the foothills of the San Gabriel mountain range.

The original Spanish town or pueblo, located close to a series of man-made water ditches or *zanjas* that drained water from these mountains, was built around a square, which is the historic plaza area of the modern city. Urban growth was to the south, east and west from this original nucleus, especially after the coming of the railroads in the 1870s. Separate municipalities, by the 1880s, sprang up nearby, of which Pasadena (*q.v.*) is the largest; others whose interests are closely bound with Los Angeles include Alhambra, Burbank, Compton. Culver City, Glendale, Huntington Park, Inglewood, Long Beach, Santa Ana, Santa Monica, South Gate and Torrance (*qq.v.*). A sizable spur of foothills toward the west, which for a time blocked expansion in that direction, was eventually pierced by tunnels and boulevards. The problem of access to the sea was solved by annexation of a strip of land, about 20 mi. long, and $\frac{1}{4}$ mi. wide, known as the "shoestring strip." This corridor connects the metropolis with Los Angeles harbour. The city touches the ocean at the annexed to ns of San Pedro, Wilmington and Venice, and entirely surrounds such separate municipalities as Beverly Hills (*q.v.*), Vernon and San Fernando. There are about 45 relatively large municipalities within Los Angeles county (area 4.155 sq.mi.). Among them is Hollywood (*q.v.*), 8 mi. N.W. of the business district which by annexation is municipally a part of Los Angeles, but retains its name and business entity. A city ordinance, repealed in 1957, that limited the height of buildings to 150 ft.. encouraged the decentralization of Los Angeles.

Climate. — Little variability is the chief characteristic of the climate at Los Angeles and in southern California generally. Winter is a season of moderate rainfall, 15.23 in. yearly being the average. There is relatively little rain from May to October. Winter days are sunny and warm and the nights are often cold, with occasional frost in December and January. A 50-year average of the records of the U.S. weather bureau shows the mean temperature to be 62.4". There is a 72% possibility of daily sunshine, an average of 179 clear' days each year, and only 37 days with more than .01 in. of rain. However, serious floods have occurred, notably in 1914 and in 1938; the greatest disaster was in 1928 when the St. Francis dam unit of the Los Angeles aqueduct collapsed resulting in violent floods of the Santa Clara river through Los Angeles and Ventura counties. Los Angeles experienced a moderate earth tremor about once every five years during the first half of the 20th century. The earliest recorded earthquake occurred in 1769 when the expedition led by Gaspar de Portola (see *History,* below) reached the banks of the Santa Ana river, which was appropriately named El *Rio del dulce nombre de Jesús de los temblores* ("the river of the sweet name of Jesus of the earthquakes").

The average wind velocity of only 6.1 mi. per hour, one of the lowest of any major U.S. city, has directly contributed to Los Angeles' modern problem, a seriously detracting climatic factor locally called smog. Pollution of the atmosphere by choking, noxious fumes causes uncomfortable eye irritation and has led to the establishment of an air pollution control district, operated by the Los Angeles county board of supervisors. This agency has conducted studies which traced smog to three main sources: automobile exhausts. industry and home incinerators. In 1956–57 local regulations forbade the burning of trash, and home incineration was replaced by the city's first thorough municipal rubbish collection system. Surveillance of industrial air pollution failed to reduce the climatic discomfort of Los Angeles. Two warning systems (one anticipatory, the other remedial) had to be instituted for the protection of health by averting hazardous concentrations of contamination. Eye irritation is especially severe in the summer months.

Population Characteristics. — In the past, the relationship of good climate to spectacular growth marked the development of Los Angeles. Sunny skies and the attractions of outdoor life caused population within the city limits to soar from 576,673 in 1920 to 1,238.048 in 1930. Further increase in the 1930s occurred partially because of the immigration of job hunters from depressed areas, retired persons and Hollywood aspirants. According to the census bureau. the city's population grew from 1,504.277 in 1940 to 1,970,358 in 1950. By 1960 it ranked as the third largest city in the U.S. The population booms of the 1880s and 1920s were eclipsed during and after World War II when expansion was accelerated by a huge influx of workers for defense industries such as airplane, missile and ship construction. The 1960 census of city and county population was 2,479,015 and 6,038,771 respectively. The Los Angeles-Long Beach standard metropolitan statistical area, comprising Los Angeles and Orange counties, had reached a population of 6,742.696 in 1960 and so surpassed greater Chicago as the nation's second largest population mass. Demographers forecast a population of 10,500.000 persons for the Los Angeles metropolitan area by 1975, when the city should (if annual population growth of about 240.000 should continue) become the largest in the U.S. The population. aside from groups that characterize other large American cities, includes considerable numbers of Mexicans. Chinese, Japanese and Filipinos.

History.—On hug. 1, 1769 a Spanish exploring expedition under Gaspar de Portolá (*q.v.*) and Father Juan Crespi, traveling northward from the peninsula of Lower California through San Diego, reached an Indian village called Yang-na near a stream, at the present site of Los Angeles. They named the place Our Lady Queen of the Angels (*Nuestra Señora* la *Reina* de Los Ángeles), The Indian settlement remained relatively undisturbed for 12 more years. Then, on Aug. 18, 1781, as part of Spain's design to colonize California more thoroughly, the future city's first permanent residents arrived after a 100-day march northward from Mexico through the blistering heat of the deserts. These humble, mostly illiterate folk consisted of 12 families (46 persons in all), of mestizo (Spanish-Indian), Negro and Spanish blood. On Sept. 4, 1781, California's Spanish governor, Felipe de Neve, gave the community of Los Angeles official status as the territory's second (after San Jose, founded in 1777) pueblo.

The nearby Franciscan mission of San Gabriel—still in existence as an intact landmark—had been established ten years earlier a few miles from the centre of the new pueblo. Development of a better overland route from Sonora and Sinaloa to California (opened as early as 1775 by Juan Bautista de Anza) markedly increased the number of travelers that had come over the Lower California route. The new arrivals cleared the wild mustard and sagebrush and settled upon land grants given them by Spain's authority. They thereby began the great southern California ranchos of the future, some of which were to be larger than whole European countries.

After Mexico's independence from Spain (1822) frequent political disturbances and revolts hampered the social and economic stability of the little town. The few Americans who visited it during this period included the fur trapper Jedediah Strong Smith, the first white man to come overland, in 1826. via San Gabriel mission: from the Missouri river frontier settlements. In search of beaver and land otter. Smith preceded the first organized overland pioneers (the William Workman-John Rowland party of 1841) into Los Angeles by 15 years. During the 1830s, however, other American fur trappers such as James Ohio Pattie and Ewing Young reached Los Angeles, pioneering the future western routes of the covered-wagon migrants.

In 1835 the Mexican congress declared Los Xngeles the capital of California, an edict that was hardly enforced by governors who favoured the north. For a time, just prior to the C.S. conquest of 1846, Gov. Pio Pico, California's last Mexican governor, removed the capital to Los Angeles. The city was rent by north-south and local factional quarrels when war broke out between Mexico and the United States. With the appearance of C.S. troops under Commodore Robert Field Stockton and Capt. John Charles Frémont (*qq.v.*), the Mexican defenders of Los Xngeles fled and the U.S. flag was raised over the city on Aug. 13, 1846. An insufficient garrison of 50 men, left in control, was compelled in October to withdraw because of a revolt of the inhabitants, and Los Angeles was not retaken until Gen. Stephen Watts Kearny and Commodore Stockton entered the city from San Diego in Jan. 1847.

After a short period as a military garrison Los Angeles reverted to civilian rule under U.S. control. On April 4, 1850, the city was incorporated and became the county seat. and in that year the first English-language school was opened and the first Protestant church established. Los Angeles thrived upon a big cattle trade with California's northern mines. At first a lawless frontier town, the files of the Los Angeles Star, southern California's first substantial newspaper, are filled with stories of almost routine daily violence during the 1850s and 1860s.

Until the building of the railroads, large-scale immigration remained limited by California's remoteness and isolation. Distance alone. not to speak of such natural barriers as deserts and almost impassable mountains, restricted communication with the rest of the world. Such travelers as ventured to the west in the two decades after the gold rush of 1848–49 tended to move toward San Francisco, then a larger, more cosmopolitan, better-known city. In 1869, however, the transcontinental railroad era damned. Before that time (1866), Pres. Andrew Johnson confirmed the city's Spanish and Mexican pueblo land titles (consisting of 17.000 ac.). This action was particularly important as the claims of numerous residents under grants issued by the original pueblo rested on these titles.

Los Xngeles finally attained a railroad connection with San Francisco in 1876, and with the eastern U.S., via the Santa Fe system, in 1885. An immense tide of immigration soon thereafter enveloped southern California, partly because of a vigorous rate war between the Southern Pacific and Santa Fe railroad companies. In the year 1887 railroad fares from Los Angeles to Chicago (and other Mississippi valley terminals) dropped to $1. The dawn of the railroad age held commercial implications for Los Angeles as well as increasing its population. As early as 1877 local growers sent a carload of oranges eastward by rail. Then began a new era of horticultural enterprise. The railroad rate war and a simultaneous land boom soon created thousands of new customers for southern California's farmers and merchants. A significant proportion of the travelers to Los Xngeles in the 1880s became permanent settlers. It is from the real estate boom of 1887 that the tourist era also dates.

But Los Angeles, located 20 mi. from the ocean, could not expect to become a great metropolis without a harbour. San Pedro. an open roadstead, with scanty protection from the sea. had served as its only port facility. Before a harbour was finally built, a long political battle ensued with Collis P. Huntington and Southern Pacific railway interests. These wanted a $4,000,000 facility built: with government subsidy, at Santa Monica, rather than in the San Pedro-Wilmington area. The struggle over the site of the city's future harbour, with San Pedro favoured by a civic group known as the Free Harbour league, did not come to an end until 1896. That year the U.S. congress voted an appropriation of $2,900,000 to build an artificial harbour for Los Angeles at San Pedro, thereby defeating the Huntington interests. Three years later the city celebrated the Free Harbour jubilee and 20.000 persons gathered at San Pedro to watch the dumping of the first barge of stone for a breakwater. Construction of the harbour was finally completed in 1914 and. aided by traffic through the new Panama canal, Los Xngeles began almost immediately to benefit by this new world trade route. Thereafter the history of Los Angeles was marked by continued commercial and industrial expansion, and civic improvements.

Administration and Finance.—The city of Los Angeles is governed under a charter in operation from July 1, 1925. It provides for the initiative, the referendum, the recall and an executive budget. Elected at large are the mayor (the chief executive, with wide powers of appointment), the city attorney, the controller and seven members of the board of education. The 15 members of the city council (the legislative body) are elected by districts for a term of two years. They handle budget and tax problems, public improvements and local civil service matters. The principal functions of government are entrusted to 16 commissions of 5 members each, appointed by the mayor. which appoint and fix the salary of general managers for their departments. There is also a municipal housing commission consisting of 12 members together with 4 judges and the president of the chamber of commerce. All the above groups work in co-operation with a powerful board of county supervisors, who govern both urban and rural areas and control the many special districts and agencies in Los Angeles county.

In Southern California banking developed later and on a smaller scale than in the northern part of the state. Banks existed in San Francisco 15 years before they were established in Los Angeles. The first city bank mas opened by Isaias W. Hellman in 1865. In 1868 Hellman bought out the rival bank of William Workman and his son-in-law Francisco P. F. Temple and in 1871 joined forces with California's Gov. John G. Downey to form the Farmers and Merchants bank, which became Los Angeles' first large bank. The development of the city as southern California's banking and financial centre was the natural outcome of population growth. Los Angeles has long been the home of numerous building and loan associations which have supplied much capital for real estate development. This capital is invested directly in land, buildings, oil and manufactures and there is also a large local investment in securities. The area is ranked as the third largest financial centre in the U.S.

Commercial and Industrial Development. — The economy of greater Los Angeles is exceedingly varied as well as dynamic. The reasons for its continuing prosperity were many and diverse.

Agriculture.—The city's first commerce was highly agricultural. Following the gold rush of 1848–49 the growth of population furnished an urgent market for cattle, grain and other foodstuffs. Prior to 1860 fully 60% of California's population was engaged in mining; the southern counties, of which Los Angeles was the centre, became the agricultural suppliers of this moneyed population. In 1850 cattle sold for as high as $500 per head and the great ranchos of the south flourished. Until drought conditions and falling prices in the 1860s damaged the sheep and cattle industries, Los Angeles was known as "queen of the cow counties." Grain, wheat and fruit production also made Los Angeles important agriculturally. Wine was made from the mission variety of grape from the early Spanish period. As early as 1831 there were about 100 ac. of vineyards at Los Angeles, containing about half of the state's 200,000 vines. The Camulos rancho at nearby Ventura was renowned for its fruit long before the gold rush occurred. William Wolfskill and Don Luis Vignes experimented on a small scale with the growing of grapes and oranges throughout the 1860s on the site of the modern downtown area.

It was the orange industry that first brought Los Angeles widespread agricultural acclaim. At nearby Riverside (*q.v.*) in 1873 Luther Calvin and Eliza Tibbets planted the first Washington navels, a new variety of seedless orange from Bahia, Braz. The climate and soil proved so well suited to this species of orange that it attained an agricultural perfection unmatched by any other fruit. The new industry added immeasurably to the commercial stability of Los Angeles. With the development of large-scale wine production at nearby Cucamonga, egg production in the San Fernando valley and a big dairy industry at Norwalk, Los Angeles achieved agricultural maturity well before the turn of the 20th century.

At mid-20th century Los Angeles county had led the nation in the value of its agricultural production each year since 1910. The city was a marketing centre for a wide diversity of crops, including oranges, lemons, apricots, peaches, almonds, walnuts, truck vegetables, figs, avocados, poultry, grain, alfalfa, livestock and dairying. The first outstanding success in co-operative farm marketing was made by the orange industry's local California Fruit Growers' exchange. This organization, as well as the California Walnut Grower's association, and the avocado and lemon exchanges, established headquarters in Los Angeles. However, agriculture steadily yielded large areas of fertile land formerly devoted to the raising of crops and livestock to real estate subdivisions, defense plants, new industrial establishments and space-consuming freeways. Los Angeles county's status as a leading county in agricultural production slipped markedly as the area became increasingly industrialized.

Manufactures.—Early manufacturing was chiefly for local needs and included such products as soap, confectioneries (utilizing locally grown sugar beets), beverages and brewing, as well as household goods. By 1925 Los Angeles, nevertheless, ranked first among California cities with a manufacturing output valued at more than $500,000,000, a payroll of 58,000 and an annual wage expenditure of $86,000,000. A significant feature of this development was the shifting of manufacturing leadership from San Francisco to Los Angeles. In 1900 San Francisco ranked first among California's manufacturing cities but by 1910 had shown little increase in output while Los Angeles had advanced 100% in the same period. The shortages created by World War I further encouraged industrial enterprise at Los Angeles. World War II, with its Pacific fronts craving supplies, further stimulated, indeed forced, rapid industrial progress. By mid-20th century Los Angeles was a leading manufacturer of military and commercial aircraft.

After the war, the city had about 10.000 factories in the metropolitan area and by the early 1960s the number had increased to more than 16,000. Production of transportation equipment, motion pictures, fabricated metal products, machinery, petroleum products and printing formed a large part of this activity. Los Angeles also ranks as a fashion centre for sportswear and women's apparel; glass, chemicals, cement, paints, food processing and fish canning are also leading products. Until Japan entered the world market, southern California for decades had what amounted to a monopoly on the packing of tuna and Los Angeles became the largest fish-packing (including sardines) and fish-distributing centre in the U.S. Production of fish meal and fish oil are important by-products of this industry. Branch plants of eastern U.S. concerns are engaged in automobile assembling and the manufacture of tires, furniture, glass, textiles, tin cans, paper, steel and metal articles. Before the Fontana steel mill was built in 1942, Los Angeles foundries relied upon scrap and pig iron from England, Belgium and Utah and upon coke from Colorado.

Motion Pictures. — Reliable constancy of sunshine and varied scenery brought the motion-picture industry to Los Angeles. As late as 1909 only 4,000 people were living in Hollywood. At the turn of the century, with ample land for studios, it became with Universal City, Burbank and Culver City an international centre for this industry. By the 1960s, however. television had changed the nature of the industry as even the largest studios gave way to the production of films for TV. At the height of its success Hollywood employed more than 100,000 persons in the making of films. (See HOLLYWOOD; MOTION PICTURES.)

Natural *Resources.*—Petroleum and water power were the first resources developed on a large scale. Electricity was generated in the mountains and Los Angeles pioneered long-distance electric power transmission and the linking of large electric networks. Within a radius of 300 mi are valuable deposits of metals and minerals: copper, petroleum, soda, salt, potash, silica, infusorial earth, talc, graphite, limestone, building stone, marble and onyx. Except for utilization of borax and iron (from nearby Eagle mountain) these resources have not been widely exploited.

Associated with Los Angeles as much as oranges or motion pictures, however, has been large-scale oil production. A natural bituminous pitch, oozing out of the earth and called brea, was used by the Indians and early Spaniards to coat the roofs of their dwellings. After crude experiments to distill this product, in the 1850s and 1860s, there followed the colourful era of Edward L. Doheny who began the first widespread development of the gas and oil fields surrounding the city in the 1890s. Several oil companies mere founded within the first decades of the 20th century and vast quantities of oil were taken from newly discovered Signal Hill (1921), Santa Fe Springs (1921) and Huntington Beach (1920). The production of these three nearby fields was so great that they frequently upset the national oil price, storage and distribution structure throughout the 1920s and 1930s. Hundreds of millions of barrels were produced by these and other Los Angeles wells. Not only did the petroleum industry enrich many individuals; it also became a great source of revenue for the state and provided widespread employment. The oil industry also helped make Los Angeles a transportation hub for ships, the railroad and, later, the trucking industry.

Transportation —The development of transportation for Los Angeles has a long and colourful history. After U.S. occupation (1847) regular sea trade was established between San Pedro harbour and San Francisco, and mail was carried fortnightly by land between the latter city and Los Angeles. The first freight wagon overland from the east arrived in 1851, the first overland stage in 1858. In 1860. a ten-day pony express linked Los Angeles with the Missouri river. A local railway from Los Angeles to San Pedro harbour was opened in 15'69. The Southern Pacific railway from San Francisco to Los Angeles was completed in 1876. Until the Santa Fe connected the city with the east in 1835 the Southern Pacific company, under Collis P. Huntington, enjoyed a virtual monopoly of railroad transportation throughout California and into Los Angeles. By the 20th century this monopoly had been broken and the city had three direct railways to the east.

A municipal transport system of buses links the city with its harbour, beaches and various airports. At one time the Pacific Electric railway, a subsidiary of the Southern Pacific, had 1,161 mi. of track radiating from downtown Los Angeles to points as far outside the city as Redlands and Balboa beach. These inter-urban rail lines gave way to bus routes. Los Angeles is a terminal for various national highways and, because of the heaviest per capita density of automobiles in the world (more than 3,000,000 registered autos), is a natural centre for California's widespread freeway system (part of a master plan of highways to solve the traffic problem) which carries a heavy truck and bus traffic.

Los Angeles is also a travel centre for the southwest and several thousand visitors arrive daily by train, bus, car, ship and airplane. Hotels, apartment houses, motels and trailer courts cater to the tourist traffic.

Air service is available for transportation northward and eastward and Los Angeles has also become a terminus for the polar air route to Europe. Its International airport ranks high in the nation in volume of commercial passengers and freight. Other nearby airports are located in Van Nuys and at the Lockheed air terminal in Burbank.

The Port of Los *Angeles.*—By sea the city also maintains shipping connections to all parts of the globe, as well as a coastal traffic to both Pacific and Atlantic ports of North and South America. In Spanish times San Pedro bay afforded an uncertain roadstead, chosen because of accessibility by level land route to the city. Despite a stage route (1852) to the harbour and later a railroad, San Francisco enjoyed most of the sea trade in the 19th century. The lengthy squabble over the future site of Los Angeles harbour ended with the annexation in 1906 of the "shoestring strip" to the ocean, giving Los Angeles municipal jurisdiction over its future harbour, the annexation of San Pedro and Wilmington (1909), the building of a breakwater by the U.S. government (1910) and of an inner harbour by the city itself (1912–14). Cargo shipments increased eight times in both tonnage and value, in the decade 1920–30. With more than 40 mi. of water front, and superior accommodations for large ocean-going vessels, facilities were enlarged in 1941 in co-operation with the separate harbour at Long Beach. After World War II Los Angeles became second only to New York in tonnage of U.S. export harbour commerce. Chief imports of both are bananas, newsprint: copra, rubber, coffee, sodium nitrate, jute, iron and steel scrap, vegetable oil and fibres. Chief exports include oil, cotton, borax. citrus fruits, asphalt, steel plates, industrial chemicals, pipes, tubes and fittings: canned fish, machinery, chemicals and automobile tires. Los Angeles harbour is an operating centre for the U.S. navy.

Water **Supply.**—Los Angeles required an unrelenting supply of mater for industrial and domestic purposes. Located in a semi-desert region, water was crucial to its growth. In 1904 William Mulholland, chief engineer of the city's water department, suggested an aqueduct to the Sierra Nevada range through the Mojave desert. By 1908 city bonds were voted, and work begun upon a most controversial project which virtually depleted Owens lake and turned part of the southern Sierra into a desert wasteland. Los Angeles aqueduct, finished in 1913, was 233 mi. in length and the longest work of its kind in the world. The cost of construction was nearly $25,000,000, including 142 tunnels, 97 mi. of covered conduit, 12 mi. of siphons, 39 mi. of lined canal, and 24 mi. of unlined canal. Despite a daily capacity of 288,000,000 gal., and additional water supplies from the Los Angeles river, by the 1930s the city began to fall seriously behind in its water requirements Construction in 1936 of the giant Colorado river (*q.v.*) aqueduct, part of a $220,000.000 project piercing six mountain ranges with 38 tunnels totaling 108 mi., afforded an additional allotment of 677,000,000 gal. daily and provided a new water supply to 13 cities in the metropolitan district. The major electrical energy comes over a transmission line of 266 mi. from Hoover (formerly Boulder) dam. By the 1950s the city was keenly aware that new sources of water supply would have to be developed. However, California's water problems became ensnarled in a bitter north-south sectional controversy over retention of water rights by northern "counties of origin" which were reluctant to release further water resources to a seemingly insatiable Los Angeles. The north needed flood control projects almost as much as the south needed mater, but political factionalism stymied co-operation in launching such remedial programs as the controversial Feather river project. which finally was begun officially in 1960.

Cultural and Educational Activities. — In addition to its numerous well-known "motion-picture palaces," Los Angeles supports considerable legitimate theatre. Hollywood is the centre of energetic little theatre activity. The Player's Ring, Huntington-Hartford theatre and Pasadena's Community playhouse are familiar sites. Extensive television and radio facilities have been built in Los Angeles, from which many national and regional network programs emanate.

Grand opera is usually presented in Shrine auditorium, seating 7,000 persons. Orchestra programs and other recitals are given in the Philharmonic auditorium. As the climate makes outdoor entertainment attractive. the city has a number of gathering places such as the Los Angeles coliseum seating 105,000 persons, a sports arena for athletic events and conventions (35,000), Hollywood Bowl (25,000), the adjoining Pilgrimage Play amphitheatre and outlying auditoriums, such as the Pasadena Rose Bowl (89,000). The Symphony Under The *Stars* is presented in Hollywood Bowl and ballet and outdoor drama are presented each summer at the municipal Greek theatre in Griffith park.

The Los Angeles County Museum of History, Science, and Art in Exposition park exhibits skeletons of prehistoric mammals from nearby La Brea pits. It also maintains an important art museum located near the state museum of science and industry. The Southwest museum at Highland Park specializes in the civilizations of the southwestern United States, Mexico and Central America and is particularly strong in materials concerning the American Indian. Its Casa de Adobe is a replica of an early Spanish colonial home, complete with furnishings. At Barnsdall park in Hollyhock house, a structure of Mayan inspiration, built in 1913 by Frank Lloyd Wright, is located the Municipal Art gallery. the site also of cultural activities and small musicales. City zoos are located at Elysian and Griffith parks. At Griffith observatory are 12- and 6-in. refracting telescopes, a 3-in solar telescope; a museum of the physical sciences; and a planetarium. The function of these latter facilities is to interpret the universe to the visitors nho patronize the observatory's educational program.

Numerous professional writers, artists and architects have been attracted by southern California and have made Los Angeles and Hollywood their home.

The Los Angeles public library with more than 60 branch*s has about 2,250,000 volumes. The Los Angeles county public library, also with more than 60 branches, has over 1,000,000 volumes. The city has special libraries belonging to colleges, professional associations and business concerns, devoted to law, medicine, architecture, mining, petroleum, minerals and industrial subjects. One of these is the William Andrews Clark library of the University of California (devoted to the collection of books on Anglo-American civilization) and the Henry E. Huntington library and art gallery (at nearby San Marino) which is rich in rare books and manuscripts, mostly English and American, with collections of incunabula. There is also an outstanding collection of portraits and landscapes of the English painters of the "golden age"— Thomas Gainsborough, Sir Joshua Reynolds, Sir Thomas Lawrence and George Romney. The J. Paul Getty museum, near Santa Monica, includes collections in two major fields: French 18th-

H. ARMSTRONG ROBERTS

VIEW OF DOWNTOWN LOS ANGELES SHOWING THE CITY HALL ON THE LEFT

century art and Greek and Roman sculpture.

Enrollment in the Los Angeles public schools during the early 1960s totaled more than 600,000. In a 15-year period after World War II, enrollment in the city's high schools increased by 60% while elementary school growth during the same period was 75%.

Among the major institutions for higher education, in order of their founding, are: (1) the private coeducational University of Southern California (1880), in the central part of the city; (2) Occidental college (1887), located on an attractive campus in the Eagle Rock section, at the northern border of Los Angeles, a private coeducational college devoted to the liberal arts and sciences; (3) California Institute of Technology (1891), at Pasadena, a private institution whose work is largely confined to scientific and engineering subjects; it is notable for pure science and research. At the Institute's Jet Propulsion laboratory the United States' first earth satellites were constructed in 1957; (4) Loyola University of Los Angeles (1911), Roman Catholic, with courses in engineering, commerce, premedical studies and law; (5) the public University of California at Los Angeles (1919), on a huge, sprawling campus at the western border of the city; it is increasingly graduate in character, but gives complete university training. Its facilities include schools of law, medicine and engineering. Other nearby public institutions are Los Angeles state college (1947) and San Fernando Valley state college (1956). Located in greater Los Angeles are Whittier college (1901) ; the Associated colleges, five institutions at Claremont, and Redlands university (1907). All except the state institutions were founded by religious denominations but, by agreement with their respective churches, many gave up all organic denominational connection early in the 20th century.

Parks and Recreation. — Los Angeles city and county maintain several hundred parks, playgrounds, swimming pools and youth centres. Among these are: Griffith park, 4.253 ac.; Exposition park, 114 ac., with Los Angeles museum; Elysian park, 599 ac., in a natural state; Sycamore grove, 15 ac., Lincoln park, 46 ac., and Pershing square, the only park in the business section besides the old Spanish plaza. At the latter is the old Plaza church, one of the plaza's many historic buildings dating from the period 1800–12 onward. Nearby are the Lugo house, the city's first multistory building, dating from 1840 when it was built by Don Vicente Lugo; it was later used for a time by St. Vincent's college (later Loyola university) as its first campus. Olvera street, called El Paseo by the Spaniards, is a brick walkway named for Don Agustin Olvera, and visited traditionally by tourists. Avila adobe, a private museum on this street, was built in 1818 by Don Francisco Avila; surrounding it are several dozen shops that sell Mexican handicrafts, including several candlemaking establishments. Also near the Plaza and Olvera street there stands the Pico house, a hotel on Main street built in 1869 by Gov. Pio Pico.

Another tourist attraction is La Brea pits. Located further west on Wilshire Blvd., these "pitch springs," as they were known when utilized by the Indians, were discovered by the Portolá exploring expedition of 1769. These fossil-bearing tar pits, containing prehistoric remains of extinct animals once caught in sticky seepage, came into the possession of G. Allan Hancock, who gave them to the city in 1915 for park development purposes. Hancock park now contains life-size restorations of such prehistoric animals as the sabre-toothed tiger, mastodon, giant ground sloth and prehistoric camels and bison.

Many tourists visit Mt. Wilson, site of the 100-in. Carnegie telescope located northeast of the city, Lake Arrowhead and Big Bear lake in the San Bernardino mountains and Santa Catalina island. 23 mi. S.W. from San Pedro. Other attractions include Disneyland. Knott's berry farm, Pacific Ocean park and the Marineland of the Pacific, an oceanarium near Palos Verdes.

Since 1957 Los Angeles has been the home of the former Brooklyn Dodgers, a professional major (National) league baseball club. In 1961 the Los Angeles Angels, an American league club, began play. The Los Angeles (formerly Cleveland) Rams of the professional National Football league are also located there.

City Planning and problems of Growth. — Once a sleepy pueblo of red-tiled, whitewashed adobe buildings and muddy streets, the town presented a distinctive impression upon travelers in former times. Its population at the turn of the 20th century was 102,489 inhabitants. Baedeker's Guide said in 1899 that within the preceding decade "its adobe houses have given place almost entirely to stone and brick business blocks and tasteful wooden houses." The typical "California house" of the early 20th century was frequently an adaptation of Spanish design and the bungalow from India. In fact, southern California's architecture is still highly eclectic. The Monterey-style house, with its balconies and terraces became especially popular. Stucco or wood frame construction were alternately featured by builders who pioneered real estate tracts that mushroomed interminably in a horizontal construction boom that eventually obliterated the Los Angeles countryside.

Only after 1925 did the city develop a real civic centre, with its nearby Spanish-style union passenger railroad terminal and accompanying government buildings. By the 1960s these developments were giving way to massive redesigning of the city's entire civic centre. A central mall became the site of a series of city, county, state and federal buildings. Slum clearance and relocation developments were simultaneously transforming the Bunker Hill region into a new commercial and residential area. After the removal in 1957 of a 150-ft. height maximum on public buildings came the construction of many 20- to 40-story buildings that line 15 mi. of the city's central sector and its westward extension into the Wilshire boulevard district with an increasingly vertical skyline of apartment houses and office buildings.

Construction of freeways. parks, airfields, schools, fire stations, libraries, sewers and other facilities on the city's expanding periphery barely kept up with the population avalanche that came to Los Angeles after World War II. Statistics for the 1950s indicated that on the average one new person enters southern California every 55 seconds. A new school was needed for additional pupils every Monday morning into the 1960s. Each year Los Angeles added a city larger than Syracuse, N.Y. The costs of such expansion were great as municipal plans became obsolete even before they emerged from blueprints.

All this frenzied growth was not without concern to those residents who knew the city when it was a pleasanter place in which to live. The smog, increased traffic congestion, industrialization and other municipal problems decreased the charm of rural and suburban living. The traditionally colourful orange groves and vineyards made way for aircraft factories, steel mills, housing developments and large apartment construction. Nevertheless there was no evidence that migration to southern California in general, and Los Angeles in particular, would taper off. The pattern indicated the city would move outward to swallow up even more of its countryside. Population experts predicted a vast urban complex stretching almost solidly from Santa Barbara to San Diego, its centre — and controlling focus — Los Angeles.

LOS ISLANDS (ISLAS DE LOS ÍDOLOS), a group of islands off the coast of Guinea, West Africa, south of Sangarea bay. and about 80 mi. N.N.W. of Freetown. Sierra Leone. There are five principal islands: Tamara. Factory. Crawford. White (or Ruma) and Coral. The two largest islands are Tamara and Factory. These two islands lie parallel to each other. Tamara to the west; they form a' sort of basin, in the centre of which is the islet of Crawford. The two other islands are to the south. The archipelago is of volcanic formation. Tamara and Factory islands forming part of a ruined crater. with Crawford Island as the cone. All the islands are richly clothed with palm trees and flowering underwood. The inhabitants are immigrants of the Baga tribe of Senegambian Negroes, whose home is the coast land between the Pongo and Nunez rivers. In 1818 Sir Charles McCarthy, governor of Sierra Leone, obtained the cession of the islands to Great Britain from the chiefs of the Baga country, and in 1882 France recognized them to be a British possession. By the Anglo-French convention of April 8, 1904. the islands were ceded to France. In Oct. 1958, French Guinea became the Republic of Guinea, and Los Islands became part of it.

LOS RÍOS, province in the coastal lowland of Ecuador, bounded west by Guayas, north by Pichincha and Cotopaxi, east by Bolivar and south by Guayas. Area, 2,292 sq.mi. Pop. (1960 est.) 219.800. Its capital is Babahoyo. pop. (1959 est.) 13.100. The province is mostly in the lowlands west of the mountains, along the middle courses of the Rio Vinces and of the Río Babahoyo. tributaries of the Rio Guayas. The chief land use is for beef cattle, bananas, cacao. sugar cane and rice. From the forests come balsa wood, timber, tagua nuts and rubber. As the name suggests, transportation is almost entirely by river boat to Guayaquil. Steamers reached Babahoyo even during the dry season and in flood season can ascend to Zapotal. (P. E. J.)

LOS SANTOS, a small province in southern Panamá occupying much of the hilly, Azuero peninsula and facing the Gulf of Panamá. Area, 1.494 sq.mi. Pop. (1960) 70.372, of which 70% was rural. The largest town and capital is Las Tablas, pop. (1960) 3.326; it is 8 mi. N.W. of the port of Mensabé. Los Santos is important agriculturally, ranking high in the production of corn, rice, sugar, swine, cattle and poultry. The province is a major supplier of eggs and chickens to the urban centres in and near the Canal Zone, to which it ships products by boat and truck. (C. F. I.)

LOSSIEMOUTH, a seaport and small burgh of Moray, Scot., at the mouth of the Lossie on the Moray firth, $5\frac{1}{2}$ mi N. of Elgin. Pop. of burgh (1961) 5,855; area 0.7 sq.mi. Lossiemouth, or the old town, dates from 1700, Seatonn is somewhat later, Branderburgh, farther north, grea nith the harbour and began about 1830 and Stotfield is now purely modern, although on the site of the oldest settlement. In the 15th century Lossiemouth succeeded Spynie as Elgin's port. when that tonn was silted up by sand and shingle, but it declined nith the migration of the herring until its popularity as a seaside town brought back its prosperity. There are long sandy beaches and a fine golf course. Fishing is still the main industry (whitefish only) and the town has a fleet of 80 seine-net boats. J. Ramsay MacDonald (1866–1937) was born in Lossiemouth. The cliffs at Covesea, 2 mi. \Ir.. contain caves, in one of which prehistoric weapons were found and the roof of another is carved with early Celtic ornamentation. On the coast is Covesea lighthouse.

Nearly midway between Lossiemouth and Elgin stand the massive ruins of the palace of Spynie, formerly the castle of the bishops of Moray. The large toner, with walls nine feet thick, was built about 1470.

LOSSKI, NIKOLAI ONUFRIEVICH (1870–), Russian philosopher, was born at Kreslavka near Vitebsk on Dec. 6, 1870. He was educated at Kreslavka and at the University of St. Petersburg (Leningrad), where he was professor, 1916–21. In 1922 he was compelled to leave the U.S.S.R. and went to live in Prague. He nas a professor in Bratislava, 1942–45. After World War II he emigrated to the U S. and became a professor in the Russian Orthodox seminary, New York (professor emeritus, 1950). According to Losski's viens, knowledge is immediate contemplation (intuition). His intuitionalism differs from Bergson's in so far as he considers the ideal-rational forms to be elements of realities, intuitively cognizable. Losski assumes not only concrete real being, but concrete ideal being as well; *i.e.*, supratemporal and supraspatial substantial agents nith creative force, which are the basis of spatiotemporal being. This doctrine leads Losski to his teaching of the freedom of the will. Among Losski's most important books are *Die Grundlehre der Psychologie vom Standpunkte des Voluntarismus,* published in Russian (1903), in German (1905); *The Intuitive Bases of Knowledge* (1904; Eng. trans., 1919); *Handbuch der Logik* (1922); *Tlze World as an Organic Whole* (Eng. trans.. 1928); *Freedom of Will* (Eng. trans. 1932); *Value and Existence* (Eng. trans . 1935); *Des conditions de la ntorale absolue* (French trans.. from Russian manuscript, 1948) ; and *History of Russian Philosophy* (1951).

LOSTWITHIEL, a market tonn and municipal borough in the Bodmin parliamentary division of Cornwall. Eng., on the Fowey river, 6 mi S.S.E. of Bodmin. Pop. (1961) 1,954. Area 4.9 sq.mi. St. Bartholomem's church has a fine Early English tower and a Decorated spire. A bridge of the 14th or early 1jth century crosses the river. The Shire hall or Duchy palace includes remains of a building, called the Stannary prison, dating from the 13th century. The Western Region railway route has workshops there. The boundaries of the borough were further extended in 1934.

Lostwithiel probably owed its existence to the neighbouring circular castle of Restormel, restored in 1930. The first charter dates back to about 1190. The Pipe Rolls (1194–1203) show that Robert de Cardinan, lord of Restormel, paid ten marks yearly for having a market at Lostwithiel. He surrendered to the burgesses all the liberties given them by his predecessors (*antecessores)* mhen they founded the town. Isolda, granddaughter of Robert de Cardinan, gave the town to Richard. king of the Romans, who granted to the burgesses a guild merchant and many privileges, as well as a yearly fair and a weekly market. His son Edmund decreed that the coinage of tin should be at Lostwithiel only. In 1609 a charter of incorporation provided for courts of record and piepowder. From 130j to 1832 two members represented Lostwithiel in parliament, but under the Reform act (1832) the borough became merged in the county.

For the victory gained by Charles I over the earl of Essex in 1644. *see* CIVIL WAR. ENGLISH.

LOT, in the Bible, the legendary ancestor of the two Palestinian peoples, Moab and Ammon (Gen. xix. 30–38; *cf.* Ps. lxxxiii, *8);* he appears to have been represented as a Horite or Edomite. As the son of Haran and grandson of Terah. he was Abraham's nephen and he accompanied his uncle in his migration from Haran to Canaan. Near Bethel Lot separated from Abraham. because of disputes betneen their shepherds and, being offered the first choice, chose the fertile and nell-irrigated Jordan valley. It was in this district that the cities of Sodom and Gomorrah (*q.v.*) were situated. He was saved from their fate by two divine messengers nho spent the night in his house, and next morning led Lot. his wife and his two unmarried daughters out of the city. His wife looked back and was changed to a pillar of salt, but Lot with his two daughters escaped first to Zoar and then to the mountains east of the Dead sea. where the daughters planned and executed an incest by which they became the mothers of Moab and Ben-Ammi (i e, Ammon). The account of Chedorlaomer's invasion and of Lot's rescue by Abraham. recounted in Gen xiv. belongs to an independent source, the age and historical value of which has been much disputed. *See* ABRAHAM; AMMONITES; MOAB.

LOT, a department of south-western France, formed in 1790 from the district of Quercy, part of the old province of Guyenne. It is bounded N. by Corrèze, W. by Dordogne and Lot-et-Garonne, S. by Tarn-et-Garonne, and E. by Aveyron and Cantal. Area 2,018 sq.mi. Pop. (1936) 162,572. The department is that part of the south-western slope of the Massif Central which is drained by the river Lot, navigable with the help of locks, while its northern portion is crossed by the parallel Dordogne, both streams flowing west to the Garonne-Gironde. On its eastern side, towards the heights of Cantal, there are hills 2,560 ft. in height. The centre of the department is occupied by a calcareous Jurassic plateau called the Causses, 700–1,300 ft. (Causse de Martel north of the Dordogne, Causse de Gramat or de Rocdmadour between Dordogne and Lot, and Causse de Cahors south of Lot). On the west, stream dissection has formed a series of hills fringing the plain of Aquitaine. Water soaks through the porous surface of the causses and vanishes down its many fissures (igues) and springs emerge lower down to form large streams in the narrow and beautiful valleys. Temperature varies greatly between the warm valleys and the highlands of impermeable rock in the east; rainfall is somewhat above the average for France. Wheat, oats, maize, buckwheat and rye are the chief cereals. Wines are well known. The north-east cantons produce large quantities of chestnuts, walnuts, truffles, plums, and potatoes are also grown. Sheep abound, but cattle, pigs, horses, mules and goats are also reared, as well as poultry and bees. Some iron and coal are mined, and a little zinc. Limestone is quarried. The three arrondissements are those of Cahors, the capital, Figeac and Gourdon; there are 29 cantons and 331 communes.

Lot belongs to the 17th military district (Toulouse), and to the *académie* of Toulouse, its court of appeal is at Agen, and it is in the province of the archbishop of Albi, bishopric of Cahors. It is served by the Orléans railway. Cahors, Figeac and Rocamadour are the principal places. The fine feudal fortress at Castelnau has an audience hall of the 12th century, the Romanesque abbey-church at Souillac has a finely sculptured entrance. The plateau of Puy d'Issolu, near Vayrac, is believed by most authorities to be the site of the ancient Uxcellodunum, the scene of the last stand of the Gauls against Julius Caesar in 51 B.C. Lot has many dolmens.

LOT, a river of southern France, about 300 m. long, rising in the Hercynian gneisses of the Cévennes on Mt. du Goulet, at a height of 4,918 feet. Its direction is westward through a deep gorge between the Causse of Mende and Aubrac mountains, and the tableland (causses) of Sauveterre, Sévérac and Comtal. It passes off the gneisses near Capdenac; hence its sinuous course crosses the plateau of Quercy, of Jurassic limestones, to enter a wider fertile plain, covered with Tertiary deposits and alluvium. Its largest tributary, the Truyère (right), joins it at Entraygues. Lower down it receives the Dourdou (left) and the Célé (right) above Cahors, below which is the town of Villeneuve-sur-Lot. The Lot is canalized and navigable between the Garonne and Bouquiès (160 miles).

LOT-ET-GARONNE, a department of south-western France, formed in 1790 of Agenais and Bazadais, two districts of the old province of Guienne, and of Condomois, Lomagne, Brullois and pays d'Albret, formerly portions of Gascony. It is bounded W. by Gironde, N. by Dordogne, E. by Lot and Tarn-et-Garonne, S. by Gers and S.W. by Landes. Area, 2,079 sq.mi. Pop. (1936) 252,761. The department is that part of the Garonne basin above and below the point at which the Lot joins it. The north-east and the south are hilly, and in the west are the borders of the Landes (*q.v.*). The Garonne, the Lot and the Drot, a right bank tributary of the Garonne, are navigable. The mean temperature of Agen is 56·6° F, or 5° above that of Paris; the annual rainfall, from 20 to 24 in., is nearly the least in France. Of cereals wheat is the chief, with oats and maize. Potatoes, vines and tobacco are important sources of wealth. The best wines are those of Clairac. Vegetables and fruit, especially plums, prunes d'ente and apricots, are grown. The chief trees are the pine and the oak; there is a good deal of forest and the cork-oak flourishes in the Landes. Horned cattle are the chief live stock. Poultry and pigs are also reared profitably. There are deposits of iron in the department. The forges, blast furnaces and foundries of Fumel are important; and agricultural implements and other machines are manufactured. The making of lime and cement, of tiles, bricks and pottery, of confectionery and dried plums (*pruneaux d'Agen*) and other delicacies are important. At Tonneins (pop. [1936] 4,506) there is a national tobacco manufactory. Cork cutting, of which the centre is Mézin, candle-making, tanning and paper making are other industries. The arrondissements are three, named from the towns of Agen, Marmande and Villeneuve-sur-Lot, and there are 35 cantons and 326 communes.

Agen, the capital, is the seat of a bishopric under Bordeaux and of the court of appeal. The department belongs to the region of the XVII. army corps (Toulouse), the *académie* of Bordeaux. Lot-et-Garonne is served by the lines of the Southern and the Orléans railways. The department possesses Roman remains at Mas d'Agenais and at Aiguillon. The churches of Layrac, Monsempron, Mas d'Agenais, Moirax, Mézin and Vianne are of interest, as also are the 13th century fortifications of Vianne, and the châteaux of Xaintrailles, Bonaguil, Gavaudun and of the industrial town of Casteljaloux.

LOTHAIR I. (795–855), Roman emperor, was the eldest son of the emperor Louis I., and his wife Irmengarde. Little is known of his early life, which was probably passed at the court of his grandfather Charlemagne, until 815, when he became ruler of Bavaria. When Louis in 817 divided the empire between his sons, Lothair was crowned joint emperor at Aix-la-Chapelle and given a certain superiority over his brothers. In 821 he married Irmengarde (d. 851), daughter of Hugo, count of Tours; in 822 undertook the government of Italy; and, on April j, 823, was crowned emperor by Pope Paschal I. at Rome. In Nov. 824 he promulgated a statute which reserved the supreme power to the secular potentate, and he afterwards issued ordinances for the good government of Italy. On his return to his father's court his step-mother Judith persuaded him to secure a kingdom for her son Charles, a scheme which was carried out in 829. Lothair, however, soon changed his attitude, and spent the succeeding decade in constant strife over the division of the empire with his father. He was alternately master of the empire, and banished and confined to Italy; at one time taking up arms in alliance with his brothers and at another fighting against them; whilst the bounds of his appointed kingdom were in turn extended and reduced.

When Louis was dying in 840, he sent the imperial *insignia* to Lothair, who, disregarding the various partitions, claimed the whole of the empire. Negotiations with his brother Louis and his half-brother Charles, both of whom armed to resist this claim, were followed by an alliance of the youngtr brothers against Lothair. A decisive battle was fought at Fontenoy on June 25, 841, when, in spite of his personal gallantry, Lothair was defeated and fled to Aix. With fresh troops he entered upon a war of plunder, but he was compelled to surrender Aix to his brothers. In June 842 the brothers met on an island in the Sâone, and agreed to an arrangement which eventually developed into the treaty of Verdun (843).

By this Lothair received Italy and the imperial title, together with a stretch of land between the North and Mediterranean seas lying along the valleys of the Rhine and the Rhône. He abandoned Italy to his eldest son, Louis, and remained in his new kingdom, engaged in alternate quarrels and reconciliations with his brothers, and in efforts to defend his lands from the attacks of the Normans and the Saracens. In 855 he fell ill, and divided his lands between his three sons. On Sept. 23 he entered the monastery of Prüm, where he died six days later.

LOTHAIR II. or **III.** (*c.* 1070–1137), surnamed the "Saxon," Roman emperor, son of Gebhard, count of Supplinburg, succeeded to extensive lands around Helmstadt in Saxony, on his father's death in 1075. Gebhard had been a leading opponent of the emperor Henry IV. in Saxony, and his son, taking the same attitude, assisted Egbert II., margrave of Meissen, in the rising of 1088. His position in Saxony was increased by his marriage (1100) with Richenza, daughter of Henry, count of Nordheim. Having assisted the German king, Henry V., against his father in 1104, Lothair was appointed duke of Saxony by Henry, when Duke Magnus, the last of the Billungs, died in 1106. His independent attitude brought him into collision with Henry V., to whom, however, he was forced to submit after an unsuccessful rising in 1112. In 1112 Lothair supported the claim of Siegfried, count of Ballenstadt to inherit the domains of Ulrich II., count of Weimar and Orlamunde, against the emperor, Henry V. The rebels were defeated, and Siegfried was killed at Warnstadt in 1113, but his son secured possession of the disputed counties. After the defeat by Lothair of Henry's forces at Welfesholz on Feb. 11, 1115, events called Henry to Italy; and Lothair appears to have been undisturbed in Saxony until 1123, when the death of Henry II., margrave of Meissen and Lusatia raised a dispute as to the right of appointment to the vacant margraviates. A struggle ensued, in which victory remained with the duke.

When Henry V. died in 1125, Lothair was chosen German king at Mainz on Aug. 30, 1125. His election was largely owing to the efforts of the papal party. The new king was crowned at Aix-la-Chapelle on Sept. 13, 1125. Lothair requested Frederick of Hohenstaufen to restore to the crown the estates bequeathed to him by the emperor Henry V. Frederick refused, and was placed under the ban. Lothair, unable to capture Nuremberg, gained the support of Henry the Proud, the new duke of Bavaria, by giving him his daughter, Gertrude, in marriage, and that of Conrad, count of Zahringen, by granting him the administration of the kingdom of Burgundy, or Arles. But Conrad of Hohenstaufen, the brother of Frederick, was chosen German king in December 1127, and was quickly recognized in northern Italy. But by the end of 1129 the Hohenstaufen strongholds, Nuremberg and Spires, were in Lothair's possession. This struggle was accompanied by disturbances in Lorraine, Saxony and Thuringia, but order was soon restored after the resistance of the Hohenstaufen had been beaten down. In 1131 the king led an expedition into Denmark; resistance was offered, and the Danish king, Niels, promised to pay tribute to Lothair.

The king's attention at the time was called to Italy where two popes, Innocent II. and Anacletus II., were clamouring for his support. At first Lothair remained heedless and neutral; but in March 1131 he was visited at Liége by Innocent, to whom he promised his assistance. Crossing the Alps with a small army in September 1132, he reached Rome in March 1133, accompanied by Innocent. As St. Peter's was held by Anacletus, Lothair's coronation as emperor took place June 4, 1133 in the church of the Lateran. He then received as papal fiefs the vast estates of Matilda, marchioness of Tuscany, thus securing for his daughter and her Welf husband lands which might otherwise have passed to the Hohenstaufen. He returned to Germany, where he restored order in Bavaria, and on the lower Rhine. Resuming the struggle against the Hohenstaufen, Lothair soon obtained the submission of the brothers, who retained their lands, and a general peace was sworn at Bamberg. The emperor's authority was now generally recognized, and the annalists speak highly of the peace and order of his later years. In 1135, Eric II., king of Denmark, acknowledged himself a vassal of Lothair; Boleslaus III., prince of the Poles, promised tribute and received Pomerania and Riigen as German fiefs; while the eastern emperor, John Comnenus, implored Lothair's aid against Roger II. of Sicily.

The emperor seconded the efforts of his vassals, Albert the Bear, margrave of the Saxon north mark, and Conrad I., margrave of Meissen and Lusatia, to extend the authority of the Germans in the districts east of the Elbe, and assisted Norbert, archbishop of Magdeburg, and Albert I., archbishop of Bremen, to spread Christianity. In Aug. 1136, attended by a large army, Lothair set out upon his second Italian journey. The Lombard cities were either terrified into submission or taken by storm; Roger II. was driven from Apulia; and the imperial power enforced over the whole of southern Italy. A mutiny among the German soldiers and a breach with Innocent concerning the overlordship of Apulia compelled the emperor to retrace his steps. An arrangement was made with regard to Apulia, after which Lothair, returning to Germany, died at Breitenwang, a village in the Tirol, on Dec. 3 or 4, 1137. Lothair has been described as the "imitator and heir of the first Otto." His reign was regarded, especially by Saxons and churchmen, as a golden age for Germany.

BIBLIOGRAPHY.—The main authorities for the life and reign of Lothair are: "Vita Norberti archiepiscopi Magdeburgensis"; Otto von Freising, "Chronicon Annalista Saxo" and "Narratio de electione Lotharii" all in the *Monumenta Germaniae historica. Scriptores,* Bande vi., xii. and xx. (Hanover and Berlin, 1826–92). The best modern Works are: L. von Ranke, *Weltgeschichte,* pt. viii. (Leipzig, 1887–88); W. von Giesebrecht, *Geschichte der Deutschen Kaiserzeit,* Band iv. (Brunswick, 1877), Band v. (Leipzig, 1888); Ph. Jaffe, *Geschichte des Deutschen Reiches unter Lothar* (1843); W. Bernhardi, *Lothar von Supplinburg* (Leipzig, 1879); O. von Heinemann, *Lothar der Sachse und Konrad III.* (Halle, 1869); and Ch. Volkmar, "Das Verhaltniss Lothars III. zur Investiturfrage," in the *Forschungen zur Deutschen Geschichte,* Band xxvi. (Gottingen, 1862–86).

LOTHAIR (941–986), king of France, son of Louis IV., succeeded his father in 954, and was at first under the guardianship of Hugh the Great, duke of the Franks, and then under that of his maternal uncle Bruno, archbishop of Cologne. The beginning of his reign was occupied with wars against the vassals, particularly against the duke of Normandy. Lothair attempted to recover Lorraine by a sudden attack, and in the spring of 978 nearly captured the emperor Otto II. at Aix-la-Chapelle. In the autumn Otto invaded France, penetrating as far as Paris, but was forced to retreat with heavy loss. Peace was concluded in 980 at Margut-sur-Chiers, and in 983 Lothair was even chosen guardian to the young Otto III. Towards 980, however, Lothair quarrelled with Hugh the Great's son, Hugh Capet, who, at the instigation of Adalberon, archbishop of Reims, became reconciled with Otto III. Lothair died on March 2, 986. By his wife Emma, daughter of Lothair, king of Italy, he left a son who succeeded him as Louis V.

See F. Lot, *Les Derniers Carolingiens* (Paris, 1891); and the *Recueil des actes de Lothaire et de Louis V.,* edited by L. Halphen and F. Lot (1908).

LOTHAIR (825–869), king of the district called after him Lotharingia, or Lorraine, was the second son of the emperor Lothair I. On his father's death in 855, he received for his kingdom a district lying west of the Rhine, between the North Sea and the Jura mountains, which was called Regnum Lotharii and early in the 10th century became known as Lotharingia or Lorraine. On the death of his brother Charles in 863 he added some lands south of the Jura to this inheritance. The reign was chiefly occupied by efforts on the part of Lothair to obtain a divorce from his wife Teutberga, a sister of Hucbert, abbot of St. Maurice (d. 864); and his relations with his uncles, Charles the Bald and Louis the German, were influenced by his desire to obtain their support to this plan. Louis favoured the divorce, and Charles opposed it, while neither lost sight of the fact that Lothair was without male issue. Lothair put away Teutberga; but Hucbert took up arms on her behalf, and after she had submitted successfully to the ordeal of water, Lothair was compelled to restore her in 858. He then won the support of his brother, the emperor Louis II., by a cession of lands, and obtained the consent of the local clergy to the divorce and to his marriage with Waldrada, which was celebrated in 862. A synod of Frankish bishops confirmed this decision at Metz (863), but Teutberga fled to the court of Charles the Bald, and Pope Nicholas I. declared against the decision of the synod. An attack on Rome by the emperor failed, and in 865 Lothair again took back his wife. Teutberga, however, now expressed her desire for a divorce, and Lothair went to Italy to obtain the assent of the new pope Adrian II. On the return journey he died at Piacenza on Aug. 8, 869. He left, by Waldrada, a son Hugo who was declared illegitimate, and his kingdom was divided between Charles the Bald and Louis the German.

See Hincmar, "Opusculum de divortio Lotharii regis et Tetbergae reginae," in *Cursus completus patrologiae,* tome cxxv., edited by J. P. Migne (Paris, 1857–79); M. Sdralek, *Hinkmars von Rheims Kanonistisches Gutachten über die Ehescheidung des Königs Lothar II.* (Freiburg, 1881); E. Diimmler, *Geschichte des ostfränkischen Reiches* (Leipzig, 1887–88); and E. Mühlbacher, *Die Regenten des Kaiserreichs unter den Karolingern* (Innsbruck, 1881).

LOTHIAN, MARK KERR, FIRST EARL OF (d. 1609), the eldest son of Mark Kerr (d. 1584), abbot, and then commendator, of Newbattle, was a member of the famous border family of Ker of Cessford. Mark Kerr was an extraordinary lord of session under the Scottish king James VI; he became Lord Newbattle in 1587, and earl of Lothian in 1606. He died on April 8, 1609, having had, as report says, 31 children by his wife, Margaret (d. 1617), daughter of John Maxwell, 4th Lord Herries.

LOTHIAN, PHILIP HENRY KERR, 11TH MARQUESS OF (1882–1940), British ambassador to the United States, was born April 18, 1882. He was educated at the Oratory school, Birmingham, and at New college, Oxford university. In 1905 he was appointed assistant secretary of the Inter-Colonial Council of Transvaal and Orange River Colony and of the Railway Committee of Central South African Railways, and in those capacities he went to South Africa, where he remained until 1910. In South Africa he edited a magazine, *The State,* which favoured union of the South African colonies. After his return to England, he became editor of *The Round Table, a* journal of government and politics. Lloyd George made Kerr his secretary in 1916, in which capacity he assisted in preparing the Versailles treaty. He resigned in 1921 to direct the United Newspapers, Ltd.; served in the British cabinet as parliamentary under-secretary of the India office (1931–32); was chairman of the Indian Franchise committee (1932); and was secretary of the Rhodes trust, which administers the Rhodes scholarships (1925–39). In 1939 he was appointed British ambassador to the United States, a position he held until his death, Dec. 12, 1940, in Washington, D.C.

In the early 1930s, Kerr was an advocate of appeasing Germany but he abandoned that position after Hitler's seizure of Czechoslovakia. His chief effort as ambassador was to obtain war materials for Britain from the United States.

LOTHIAN. This name was formerly applied to a considerably larger extent of country than the three counties of Linlithgow, Edinburgh and Haddington Roxburghshire and Berwickshire at all events were included in it, probably also the upper part of Tweeddale (at least Selkirk). It would thus embrace the eastern part of the Lowlands from the Forth to the Cheviots, *i.e.,* all the English part of Scotland in the 11th century. This region formed from the 7th century onward part of the kingdoms of Bernicia and Northumbria. It cannot have come into English hands before the last decades of the previous century; for in the *Historia Brittonum* the Bemician king Theodoric, whose traditional date is 572–579, is said to have been engaged in war with four Welsh kings. One of these was Rhydderch Hên who, as we know from Adamnan, reigned at Dumbarton, while another named Urien is said to have besieged Theodoric in Lindisfarne. If this statement is to be believed it is hardly likely that the English had by this time obtained a firm footing beyond the Tweed. Most probably the greater part of Lothian was conquered by the Northumbrian king Aethelfrith, who, according to Bede, ravaged the territory of the Britons more often than any other English king, in some places reducing the natives to dependence, in others exterminating them.

In the time of Oswio the English element became predominant in northern Britain. His supremacy was acknowledged both by the Welsh in the western Lowlands and by the Scots in Argyllshire. On the death of the Pictish king Talorgan, the son of his brother Eanfrith, he seems to have obtained the sovereignty over a considerable part of that nation also. Early in Egfrith's reign an attempt at revolt on the part of the Picts proved unsuccessful. We hear at this time also of the establishment of an English bishopric at Abercorn, which, however, only lasted for a few years. By the disastrous overthrow of Egfrith in 685 the Picts, Scots and some of the Britons also recovered their independence. Yet we find a succession of English bishops at Whithorn from 730 to the 9th century, from which it may be inferred that the southwest coast had already by this time become English. The Northumbrian dominions were again enlarged by Eadberht, who in 750 is said to have annexed Kyle, the central part of Ayrshire, with other districts. In conjunction with Oengus mac Fergus, king of the Picts, he also reduced the whole of the Britons to submission in 756. But this subjugation was not lasting, and the British kingdom, though now reduced to the basin of the Clyde, whence its inhabitants are known as Strathclyde Britons, continued to exist for nearly three centuries. After Eadberht's time we hear little of events in the northern part of Northumbria, and there is some reason for suspecting that English influence in the southwest began to decline before long, as our list of bishops of Whithorn ceases early in the 9th century; the evidence on this point, however, is not so decisive as is commonly stated. About 844 an important revolution took place among the Picts. The throne was acquired by Kenneth mac Alpin, a prince of Scottish family, who soon became formidable to the Northumbrians. He is said to have invaded "Saxonia" six times, and to have burned Dunbar and Melrose. After the disastrous battle at York in 867 the Northumbrians were weakened by the loss of the southern part of their territories, and between 883 and 889 the whole country as far as Lindisfarne was ravaged by the Scots. During the next 50 years the influence of the Scottish kingdom seems to have increased in the south, and in 945 the English king Edmund gave Cumberland, *i.e.,* apparently the British kingdom of Strathclyde, to Malcolm I, king of the Scots, in consideration of his alliance with him. Malcolm's successor Indulph (954–962) succeeded in capturing Edinburgh, which thenceforth remained in possession of the Scots. His successors made repeated attempts to extend their territory southwards, and certain late chroniclers state that Kenneth II in 971–975 obtained a grant of the whole of Lothian from Edgar. Whatever truth this story may contain, the cession of the province was finally effected by Malcolm II by force of arms. At his first attempt in 1006 he seems to have suffered a great defeat from Uhtred, the son of earl Waltheof. Later, however, he succeeded in conjunction with Eugenius, king of Strathclyde, in annihilating the Northumbrian army at Carham on the Tweed *(c.* 1016 or 1018?), and Eadulf Cudel, the brother and successor of Uhtred, ceded all his territory to the north of that river as the price of peace. Henceforth in spite of an invasion by Aldred, the son of Uhtred, during the reign of Duncan, Lothian remained permanently in possession of the Scottish kings. *(See* SCOTLAND.)

LOTI, PIERRE (the pen name of Louis Marie Julien Viaud) (1850–1923), French author, was born at Rochefort on Jan. 14, 1850. His education began in Rochefort, but at the age of 17, following the tradition of his family, he entered the navy and began to attend the naval school at Brest. He gradually rose in his profession, attaining the rank of captain in 1906, and in 1910 was placed on the reserve list. His pseudonym is said to have been due to his extreme shyness and reserve in early life, which made his comrades call him after *le Loti,* an Indian flower which grows in unfrequented spots. He was never given to books or study, and it was not until 1876 that he was persuaded to write down and publish some curious experiences at Constantinople, in *Aziyadé,* a book which, like so many of Loti's, seems half a romance, half an autobiography. Thereafter he continued to write novels, which were mainly reminiscent of his travels. While taking part as a naval officer in the Tonking war, Loti exposed a series of scandals which followed on the capture of Hué (1883), and was suspended from the service for over a year. He continued silent for some time, but in 1886 published his most famous book, *Pêcheur d'Islande,* a novel of life among the Breton fisher-folk. In May 1891 he was elected a member of the French academy. He died at Hendaye (Basses Pyrénées), June 10, 1923.

Loti's greatest successes were gained in the species of confession, half-way between fact and fiction, of his earlier books. His later books of pure description were rather empty, for in spite of the beauty and melody and fragrance of his works, his mannerisms are likely to pall. With all his limitations, however, he was, in mechanism of style and cadence, one of the most original and talented French writers of the second half of the 19th century.

Among his most important works are: *Rarahu* (1880), republished as *Le Mariage de Loti; Le Roman d'un Spahi* (1881); *Mon frère Yves* (1883); *Propos d'exil* (1887); *Madame Chrysanthbme* (1887); *Au Maroc* (1890); *Le Livre de la pitié et de la mort* (1891); *Fantôme d'orient* (1892); *Ramuntcho* (1897); *L'Inde (sans les Anglais)* (1903); *La troisième jeunesse de Mme. Prune* (1905); *Les Désenchantées* (1906; Eng. trans. by C. Bell); *La Mort de Philae* (1908); *Judith Renaudin* (Théâtre Antoine, 1904).

LOTICHIUS or LOTICH, **PETRUS SECUNDUS** (1528–1560), German humanist, was born at Schluchtern, Hesse-Cassel. In 1547 he was a member of the army of the Protestant league of Schamlkalden which was defeated by the forces of Charles V at Miihlberg. Lotichius was made professor of medicine at Heidelberg in 1557 and he died in that city three years later. Lotichius is noted for his poems, particularly his elegies. of which he left several volumes. Stylistically they resemble the works of some of the classic Latin poets.

LÖTSCHEN PASS or LÖTSCHBERG, an easy glacier pass (8,825 ft) leading from Kandersteg (Bernese Oberland) to the Lotschen valley (Valais), Switzerland. It is first mentioned in 1352, but was probably crossed earlier by the Valaisans, who colonized various parts of the Bernese Oberland.

In 1384 and in 1419 battles were fought on it between the Bernese and the Valaisans, uhile in 1698 a mule path (of which traces still exist) was constructed on the Bernese slope, though not continued beyond. The railway between Berne and Brig passes beneath the pass in the Lotschberg tunnel (9 mi. long and built in 1906–12). The tunnel starts above Kandersteg and enters the Lotschen valley at Goppenstein. This pass is to be distinguished from the Lotschenlucke (10,512 ft.), another glacier pass which leads from the head of the Lotschen valley to the Great Aletsch glacier

LOTTERY, a scheme for the distribution of prizes to be determined by chance, was reputedly an invention of the Romans. In its usual form, tickets are sold bearing different numbers Duplicates are placed in a drum or wheel from which winning numbers are drawn on a specified date

Although the Roman emperors Nero and Augustus used lotteries to distribute slaves, houses or ships as prizes. the chances were free. Lotteries in the modern sense originated in Italy during the middle ages spreading to France. Germany and Austria where rulers used them to raise revenue.

France first used lotteries as state revenue measures in 1539 although they had been permitted there under the name of *blanques* in 1520 by edict of Francis I.

The first English lottery drawing was held in 1569. In 1612 the Virginia company's colonial expedition was partly financed through a lottery. English lotteries encouraged mass gambling. Fraudulent drawings and the counterfeiting of tickets were commonplace. In the Lottery Act of 1823 Parliament provided for their discontinuance.

A century later, following agitation for legalized lotteries, a Royal commission in 1932 reported unanimously against permissive legislation, pointing out that existing prohibitory acts stemmed from evils prevailing when they were legal.

American colonial lotteries, patterned after those in England, were used to raise money for public improvements and to assist in the financing of colleges including Columbia Harvard, Dartmouth and Williams. In 1762 the Pennsylvania Provincial assembly denounced lotteries, declaring they were responsible for vice and idleness and were injurious to trade. Following the Revolutionary War lotteries flourished throughout the nation. Abuses including fraud were commonplace. Various state legislative committees recommended their abolishment. In 1833 legislation enacted in Massachusetts, New York and Pennsylvania outlawed lotteries, and early in 1834 similar action was taken by Ohio, Vermont, Maine, New Jersey, New Hampshire and Illinois. Provisions prohibiting legislatures from authorizing lotteries in the future were inserted in many state constitutions.

Following the Civil War the Louisiana Lottery company 'obtained from the state legislature a 2j-year charter effective Jan. 1, 1869. Its ostensible purpose was to raise money for the New Orleans Charity hospital. The lottery company became tremendously wealthy, politically powerful and corrupt. Pres. Benjamin Harrison, in a special message on July 30, 1890, to the U.S. senate and house of representatives declared: "The people of all the states are debauched and defrauded . . . by the Louisiana Lottery." He recommended that "severe and effectual legislation . . . be promptly enacted to enable the Post Office Department to purge the mail of all letters, newspapers, and circulars relating to the business." Congress responded by enacting legislation making it a federal crime to deposit lottery matter in the United States mails. In the Louisiana election of 1892, the lottery was the sole issue in the governor's contest. The antilottery candidate won and the lottery was outlawed.

Since that time lotteries have been illegal in the United States except in a few states where bingo (*q.v.*), a form of lottery, is permitted when conducted by specified religious or fraternal organizations for charity.

Policy, a form of lottery, flourishes among Negroes in urban areas. Pellets numbered 1 to 78 are deposited in a drum shaped wheel. Players wager that certain numbers will appear among twelve that are selected at the drawing. A bet that three particular numbers will be selected is known as a gig, four numbers a horse and five numbers a jack. Odds against the players are enormous.

Bolita.—A lottery similar to policy is bolita, played in Puerto Rico, and in the United States among Cuban and Puerto Rican groups. In this lottery, numbered balls from one to 100 are placed in a canvas sack. A small tear is made in the sack and the drawer inserts his hand and grasps one of the numbered balls. The sack is then split open and the remaining balls allowed to fall out. Although the odds are actually 99 to 1, the winning number usually pays only 70 for 1.

Numbers Game differs from policy largely in the method of selecting the winning numbers. Numbers game winners are determined from specified digits in such publicized figures as bank clearances, U.S. Treasury balances or pari-mutuel payoffs in designated races.

Legalized lotteries have a long and continuous history in Central and South American countries and exist in several European countries. Following World War II Russia used a lottery scheme to sell bonds for economic development financing. Non-winners received no interest on their bonds while winners received prizes. Among the best known lotteries are the Irish Sweepstakes, and Tattersalls in Australia.

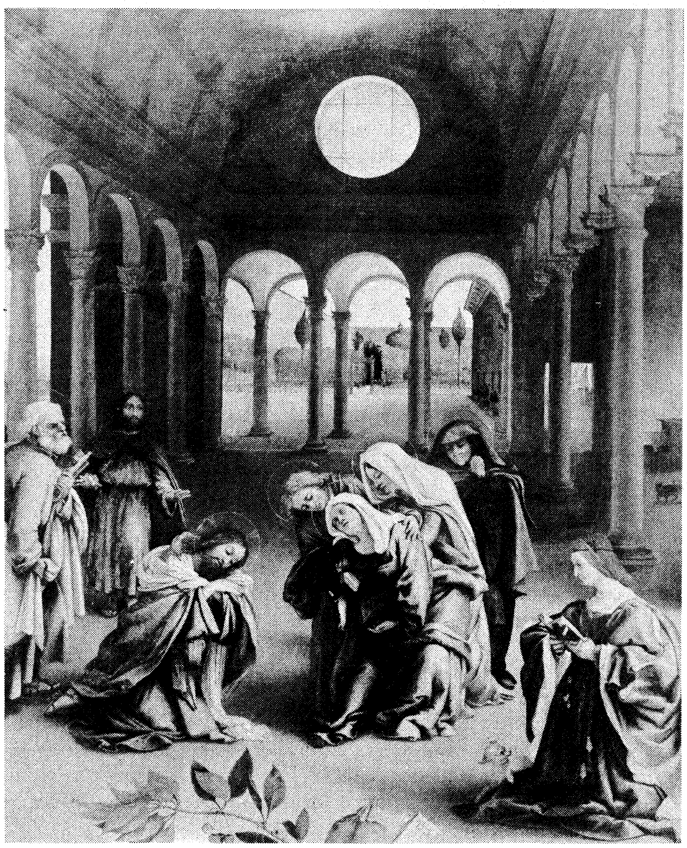
LOTTO, LORENZO (c. 1480–1556), Italian painter, was born in Venice, but in the earlier years of his life lived at Treviso and always remained somewhat apart from the main Venetian tradition.

His earliest dated pictures. the "Madonna and St. Peter Martyr" (1503) and the "Portrait of Bishop de' Rossi" (1505), both in Naples together with its allegorical cover, now in Washington, D.C., have unmistakable quattrocento traits in the treatment of the drapery and landscape and the cool tonality. To his early period belong the "Assumption of the Virgin," at Asolo, and "St. Jerome in the Wilderness" (1506) at the Louvre; the altarpiece at Sta. Cristina near Treviso (1507); the Recanati polyptych and "Madonna and Saints" (1508), at the Villa Borghese; and "Marriage of Catherine," at Munich

Lotto was in Rome between 1508 and 1512, when Raphael was painting the Stanza della Segnatura. A document in the Corsini library mentions that Lotto received 100 ducats as an advance payment for fresco work in the upper floor of the Vatican, but there is no evidence that this work was ever executed. In the next dated norks, the "Entombment" (1512) at Jesi and the "Transfiguration." "St James" and "St. Vincent" at Recanati, Lotto has abandoned the dryness and cool colour of his earlier style, and adopted a fluid method and a blonde. joyful colouring.

In 1513 Lotto mas living in Bergamo, where he had entered into



PHOTOGRAPHISCHE GESELLSCHAFT

"CHRIST TAKING LEAVE OF HIS MOTHER" BY LORENZO LOTTO. AT THE KAISER FRIEDRICH MUSEUM, BERLIN

a contract for 500 gold ducats to paint an altarpiece for S. Stefano, completed in 1516 and now at S. Bartolommeo.

From the next years. spent mostly at Bergamo, date the London portrait of the della Torre brothers (1515); the "Susanna and the Elders" (1517) in the Contini collection, Florence; the Dresden "Madonna" (1518); the London portrait of the' Prothonotary Giuliani (c. 1520) and the "Madonna and Two Saints" (1521); the Madrid "Bride and Bridegroom" (1523); the Berlin "Christ Taking Leave of His Mother" (1521) and the "Youth Against a Red Curtain" (c. 1525); the "Young Man in His Study" (c. 1524) at the Venice academy; numerous altarpieces in and near Bergamo, together with the fine series of frescoes in the Oratorio Suardi at Trescore, near Bergamo (1524), and the remarkable designs for the inlaid choir stalls in Sta. Maria Maggiore.

In 1526 or 1527 Lotto returned to Venice, where Titian ruled supreme in the world of art; and it was only natural that the example of the great master should have fired him to emulation. However, it was only a passing phase; even in the Carmine altarpiece of "St. Nicholas of Bari" (1529), which is his nearest approach to Titian, he retained his individualized, as opposed to Titian's generalized, expression of emotion. From the Venetian years 1526 to 1529 date the portraits "Andrea Odoni" at Hampton Court and "Bishop Tommaso Negri" at Split (both 1527); the so-called "Lucretia" at London, the "Man on a Terrace" at Cleveland and the "Man Holding a Claw" at Vienna (all c. 1527); the Recanati "Annunciation" and the Brescia "Adoration of the Shepherds" (c. 1528); and the strangely misnamed "Triumph of Chastity" at the Rospigliosi palace in Rome.

Among pictures executed between 1529 and 1540, chiefly in the Marches, are the Louvre "Christ and the Adulteress" (c. 1530); the "Youth Against a Green Curtain" (*c.* 1530) and the "St. Sebastian" and "St. Christopher" (1531) at Berlin; the "Crucifixion" (1531) at Monte San Giusto; the "Visitation" (*c.* 1530) and the "St. Lucy Altarpiece" (1532) at Jesi; the Bergamo "Holy Family and Catherine" (1533); male portraits at Villa Borghese (*c.* 1530) and Palazzo Doria (c. 153j) in Rome; the Uffizi "Madonna and Saints" (1534); and the monumental Cingoli "Madonna of the Rosary" (1539).

Between 1540 and 1548 Lotto was in Venice and Treviso and was once more influenced by Titian. Works of these years include the "St. Antonino Giving Alms" (1542), in SS. Giovanni e Paulo, and the "Madonna and Saints" (1546) in San Giacomo dell'Orio at Venice; the portraits of "Messer Febo da Brescia" and of "Madonna Laura da Pola" (1544) as well as the "Pietà" and the "Portrait of an Old Man" all in the Brera at Milan; the "Madonna and Saints" (c. 1546) in Sta. Maria della Piazza at Ancona; the "Family Group" (1547) in London; and the "Madonna in Glory" (1548) at Mogliano.

In 1549 Lotto went once again to the Marches where he painted the "Assumption" now in the Ancona museum. In 1550 he lost his voice and partly his eyesight. In 1554 he made over all his belongings to the Holy House at Loreto and began one of his most sensitive masterpieces, the "Presentation in the Temple," which remained unfinished at his death in the autumn of 1556.

LOTUKO: see LOATUKO.

LOTUS, a popular name applied to several plants. The lotus fruits of the Greeks belonged to *Zizyphus* lotus, a bush native in south Europe. It has large fruits containing a mealy substance, which can be used for making bread and fermented drink. In ancient times the fruits were an article of food among the poor. A wine made from the fruit was thought to produce content and forgetfulness (hence the "Lotophagi" or lotus-eaters). *Zizyphus* is a member of the family Rhamnaceae.

The Egyptian lotus was a water lily, Nymphaea lotus: also the sacred lotus of the Hindus, Nelumbium nelumbo, and the American lotus, N. *pentapetolum*. The lotus tree, known to the Romans as the Libyan lotus, was probably *Celtis* australis, the nettle tree (*q.v.*), a southern European tree, a native of the elm family, with fruits like small cherries, first red and then black. Lotus of botanists is a genus of the pea family (Leguminosae). containing a large number of species of herbs and undershrubs widely distributed in the temperate regions of the old world. It is represented in Britain by L. corniculatus, bird's-foot trefoil, a low-growing herb. common in pastures and waste places, with clusters of small bright yellow pealike flowers, which are often streaked with crimson; the popular name is derived from the pods which when ripe spread like the toes of a bird's foot. (X.)

BLOSSOM AND SEED POD OF THE HINDU LOTUS (NELUMBIUM NELUMBO)

In decoration, the lotus, through gradual conventionalization, became one of the most prolific ornamental forms. Its universal use in Egypt resulted from its symbolic association with the Nile, the giver of life. The flower itself is represented as a common votive offering and is frequently painted as though tied on to shrines or house pillars.

The conventionalized form is not only the origin of the lotus bud capital, and the late lotus flower capital, but also serves in various wavs as a basis for borders and allover patterns. Two conventionalized varieties, the trilobe or three-leaved lotus, and the lotus palmette (in which the flower is combined with a semicircle or semiellipse of radiating petals above it), were largely used by the Assyrians and all the peoples along the eastern shore of the Mediterranean. Thus the lotus is at the basis of such varying forms as the Assyrian sacred tree and those Phoenician stele capitals which were the parents of the Ionic order.

Lotus flower bud and palmette forms are also the origin of a great number of Greek, painted ceramic patterns and from them evolved into the eggs and dart and into the anthemion (*q.v.*). The Romans not only borrowed and modified these Greek lotus derivatives but also received further lotus forms from Etruscan art. Lotus derivatives, like many other Roman decorative motives, appear in modified form throughout Byzantine and Romanesque art.

Lotus forms or derivatives are common even in the 20th century; thus their influence can be traced continuously back from modern times. through the Renaissance, medieval. Roman. Greek and western Asiatic work to its source in Egypt at least 5,000 years ago.

For a complete, though not entirely sound discussion, *see* W. H. Goodyear, *Grammar of the Lotus* (1891). (T. F. H.)

LOTUS-EATERS (LOTOPHAGI), a people encountered by Odysseus in the journey recounted in the *Odyssey*. They lived on a plant called *lotos,* which they offered to Odysseus' men. Those who ate of it forgot home and friends and wanted only to remain there and eat of that food.

It should be plain enough that the lotus-eaters and their country are situated in fairyland, but in addition to interpreting the story allegorically, many ancient scholars amused themselves by trying to identify them with some people of northern Africa, since that continent produces one or two edible plants called *lotos* by the Greeks. This foolishness has been imitated by some moderns.

The phrase "to eat lotus" is used metaphorically by numerous ancient writers to mean "to forget." "to be unmindful."

See HOMERIC POEMS; ODYSSEUS.

LOTZE, RUDOLF HERMANN (1817–1881), German philosopher who bridged the gap between classical German philosophy and 20th-century idealism, was born at Bautzen, on May 21, 1817, the son of a physician. After studies in the *Gymnasium* of Zittau he entered the University of Leipzig in 1834. Four years later he gained doctorates of philosophy and of medicine.

Lotze's studies were governed by two distinct interests. The first was scientific, based upon mathematical and physical studies under the guidance of E. H. Weber, W. Volckmann and G. T. Fechner. The second was his aesthetical and artistic interest, which was developed under C. H. Weisse. His vocation then seemed to be the reconciliation of science with art, literature and religion; and hence the central point of his philosophy has been described as an analysis of the concept of the mechanism of nature with the object of proving that this concept necessarily leads to the assumption of an ideal principle of existence. While a lecturer at Leipzig he published two short works, his *Metaphysik* (1841) and his *Logik* (1843), which laid the foundation of his system. In 1844 he was appointed professor of philosophy at Gottingen, where he remained until 1881. During this period he produced his most important works.

The first of Lotze's works to attract attention were articles contributed to Rudolf Wagner's *Handwörterbuch der Physiologie* in which Lotze combated the then current vitalistic theories. He first became generally known through his *Allgemeine Pathologie und Therapie als mechanische Naturwissenschaften* (1842; 2nd ed., 1848). To the same period belong his more systematic *Allgemeine Physiologie des korperlichen Lebens* (1851) and his *Medicinische Psychologie oder Physiologie der Seele* (1852). Notwithstanding the idealistic position adopted in his earlier works, his polemic against vitalistic theories led him to be regarded as a materialist, and to correct this misinterpretation he published his *Streitschriften* (1857).

In 1856 Lotze had published the first volume of his chief work, the *Mikrokosmus*, the second volume of which appeared in 1858 and the third in 1864. This contained a comprehensive account of his philosophical views. In 1868 he published his *Geschichte der Aesthetik in Deutschland.* He then planned to set out in three further volumes a more systematic account of his philosophy as a whole. The first of these, *Logik,* appeared in 1874 (2nd ed., 1880), the second. *Metaphysik*, in 1879. The third, dealing with practical philosophy, art and religion, was uncompleted at Lotze's death, which took place on July 1, 1881, a few months after he had moved from Gottingen to the chair of philosophy at Berlin.

Lotze belongs to the earliest phase of the transition from a conception of philosophy which claims or assumes that by deductive reasoning or reflection discoveries can be made about the nature of the universe to the view that philosophy is concerned only with the analysis and clarification of concepts. Though influenced in his early studies by Fichte, Schelling and Hegel, Lotze came to reject the methodology of these philosophers and more especially the dialectical method of Hegel. But neither in the method nor in the content of his philosophy did he differ so widely from his predecessors as he himself believed. Though rejecting dialectical methods, he relied upon reflection to defend hypotheses concerning the nature of reality which cannot be presented as self-evident or as evidenced by scientific observation. His conclusions were in accord with the idealist tradition. He believed that all that appears to us must be conceived as a reality, the nature of which must be construed as akin to our own nature and our own mental life. He held that this ultimate reality is an infinite divine being, within which finite individuals act and live.

More distinctive were Lotze's views concerning mechanism and teleology. He opposed the prevailing doctrine that mechanical laws apply only to inorganic matter and that processes in living things are determined by final causes and vital forces. His contention was that the laws that govern particles of matter in the inorganic world governed these particles also when they were combined in a living body. But he also rejected the view still widely assumed that explanations in terms of efficient causes and explanations in terms of final causes are alternative and incompatible. He held that mechanism is the instrument of purpose—that we explain why a living thing does what it does in terms of ends and how it does what it does in mechanistic terms. (This conception of the relation of mechanism and teleology later derived support from biological studies of directed behaviour and from the work of cyberneticians, who constructed mechanisms which behave like goal-directed living things; *see* CYBERNETICS.) Lotze argued that God in creating and maintaining the world and in attaining his ends does so entirely through the laws disclosed by the natural sciences.

As professor of philosophy at Gottingen, where he followed Herbart and was followed by G. E. Miiller, Lotze takes his place in a distinguished succession of philosophers who influenced the development of psychology as an independent science. His *Medicinische Psychologie* was the prototype of the many physiological psychologies which were to follow. His doctrine of "local signs" still receives attention from students of the theory of space perception. Retaining the doctrine of the soul, he attempted a more detailed analysis than had hitherto been attempted of the phases through which physical stimulation generates sensation and other experiences.

His interest in art and in morals and the biological approach necessary to the study of medicine combined to lead him to place special emphasis upon feeling and emotion. His contributions to the philosophy of mind and to psychology distinguish him both from the rationalist philosophers and from the intellectualist, sensationist and associationist psychologists. His influence was to be reinforced by other developments in biology, notably the Darwinian theory of evolution.

Lotze's influence upon the development of experimental psychology was mainly through his pupils and disciples such as C. Stumpf and G. E. Miiller. His psychological doctrines were interpreted by James Ward in Great Britain and by George T. Ladd in the United States. Each occupied in his own country a position similar to that of Lotze in Germany, and both played a significant part in the transition of psychology from being a philosophy of mind to being the study of its natural history.

LOUBET, ÉMILE FRANÇOIS (1838–1929), 7th president of the French republic, was born on Dec. 30, 1838, the son of a farmer at Marsanne (Drôme). He practised at the Paris bar and in the crisis of 1870 backed L. Gambetta's policy. He entered the chamber of deputies in 1876 and worked for the republican cause, especially for education, attacking the clerical system established by the Loi Falloux, and working for the establishment of free, obligatory and secular primary instruction. In 1880 he became president of the departmental council in Drome. Loubet entered the senate in 188 j and became minister of public works in the Tirard ministry (December 1887—March 1888).

Forming his own ministry in 1892, Loubet held the office of minister of the interior as well as the premiership, and so had to deal with the Xnarchist outrages and strikes of that year. His ministry fell in November over the Panama scandal, but for a time Loubet continued to serve as minister of the interior under Alexandre Ribot (*q.v.*). In 1896 he became president of the senate, in Feb. 1899 president of the republic.

Loubet's presidency was marked by three major crises. In June 1899 he summoned P. M. Waldeck-Rousseau to form a ministry to settle the Dreyfus case and appealed to republicans of all shades to rally behind it. Acting on the advice of Gen. Gaston Galliffet, minister of war. Loubet eventually remitted the sentence passed on Dreyfus at Rennes. Secondly. friction between France and the Vatican intensified after Pius X became pope (Aug. 1903). It reached its height in March 1904 when Pius protested against Loubet's official visit to the king of Italy in Rome. Under E. Combes. anticlericalist policies triumphed, and in 1905 church and state mere separated amid violent controversy.

International tensions also reached their height, but frictions with Great Britain were satisfactorily ended by the Anglo-French entente of 1904. Loubet's tough peasant qualities. combined with a genial simplicity and an unaffected dignity, enabled him to fulfill with success one of the most exacting presidencies of the third republic.

After his term of office ended (Jan. 1906) he retired into private life and died at Montélimar, of which he had been mayor and deputy, on Dec. 20, 1929.

See A. Combarieu, *Sept ans à l'Elysée avec le Président Loubet* (Paris, 1932). (D. TN.)

LOUDON, ERNST GIDEON, FREIHERR VON (1717–1790), Austrian soldier, was born on Feb. 2, 1717, at Tootzen, Livonia, where his family, of Scottish origin, had been settled since before 1400. His father had been in the Swedish service; the boy entered the Russian army as a cadet in 1732, saw service in 1734, 1735, and 1738–39, then resigned (1741), and after vainly applying for employment with Frederick the Great, became a captain in Trenck's corps in Vienna. Soon after the outbreak of the Seven Years' War he became colonel, in 1757 major-general of cavalry, and in 1758 forced Frederick to raise the siege of Olmiitz. In 1760 he won a further victory at Kunersdorf, was promoted feldzeugmeister and made commander-in-chief in Bohemia, Moravia and Silesia.

He was successful at Landshut and Glatz, but was defeated by Frederick at Liegnitz (Aug. 15, 1760), which action led to bitter controversy with Daun and Lacy, the commanders of the main army, who, Loudon claimed, had left his corps unsupported. In 1761 he operated again in Silesia, but was hampered by the inactivity of his Russian allies. (*See* SEVEN YEARS' WAR.) His tireless activity continued to the end of the war, in conspicuous contrast with the temporizing strategy of Daun and Lacy, and led in the last three years of the war to ever-increasing friction between the "Fabius" and the "Marcellus," as they were called, of the Austrian army.

After the peace dissensions continued between Loudon and Lacy, and Loudon only remained in the army at the special request of Maria Theresa, acting as commander-in-chief in Bohemia and Moravia 1769–72. In 1776 he settled at Hadersdorf near Vienna, and was made a field-marshal in Feb. 1778.

In the same year he was reconciled with Joseph II. and Lacy and commanded one of the two armies in the field in the war of the Bavarian Succession, but this time with only moderate success. He then retired again to Hadersdorf; but recalled after the reverses of the other generals in the Turkish War, he was made commander-in-chief, and won a last brilliant success by capturing Belgrade in three weeks, 1789. He died on July 14 at Neu-Titschein in Moravia, still on duty. His last appointment was that of commander-in-chief of the armed forces of Austria, which had been created for him by the new emperor Leopold. Loudon was buried in the grounds of Hadersdorf.

See memoir *by* v. Arneth in *Allgemeine deutsche Biographie, s.v.* "Loudon," and life by G. B. Malleson.

LOUD-SPEAKER (SPEAKER), a device for converting electrical into acoustical signal energy that is radiated into a room or open air. The term "signal energy" indicates that the electrical energy has a specific form such as that corresponding to a speech or music signal. The speaker should preserve the essential character of this signal energy in converting the energy from electrical to acoustical form. This definition of a loud-speaker excludes such devices as buzzers, gongs, sirens and the like in which the acoustical signal does not correspond in form to the electrical signal. The part of the speaker that converts electrical into mechanical energy is frequently called the motor. The motor vibrates an element called the diaphragm that in turn vibrates the air in immediate contact with it. The vibration results in slight pressure changes in the air above and below atmospheric pressure. These pressure changes are transmitted into the room or open air as a sound wave (see SOUND).

Kinds.—Speakers are conveniently classified by the kind of motor employed to convert the electrical into mechanical energy. Common types are the moving coil or "dynamic," and the magnetic armature or "magnetic." Less common are the piezoelectric or crystal and electrostatic or condenser types. The moving-coil and magnetic-armature types are both technically defined as magnetic types because the mechanical forces result from the interaction of a steady magnetic field and a magnetic field produced by the electrical current. In the moving-coil motor the signal current passes through a coiled conductor and produces a varying magnetic field that interacts with a steady field. This interaction results in a force that moves the coil, which in turn moves the attached diaphragm. The strength or magnitude of the force is proportional to the strength of the current. In the magnetic-armature type the signal current passes through a fixed coil that induces a magnetic field in a movable element of magnetic material called the armature. Speakers using the latter motor are popularly called "magnetic." Those using moving-coil motors, particularly when they are of the large direct-acting diaphragm type, are popularly called "dynamic." The fixed magnetic field required by magnetic speakers may be supplied by a permanent magnet or by an electromagnet. The term "electrodynamic" is said to have been applied originally to early commercial versions of moving-coil speakers. The prefix "electro" had no bearing on the source of the fixed or steady magnetic field supplied by either electromagnets or permanent magnets.

In piezoelectric or crystal speakers the force produced by a crystal having piezoelectric properties moves the diaphragm. In electrostatic or condenser speakers a very light conducting diaphragm is used as one electrode of a condenser or capacitor and suspended so it vibrates freely. The fixed electrode (or electrodes) is closely spaced from the moving one. Both of these types have had limited application because of their relatively low conversion efficiency and power output limitations at low frequencies.

Alternatively speakers are classified as horn and hornless or direct-radiator types. A horn speaker has a horn attached to a relatively small diaphragm. The large or mouth end of the horn behaves as a large lightweight diaphragm that radiates sound more efficiently than the small diaphragm. The horn proportions, including the rate of area expansion or flare, are selected to give the desired compromise betneen efficiency, frequency response, directional properties and size. To reproduce low frequencies the rate of expansion or flare must be small, necessitating a long horn, and the mouth must be large. Low-frequency horns are therefore large. High-frequency horns are small and are frequently used as the high-frequency speakers in multispeaker systems. Horn speakers may be made quite efficient. They are therefore primarily used where efficiency and high acoustic power output are important and size less important.

In the direct-radiator or hornless speakers the diaphragm is made large enough to radiate directly into unconfined air. To prevent the low-frequency front and back waves from interfering or neutralizing each other, a rigid surface or baffle must be interposed as an extension of the diaphragm support. This extension may take the form of an open-back box or cabinet, a totally enclosed box, a box closed except for a vent or port or a conduit or duct which may be folded. The open cabinet is commonly employed in radio and television receivers. The closed box is lined with sound-absorbing material and is used when the radiation from an open back is objectionable. The closed box tends to give more uniform low-frequency response and is less influenced by proximity to a room wall but sacrifices some efficiency. The vented enclosure augments a portion of the low-frequency range. The "boomy" or excessively resonant low-frequency response present in some types arises primarily from the use of too small an enclosure and a speaker nith excessive diaphragm support stiffness.

Development.— Historically the horn type speaker first attained commercial success. The electrical signals generated by early radio receivers were very feeble, and a telephone receiver had to be held to the ear to obtain an audible signal. Because of their relatively nidespread introduction in World War I, vacuum tubes or valves were rapidly incorporated in the radio set design of the postwar era. This practice made available the much greater electrical signal energy required to operate a speaker. Many early speakers consisted of a telephone receiver, sometimes slightly modified to accept the greater signal energy, to which a horn was attached. The horn improved the efficiency of the electrical-to-acoustical energy conversion process although at the expense of naturalness of reproduction. The need for greater electrical energy for speakers led to the development of more powerful tubes and these in turn permitted the use of less efficient but more natural sounding speakers. Magnetic armature speakers employing large-area conical paper or cloth diaphragms were followed by the moving-coil or "dynamic" types employing moderate-size conical paper diaphragms. The latter are used almost universally in radio and television receivers because of their low cost, simple construction, frequency range and small size even when designed to reproduce relatively low frequencies. Their major disadvantage is low efficiency but this became of relatively little importance in view of the ease with which adequate signal energy could be obtained in receivers or amplifiers operated from external power sources.

Design Problems.— The major speaker-design problems arise from the frequency range to be produced and the need for attaining adequate efficiency. Other factors such as uniformity of response with frequency, uniform directivity or spatial distribution of the emitted sound, linearity or proportionality of the acoustic output and electrical input over the necessary signal-intensity range must also be considered. An ideal speaker would be capable of faithfully reproducing at least any sound the human ear can hear. This range involves sound intensities differing by a factor of more than 10,000,000,000,000, frequencies from about 20 to 20,000 cycles per second and sounds varying rapidly in character. In practice these difficult requirements are modified by the limitations of the associated sound-reproducing system, by the infrequent occurrence and relative unimportance of certain sounds and by the tolerance or charitability of the ear. Background noise at the microphone and at the listener's location and electrical disturbances in the signal-transmission system limit the minimum speaker signal intensity that can be heard. The intensity of the louder common speech and music sounds is substantially below the maximum intensity the ear will tolerate without pain. These factors reduce the ratio of maximum to minimum intensity required of a complete sound-reproducing system. including speaker, to approximately 1,000,000 to 1— an attainable but not commonly realized value. These numerical values are large but psychological tests have shown that over much of the useful intensity range the intensity has to be increased by a factor of from five to ten for the listener to judge that the loudness has doubled. The ideal frequency range required of the speaker is also reduced by the noise that obscures or masks the very high and very low frequencies, which are difficult to hear. The infrequent occurrence of these extreme frequencies also reduces their importance. Consequently even a range from 40 to 15,000 cycles is useful primarily in experimental and controlled studio reproduction. A range from 80 to 8,000 cycles in an otherwise distortion-free system is capable of giving very realistic and emotionally satisfying reproduction.

The speaker should treat all frequencies alike. This requirement means uniform electrical-signal-to-sound conversion efficiency at all frequencies— a goal difficult to attain in a single speaker. In a high-quality speaker the change in efficiency with frequency will occur gradually and compensation may be provided for this in the electrical system. The speaker should also treat all frequencies alike for all listener locations. This requirement involves the factors of distance to the listener and angle between the principal axis of the speaker and the listener location. Outdoors and in large auditoriums the speakers are directed toward the more remote listeners to attempt to maintain the intensity in their region. It is hard to radiate all frequencies equally well toward each listener location. Radiation, interference, focusing and similar space effects in the sound field depend on the relation between the diaphragm size and shape and the length of the sound nave. The length of 8,000- and 80-cycle sound waves is 1.7 and 170 in. respectively (these vary inversely with frequency).a variance which accounts in large measure for the difficulty of obtaining uniform space distribution and radiation efficiency over the broad frequency range. When the sound wave is long compared to the maximum dimension of the horn mouth or exposed diaphragm the speaker is nondirectional. When the wave is very short there tends to be marked concentration of the sound in a narrow beam. This effect is reduced by subdividing a horn into a number of small horns or cells (which accounts for their designation as "cellular horns"). by the use of acoustical lenses and by special mouth shapes involving a narrow dimension that produces less concentration. In the case of large exposed or direct-radiating diaphragms the effect is reduced by providing concentric circular diaphragm segments that help confine the diaphragm vibration to the region near the apex at high frequencies, thereby reducing the effective diaphragm size and broadening the radiated beam. More uniform space distribution and conversion efficiency are also obtained by using two or more speakers, each covering a portion of the frequency range.

The acoustical environment of the speaker influences its performance. Both direct and reflected sound reach the listener. In small rooms the reflected sound may markedly influence the speaker performance and what the listener hears. Much poor low-frequency performance attributed to speakers actually arises because a small room has few low resonant frequencies and these are widely separated in frequency. Consequently the speaker can transmit sound energy efficiently through the room to the listener only in narrow low-frequency bands.

EOUDUN, a town of western France, capital of an *arrondissement*, in the *département* of Vienne, 45 mi. by rail S.W. of Tours. Pop. (1954) 4,677. Loudun (*Laudunum*) was a town of importance during the religious wars and gave its name in 1616 to a treaty favourable to the Protestants. Of the old walls a single gateway and two towers remain. A 12th-century rectangular donjon of the castle of the counts of Anjou is preserved; at its base traces of Roman constructions have been found, with fragments of porphyry pavement, mosaics and mural paintings.

There is a Carmelite convent; the old Romanesque church of Sainte Croix is now used as a market. The Gothic church of St. Pierre-du-Marché has a Renaissance portal and a high stone spire.

There are several old houses in the town.

The manufacture of farm implements is carried on, and there is a considerable trade in agricultural products. wine, etc.

LOUGHBOROUGH, ALEXANDER WEDDERBURN, 1ST BARON: see ROSSLYN, ALEXANDER WEDDERBURN, 1ST EARL OF.

LOUGHBOROUGH, a municipal borough (1888) in the Loughborough parliamentary division of Leicestershire, Eng.. near the Soar and on the Loughborough canal, 11 mi. N.N.W. of Leicester by road. Pop. (1951) 34,731. Area 14.4 sq.mi. There was a settlement there before the Roman invasion: but evidence of the Roman occupation is scanty. In Saxon times Loughborough was becoming a place of some size, and later reference is made to the township in Domesday Book. Grants for markets and fairs were made in the 13th century, when the wool trade was an important feature of the district. Lacemaking later became the chief industry, but when John Heathcoat's machines were destroyed by the Luddites the industry lost much of its importance.

The town is a marketing centre in a large and fertile agricultural district, lying to the east of Charnwood forest. The town hall and corn exchange (1855) stand prominently in the market place. Loughborough's principal industries are electrical engineering, bell founding and the manufacture of hosiery, lifting machinery and pharmaceutical goods.

Loughborough is an educational centre?Loughborough College of Technology being of very wide repute, while the Training college is the largest college in the country for men schoolteachers; there are also a college of further education and a college of art. The grammar school was founded by Thomas Burton: a wool merchant, in 1495. He and the Taylors, who established the bell-founding industry, are commemorated in the parish church. The memorial for World Wars I and II is a tower and carillon of 47 bells, which was built by public subscription and opened in 1923.

LOUGHREA, a market town of County Galway, Ire., on the northern shore of Lough Rea, 116 mi. W. of Dublin by road. Pop. (1956) 2,834. There are slight remains of an Early English Carmelite friary, dating from about 1300. Loughrea is the seat of the Roman Catholic bishop of Clonfert, and has a cathedral built in 1900–05. A part of the castle of Richard de Burgh, founder of the friary. still survives. and there are traces of the town fortifications. In the neighbourhood are a cromlech, "souterrains" (underground passages and chambers) and two ruined towers. Crannogs (*q.v.*), or prehistoric stockaded islands, have been found in the lough.

LOUHANS, a town of east-central France in the department of Saône-et-Loire, 34 mi. N.N.E. of Mâcon by road. Pop. (1954) 3.726. Its church has a fine 15th-century tower with a carved balustrade. The main street is arcaded. The town is the central market of the agricultural plain of Bresse, with much trade in chickens and horses. It has a subprefecture and a tribunal of commerce.

LOUIS I (778–840), surnamed the "Pious," Roman emperor, third son of the emperor Charlemagne and his wife, Hildegarde, was born at Chasseneuil in central France, and crowned king of Aquitaine in 781. He received a good education; but since his tastes were ecclesiastical rather than military, the government of his kingdom was mainly conducted by his counsellors. Louis, however, gained sound experience in warfare in the defense of Aquitaine, shared in campaigns against the Saxons and the Avars and led an army to Italy in 792. In 794 or 795 he married Irmengarde, daughter of Ingram, count of Haspen. After the deaths of his two elder brothers, Louis, at his father's command, crowned himself coemperor at Aix-la-Chapelle on Sept. 11. 813, and was formally associated in the government of the empire, of which he became sole ruler, in the following January. He earned the surname of "Pious" by banishing his sisters and others of immoral life from court; by attempting to reform and purify monastic life; and by showing great liberality to the church. In Oct. 816 he was crowned emperor at Reims by Pope Stephen IV; and at Aix in July **817** he arranged for a division of his empire among his sons.

This was followed by a revolt of his nephew Bernard, king of Italy; but the rising was easily suppressed, and Bernard was mutilated and killed.

The emperor soon began to repent of this cruelty, and when his remorse had been accentuated by the death of his wife in 818, he pardoned the followers of Bernard and restored their estates, and in 822 did public penance at Attigny. In 819 he married Judith, daughter of Welf I, count of Bavaria, who, in 823 bore him a son Charles, afterward called "the Bald." Judith made unceasing efforts to secure a kingdom for her child; and with the support of her eldest stepson, Lothair, a district was carved for Charles in 829. Discontent at this arrangement increased to the point of rebellion, which broke out the following year, provoked by Judith's intrigues with Bernard, count of Barcelona, whom she had installed as her favourite at court. Lothair and his brother Pippin joined the rebels; and after Judith had been sent into a convent and Bernard had fled to Spain, an assembly was held at Compiègne, when Louis was practically deposed and Lothair became the real ruler of the empire. Sympathy was, however, soon aroused for the emperor, who was treated as a prisoner, and a second assembly was held at Nimwegen in Oct. 830, when, with the concurrence of his sons Pippin and Louis, he was restored to power and Judith returned to court.

Further trouble between Pippin and his father led to the nominal transfer of Aquitaine from Pippin to his brother Charles in 831. The emperor's plans for a division of his dominions then led to a revolt of his three sons. Louis met them in June 833 near Kolmar, but possibly because of the influence of Pope Gregory IV, who took part in the negotiations, he found himself deserted by his supporters, and the treachery and falsehood which marked the proceedings gave to the place the name of *Lügenfeld*, or the "field of lies." Judith, charged with infidelity, was again banished; Louis was sent into the monastery of St. Medard at Soissons; and the government of the empire was assumed by his sons. The emperor was forced to confess his sins, and declare himself unworthy of the throne, but Lothair did not succeed in his efforts to make his father a monk. Sympathy was again felt for Louis, and when the younger Louis had failed to induce Lothair to treat the emperor in a more becoming fashion, he and Pippin took up arms on behalf of their father. The result was that in March 834 Louis was restored to power at St. Denis; Judith once more returned to his side; and the kingdoms of Louis and Pippin were increased. The struggle with Lothair continued until the autumn, when he submitted to the emperor and was confined to Italy. To make the restoration more complete, a great assembly at Diedenhofen declared the deposition of Louis to have been contrary to law, and a few days later he was publicly restored in the cathedral of Metz. In Dec. 838 Pippin died, and a new arrangement was made by which the empire, except Bavaria, the kingdom of Louis, was divided between Lothair, now reconciled to his father, and Charles. The emperor was returning from suppressing a revolt on the part of his son Louis, provoked by this disposition, when he died on June 20, 840, on an island in the Rhine near Ingelheim. He was buried in the church of St. Arnulf at Metz.

Louis was a man of strong frame, who loved the chase, and did not shrink from the hardships of war. He was, however, easily influenced and was unequal to the government of the empire bequeathed to him by his father. No sustained effort was made to ward off the inroads of the Danes and others, who were constantly attacking the borders of the empire.

Louis, who is also called *Le Débonnaire,* counts as Louis I, king of France.

LOUIS II. (825–875): Roman emperor, eldest son of the emperor Lothair I., was designated king of Italy in 839, and was crowned king at Rome by Pope Sergius II. on June 15, 844. In 850 he was crowned joint emperor at Rome by Pope Leo IV., and soon afterwards married his cousin, Engelberga, a daughter of King Louis the German, and undertook the independent government of Italy. On the death of his father in Sept. 855 he became sole emperor. In 857 he allied himself with Louis the German against his brother Lothair, king of Lorraine, and King Charles the Bald, but after he had secured the election of Nicholas I. as pope in 858, he became reconciled with his brother. In 863, on the death of his brother Charles, Louis received the kingdom of Provence. In 864 he quarrelled with Pope Nicholas I. over his brother's divorce, which the pope had declared invalid, and in February reached Rome with an army, but made peace with the pope and left the city.

In 866 he routed the Saracens, but could not follow up his successes owing to the want of a fleet. In 869, with the assistance of his ally, the eastern emperor, Basil I., he captured Bari, the headquarters of the Saracens He had withdrawn into Benevento to prepare for a further campaign, when he was treacherously robbed and imprisoned by Adelchis, prince of Benevento, in Aug. 871, but was released a month later. Returning to Rome, he was crowned a second time as emperor by Pope Adrian II. on May 18, 872. After further successes against the Saracens, who were driven from Capua, he returned to northern Italy. He died, somewhere in the province of Brescia, on Aug. 12, 875, and was buried in the church of St. Ambrose at Milan, having named as his successor in Italy his cousin Carloman, son of Louis the German.

Dummler, *Geschichte des ostfrankischen Reiches* (Leipzig, 1887–88).

LOUIS III. (c. 880–928), surnamed the "Blind," Roman emperor, was a son of Boso, king of Provence or Lower Burgundy and Irmengarde, daughter of the emperor Louis II. The emperor Charles the Fat took Louis under his protection on the death of Boso in 887; but Louis was not recognized as king of Provence until 890, when Irmengarde had secured the support of the Bavarian king Arnulf and of Pope Stephen V. In 900, after the death of the emperor Arnulf, he went to Italy to obtain the imperial crown. He was chosen king of the Lombards at Pavia, and crowned emperor at Rome in Feb. 901 by Pope Benedict IV. He gained a temporary authority in northern Italy, but was soon compelled by his rival Berengar, margrave of Friuli, to leave the country. In 904, however, he went again to Italy, where he secured the submission of Lombardy; but on July 21, 905, he was surprised at Verona by Berengar, who blinded him and sent him back to Provence, where he remained until his death, at Arles, in Sept. 928. He married Adelaide, possibly a daughter of Rudolph I., king of Upper Burgundy. His eldest son, Charles Constantine, succeeded only to the county of Vienne.

Dummler, *Geschichte des ostfrankischen Reichs* (Leipzig, 1887–88); and *Gesta Berengarii imperatoris* (Halle, 1871); and F. de Gingins-la-Sarra, *Mémoires pour servir à Phistoire de Provence et de Bourgogne Jurane* (Zürich, 1851).

LOUIS IV., or **V.** (c. 1287–1347), surnamed the Bavarian, Roman emperor and duke of Upper Bavaria, was the second son of Louis II., duke of Upper Bavaria and count palatine of the Rhine, and Matilda, daughter of the German king Rudolph I. At his father's death in 1294 he inherited, jointly with his elder brother Rudolph, Upper Bavaria and the Palatinate, but passed his time mainly at the court of the Habsburgs in Vienna. In the quarrel with his brother over their joint possessions, Louis was supported by his uncle Albert I., the German king. Rudolph promised in 1301 to admit his brother to a share in the government of Bavaria and the Palatinate. When Albert was murdered in May 1308, Louis became a candidate for the German throne; but his claim was not strongly supported. The new king, Henry VII., was very friendly with Rudolph, and as the promise of 1301 had not been carried out, Louis demanded a partition of their lands, and received the north-western part of Upper Bavaria in 1310, but Rudolph refused to surrender any part of the Palatinate. In 1310, on the death of Stephen I., duke of Lower Bavaria, Louis undertook the guardianship of his two young sons. This led to a war between the brothers, which lasted till June 1313, when peace was made at Munich. Frederick III (the Fair), duke of Austria, called in by the nobles of Lower Bavaria, was defeated at Gammelsdorf on Nov. g, 1313.

In Aug. 1313 the German throne had again become vacant, and Louis was chosen at Frankfort on Oct. 20, 1314, and crowned at Aix-la-Chapelle on Nov. 25. War followed between Louis and the rival candidate, Frederick of Austria. Louis's embarrassments were complicated by a new dispute with his brother; but in 1317 Rudolph renounced his claims on Upper Bavaria and the Palatinate in consideration of a yearly subsidy and Louis was able to give undivided attention to the war with Frederick. On Sept. 28, 1322, a battle was fought at Muhldorf, which ended in a complete victory for Louis, owing mainly to the timely aid of Frederick IV. of Hohenzollern, burgrave of Nüremburg. Frederick of Austria was taken prisoner, but the struggle was continued by his brother Leopold until the latter's death in 1326. Attempts to enable the two kings to rule Germany jointly failed, and about 1326 Frederick returned to Austria. Supported by Philip V. of France in his desire to free Italy entirely from German influence, Pope John XXII. refused to recognize either Frederick or Louis, and asserted his own right to administer the empire during a vacancy.

After the battle of Miihldorf Louis sent Berthold of Neifen, count of Marstetten, into Italy with an army, which soon compelled the papal troops to raise the siege at Milan. The pope threatened Louis with excommunication unless he resigned his kingdom within three months. The king thereupon appealed to a general council, and was placed under the papal ban on March 23, 1324, a sentence which he answered by publishing his charges against the pope. In the contest Louis was helped by the Minorites, who were upholding against John the principle of clerical poverty, and by the writings of Marsilius of Padua (who dedicated to Louis his Defensor *pacis*), William of Occam, John of Jandun and others. Taking the offensive, Louis met his Ghibelline supporters at Trent and reached Italy in March 1327; and in May he received the Lombard crown at Milan.

Louis compelled Pisa to surrender and on Jan. 17, 1328, he was crowned emperor in St. Peter's by Sciarra Colonna, a Roman noble; he answered the continued attacks of Pope John by pronouncing his deposition, and proclaiming Peter of Corvara pope as Nicholas V. He then undertook an expedition against John's ally, Robert, king of Naples, but, disunion among his troops and scarcity of money and provisions drove him again to Rome, where, finding that his exactions had diminished his popularity, he left the city, and after passing six months at Pisa, returned to Germany in Jan. 1330. The struggle with the pope was renewed in Germany, and a formidable league had been formed against Louis. He was prepared to assent to very humiliating terms, and agreed to abdicate; but negotiations were interrupted by the pope's death in Dec. 1334. John's successor, Benedict XII., was prevented from coming to terms by the influence of Philip VI. of France. Overtures for peace were made to Philip, but without success; and in July 1337 Louis concluded an alliance with Edward III., king of England, and made active preparations for war. During these years his attention was also occupied by a quarrel with John, king of Bohemia, over the possession of Tirol, by a campaign in Lower Bavaria, and a futile expedition against Nicholas I., bishop of Constance. His position was improved when the electors meeting at Rense in July 1338 banded themselves together to defend their elective rights, and when the diet at Frankfort confirmed a decree which declared that the German king did not need the papal approbation to make his election valid.

The heiress of Tirol, Margaret Maultasch, quarrelled with her husband, John Henry, margrave of Moravia, and fled to the protection of Louis, who seized the opportunity to declare ber marriage void and to unite her in 1342 with his son Louis. The emperor also increased his possessions by his own marriage. In 1322 his first wife, Beatrice, daughter of Henry III., count of Glogau, had died and by his second marriage with Margaret, daughter of William III., count of Holland, he obtained, at the death of her brother, count William IV., in 1345, possession of Holland, Zealand and Friesland. In 1341 he recovered a portion of the Palatinate, and soon deserted Edward of England and came to terms with Philip of France. In the course of a war between Louis and the enemies made by his policy of acquisition which ensued in Germany he was forced to submit to humiliating terms, though he would not accept the election of Charles, margrave of Moravia (afterwards the emperor Charles IV.) as German king in July 1346. Charles consequently attacked Tirol; but Louis died suddenly at a bear-hunt near Munich on Oct. 11, 1347. He was buried in the Frauenkirche at Munich, where a statue was erected to his memory in 1622 by Maximilian I., elector of Bavaria, and where a second was unveiled in 1905. He had seven sons, three of whom were subsequently electors of Brandenburg, and ten daughters.

As a soldier Louis possessed skill as well as bravery, but he lacked perseverance and decision in his political relations; and the fact that he remained almost undisturbed in the possession of Germany in spite of the utmost efforts of the popes, is due rather to the political and intellectual tendencies of the time than to his good qualities. He encouraged trade and commerce and gave a new system of laws to the duchy.

BIBLIOGRAPHY.—Many of the authorities for the life and reign of Louis are found in the *Fontes rerum Germanicarum*, Bande i. and iv., edited by J. F. Bohmer (Stuttgart, 1843–68). Among these is the *Vita Ludovici IV.*, by an unknown author. A number of important documents are found in the *Regesta imperii 1314–1347*, ed. J. F. Bohmer and J. Ficker (Innsbruck, 1865); *Acta imperii selecta*, ed. J. F. Bohmer and J. Ficker (Innsbruck, 1870); *Urkunden zur Geschichte des Romerzuges Konigs Ludwigs des Bayern*, ed. J. Ficker (Innsbruck, 1865); *Urkundliche Beiträge zur Geschichte Kaisers Ludwigs IV.*, ed. C. Hofler (Munich, 1839); *Vatikanische Urkunden zur Geschichte Kaisers Ludwigs des Bayern*, Bande v. and vi. (Stuttgart, 1877–88); *Vatikanische Akten zur Deutschen Geschichte in der Zeit Kaisers Ludwigs des Bayern*, ed. S. Riezler (Innsbruck, 1891). In the *Forschungen zur Deutschen Geschichte* (Gottingen, 1862–86), Band. xx., is found *Urkunden zur Bairischen und Deutschen Geschichte 1256–1343*, ed. S. Riezler; and in Band xiii. is C. Häutle's *Beiträge zum Itinerar Kaiser Ludwigs*.

LOUIS I., king of Bavaria (1786–1868), son of the then prince, afterwards duke and elector, Max Joseph of Zweibrücken and his wife, Princess Augusta of Hesse-Darmstadt, was born at Strasbourg on Aug. 25, 1786. He was educated at home and at the universities of Landshut and Göttingen. Both the classics and contemporary classical poetry took hold upon his receptive mind (he visited Goethe in 1827). As a patron of the arts he proved himself as great as any who had ever occupied a German throne, and he was himself more than a mere dilettante.

The crown prince (his father had become elector in 1799 and king of Bavaria in 1805), became the leader of the small anti-French party in Bavaria. Napoleon sought in vain to win him over, and Louis fell more and more out of favour with him. Their relations continued to be strained, although in the campaigns of 1807 and 1809, in which Bavaria was among the allies of France, Louis won his laurels in the field. He married in 1810 Princess Therese of Saxe-Hildburghausen (1792–1854). Three daughters and four sons were born of this marriage, one of whom succeeded him as Maximilian II., while another, Luitpold, became prince regent of Bavaria on the death of Louis II. Louis resided chiefly at Innsbruck or Salzburg as governor of the circle of the Inn and Salzach. In 1815 he attended the congress of Vienna, where he sought to obtain the restoration of Alsace and Lorraine to Germany; and later in the year he was with the allies in Paris, using his influence to secure the return of the art treasures carried off by the French.

After 1815 also the crown prince maintained his anti-French attitude, and in 1817 his influence secured the fall of Comte Montgelas. Louis took great interest in the work of organizing the Bavarian constitution (1818) and defended it against Metternich and the Carlsbad Decrees (1819); he was also an ardent Philhellene. He succeeded to the crown of Bavaria on Oct. 12, 1825, and at once embarked upon a moderate constitutional policy, in which he found himself in general agreement with the parliament. Although a loyal Catholic he none the less opposed ultramontanism and the Jesuits. He improved the internal administration of the State, and especially that of the finances. He was a warm friend of learning, and in 1826 transferred the University of Landshut to Munich, where he placed it under his special protection. In the course of his visits to Italy he formed friendships with famous artists, notably with Thorwaldsen and Cornelius. He had the assistance of the painter Martin Wagner in procuring works of art for the great Munich collections.

Under the influence of the July revolution of 1830 he began to be drawn into the current of reaction; and though he never took up such a hostile attitude towards constitutional ideas as his brother-in-law, King Frederick William IV., he allowed the reactionary system of surveillance which commended itself to the German Confederation after 1830 to be introduced into Bavaria (*see* BAVARIA: *History*). As a follower of the ideas of Friedrich List, he furthered the foundation of the Zollverein in the year 1833 and the making of canals. Of European importance was his enthusiasm for the liberation of Greece from the rule of Turkey, and his generous financial assistance. After his second son Otto (*q.v.*), had become king of Greece in 1832, Greek affairs became the central point of his foreign policy. In 1862 Otto was forced to abdicate. For this unfortunate issue Louis was not without blame; for he had totally misunderstood the national character of the Greeks and the problems involved in the attempts to govern them by bureaucratic methods. After Karl Abel became the head of the ministry in 1837 the strict Catholic party influenced affairs more and more decisively. For a while, indeed, this opposition did not impair the king's popularity, due to his amiable character, his extraordinary services in beautifying his capital at Munich, and to his lavish charity. But his disastrous *liaison*, beginning in 1846, with Lola Montez, the Spanish dancer, brought him into conflict with his people. She used her great influence against the clerical policy of Abel. The ministry protested against her proposed naturalization in the memorandum of Feb. 11, 1847. The king replaced Abel's Clerical ministry by a more accommodating Liberal one under Zu Rhein under which Lola Montez without more difficulty became comtesse de Lansfeld. The revolutionary movement of 1848 and the pressure of the popular opposition compelled Louis to banish the countess. On March 20, 1848, he abdicated in favour of his son Maximilian.

In his retirement Louis continued to play the Maecenas magnificently. His popularity, shaken by the Montez affair, was partially recovered. To him Munich owes her finest art collections and most remarkable buildings, especially the acquisition of the famous Rhenish collection of the Boisserée brothers; also the Walhalla, the Glyptothek, the two Pinakotheken, the Odeon, the University, and many other magnificent buildings. The rôle of Munich as a great art centre would have been impossible without the splendid munificence of Louis I. He died on Feb. 28, 1868 at Nice, and was buried in Munich.

Kobell, *Unter den vier ersten Königen Bayerns* (1894); J. B. Sepp, *Louis I. Augustus, König von Bayern, und das Zeitalter der Wiedergeburt der Künste* (and ed., 1903).

LOUIS II., king of Bavaria (1845–1886), son of his predecessor Maximilian II. and Maria, daughter of Prince William of Prussia, was born at Nymphenburg on Aug. 25, 1845. With his brother Otto, Louis received a simple and serious education modelled on that of the German *Gymnasien.* Military instruction, physical exercises and sport, in spite of the crown prince's strong physique, received little attention. He developed a taste for solitude, which was combined with the romantic tendencies and musical and theatrical tastes traditional in his family.

Louis succeeded to the throne on March 10, 1864, at the age of eighteen. The early years of his reign were marked by a series of most serious political defeats for Bavaria. In the Schleswig-Holstein question. though he was opposed to Prussia and a friend of Duke Frederick VIII. of Augustenburg, he had not the material forces necessary effectively to resist Bismarck. Again, in the war of 1866, Louis and his minister, von der Pfordten, took the side of Austria, and at the conclusion of peace (Aug. 22) Bavaria had, in addition to the surrender of certain small portions of her territory, to agree to the foundation of the North German Confederation under the leadership of Prussia. The king's Bavarian patriotism, one of the few steadfast ideas underlying his policy, was deeply wounded, but he faced the inevitable, and wrote a letter of reconciliation (Aug. 10) to King William of Prussia. The defeat of Bavaria in 1866 showed the necessity of army reform. Under the new Liberal ministry of Hohenlohe (Dec. 29, 1866–Feb. 13, 1870) and under Prauckh as minister of war, a series of reforms were carried through which prepared for the victories of 1870. In his ecclesiastical policy Louis strove for a greater independence of the Vatican, and maintained friendly relations with Dollinger (*q.v*); but without extending his protection to the anti-Roman movement of the Old Catholics. Early in 1870 Louis formed a more Conservative cabinet under Count Bray-Steinburg. On the outbreak of the Franco-Prussian War he at once took the side of Prussia, and gave orders for mobilization. In 1871 it was he who offered the imperial crown to the king of Prussia; but not on his own initiative. Bismarck not only determined the king of Bavaria to take the decisive step which put an end to a serious diplomatic crisis, but actually drafted the letter to King William which Louis copied and despatched without changing a word.

In the early years of his reign Louis formed an intimate friendship with Richard Wagner, whom from May 1864 to Dec. 186; he had constantly in his company. He paid 18,000 gulden of debts for him, and granted him a yearly income of 4,000 gulden (afterwards increased to 8,000). A series of performances of the Wagnerian music-dramas was instituted in Munich under the personal patronage of the king, and when the further plan of erecting a great festival theatre in Munich for the performance of Wagner's "music of the future" broke down in the face of the passive resistance of the local circles interested, Louis conceived the idea of building at Bayreuth, according to Wagner's new principles, a theatre worthy of the music-dramas. For a time Louis was entirely under Wagner's influence, and there is extant a series of emotional letters of the king to Wagner. Public opinion in Bavaria turned against Wagner. He was attacked for his foreign origin, his extravagance, his intrigues, his artistic utopias, and last but by no means least, for his unwholesome influence over the king. Louis had to give him up. But in 1866, in the midst of the preparation for war, the king hastened in May to Triebschen, near Lucerne, in order to see Wagner again. In 1868 they were seen together in public for the last time at the festival performances in Munich. In 1876 Wagner's *Ring des Nibelungen* was performed for the first time at Bayreuth in the presence of the king. Later, in 1881, the king formed a brief friendship with Joseph Kainz the actor. In Jan. 1867 he became betrothed to Duchess Sophie of Bavaria (afterwards Duchesse d'Alençon), daughter of Duke Max and sister of the empress of Austria; but the betrothal was dissolved in October of the same year.

Louis presently showed serious signs of an ill-balanced mind, and when ministers sought to check his wild extravagance, which included the building of many magnificent castles, he became violent. The unfortunate king was declared insane on June 8, 1886, and his uncle, Prince Luitpold. assumed the regency. Louis was placed under restraint. On June 13, 1886, he was drowned in the Starnberger See, together with his doctor, von Gudden, who had unwisely gone for a walk alone with his patient, whose physical strength was enormous. Louis's brother Otto, who succeeded him as king of Bavaria, was also incurably insane.

LOUIS III., king of Bavaria (1845–1921), was born on Jan. 7, 1845, and assumed the regency in succession to his father on Dec. 12, 1912. In accordance with the bill passed by the Bavarian diet he assumed the crown on Nov. 5, 1913. After the proclamation of the republic on Nov. 7, 1918, the king, with the queen and his daughters, left Munich. The royal family resided first at Berchtesgaden, and afterwards at a castle assigned to them on the shores of Chiem See. On Nov. 13 he formally signed his abdication, and relieved all Bavarian officials, officers and soldiers from their oath of allegiance. He died at Sarvar, Hungary, on Oct. 17, 1921.

LOUIS (804–876), surnamed "the German," king of the East Franks, was the third son of the emperor Louis I. When the emperor divided his dominions between his sons in 817, Louis received Bavaria and the neighbouring lands, but did not undertake the government until 825, when he began to fight the Slavs on his eastern frontier. In 827 he married Emma, daughter of Welf I., count of Bavaria, and sister of his stepmother Judith. He interfered in the quarrels arising from Judith's efforts to secure a kingdom for her own son Charles, and the consequent struggles of Louis and his brothers with the emperor Louis I. (*q.v.*). When the elder Louis died in 840 and his eldest son Lothair claimed the whole Empire, Louis in alliance with his half-brother, king Charles the Bald, defeated Lothair at Fontenoy on June 25, 841. By the Treaty of Verdun (August 843), Louis received the bulk of the lands of the Carolingian empire lying east of the Rhine, including a district around Speyer, Worms and Mainz, Bavaria, where he made Regensburg the centre of his government, Thuringia, Franconia and Saxony.

Louis may truly be called the founder of the German kingdom, though his attempts to maintain the unity of the Empire proved futile. In 842 he crushed a rising in Saxony, compelled the Abotrites to own his authority, and undertook campaigns against the Bohemians, the Moravians and other tribes. He did not succeed in freeing his shores from the ravages of Danish pirates. At his instance synods and assemblies were held where laws were decreed for the better government of church and state. From 853 onwards, he attempted to secure the throne of Aquitaine, offered to him by the oppressed subjects of Charles the Bald. But treachery and desertion in his army, and the loyalty of the Aquitanian bishops to Charles prevented success, and Louis renounced his claim by a treaty signed at Coblenz on June 7, 860.

In 8jj the emperor Lothair died, and was succeeded in Italy by his eldest son Louis II., and in the northern part of his kingdom by his second son, Lothair. The weakness of these kingdoms afforded opportunities for intrigue by Louis and Charles the Bald, whose interest was increased by the fact that both their nephews were without male issue. Louis supported Lothair in his efforts to divorce his wife Teutberga, for which he received a promise of Alsace, but in 865 Louis and Charles renewed the peace of Coblenz, and doubtless discussed the possibility of dividing Lothair's kingdom. In 868 at Metz they agreed definitely to a partition; but when Lothair died in 869, Louis was ill, and his armies were engaged with the Moravians. Charles the Bald accordingly seized the whole kingdom; but Louis compelled him by a threat of war to agree to the Treaty of Mersen, which divided it between the claimants.

The later years of Louis were troubled by risings on the part of his sons, the eldest of whom, Carloman, revolted in 861 and in 863; an example followed by the second son Louis, who in a further rising was joined by his brother Charles. A report that Louis II. was dead led to peace between father and sons. The emperor, however, was not dead, but a prisoner; and as he was the nephew and son-in-law of Louis, that monarch hoped to secure both the imperial dignity and the Italian kingdom for his son Carloman. Meeting his daughter Engelberga, the wife of Louis II., at Trent in 872, Louis made an alliance with her against Charles the Bald, and in 874 visited Italy on the same errand. The emperor, having named Carloman as his successor, died in August 875, but Charles the Bald reached Italy before his rival, and by persuading Carloman to return, secured the imperial crown. Louis was preparing for war when he died on Sept. 28, 876 at Frankfort. He was in war and peace alike, the most competent of the descendants of Charlemagne. He obtained for his kingdom a certain degree of security against the Normans, Hungarians, Moravians and others. He lived in close alliance with the Church, to which he was very generous, and supported its missionary schemes.

Hist.* (vol. 3, 1922).

LOUIS (893–911), surnamed the "Child," king of the Franks, last of the German Carolingians, son of the emperor Arnulf, was born at Ottingen, designated by Arnulf as his successor in Germany in 897, and crowned on Feb. 4, 900. His chief adviser was Hatto I., archbishop of Mainz; and during his reign the kingdom was ravaged by Hungarians and torn with internal strife. He died in August or September 911 and was buried at Regensburg.

See O. Dietrich, *Beiträge zur Geschichte Arnolfs von Kärnthen und Ludwigs des Kindes* (1890).

LOUIS II. (846–879), king of France, called "le Bègue" or "the Stammerer," a son of Charles II. the Bald, Roman emperor and king of the West Franks, was born on Nov. 1, 846. After the death of his elder brother Charles in 866 he became king of Aquitaine, and in October 877 he succeeded his father as king of the West Franks, but not as emperor. He was crowned king by Hincmar, archbishop of Reims, on Dec. 8, following, and in Sept. 878 he was consecrated afresh by Pope John VIII. After an ineffectual reign of eighteen months Louis died at Compikgne on April 10 or 11, 879. By his first wife, Ansgarde, a Burgundian princess, he had two sons, his successors, Louis III. and Carloman; by his second wife, Adelaide, he had a posthumous son, Charles the Simple, who also became king of France.

The emperor Louis I. is counted as Louis I., king of France.

LOUIS III. (*c.* 863–882), king of France, was a son of Louis II. and with his brother Carloman succeeded his father as king in April 879. In consequence of the doubts cast upon the legitimacy of the young princes, it was proposed to offer the crown to the East Frankish ruler Louis, a son of Louis the German. But in September 879 the brothers were crowned at Ferrihres by Anshgisus, archbishop of Sens. A few months later they divided their kingdom, Louis receiving the part of France north of the Loire. They acted together against the Northmen, over whom in August 881 they gained a memorable victory, and against Boso, who claimed sovereignty over Burgundy and Provence. On Aug. 5, 882 Louis died at St. Denis and Carloman became sole king.

LOUIS IV. (921–954), king of France, surnamed "d'Outremer" *(Transmarinus),* was the son of Charles III. the Simple. On his father's imprisonment in 922, his mother Odgiva (Eadgyfu), sister of the English king Aethelstan, fled with him to England—a circumstance to which he owes his surname. But after the death of the usurper Rudolph (Raoul), Ralph of Burgundy, Hugh the Great, count of Paris, and the other French nobles, chose Louis for their king, and the lad was consecrated at Laon on June 19, 936. His reign was marked by a series of rebellions of the French nobles who refused to recognize his authority, and by an irruption of the Hungarians into Burgundy and Aquitaine (937). Backed by the Pope, Louis showed great zeal in quelling these revolts, and by an alliance with Otto the Great, formerly one of his most determined enemies, he gained a temporary success. The powerful vassal, Hugh the Great, was in 948 forced to make submission and to restore Laon to his sovereign; but the last years of the reign were troubled by fresh difficulties with Hugh the Great and also by an irruption of the Hungarians into the south of France. Louis died on Sept. 10, 954, and was succeeded by his son Lothair.

The chief authority for the reign is the chronicler Flodoard. *See* also Ph. Lauer, *La Règne de Louis IV d'Outre-Mer* (1900); and A. Heil, *Die politischen Beziehungen zwischen Otto dem Grossen und Ludwig IV. von Frankreich* (1904).

LOUIS V. (967–987), "le Fainéant" king of France, succeeded his father Lothair in March 986, and finally embroiled the Carolingian dynasty with Hugh Capet and Adalberon, archbishop of Reims. Louis died in May 987, his mother Emma being accused of having poisoned him.

See F. Lot, *Les Derniers Carolingiens* (1891); and the *Recueil des actes de Lothaire et de Louis V., ed. L.* Halphen and F. Lot (1908).

LOUIS VI. (1081–1137), king of France, surnamed "the Fat," "the Wideawake" or "the Bruiser," was the son of Philip I. and Bertha of Holland. He became associated with his father in the government about 1098, and by his victories over the English and the brigands, he won the support of the army against his step-mother, Bertrada, who tried to poison him. On the death of Philip I., in 1108, Louis was faced by powerful and rebellious barons, but after a hurried coronation at Orleans, he continued his policy of putting down feudal brigands and destroying their strongholds in the fle de France. So strong, however, were his enemies, that 24 years of continuous warfare were needed to root out the robber barons who lived on the plunder of the roads leading to Paris. In his opposition to the English, Louis was equally energetic. He supported William Clito, son of Robert of Normandy, against Henry I., and although worsted in the war which followed he continued to uphold the claims of his protegb. To oppose the forces of the emperor, Henry V., who had become the ally of the king of England, Louis even succeeded in gathering a national army under his flag, and thus temporarily consolidated his realm. Not only did he consolidate France, however, but he extended his power by acquiring control over Flanders.

In all his wars Louis fought in person, and for his prowess gained the reputation of a national hero, the protector of the poor, the Church, the peasants and the towns. He encouraged the communal movement on the fiefs of his vassals, and granted privileges to towns on his domains, but the title of "Father of the Communes," by which he is sometimes known, is not deserved. Neither was Louis the author of the movement for the emancipation of the serfs, his attitude being to favour emancipation only when it promised greater chance of profit. He was a great benefactor to the Church, aided the new, reformed monastic congregations of Cîteau, Prémontré and Fontevrault and chose his two chief ministers, Étienne de Garlande and Suger (*q.v.*) from the clergy. Louis died on Aug. 1, 1137.

See A. Luchaire, *Louis le Gros, annales de sa vie et son règne* (1890); and "Les Premiers Capétiens," in E. Lavisse's *Histoire de France;* Thomson, *Development of the French Monarchy under Louis VI. le Gros* (1895).

LOUIS VII. (*c.* 1121–1180), king of France, son of Louis VI. the Fat, was associated with his father and anointed by Innocent II. in 1131. In 1137 he succeeded his father, and in the same year married at Bordeaux Eleanor, heiress of William II., duke of Aquitaine. In the first part of his reign he was vigorous and jealous of his prerogatives, but after his crusade his religiosity developed to such an extent as to make him utterly inefficient. His accession was marked by no serious disturbances, save the risings of the burgesses of Orleans and of Poitiers, but he came into violent conflict with Pope Innocent II. The archbishopric of Bourges became vacant, and the king supported as candidate the chancellor Cadurc, against the pope's nominee Pierre de la

Châtre, swearing upon relics that so long as he lived Pierre should never enter Bourges. This brought the interdict upon the king's lands. He became involved in a war with Theobald, count of Champagne, which lasted two years (1142–44). The royal army occupied Champagne, and captured Vitry, where many persons perished in the burning of the church. Geoffrey the Handsome, count of Anjou, by his conquest of Normandy threatened the royal domains, and Louis VII by a clever manoeuvre threw his army on the Norman frontier and gained Gisors, one of the keys of Normandy.

At his court, which met in Bourges, Louis declared on Christmas day, 1145, his intention of going on a crusade. St. Bernard preached the crusade at Vézelay (Easter, 1146), and Louis set out from Metz in June 1147, on the overland route to Syria. The expedition was disastrous, and he regained France in 1149, overcome by humiliation. He caused a council at Beaugency (on March 21, 1152) to annul his marriage with Eleanor of Aquitaine, under pretext of kinship. Eleanor married Henry II of England in the following May, and brought him the duchy of Aquitaine. Louis VII led a half-hearted war against Henry; but in Aug. 1154 gave up his rights over Aquitaine, and contented himself with an indemnity. In 1154 Louis married Constance, daughter of the king of Castile, and their daughter Marguerite he affianced imprudently by the treaty of Gisors (1158) to Henry, eldest son of the king of England, promising as dowry the Vexin and Gisors. After the death of Constance (1160), Louis VII married Adèle of Champagne. Louis VII gave little sign of understanding the danger of the growing Angevin power, though in 1159 he aided Raymond V, count of Toulouse, against Henry II. At the same time the emperor Frederick I in the east was making good the imperial claims on Arles. When the schism broke out, Louis took the part of the pope, Alexander III. He supported Henry's rebellious sons, but acted slowly and feebly, and so contributed to the break-up of the coalition (1173–74).

Finally, in 1177, the pope intervened to bring the two kings to terms at Vitry. By his third wife, Adble, Louis had an heir, the future Philip Augustus, born on Aug. 21, 1165. He had him crowned at Reims in 1179, and died on Sept. 18, 1180.

BIBLIOGRAPHY.—R. Hirsch, *Studien zur Geschichte König Ludwigs VII. von Frankreich* (1892); A. Cartellieri, *Philipp II. August von Frankreich bis zum Tode seines Vaters, 1165–1180* (1891); A. Luchaire, *Études sur les actes de Louis VII.* (1885), and section in E. Lavisse's *Histoire de France,* tome iii, 1st part, pp. 1–81.

LOUIS VIII (1187–1226), king of France, eldest son of Philip Augustus and of Isabella of Hainaut, was born in Paris on Sept. 5, 1187. Louis left the reputation of a saint, but was also a warrior prince. In 1213 he led the campaign against Ferrand, count of Flanders; in 1214, while Philip Augustus was winning the victory of Bouvines, he held John of England in check, and was victorious at La Roche-aux-Moines. In the autumn of 121; Louis received from a group of English barons, headed by Geoffrey de Mandeville, a request to "pluck them out of the hand of this tyrant" (John), Louis himself prepared to invade England. The expedition was forbidden by the papal legate, but Louis landed at Stonor on May 22, 1216. (See ENGLISH HISTORY.) The pretexts on which he claimed the English crown were set down in a memorandum drawn up by French lawyers in 1215. These claims—that John had forfeited the crown by the murder of his nephew, Arthur of Brittany, and that the English barons had the right to dispose of the vacant throne—lost their plausibility on the death of King John and the accession of his infant son as Henry III in Oct. 1216. The papal legate, Gualo, arrived in England at the same time as Louis. He excommunicated the French troops and the English rebels; and, after the "Fair of Lincoln," in which his army was defeated, Louis resigned his pretensions, though by a secret article of the treaty of Lambeth (Sept. 1217) he secured a small war indemnity.

Louis had assisted Simon de Montfort in his war against the Albigenses in 121j; and after his return to France he again joined the crusade. With Simon's son and successor, Amaury de Montfort, he directed the brutal massacre which followed the capture of Marmande. Philip Augustus dying on July 14, 1223, Louis VIII was anointed at Reims on Aug. 6. He continued his father's policy. His reign was taken up with two great designs: (1) to destroy the power of the Plantagenets; and (2) to conquer the heretical south of France. An expedition conquered Poitou and Saintonge (1224) but did not succeed in securing possession of Aquitaine. In 1226 he led the crusade against the Albigenses in the south, forced Avignon to capitulate and received the submission of Languedoc. While passing the Auvergne on his return to Paris, he died at Montpensier on Nov. 8, 1226. His reign, short as it was, brought gains to the royal domains. He had married in 1200 Blanche of Castile, daughter of Alphonso VIII (or IX) of Castile and granddaughter of Henry II of England, who bore him 12 children; his eldest surviving son was his successor, Louis IX.

BIBLIOGRAPHY.—C. Petit-Dutaillis, *Elude sur la vie et le règne de Louis VIII* (Paris, 1894); E. Lavisse, *Histoire de France,* vol. iii (Paris, 1904); R. Fawtier, *Les Capétiens et la France* (Paris, 1942).

LOUIS IX (1214–1270), king of France, known as Saint Louis, was born on April 25, 1214. His father, Louis VIII, died in 1226, but his mother, Blanche of Castile, secured her son's coronation at Reims on Nov. 29, 1226; and mainly by the aid of the papal legate, Romano Frangipani, bishop of Porto (d. 1243), and of Thibaut (Theobald) IV, count of Champagne, was able to thwart the rebellious plans of Peter of Dreux (Pierre Mauclerc, duke of Brittany) and Philip Hurepel, a natural son of Philip Augustus. Peter and Thibaut were both obliged to go on crusade. Louis IX married Margaret, daughter of Raymund-Berengar IV, count of Provence, in May 1234. The reign was comparatively uneventful. A rising of the nobles of the southwest reached threatening dimensions in 1242, but the king's armies easily overran the lands of the rebel Hugh de Saintonge and defeated Henry III of England, who had come to his aid, at Saintes. Raymond VII, count of Toulouse, yielded without resistance upon the advent of two royal armies and accepted the peace of Lorris in Jan. 1243.

At the end of 1244, during an illness, Louis took the cross. He had already been much distressed by the plight of John of Brienne, emperor at Constantinople, and bought from him the crown of thorns, parts of the true cross, the holy lance and the holy sponge. The Sainte Chapelle in Paris still stands as a monument to the value of these relics to the saintly king. But the quarrel between the papacy and the emperor Frederick II, in which Louis maintained a watchful neutrality—interfering only to prevent the capture of Innocent IV at Lyons—and the difficulties of preparing the crusade delayed his embarkation until Aug. 1248. His defeat and capture at Mansura in Feb. 1250 and the next four years spent in Syria in captivity, in diplomatic intrigues and finally in raising the fortifications of Caesarea and Joppa are events which belong to the history of the crusades (*q.v.*). His return to France was urgently needed, since Blanche of Castile, whom he had left as regent, had died in Nov. 1252, and upon the removal of her strong hand feudal turbulence had begun to show itself.

This period between his first and second crusades (1254–69) is the real age of Saint Louis in the history of France. He imposed peace between warring factions of his nobility by mere moral force, backed up by something like an awakened public opinion. His nobles often chafed under his unrelenting justice but never dared rebel. The most famous of his settlements was the treaty of Paris, drawn up in May 1258 and ratified in Dec. 1259, by which the claims of Henry III of England were adjusted. Henry renounced absolutely Normandy, Anjou, Touraine, Maine and Poitou and received, on condition of recognizing Louis as liege suzerain, all the fiefs and domains of the king of France in the diocese of Limoges, Cahors and Perigueux and the expectation of Saintonge south of the Charente and also Agenais, if they should fall to the crown of France by the death of Alphonse of Poitiers. This treaty was unpopular, since the king surrendered a large part of France that Henry had not won; but Louis was satisfied that the absolute sovereignty over the northern provinces more than equalled the loss in the south.

Louis made a similar compromise with the king of Aragon in the treaty of Corbeil (1258), whereby he gave up the claims of kings of France to Roussillon and Barcelona, which dated from the conquest of Charlemagne. The king of Aragon in his turn gave up his claims to part of Provence and Languedoc, with the exception of Narbonne. Louis's position was strikingly shown in 1264, when the English barons submitted their attempt to bind Henry III by the Provisions of Oxford to his arbitration. His reply in the "Dit," or Mise, of Amiens was a flat denial of all the claims of the barons and failed to avert the civil war.

Upon the whole Louis maintained peace with his neighbours, although both Germany and England were torn with civil wars. He sanctioned the conquest of Naples by his brother Charles, duke of Anjou.

On March 24, 1267, Louis proclaimed his purpose of going on a second crusade. Three years of preparation followed; then on July 1, 1270, he sailed from Aigues Mortes for Tunis, whither the expedition seems to have been directed by the machinations of Charles of Anjou, who, it is claimed, persuaded his brother that the key to Egypt and to Jerusalem was that part of Africa which was his own most dangerous neighbour. After seven days' voyage to Carthage, one month of the summer's heat and plague decimated the army; and, when Charles of Anjou arrived, he found that Louis had died of the plague on Aug. 25, 1270.

Saint Louis stands in history as the ideal king of the middle ages. An accomplished knight, physically strong in spite of his ascetic practices, fearless in battle, heroic in adversity, of imperious temperament, unyielding when sure of the justness of his cause, energetic and firm. he was indeed "every inch a king." Moreover, he was a great saint, devout without excessive bigotry, submissive to the church but interested in the doctrinal controversies of his time. Above all, his constant care of justice and order altered the character of the Capetian monarchy: by submitting the *baillis* to a closer inspection by means of "grandes enquêtes," no less than by promulgating a series of writs (for good morals, against blasphemy, against trials by combat, against forgery, etc.), he reinforced the royal authority, to which his own person imparted a prestige never attained by it before, while his power verged on absolutism. He had neither favourite nor prime minister. Louis was canonized in 1297.

The best contemporary account of Louis IX is to be found in the *Histoire de Saint Louis* by Jean, sire de Joinville (*q.v.*), published in a Modern French version as *La Vie de Saint Louis, by H.* Longnon (Paris, 1929) and in English, as *The History of Saint Louis* by Joan Evans (Oxford, 1938). *See* also C. V. Langlois in *Histoire de France,* ed. by E. Lavisse, vol. iii (Paris, 1904); C. Petit-Dutaillis and P. Guinard, *L'Essor des ttats d'occident (Histoire générale,* ed. by G. Glotz, section "Moyen Age," vol. iv, p. 2, Paris, 1944); R. Fawtier, *Les Capétiens et la France* (Paris, 1942); A. Garreau, *Saint Louis et son voyaume* (Paris, 1949); H. A. LOUIS X (1289–1316), king of France and Navarre, called LE HUTIN or "the Quarreller," was the eldest son of Philip IV of France and of Joan of Navarre. Born at Paris on Oct. 4, 1289, he took the title king of Navarre on the death of his mother (April 2, 1305); he succeeded his father on Nov. 30, 1314. Baronial reaction against the growth of the royal power under Philip had already shown itself in a number of leagues and provincial assemblies, and Louis had to dismiss most of his father's councillors (Enguerrand de Marigny was hanged) and to grant a number of charters recognizing the nobility's rights (the first to the Normans on March 19, 1315) and similar ones to the clergy. The baronial movement in France was, however, much less serious for the royal power than the contemporary one in England: lacking political ideas and leaders, the nobility asked redress of local grievances only, not against the king but against his officers, and Louis was clever enough to use evasive formulas which in reality conceded nothing but gave to the nobility the illusion that its complaints were most seriously considered. In foreign policy Louis inherited the Flemish problem from his father: Robert of Béthune, count of Flanders, refused to do homage as promised in the treaty of Athis-sur-Orge (1305); an army sent to Flanders in 1315 achieved little because of bad weather. An ordinance of 131j invited the serfs of the royal domains to buy their liberty and even obliged them; for fiscal reasons, to do so. Louis died on June 5, 1316. By his first wife, the notorious Margaret of Burgundy, who was convicted of adultery and died in prison, he had one daughter, Joan, who married Philip, count of Evreux and king of Navarre; by his second wife, Clemence of Hungary, he left a posthumous son, King John I.

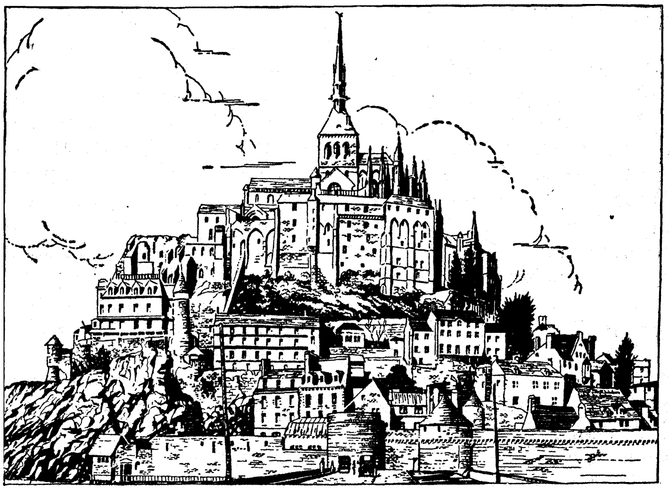
LOUIS XI (1423–1483), king of France, the son of Charles VII and his queen, Mary of Anjou, was born on July 3, 1423, at Bourges. where his father, then nicknamed the "King of Bourges," had taken refuge from the English. At the birth of Louis part of France was in English hands; when he was five years old, Joan of Arc appeared; he was just six when his father was crowned at Reims. But his boyhood was spent apart from these stirring events, in the castle of Loches, where he had as tutors Jean Majoris and Bernard of Armagnac.

In June 1436 Louis was married to Margaret (c. 1425–45), daughter of James I of Scotland. Three years after this unhappy marriage Louis entered upon his stormy political career. Sent by his father in 1439 to direct the defense of Languedoc against the English and to put down the brigandage in Poitou, he was induced by the rebellious nobles to place himself at the head of the Praguerie (*q* v.). Charles VII pardoned him this rebellion, and he was fighting the English in 1440 and aided his father to suppress the revolt of the count of Armagnac in 1443. In 1444 he led an army of from 15,000 to 20.000 mercenaries and brigands—the product of the Hundred Years' War—against the Swiss of the canton of Basle. After an ineffective siege, he made peace with the Swiss confederation and led his robber soldiers into Alsace to ravage the country of the Habsburgs, who refused him the promised winter quarters. Meanwhile, his father, making a parallel campaign in Lorraine, had assembled his first brilliant court at Nancy; and, when Louis returned, he found the king completely under the spell of Agnès Sorel. The death in 1445 of Louis's wife, Margaret, who mas a great favourite of Charles VII's, made the rupture complete. From that year until the death of the king, father and son were enemies. Louis prepared a plot to seize the king and his minister Pierre de Brézé. The plot was revealed to Charles, who banished his son to Dauphiné (1447). Louis never saw his father again.

Louis dismissed the governor of Dauphiné and settled the boundaries between it and the territories of the duke of Savoy and



THE ABBEY OF MONT-ST.-MICHEL, MADE FAMOUS BY LOUIS XI, WHO INSTITUTED THERE THE ORDER OF KNIGHTS OF ST. MICHAEL

of the papacy; and he enforced his authority over perhaps the most unruly nobility in western Europe, both lay and ecclesiastical. He made a secret treaty with the duke of Savoy. which was to give him right of way to Genoa, and made arrangements for a partition of the duchy of Milan. The alliance with Savoy was sealed by the marriage of Louis with Charlotte, daughter of Duke

Ludovico, in 1452, in spite of the formal prohibition of Charles VII. The king marched south but withdrew again, leaving his son unsubdued. Four years later, as Charles came to the Bourbonnais, Louis, fearing for his life, fled to Flanders to the court of Philip the Good, duke of Burgundy, leaving Dauphiné to be definitely annexed to the crown of France. The policy of the dauphin was reversed; his ten years' work was undone. Meanwhile, he was installed in the castle of Genappe, in Brabant, where he waited impatiently for five years for the death of his father, keeping himself posted by spies on every stage of the king's illness and thus laying himself open to the unsubstantiated accusation, believed by Charles himself, that he had hastened the end by poison.

On Aug. 15, 1461, Louis was anointed and crowned at Reims. His first act was to strike at the faithful ministers of Charles VII. Pierre de Brézé and Antoine de Chabannes were captured and imprisoned. But the more serviceable of the officers of Charles VII were for the most part soon reinstated; Louis's advisers a-ere mostly men of the middle class. Among the most prominent of these men, in addition to Brézé, Chevalier and Chabannes, were Tristan Lermite, Jean de Daillon, Olivier Le Daim (the barber) and, after 1472, Philippe de Commines, drawn from the service of Charles the Bold of Burgundy. who became his most intimate adviser and his biographer. This entourage was not a good one; and Louis's complex character, in which piety was combined with a ruthlessness and a dissimulation that earned him the name of *universelle aragne* ("universal spider"), was unlikely to seem attractive. However, he had the high qualities of a king: intelligence, energy and a knowledge of his duty. His advisers were loyal, and he won a great victory over the last feudal lords, enlarged the royal domain, imposed his authority and developed the wealth of the kingdom.

Louis XI began his reign with the same high-handed treatment of the nobles which had marked his rule in Dauphiné, going so far as to forbid them to hunt without his permission. He forced the clergy to pay long-neglected feudal dues and intrigued against the great houses of Anjou and Orleans in Italy. The malcontent nobles soon began to plan revolt. Discharged officers of Charles VII, like Jean Dunois and John II, duke of Bourbon, stirred up hostility to the new men of the king; and Francis II, duke of Brittany, was soon embroiled with Louis over an attempt to assert royal control over that practically independent duchy. The dissatisfied nobility found their greatest ally in Charles the Bold. afterward duke of Burgundy, and in 1465 formed a "league of public welfare" and declared war on their king. The nominal head mas the king's brother Charles, duke of Berry. then 18 years old, a weak character, the tool of the rebels as he was later the dupe of the king. Every great noble in France was in the league, except Gaston of Foix—who kept the south of France for the king—and the counts of Vendôme and Eu.

The whole country seemed on the verge of anarchy. It was saved by the refusal of the lesser gentry to rise and by the alliance of the king with the citizen class. After a successful campaign in the Bourbonnais, Louis fought an indecisive battle with Burgundians who had marched on Paris, at Montlhéry, on July 16, 1465. and then stood a short siege in Paris. On Sept. 28 he made a truce with Charles the Bold, and in October the treaties of Conflans and Saint Maur-les-Fossés ended the war. The king yielded at all points; gave up the "Somme towns" in Picardy, for which he had paid 200,000 gold crowns, to Philip the Good, thus bringing the Burgundians close to Paris and to Normandy. Charles, the king's brother, was given Normandy as an appanage, thus joining the territories of the rebellious duke of Brittany with those of Charles the Bold. The kingdom was plundered both by royal tax-gatherers and by unsubdued feudal lords.

Two months after he had granted Normandy to Charles. Louis took advantage of a quarrel between the duke of Brittany and his brother to take it again, sending the duke of Bourbon "to aid" Charles, while Dunois and Chabannes prepared for the struggle with Burgundy. The death of Duke Philip, on June 1j. 1467, gave Charles the Bold a free hand. He gained over Edward IV of England, whose sister Margaret he married; but while he was celebrating the wedding Louis invaded Brittany and detached Duke Francis from alliance with him. Normandy was completely reduced. The king's triumph was followed by his greatest mistake. After an interview between Charles and Louis at Péronne false news of Charles's death was spread, apparently at Louis's instigation. The king was humiliated and renewed intrigues followed. He attempted a diversion by assisting the Lancastrians in England. A new revolt was planned in 1471 hut came to nothing. The country was saved a desperate civil war by the death of the king's brother Charles, the nominal head of the coalition, on May 24, 1472. Charles the Bold, who had again invaded France, was obliged to make a lasting truce. Louis then forced the duke of Brittany to make peace and turned against John V, count of Armagnac, whose death at the opening of March 1473 ended the power of one of the most dangerous houses of the south. The first period of Louis's reign was closed, and with it closed the danger of dismemberment of France. John of Aragon continued the war in Roussillon and Cerdagne for two years. After the capture of Perpignan on March 10, 1475, the wise and temperate government of Imbert de Batvrnay and Boffile de Juge slowly pacified the new provinces. The death of Gaston IV, count of Foix, in 1472 opened up the struggle for Navarre.

The overthrow of Charles the Bold was the second great task of Louis XI. Charles's ally. Edward IV, invaded France in June 1475, but Louis bought him off on Aug. 29, at Picquigny. In September the invaders recrossed to England. The count of Saint Pol, who had continued to play his double part, was surrendered by Charles to Louis and executed, as was also Jacques d'Armagnac, duke of h'emours. Louis subsidized the Swiss and René II of Lorraine in their war upon Charles. The defeat and death of the duke of Burgundy at Nancy on Jan. 5, 1477, was the crowning triumph of Louis's diplomacy. But he was so eager to seize his rival's whole inheritance that definite peace was not established until after the death of Mary of Burgundy, Charles's daughter, who had married Maximilian of Austria; but by the treaty of Arras (1482) Louis received Picardy, Artois and the Boulonnais, as well as the duchy of Burgundy and Franche Comté. The Austrians were left in Flanders, a menace and a danger. The unification of France was completed (except for Brittany); and the frontiers were extended by the acquisition, upon the death of René of Anjou in 1480, of the duchies of Anjou and Bar and, upon the death of Charles II, count of Maine, in 1481, oi Maine and Provence. Of the Angevin inheritance only Lorraine escaped the king.

Failure in Spain was compensated in Italy. Without waging war Louis made himself virtual arbiter of the fate of the principalities in the north, and his court was always besieged by ambassadors from them. After the death of Charles the Bold, Yolande, duchess of Savoy, was obliged to accept the control of Louis. who was her brother. In Milan he helped to place Ludovico il Moro in power in 1479, but he reaped less from this supple tyrant than he had expected. Pope Sixtus IV, the enemy of the Medici, was also the enemy of the king of France. When Sixtus threatened Florence after the Pazzi conspiracy (1478), Louis aided Lorenzo dei Medici to form an alliance with Naples, which forced the papacy to come to terms. After his victory over the feudal lords. Louis imposed his authority over his other subjects. Ecclesiastical elections were taken under his control. He was continually in violent dispute with the parlement of Paris and made "justice" another name for arbitrary government; yet he dreamed of a unification of the local customary laws (*coutumes*) of France. The states-general met but once in his reign, in 1468, and then no talk of grievances was allowed: his object was only to get them to declare Kormandy inalienable from the crown; he raised his revenue without consulting them. His financial demands were enormously greater than ever before and he drained the land and towns of enormous sums. However, he was supported by the upper bourgeoisie, the aristocracy of the "good cities" which had been his allies against the nobles; for instance, Jean de Beaune and Jean Briçonnet of Tours and Pierre Doriole of La Rochelle. Numerous edicts tended to restrict to certain privileged families the rank of master workman in the guilds. Louis encouraged the cloth and silk industries and the working of mines and favoured the introduction of printing into France. He planned to unify the various systems of weights and measures. The maritime trade and the Lyons fairs took advantage of his treaties with England and the Hansa towns. Louis even dreamed of a company to monopolize the trade of the Mediterranean.

The contemporaries of Louis XI, who did not love him, looked only at his demands. During the last two or three years of his life Louis lived in great isolation, "seeing no one, speaking with no one, except such as he commanded," in the chateau of Plessis-les Tours, 2 mi. S.W. of Tours, that "spider's nest" bristling with watchtowers, and guarded only by the most trusty servitors. A swarm of astrologers and physicians preyed upon his fears and his purse. But, however foolish in his credulity, he still made his strong hand felt both in France and in Italy, remaining to the last "the terrible king." His fervent prayers were interrupted by instructions for the regency which was to follow. He died on Aug. 30,1483, and was buried in the church at Cléry, not at St. Denis. He left a son, his successor Charles VIII, and two daughters.

LOUIS **XII.** (1462–1515), king of France, was grandson of Louis of Orleans, the brother of Charles VI., and son of the poet prince, Charles of Orleans, who, after the battle of Agincourt, spent twenty-five years of captivity in England. Louis was duke of Orleans until his accession to the throne. He married at fourteen, Joan, daughter of Louis XI. He revolted against Charles VIII., and for three years (1488–91) was a prisoner. In 1494 he held a command in the invasion of northern Italy. He succeeded Charles VIII. in 1499. He enjoyed a genuine popularity, and in 1506 the estates of Tours conferred on him the surname of *Père du Peuple.* He led in person several armies into Italy, and proved as severe and pitiless towards his enemies as he was gentle and clement towards his subjects. Louis had two daughters. After his accession he divorced Joan, and married, in 1499, Anne of Brittany, the widow of Charles VIII. On her death in January 1514, he married in 1514, for political reasons, Mary Tudor, sister of Henry VIII. of England. (See MARY, queen of France.) He died on Jan. 1, 1515.

LOUIS XIII. (1601–1643), king of France, was the son of Henry IV. and of Marie de' Medici. He became king on his father's assassination in 1610; but his mother at once seized the full powers of regent. She determined to bring France into alliance with Spain and the Austrian house. Louis was to marry Anne of Austria, daughter of the Spanish king, Philip III., and the Spanish prince, afterwards Philip IV., himself was to marry the Princess Elizabeth, the king's sister. The marriages were concluded in 1615. The next years were full of civil war and political intrigue, during which the queen relied upon the Marshal d'Ancre. Louis XIII. was attached to Charles d'Albert, sieur de Luynes; and with his help he arrested Marshal d'Ancre, and on his resistance had him assassinated. From this time to her death the relation between the king and his mother was one of concealed or open hostility. The article on FRANCE must be consulted for the intricate events of the following years.

The decisive incident for his private life as well as for his reign was the entrance of Cardinal Richelieu (*q.v.*) hitherto the queen's chief adviser, into the king's council in 1624. Henceforth the policy of France was directed by Richelieu, who returned to the policy of Henry IV. abroad, and asserted the power of the crown against all rivals at home. This policy brought Louis into unremitting conflict with the Protestants and the nobles of France, but also made him the enemy of his mother, of his brother Gaston of Orleans, who made himself the champion of the cause of the nobles, and sometimes even of his wife. It is not easy to define his relations to Richelieu. He was convinced of his loyalty and of his genius, and in the end always supported his policy. But he disliked the friction with his family circle which this policy produced. For the most part his share in the great events of the reign was a passive one. There were certain occasions when it seemed as if he would oppose Richelieu. The chief of these was what is known as the "Day of Dupes" (1630). Then the queen-mother and the king's brother passionately attacked the minister, and for a moment it was believed that Richelieu was dismissed and that the queen-mother and a Spanish policy had triumphed. But the minister regained his ascendancy over the king, punished his enemies and forced Marie de' Medici and Gaston of Orleans to sue for pardon. In 1631 Gaston fled to Lorraine and the queen-mother to Brussels. Gaston soon returned, to plot, to fail and to sue for pardon again and again; but Marie de' Medici ended her life in exile.

But the last great effort to overthrow Richelieu was the conspiracy of Cinq-Mars (*q.v.*), one of the king's personal favourites. Cinq-Mars believed himself secure of the king's favour. But Richelieu discovered his treasonous relations with Spain, and defeated his plot. Louis was reconciled to his minister. "We have lived too long together to be separated" he is reported to have said (September 1642). Yet when Richelieu died in December of the same year he allowed himself to speak of him in a jealous and satirical tone. He died himself a few months later (May 1643). (*See* also RICHELIEU, ARMAND JEAN DU PLESSIS DE.)

The chief source of information on Louis XIII.'s life is to be found in the contemporary memoirs, of which the chief are: Bassompierre, Fontenay-Mareuil, Gaston d'Orléans, Montrésor, Omer Talon. Richelieu's own Memoirs are chiefly concerned with politics and diplomacy. Of modem works those most directly bearing on the king's personal life are R. de Beauchamp, *Louis XIII. d'après sa correspondance avec le cardinal de Richelieu;* G. Hanotaux, *Histoire du cardinal de Richelieu* (1893–96); Rossignol, *Louis XIII. avant Richelieu;* M. Topin, *Louis XIII. et Richelieu* (1876). *See* too Professor R. Lodge, *Richelieu;* J. B. *H.* R. Capefigue, *Richelieu, Mazarin et la Fronde* (1835–36); and Dr. J. H. Bridges, *Richelieu, Mazarin and Colbert* (1866); Aymes, *La France sous Louis XIII.* (1909); *Lettres de la main de Louis XIII.* (2 pt. 1914).

For full bibliography *see* G. Monod, *Bibliographie de l'histoire de France; Cambridge Modern History,* vol. iv. ("The Thirty Years' War"); Lavisse et Rambaud, *Histoire générale,* vol. v. ("Guerres de religion").

LOUIS **XIV.** (1638–1715), king of France, was born at Saint-Germain-en-Laye on Sept. 5, 1638, the son of Louis XIII. and Anne of Austria. The death of his father made the child of five king on May 14, 1643. Power lay in the hands of the queen-mother and of her minister, Cardinal Mazarin, who had to face the domestic troubles of the Fronde and the last stages of the Thirty Years' War. Twice the court had to flee from Paris; once when there was a rumour of intended flight the populace was admitted to see the king in his bed. The memory of these humiliations played their part in developing later the autocratic ideas of Louis. Mazarin triumphed alike over his domestic and his foreign opponents. The Fronde was at an end by 1653; the peace of Westphalia (1648) and the peace of the Pyrenees (1659) marked the success of the arms and of the diplomacy of France. Louis XIV. was now twenty-one years of age. The peace of the Pyrenees was cemented by the marriage of Louis to his cousin, the Infanta Maria Theresa.

The marriage took place at once, and the king entered Paris in triumph in 1660. Mazarin died in the next year; and the king at once announced his intention of being his own first minister. He built up a thoroughly personal system of government, and presided constantly over the council and many of its committees.

Even the greatest of his ministers found themselves controlled by the king. Fouquet, the finance minister, was overthrown and condemned to perpetual imprisonment. Those who had most of the king's confidence afterwards were Colbert for home affairs; Lionne for diplomacy, Louvois for war; but as his reign proceeded he became more intolerant of independence of judgment in his ministers.

His court was brilliant. In art and in literature, the great period, which is usually called by the king's name, had in some respects passed its zenith when he began to reign. But France was unquestionably the first state in Europe both in arms and arts, and within France the authority of the king was practically undisputed. The nation, proud of its pre-eminence and weary of civil war, saw in the king its true representative and the guarantee of its unity and success. Louis played the rôle of *Grand Monarque* to perfection. His wife Maria Theresa bore him children but there was no community of tastes between them, and the chief influence at court is to be found not in the queen but in the succession of avowed mistresses: Louise de la Vallière, Madame de Montespan and Madame de Maintenon (*q.v.*), who ruled, however, not as mistress but as wife. Through her influence the king was reconciled to his wife, and, when Maria Theresa died in 1683, Madame de Maintenon shortly afterwards (in 1684) became the king's wife, though this was never officially declared. Under her influence the court lost most of its gaiety, and religion came to exercise much control over the life and the policy of the king.

The first years of the king's rule were marked by the great schemes of Colbert for the financial, commercial, industrial and naval reorganization of France, and in these schemes Louis took a deep interest. But in 1667 began the long series of wars, which lasted with little real intermission to the end of the reign. (*See* FRANCE.) The War of Devolution (or the Queen's War) in 1667–68 to enforce the queen's claim to certain districts in the Spanish Netherlands, led to the Dutch War (1672–78), and in both these wars the supremacy of the French armies was clearly apparent. The next decade (1678–88) was the real turning point in the history of the reign, and the strength of France was seriously diminished. The chief cause of this is t~ be found in the revocation of the Edict of Nantes. The French Huguenots found their privileges decreased, and then, in 1685, the edict was altogether withdrawn. The results were ruinous to France, which lost many thousands of her best citizens and, also, Protestant alliances in Europe which had been in the past her great diplomatic support. The English Revolution of 1688 changed England from a wavering ally into the most determined of the enemies of France.

The war with the Grand Alliance, of which King William III. was the heart and soul, lasted from 1688 to 1697; and the treaty of Ryswick, which brought it to an end, deprived France of certain territories on her frontier. But Louis saw in the Spanish question a chance of more than making up for this loss. The Spanish king Charles II. was dying, and the future of the possessions of Spain was doubtful. The astute diplomacy of Louis succeeded in winning the inheritance for his grandson Philip. But this involved France and Europe in an immense war (1700) and by the Peace of Utrecht (1713), though the French prince retained the Spanish crown, France had again to make concessions of territory.

The peace found France burdened with debt; the reforms of Colbert were ruined; and opposition to the king's régime began to make itself felt. Peace brought some relief to France, but the last years of the king's life were gloomy in the extreme. His eldest son, the dauphin, died in April 1711; his eldest grandson the duke of Burgundy in Feb. 1712; and his great-grandson the duke of Brittany in March 1712. The heir to the throne was now the duke of Burgundy's son, the duke of Anjou, afterwards Louis XV. The king died on Sept. 1, 1715, after the longest recorded reign in European history. The judgment of posterity has not repeated the flattering verdict of his contemporaries; but he remains the model of a great king in all that concern the externals of kingship.

The reign Louis XIV. is particularly rich in memoirs describing the life of the court. The chief are Madame de Motteville's memoirs for the period of the Fronde, and the letters of Madame de Sévigné and the memoirs of Saint-Simon for the later period. The king's ideas are best seen in the *Mémoires de Louis XIV. pour l'instruction du dauphin* (edited by Dreyss, 2 vols.). His private life is revealed in the letters of Madame de Maintenon and in those of Madame, Duchesse d'Orléans. *See* also Voltaire, *Siècle de Louis XIV.*; P. Clément, *Histoire de la vie et de l'administration de Colbert;* Blennerhasset, *Louis and Madame de Maintenon* (1910); Martin and Besançon, *Hist. du crédit en France sous le règne de Louis XIV.* (1913); d'Angelo, *Luigi XIV. et la Santa Sede, 1689–93* (1914); M. ("The Age of Louis XIV.") of the *Cambridge Modern History;* and vol. vi. ("Louis XIV.") of the *Histoire générale* of Lavisse and Rambaud.

LOUIS XV. (1710–1774), king of France, was the great-grandson of Louis XIV. and the third son of Louis, duke of Burgundy, and Marie Adelaide, princess of Savoy. He was five years old when Louis XIV. died. With the help of the parlement of Paris the arrangement for a council of regency made by the late king was set aside, and the duke of Orleans was declared regent with full powers. Fleury, bishop of Fréjus, was appointed the king's tutor. He attained his legal majority at the age of thirteen, shortly before the death of the duke of Orleans. His first minister was the incapable duke of Bourbon, who in 1725 procured his marriage to Maria Leszczynska, daughter of the exiled king of Poland. In 1726 the duke of Bourbon was displaced by the king's tutor, Fleury, who exercised almost absolute power. His administration was successful and peaceful until the year 1734, when France intervened in Poland on behalf of the queen's father. The peace of Vienna (1735) secured to France the possession of Lorraine. In 1740 France drifted into the war of the Austrian Succession as an ally of Frederick of Prussia and the enemy of England, and of Maria Theresa of Austria.

On Fleury's death in 1743 Louis XV. determined to rule alone, but he was not strong enough in will or intellect to rule effectively. The queen for some time seems to have secured his affections, and she bore him seven children. But Louis entertained a series of mistresses. The first to acquire notoriety was the duchess of Châteauroux, the third sister of one family who held this position. He dismissed her in a fit of piety after an illness, but her place was taken in 1745 by Madame de Pompadour, whose influence on public affairs was a fatal one. She had many rivals during her lifetime and on her death in 1764 she was succeeded by Madame du Barry (*q.v.*). To the last Louis maintained the pretence of personal rule, but the machinery of government fell out of gear, and the disorder of the finances was never remedied before the revolution of 1789.

The peace of Aix-la-Chapelle (1748), which ended the war of the Austrian Succession, brought no gains to France in spite of her victories at Fontenoy and Raucoux; and the king was blamed for the diplomatic failure. The interval between this war and the Seven Years' War (1756) saw that great reversal of alliances which is sometimes called the "Diplomatic Revolution"; whereby France repudiated the alliance of Frederick the Great and joined hands with her old enemy Austria. The intrigues of Madame de Pompadour played in this change an important though not a decisive part. It was the cause of immense disasters to France; for after a promising beginning, both by land and sea, France suffered reverses which lost her both India and Canada and deprived her of the leading position which she had so long held in Europe. Her humiliation was declared by the peace of Paris (1763).

The article on the history of France (*q.v.*) shows how there arose during the last years of Louis XV.'s reign a strong reaction against the monarchy and its methods. In the parlements, provincial and Parisian; in religion and in literature, a note of opposition was struck which was never to die until the monarchy was overthrown. France annexed Corsica in 1768, but this was felt to be the work of the minister Chauvelin, and reflected no credit on the king. He died on May 10, 1774.

For the king's life generally *see* the memoirs of Saint-Simon, d'Argenson, Villars and Barbier, and for the details of his private life E. Boutaric, *Correspondance secrète de Louis XV.;* Madame de

Pompadour's *Correspondance* published by P. Malassi; Dietric, *Les Maîtresses de Louis XV.;* and Fleury, *Louis XV. intimes et les petites maîtresses* (1909).

For the system of secret diplomacy and organized espionage, *see* Albert duc de Broglie, *Le Secret du roi, Correspondance secrète de Louis XV. avec ses agents diplomatiques 1752–1774* (1878); Cahen, *Les querelles religieuses et parlementaires sous Louis XV.* (1913); and for a general account of the reign, H. Carré, *La France sous Louis XV.* (Paris, 1891); Mouffle d'Angerville, *The Private Life of Louis XV.* (1924); also C. Saint-André, *Louis XV.* (1921). For other works, general and special, *see* G. Monod, *Bibliographie de la France*, and the bibliography in the *Histoire générale* of Lavisse and Rambaud, vol. vii., and the *Cambridge Modern History*, vol. vi.

LOUIS XVI. (1754–1793), king of France, was the son of Louis, dauphin of France, the son of Louis XV., and of Marie Joseph of Saxony, and was born at Versailles on Aug. 23, 1754, being baptized as Louis Augustus. His father's death in 1765 made him heir to the throne, and in 1770 he married Marie Antoinette (*q.v.*) daughter of the empress Maria Theresa. He was twenty years old when the death of Louis XV. on May 10, 1774, placed him on the throne. He began his reign under good auspices, with Turgot, the greatest living French statesman, in charge of the disorganized finances; but in less than two years he dismissed him. Turgot's successor, Necker, however, continued the régime of reform until 1781, and it was only with Necker's dismissal that the period of reaction began. Marie Antoinette then obtained that ascendancy over her husband which was partly responsible for the extravagance of the ministry of Calonne.

The third part of his reign began with the meeting of the states-general on May 4, 1789, which marked the opening of the Revolution. The revolt of Paris and the taking of the Bastille on July 14 were its results. The suspicion, not without justification, of a second attempt at a *coup d'état* led on Oct. 6, to the "capture" of the king and royal family at Versailles by a mob from Paris, and their transference to the Tuileries. In spite of the growing radicalism of the clubs, however, loyalty to the king remained surprisingly strong. When he swore to maintain the constitution, then in progress of construction, at the festival of the federation on July 14, 1790, he was at the height of his popularity. Even his attempted flight on June 20, 1791, did not entirely turn the nation against him. Arrested at Varennes, he was maintained as a constitutional king, and took his oath on Sept. 13, 1791.

But already a party was forming in Paris which demanded his deposition. This first became noticeable in connection with the affair of the Champ de Mars on July 17, 1791. Crushed for a time the party gained strength through the winter of 1791–1792. The declaration of war against the emperor Francis II., nephew of Marie Antoinette, was forced upon the king by those who wished to discredit him by failure, or to compel him to declare himself openly an enemy to the Revolution. Their policy proved effective. The failure of the war, which intensified popular hatred of the Austrian queen, involved the king; and the invasion of the Tuileries on June 20, 1792, was but the prelude to the conspiracy which resulted on Aug. 10, in the capture of the palace and the "suspension" of royalty by the Legislative Assembly until the convocation of a national convention in September. On Sept. 21, 1792, the Convention declared royalty abolished, and in January it tried the king for his treason against the nation, and condemned him to death. He was executed on Jan. 21, 1793.

Louis XVI. was weak in character and mentally dull. His courage and dignity during his trial and on the scaffold has left him a better reputation than he deserves. His diary shows how little he understood, or cared for, the business of a king. Days on which he had not shot anything at the hunt were blank days for him. The greater part of his time was spent hunting. He also amused himself making locks, and a little at masonry. On one point only, he actively resisted the Revolution. A devoted and sincere Roman Catholic, he refused at first to sanction a constitution for the church in France without the pope's approval, and after he had been compelled to allow the constitution to become law he intrigued feebly against the Revolution. When he gave in, he delayed his acquiescence until it had the air of a surrender.

Having lost his elder son in 1789 Louis left two children, Louis Charles, usually known as Louis XVII. (*q.v.*), and Marie Thérèse Charlotte (1778–1851), duchess of Angoulême. The "orphan of the Temple," as the princess was called, was in prison for three years, during which time she remained ignorant of the fate which had befallen her parents. She died on Oct. 19, 1851. Her life by G. Lênotre has been translated into English by J. L. May (1908).

See the articles French Revolution and Marie Antoinette. F. X. J. Droz, *Histoire du règne de Louis XVI.* (3 vols., 1860), a sane and good history of the period; and Arsène Houssaye, *Louis XVI.* (1891). *See* also the numerous memoirs of the time, and the marquis de Ségur's *Au couchant de la monarchie, Louis XVI. et Turgot* (1910); de Baissière, *La mort du roi, 21 janvier 1793* (1909); Durfel, *La diplomatie de la France sous Louis XVI.* (1919).

LOUIS XVII., Charles (1785–1795?), titular king of France, second son of Louis XVI., and Marie Antoinette, was born at Versailles on March 27, 1785, and given the title of duke of Normandy, becoming dauphin on the death of his elder brother on June 4, 1789. In 1792 his parents and the rest of the royal party were imprisoned in the Temple—at first in the smaller tower; on Oct. 27 they were moved to the larger tower, and Louis was separated from his mother and aunt to be put in his father's charge, except for a few hours daily, but he was restored to the women when Louis was finally isolated at his trial.

On Jan. 21, 1793, Louis became, for the royalists, king of France, and the comte de Provence gave himself the title of regent. Plots were engineered for the escape of the prisoners by the Chevalier de Jarjayes, the baron de Batz (*q.v.*) and Lady Atkyns (*q.v.*). On July 3 the dauphin was given into the charge of Simon, a cobbler who had been named his guardian by the Committee of General Security. Although the Simons were unfit guardians there is little evidence that the child was actually ill-treated On Oct. 6 Chaumette, Hébert and others visited him, and secured from him admissions of infamous accusations against his mother, and next day he met his sister, Marie Thérèse, for the last time. On Jan. 19 the Simons left the Temple.

Two days after their departure Louis is said by the Restoration historians to have been put in a dark room which was barricaded, while food was passed through the bars; and according to the legend nobody entered the room for six months, till Barras visited him after the 9th Thermidor (July 27, 1794). The child made no complaint to Barras, probably because he feared to do so. After this his condition improved; he was visited during the day by his new attendant, a creole named Jean Jacques Christophe Laurent (1770–1807), who had assistance from a man named Gomin after Nov. 8. From about this time the prisoner was inspected by representatives of the civil committee of the 48 sections of Paris, and on Dec. 19, 1794, he was visited by three commissioners from the Committee of General Security—J. B. Harmand de la Meuse, J. B. C. Mathieu, and J Reverchon—who extracted no word from him. On Laurent's retirement Étienne Lasne was appointed on March 31, 1795, to be the child's guardian. In May 1795 Louis was seriously ill, and a doctor, P. J. Desault, who had visited him seven months earlier, was summoned. Desault died suddenly, not without suspicion of poison, on June 1, and it was some days before Doctors Pelletan and Dumangin were called. Then it was stated that on the 8th Louis Charles had died. Next day an autopsy was held, at which it was stated that a child apparently about ten years of age "which the commissioners told us was the late Louis Capet's son," had died of a scrofulous affection of long standing. He was buried on the 10th in the cemetery of Ste. Marguerite, but no stone was erected to mark the grave.

Immediately on the announcement of the dauphin's death there arose a rumour that he had escaped. Simien Despréaux, one of Louis XVIII.'s own authors, stated in 1814 that Louis XVII. was living, and Eckard left among his unpublished papers a statement that many members of "an assembly of our wise men" named Louis XVII. as the prince whom they wished to have. The royal family made no serious attempt to ascertain the truth, and the removal of Louis XVII. suited the comte de Provence (now Louis XVIII. for the émigrés) as well as it did the Revolutionary

Government.

The most important of some 40 pretenders under the Restoration were Karl Wilhelm Naundorff (*q.v.*) and the comte de Richemont. According to Naundorff, Barras determined to save the dauphin in order to please Joséphine Beauharnais, the future empress, having conceived the idea of using the dauphin's existence as a means of dominating the comte de Provence in the event of a restoration. The dauphin was concealed in the fourth storey of the Tower, a wooden figure being substituted for him. Laurent, to protect himself from the consequences of the substitution, replaced the wooden figure by a deaf mute, who was presently exchanged for the scrofulous child of the death certificate. The deaf mute was also concealed in the Temple. It was not the dead child but the dauphin who left the prison in the coffin, whence he was extracted by his friends on the way to the cemetery. Richemont's tale is that the woman Simon, who was genuinely attached to him, smuggled him out in a basket. Richemont was in prison in Milan for seven years and began to put forward his claims in Paris in 1828. In 1834, he was condemned to 12 years' imprisonment. He escaped after a few months and left the country, to return in 1840. He died at Gleize on Aug. 10, 1853.

If the dauphin did escape, it seems probable that he perished shortly afterwards or lived in a safe obscurity. The account of the substitution in the Temple is well substantiated, even to the names of the substituted. Lady Atkyns was trying by every possible means to get the dauphin out of his prison when he was apparently already in safe hands, if not outside the Temple walls. A child was in fact delivered to her agents, but he was found to be a deaf mute.

The official version of the dauphin's history as accepted under the Restoration was drawn up by Simien Despréaux in his uncritical *Louis XVII.* (1817), and is found, fortified by documents, in M. Eckard's *Mémoires historiques sur Louis XVII.* (1817) and in A. de Beauchesne's *Louis XVII., sa vie, son agonie, sa mort. Captivité de la famille royale au Temple* (2 vols., 1852, and many subsequent editions), contains copies of original documents. L. de la Sicotière, "Les faux Louis XVII.," in *Revue des questions Historiques* (vol. xxxii., 1882), deals with the pretenders Jean Marie Hervagault, Mathurin Bruneau and the rest; *see* also Dr. Cabanes, *Les Morts mystérieuses de l'histoire* (1901), and revised catalogue of the J. Sanford Saltus collection of Louis XVII. books (New York, 1908); also J. H. Hanson, *The Lost Prince* (1854); E. R. Buckley, *Monsieur Charles, The Tragedy of the True Dauphin* (1927).

For De Richemont see *Mdmoires du duc de Normandie, fils de Louis XVI., écrits et publiés par lui-même* (1831), compiled, according to Quérard, by E. T. Bourg, called Saint Edme; Morin de Guérivière, *Quelques souvenirs . . .* (1832); and J. Suvigny, *La Restauration convaincue . . . ou preuves de l'existence du fils de Louis XVI.* (1851).

Since 1905 a monthly periodical has appeared in Paris on this subject. entitled *Revue historique de la question Louis XVII.*

LOUIS XVIII. (Louis le Désiré) (1755–1824). Louis-Stanislas-Xavier, comte de Provence, third son of the dauphin Louis, son of Louis XV. and Maria Josepha of Saxony, was born at Versailles on Nov. 17, 1755. His education was supervised by the devout duc de la Vauguyon, but his own taste was for the writings of Voltaire and the encyclopaedists. On May 14, 1771, took place his marriage with Louise-Marie-Joséphine of Savoy. During the long absence of heirs to Louis XVI., "Monsieur," as heir to the throne, courted popularity and took an active part in politics, but the birth of a dauphin (1781) was a blow to his ambitions. He opposed the revival of the *parlements,* wrote a number of political pamphlets, and at the Assembly of Notables presided, like the other princes of the blood, over a bureau, to which was given the name of the *Comité des sages;* he also advocated the double representation of the *tiers.* At the same time he cultivated literature, entertaining poets and writers both at the Luxembourg and at his chbteau of Brunoy (*see* Dubois-Corneau, *Le Comte de Provence à Brunoy,* 1909), and gaining a reputation for wit by his verses and *mots* in the salon of the charming and witty comtesse de Balbi, one of Madame's ladies, who had become his mistress, and till 1793 exerted considerable influence over him. He did not emigrate after the taking of the Bastille, but, possibly from motives of ambition, remained in Paris. In June 1791, however, at the time of the flight to Varennes, he also fled by a different route, and, in company with the comte d'Avaray—who subsequently replaced Mme. de Balbi as his confidant, and largely influenced his policy—reached Brussels, where he joined the comte d'Artois and proceeded to Coblenz, now the headquarters of the emigration.

Here, living in royal state, he put himself at the head of the counter-revolutionary movement, appointing ambassadors, soliciting the aid of the European sovereigns, and especially of Catherine II. of Russia. Out of touch with affairs in France and surrounded by violent anti-revolutionists, headed by Calonne and the comte d'Artois, he followed an entirely selfish policy, flouting the National Assembly, issuing uncompromising manifestoes (Sept. 1791, Aug. 1792, etc.), and obstructing in every way the representatives of the king and queen. After Valmy he had to retire to Hamm in Westphalia, where, on the death of Louis XVI., he proclaimed himself regent: from here he went south, with the idea of encouraging the royalist feeling in the south of France, and settled at Verona, where on the death of Louis XVII. (June 8, 1795) he took the title of Louis XVIII. From this time onward his life is a record of constant wanderings, negotiations and conspiracies. In April 1796 he joined Condé's army on the German frontier, but was shortly requested to leave the country, and accepted the hospitality of the duke of Brunswick at Blanckenberg till 1797, when, this refuge being no longer open to him, the emperor Paul I. permitted him to settle at Mittau in Courland, where he stayed till 1801. All this time he was in close communication with the royalists in France, but was much embarrassed by the conflicting policy pursued by the comte d'Artois from England, and was largely at the mercy of corrupt and dishonest agents.[1] At Mittau was realized his cherished plan of marrying Madame Royale, daughter of Louis XVI., to the duc d'Angoulême, elder son of the comte d'Artois. From Mittau, too, was sent his well-known letter to Bonaparte (1799) calling upon him to play the part of Monk, a proposal contemptuously refused, though Louis in turn declined to accept a pension from Bonaparte, and later, in 1803, though his fortunes were at their lowest ebb, refused to abdicate at his suggestion and accept an indemnity.

Suddenly expelled from Mittau in 1801 by the capricious Paul I., Louis made his way, in the depth of winter, to Warsaw, where he stayed for three years. All this time he was trying to convert France to the royalist cause, and had a *conseil royal* in Paris, founded at the end of 1799 by Royer-Collard, Montesquiou, and Clermont-Gallerande, but after 1800, and still more after the assumption by Napoleon of the title of emperor (May 1804), the royalist cause appeared hopeless. In Sept. 1804 Louis met the comte d'Artois at Calmar in Sweden, whence they issued a protest against Napoleon's action. Warned that he must not return to Poland, he gained permission from Alexander I. again to retire to Mittau. After Tilsit, however (1807), he was again forced to depart, and took refuge in England, where he stayed first at Gosfield in Essex, and afterwards (1809 onwards) at Hartwell in Buckinghamshire. In 1810 his wife died, and in 1811 d'Avaray died, his place as favourite being taken by the comte de Blacas.[2] After Napoleon's defeats in 1813 the hopes of the royalists revived, and Louis issued a fresh manifesto, in which he promised to recognize the results of the Revolution. Negotiations were also opened with Bernadotte, who seemed willing to support his cause, but was really playing for his own hand.

In March 1814 the allies entered Paris, and thanks to Talleyrand's negotiations the restoration of the Bourbons was effected, Louis XVIII. entering Paris on May 2, 1814, after issuing the declaration of St. Ouen, in which he promised to grant the nation a constitution (*octvoyer une charte*). He was now nearly 60, wearied by adversity, and a sufferer from gout and obesity. But though clear-sighted, widely read and a good diplomatist, his impressionable and sentimental nature made him too subject to personal and family influences. His concessions to the reactionary and clerical party of the *émigrés,* headed by the comte d'Artois and the duchess d'Angoulême, aroused suspicions of his loyalty to the constitution, the creation of his *Maison militaire,* alienated

[1] *See* E. Daudet, *La Conjuration de Pichegru* (Paris, 1901).

[2] Pierre-Louis-Casimir, comte (afterwards duc) de Blacas d'Aulps, was as rigidly royalist as d'Avaray, but more able.

the army, and the constant presence of Blacas made the formation of a united ministry impossible. After the Hundred Days, during which the king was forced to flee to Ghent, the dismissal of Blacas was made one of the conditions of his second restoration. On July 8 he again entered Paris, "in the baggage train of the allied armies," as his enemies said, but in spite of this was received with the greatest enthusiasm by a people weary of wars and looking for constitutional government. He was forced to retain Talleyrand and Fouché in his first ministry, but took the first opportunity of ridding himself of them when the elections of 1815 assured him of a strong royalist majority in the chamber (the *chambre introuvable,* a name given it by Louis himself). At this time he came into contact with the young Élie Decazes (*q.v.*), prefect of the police under Fouché, who now became his favourite and gained his entire confidence. Having obtained a ministry in which he could trust, with the duc de Richelieu at its head, and Decazes as minister of police, the king gave it his loyal support and did his best to shield his ministers from the attacks of the royal family. In Sept. 1816, alarmed at the violence of the *chambre introuvable,* he was persuaded by Decazes to dissolve it. An attempt on the part of the Ultras to regain their ascendancy over the king, by conniving at the sudden return of Blacas from Rome to Paris, ended in failure.

The king's policy throughout was one of prudence and common sense. While Decazes, who succeeded Richelieu as president of the council in Dec. 1818, was still in power, the king's policy to a large extent followed his, and was rather liberal and moderate, but after the assassination of the duc de Berry (1820), when he saw that Decazes could no longer carry on the government, he sorrowfully acquiesced in his departure, showered honours upon him, and transferred his support to Richelieu, the head of the new ministry. In the absence of Decazes a new favourite was found to amuse the king's old age, Madame du Cayla (Zoé Talon, comtesse du Cayla), a protégée of the vicomte Sosthène de la Rochefoucauld and consequently a creature of the Ultres. As the king became more and more infirm, his power of resistance to the intrigues of the Ultras became weaker. The birth of a posthumous son to the duc de Berry (Sept. 1820), the death of Napoleon (May 5, 1821) and the resignation of Richelieu, left him entirely in their hands, and after Villèle had formed a ministry of an ultra-royalist character, the comte d'Artois was associated with the government, which passed more and more out of the king's hands. He died on Sept. 16, 1824. Louis XVIII. had the Bourbon characteristics, their love of power, a certain nobility of demeanor, and a consciousness of dignity. But he was cold, unsympathetic and calculating. He had a talent for intrigue, to which was added an excellent memory and a ready wit. An interesting judgment of him is contained in Queen Victoria's *Letters,* vol. i., in a letter by Leopold I., king of the Belgians, dated Nov. 18, 1836, "Poor Charles X. is dead. . . . History will state that Louis XVIII. was a most liberal monarch, reigning with great mildness and justice to his end, but that his brother, from his despotic and harsh disposition, upset all the other had done and lost the throne. Louis XVIII. was a clever, hard-hearted man, shackled by no principle, very proud and false. Charles X. an honest man, a kind friend." As a personal, rather than a political estimate, this is just.

BIBLIOGRAPHY.—There is no trustworthy or complete edition of the writings and correspondence of Louis XVIII. From his own hand are *Relation d'un voyage à Bruxelles et à Coblentz, 1791* (1823) and *Journal de Marie-Thérèse de France, duchesse d'Angoulême, corrige', et annoté par Louis XVIII.,* edit. Imbert de St. Amand (1894). Some of his letters are contained in collections, such as *Lettres et instructions de Louis XVIII. au comte de Saint-Priest,* edit P. B. de Barante (1845); *Lettres d'Artwel: correspondance politique et privée de Louis XVIII.,* addressed to d'Avaray (1880); *Talleyrand et Louis XVIII. corr. pendant le congrès de Vienne, 1814–1815,* edit. G. Pallain (1881, Eng. trans. 2 vols., 1881); *see* also the correspondence of Castlereagh, Metternich, J. de Maistre, the Wellington Despatches, etc., *Corr. diplomatique de Pozzo di Borgo avec le comte de Nesselrode* (2 vols., 1890–97), the correspondence of C de Rémusat, Villèle, etc. *See* also E. (1908). *See* also the chief memoires of the period, such as those of Talleyrand, Chateaubriand, Guizot, duc de Broglie, Villèle, Vitrolles, Pasquier, L. F. S. de la Rochefoucauld (15 vols., 1861–64), and of the comtesse de Boigne, edit. C. Nicoullaud (1907).

LOUIS II. (1506–26), king of Hungary and Bohemia, was the only son of Wladislaus II., king of Hungary and Bohemia, and the French princess Anne of Candale. Prematurely born at Buda on July 1, 1506, it required all the resources of medical science to keep the sickly child alive, yet he developed so precociously that at the age of 13 he was well bearded and moustached, while at 18 his hair was silvery white. His parts were good and he could speak and write six languages at a very early age, but the zeal of his guardians and tutors to make a man of him betimes nearly ruined his feeble constitution, while the riotous life led by him and his young consort, Maria of Austria, whom he wedded on Jan. 13, 1522, speedily disqualified him for affairs, so that at last he became an object of ridicule at his own court. He was crowned king of Hungary on June 4, 1508, and king of Bohemia on May 11, 1509, and was declared of age when he succeeded his father on Dec. 11, 1521. But during most of his reign he was the puppet of the magnates and kept in such penury that he was often obliged to pawn his jewels to get proper food and clothing, while his guardians and the Hungarian nobles rent the kingdom with their factions. In the last struggle with the Turks, which was brought on partly by Louis's own folly, the young king was deserted by the nobles who should have helped him. His army was utterly defeated at Mohács, Aug. 29, 1526, and he himself is said to have been drowned in his flight from the field (*see* HUNGARY: *History*). After his death the Crowns of Hungary and Bohemia passed to the Habsburg dynasty.

See *Rerum Hungaricarum libri* (vol. ii., ed. Ferencz Toldy, Budapest, 1867); and József Podhradczky, *King Louis* (Hung.) (1860).

LOUIS I. (1326–82), called "the great," king of Hungary and Poland, was the third son of Charles Robert, king of Hungary, and Elizabeth, daughter of the Polish king, Ladislaus Lokietek. On July 21, 1362, he was crowned king of Hungary in succession to his father. He engaged in a prolonged struggle against Venice for the Adriatic sea-board. On July 1, 1346, he was defeated by the Venetians at Zara, which had placed itself under the protection of Hungary. The battle has been immortalized by Tintoretto. In 1357, however, Louis formed a league of all the enemies of Venice, including the emperor, the Habsburgs, Genoa and other Italian towns, and forced her to cede most of the Dalmatian towns and renounce the title of duke of Dalmatia and Croatia, hitherto borne by the doge. (Treaty of Zara, Feb. 18, 1358.) In the same year the republic of Ragusa voluntarily submitted to him, Louis undertaking its defence against an annual tribute. The third Venetian War (1378–81), where Louis was again helped by Genoa, was ended by the congress of Turin (1381), Venice virtually surrendering Dalmatia to Louis and undertaking to pay him an annual tribute of 7,000 ducats. The persistent hostility of Venice is partially attributable to her constant fear lest Louis should inherit the crown of Naples and thus threaten her trade and her sea-power from two sides.

Louis's younger brother Andrew had wedded Joanna, granddaughter and heiress of old King Robert of Naples, on whose death, in 1343, she reigned in her own right, and is strongly suspected of having secured her consort's assassination in 1345. Although Louis claimed the throne, and twice occupied Naples, he could never secure the crown. At last in 1378 Joanna, having made the mistake of recognizing the antipope Clement VII., was promptly deposed and excommunicated in favour of Prince Charles of Durazzo, who had been brought up at the Hungarian court. With the Habsburgs, Louis generally maintained friendly relations, and his differences with Rudolph of Wabsburg were composed without war at the peace congresses of Nagyszombat (1360) and of Pressburg (1360). On the death of his uncle, the childless Casimir the Great of Poland, who had been Louis's lifelong friend, and had appointed him his successor, Louis was crowned king of Poland (Nov. 17, 1370). This personal union of the two countries was more glorious than profitable. Louis was never able to establish real authority over his Polish subjects although in 1374 he compelled them by force to recognize his daughter Maria and her affianced husband, Count Sigismund of Brandenburg, as their future king and queen. Against the Turks, who were now beginning to threaten Europe, Louis took little or no action. He died suddenly at Nagyszombat, Sept. 10, 1382. He left two daughters Maria and Jadwiga (the latter he destined for the throne of Hungary) under the guardianship of his widow. She was the daughter of the valiant ban of Bosnia, Stephen Kotromaric, and she was married in 1353.

See *Rationes Collectorum Pontif. in Hungaria, 1281–1375* (Budapest, 1887); Dano Gruber, *The Struggle of Louis I, with the Venetians for Dalmatia* (Croat.) (Agram, 1903); Antal Pór, *Life of Louis the Great* (Hung.) (Budapest, 1892); and *History of the Hungarian Nation* (Hung.) (vol. iii., Budapest, 1895).

LOUIS, the name of three lungs of Naples.

Louis I., duke of Anjou and count of Maine (1339–1384), was the second son of John II., king of France, and was born at Vincennes on July 23, 1339. As duke of Anjou he led a wing of the French army at the battle of Poitiers. He was a hostage for the treaty of Brétigny in 1360, but he broke his parole in 1363 and so brought about King John's return into captivity. He took part in the war against England which was renewed in 1369, uniting the rival houses of Foix and Armagnac in the common cause, and in other ways rendering good service to his brother, King Charles V. Anjou's entrance into the troubled politics of Italy was one result of the papal schism which opened in 1378. Anxious to secure the support of France, the antipope Clement VII. persuaded the queen of Naples, Joanna I. (*q.v.*), to name Louis as her heir, and about the same time the death of Charles V. (Sept. 1380) placed the duke in the position of regent of France. Neglecting France to prosecute his ambitions in Italy, he collected money and marched on Naples; but although helped by Amadeus VI., count of Savoy, he was unable to drive his rival, Charles, duke of Durazzo, from Naples. His army destroyed by disease, Louis died at Biseglia, near Bari, on Sept. 20, 1384, leaving two sons, his successor, Louis II., and Charles, duke of Calabria.

Louis II., duke of Anjou (1377–1417), born at Toulon on Oct. 7, 1377, took up the struggle for Naples after his father's death and was crowned king by Clement VII. in 1389. After carrying on the contest for some years he took refuge in France. He made other attempts to secure the kingdom of Naples, which was now in the possession of Ladislas, a son of Charles of Durazzo, and he gained a victory at Roccoserra in May 1411. He was again driven back to France, and he died at Angers on April 29, 1417. He married Yolande, a daughter of John I., king of Aragon.

Louis III., duke of Anjou (1403–1434), born on Sept. 25, 1403, son of Louis II., attempted to conquer Naples in 1420; he died at Cosenza on Nov. 15, 1434. In 1424 Louis received from King Charles VII. the duchy of Touraine.

Another titular king of Naples of this name was Louis, a son of Philip, prince of Taranto. In 1346 he became the husband of Joanna I., queen of Naples, and in 1352 he was crowned king. After attempting to conquer Sicily he died on May 26, 1362.

LOUIS, JOE (Joseph Louis Barrow) (1914–), U.S. boxer, held the heavyweight championship of the world longer (1937–49) than any other champion in the division. Born May 13, 1914, at Lexington, Ala., he began his boxing career in Detroit, Mich., winning 43 of 54 amateur bouts by knockouts. In his prime Louis stood 6 ft. 1½ in. and weighed about 200 lb. He had his first professional fight in 1934, and a year later, fought five times in 25 days during one stretch.

Louis knocked out James Braddock in eight rounds to win the world title in Chicago, June 22, 1937, and become the second Negro heavyweight champion. He knocked out six world champions—Primo Carnera, Jack Sharkey, Braddock, Max Baer, Max Schmeling and Joe Walcott. He defended his title 25 times, or more times than the preceding eight champions together. He grossed an estimated $4,225,000 and participated in three of boxing's eight all-time $1,000,000 gates. Louis retired in May 1949, came out of retirement on Sept. 27, 1950, and lost a 15-round decision to Ezzard Charles in a title match. *See* also Boxing.

(J. D. McC.)

LOUIS, JOSEPH DOMINIQUE, Baron (1755–1837), French statesman and financier, was born at Toul, *département* of Meurthe, on Nov. 13, 1755, and was educated for the priesthood. At the outbreak of the French Revolution, the abbé Louis already had some reputation as a financial expert. He was in favour of the constitutional movement, and at the festival federation of July 14, 1790, he assisted Talleyrand, then bishop of Autun, to celebrate mass at the altar erected in the Champ de Mars. In 1790, however, he emigrated to England, where he spent his time studying English institutions and especially the financial system of William Pitt.

Returning to France on the establishment of the consulate, he served successively in the ministry of war, the council of state and in the finance department, both in Holland and in Paris. Made a baron of the empire in 1809, he nevertheless supported the Bourbon restoration and was minister of finance in 1811. Baron Louis served as a deputy from 1815 to 1824 and from 1827 to 1832. He resumed the portfolio of finance in 1815, which he held also in the Decazes ministry of 1819; he was the first minister of finance under the government of Louis Philippe, and held the same portfolio in 1830 and 1831. In 1832 he was made a peer of France. Baron Louis died at Bry-sur-Marne on Aug. 26, 1837.

LOUIS or **LEWIS,** a masculine proper name derived from Frankish *Chlodowîch,* Latinized as *Lodhuvicus,* whence O.Fr. *Lodhuwigs, Loys,* and later *Louis; cf.* Ger. *Ludwig.* It means "famous in fight" and was borne by many sovereigns.

The "Louis" or "Louis d'or" was a term applied to the gold coins of France prior to the Revolution. The franc (*q.v.*) and livre were silver coins which had shrunk in value to such an extent that larger coins were needed, and just as England adopted the guinea so did the French kings have gold coins struck and called after their name. After the Revolution Napoleon continued the practice. but called the coins "Napoleons."

LOUISBURG or Louisbourg, a town and port of entry of Cape Breton, Nova Scotia, Canada, the terminus of the Sydney & Louisburg railway, 39 mi. from Sydney. Pop. (1956) 1,314. Under the French *régime,* Louisburg was second only to Quebec. A fortress was erected at enormous expense, and the city was the centre of the cod fisheries. The fortress was, however, captured in 1745 by the American colonists, under Sir William Pepperell (1696–1759), assisted by the British fleet, and again in 1758 by a British land and sea force under General Jeffrey Amherst (1717–1797) and Admiral Boscawen. The jealousy of the British settlement of Halifax led to its almost utter destruction. and only a few casemates now remain. Under English rule a fishing village grew up on the other side of the harbour. This harbour is deep, and open save for occasional drift ice in the spring. The site of the fortifications is now the Louisburg National Historic park.

LOUISE (Auguste Wilhelmine Amalie Luise) (1776–1810), queen of Prussia. was born on March 10, 1776, in Hanover, daughter of Prince Charles of Mecklenburg-Strelitz and a princess of Hesse-Darmstadt. In 1793 Louise met at Frankfurt the crown prince of Prussia, afterward King Frederick William III, whom she married on Dec. 4. As queen of Prussia she commanded universal respect and affection, and won a great name by the dignity and unflinching courage with which she bore the sufferings inflicted on her and her family during the Napoleonic Wars. After the battle of Jena she went with her husband to Konigsberg, and when the battles of Eylau and Friedland had placed Prussia absolutely at the mercy of France. she made a personal appeal to Napoleon at his headquarters in Tilsit, but without success. Early in 1808 she accompanied the king from Memel to Konigsberg, whence, toward the end of the year, she visited St. Petersburg, returning to Berlin on Dec. 23, 1809. During the war Napoleon attempted to destroy the queen's reputation, but the only effect of his charges in Prussia was to make her more deeply beloved. She died on July 19, 1810, at Strelitz.

LOUISE OF SAVOY (1476–1531). duchess of Angoulême, mother of Francis I of France, was daughter of a cadet of the house of Savoy, Philip, count of Bresse, afterward duke of Savoy, and of Marguerite de Bourbon. At the age of 12 she was married to Charles of Valois, count of Angoulême, great-grandson of King Charles V. The count died in 1496, leaving her the mother of two children, Marguerite (b. 1492) and Francis (b. 1494). The accession of Louis XII, who was childless. made Francis of Angoulême the heir presumptive to the throne of France. Louise brought her children to the court and received Amboise as her residence. She lived henceforth in fear lest Louis should have a son, and in consequence there was a secret rivalry between her and the queen. Anne of Brittany. Finally, her son became king on Jan. 1, 1515, by the death of Louis XII. From him Louise received the county of Angoulême, which was erected into a duchy, the duchy of Anjou, and the counties of Maine and Beaufort. She was then given the title of "Madame."

From 1515 to her death she took the chief share in the government. The part she played has been variously judged and is not yet completely elucidated. It is certain that Louise had a clear head, practical good sense and tenacity. In the critical situation after the battle of Pavia (1525) she maintained order in the kingdom and maneuvered very skillfully to detach Henry VIII of England from the imperial alliance. But she appears to have been passionate, exceedingly rapacious and ever careful of her own interest. In her malignant disputes with the constable de Bourbon on the question of his wife's succession, she goaded him to extreme measures, and her rapacity showed itself also in her dealings with the *surintendant des finances,* J. de Beaune, baron de Samblançay, who diverted the money intended for the French soldiers in Italy into the coffers of the queen, and suffered death in consequence. She died in 1531, and Francis reunited to the crown her domains, which comprised the Bourbonnais, Beaujolais, Auvergne, la Marche. Angoumois, Maine and Anjou.

There is extant a *Journal* of Louise of Savoy, ed. by Guichenon in his *Histoire généalogique de la maison de Savoie,* vol. iv (1778–80).

See *Poésies de François I''' et de Louise de Savoie* . . . , ed. by Champollion-Figeac (1847); De Maulde, *Louise de Savoie et François Ier* (1895); G Jacqueton, *La Politique exte'rieure de Louise de Savoie* . . . (1892); H Hauser, "Étude critique sur le Journal de Louise de Savoie," *Revue historique,* vol 86 (1904).

LOUISE ULRICA, or LOVISA ULRIKA (1720–1782), queen of Sweden, was born in Berlin, the fifth daughter of Frederick William I of Prussia and Sophia Dorothea of Hanover, and educated with her brothers and sisters by French governesses and tutors. Her father's favourite, she was made coadjutor of Quedlinburg in 1738. Her marriage to the Swedish crown prince, Adolphus Frederick, which took place in 1744, was arranged by the empress Elizabeth of Russia; her brother Frederick II would have preferred the prince to marry his youngest sister. Amalia. Her eldest son, the future Gustavus III of Sweden, was born in 1746.

In 1750 Louise Ulrica quarreled with her former friend Count Carl Gustaf Tessin, and on her husband's accession to the throne in 1751 she became the leader of the "court party," seeking to abolish the existing constitution and to strengthen the monarchy against aristocratic feudalism. Her brother Frederick advised her to be more cautious and refused to lend her money to buy support for her plans. After the failure of a coup d'état in 1756, she was unable to prevent Sweden's entering the war against Prussia in 1757 *(see* SEVEN YEARS' WAR); but the disastrous course of the war eventually strengthened her position, and she was instrumental in promoting negotiations for peace in 1762. On her husband's death, early in 1771, she went to Berlin, where she stayed till 1772. Frederick tried to help her in her difficulties with her son, then king of Sweden, who, however, was unwilling to take her advice and showed himself increasingly antagonistic to her till her death in 1782.

Louise Ulrica encouraged the arts and sciences and did much to promote French cultural influence. She was a notable patron of Linnaeus; she invited Voltaire to settle in Sweden; and in 1753 she founded the Royal Academy for Art and Science (from which however the brilliant Tessin was excluded). Her letters (ed by Fritz Arnheim, 2 vol., Gotha, 1909–10) and her memoirs (Halle, 1885) have much in common with those of her sister Wilhelmina, margravine of Bayreuth, but, though partial, are more reliable.

See Olof Jagerskiold, *Lovisa Ulrika* (Stockholm, 1945).

LOUISIADE ARCHIPELAGO, a chain of islands in the Pacific ocean, extending southeastward from the easternmost promontory of New Guinea and included in the Australian territory of Papua. The islands number more than 80 and are interspersed with reefs. They are rich in tropical forest products, while gold is also obtained. The islands were probably observed by Luis Vaez de Torres in 1606, but were named by L. A. de Bougainville in 1768 after Louis XV.

LOUISIANA, one of the west south central states of the United States at the mouth of the Mississippi river, on the north coast of the Gulf of Mexico. Shaped like a boot, it is bounded on the north by Arkansas; on the east by the Mississippi river and the state of Mississippi; on the south by the Gulf of Mexico; on the west by Texas. The state has an area of 48,523 sq.mi., of which 3,417 are water surface (including 1,060 sq.mi. of landlocked bays called lakes). It borders the Gulf of Mexico for 366 mi. It ranks 31st in size among the states and is popularly known as the "Pelican state"; sometimes as the "Bayou state" and the "Creole state." It was admitted to the union April 30. 1812, and was the 18th state to enter. The 64 political subdivisions called parishes correspond to counties in the other states (see *Government,* below). Baton Rouge is the capital. The state flag consists of a field of dark blue bearing a white pelican feeding and protecting her brood and a white ribbon below with the state motto, "Union, Justice and Confidence." The unofficial state bird is the eastern brown pelican; the official state flower is the magnolia.

PHYSICAL GEOGRAPHY

Physical Features. — Louisiana lies roughly between 28° and 33" N. and between 89° and 94° W. Geologically it is a new creation and is classified as a coastal plain province. Its soils were formed as submarine deposits. The average elevation of the state is approximately 100 ft.; the highest point is in Bienville parish, 535 ft. above sea level. The physiographic features may be placed in five classifications: uplands, bluffs, alluvial plains, prairies and coastal marshes. These were successive stages in the geologic process of forming the state. The uplands, or pine hills, are divided into three areas: (1) north of Lake Pontchartrain and east of the Mississippi river; (2) west of Red river; and (3) the north Louisiana uplands lying between the Red and Ouachita rivers. The bluffs run through the second tier of parishes west of the Mississippi above the mouth of the Red river. The alluvial lands are in the flood plains of the rivers, especially the Mississippi, Ouachita and Red. The prairies become increasingly common south of the Red river and constitute the entire south estern part of the state. The prairies are generally treeless except for marginal timber along the sluggish meandering streams. They are generally 20 to 30 ft. above sea level and shade off into the coastal marshes. The coastal marshes are generally 20- to 30-mi. wide but may reach a width of 60 mi. The alluvial lands and the coast swamps comprise about 20,000 sq.mi. or better than 40% of the area of the state,

Louisiana has within its borders about 7,500 mi. of navigable waters, including harbours, bays and sounds. The principal rivers are the Mississippi, which flows nearly 600 mi. through and along the border of the state, the Red, the Ouachita, the Tensas, the Atchafalaya. the Calcasieu, the Vermilion, the Sabine and the Pearl. Louisiana is the only state that is divided by the Mississippi river. There are a number of bayous which are of great economic importance for navigation, drainage and scenic beauty. The largest of these are Bartholomew, Dorcheat, Macon, Boeuf, Plaquemine, Lafourche and Teche. The alluvial portion of the state, especially below the mouth of the Red river, is an intricate network of these bayous: before their closure by a levee system they served partially, in time of flood, to carry off the escaping surplus of river waters.

The alluvial region of the state is mainly protected against overflow by a system of levees, or earthen walls, that hold the waters within the stream channels. The state and federal government co-operated in the construction and maintenance of this system,

HISTORICAL AND INDUSTRIAL VIEWS OF LOUISIANA

Top left: Industrial chemical plant at New Orleans. Manufacturing of petrochemicals is a major industry in Louisiana

Top right: underground mining of salt. Three of the largest salt mines in the world are located in the southern section of the state

Centre left: Old state capitol at Baton Rouge. It was burned during the Civil War and rebuilt in 1832

Centre right: Shrimp boats at anchorage in Venice, in the delta region of the Mississippi river. Shrimp are an important product of the coastal fisheries

Bottom left: Loading oil at the Calcasieu river docks in the city of Lake Charles, southwestern Louisiana

Bottom right: Museum at St. Martinville which was settled by the Acadians, exiled from Nova Scotia, about 1760 although, the national government did not give aid, except for a grant of swamplands in 1850, until 1879, when it began acting through a board of engineers known as the Mississippi River commission. The levee system and flood-control projects represent an expenditure of upward of $500,000,000. Some of the levees are 50-ft. high with a base 100-ft. wide. There are more than 1,700 mi. of levees in the state along the Mississippi, Red, Ouachita and Atchafalaya rivers and other streams.

Some of the lakes, such as Lakes Pontchartrain, Maurepas, Borgne and Sabine, are merely landlocked salt-water bays, the waters of which rise and fall with the tides. Other lakes are cutoff meanders of the Mississippi and Red rivers, knonn as oxbow lakes. Others are the result of clogging or blocking the outlets of a river, which impeded the flow and forced the water into swamps and low places. Examples are found along Red river.

Climate. — The climate is semitropical and exceptionally equable over large areas. The mean temperature for southern Louisiana is 68.2° F., and is affected by prevailing southerly winds and the network of bays, bayous and lakes. The differences of mean annual temperature are almost wholly caused by differences of latitude or elevation. The mean annual temperature for northern Louisiana is 65.2°. The lowest temperature recorded at New Orleans is 7° and the highest 102". The lowest and highest temperatures recorded at Shreveport, about 300 mi. N.W., are −5° and 110° respectively. New Orleans has an average of 60 in. of rainfall annually and the mild climate makes possible a growing season averaging 330 days per year. Shreveport has an average precipitation of 44.8 in. and the growing season averages about 209 days. The first severe frost seldom comes before Nov. 15 in the Shreveport area, and the last one is usually before March 15.

Soil. — Louisiana lies entirely in the coastal plain and the soil was once marine sediments. The soil of the uplands, or rolling hills, is now relatively low in nutrient level. This soil is relatively coarse and adapted to forest growth, especially pine trees. It requires fertilizers to produce good crops of cotton and corn. The alluvial and bluff soils are fertile and produce abundant crops. The prairie soil is clay and clay-loam and is well adapted to rice culture and to pasturing. The coastal marshes are used primarily for the production of fur-bearing animals and for sanctuaries for birds and migratory fowl, for which the state is well known.

Vegetation. — The state has approximately 150 species of trees. The five varieties of pine are the most valuable. The cypress of the swamps; the tupelo gum, slash pine, sweet and black gums of the lowlands; the shortleaf and longleaf pines, the hickory, 15 varieties of oak and birch on the uplands; plus the trees of minor importance make up the state's forests. Although most of the virgin stands of pine, cypress and tupelo gum have been cut, farmers with woodland plots and onners of cutover tracts have engaged in reforestation and more than half the land area is in forests. The Kisatchie National forest, in the central part of the state, is one of the largest of the reforestation projects. Approximately 12,500,000 pine seedlings were planted there during one 12-month period.

Louisiana has a great variety of wild flowers and shrubs. Azaleas, camellias, crepe myrtles, redbuds and magnolias bloom in profusion, both wild and cultured.

Animal Life. — The variety and number of wild animals and fowl give the state the reputation of being a hunter's paradise. The white-tailed deer is found throughout the state and the black bear and the wildcat inhabit the swamp forests. The smaller mammals include opossum, raccoon, otter, skunk, gray fox, squirrels, cottontail and marsh rabbit, weasel, mink, rats, muskrat and moles. Louisiana leads all other states in the number of fur-bearing animals and formerly led in the value of furs produced, but in the second half of the 20th century the value of Louisiana furs declined considerably.

It has been found that 108 species of amphibians and reptiles are native to the state. There are 42 amphibians with 18 belonging to the salamander group; the remaining 24 are frogs and toads. The native reptiles are represented by 66 species, of which the alligator is the largest. There are ten different kind of lizards and 35 species of snakes. Fortunately, only five species of snakes are poisonous. These are the coral snake, the copperhead, the water moccasin, the ground rattler and the canebrake rattler. Twenty species of turtle are native to the state.

The coastal marshes are the greatest winter resort in North America for mild ducks and geese. The commonest varieties of ducks are the mallard, teal, shoveler, gadwall and pintail. It is thought that most of the blue geese of North America winter in the marsh area of the state. The coastal area is visited by many sea birds, such as the laughing gull, royal tern, brown pelican, plover, black skimmer and sandpiper. The area is the habitat, also, of the marsh wren, seaside sparrow, Louisiana heron, Wilson's snipe, woodcock and red-winged blackbird.

Among the swamp-loving birds are the American egret, wood duck, great blue heron, ivory-billed woodpecker, bald eagle, cardinal and warbler. In addition to the ducks and geese, the principal game birds are the turkey, bobwhite, upland plover and dove. The wild turkey is found on or near the bluffs adjacent to the stream bottoms. In the upland areas can be found the thrasher, wood thrush, blue jay, mockingbird, catbird, southern whippoorwill, flicker, redheaded woodpecker, Baltimore oriole, bluebird, tanager and bunting.

State and National Parks. — The most important of the state parks are Audubon, Abita Springs, Bogue Falaya, Chemin-A-Haut, Chicot, Fontainebleau, Ft. Macomb. Ft. Pike, Lake Bistineau and Longfellow-Evangeline. The state has a number of game preserves for wildlife and migratory fowl in particular. The most important of these are the Louisiana State Wild Life refuge, State Public Game and Fish preserve, the Terzia Wild Life refuge, Sabine Migratory Waterfowl refuge, Lacassine Migratory Waterfowl refuge, Russell Sage Wild Life Refuge and Game preserve, Rockefeller Wild Life Refuge and Delta Migratory Waterfowl refuge. There are a number of fish hatcheries, pine seedling nurseries and the state forest near Alexandria.

Chalmette National Historical park was the scene of part of the battle of New Orleans (*see* also *Historic Sites,* below). The Caney Creek and Cornie Creek parks are recreational and forestry development areas under the supervision of the federal government.

Historic Sites. — The first permanent European settlement in the present state of Louisiana was Fort St. Jean Baptiste (Natchitoches) built in 1714 by Juchereau de St. Denis. Fort Los Adais, near Robeline, was built in 1721 by the Spanish. Its location has been marked or restored and so have Fort Jesup in Sabine parish, Forts Jackson and St. Philip in Plaquemines parish and Fort Humbug in Caddo. Chalmette National Historical park is in the Chalmette battlefield and the Pleasant Hill and the Mansfield battlefields have areas set aside as parks. The *Vieux Carré* in New Orleans contains many historic buildings such as the Cabildo and St. Louis cathedral; the U.S. military barracks in Baton Rouge were constructed in 1822. The most noted Indian sites are the Indian mounds at Jonesville, Marksville and Poverty Point on Bayou Macon near Delhi.

HISTORY

Indians inhabited the northern portion of the state approximately 2,500 years before Columbus' voyages to the new world, as revealed by the mounds at Poverty Point on Bayou Macon. At the time and for a few hundred years preceding the arrival of Europeans in the region, various tribes of the Caddoan confederacy occupied the northern half of the state. At the time white men came remnants of various other tribes were found in the eastern and southern portions of the state.

The Spanish knew of the land on the northern shores of the Gulf of Mexico by 1510 and it is possible that one or more Spanish explorers saw the mouth of the Mississippi river before the followers of Hernando De Soto. Alonso Álvarez de Piñeda was in the region in 1519, as was the expedition led by Pánfilo de Narváez, 1529–31, but there is no positive proof that either saw the Mississippi. De Soto crossed the river below Memphis and it is probable that he entered the present state of Louisiana before he died. Survivors of his expedition descended the river to its mouth in 1543. Having found no gold or silver mines, the Spanish made no effort to plant colonies on or near the Mississippi river. In *1682* René Robert Cavelier, sieur de La Salle went down the river from the French possessions in Canada and claimed all the land drained by the river and its tributaries for Louis XIV of France and named it Louisiana. La Salle obtained permission to establish a colony in *1684,* failed to find the mouth of the river and landed on the coast of Texas. His efforts to locate the river were futile and he was slain by some of his men in 1687. Eleven years later Pierre le Moyne sieur d'Iberville *(1661–1706)* took up the task of colonizing Louisiana and in *1699* built a fort near the present city of Biloxi, Miss. The next year he erected a fort on the Mississippi *18* leagues (about *40* mi.) above its mouth. This was the first settlement in what is now the state of Louisiana. Antoine Crozat (1655–1738) was granted possession of Louisiana in *1712* for a period of 15 years. The proprietary contract was terminated in 1717, but the first permanent settlement in the present state was made at Natchitoches, on the Red river, in 1714. Louisiana was too much of a drain on the royal treasury and the territory was granted in *1717* to a company organized by John Law (*q.v.*), who did much for the colony before surrendering Louisiana to the crown in *1731.* Jean Baptiste le Moyne, sieur de Bienville *(1080–* 1768), a younger brother of D'Iberville, was the guiding spirit of the colony from *1699* until *1743.* It was he who founded New Orleans in *1718.* The French began the cultivation of rice, tobacco and sugar cane, but it was not until *1795* that sugar cane became a commercial crop.

The Spanish Period. — The secret treaty of Fontainebleau, Nov. 3, 1762, transferred Louisiana from France to Spain. The next year England received that portion of Louisiana lying east of the Mississippi and Iberville rivers and Lakes Maurepas and Pontchartrain. Many colonists were unhappy over the transfer to Spain and the leaders resisted Spanish possession. When the director of Louisiana, D'Abbadie, issued the proclamation of transfer in *1764* the colonial leaders petitioned to remain French. The first governor Spain sent over, Antonio de Ulloa (1716–95), never took formal possession and was ordered to leave in *1768.* Alexander O'Reilly, an Irish officer in the Spanish army was sent to the colony with a force of about *3,000* men. His affability caused suspicion to subside until he had ascertained the identity of the leaders who opposed Spanish rule. He then invited them to a reception, arrested them, executed five and sent the others to prison in Havana, Cuba. The succeeding Spanish rulers were liberal and tolerant. While Spanish was the official language, the colony remained French in manners and customs. The Spanish governors, while neglecting to enforce the regulations of commerce, instituted a number of reforms that proved beneficial to the people and in the course of time the populace came to appreciate the benefits of Spanish rule. The Spanish officials received the French exiles from Acadia and granted them lands along Bayou Teche. These Acadians made a distinct contribution to the cultural and economic life of the state.

Some of the Spanish governors endeavoured to induce the people living in the region east of the Mississippi river and west of the Appalachian mountains to secede and join Spanish Louisiana. The river, as the highway of transportation, was used as a bargaining weapon in these efforts.

In *1800* Napoleon coerced Spain into ceding Louisiana to France. The United States frowned upon the transfer because free navigation of the Mississippi was imperative to the people who lived in the valley. Xapoleon sold Louisiana,to the United States, which took formal possession Dec. *20, 1803.* William C. C. Claiborne was appointed by President Jefferson to receive Louisiana from the French official, Pierre Clement de Laussat. A short time thereafter Claiborne was made governor of the territory. (See LOUISIANA PURCHASE.)

Territory and Statehood. — Congress provided a government for the territory on March *25, 1804.* The act divided the Louisiana Purchase into two territories. The portion south of 33° N. became the Territory of Orleans, with an estimated population of *30,000.* The act forbade importing slaves from foreign countries, made English the official language and provided a government less democratic than if the inhabitants had been Anglo-Saxon. The people desired immediate statehood. After the census of *1810,* the people in the territory of Orleans held a convention to frame a state constitution and Louisiana became a state April *30, 1812.*

Spain refused to surrender the area east of the Mississippi river, and this area south of 31° N., east to the Pearl river and north of Lake Pontchartrain, revolted in Sept. *1810* and established the Republic of West Florida. Three months later, however, it came under the jurisdiction of Governor Claiborne. A few days after Louisiana was admitted to the union, congress added Rest Florida to the state. This area is often referred to as the "Florida parishes."

Claiborne was elected the first governor of the state in *1812* and in that year the first steamboat descended the Mississippi river to New Orleans. Gen. Andrew Jackson's forces defeated a British army under Gen. Edward Pakenham at Chalmette, near New Orleans, Jan. *8, 1815,* two weeks after the treaty of Ghent was signed ending the War of *1812.*

Up to *1860* the state increased in population and prospered from agriculture and commerce. During this period the sugar-cane and cotton plantations were flourishing. The river steamboats dominated transportation and New Orleans was the gateway for the trade of the Mississippi valley. The capital was moved from New Orleans to Donaldsonville, *1828–31,* and to Baton Rouge, 1849–64. After *1882* Baton Rouge was the capital but a number of state offices remain in New Orleans.

Civil War and Reconstruction. — Louisiana formally seceded from the union Jan. *26, 1861* and six weeks later joined the Confederate States of America. During *1861,* many of the young men in military units were sent to Tennessee, Kentucky and Virginia to defend the borders of the Confederacy. New Orleans was taken in April *1862* by a naval force under Adm. D. G. Farragut and an army commanded by Gen. B. F. Butler. Butler's military administration became so notorious that he was replaced in Dec. *1862* by Gen. N. P. Banks. The capture of Vicksburg and Port Hudson by Union forces in July *1863* opened the Mississippi to navigation. The attempt to capture Shreveport on the Red river resulted in the defeat of General Banks by the Confederates under Gen. Richard Taylor at Sabine CrossRoads, near Mansfield, April *8, 1864.*

The reconstruction of the state began in Dec. *1862,* when President Lincoln ordered the Union military government to hold elections for congress. Those chosen were seated in Feb. *1863.* Civil government superseded military rule in March *1864* and during the year a convention assembled to rewrite the state constitution. The reconstructed government represented half of the area, two thirds of the population of the state and was backed by the army.

The Confederate government under Gov. Thomas O. Moore *(1860–64)* and Gov. Henry W. Allen (1864–65), was at Shreveport. Thus Louisiana had two governments during most of the war. The people of Louisiana accepted military defeat and by *1866* the former Confederates had succeeded in gaining possession of most of the local government and most of the state offices, although not of the governorship. The radicals were not pleased with the situation and wanted to convene a convention to rewrite the constitution. Unable to call a convention through the medium of state government, they endeavoured to reconvene the constitutional convention of *1864.* The effort to disperse the illegal convention in *1866* resulted in the death of almost *50* persons, mostly Negroes. The incident was used by politicians to overthrow presidential reconstruction and institute congressional reconstruction in *1867.* The state constitution of *1868* gave suffrage to the Negroes and disfranchised a large number of white citizens. Probably no other southern state suffered as much as Louisiana under the corrupt carpetbag government of *1868–76,* during the administrations of Henry Clay Warmoth (1868–72), P. B. S. Pinchback (one month in *1872)* and William Pitt Kellogg *(1872–76).* The Democrats claimed the election of John McEnery in *1872,* but the federal government supported the Republican, Kellogg. A number of clashes occurred between the factions, the most noted of which was Sept. *14, 1874,* in New Orleans, when the White league briefly wrested control of the city from the Republican police. In *1876* the Democrats claimed that Gen. Francis T. Nicholls was elected but the Republicans claimed that S. B. Packard had won. Their claims were intertwined with the choice of presidential electors for that year. The Republicans manipulated the state returning board and sent two sets of election returns to congress and the Democrats sent their returns. The electoral commission accepted the Republican electors, just as it did those in dispute from South Carolina, Florida and Oregon. Both Nicholls and Packard took the oath as governor in Jan. 1877 and set up rival governments which continued until President Hayes ordered the withdrawal of federal troops from the capital on April 20, 1877, and the white Democratic party was left in control.

After 1877 the state began to reconstruct its economy. Efforts were made to attract settlers; a new constitution was written in 1879; the channel of the Mississippi river was deepened at its mouth by the construction of jetties to increase maritime shipping, and railroads were built to facilitate overland transportation; levees were constructed to prevent floods; and efforts were made to curb the ravages of malaria and yellow fever. By 1900 the state had made some headway and was on the threshold of spectacular economic developments through the exploitation of the state's abundant natural resources of oil, gas, sulfur, salt and timber.

20th Century. — In the spring of 1927 the most devastating flood in the history of the state inundated 1,300,000 ac., drove 300,000 people from their homes and destroyed millions of dollars' worth of property. The catastrophe proved the inadequacy of the existing levees and demonstrated that flood control of the Mississippi river was a responsibility of the federal government. In 1928 congress responded by appropriating $325,000,000 for that purpose.

The government of Louisiana was dominated by landed gentry until 1928 when the election of Huey P. Long as governor challenged the old regime and a tumultuous political era began with the rural and working classes pitted against the urban leaders. Long won a vast following and built a formidable political machine. In the U.S. senate (1930–35) he attracted national attention with his Share the Wealth program before he was assassinated in 1935. He had modernized the highway system; expanded the Louisiana State university and hospitals; provided free textbooks for school children; constructed a new state capitol and governor's mansion; and built a sea wall, an airport, a bridge over the Mississippi river and a spillway at New Orleans. His political machine lost in the governor's election of 1940, after Oscar K. Allen and Richard W. Leche had been elected governor in 1932 and 1936, respectively, and Alvin O. King (Jan. to May 1932), James A. Noe (Jan. to May 1936) and Earl K. Long (June 1939 to May 1940) had served to fill unexpired terms.

The so-called reform administrations of governors Sam H. Jones and James H. Davis appeared to achieve some improvement. Earl K. Long, brother and political heir of Huey, was elected in 1948 and expenditures for education, hospitals and welfare were greatly increased. Robert F. Kennon defeated Long's candidate, Judge Carlos G. Spaht, in 1952 but Long was elected again in 1956. Governor Long. in three mental institutions within a period of a month in 1959. sought to circumvent the constitutional provision that a governor could not succeed himself but eventually filed as a candidate for lieutenant governor on the ticket of James A. Noe. The ticket was defeated in the primary. Long was subsequently elected to congress from the 8th district but died suddenly on Sept. 5, 1960. Governmental expenditures in Louisiana increased precipitously after 1930, in greater proportion than did those of neighbouring states.

In national politics the traditionally Democratic state was carried by the Dixiecrats in a three-cornered fight among the States' Rights Democrats, Democrats and Republicans in 1948. In 1952 both Democratic and Republican presidential candidates campaigned in the state for the first time in many decades. The Democratic candidate. Adlai Stevenson, carried the state. In 1956, with less than 40% of the electorate voting, a Republican presidential candidate, Dwight Eisenhower, carried the state for the first time since Reconstruction (1877) but in 1960 Louisiana returned to the Democratic fold, casting its vote for John F. Kennedy.

GOVERNMENT

The Roman law was the basis of legal procedure in Louisiana under both French and Spanish regimes. The French and Spanish had divisions of territory for religious administration. These religious divisions, known as parishes, were conveniently used for civil administration, hence the names of saints in parish nomenclature. The territorial act of 1804 used "county" to designate governmental subdivisions. In 1807 the nomenclature for these units was changed back to "parish" and that term still is used for 64 local units of government.

Louisiana has had ten constitutions since becoming a state in 1812; the present constitution, adopted June 18, 1921, has been amended more than 300 times.

The legislative branch of government consists of two houses—the senate with 39 senators elected from 33 districts and the house of representatives of 101 members. The regular session of the legislature, convening in May of the even-numbered years, is limited to 60 days. The session convening in May of the odd-numbered years, is limited to 30 days and can only consider financial legislation unless three-fourths of the members consent.

The judicial authority is vested in a supreme court, 7 courts of appeal and 25 judicial district courts, with each police jury (parish governing body) authorized to establish justice of peace courts. and with municipalities having the power to create juvenile and municipal courts. The supreme court is composed of a chief justice and six associate justices, elected from five supreme court districts (district one elects two). Their term is for 14 years with the term of two expiring every two years. The state, exclusive of the parish of Orleans, is divided into two circuits, with three courts of appeal in each and an additional court for Orleans parish. Each court of appeal has three judges elected for a term of 12 years. There are 25 judicial districts, with one judge elected for a period of six years to serve each judicial district court, except three districts that have two or three judges each.

The executive branch of government consists of the governor, lieutenant governor, auditor, treasurer, secretary of state, registrar of the land office, commissioner of agriculture and labor, commissioner of conservation, attorney general and superintendent of public instruction.

Suffrage is granted to every citizen of the state who has attained the age of 21 and who has resided in the state two years, in the parish one year and in the precinct three months preceding the election; who is legally enrolled as a registered voter; and who is of good character.

Real-estate taxes have become a minor source of state revenue. The chief source of revenue is the general sales' tax; other sources of revenue are severance taxes; mineral leases and royalties, gasoline, income, tobacco, beverage and gas-gathering taxes; vehicle licences and fees; corporation franchise taxes; excise licence taxes; and insurance licences and fees. The chief expenditures are for education, public welfare, highways, hospitals and institutions, homestead exemptions, debt service and general government.

Law. — Louisiana civil law is based to a great extent on the French and Spanish laws and especially the Code Napoléon. The other states base their laws on the common law of England. Louisiana was first of the southern states to abolish the poll tax and the first state to provide free textbooks and free lunches for elementary-school students. A law was enacted in 1936 to exempt from taxation homesteads up to a valuation of $2,000.

POPULATION

The descendants of the French are found in the area bounded roughly by a line from the southwest corner of the state to the juncture of the Red and Mississippi rivers and from that point along the Mississippi to the Gulf of Mexico. Few Spanish came during the 35 years the colony belonged to Spain. St. Bernard has the largest Spanish influence. The Italians, the most numerous of the modern immigrant groups, are principally in the cities. Hungarians are found in the strawberry belt, Slovenians in the fishing and citrus-fruit districts and Germans in and near New Orleans.

The population of Louisiana has increased steadily since 1810 when it was 76,556; in 1850 it was 517,762; in 1900, 1,381,625;

*Populations are reported as constituted at date of each census. †Ward 4 of Jefferson parish, which includes Westwego.

Note: A dash indicates place did not exist during reported census or data not available.

in 1950, 2,683,516; and in 1960 was 3,257,022. The population per square mile in 1960 was 67.1 as compared with 55.3 in 1950 and with 49.6 for the U.S. in 1960. The 1960 census gave 63.3% of the population living under urban conditions as compared to 54.8% in 1950 and 41.5% in 1940 which indicates a marked acceleration of the urbanization trend first noted about 1900. The three standard metropolitan statistical areas (Baton Rouge, New Orleans and Shreveport) in 1960 contained about 42% of the total population of the state. The number of Negroes is not increasing in population as rapidly as the white race and the Negroes are moving to urban areas. Negroes constituted 33% of the population in 1950 and 28% in 1940. The number of people over 65 and the number under 15 years of age constitute a larger relative percentage of the total population; that is. the age group. 15 to 65, is not increasing in numbers as rapidly as the younger and older age groups. The number of births per 1,000 population in 1950 was 29.7% and in 1940 it was 24.9%. The number of deaths per 1,000 population in 1950 was 8.8% and in 1940 was 10.8%.

EDUCATION

Elementary and Secondary.—Education was the function and responsibility of the church during the French period. During the Spanish period, although the church exerted the most powerful influence, the government did make a pretense of establishing a free public-school system in 1771 when four professors were sent from Spain and Governor Unzaga was ordered to pay their salaries out of the general fund until permanent taxes for the purpose could be provided. Only one such school was opened (in 1772) and it never enrolled more than 30 students.

During the early years of the American period the people were too busy developing the new country to devote much energy and attention to schools. This was especially true of the Anglo-Saxon Protestants who settled the uplands of northern Louisiana before 1860. The Anglo-Saxons who settled in the southern portion of the state, were, generally speaking, sons of slave owners of Virginia and the Carolinas, who believed that education was the responsibility of parents and who hired tutors or sent their children to private schools. This class; together with the older French settlers, who considered education to be a function of the church, usually controlled the government of the state and never made a sincere effort, such as New England made, to establish a free tax-supported school system. Hence education received only token support and few free schools were opened outside New Orleans. John McDonogh, a wealthy New Orleans merchant and financier who died in 1850, left half his fortune for the promotion of education in New Orleans. Before the American Civil War most of the free schools there were supported from this fund.

A few tax-supported schools were opened in the 1880s but the economic conditions of the state did not make possible the development of a free-school system until 1910. Tremendous progress has been made since that time in the number of children in school; the number and training of the teachers; the financial expenditures; and the construction of school plants. Although earlier statutes authorized parish police jurors to provide free textbooks for the children of parents unable to purchase them, Governor Long in 1928 sponsored a free-textbook law for all the children of the state. Later governors instituted free-lunch programs and paper, pencils and other materials were provided from tax funds. The automobile and the development of good roads made possible the consolidation of schools so that better-trained teachers and modern library, laboratory and classroom facilities became generally available. The one-room school has disappeared. In the second half of the 20th century approximately 94% of the children between 6 and 18 years of age attend school; public high schools enroll a larger proportion of the elementary school graduates than ever before and a greater proportion of high-school graduates enter college. Education is the most important enterprise in the state and takes the largest portion of the tax dollar. The annual state budget for education increased precipitously in the decade after 1950, reaching more than $175,000,000 or about $55 per child for the more than 900,000 children of school age in the state; expenditures per pupil in average daily attendance reached $330.

Administration.—The head of the public-school system is the state superintendent of public education who is elected for a term of four years by popular vote. An 11-member state board of education, elected by popular vote for overlapping terms, has general jurisdiction over all tax-supported elementary, high, special and trade schools and institutions of higher learning except Louisiana State university, its branches in New Orleans and Chambers and its medical school, also in New Orleans, which are under the supervision of a special board of 15 members appointed by the governor for a term of 14 years, the term of two members expiring every two years. In addition, each of the parishes and three of the cities have school boards, with a superintendent.

In the second half of the 20th century there were about 24,000 teachers and principals in the tax-supported elementary and secondary schools. Of these approximately 16,000 were white, staffing about 850 schools with approximately 400,000 students; about 8,000 were Negroes staffing about 550 Negro schools with approximately 126,000 students. The salary schedule is the same for all teachers of equal training and experience. After World War II the state made impressive efforts to provide equal facilities for white and Negro children.

Private and parochial schools for white children number about 240 with about 3,000 teachers and approximately 95,000 students. There are about 100 such schools for about 23,000 Negro students, taught by about 650 teachers.

Segregation.—The first compulsory school attendance laws were enacted in 1916. By 1950 attendance in elementary schools was compulsory for children between the ages of 7 and 15, inclusive.

Following the U.S. supreme court decision (1954) declaring racial segregation in the public schools to be unconstitutional the Louisiana legislature in 1956 exempted from the compulsory attendance laws any school ordered by the federal courts to desegregate and the state constitution was amended, authorizing the legislature to maintain segregation. The 1960 legislature enacted additional measures but court decisions that same year indicated that all such acts would be held unconstitutional, and while they might delay integration they could not prevent it.

Higher Education. — The growth and development of higher education was dependent upon the elementary- and secondary-school system and therefore lagged behind it. The State Seminary of Learning and Military institute opened near Alexandria in 1860 with William T. Sherman as president and eventually grew into the Louisiana State University and Agricultural and Mechanical college. It is one of the state's two land-grant schools, the other being Southern University and Agricultural and Mechanical college (for Negroes). The buildings burned in 1869 and the institution was moved to Baton Rouge where it was housed in the State School for the Deaf until 1885. The Agricultural and Mechanical college was moved from Donaldsonville to Baton Rouge in 1877, to be operated in conjunction with the university because of limited finances; the temporary union has proved to be permanent. Two brothers, David French Boyd and Thomas Duckett Boyd, directed the institution for most of the period, 1884–1927, the latter serving as president from 1896 to 1927. Gov. John Milliken Parker advocated a greater Agricultural and Mechanical college in 1920 and purchased a plantation for the site. The university rejoined the college on its 4,700 ac. campus in 1925. The buildings and equipment represent an investment in excess of $50,000,000. The medical school was established in New Orleans (1934) as a branch of the university and in 1958 Louisiana State university in New Orleans was opened as another branch. A junior-college branch was established at Chambers in 1959. The university was ordered by the U.S. courts to admit Negroes to its graduate and professional schools (1951) and then to its undergraduate branch at New Orleans (1958). At various dates the courts ordered Negro admission to Southeastern Louisiana college, Southwestern Louisiana institute and McNeese State college. The institution is divided into various colleges and offers programs for advanced degrees.

The Louisiana State Normal school, opened at Natchitoches in 1884, was made a four-year college in 1917 and the name was changed accordingly. For 30 years it enjoyed a monopoly of training teachers for the public schools. After the other state colleges began training teachers, the Normal college expanded its services and the name was changed to Northwestern State College of Louisiana. It is divided into five schools: arts and sciences, applied arts and sciences, education, nursing and the graduate school.

Louisiana Polytechnic institute, Ruston, was established in 1895 as the Louisiana Industrial Institute and college. It was made a four-year college in 1917 and its name was changed in 1926. The organization consists of six schools: arts and sciences, agriculture and forestry, business administration and economics, education, engineering and home economics. The teacher-training program began in 1917 and a graduate program for the master's degree in 1958.

The Southwestern Louisiana institute, Lafayette, was opened in 1901 as the Southwestern Louisiana Industrial institute. It is organized into schools of agriculture, commerce, engineering, home economics, liberal arts and nursing. With over 5,000 students, it has the second largest enrollment of any state-supported college. It began a graduate program for the master's degree in 1956. In 1960 the name was changed to University of Southwest Louisiana.

Southeastern Louisiana college, Hammond, operated as the Tangipahoa junior college in the early 1920s, then as the Florida Parishes junior college and was taken over by the state and made a four-year college in the late 1930s. It is organized into three schools: liberal arts, applied sciences and education.

Northeast Louisiana State college, Monroe, had its origin in the Ouachita Parish Junior college in the early 1930s. It was taken over by the Louisiana State university in 1934 and operated as a branch junior college. In 1950 the legislature made it a four-year college and placed it under the jurisdiction of the state board of education with the name changed to the Northeast Louisiana State college. It has schools of arts and sciences, pure and applied sciences, education, fine arts and pharmacy.

McNeese State college, Lake Charles, began as a junior-college branch of Louisiana State university in 1939. The legislature, in 1950, changed its name, made it a four-year college and placed it under the jurisdiction of the state board of education.

The Francis T. Nicholls State college was authorized in 1946 as the Francis T. Nicholls junior college of Louisiana State university. In 1956 the legislature designated it as a four-year college and placed it under the state board of education. The instruction is divided into three divisions designated as colleges: applied sciences, arts and sciences and education.

The state operates two institutions of higher education for its Negro citizens: Southern University and Agricultural and Mechanical college and Grambling college. Southern university was founded in 1880 in New Orleans and was moved to Scotlandville (near Baton Rouge) in 1914. Progress was slow during the early years because the state was not in a financial condition to support higher education until around 1920 and relatively few students sought a college education before that date. Increasing prosperity enabled the state to provide more funds for buildings, equipment and salaries, the increase in funds being precipitous in the period 1940–60. The institution has divisions of arts and science, agriculture, home economics and industrial and technical education (formerly mechanic arts), health and physical education, business, music, a graduate school and a law school. The enrollment is more than 5,000.

Grambling college had its origin in 1900 when Booker T. Washington, president of Tuskegee institute, sent one of his recent graduates, Charles Adams, to establish a private school for Negroes at Grambling. Lincoln parish assumed support of the school in 1915 and the state took it over in 1928 and operated it as a normal school to train teachers and leaders in agriculture. It was made a four-year college of liberal arts and a teachers college in 1940 and has had a phenomenal growth since the end of World War II. The institution is operated by departments under the immediate supervision of the dean of the college.

Private institutions of higher learning include four Roman Catholic schools in New Orleans: Loyola university (for men, founded 1912); Notre Dame seminary (for men, 1923); St. Mary's Dominican college (for women, 1920); and Xavier University of Louisiana (1925). Also in New Orleans are Dillard university (Congregational Christian and Methodist, 1930); Tulane university nonsectarian, 1834 and Newcomb college (The H. Sophie Newcomb Memorial College of Tulane university) (for women, 1886). Centenary College of Louisiana (Methodist, 1840) is at Shreveport and Louisiana college (Louisiana Baptist convention, 1906) is at Pineville.

HEALTH AND WELFARE

Beginning about 1906 Louisiana made rapid progress in eradicating and controlling disease. Laws were passed and enforced to destroy the breeding places of mosquitoes, thereby reducing malaria and yellow fever; rats were exterminated to reduce the spread of such diseases as bubonic plague; the hookwork disease was attacked; houses were screened; public drinking cups were outlawed to help control the spread of tuberculosis; and other measures in the interest of better health were enacted.

Hospitals. — The first charity hospital was built in New Orleans in 1736 with the bequest of a sailor, Jean Louis. This was the forerunner of the Charity hospital there constructed by the state in 1930 at a cost of $13,000,000. Additions costing approximately $7,500,000 have been made. Charity hospitals are found in all the larger urban centres, as, for example, the Confederate Memorial hospital in Shreveport, the E. A. Conway hospital in Monroe and the Huey P. Long Charity hospital in Pineville. The East Louisiana hospital for the mentally ill at Jackson is the oldest (1847) and largest of its kind in the state. The mentally ill also are provided for in the Central Louisiana State hospital at Pineville and the Southeast Louisiana hospital at Mandeville and there are sections and wards for the mentally ill in most of the state hospitals. The federal government has two magnificent hospitals for veterans of the armed forces, at Pineville and Shreveport.

The Spanish Governor Miro (1785–92) was responsible for establishing a hospital for lepers (Hansen's disease) in New Orleans. This was the beginning of a state leprosarium, established at Carville in 1894 and taken over by the federal government in 1921. Officially designated the U.S. Marine Hospital No. 22, it is the only leprosarium in the continental United States.

In addition to the tax-supported hospitals there are a number of private- and church-supported institutions. The Roman Catholic Church has had unusual success in operating hospitals and the Protestant denominations, the Baptist in particular, have entered this field of service.

Welfare. — A state-wide poor law was passed as early as 1880 requiring every parish in the state to provide for its poor and infirm through local taxation. Various laws after 1900 provided pensions for dependent mothers, compensation to incapacitated workers and child welfare. The first state-wide system of relief grew out of the need resulting from the depression of the early 1930s. In 1932 an unemployment relief committee was set up to supervise the distribution of relief funds provided by the federal Reconstruction Finance corporation. Within a period of three years a local welfare agency was in existence in every parish. A state department of public welfare was created by act of the legislature June 26. 1936.

The welfare services have expanded to enormous proportions. The budget of the welfare department in the second half of the 20th century was almost equal to the budget for education. The largest items of expenditure were for old-age assistance. for dependent children, for the permanently and totally disabled and for general assistance. By the 1960s, 70% of the population age 65 and over were receiving some form of relief.

THE ECONOMY

Louisiana has a mild climate and more and more people have been attracted to the state to live, as is borne out by the number of adults who move into the state and by the growing population. The state also has attracted a number of industries since passing in 1946 a law granting new industry tax exemption for a period of ten years.

The trend toward better homes was pronounced after 1935. New construction was of better quality and more of the rural homes were painted. By the second half of the 20th century practically all urban homes had electricity, running water and indoor plumbing and an increasing number of rural homes had these conveniences. Electricity made possible radios, television and artificial refrigeration, thus bringing education and entertainment and recreation into the home; refrigeration helped to preserve meats, fruits and vegetables. Most of the homes, even in the rural areas, were heated by natural or manufactured gas. The wood formerly burned for heating and cooking was sold for pulpwood and other uses.

Agriculture. — Agriculture was the chief occupation and the main source of income for the people until World War II. Agriculture is still important although it has been superseded by manufacturing as the leading industry in the state. The number of farm workers declined from about 200,000 at the end of World War II to about 150,000 in the second half of the 20th century. The number of farms also decreased from about 150,000 to about 110,000 while the average value of farms rose from about $3,500 to almost $10,000 and the size of the average farm increased from about 65 ac. to more than 100 ac. (but about 46% of the farms were less than 30 ac. in size). At the same time the number of acres that were harvested decreased from almost 3,500,000 ac. to about 2,500,000 ac. This trend was evident in the reduction of acres in row crops and the increasing acreage in pasture for livestock and for growing forests. In the second half of the 20th century the total annual value of Louisiana agricultural products reached $320,000,000, of which livestock products accounted for about $140,000,000, plus $30,000,000 in government payments.

The major crops, ranked according to value, were cotton lint and cottonseed, rice, sugar cane, corn, hay and sweet potatoes. In the ten years after World War II the average acreage planted in cotton was about 825,000 ac. with an average production of about 600.000 bales (500 lb. per bale) worth more than $100,000,000. The acreage planted in cotton. however, was decreasing, in some years dropping to fewer than 400,000 ac. planted and a production of less than 300.000 bales. Louisiana has led all the states in the production of rice. During the post-World War II years an average of about 600,000 ac. were planted nith the annual production exceeding 1,000,090,000 lb. worth approximately $60,000,000. Louisiana produces most of the sugar from sugar cane in continental United States, with Florida producing a small amount. The average acreage planted in sugar cane in the post-World War II period was about 250,000 ac. which produced more than 5,000.000 tons of sugar worth more than $33,000,000. The corn planted during the period averaged almost 800.000 ac. and production was about 14,000,000 bu. valued approximately at $20.000.000; the hay crop averaged about 350.000 ac. with 434,000 tons valued at $10,000,000. Louisiana ranks first in the productian of sweet potatoes. The crop averaged about 90,000 ac. and produced 500,000.030 lb. worth more than $15,000,000. Rice and sugar cane are the only field crops with restricted areas of production. The sugar-cane region is confined, almost exclusively, to the Mississippi delta and Bayou Teche regions, while the chief area of rice production is the prairie region of the southwestern part of the state.

The rice farms were almost the only farms irrigated until the second half of the 20th century. The water was procured from the streams flowing through the rice-growing area and from deep wells. During the 1950s light-weight aluminum pipe became available and enabled vegetable and even cotton and corn crops to be irrigated during dry years. The nater was procured largely from streams and ponds.

The groning of vegetables has not been exploited to any great extent to utilize the soil and climate. It has developed most in the vicinity of New Orleans. With the growth of other large urban centres, the groaing of vegetables in these vicinities has increased. Louisiana ranks first among the states in the production of strawberries. The stranberry area is in the Florida parishes. east of Baton Rouge, but the plant can be gronn in most of the state. Other commercial vegetable crops are Irish potatoes, snap beans, green peppers, shallots, cabbages, tomatoes. watermelons, onions and cucumbers. The crop of oranges, grown south of New Orleans, is important. Peach growing in north Louisiana has proven profitable. Other important farm products are pecans, peanuts, figs, tung oil nuts and soybeans.

Livestock is playing an increasing role on Louisiana farms notwithstanding the rapid decline in the number of horses, mules, hogs and sheep. Mechanization is rapidly replacing the horse and the mule. In the ten years after World War II they numbered an average of 210,000. valued at $12,402.000. By 1960 the number decreased to less than 100,000. Hogs averaged 574,000 head in the post-World War II period. By 1960 the number was below 400,000. Sheep dropped from an average of almost 120,000 to feu-er than 100.000 head, but the value increased from less than $1,000,000 to more than $1,100.000. In livestock, cattle led in value followed by commercial broilers, hogs, horses and mules, chickens and sheep.

Industry. — The industries of Louisiana are those associated, for the most part, with petroleum, lumbering, sugar, rice and cottonseed. Manufacturing could be classified, also, as those processing: (1) food and kindred products; (2) petroleum; (3) forest products; and (4) chemical and allied products. Industries processing agricultural raw material are seasonal. Examples are cottonseed oil mills, sugar refineries, syrup mills and canning plants. Manufacturing increased at a rapid rate after World War II, especially in the rubber, petroleum-chemical, aluminum making and papermaking industries. In the second half of the 20th century there were more than 2,000 manufacturing plants operating in the state with almost 150.000 production workers and an annual payroll of more than $600,000,000. The value added by manufacturing amounted to approximately $1,500,000,000 annually.

While the amount of board feet of lumber produced declined in the second half of the 20th century the amount of wood pulp increased from 590,000 tons annually before World War II to approximately 1,500,000 tons. Louisiana has approximately 16,-000,000 ac. in forests with 41,436,000,000 board feet of standing timber; the annual growth is approximately equal to the amount harvested. The pine and cypress forests make up most of the softwoods while the leading hardwoods are oak, red gum and tupelo gum. It has been demonstrated that pine trees grow faster in Louisiana than anywhere else in the world. The soil, rainfall and long growing season of the state are ideally adapted to the growth and manufacture of timber and timber products.

Mining. — The principal minerals of the state are petroleum (including gas), salt, sand and gravel, and sulfur. The value of minerals produced in the second half of the 20th century was more than $1,500,000,000 a year. Louisiana ranks third of all the states in the value of minerals and produces more than 8% of the total value of all minerals in the nation. Nine-tenths of the total labour force in the mineral industry was producing petroleum, natural gas and natural-gas liquids. Petroleum production increased from 23,000,000 bbl. (42 gal. per barrel) to more than 323,000,000 bbl. in the quarter century following 1930. Natural-gas production increased from about 700,000,000,000 cu.ft. after World War II to about 2,000,000,000,000 cu.ft. in the second half of the 20th century and natural-gas liquids rose from 17,000,000 bbl. to 26,000,-000 bbl. The total proved reserves in the second half of the 20th century were petroleum, 3,858,000,000 bbl., natural gas, 51,436,-000,000,000 cu.ft., and natural-gas liquids, 1,019,000,000 bbl.

Only Texas and California produce more petroleum and natural gas than Louisiana and they are the only states that have more proved reserves. Louisiana ranks fourth among the states in the production of salt, and sulfur production for industrial use began in the state. Louisiana has been surpassed by Texas, but the opening in 1933 of the Grande Écaille mine, about 50 mi. S. of New Orleans, greatly increased sulfur production in Louisiana. The mining of sulfur along the gulf coast by the Frasch process is accomplished by pumping superheated steam into the sulfur rock, melting and forcing it to the surface through pipes. The sulfur is often hundreds of feet beneath the surface of the earth and sometimes there is a layer of quicksand above the sulfur. The annual average production of sulfur, about 1,000,000 tons before 1950, after 1950 reached more than 2,000,000 tons valued at more than $50,000,000. Sulfur and petroleum form the base for the growing petroleum-chemical industry in the state. The average annual production of salt, about 2,000,000 tons before 1950, after 1950 rose to approximately 3,500,000 tons. There are a number of known untouched salt domes in the state. The best-known mines are at Avery Island. Jefferson Island and Winnfield. The average annual production of cement, about 4,500,000 bbl, before 1950, after 1950 increased to about 7,500,000 bbl. The cement is procured from clays and oyster shells. The mining of miscellaneous clays, which previously averaged about 300,000 tons, more than doubled in the second half of the 20th century.

The value of all mineral production in the state exceeds $1,500,-000,000 annually, with petroleum the most valuable, accounting for $1,000,000,000, natural gas for $250,000,000 and natural-gas liquids, for $80,000.000. The number of producing oil wells, fewer than 10,000 in 1948, increased to more than 20,000 ten years later. The average daily production per well, however, had decreased from 54.7 bbl. to 41.3 bbl. for the same period.

Fisheries and Wildlife. — Louisiana is widely known for the quality and great variety of its fresh- and salt-water fish. The value of the annual catch is approximately $33,000,000 and 31,000 persons are employed in the industry. The leading salt-water fish are shrimp, oysters, crabs, pompanos, redfish, bluefish, Spanish mackerel, flounder, grouper (yellow bass) and drumfish. The fresh-water streams abound in perch, basses, barfish, catfish, gaspergou (a fresh-nater drumfish), sacalait (also known as crappie, warmouth and killfish), bullfrogs and buffalo fish. The annual catch of buffalo fish approaches 12,000,000 lb. and that of catfish approximates 5,000,000 lb. Louisiana supplies approximately 34,-000.000 lb. of shrimp annually worth about $10,000,000. The 10.000.000 lb. of oysters taken annually from 477.000 ac. of oyster beds have a value approximating $3,000,000. The oyster shells are important as a source of lime for making cement, and for liming or "sweetening" acid soils. The state is the leading producer, also, of diamondback terrapins, crabs and bullfrogs.

The original French settlers came to Louisiana for the fur trade and the state leads all others in the number but not in the value of furs produced. The annual yield approaches 2,500,000 pelts worth approximately $3,000,000. The muskrat leads in number and value, followed in value by mink, nutria, otter, raccoon and opossum. The wildlife and fisheries commission spends approximately $500,000 annually supervising the wildlife and fisheries.

Trade. — New Orleans ranks second among the ports of the U.S. in value of exports and imports; approximately 10% of the national foreign trade passes through the port. More than 100 steamship lines offer regular sailings from the port. Approximately 65 firms in the towing barge business operate through New Orleans with 15.000 mi. of commercial waterways converging on the city bringing over 150,000.000 tons of freight annually. The port annually handles more than 10,000,000 tons of foreign goods valued at more than $1,500,000,000. The most valuable imports are bananas, coffee and molasses.

The ports of Lake Charles, Baton Rouge and Morgan City have, in the second half of the 20th century, become increasingly important in the foreign trade of the state. In the second half of the 20th century about 25,000 retail firms annually sold more than $2,225,000.000 worth of merchandise and about 3,500 wholesale firms approximately $150,000,000 worth. Business activity by 1960 was 70% above the average of ten years earlier. Over 600,-000 persons nere employed in the state, with average weekly earnings of about $83; the per capita income for the state was a little over $1,500 compared to the national average of about $2.000.

Transportation and Communication. — In the second half of the 20th century there were ten major railroads, with 6,000 mi. of track; nine commercial airlines and approximately 100 airports; 5,000 mi. of navigable streams; 1,100 mi. of intercoastal canals; and almost 50.000 mi. of vehicular roads, of which more than 15,000 mi. were under state control, and of these approximately 14,000 mi. were paved with asphalt or concrete. There are over 5,000 bridges in the highway system. Two bridges at New Orleans, one at Baton Rouge and one at Natchez span the Mississippi river. Other important bridges span the Red, Ouachita and Atchafalaya rivers at important points.

There are 18 daily newspapers with paid circulation of more than 700.000. Practically every town of a few thousand population has a radiobroadcasting station and the larger cities have one or more televising stations.

Culture and Recreation. — Most of the larger urban centres have little theatre groups for the performance of amateurs on the stage. The New Orleans Opera association and similar organizations at most of the colleges and universities stage plays. produce operas and give concerts of creditable quality. A number of musical groups such as the New Orleans Symphony orchestra, the Shreveport symphony and others give excellent group and solo performances. The educational extension department of Louisiana State university has attempted to preserve the folklore, folk dances and artcrafts of the Xcadians. The Louisiana State library has promoted the establishment of parish libraries with bookmobiles to transport the books directly to rural families. The university, through its agricultural extension department, has endeavoured to organize "communities" of farm families throughout the state for recreational purposes.

There are a number of fairs to teach and demonstrate improved machinery, utensils, livestock and poultry. The largest of these is the state fair at Shreveport. There are a number of festivals nith colourful pageants and ceremonies, such as the Shrimp festival at Morgan City, the Rice festival at Crowley, the Forest festival at Winnfield, the Yambilee at Opelousas and the Peach festival at Ruston. The Mid-Winter Sports carnival at New Orleans, which sponsors the Sugar Bowl football game on New Year's day and the Christmas festival at Natchitoches are well known. The oldest and most famous of the festivals is Mardi Gras in New Orleans. See also Index references under "Louisiana" in the Index volume.

LOUISIANA PURCHASE. In 1803 the United States purchased from Napoleonic France the then vaguely delineated western half of the Mississippi river basin. This region was then known as "Louisiana." and its acquisition by the United States is referred to as the Louisiana Purchase. The term is commonly applied to the territory involved as n·ell as to the act of purchase.

The Louisiana territory had been the object of old world interests ior many years before 1803. Explorations and scattered settlements in the 17th and 18th centuries had given France control over the river itself and title to most of the Mississippi valley. The first serious disruption of French control over Louisiana came during the Seven Years' War (*q.v.*). In 1762 France ceded Louisiana west of the Mississippi river to Spain and in 1763 transferred virtually all of its remaining possessions in North America to Great Britain. This arrangement. however, proved temporary. French power rebounded under the subsequent military leadership of Napoleon Bonaparte and on Oct. 1, 1800, Napoleon induced a reluctant King Charles IV of Spain to agree for a consideration to cede Louisiana back to France. King Charles gave at least his verbal assent on the condition that France would never alienate the territory to a third power. And with this treaty of retrocession. known as the treaty of San Ildefonso. would go not only the growing and commercially significant port of New Orleans but the strategic mouth of the Mississippi river.

Reports of the supposed retrocession soon were received by official Washington—and with deep misgivings. During the preceding i2 years, Americans had streamed westward into the valleys of the Cumherland. Tennessee and Ohio rivers. The very existence of these new settlers depended on their right to use the Mississippi river freely and to make transshipment of their exports at New Orleans. By terms of the treaty of San Lorenzo, Spain in 1795 had granted to the United States the right to ship goods originating in American ports through the mouth of the Mississippi without paying duty and also the right of deposit, or temporary storage, of American goods at New Orleans for transshipment. But in 1802 Spain in effect revoked the right of deposit. and so it was in an atmosphere of growing tension in the west that Pres. Thomas Jefferson was confronted with the prospect of a new, wily and more powerful keeper of the strategic window to the Gulf of Mexico.

The news of the retrocession remained unconfirmed for months. and understandably so. Quite apart from persistent and conflicting rumours that would naturally surround secret negotiations of this magnitude. it was subsequently revealed that King Charles had put off signing the retrocession order until Oct. 15, 1802. But even though it was extremely difficult for American agents in Paris to ascertain the exact facts pertaining to the status of Louisiana. the information that did reach President Jefferson was disquieting. The president, sensitive to America's growing interests in the west. would look upon any foreign power that controlled the Mississippi river mouth as a "natural and habitual enemy" of the United States, and he was quick to view the possible possession of this region by Napoleon with added misgivings. "The day that France takes possession of New Orleans," the normally pro-French Jefferson wrote Robert R. Livingston. the U.S. minister at Paris, ". . . we must marry ourselves to the British fleet and nation."

Jefferson meanwhile instructed Livingston to take two steps: (1) to approach Napoleon's minister, Charles Maurice de Talleyrand. with the object of preventing the retrocession in the event this act had not yet been completed; (2) to try to purchase at least New Orleans if the property had actually been transferred from Spain to France. Direct negotiations with Talleyrand. however. appeared to be all but impossible. For months Livingston had to be content with tantalizing glimmerings of a possible deal between France and the United States. But even these faded as news of the Spanish governor's revocation of the right of deposit reached the U.S. minister. With this intelligence he had good reasons for thinking the worst: that Napoleon Bonaparte may have been responsible for this unfortunate act; that his next move might be to close the Mississippi river entirely to the Americans. Livingston had hut one trump to play and he played it with a flourish. He made it known that a *rapprochement* with Great Britain might. after all. best serve the interests of his country, and at that particular moment an Anglo-American *rapprochement* was about the least of Napoleon's desires.

No one can write with certainty of the mental deliberations of the first consul. But there are good reasons for believing that French failure in Santo Domingo. the imminence of renewed war with Great Britain and financial stringencies may all have prompted Napoleon in 1803 to offer for sale to the United States the entire Louisiana territory. At this juncture. James Monroe arrived in Paris as Jefferson's minister plenipotentiary: and even though the two American ministers possessed neither instructions nor authority to purchase the whole of Louisiana. the negotiations that followed, with Barbé-Marbois acting for Napoleon, moved swiftly to a conclusion. A treaty was signed on May 2, but was antedated to April 30. By its terms the Louisiana territory, in the form France had received it from Spain, was sold to the United States. For this vast domain the United States agreed to pay $11,-250.000 outright and assumed claims of its citizens against France in the amount of $3,750,000. Interest payments incidental to the final settlement made the total price $27,267,622.

Minister Livingston, with the help of Monroe, had bargained well, and he knew it. As he was about to affix his signature to the documents. Livingston is reported to have said: "We have lived long, but this is the noblest work of our whole lives. . . . From this day the United States take their place among the powers of the first rank . . ." Napoleon, too. reflected upon what he had done and remarked to Barbé-Marbois: "This accession of territory (by the Americans) affirms forever the power of the

United States, and I have just given England a maritime rival that sooner or later will lay low her pride."

But what had the Americans really bought? According to art. I of the terms of sale, "The colony or province" of Louisiana consisted of the "same extent" that it had under Spain at the time of the retrocession (1800) and that it had when France possessed it (prior to 1762); art. II specifically took in all adjacent islands (and this would, of course, include the vital Isle of Orleans); "all public lots and squares, vacant lands and all public buildings. fortifications, barracks, and other edifices which are not private property," and archives.

The wording of art. I was vague; it did not precisely describe the boundaries. It gave no assurances that West Florida was to be considered a part of Louisiana; neither did it delineate the southwest boundary. The American negotiators were fully aware of this. When Livingston later questioned Talleyrand on the matter, the reply was: "I do not know . . . I can give you no direction; you have made a noble bargain for yourselves, and I suppose you will make the most of it."

But before the United States could establish fixed boundaries to Louisiana there arose a basic question concerning the constitutionality of the purchase. Did the constitution of the United States provide for an act of this kind? The president, in principle a strict constructionist, thought that an amendment to the constitution might be required to legalize the transaction; but, after due consideration and considerable oratory, the senate approved the treaty by a 24 to 7 vote.

The setting of fixed boundaries awaited negotiations with Spain and Great Britain. The exasperating dispute with Spain over the ownership of West Florida and Texas was finally settled by the purchase of the Floridas from Spain in 1819 and the establishment of a fixed southwest boundary line. This line followed the Sabine river from the Gulf of Mexico to the parallel of 32° N.; ran thence due north to the Red river, following this stream to the meridian 100° W.; thence north to the Arkansas river and along this stream to its source; thence north or south as the case might be (the source of the Arkansas was not then known) to the parallel of 42° N. and west along this line to the Pacific ocean. The northern boundary was amicably established by an Anglo-American convention in 1818. It established the 49° parallel N. between the Lake of the Woods and the Rocky mountains as the American-Canadian border. The Rocky (then referred to as "Stony") mountains were accepted as the western limit of the Louisiana territory, and the Mississippi river was considered for all practical purposes the eastern boundary of the great purchase. The new territory, which comprised 828,000 sq.mi. and doubled the size of the United States, was acquired at a cost of less than three cents per ac. Much of the territory turned out to contain rich mineral resources, productive soil, valuable grazing land, forests and wildlife resources of inestimable value. Out of this empire were carved in their entirety the states of Louisiana, Missouri, Arkansas, Iowa! North Dakota, South Dakota, Nebraska and Oklahoma; in addition, the area included most of the land in Kansas, Colorado, Wyoming, Montana and Minnesota.

The acquisition of the Louisiana territory greatly strengthened the United States, materially and strategically. It provided a powerful new impetus to westward expansion of the American people, and in a constitutional sense it established in practice the doctrine of implied powers of the federal constitution. The Louisiana Purchase was what often has been said of it, the greatest bargain in American history. *See* also LOUISIANA: *History*.

BIBLIOGRAPHY.—The official literature is in the *American State Papers, Foreign Relations,* vol. II, IV; *Public Lands,* vol. II; diplomatic papers are reprinted in *House Document 431, 57th* Congress, 2d session (1903). Among the more useful secondary accounts are John K. Hosmer, *The History oj the Louisiana Purchase* (1902); Ripley Hitchcock, *The Louisiana Purchase and the Exploration, Early History and Building of the West* (1903); Curtis M. Geer, *The Louisiana Purchase and the Westward Movement* (1901); Thomas M. Marshall, *A History of the Western Boundary of the Louisiana Purchase, 1819–1841* (1911); E. S. Brown, *The Constitutional History of the Louisiana Purchase* (1920). Extremely interesting, but heavily weighted on Napoleon's venture in Santo Domingo, is Henry Adams, *History of the United States,* vol. I–II (1889). (O. O. W.)

LOUIS OF NASSAU (1538–1574), son of William, count of Nassau, and Juliana von Stolberg, and younger brother of William the Silent, was one of the leaders of the league of nobles who signed the document known as the Compromise in 1566, and was a member of the deputation that presented the petition of grievances called the Request to the regent, Margaret of Parma. On the arrival of Alva at Brussels. Count Louis, with his brother William, withdrew from the Netherlands and raised a body of troops in defense of the patriot cause. In the spring of 1j68 Louis invaded Friesland, and at Heiligerlee, on May 23, completely defeated a Spanish force under Count Aremberg, who was killed. Alva annihilated the levies of Louis at Jemmnigen (July 21), Louis himself escaping by swimming across an arm of the Ems. He now joined William, who in October had to beat a hasty retreat before Alva's superior skill. The brothers then made their way to the camp of Admiral Coligny.

Louis took an active part in the Huguenot campaign and fought heroically at Jarnac and Moncontour. In 1572 Louis raised a small force in France and, suddenly entering Hainaut, captured Mons (May 23). There he was besieged by Don Frederick of Toledo, Alva's natural son: who blockaded all approach to the town. William made an attempt to relieve his brother, but failed, and Mons surrendered (Sept. 17). Louis withdrew to his home, Dillenburg, to raise money and troops for another invasion of the Netherlands. In the hope of diverting the Spaniards from the siege of Leyden, Louis with his brothers John and Henry, at the head of a mixed force, crossed the frontier near Maastricht and advanced to the Mookerheide near Nijmegen. There he was attacked by Sancho d'Avila and routed. Both Louis and his younger brother Henry were killed.

LOUIS PHILIPPE I, king of the French (1773–1850), was the eldest son of Louis Philippe Joseph, duc d'Orléans (known during the Revolution as Philippe Egalité), and of Louise Marie Adelaide de Bourbon, daughter of the duc de Penthièvre, and was born at the Palais Royal in Paris on Oct. 6. 1773. The legend that he was a supposititious child is dealt with elsewhere. (See MARIA STELLA, countess of Newborough.) The godparents of the duc de Valois, as he was entitled till 1785, were Louis XVI and Queen Marie Antoinette; his governess was the famous Madame de Genlis, to whose influence he doubtless owed his wide if superficial knowledge: his orderliness and perhaps his parsimony. Known from 1785 as the duc de Chartres. he was 16 at the outbreak of the Revolution. with which, like his father. he at first identified himself. In 1790 he joined the Jacobin club. in which the moderate elements still predominated, and attended the debates of the national assembly. Hc thus became a *persona grata* with the party in power; he was already a colonel of dragoons. and in 1792 he was given a command in the army of the north. As a lieutenant general, at the age of 18, he was present at Valmy (Sept. 20) and Jemappes (Nov. 6).

The republic had meanwhile been proclaimed, and the duc de Chartres, now like his father surnamed Egalité, posed as its zealous adherent. Fortunately for him, he was too young to be elected to the Convention, and while his father was voting for the death of Louis XVI he was serving under Dumouriez in the Netherlands. He shared in the defeat of Neerwinden (March 18. 1793), was implicated with Dumouriez in the plot to overthrow the republic and on April j escaped with him into the Austrian lines. He went first, with his sister Madame Adelaide, to Switzerland. where he obtained a situation as professor in the college of Reichenau under the assumed name of Chabaud de la Tour, mainly in order to escape from the fury of the *émigrés*. The execution of his father in Nov. 1793 had made him duc d'Orléans, and he now became the centre of the intrigues of the Orleanist party. In 179j he was at Hamburg with Dumouriez, who still hoped to make him king. With characteristic caution Louis Philippe refused to commit himself, and announced his intention of going to America; but in the hope that something might happen in France to his advantage, he postponed his departure, travelling instead through the Scandinavian countries. But in 1796, the Directory having offered to release his mother and his two brothers, who had been kept in prison since the Terror, on condition that he go to America, he set sail for the United States, and in October settled in Philadelphia, where in Feb. 1797 he was joined by his brothers the duc de Montpensier and the comte de Beaujolais. The news of the coup d'état of 18 Brumaire decided them to return to Europe. They returned in 1800, only to find Napoleon Bonaparte's power firmly established. Immediately on his arrival, in Feb. 1800, the duc d'Orléans, at the suggestion of Dumouriez, sought an interview with the comte d'Artois, through whose instrumentality he was reconciled with the exiled king, Louis XVIII. The duke, however, refused to join the army of Condé and to fight against France, an attitude in which he persisted, while maintaining his loyalty to the king. He settled with his brothers at Twickenham.

On May 18, 1807, the duc de Montpensier died at Christchurch in Hampshire of consumption. The comte de Beaujolais was ill of the same disease, and in 1808 the duke took him to Malta, where he died on May 29. The duke now, in response to an invitation from King Ferdinand IV, visited Palermo, where, on Nov. 25, 1809, he married Princess Maria Amelia, the king's daughter. He remained in Sicily until the news of Napoleon's abdication recalled him to France. He was cordially received by Louis XVIII; his military rank was confirmed, he was named colonel general of hussars, and such of the vast Orléans estates as had not been sold were restored to him by royal ordinance. This made him enormously rich.

Meanwhile, his sympathy with the Liberal opposition brought him again under suspicion. His attitude in the house of peers in the autumn of 1815 cost him a two years' exile to Twickenham; he courted popularity by having his children educated *en bourgeois* at the public schools; and the Palais Royal was the rendezvous of that middle class by which he was to be raised to the throne.

His opportunity came with the revolution of 1830. During the three "July days" the duke kept himself discreetly in the background, retiring first to Neuilly, then to Raincy. Meanwhile, Thiers issued a proclamation pointing out that a republic would embroil France with all Europe, while the duc d'Orléans, who was "a prince devoted to the principles of the Revolution" and had "carried the tricolour under fire," would be a "citizen king" such as the country desired. This view was that of the rump of the chamber still sitting at the Palais Bourbon, and a deputation headed by Thiers and Laffitte waited upon the duke to invite him to place himself at the head of affairs. He returned with them to Paris on July 30, and was elected by the deputies lieutenant general of the realm. The next day, wrapped in a tricolour scarf, he went on foot to the *hôtel de ville*—the headquarters of the Republican party—where he was publicly embraced by Lafayette as a symbol that the republicans acknowledged the impossibility of realizing their own ideals and were prepared to accept a monarchy based on the popular will. Hitherto, in letters to Charles X, he had protested the loyalty of his intentions, and the king now nominated him lieutenant general and, abdicating in favour of his grandson the comte de Chambord, appointed him regent. On Aug. 7, however, the chamber by a large majority declared Charles X deposed, and proclaimed Louis Philippe "king of the French, by the grace of God and the will of the people."

For the trappings of authority he cared little. To conciliate the revolutionary passion for equality he was content to veil his kingship for a while under a middle-class disguise. He erased the royal lilies from the panels of his carriages; and the Palais Royal, like the White House at Washington, stood open to all and sundry who cared to come and shake hands with the head of the state. This pose served to keep the democrats of the capital in a good temper and so leave him free to consolidate the somewhat unstable foundation of his throne and to persuade his European fellow sovereigns to acknowledge in him not a revolutionary but a conservative force. But when once his position had been established, it became clear that he possessed all the Bourbon tenaciousness of personal power.

When a "party of resistance" came into office with Casimir-Périer in March 1831, the speech from the throne proclaimed that "France has desired that the monarchy should become national, it does not desire that it should be powerless"; and the migration of the royal family to the Tuileries symbolized the right of the king not only to reign but to rule. Republican and Socialist agitation, culminating in a series of dangerous risings, strengthened the position of the king as defender of middle-class interests; and since the middle classes alone were represented in parliament, he came to regard his position as unassailable. Little by little his policy became more purely dynastic. His position in France seeming assured, he sought to strengthen it in Europe by family alliances. The fact that his daughter Louise was the consort of Leopold I, king of the Belgians, had brought him into intimate relations with the English court. Broken in 1840 during the affair of Mohammed Ali, the *entente* with Great Britain was patched up in 1841 by the Straits convention, and recemented by visits paid by Queen Victoria and Prince Albert to the Château d'Eu in 1843 and 1845 and of Louis Philippe to Windsor in 1844, only to be irretrievably wrecked by the affair of the "Spanish marriages," a deliberate attempt to revive the traditional Bourbon policy of French predominance in Spain. If in this matter Louis Philippe had seemed to sacrifice the international position of France to dynastic interests, his attempt to re-establish it by allying himself with the reactionary monarchies against the liberals of Switzerland finally alienated from him the French Liberal opinion on which his authority was based. When, in Feb. 1848, Paris rose against him, he found that he was isolated.

Charles X, after abdicating, had made a dignified exit from France. Louis Philippe was less happily situated. Escaping with the queen from the Tuileries by a back entrance, he made his way with her in disguise to Honfleur, where the royal couple found refuge in a gardener's cottage. They were smuggled out of the country by the British consul at Havre as Mr. and Mrs. Smith, arriving at Newhaven "unprovided with anything but the clothes they wore."

They settled at Claremont, placed at their disposal by Queen Victoria, under the incognito of count and countess of Neuilly. There on Aug. 26, 1850, Louis Philippe died.

Louis Philippe had eight children. His eldest son, the popular Ferdinand Philippe, duc d'Orléans (b. 1810), who had married Princess Helena of Mecklenburg, was killed in a carriage accident on July 13, 1842, leaving two sons, the comte de Paris and the duc de Chartres. The other children were Louise, consort of Leopold I, king of the Belgians; Marie, who married Prince Alexander of Württemberg and died in 1839; Louis Charles, duc de Nemours; Clementine, married to the duke of Coburg-Kohary; François Ferdinand, prince de Joinville; Henri Eugène, the duc d'Aumale; and Antoine Philippe, the duc de Montpensier, who married the younger sister of Queen Isabella II of Spain.

Bibliography.—F. A. Gruyer, *La Jeunesse du roi Louis-Philippe, d'après les pourtraits et des tableaux* (1909), de luxe edition, with beautiful reproductions of portraits, miniatures, etc.; Denys Cochin, *Louis-Philippe* (1918). Of general works on Louis Philippe's reign may be mentioned G. Weill, *La France sous la monarchie de juillet* (1902); and the relevant chapters in Lavisse and Rambaud's *Histoire Générale* (1898) and the *Cambridge Modern History* (1907 and 1909), in which further works will be found in the bibliographies attached by Emile Bourgeois to his chapters (vol. x, p. 844; vol. xi, p. 874). Louis Philippe himself published the *Journal du duc de Chartres, 1790–91; Mon Journal, événements de 1815*, 2 vol. (1849); *Discours, allocutions et réponses de S. M. Louis-Philippe, 1830–46;* and after his death was issued his *Correspondance, mémoire et discours inédits* (1863).

(W. A. P.)

LOUIS STYLES refer to the artistic trends during the reigns of Louis XIII, XIV, XV and XVI of France; the styles coincide roughly with the broader classifications of late Renaissance, baroque, rococo and neoclassical art (*qq.v.*), respectively. With Louis XIII (1610–43) the contemporary Italian influence, as exemplified in the Luxembourg palace, was strong. Under Louis XIV (1643–1715) the building of the Versailles palace, establishment of the academies and royal manufactury of tapestries, furniture and ceramics gained cultural hegemony for France. The sober restraints of the baroque grand manner were cast off with Louis XV (1715–74) in favour of the capricious, graceful rococo, which flourished in such smaller Parisian residences as the Hôtel Soubise. The simple classic ideal, as seen in the Petit Trianon, once again reasserted itself in Louis XVI's reign (1774–93).

See S. F. Kimball, *The Creation of the Rococo (1943).* (WM. F.)

LOUISVILLE, the largest city and seat of Jefferson county, Ky., U.S., is the metropolitan centre of the state. It is located on the south bank of the Ohio river opposite the Falls of the Ohio, the rock ledge which divides the water levels, about 90 mi. S.W. of Cincinnati. The city spreads across the broad level shoulder of the Ohio flood plain between the river and the rim of knobs. This plain is a fertile area, which was once overflowed and enriched by the Ohio river. In the past the city had recurrent floods which caused heavy damage to property, notably the great flood of Jan.–Feb. 1937. In 1956, a 17-mi. levee was completed along the river front to seal out floodwaters.

Metropolitan Louisville spreads over almost three-quarters of the 375 sq.mi. of Jefferson county. In 1960 the standard metropolitan statistical area, comprising Jefferson county in Kentucky and Clark and Floyd counties in Indiana, had a population of 725,139 persons, 390,639 in the city and 610.947 in Jefferson county. This represented an increase of 25.7% since 1950.

History. — Legend has it that the sieur de La Salle visited the site in 1669, but this is indeed doubtful. French and British traders stopped at the Falls of the Ohio before the middle of the 18th century, but details of their visits are unrecorded. On July 8, 1773, Capt. Thomas Bullitt reached the falls with a commission from William and Mary college in Virginia to survey the lands in this area. Though the county surveyor refused to approve this survey, Lord Dunmore, the governor of Virginia, conveyed it in Dec. 1773 to his friend John Connolly. In June 1774 Daniel Boone and Michael Holsteiner came from Virginia to warn the survey party of the outbreak of Lord Dunmore's War against the Indians.

In May 1778, George Rogers Clark (*q.v.*) landed his militia company on Corn Island opposite the mouth of Beargrass creek and began preparation for the conquest of the British-held Old Northwest. Clark built blockhouses for his stores, and cabins ior some of the colonists who had come with him. Most of the settlers moved to the mainland the following winter and established themselves in Fort-on-Shore (Ft. Nelson) within the present limits of Louisville. Trustees were appointed to lay out a town and a town government was organized in April 1779; on May 14, 1780, the Virginia legislature, petitioned by the townsfolk, declared that Connolly had forfeited his title (he had been actively pro-British during the American Revolution) and incorporated the settlement under the name of Louisville, in recognition of the assistance given by Louis XVI of France to the colonies in the Revolutionary War. Between 1580 and 1811 Louisville became an important frontier and flatboat trading place, and its growth was greatly stimulated by the successful introduction of steam navigation. Nicholas Roosevelt docked the "New Orleans:" the first steamboat on the western waters, in 1811 and inaugurated the steamboat era which was one of the town's most dramatic moments. By 1820 Louisville had become a major river port and its facilities were further stimulated by the construction (1825–30) of the canal around the Falls of the Ohio. The steamboat spread the city's commercial influence over a vast area. Louisville merchants were engaged in trade with both the south and the middle west and cotton planters depended upon them for supplies. The town's printers furnished books and periodicals to an ever-widening educational trade area, and its newspapers were read from Alabama to Illinois.

In 1828 the town was chartered as a city and received successive charters in 1851, 1870, 1893 and 1926.

In the American Civil War, Louisville was early occupied by Federal troops who made it a military headquarters and a major supply depot throughout the struggle. Though no fighting took place in the city, its war history constitutes one of its most exciting chapters. Except for the disruption of trade and the normal intercourse with the rest of Kentucky, Louisville escaped the ravages of war. Large numbers of slaves flocked to the town from the plantations seeking passes to enable them to cross the river to Indiana and freedom.

Immediately after the war, Louisville businessmen began a campaign to reclaim the South's trade. The Louisville and Nashville railroad was already directed toward the heart of the south, and this important rail line nas extended to Mobile. Xla.. and New Orleans, La., and then to Jacksonville, Fla. Both merchant and railway officials helped locate store sites in the south as outlets for goods transported by rail from Louisville distributors.

In March 1890 a tornado caused the loss of more than 100 lives and did extensive property damage. Louisville's economy remained stabilized but was given a boost during World War I with the building of Camp Zachary Taylor just outside the city and the influx of thousands of soldiers. Later the enlargement of nearby Ft. Knox (*q.v.*) had a similar effect. By mid-20th century newer industries, notably the 1,000-ac. manufacturing plant called Appliance Park, quickened the city's economic pulse.

Industry. — Since 1865 Louisville manufacturers have produced a highly diversified assortment of goods. Traditional manufactures are processed meats, flour, wagons and carriages, whisky, beer, tobacco products, plumbing fixtures, processed foods, wood products, chemicals, textiles, sporting goods, musical instruments, metal goods and clothing. Newer industries include automobiles, tractors, farm implements, rubber goods, electrical machinery and aluminum products. Louisville is still an important printing centre producing large numbers of magazines, comic books, catalogues, commercial brochures and beer and whisky labels. The American Printing House for the Blind which publishes books in braille, is located there.

Culture and Recreation. — From its beginning Louisville was an important cultural centre. Its newspapers, especially the Louisville *Journal*, edited by George D. Prentice, 1830–68, and the Louisville *Courier-Journal*, edited 1868–1918, by "Marse" Henry Watterson, are distinguished in the history of U.S. journalism. Among the cultural institutions which have given the city character are the Louisville Free Public library. the Speed Memorial Art museum and the Filson club (founded 1884 as a historical library and museum).

The city's system of public education began in 1829. The University of Louisville (founded in 1798 as Jefferson seminary and chartered under its present name in 1846) has, among others, faculties of law, medicine and engineering, and is municipally owned. Among the other educational institutions are the Roman Catholic colleges Bellarmine (1950), Nazareth (1920) and Ursuline (established in 1921 as Sacred Heart junior college and chartered under its present name in 1938); and the Southern Baptist Theological seminary (1859) and the Louisville Presbyterian Theological seminary (1901). The Louisville public school system was one of the first large southern city systems to abandon the practice of racial segregation in compliance with the 1954 supreme court decision, which held segregation to be unconstitutional.

Louisville has abundant recreational facilities. Cherokee park, a 406-ac. woodland in the rolling hills east of the city, is a fine natural playground. Adjoining this tract is Seneca park which contains a golf course: a small lake and public playgrounds. Central park, in the heart of the city, has tennis courts, wading pools, a natural amphitheatre and other recreational facilities.

Louisville is a well-known sporting centre. Since 1875 it has been the scene of the annual Kentucky Derby, America's horse-racing classic, run at Churchill Downs. The Kentucky state fair, one of the oldest agricultural fairs in the U.S., features an annual horse show which almost rivals the derby in interest. The large armoury building and Freedom hall have been the scenes of numerous amateur and professional sporting events, including basketball, prize fights, wrestling matches and ice hockey. The Louisville Colonels, an American association .baseball team. has a history which goes back to 1867 when the Louisville Eclipse team was organized. The city played an important part in the organization of the National league in 1856. Babe Browing, an early professional player, is credited with introducing the design for the famous "Louisville slugger" baseball bat which is manufactured there. (T. D. C.)

LOUNSBURY, THOMAS RAYNESFORD (1838–1915), U.S. scholar, was born at Ovid, N.Y., on Jan. 1, 1838, and educated at Yale university (A.B., 1859; A.M., 1877). He was on the editorial staff of the *American Encyclopaedia* 1860–62, and then enlisted in the 126th N.Y. volunteers to serve through the Civil War. In 1870 he became instructor and in 1871 professor of English language and literature in the Sheffield Scientific school of Yale university. In 1906 he was retired as professor emeritus. He was also librarian of the Sheffield Scientific school 1873–1906. He won recognition as a scholar in both branches of his subject: study of the English language and study of its literature. His *History of the English Language* (1879) is characterized by Brander Matthews as "a little masterpiece of carefully controlled information, and of marvellously lucid exposition." He followed this with later studies of pronunciation, usage and spelling no less authoritative: *The Standard of Pronunciation in English* (1904); *The Standard of Usage in English* (1908); *English Spelling and Spelling Reform* (1909). He was one of the most influential of those who advocated spelling reform and was one of the organizers, and later president, of the simplified spelling board. His studies in literature show him a master of his successive subjects. His first was a *Life of James Fenimore Cooper* (1882). *Studies in Chaucer* in three impressive volumes (1891) remains an enduring work. His *Shakespeare as a Dramatic Artist* (1901), *Shakespeare and Voltaire* (1902), and *The Text of Shakespeare* (1906) marked him as one of the foremost writers on Shakespearian subjects. He also wrote *The Early Literary Career of Robert Browning* (1910) and edited the complete works of Charles Dudley Warner.

Lounsbury died on April 9, 1915.

LOURDES, a town of southwestern France in the *département* of Hautes-Pyrénées, at the foot of the Pyrénées, 12 mi. S.S.W. of Tarbes on main line of Southern railway between that town and Pau. Pop. (1954) 14,110. The origin of Lourdes is uncertain. From the 9th century onward it was the most important place in Bigorre, largely owing to its famous fortress. In 1360 it passed by the treaty of Brétigny from the French to the English, who lost it to the French in 1406. During the religious wars the castle held out successfully against the Protestant troops. From the reign of Louis XIV to the beginning of the 19th century the castle was used as a state prison. After the visions of Bernadette Soubirous, a peasant girl, in 1858, their authentication by a commission of enquiry appointed by the bishop of Tarbes, and the authorization by the pope of the cult of Our Lady of Lourdes, the quarter on the left bank of the Gave sprang up, and thousands of pilgrims annually visit the town, August being the favourite month.

Several religious communities have been named after Our Lady of Lourdes. Of these one, consisting of sisters of the third order of St. Francis, called the Congregation of Our Lady of Lourdes (founded 1877), has its headquarters in Rochester, Minnesota. Another, the Order of Our Lady of Lourdes, was founded in 1883 for work in the archdiocese of New Orleans. Lourdes is divided into an old and a new town by the Gave de Pau, which at this point leaves the valley of Argelès and turns abruptly to the west. The old quarter on the right bank surrounds a scarped rock, on which stands the fortress with its large square 14th century keep. A tower of the 13th or 14th century, surmounting a gateway known as the Tour de Garnabie is part of the old fortifications. The old quarter is united with the new by a bridge which is continued in an esplanade leading to the basilica. the church of the Rosary and the Grotto, with its spring of healing water, where the Virgin Mary is believed in the Roman Catholic world to have revealed herself repeatedly to Bernadette Soubirous. A statue of the Virgin stands on a rock projecting above the grotto, the walls of which are covered with crutches and other votive offerings; the spot is marked by a basilica built in 1876 above the grotto. The Byzantine church of the Rosary was built in front of and below the basilica from 1884 to 1889. Near the grotto are other caves, where prehistoric remains have been found.

Lourdes is the seat of the tribunal of first instance of the *arrondissement* of Argeles. There are slate quarries and the pastures support a breed of valuable Aquitaine cattle

LOURENÇO MARQUES, capital of Mozambique, on Delagoa bay, and 396 mi. by rail via Pretoria from Johannesburg. A census completed in 1950 gives the population as 93,265. The large majority of non-Europeans are Africans, but there are also many Indians. Foreigners are employed in the town, which is built upon a low-lying spit of sand, formerly surrounded by swamps which have now been filled in, providing a large area for business and other occupation, and on the hills behind it. The streets are regularly laid out, and most of them are tar-surfaced: in the town and suburbs are several fine buildings, among which are the railway station. municipal market, post and telegraph offices, the treasury, the residency, the British consulate, offices of the attorney general and the palatial Polana hotel. There are Roman Catholic, Anglican and Wesleyan Methodist churches, and the large church of the Mission Suisse Romande. The handsome Avenida Aguiar, in which are situated the fine municipal gardens, adjacent to which is the municipal museum, leads to the upper town. The electric tram system was replaced by a municipal bus service, and motor buses ply between the lower and the upper town.

At Ponta Vermelha (Reuben point), which marks the spot where the river enters the bay, were built cavalry barracks, the wireless station and many private residences of the wealthier citizens. The climate is almost ideal in the winter months and sea breezes temper somewhat the summer heat. The mean annual temperature (14 years) was 72° F. There is a large military and civil hospital in the town and also several nursing homes. Water, brought from the Umbeluzi river 18 mi. away, is of excellent quality.

Trade. — There is safe entrance to the harbour, the minimum depth in the Cockburn channel being 29 ft. At its mouth, the river is about 2 mi. across. Lourenqo Marques is the nearest port to the Rand gold mines. It is 7.308 mi. from London via Capetown, and 8,460 mi. via the Suez canal. The wharf of reinforced concrete is about a mile long, and can accommodate 12 large steamers at once. There are large warehouses, in addition to the transit shed and national warehouse. Telegraph, telephone and railway booking offices are on the wharf; and a clock gives the official time, a three-hour signalling device giving the time to shipping.

There are regular services of British, Portuguese, German, American, and other lines. The great bulk of the traffic of the port is that in transit to the Union of South Africa. Over 50% of the import trade of Johannesburg is with Lourenqo Marques. (For convention regulating this traffic, *see* PORTUGUESE EAST AFRICA.) Union duties can be paid in Lourenço Marques. The port possesses two coaling plants, capable of handling respectively 400 and 600 tons an hour. Great Britain, Portugal and Germany, in that order, long had the bulk of the import trade. Most of the imports, being forwarded to the Transvaal, figure also as exports.

A great proportion of the trade of the town, the forwarding trade especially, is in the hands of British firms. The retail trade and the native trade is very largely in the hands of Indians. The chief articles imported are foodstuffs and liquors, iron, mineral oils, inks and dyes, timber and livestock. These all form part of the transit trade. There is little export trade by sea except in coal, chiefly from the collieries at Middelburg, Transvaal. The chief import for local consumption is wine.

History. — For the early history of the town *see* DELAGOA BAY. The existing town dates from about 1850, the previous settlement having been entirely destroyed by natives. In 1871 the town was described as a poor place, with narrow streets, fairly good flat-roofed houses, grass huts, decayed forts and rusty cannon, enclosed by a wall 6 ft. high then recently erected and protected by bastions at intervals. The growing importance of the Transvaal led, however, to greater interest being taken in Portugal in the port. A commission was sent by the Portuguese government in 1876 to drain the marshy land near the settlement, to plant the blue gum tree, and to build a hospital and a church. It was not, however, until the end of the 19th century that any marked development took place in the town, and up to 1903 cargo had to be discharged in tugs and lighters. Later, a wooden wharf preceded the present reinforced concrete one. The settlement was declared a village in 1876, a corporate town in 1887, and in 1907 became the capital of the province.

In 1873–77 the president of the Transvaal endeavoured, unsuccessfully, to get a railway built from Pretoria to Delagoa bay. Later, a company was organized which built a line from the coast to the frontier as marked on maps of 1883, and this railway was opened in 1888. The Portuguese government insisted that the line must be continued another 5 mi. to the frontier as fixed after 1883. This led to disputes, seizure of the line, etc., and a long arbitration. Meantime, however, the railway had been completed and was opened for through traffic to Pretoria on July 8, 1895.

In 1906–10 another railway (47 mi. long) was built from Lourenço Marques due west to the Swaziland frontier, being a link in a new line to shorten the distance by rail between the Rand and the sea by some 60 mi.

The text of the railway arbitration award was published in French at Berne in 1900. Annual reports on the trade of Lourenço Marques are issued by the British foreign office.

LOUSE, a name commonly applied to small wingless insects parasitic upon birds and mammals and belonging to the orders Mallophaga (biting lice) and Anoplura (sucking lice). The word louse is also applied in a popular sense to many animals other than the true lice, *e.g.,* wood louse, fish louse (see CRUSTACEA), book louse of the insect order Psocoptera (*q.v.*), plant louse (see APHIDES) and bark louse (see SCALE INSECT). The true lice are hairy. flattened insects with short, three- to five-segmented antennae; the eyes may be reduced or wanting; and the tarsi are one- or t o-segmented with strongly developed claws for clinging to their hosts. The eggs are attached to hairs, feathers or clothing, and the young lice are active as soon as they emerge. In structure and habits the immature lice resemble the adults, but they pass through several molts before reaching sexual maturity. When lice are numerous they cause great irritation to the hosts, upon whose bodies their whole life is passed.

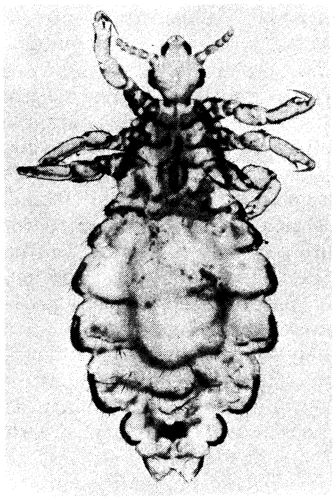
The Mallophaga or biting-lice constitute a separate order of insects although they were previously classed as a suborder of the Anoplura. Biting lice attack birds chiefly, and some mammals; however, they are not parasites of man, except perhaps accidentally and then only temporarily. They are rarely over one-fourth inch in length, and range in colour from whitish, through yellow, red and brown, to black (see MALLOPHAGA).

The order Anoplura (also known as the Siphunculata) is restricted to the sucking lice, all of which have extrusible mouthparts adapted for piercing and sucking. They live by imbibing the blood or tissue fluids of mammals. None are parasitic on birds or reptiles. They are usually smaller than biting lice, all being less than one-third inch in length, and range in colour from whitish to yellow.

Sucking lice show distinct host specificity; that is, one species of louse is restricted to a species or a small group of species of hosts, usually within a single genus. Genera of lice are characteristic of certain families or related families of mammals. The louse family Pediculidae is peculiar to the primates (monkeys, apes, man), the Echinopthiriidae to the marine carnivores (seals, sea lions, walruses) and the Haematopinidae to the rodents, rabbits and ungulates with very few exceptions. Vernon L. Kellogg has suggested that the presence of related lice on related groups of hosts is evidence of parallel evolution of parasites and hosts.

In addition to man and his domestic mammals a wide variety of wild mammals are infested by these insects, each host, genus or species having its own characteristic parasites. A few hosts such as man, the domestic cow and some rodents have two characteristic species of sucking lice, but usually only one species is found on a host. Although sucking lice are largely restricted to old world primates, marine carnivores, rodents, rabbits and ungulates, several species are known from insectivores. The domestic dog is one of the few land carnivores parasitized by sucking lice. No species of Anoplura are known from monotremes (platypus, etc.), Australian marsupials (kangaroo, etc.), bats, elephants or cetaceans (whales, dolphins, etc.).

The best-known species of louse is the sucking louse of man, *Pediculus humanus*, which infests the human race wherever modern hygienic practices have not been instituted. Its distribution is almost coextensive with that of the human race and the antiquity of this association is demonstrated by the presence of lice on ancient mummies from Egypt and the southwestern United States. This species has apparently been inherited by man from his remote primate ancestors. There are two varieties of the common human louse, viz., *Pediculus humanus* var. *capitis,* the head louse, and *P. humanus* var. *corporis,* the body louse or "cootie." The human louse in heavy infestations may cause serious skin irritations, but far more serious is its role as the carrier from man to man of the pathogenic agents of epidemic typhus fever (see TYPHUS FEVER), trench fever of World War I and louse-borne relapsing fever (in contrast to tick-borne relapsing fever) (see RELAPSING FEVER).



ROSS E. HUTCHINS

HUMAN BODY LOUSE (PEDICULUS HUMANUS), ABOUT 20 TIMES ENLARGED

The terrible role of these diseases in the history of man is related by Hans Zinsser in Rats, Lice *and* History (1935). Epidemic typhus fever has been a scourge whenever populations have been disrupted or concentrated by war, famine or floods and the attendant insanitary conditions.

The only other louse which infests man is the pubic or crab louse, *Phthirus* inguinalis (pubis), which is occasionally found in the hair of the armpits, in the eyebrows and beard as well as in the pubic regions. It is not known to be an important disease vector.

Related species of lice are *Pediculus schäffi,* of the chimpanzee: and *Phthirus gorillae* of the gorilla. The other lice from old world primates are included in the genus *Pedicinus*. Pediculus *mjöbergi,* which is almost indistinguishable from the human louse, is recorded from several species of new world monkeys. It is generally considered that these monkeys have acquired the parasite by contact with man, although it may be established on wild monkeys.

Some of the common lice of domestic animals are *Haematopinus* suis of the pig, H. asini of the horse, H. eurysternus and *Linognathus vituli* of the cow and L. setosus of the dog.

In infestations on man, DDT, lindane and other chemical dusts have proved effective insecticides for lice, and poisonous gases, chemical solutions and heat sterilization have been used to delouse infested clothing. Chemical dips or sprays are used on infested domestic animals.

See INSECT; see also Index references under "Louse" in the Index volume.

See C. F. Craig and E. C. Faust Clinical Parasitology, thoroughly rev. by E. C. Faust and P. F. Russell, 6th ed., chap. 38 (1957); U.S. Department of Agriculture, "Insects," *1952* Yearbook *of Agriculture* (1952).

(W. L. J.; X.)

LOUTH, a maritime county in the province of Leinster, Ireland, bounded northeast by Carlingford bay and County Down, east by the Irish sea. southwest by Meath, and northwest by Monaghan and Armagh. It is the smallest county in Ireland, its land area being 202,806 ac. or 316.8 sq.mi. Pop. (1961) 67.284.

Much of the county is occupied by an undulating lowland of much-folded Silurian shales and fine-grained sandstones; but Carboniferous limestone overlies these rocks north and east of Dundalk. Igneous rocks form a mountainous promontory, approaching 2,000 ft. in height on the border of Carlingford lough. A raised beach provides a flat terrace at Greenore. As in the adjacent parts of Armagh and Monaghan, lead is worked.

Apart from the promontory of Clogher head, which rises abruptly to 180 ft., the coast is mostly low and sandy. Carlingford lough is navigable beyond the limits of the county, and Carlingford and Greenore are watering places on the Co. Louth shore. The Bay of Dundalk stretches to the town of that name and affords convenient shelter.

The principal rivers, the Fane, the Lagan, the Glyde and the Dee, flow eastward. The Boyne is navigable for large vessels as far as Drogheda.

The territory which afterward became County Louth was included in the principality of Uriel, Orgial or Argial, which embraced also the greater part of Meath, Monaghan and Armagh. The chieftain of the district was conquered by John de Courcy in 1183, and Louth or Uriel was among the shires generally considered to have been created by King John, and peopled by English settlers. Until the time of Elizabeth I it was included in the province of Ulster. The cromlech of Ballymascanlan lies between Dundalk and Greenore. Danish raths and other forts are numerous. The most interesting monastic ruins are at Monasterboice and Mellifont, both near Drogheda. At the former site are two churches, the larger dating probably from the 9th century, the smaller from the 13th; a round tower, 110 ft. high; and three crosses, two decorated. Ardee, incorporated in 1376, has a 13th-century castle. At Dunbar a charter of Charles II (1679) granted the right to elect a sovereign. Louth, $5\frac{1}{2}$ mi. S.W. from Dundalk, gave its name to the county, and contains ruins of an abbey to which was attached one of the most noted early schools in Ireland.

In the lower regions the soil is a rich deep mold, adapted for cereals and green crops. Agriculture generally is in an advanced condition, and the farms are well drained. Oats, wheat, barley, potatoes and turnips are cultivated. Cattle, sheep, pigs and poultry represent the bulk of the livestock. Linen manufactures are of some importance. The deep-sea and coast fishery has its headquarters at Dundalk, and the salmon fisheries at Dundalk (Castletown river) and Drogheda (River Boyne). The county is traversed by the Northern railway and Dundalk is connected with Greenore by railway.

Louth returns three members to Dáil Eireann. Although the county is part of the province of Leinster, Louth is included in the Roman Catholic archdiocese of Armagh.

LOUTH, a market town and municipal borough in the Parts of Lindsey and the Louth parliamentary division of Lincolnshire, England, on the river Lud where it flows out of the Wolds, 26 mi. E.S.E. of Lincoln by road. Pop. (1951) 11,135. Area 4.4 sq.mi. Louth is first mentioned in Domesday as a borough held, as it had been in Saxon times, by the bishop of Lincoln, who had a market there. The see surrendered the manor to Henry VIII who granted it to Edward, earl of Lincoln; it was recovered by the crown before 1562. Louth owed its early prosperity to the adjacent Cistercian abbey, founded in 1139 by Alexander, bishop of Lincoln. A manor court under the presidency of the bishop's high steward governed the town, the reeve being elected by 18 ex-reeves. During the 13th and 14th centuries nine religious guilds were founded in the town. The markets. said to have been held from ancient times, and the three fairs, on the third Sunday after Easter and the feasts of St. Martin and St. James, were confirmed in 1551. Louth was a centre of the wool trade as early as 1297. The Perpendicular church of St. James was completed about 1515, and the grammar school was refounded and endowed by Edward VI in 1551. Louth is the centre of a large agricultural area with a well-known cattle market. Industries include malting and the manufacture of preserves and agricultural implements.

LOUTHERBOURG (LUTHERBURG), **PHILIPPE** JACQUES DE (1740-1812), landscape painter, engraver and especially successful theatrical scene designer of Polish origin who became a naturalized Englishman, was born at Fulda, Ger., on Oct. 31, 1740. He received his first training under his father, a miniature painter. Later, about 1755, he worked at Paris under Carle van Loo and Francesco Casanova. He was received into the academy in 1767 and exhibited battle scenes, landscapes and marine paintings at the Salon, where he won the praise of Diderot who considered him as an inferior Vernet with an admixture of Berghem. In 1771 he went to London with an introduction to David Garrick who paid him £500 a year as his regular adviser on scenic effects at Drury Lane theatre from 1773. In 1781 he turned his talents to the Eidophusikon, an elaborate moving panorama combined with dramatic lighting effects and music, which enjoyed considerable success. Later he retired to Hammersmith where he practised as a faith healer. He also devised a system for reproducing paintings in colour which occasionally deceives even modern critics. He died on March 11, 1812. Loutherbourg had a marked talent for ingenious dramatic effects in oil paintings, but as he seldom referred to nature, his theatrical work was probably better adapted to his abilities than landscape painting.

See W. T. Whitley, *Artists and Their Friends in England 1700–1799*, vol. 2 (1928); E. K. Waterhouse, *Painting in Britain 1530 to 1790* (1953). (F. J. B. W.)

LOUVAIN (Flem. *Leuven*), a town of Belgium in the province of Brabant, of which it was the capital in the 14th century before the rise of Brussels. Pop. (1955 est.) 34,206. Local tradition attributes the establishment of a camp here to Julius Caesar, but Louvain only became important in the 11th century as a residence for the dukes of Brabant. In 1356 Louvain was the scene of the famous *Joyeuse Entrée* of Wenceslas, the principal charter of Brabant. At that time it had a population of at least 50,000 and was the centre of the wool trade in central Belgium. The guild of weavers numbered 2,400 members. The old walls of Louvain, $4\frac{1}{2}$ mi. in circumference, have been replaced by boulevards, but within them is much cultivated ground. Soon after the *Joyeuse Entrée* a feud began between citizens and patricians, and eventually the duke threw in his lot with the latter. After a struggle of over twenty years' duration the White Hoods, as the citizens called themselves, were crushed. In 1379 they massacred seventeen nobles in the town hall, but this brought the vengeance of the duke, to whom in 1383 they made the most abject surrender. Many weavers fled to Holland and England, the duke took up residence in the strong castle of Vilvorde, and Brussels prospered at the expense of Louvain. What it lost in trade it partially recovered as a seat of learning, for in 1426, Duke John IV of Brabant founded there a university, and ever since Louvain university has enjoyed the first place in Belgium. It has always prided itself most on its theological teaching. In 1432 the university was established in the old Cloth Workers' Hall, a building dating from 1317, with long arcades and graceful pillars supporting the upper stories. In the 16th century there were 6,000 students, and four residential colleges are attached to the university. The aula and the university library were burnt in the German invasion of 1914. A new library was built (1921–28) by gifts from citizens of the United States, and books and fittings came from many nations. The library had more than 600,000 volumes. It was again destroyed by fire during the German attack in May 1940. The town hall is one of the richest examples of pointed Gothic. Mathieu de Layens, master mason, built it (1448 to 1463) in three stories, each with ten pointed windows facing the square.

The church of St. Peter (1425–97), damaged in 1914, was restored. It has seven chapels, in two of which are fine pictures by Dierik Bouts formerly attributed to Memling. Much of the iron and brass work is by Jan Matsys. There are other interesting churches in Louvain, viz., Ste. Gertrude, St. Quentin, St. Michael and St. Jacques, the last with a fine De Crayer (St. Hubert).

LOUVER (LOUVRE, LUFFER), in architecture, was originally a lantern or cupola built on the ridge of the roof of the great hall of a medieval house to let out the smoke. The term was later generally applied to a system of slanting boards, sheets of metal or glass, or other material, so arranged as to permit the passage of air while restricting the view, the sun, rain water, or any combination thereof. 'Three large adjustable horizontal louvers were used in each room of the Ministry of Education building in Rio de Janeiro (Oscar Niemayer, 1936) as sun protection. Immense, adjustable, vertical aluminum louvers, one story high (repeated on each story) serve as sun protection on all four sides of the Pan American Life Insurance building, New Orleans, La. (Skidmore, Owings and Merrill, 1951). Since louvers are practical, simple and usually attractive they have become a popular feature of contemporary architecture. (H. Mn.)

LOUVET DE COUVRAI, JEAN BAPTISTE (1760–1797), French writer and politician, was born in Paris on June 12, 1760. He became a bookseller's clerk, and published two novels, *Les Amours du chevalier de Faublas* (1787–89), and *Emilie de Varmont,* which attracted some attention. *Paris justifié,* a reply to Mounier's proposal that the court should be established elsewhere (Oct. 1789), led to Louvet's election to the Jacobin club, and he energetically opposed the moderate constitutional royalty advocated by Lafayette and others. On Dec. 25, 1791 he presented at the bar of the assembly his *Pétition contre les princes.*

Louvet was elected deputy to the assembly, and attached himself to the Girondists, publishing, at Roland's expense, a biweekly *journal-affiche* called *La Sentinelle* (March-Nov. 1792). On Aug. 10 he became editor of the *Journal des Débats,* in which he violently attacked Robespierre, Marat and the other Montagnards. His violent invective, coupled with his courageous attitude at the trial of Louis XVI, discredited the Girondists, and he fled after the crisis of May 31, 1793. *(See* Girondists.)

After Robespierre's fall, Louvet was recalled to the convention and elected a member of the committee of the constitution, president of the assembly, and a member of the committee of public safety. He advocated union among republicans in *La Sentinelle,* which he revived. Under the directory (1795) he was elected member and secretary of the Council of Five Hundred. The bookseller's shop which he had again set up in the Palais Royal was attacked, and Louvet and his wife again fled from Paris. He was appointed consul at Palermo, but died on Aug. 25, 1797, before taking up his post.

Louvet published a part of his memoirs in 1795 under the title *Quelques notices pour l'histoire et le récit de mes périls depuis le 31 mai 1793,* giving a vivid picture of the sufferings of the proscribed Girondists. The first complete edition was published in 1889, ed. F. A. Aulard, *Mémoires de Louvet de Couvrai.*

LOUVOIS, FRANCOIS MICHEL LE TELLIER, Marquis de (1641–1691), French statesman, war minister of Louis XIV, was born at Paris on Jan. 18, 1641. He was the son of Michel le Tellier, whom he succeeded as war minister in 1666. His talents were perceived by Turenne in the war of Devolution (1667–68), who gave him instruction in the art of providing armies. After the peace of Aix-la-Chapelle, Louvois organized the French army. The work of Louvois in the years 1668–72 is bound up with the historical development of the French army and of armies in general. *(See* Army.) Louvois reorganized the military orders of merit, founded the Hôtel des Invalides, and enrolled the nobility and gentry of France for service in the army or at court. The success of his measures is to be seen in the victories of the great war of 1672–78. After the peace of Nijmwegen Louvois was high in favour, his father had been made chancellor, and the influence of Colbert was waning. The surprise of Strassburg in 1681 in time of peace was planned and executed by Louvois and Monclar.

A saving clause in the revocation of the Edict of Nantes, which provided for some liberty of conscience, if not of worship. Louvois sharply annulled. He claimed the credit of inventing the dragonnades, and mitigated their rigour only in so far as licence was prejudicial to discipline. Colbert died in 1683, and Louvois took the ministry for public buildings. Louvois died suddenly on July 16, 1691. Louvois was a war minister only equalled by Carnot. Both organized old armies on a new system, both were admirable contrivers of campaigns, and both devoted themselves to the material well-being of the soldiers. In private life and in the means employed for gaining his ends, Louvois was unscrupulous. His sudden death caused a suspicion of poisoning.

The principal authority for Louvois's life and times is Camille Rousset's *Histoire de Louvois* (1872), a great work founded on the 900 volumes of his despatches at the Depôt de la Guerre. Saint-Simon from his class prejudices is hardly to be trusted, but Madame de Sévigné throws many side lights on his times. *Testament politique de Louvois* (1695) is spurious; L. André, M. *Le Tellier de Louvois et l'organisation de l'armée monarchique* (1906).

LOUYS, PIERRE (1870–1925), French novelist and poet, was born at Paris on Dec. 10, 1870. When he was 19 he founded a review. *La Conque,* which brought him into contact with the leaders of the Parnassians, and counted Swinburne, Maeterlinck, Mallarmé and others among its contributors. He won notoriety by his novel *Aphrodite* (1896), which gave a vivid picture of Alexandrian morals at the beginning of the Christian era. His *Chansons de Bilitis, roman lyrique* (1894), which purported to be a translation from the Greek, is a glorification of Sapphic love, whose delicate decadent prose is typical of a modern French literary school. Some of the "songs" were set to music by Debussy and others. Later books are: *La Femme et le pantin* (1898) ; *Les Aventures du roi Pausole* (1900); *Sanguines* (1903); *Archipel* (1906) He died on June 4, 1925.

See Gaubert, *Pierre Louys* (1904).

LOVAT, SIMON FRASER, 12th Baron (c. 1667–1747), Scottish chief and Jacobite intriguer, was born about 1667 and was the second son of Thomas Fraser, third son of the 8th Lord Lovat. Young Simon was educated at King's College, Aberdeen, and one of his first acts on leaving college was to recruit 300 men from his clan to form part of a regiment in the service of William and Mary, in which he himself was to hold a command. Among other outrages in which he was engaged about this time was a rape and forced marriage committed on the widow of the 10th Lord Lovat with the view apparently of securing his own succession to the estates. A prosecution having been instituted against him by Lady Lovat's family, Simon retired first to the Highlands, and afterward (1702) to the court of St. Germain.

He planned to land 5,000 French troops at Dundee. where they might reach the northeastern passes of the Highlands in a day's march, and divert the British troops till the Highlands should have time to rise. Immediatelv afterward 500 men were to land on the west coast, seize Fort William or Inverlochy. and thus prevent the access of any military force from the south to the central Highlands His plan was continuously kept in view in all future attempts of the Jacobites, and finally acted on in the outbreak of 1745 Lovat was despatched (1703) on a secret mission to ascertain what forces the chiefs might bring into the field. He found little disposition to rebellion. and he then decided to reveal all that he knew to the government of Queen Anne. He persuaded the duke of Queensberry that his rival, the duke of Atholl, was in the Jacobite plot, and that if Queensberrp supported him he could obtain evidence of this at St. Germain. Queensberry foolishly entered into the intrigue with him against Atholl, but when Lovat had gone to France with a pass from Queensberry the affair was betrayed to Atholl by Robert Ferguson, and resulted in Queensberry's discomfiture. The story is obscure, and is complicated by partisanship on either side; but Lovat was certainly playing a double game. Suspicions got afloat as to Lovat's proceedings, and on his return to France he was imprisoned in the castle of Angoulême. He remained nearly ten years under supervision, until in Nov. 1714 he made his escape to England.

For about 25 years after this he was chiefly occupied in lawsuits for the recovery of his estates and the re-establishment of his fortune. The intervals were filled by Jacobite and Anti-Jacobite intrigues, in which he betrayed both parties. When the rebellion of 1745 broke out, Lovat represented to the Jacobites that his weak health and advanced years prevented him from joining the standard of the prince in person, while to the Lord President Forbes he professed his cordial attachment to the house of Hanover, and expressed regret that his son had joined the Pretender and taken with him a strong force from the clan of the Frasers. The truth mas that the lad was unwilling to go, but was compelled by his father, After the battle of Culloden he was obliged to retreat to the Highlands. Lovat, after enduring extreme hardships in his wanderings, was at last arrested on an island in Loch Morar. He was conveyed in a litter to London, and after a trial of five days sentence of death was pronounced on March 19, 1747. He was beheaded on April 9.

His son Simon Eraser, Master of Lovat (1726–1782) (not to be confused with another Simon Fraser who saw somewhat similar service and was killed in 1777 at the battle of Saratoga), was a soldier, who at the beginning of the Seven Years' War raised a corps of Fraser Highlanders for the English service, and at the outbreak of the U.S. War of Independence raised another regiment which took a prominent part in it. He fought under Wolfe in Canada, and also in Portugal, and rose to be a British major-general. The family estates were restored to him, but the title was not revived until 1837.

See *Memoirs of Lord Lovat* (1746 and 1767); J. Hill Burton, *Life of Simon, Lord Lovat* (1847); J. Anderson, *Account of the Family of Frizell or Fraser* (Edinburgh, 1825); A. Mackenzie, *History of the Frasers of Lovat* (Inverness, 1896); Mrs. A. T. Thomson, *Memoirs of the Jacobites* (1845–46); and W. C. Mackenzie, *Simon Fraser, Lord Lovat* (1908); *Papers relating to Simon, Lord Lovat* edited by J. R. N. Macphail (1924).

LOVEBIRD, a name bestowed, chiefly by dealers and their customers, on some of the smaller short-tailed parrots, from the affection which examples of opposite sexes exhibit towards each other. They belong to the genera *Forpus* (5 spp.) and *Agapornis* (9 spp.), the former being South American, the latter African. One of the birds most commonly called lovebird, which, however, bears no near relationship to the above, but is a small, long-tailed parrot, is the budgerigar (*Melopsittacus undulatus*) now familiar throughout the world, being bred by hundreds in aviaries. Its native country is Australia.

LOVEJOY, ELIJAH (1802–1837), U.S. abolitionist, was born at Albion, Me., on Nov. 9, 1802, and graduated at Waterville college in 1826. The following year he moved to St. Louis, Mo., where he established a school and entered journalism. Later he began to publish a religious paper called *The Observer* in which he strongly condemned slavery and recommended gradual emancipation. A letter in 1835 signed by a number of the important men of St. Louis requested him to moderate the tone of his editorials. He replied in an editorial reiterating his views and his right to publish them. Threats of mob violence forced him to move his press across the Mississippi river to Alton, Ill. There his press was destroyed by mobs several times in one year, and on the night of Nov. 7, 1837, when a mob attacked the building, Lovejoy was killed in its defense. The news of his death stirred the people of the north profoundly and led greatly to the strengthening of abolitionist sentiment.

LOVELACE, RICHARD (1618–1657), described by Edward Phillips in *Theatrum Poetarum* (1675) as "Souldier, Gentleman & Lover, and a fair pretender to the Title of Poet," came of an old Kentish family but was probably born in Holland, where his father was in the Dutch military service, in 1618. He was educated at Charterhouse and at Gloucester hall, Oxford, when, according to Anthony à Wood's *Athenae Oxonienses*, he was "accounted the most amiable and beautiful person that ever eye beheld." After leaving Oxford he retired "in great splendor to the Court." At 16, according to Wood, but possibly a little later, he wrote *The Scholars*, a comedy acted at Whitefriars, of which the prologue and epilogue survive. He took part in the two expeditions to Scotland (1639–40) and during the second wrote *The Soldier*, a tragedy never acted and now lost.

Returning to his estates in Kent, Lovelace, who had torn up a disloyal petition at the quarter sessions at Maidstone, was chosen to present (1642) a royalist petition to a hostile house of commons. For this he was imprisoned in the Gatehouse, London, where he wrote "To Althea, from Prison." Released "upon good Security" after about seven weeks, he probably went to Holland. He passed much of the next four years abroad and was wounded fighting for the French against the Spaniards at Dunkirk in 1646.

On Oct. 26, 1647, with Thomas Rawlins and Peter Lely, Lovelace, now a colonel, was admitted to the freedom of the Painters company—an unusual and significant honour. In 1648 he was again imprisoned. James Thompson, a lawyer, writing on Oct. 26, said that soldiers searching for Lovelace's brother Francis seized "divers Delinquent Jewells" in Richard's cabinet and that the incensed poet, taking it upon him "stiffly to argue property," was arrested on the pretense that something had been found in his papers (see *The Oxinden and Peyton Letters, 1642–70*). During his imprisonment, Lovelace prepared Lucasta (1649) for the press. Wood identified Lucasta with one Lucy Sacheverell, but if a real person, as is probable, she is as likely to have been a Lucas.

Lovelace continued to write commendatory verses for various publications, a practice he began at 20. Wood says he died in misery and poverty in 1658 and was buried in St. Bride's church, London, but an elegy on him was printed in 1657. He had certainly sold much of his estates, and he who was noted for generosity to ingenious men was himself helped in need by Charles Cotton, but none of the elegies supports John Aubrey's story of his unhappy death.

That Lovelace was himself planning a second volume is shown by Eldred Revett's lines "On his second poems," but *Lucasta. Posthume Poems* of *Richard Lovelace* Esq. (1659) was edited by his brother Dudley, assisted by Revett, and includes *Elegies*, dated 1660.

Lovelace was the friend of musicians, painters and writers such as Henry Glapthorne, who named his daughter Loualis after him, James Howell, Alexander Brome, Andrew Marvell and John Hall, the last of whom liked people who were "celebrated for some excellent endowment," but was so far from being a royalist that *Mercurius Elencticus* (1648) asked if he could be a fit associate for such ingenious and candid souls as Lovelace. John Sherburne, James Shirley or Thomas Stanley, who includes the other three in his "Register of Friends." Lovelace was scholarly and cultured, interested in languages, literature, music, painting, hunting, falconry and everything thought befitting a gentleman.

In his poems Lovelace generally follows the "conceited" fashions of his time, though his best songs owe much to a simplicity of thought and diction which possibly led Sir Walter Scott, when misquoting "To Lucasta. Going to the Warres" in *The Talisman*, to claim it for the earl of Montrose. Obvious criticism is summed up by John Ferriar's "Lovelace strikes, by fits a note divine," but even when Lovelace's verses are only exercises in ingenuity there is audible the voice of one whose conversation was "witty and incomparably graceful," and who succeeded in giving to plain emotions the utterance that is most effective and memorable in song.

See *The Poems of Richard Lovelace*, with an introduction by C. H. Wilkinson, 2 vol. (1925). (C. H. Wn.)

LOVELL, FRANCIS LOVELL, Viscount (1454–1487?), English politician, was a son of John, 8th Baron Lovell. As a young man he served under Richard of Gloucester in the expedition to Scotland in 1480. He had been created a viscount on Jan. 4, 1483, and while still a viscount Protector Richard made him chief butler. As soon as Richard became king, Lovell was promoted to be lord chamberlain. Lovell helped in the suppression of Buckingham's rebellion, and as one of Richard's most trusted ministers was gibbeted in Collingbourne's couplet with Catesby and Ratcliffe:

> The catte, the ratte and Lovell our dogge
> Rulyth all England under a hogge.

He had command of the fleet which was to have stopped Henry Tudor's landing in 1485, but fought for Richard at Bosworth and after the battle fled to sanctuary at Colchester. Thence he escaped next year to organize a revolt in Yorkshire. When that failed he fled to Margaret of Burgundy in Flanders. As a chief leader of the Yorkist party he had a foremost part in Lambert Simnel's enterprise. With John de la Pole, earl of Lincoln, he accompanied the pretender to Ireland and fought for him at Stoke on June 16, 1487. He was seen escaping from the battle, but was never afterward heard of. More than 200 years later, in 1708, the skeleton of a man was found in a secret chamber in the family mansion at Minster Lovell in Oxfordshire. It is supposed that Francis Lovelf had hidden himself there and died of starvation.

Collingbourne's couplet is preserved by Fabyan, *Chronicle*, p. 672. For the discovery at Minster Lovell see *Notes and Queries*, 2nd ser. i and 5th ser. x.

LOVER, SAMUEL (1797–1868), Irish novelist, artist, song writer and musician, was born in Dublin on Feb. 24, 1797. Lover began life as an artist, and was elected in 1828 a member of the Royal Hibernian academy. His love for music showed itself at an early age. At a dinner given to the poet Tom Moore in 1818 Lover sang one of his own songs, which elicited special praise from Moore. One of his best-known portraits mas that of Paganini, which was exhibited at the Royal Academy. He went to London about 1835, where his gifts rendered him popular in society; and he appeared often at Lady Blessington's evening receptions. There he sang several of his songs, later published as *Songs and Ballads,* 1839. Lover wrote some popular novels, among them *Rory O'More,* a *National Romance* (1837) and *Handy Andy, an Irish Tale* (1842). In 1844 he began to give entertainments, "Irish Evenings," illustrative of his own works. He died on July 6, 1868.

His *Life* mas written in 1874 by Bayle Bernard.

LOW, SETH (1850–1916), U.S. municipal reformer, university builder and philanthropist, was born in Brooklyn, N.Y., Jan. 18, 1850. He graduated as valedictorian of Columbia college in 1870, thereupon entering his father's prosperous importing business and becoming a leader in the silk trade.

Low was twice elected mayor of Brooklyn, and his administration (1882–85) was characterized by civil service reform, administrative efficiency, public school reorganization and advocacy of home rule, all of which attracted national attention.

Low served as president of Columbia from 1890 to 1901, transforming Columbia from a small college on a crowded city block to a large university on an impressive campus on Morningside heights. He gave coherent form to the university spirit, organized the university council, the graduate faculties of philosophy and pure science, and by absorption or alliance brought the College of Physicians and Surgeons, Barnard college, Teachers college and other important components more closely into the Columbia university system. He set an example of philanthropy by his gift of the imposing central building on the new campus, by his support of professorships and by his aid, through Barnard, of education for women. In 1899 he was a delegate to the first Hague Peace conference.

Elected mayor of greater New York in 1901, Low eliminated plaguing paternalism and demonstrated municipal administration on business principles. Failing re-election in 1903, he nonetheless continued outstanding public service, furthering education for Negroes as chairman of the trustees of Tuskegee institute from 1907 until his death, and labour-management relations as arbitrator in major disputes. He served also as president of the National Civic federation and the New York Chamber of Commerce.

Low died Sept. 17, 1916, at his home in Bedford Hills, N.Y.

LOWBOY, a small table with one or two rows of drawers, so called in contradistinction to the tallboy, or double chest of drawers. Both were favourite pieces of the 16th century, both in England and America; the lowboy was most frequently used as a dressing table, but sometimes as a side table. It is usually made of oak, walnut or mahogany, with brass handles and escutcheons. The more elegant examples of the Chippendale period have cabriole legs, claw-and-ball feet and carved knees, and are sometimes sculptured with the favourite shell motif beneath the centre drawer.

LOWDEN, FRANK ORREN (1861–1943), U.S. lawyer and politician, governor of Illinois from 1917 to 1921, was a nationally prominent advocate of reforms in governmental administration and of improvements in the social and economic condition of farmers. He was born at Sunrise City, Minn., Jan. 26, 1861, but from the age of seven grew to manhood in Hardin county, Ia. There he worked as farm hand and schoolteacher, and graduated from the state university in 1885. Quick success as an attorney followed his move to Chicago in 1886 and his graduation the next year from the Union College of Law. His marriage in 1896 to Florence, daughter of George M. Pullman (*q.v.*), had an important influence on his career. During the next decade, while counseling, directing or organizing business corporations, he established his home at "Sinnissippi," an estate near Oregon, Ill. There and on his Arkansas plantations he experimented with field crops, livestock and forestation.

His long apprenticeship in Chicago politics ended in 1904 in an unsuccessful bid for the Republican gubernatorial nomination. From then to 1912 he was a moderately progressive national committeeman of his party. In congress, 1906–11, he sponsored measures to improve the foreign service and benefit agriculture.

As governor of Illinois, in addition to vigorously upholding Pres. Woodrow Wilson's war policies, Lowden initiated a widely-imitated state budgetary and administrative structure, centralized under executive control. Although his political career climaxed in a deadlock with Leonard Wood for the Republican presidential nomination in 1920, which resulted in their both being by-passed in favour of Sen. Warren G. Harding, Lowden declined the vice-presidential nomination in 1924, sought the presidential nomination in 1928, and, as "Sage of Sinnissippi," often advised politicians and political scientists until his death at Tucson, Ariz., March 20, 1943.

Following 1920, however, farmers' welfare was Lowden's principal concern. In frequent speeches and articles and through many organizations he championed marketing co-operatives, purebred dairy cattle, and improved methods of tillage. After 1925, with the agricultural depression deepening, he supported the McNary-Haugen bills for extending federal aid to farmers. The Domestic Allotment law of 1936 embodied his proposal, made seven years previously, to tie in government assistance with soil restoration.

Lowden's papers are in Harper Library, The University of Chicago.

See William T. Hutchinson, *Lowden of Illinois,* 2 vol. (1957).

(W. T. HN.)

LOWE, SIR HUDSON (1769–1844), English general, was the son of an army surgeon, John Lowe, and was born at Galway on July 28, 1769 and was gazetted ensign in his 12th year. After the outbreak of war with France early in the year 1793, Lowe was almost continuously on active service: holding many important commands, throughout the Napoleonic Wars. Charged with the duties of quartermaster general of the army in the Netherlands in 1814–15, he was about to take part in the Belgian campaign when he was offered the command of the British troops at Genoa; but while still in the south of France he received (on Aug. 1, 1815) news of his appointment to the position of custodian of Napoleon, who had surrendered to H.M.S. "Bellerophon" off Rochefort. Lowe was to be governor of St. Helena, the place of the ex-emperor's exile.

Friction soon arose between Lowe and his prisoner. The news that rescue expeditions were being planned by the Bonapartists in the United States led to the enforcement of stricter regulations in Oct. 1816, Lowe causing sentries to be posted round Longwood garden at sunset instead of at 9 P.M. He was accused of unnecessary harshness in carrying out his instructions. It may, however, be noted that Lowe recommended that the government allowance of £8,000 a year to the Longwood household should be increased by one-half. After the death of Napoleon in May 1821, Lowe returned to England and received the thanks of George IV. In 1825–30 he commanded the forces in Ceylon, but was not appointed to the governorship when it fell vacant in 1830. In 1842 he became colonel of his old regiment, the 50th; he also received the G.C.M.G. He died in 1844.

LOWELL, ABBOTT LAWRENCE (1856–1943), U.S. educator, president of Harvard university from 1909 to 1933, was born in Boston, Mass., on Dec. 13, 1856. He graduated from Harvard, A.B. 1877, LL.B. 1880, and practised law in Boston for 17 years before turning to teaching at Harvard. In 1909 he succeeded Charles William Eliot as president. Within a few years he had realized a new scheme of "concentration and distribution" to modify Eliot's "free elective" system, devised general examinations to de-emphasize isolated course-credits, and set up a tutorial plan to supplement undergraduate lectures. During his administration Harvard more than doubled student enrollments, nearly trebled the faculty, increased endowments from $22,000,000 to $130,000,000, and added new professional schools of architecture. business administration. education and public health. Beginning in 1930 he reorganized the Harvard undergraduate body of about 3,200 students into seven separate, self-contained residential "Houses." He also originated and endowed the Society of Fellows, a selected group of younger research scholars, freed from conventional restrictions on graduate study. Author of several textbooks on European governmental systems, his influence on U.S. education is better typified by *Conflicts of Principle* (1932, rev. ed. 1956) and *At War with Academic Tradition in America* (1934), both illustrative of his lifelong concern for academic freedom. He died in Boston on Jan. 6, 1943. (N. M. Py.)

LOWELL, AMY (1874–1925), U.S. poet, critic and lecturer, was born on Feb. 9, 1874, in Brookline, Mass., of a prominent and public-spirited family. She was educated by her mother and in private schools. afterward traveling widely abroad. At 28 she began to devote herself seriously to poetry, but published nothing until 1910, when a poem appeared in the *Atlantic Monthly*. Her first volume! *A Dome of Many-Coloured Glass* (1912), was succeeded by *Sword Blades and Poppy Seed* (1914), which included her first poems in *vers libre* and "polyphonic prose"; *Six French Poets* (1915); *Men, Women and Ghosts* (1916); *Tendencies in Modern American Poetry* (1917); *Can Grande's Castle* (1918); *Pictures of the Floating World* (1919), which reflected her new preoccupation with oriental poetry; *Legends* (1921); *Fir-Flower Tablets* (1921), with Florence Ayscough; *A Critical Fable* (1922); a biography of John Keats (1925); *What's o'clock* (1925); *East Wind* (1926); and *Ballads for Sale* (1927). Throughout this period she wrote critical articles for periodicals and frequently lectured. After several years of illness, she died suddenly on May 12, 1925, at Brookline.

During her later years Miss Lowell was the most striking figure in American poetry. Her vivid and powerful personality, her independence and zest made her a conspicuous and unique figure. She epitomized her scorn of convention in such defiant gestures as smoking cigars. She replaced Ezra Pound as the leader of the poetic group called the Imagists. which Pound promptly restyled the "Xmygists" in tribute to her domineering qualities. A bold experimenter in form and technique, she remained conservative at the core, retaining conventional verse forms and in her last years severing connections with all radical schools of poetry. Characteristic qualities of her work include her mastery of the free verse (*q.v.*) technique, her brilliant use of sensuous impressions in depicting the external world, and the restrained beauty of many of' her shorter poems.

Bibliography.—For Miss Lowell's own definitions of the principles of *vers libre* and "polyphonic prose" *see* the preiaces to *Sword Blades and Poppy Seed* and *Can Grunde's Castle*, articles in *North American Review* (Jan. 1917) and *Dial* (Jan. 17, 1918). *See* also W. Bryher, *Amy Lowell: A Critical Appreciation* (1918); R. Hunt and H. Snow, *Amy Lowell* (1921); S. F. Damon, *Amy Lowell: A Chronicle* (1935); Horace Gregory, *Portrait of the Poet in Her Time* (1958).

LOWELL, JAMES RUSSELL (1819–1891), U.S. poet, critic and diplomat. who wrote extensively on a wide variety of subjects, but whose major significance probably lies in the interest in literature he helped develop through his writing. editing and teaching. Born in Cambridge, Mass., Feb. 22, 1819, he was the grandson of John Lowell and a member of the distinguished New England family which in the 20th century produced the poets Amy Lowell (*q.v.*) and Robert Lowell. His lifelong love of nature was nurtured by his rearing in the open countryside, and he had read avidly in Alexander Pope as well as in Spenser, Scott and the old ballads before he entered Harvard, where he followed his enthusiasms more than the instructions of the faculty. He graduated in 1838 and in 1840 took his degree in law, which helped fit him for his later diplomatic posts, although he did not care to practise law as a profession.

His first period. up to about 1850, was dominated by humanitarian interests, notably abolition. in accord with the pressures of the era in New England. In 1844 he was married to the gifted poet Maria White, who was also an ardent humanitarian and who had helped inspire his poems in *A Year's Life* (1841). After a three-months' editorship (with Robert Carter) of the abortive periodical *The Pioneer* in 1843, attracting work by Hawthorne, Poe and Whittier; Lowell published the appreciative *Conversations on Some Old Poets* (1845) in which literary discussion did not exclude sentimental pleas for freeing the slave and for utopianism transcending nationalism. From 1845 to 1850 he wrote about 50 antislavery articles for such periodicals as the *Pennsylvania Freeman*, the *London Daily News* and the *National Anti-Slacery Standard*. Even more effective were his *Biglow Papers* which he began to serialize June 17, 1846 (the first series of which was collected in book form in 1848); written in New England dialect, these satirized the Mexican War as an attempt to extend the area of slavery. This "miraculous year" 1848 also saw the publication of the somewhat Tennysonian *Vision of Sir Launfal*, with its humanitarian theme that "the gift without the giver is bare," and the rollicking and witty *Fable for Critics*, urging American readers to "forget Europe wholly" in glorifying native humanitarian poets such as Whittier.

Lowell's second period, roughly from 1850 to 1867, shows him gradually turning from his earlier antitraditional humanitarianism to nationalism or Unionism, in response to new pressures of the time, notably secession. A trip to Italy and England (July 1851–Oct. 1852) made him less antitraditional, as "Leaves from My Italian Journal" (1854) suggests; and the death of three of his children, followed by the death of his beloved wife in 1853, gave him a taste of sorrows beyond the remedy of legislative reform. In 1855 his lectures on English poets before the Lowell institute led to his appointment as Smith professor of modern languages at Harvard, succeeding Longfellow; these lectures were richly appreciative of the older poets but centred (as "The Function of the Poet") on the theme that America has ample resources to inspire great poetry. Again he went to Europe to study in Germany and Italy, returning in Aug. 1856 for his fruitful professorship of 20 years. In 1857 he married Frances Dunlap, who had cared for his only remaining child, Mabel; and in that year he began his four years' editorship of the new *Atlantic Monthly*, to which he attracted nearly all the major New England authors who (partly through association at the Saturday club) provided mutual stimulation and ushered in a golden day of American literature. As editor. Lowell encouraged them to find the ideal in the real, in the "simply natural" American scene and vernacular as he tried to illustrate in his second series of *Biglow Papers*, devoted to Unionism and collected from the periodicals in 1867. These include "Sunthin' in the Pastoral Line" which, along with "New England Two Centuries Ago" (1865), illustrates the way in which, in the face of the threat to the Union he drew upon his native Puritan heritage of ordered liberty, which he contrasted to what seemed to him the program of anarchy involved in disunion. His central hope in this period was that "a strong nation begets strong citizens," that (as he says in the "Ode Recited at the Harvard Commemoration" of her dead) the mutable many might find worthy perpetuation in the immutable One, a coercive Union, which he glorified in essays such as "E Pluribus Unum." "Washers of the Shroud" (1862) had warned that the nation could be preserved only if Americans subordinated "the Many's plaudits" and "Opinion's Wind" to "Knowledge, Will," and especially to obedience to the divine "Law before all time." The "Commemoration Ode," glorifying "the pith and marrow of the nation," had included the moving tribute to the martyred Lincoln in whom there was "nothing of Europe" — Lincoln who was the product of "the unexhausted West" which was to interest Lowell increasingly as one of the chief nurseries of what he regarded as distinctive national traits—self-reliant individualism, equality and optimism.

Lowell's third period, from about 1867 to the end, was inspired by the growing proof, in the corruptions of the Grant administration, that the Union's having been preserved did not automatically beget morally strong citizens. He saw that he must now change emphasis again and centre his work on ways and means of making the individual man "sole sponsor of himself," on self-mastery in the midst of greed and perpetual temptation. One of the chief means Lowell used to help a nem people, which he thought unduly optimistic and without steadying aids, was tradition, the examples of the heroes of the entire past, especially as embodied in literature. Thus, partly through his editorship (with C. E. Norton) of the *North American Review* (1864–72), Lowell published his successive critical essays on the great masters such as Dante, Chaucer, Spenser. Shakespeare. Cervantes, Calderon, Milton, Dryden, Pope. Fielding,,Lessing, Gray, Wordsworth, Carlyle and Emerson. Guided by Edmund Burke's view of an organic tradition and by Coleridge (the "first of critics"), Lowell sought to winnow and sift ideas of the past which could fruitfully be brought to bear with all their "plastic force" on the needs of contemporary Americans. Thus he exalted the Greeks' "sense of proportion, their distaste for the exaggerated"; Dante's sense of free-willed responsibility in the face of the individual's inward conflict between appetite and aspiration; and Shakespeare's view that this conflict can be resolved not so much on the theological as on the sunlit human plane. Historical tradition ("clarified experience") teaches "the value of personal character as a chief factor in what used to be called destiny." In his long reflective poem, "The Cathedral," in which he spoke of God as being "so far above, yet in and of me." Lowell wistfully concluded that the supernatural faith of the middle ages is "irrecoverable," but he concluded that modern science, agnostic as it seems, can be made to accord with a modified religious faith, that the "cure-all equality" and the "brute's license of unfettered will" need the reinforcement of "private virtue strong in self-restraint." His "Three Memorial Odes" held that true freedom is the fruit of self-control guided by the human ideal synthesized by culture and a sense of the steadying power of traditioc: these lofty "public" poems called for "symmetry of self-control." for self-discipline, for "making man sole sponsor of himself," for "rounding a whole life to the circle fair of orbed fulfillment." His achievement was rewarded by honorary degrees from Oxford (1873) and Cambridge (1874).

Lowell's literary cosmopolitanism was crowned by diplomatic responsibilitie~:Pres. Rutherford Hayes rewarded his support in the Republican convention in 1876 by appointing Lowell minister to Spain (1877–80) and ambassador to England (1880–85). Few diplomats have had Lowell's personal success in creating international good will and understanding. In England he served as president of the Wordsworth society. succeeding Matthew Arnold, with whom he is often coinpared in his idealism and many-sided social criticism; he was popular as a speaker on many notable cultural occasions, and as president of the Birmingham and Midland institute in 1884 he delivered his remarkably wise and persuasive discourse on "Democracy;" centring on the elements common to the British and U.S. governmental traditions which he contrasted in the vein of Burke with the antitraditionalism of the French Revolution. His only difficulty during his responsibility in England was with a small number oi Irishmen in English prisons (during the Fenian turmoil) who tried to get Lowell to intercede on the pretense that they had been U.S. citizens. In the change of administrations Pres. Grover C. Cleveland appointed a successor and Lowell returned home in June 1885, his wife having died in February. He made four more summer visits to England. He died in the house of his birth in Cambridge, Mass., on Aug. 12, 1891.

Lowell's tolerant defense in reviews of such realists as W. D. Howells and Henry James (who wrote two eulogistic essays on him). his long succession of critical disciples such as Barrett Wendell. George Woodberry and Clarence Stedman, not to mention writers devoted to the use of the racy vernacular such as George Eggleston and J. C. Harris, attest to the vitality of his influence. Norman Foerster in 1928 concluded that in combining impressionism. historical understanding and judicial criticism. Lowell's literary creed "is the most representative of man's artistic experience through the ages yet attained in America."

Bibliography.—The most comprehensive collection of his works is the Elmwood edition of The *Complete Writings of James Russell Lowell,* 16 vol. (1904), ed. by C. E. Norton, including the *Letters* (3 vol.); *Lowell: Representative Selections* (1947) edited by H. H. Clark and N. Foerster, contains an extensive critically annotated bibliography of studies about Lowell, as well as a documented introduction of about 140 pages including Foerster's essay on his criticism. H. E. Scudder's *Lowell: 4 Biography* (1901) is supplemented by Leon Howard's *Victorian Knight-Errant* (1952), which covers the period up to 1855 arid makes use of fresh manuscript material and by R. C. Beatty's *James Russell Lowell* (1942) which reflects the southern attitude toward his political work. (H. H. Cl.)

LOWELL, PERCIVAL (1855–1916), U.S. astronomer and founder of the Lowell observatory, was born in Boston. Mass., on March 13, 1855. A member of a brilliant family, he graduated with honours at Harvard in 1876 and after a year of travel returned to Boston where he was active in business. From 1883 to 1893 his energies were chiefly devoted to literature and travel, much of the time in the far east, which he pictured in *Choson* (1885), *The Soul of the Far East* (1888), *Noto* (1891) and *Occult Japan* (1895).

During part of this period he was counselor and foreign secretary to the special mission from Korea t~ the United States. In the 1890s, inspired by Schiaparelli's discovery of the canals on Mars. he determined to devote his fortune and energy to a study of the planets and after careful scrutiny of desirable sites founded the great observatory which bears his name at Flagstaff. Ariz.

Lowell held the theory that intelligent inhabitants of dying Mars are struggling to keep alive by a planet-wide system of irrigation from the water of the melting polar snowcaps and that the canals are bands of cultivated vegetation dependent on such irrigation, Among his books on this subject, *Mars and Its Canals* (1906) is a good example. Early in the 20th century he made an elaborate mathematical study of the perturbations of Uranus which he attributed to the action of an unseen planet beyond Neptune (*Memoir on a Trans-Neptunian Planet,* 1915); and in 1905 he organized a systematic search for such a planet by the staff of his observatory. Fourteen years after his death. this search culminated successfully in the discovery of Pluto (1930). Although Lowell's Martian theory met with opposition, the value and sincerity of his work were recognized and he received numerous honours.

Lowell died at Flagstaff. Nov. 12, 1916.

See L. Leonard: *Percival Lowell* (1921); J. A. Paterson, "Percival Lowell—His Life and Work," *Journ. Roy. Ast. Soc. Canada,* vol. 16, pp. 230 ff. (1922); A. Lawrence Lowell, *Biography of Percival Lowell* (1935). (J. C. Dx.)

LOWELL, a city and one of two seats of Middlesex county (the other is Cambridge) in the northeast section of Massachusetts, U.S. 25 mi. N.W. of Boston and 7 mi. from the New Hampshire boundary, is on the Merrimack river at the mouth of the Concord river. It is a leading manufacturing city, one of the oldest in the United States, and is the centre of a standard metropolitan statistical area including Billerica, Dracut. Tyngsborough, Chelmsford and Tewksbury. Population (1960) of city 92,107; of standard metropolitan statistical area 157,982.

At the close of the 18th century there was only a small village at the juncture of the Merrimack and Concord rivers. A carding mill was built in 1801, and in 1801 the Middlesex canal was completed around Pawtucket falls. where the Merrimack drops 35 ft. Water power provided by these falls was an important factor in the city's location and industrial development. The town was incorporated in 1826 and named for Francis Cabot Lowell. regarded as the originator of American cotton manufacturing. In 1836 the town was chartered as a city. A city-manager form of local government was adopted in 1944. The canal system. important in the growth of Lowell, comprises about 15½ mi. of waterways, parts of which run at right angles to the rivers and divide the city into sections. The waterways, along with a network of highways, compose an interrelated transportation system for industry and commerce.

In the 19th century, large numbers of foreign workers were attracted by the textile industry which reached its peak in the early 1920s and decreased thereafter. Many mills had moved to the southern states by mid-20th century, causing a decline in population. However, new industries began to replace textiles and Lowell's economy became more diversified.

About 200 ac. were set aside as an industrial park under control of a commission, and new factories located there include electronics, plastics and light metals. Other manufacturing establishments produce a wide range of goods including chemicals, machine parts, electronic equipment, fabricated rubber, household tools, cloth and art supplies.

Lowell as an early 19th-century industrial city aroused the interest of Europeans and prompted many to journey across the Atlantic to visit and write of their impressions. Michel Chevalier, the French scholar, came in 1834. Two English observers, Charles Dickens and Anthony Trollope, followed a decade later. For a greater part of the 19th century Lowell was known as the "spindle city*' and the "Manchester of America." Although best known for its pioneering textile industries, Lowell is also famous as the birthplace of the American artist, James Abbott McNeill Whistler, whose house has been converted into a museum. The city has provided two governors for hlassachusetts — Benjamin F. Butler (1883–84). and Francis T. Greenhalge (1894–96).

Lowell has a state teachers college (1894), Lowell Technological institute (1895) which offers research facilities to local industry, a city hospital and two private hospitals, one of the largest city libraries in New England and a city memorial auditorium used for community cultural and civic assemblies. (L. G. H.)

LOWESTOFT, a municipal borough, seaport and holiday town in the Lowestoft parliamentary division of Suffolk, Eng., 44 mi. N.E. of Ipswich and 27 mi. S.E. of Norwich by road. Pop. (1951) 42,834. Area 7.5 sq.mi. In 1086 Lowestoft was a hamlet in the demesne of the royal manor of Lothingland. A weekly market on Jt'ednesdays was granted in 1308 to John, earl of Richmond, together with an eight days' fair. In 1442 William de la Pole. earl of Suffolk, received a further grant of the same market and also two yearly fairs. In 1643 Lowestoft supported the royalist cause but Cromwell carried. off the chief supporters. For several centuries Lowestoft was in dispute with Yarmouth over the herring fisheries until the matter was finally settled in the house of lords in 1662. In 166j the Dutch under Adm. Jacob Opdam were defeated off Lowestoft by the English fleet commanded by the duke of York. Lowestoft china. of soft-paste porcelain, specializing in table and tea wares often bearing Chinese patterns. was made in the town from 1757 to 1802. The old town stands on high ground to the north of the present harbour which was constructed by the Norwich and Lowestoft Navigation company in 1831 and considerably extended by Samuel Morton Peto in 1846. Following the improvement of the harbour and the opening of the railway link with Norwich and London in 1847 Lowestoft developed rapidly as a port and coastal resort. The population increased from 4.671 in 1831 to 21,905 in 188j when it was granted borough status. There are good sands as well as a fine esplanade and two piers; South pier has a pavilion. Oulton Broad within the borough boundary provides yachting, motorboating and a swimming pool.

The outer and inner harbours have quays for the herring and trawl industry which is fifth in importance in the United Kingdom. and for general trade. On the south bank of the inner harbour six construction slips for vessels up to 300 ft. in length were added to the shipbuilding facilities of the port in 1954–55. Canning and food preservation, television, marine radio, electrical apparatus, vehicles. boot and shoe manufacture are other industries.

LOWIE, ROBERT HARRY (1883–1957), U.S. anthropologist, a leading figure in the development of cultural anthropology, was born June 12, 1883, in Vienna, and was brought to New York at the age of ten. He graduated from the College of the City of New York at 18 and, while teaching elementary school for three years, studied under Franz Boas at Columbia, where he received his Ph.D. in anthropology in 1908. From then until 1921 he was affiliated with the American Museum of 'Natural History in New York and undertook many of his major field trips to the Plains tribes, *inter alia* to the northern Shoshone! Assiniboine, Blackfoot and Crow. From 1921 to 1950 he was professor of anthropology at the University of California in Berkeley, serving as chairman of the department for 14 years. His honours and duties included: editorship of the *American Anthropologist* (1924–33); presidency of the American Folklore society (1916–17), the American Ethnological society (1920–21) and the American Anthropological association (1935); election to the National Academy of Sciences (1931). Awards were the Viking medal (1947) and the Huxley medal (1948).

Lonie's most original ethnographic contributions are contained in about 18 monographs on American Indians. Of these his studies on the Crow Indians engaged his most enduring interest and became classic. Later in life he turned to South American ethnography and then to the German culture in which he had been steeped in his youth. Although strongly empiric by conviction, he made distinguished theoretical contributions to the fields of kinship and social organization and folklore and religion. In his younger years he had a strong philosophical bent and wrote widely for liberal, intellectual journals. He died on Sept. 21, 1957, in Berkeley, Calif.

His outstanding books are *Culture and Ethnology* (1917), *Primitive Society* (1920), *Primitive Religion* (1924), *Origins of the State* (1927), *Crow Indians* (1935), *The History of Ethnological Theory* (1937). *Social Organization* (1948), *Toward Understanding Germany* (1954), and, published posthumously (1959), *R. H. Lowie, Ethnologist: a Personal Record,* and *Selected Papers in Anthropology* edited by Cora Du Bois (1960).

See P. Radin. "R. H. Lowie," *American Anthropologist,* vol. 60, no. 2, p. 3j8 ff. (April 1958), with a complete bibliography. (C. D. B.)

LOWIN, JOHN (1576–1653), English actor and a colleague of Shakespeare, was baptized on Dec. 9, 1576; the son of a carpenter. A goldsmith's apprentice for eight years, he joined Worcester's men as an actor in 1602. By 1603 he was a member of the King's company. He is known to have specialized in the roles of comic soldiers as well as downright villains. He created Bosola in Webster's *The Duchess of Malfi.* Shakespeare is said to have coached him in the part of Henry VIII. Lowin was also remembered for his Falstaff and the Jonsonian parts of Morose *(Epicoene)*, Volpone and Mammon *(The Alchemistj.* After the death of John Heminges, Lowin became, with Joseph Taylor, co-manager of the King's company. As such he received payments for the company's appearances in court performances. He also acquired shares as a housekeeper in the Globe and Blackfriars theatres. At the outbreak of the Great Rebellion, after the theatres' closing, Lowin became an innkeeper at Brentford. He was buried on Aug. 24, 1653. (A. M. N.)

LOWNDES, THOMAS (1692–1748), founder of the Lowndean professorship of astronomy at Cambridge university, Eng., was born in 1692. In 1725 he was appointed provost marshal of South Carolina, a post he preferred to fill by deputy. In 1727 Lowndes claimed to have taken part in inducing the British government to purchase Carolina. but he surrendered his patent when the transfer of the colony to the crown was completed. His patent was renewed in 1730, but he resigned it in 1733. He then brought various impractical commercial and financial schemes before the government. He died on May 12, 1748. By his mill he left his inherited Cheshire properties to the University of Cambridge, to be used for the foundation of a chair of astronomy and geometry.

LOW SUNDAY, first Sunday after Easter. It is called in Latin *Dominica in albis (depositis)*, "Sunday in white garments (laid aside)," in allusion to the fact that those who were baptized on Easter have put aside their white robes.

LOW-TEMPERATURE PHYSICS (CRYOGENICS) is that branch of physics which is concerned with the measurement and the interpretation of natural phenomena at low temperatures. This definition cuts across the classification of physics according to the kind of system under investigation; *e.g.,* one speaks of low-temperature nuclear physics, low-temperature solid state physics, etc.

Strictly speaking any measurement below room temperature falls into one of these categories, but it has become customary to restrict the term low-temperature physics (often called cryogenics, although this word more correctly refers to the production of low temperatures) to physical research carried out at temperatures at or below the boiling point of oxygen; *i.e.,* at temperatures below about 90° K. (All temperatures in this article will be given on the absolute scale in degrees Kelvin (° K.). The reader is reminded that on this scale the absolute zero of temperature is at 0° K.. corresponding to −459.6° F., or −273.2" C. *(See* THERMOMETRY.)

Basic Phenomena. — The discovery of techniques for reaching and sustaining very low temperatures opened a new frontier in the study of matter.

Since heat is created by the random motion of molecules (see HEAT), the elimination of it involves bringing matter as close to a static and ordered condition as nature permits. In the close-to-absolute-zero state, the opportunity for new investigation is comparable to the one that was opened when the content of the bulb used in cathode-ray experiments was brought close to a perfect vacuum.

At extremely low temperatures, the electric, magnetic and thermal properties of most substances are found to be greatly altered. Among the phenomena sometimes encountered perhaps the most striking are superfluidity and superconductivity. Some metals, when cooled below a characteristic critical temperature, are perfect conductors of electricity; a current induced in them will continue indefinitely without being maintained. Liquid helium, below a certain temperature, can flow without apparent viscosity through channels a few millionths of an inch in width.

Energy Levels and Order. — Some basic theories commonly accepted up to the turn of the 20th century mere casualties of low-temperature physics. The most striking example is the classical law of P. Dulong and A. Petit, according to which the specific heat of solids should remain constant at all temperatures, It is indeed reasonably constant at high temperatures. However, it decreases with lowering temperature and finally vanishes in the limit of the absolute zero of temperature. The article QUANTUM MECHANICS describes this more fully and discusses how first A. Einstein and subsequently P. Debye drew up quantum models to explain this unexpected low-temperature behaviour.

These models, together with other valid theories of low-temperature phenomena, form part of the modern view that the microscopic components of any physical system can have only certain discrete amounts of energy; *i.e.*, they can occupy only certain definite energy levels. This means that at the absolute zero, where a system must necessarily contain the smallest possible amount of energy, its components must all either occupy the single lowest energy level available to them, or at least, if this is not permitted by the Pauli exclusion principle, they must occupy the fe est possible and lowest possible levels. In quantum mechanical terms, the degree of disorder of a system is related to the number of energy levels occupied by the system's components in excess of the allowed minimum. According to this, therefore, the absolute zero of temperature is the point at which a system achieves its state of highest order. This is equivalent to the statement of the third law of thermodynamics (*q.v.*) that the entropy of any system vanishes at absolute zero, since the entropy is a measure of the disorder of a system. The rise in temperature of a system above the absolute zero is equivalent to its gradual disordering as its microscopic components occupy an increasing number of energy levels above the lowest possible ones. The manner in which this occurs depends uniquely on the values of these energy levels, which in turn are determined by the detailed nature and behaviour of the individual components of the system in question. Thus the importance of cryogenic research arises from the fact that experimental observation of the low-temperature characteristics of a system furnishes vital clues to its spectrum of energy levels, an understanding of which necessarily forms part of a complete theoretical analysis of the system.

A system will become disordered when the thermal energy available to its components becomes comparable to the spacing between their energy levels. This thermal energy is equal to kT, where T is the absolute temperature and k, Boltzmann's constant, is about 10– [illegible] electron volt (ev) per degree. The spacing between the levels, however, depends, as was just mentioned, on the characteristics of the system and will thus be different for different systems. Thus what is a low temperature for one system may be a high temperature for another; *e.g.*, in the absence of an external magnetic field the spacing between the levels of a system of nuclear magnetic dipoles is of the order of 10^{-7} ev, that between the levels of a system of ionic magnetic dipoles at least 10^{-5} ev. As a result, the thermal energy available at about 0.01° K. (10^{-6} ev) is high enough to distribute nuclear dipoles almost equally among the available levels, but is barely sufficient to excite a few ionic dipoles. This means that for the former system 0.01° K. is a high temperature, while for the latter it is a low one.

Experimental **Details.**—When it is desired to measure the properties of a substance at a certain temperature it is necessary to place this substance in good thermal contact with a reservoir at the desired temperature. The simplest and most convenient kind of reservoir is of course a bath of liquid. and indeed low-temperature measurements are carried out as much as possible by this means, using the liquefied form of one of the substances listed in Table I.

TABLE I.—*The Substances Commonly Used as Liquid Baths in Low-Temperature Research*

In liquefaction, the cooling of the gas to its boiling point occurs by two methods, used singly or in combination. After a gas has been compressed isothermally, it can be cooled either by adiabatic expansion, in which the gas pushes against a piston while it is thermally isolated, or by Joule-Thomson (isenthalpic) expansion, in which the gas expands through a throttle valve into a low-pressure space. The amount of gas cooled a small amount by either of these processes then precools the next batch of incoming, compressed gas in a counterflow heat exchanger, so that the next expansion begins at a slightly lower temperature and cools a little further. This process is repeated until the boiling point is finally reached. A thermodynaiaic discussion of the two expansion processes can be found in THERMODYNAMICS; detailed descriptions of various liquefiers are given by J. G. Daunt and S. C. Collins in their contributions to vol. xiv of the Encyclopedia of **Physics** (see Bibliography).

For experimental purposes the liquid which has been obtained is transferred into a so-called Dewar vessel, a double-walled, silvered glass (or highly polished metal) flask, with an evacuated space between the walls, very similar except for size to the conventional Thermos bottle. Liquid air, oxygen, nitrogen and even hydrogen can be kept in such a vessel without further thermal protection for several hours; liquid helium has such a low specific heat that it can be kept for any length of time only if the Dewar flask is in turn surrounded by a similar, larger flask containing liquid nitrogen or air.

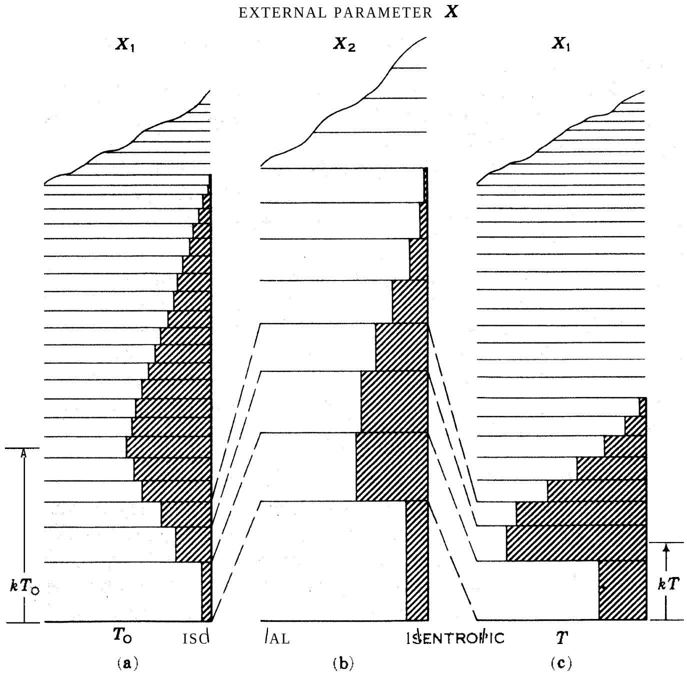
If provisions are made to seal the flask containing the liquid hermetically; *e.g.*, by means of a metal cap and neoprene O-ring gaskets, the pressure over the liquid can be reduced with large vacuum pumps, resulting in a decrease of the temperature of the liquid, down to the freezing point of all the substances listed in Table I except helium. Temperatures between the freezing point of one substance and the melting point of the next lower one can be obtained with apparatus in which the flow of heat in and out of the sample under investigation can be controlled and varied. Helium, as will be discussed in some detail in a later section of this article, does not freeze at all under any pressure less than about 25 atm., so that in principle the liquid could be pumped down to arbitrarily low temperatures. However, the vapour pressure of the liquid becomes so low at about 1" K. that this temperature represents approximately the lower limit which can be achieved by this means.

Thus it is seen that various liquids, under atmospheric or reduced pressure, provide readily available experimental tempera: tures down to about 1° K. Although the bulk of low-temperature research is being carried out in this range. tve have mentioned that for certain systems 1° K. is actually a rather high temperature, so that it is a matter of considerable physical interest to cool them further. In order to understand how this can be done it is well to return to the considerations of the state of order of a system.

The Principle of Cooling. — Consider an arbitrary system in equilibrium at some temperature T such that the thermal energy is large enough to excite most of the system's components into energy levels above the ground state. The distribution of the components among the different energy levels depends on the product of two factors, one the exponent of the ratio of the energy of a level to kT, the other an increasing function of this energy. This means that the level the energy of which is most nearly equal to kT will be most heavily populated, with a gradually lessening number of components occupying the levels of higher and lower energy on either side, as illustrated in fig. 1(A). If now there exists some external variable, such as the volume or the magnetic field, by means of which the spacing of the energy levels can be varied, then a change of this variable such as to increase the spacing of the levels will result in a redistribution of the components of the systems among fewer levels, as shown in fig. 1(B). Hence the order of the system has been increased. If this process has occurred while the system was in thermal equilibrium with some external bath at a fixed temperature, this means thermodynamically that the entropy of the system has been decreased isothermally. As discussed in THERMODYNAMICS, a system can change its entropy only by absorbing or releasing an amount of heat. Thus if the system is now isolated from its surroundings so that it cannot absorb any heat, and the external variable is then returned to its original value. the spacing of the energy levels is again what it was in fig. 1(A), but the entropy or the degree of order is still that in fig. 1(B), since the entropy has not changed in the second part of the process. Hence the system has been returned to the original external conditions with a lower degree of disorder, which means that the temperature of the system has been decreased.

This two-step operation is basic to all physical cooling processes. For a system consisting of a given number of gas molecules, the external parameter affecting the spacing of the energy levels is the volume in which the system is contained. Isothermal compression of the gas lowers its entropy, and its subsequent expansion to its original volume under conditions such that its entropy remains constant will leave the gas at a lower temperature than the initial one. For a variety of reasons, it is often both more convenient and more efficient to expand a gas under conditions such that its entropy changes by a small amount during the second step, as in Joule-Thomson expansion. However, the final state of the gas is always one of lower entropy than its initial value. In general, any cooling process involves the change of some external variable, first one way and then back to its original value, in such a way that the spacing of the energy levels is first increased and then returned to its initial configuration. All this is done so that the final degree of order of the system is higher, which corresponds to a lower temperature.

Adiabatic Demagnetization.— In the case of the isothermal compression and adiabatic expansion of a gas, the ordering of the molecules is due to their taking up increasingly regular positions and to the fact that there is less room for movement. But the disorder of microscopic particles can be due not only to their random location, but also to varying orientation of certain directional quantities, such as the electric or magnetic dipoles which may be associated with the particles. Consider, for example, a crystal of a paramagnetic salt in which associated with each molecule there is a magnetic dipole. Although the spatial disorder of the molecules has to all intents and purposes disappeared at 1° K., the orientation of the magnetic dipoles in the absence of an external magnetic field is still completely random. This is so because the spacing between the finite number of energy levels associated with the possible directions of the dipoles is so small compared with the thermal energy that all these levels are essentially equally populated. This situation, however, can be changed by applying an external magnetic field of 5–10,000 oersted, which will increase the spacing of the energy levels so much that most particles will occupy the lowest one. In terms of direction this simply means that the external magnetic field has aligned the majority of the magnetic dipoles parallel to itself. This corresponds to a high degree of order. If the salt is thermally isolated and the external field is then removed, the energy levels return to their original spacing without a change in the degree of order, which corresponds to a very low temperature for the system of dipoles. If good thermal contact exists between this and the salt as a whole, the salt will thus achieve a temperature which, depending on experimental details and the kind of paramagnetic salt used, can lie anywhere between 0.0015° and about 0.3° K. This method of cooling, called adiabatic demagnetization, was independently suggested by P. Debye and W. Giauque.



AFTER F SIMON ET AL., "LOW TEMPERATURE PHYSICS" (LONDON, 1952)

FIG. 1.—SCHEMATIC REPRESENTATION OF THE COOLING PROCESS.

The horizontal lines represent the values of the energy that the components of the system may have, the lowest line corresponding to the lowest allowed energy. The width of the shaded areas indicates the population of the energy levels. The external parameter X is changed from the value X_1 to X_2 isothermally, and back to the original value X isentropically, reducing the temperature from T_0 to T. The values of the corresponding thermal energies are shown by the length of the vertical arrows

Limits of Low-Temperature Research.—We have seen that any cooling process requires two things: some system which at the initial temperature is still in a high degree of disorder, and some external variable by means of which the spacing of the energy levels of that system can be increased. At the lowest temperatures reached by adiabatic demagnetization of a paramagnetic salt with its system of ionic magnetic dipoles, there is still the system of nuclear magnetic dipoles which even at 0.01° K. are quite randomly oriented. Furthermore, this system is affected in the same manner as the ionic dipole system by the application of an external magnetic field, so that in principle the adiabatic demagnetization of a system of nuclear dipoles can be used to achieve much lower temperatures, estimated to be of the order of 0.00001° K. or even lower. In spite of considerable technical difficulties much progress is being made in this field, especially as nuclei whose magnetic dipoles are ordered in this fashion can be used for much fundamental research; *e.g.,* research on the degree of symmetry of the physical universe.

Inevitably the question of even lower temperatures arises, and the answer is clearly that if at a temperature reached by nuclear demagnetization there is still some as yet unsuspected system with much disorder, *i.e.,* high entropy, and in addition if this system can be ordered by means of some external variable, then even lower temperatures could be achieved. The reason for trying to achieve them would be to discover this as yet unknown system, as it is always true that much can be found out about a system from studies of that range of temperature in which it changes from great disorder to a high degree of order. If, on the other hand. there is no system which is still disordered at nuclear demagnetization temperatures, then not only would it be impossible to achieve lower temperatures, but it would be quite pointless to try, as nothing further could be found out about any system or set of systems once a perfect degree of order had been achieved.

The Measurement of Temperature.— The thermometers used at low temperatures are in principle the same as those used in any other range: they contain or consist of some substance of which one readily measurable parameter varies with temperature in a systematic and reproducible fashion. At room temperature such a device is the mercury thermometer, in which the length of the column of mercury varies linearly with temperature. Thermometers used at lower temperatures include the liquid bath itself, with its temperature-dependent vapour pressure: an amount of gas kept either at constant volume or at constant pressure; and thermocouples, electrical resistors or a paramagnetic salt. The details of these devices, their accuracies and their limitations, are discussed in THERMOMETRY.

Each of these thermometers must of course initially be calibrated, which requires that for each range of temperature one must at one time or another determine the absolute temperature of some thermometric substance from first principles. Sometimes this can be done from a detailed understanding of the substance in question, from which one can then calculate the absolute temperature corresponding to any measured value of the temperature-dependent property. If such an understanding does not exist, it is necessary to invoke the fundamental thermodynamic definition of temperature, namely, that it is the ratio of the amount of heat put into a system at that temperature to the resulting change in the entropy of the system, and to determine the temperature by measuring these changes.

AREAS OF LOW-TEMPERATURE RESEARCH

As was indicated in the introductory paragraph of this article, low-temperature physics includes theoretical and experimental research on all natural phenomena at temperatures below about go° K. It therefore covers so many areas of investigation that it is impossible to give an adequate description of the entire field in this article. This is especially true as the relevance and importance of much low-temperature work can be understood only in terms of an over-all description of behaviour at all temperatures. The following, therefore, constitutes only a brief and inadequate summary of the principal areas of low-temperature physics. Technical but still general background information can be found in the reviews by D. K. C. MacDonald, P. G. Klemens, P. H. Keesom and J. van den Handel in the *Encyclopedia* of *Physics* (see *Bibliography)*, and these articles in turn contain the references needed for a thorough study.

Low-Temperature **Specific** Heats.— The specific heat of any substance is, by definition, the temperature times the derivative of entropy with respect to the temperature. For a single system, therefore, the specific heat will be appreciable only in that region of temperature in which the entropy changes; *i.e.*, in that range in which the system changes its degree of disorder. Most substances contain several such systems, and their specific heat is the sum of the specific heats of the individual systems. In order to separate the individual contributions it is necessary to extend specific-heat measurements to sufficiently low temperatures so that one or more of the systems reaches a state of order and thus an essentially vanishing specific heat. For example, the specific heat of a metallic conductor consists of two parts, one due to the metal lattice and one due to the conduction electrons. Although at normal temperatures the former is much larger than the latter, it becomes quite small at temperatures of the order of 10° K. This makes it possible to obtain the electronic specific heat of a metal.

Electronic Transport Phenomena.— In a metal at room temperature, the current and heat-carrying motion of the electrons is impeded by the vibration of the lattice even in a perfect crystal. As is indicated by the decrease of the lattice specific heat, the spacing of the vibrational energy levels of the lattice is such that at temperatures of the order of 10° K. a considerable degree of order is attained. At such low temperatures, therefore, the scattering of the electrons by the lattice is much decreased, and both the electric and thermal resistivities are due mostly to the presence of lattice imperfections, impurities and strains. Low-temperature measurements of these resistivities make possible the separate evaluation of these various contributions, and have shown the great effect which crystal defects have on the characteristics of a metal and, for that matter, of any solid. Such investigations, together with specific-heat measurements, are among the most important in the continuing attempt to reach a satisfactory understanding of the solid stale.

Magnetic Phenomena.— At various times in the preceding material we have spoken of systems of magnetic dipoles associated with microscopic particles. It is these which determine the magnetic behaviour of a substance. The low-temperature study of magnetism concentrates on two aspects of the characteristics of a magnetic dipole system. There are, in the first place, extensive investigations in which the direction of these dipoles becomes ordered when the thermal energy becomes small compared to the spacing of their directional energy levels. This spacing, in the absence of any external fields, depends on the strength and the kind of interaction of these dipoles with the electric and magnetic fields created by the surrounding microscopic particles. The determination of the temperature at which the system changes from complete disorder (even distribution of the dipoles over all available levels) to some degree of order (preferential occupation of a few of these levels) thus yields information about the strength of these interactions. Depending on the kind of interaction there are different ways in which this directional ordering can occur. In addition to the kind of ordering of the dipoles into a single direction which gives rise to ferromagnetism and occurs at the temperature called the Curie point, after its discoverer, the dipoles can line up in more complicated patterns to give rise to antiferromagnetism, as predicted by L. Neel, or ferrimagnetism, as discovered by J. L. Snoek, E. J. W. Verwey and others.
