PLANTS TO RAYMUND OF TRIPOLI

PLANTS AND PLANT SCIENCE. Living things (organisms) are commonly divided into two general groups—the animal kingdom and the plant kingdom. With higher organisms the difference between plants and animals is quite obvious: it is simple, indeed, to distinguish seaweed. ferns and trees from fish, birds and man However, in the case of the lower forms of life—bacteria, fungi, slime molds, protozoa. sponges—the distinction often is not so evident, and indeed, it is an artificial one since plants and animals probably had common ancestors in evolution (see ANIMAL).

The biologist recognizes no definite line separating animals and plants, or for that matter separating life and nonlife (see VIRUSES). But on the basis of certain fundamental differences in (1) mode of nutrition; (2) scheme of growth; (3) cell wall composition; and (4) locomotion, higher organisms may be placed in either the animal kingdom or in the plant kingdom.

1. Plants generally manufacture their own food, a process (see *Photosynthesis* below) directly associated with the presence in plant cells of tiny bodies or plastids containing chlorophyll, a vital green pigment. Animals, on the other hand, generally lack chlorophyll and are unable to manufacture their own food; they depend ultimately upon plants for food.

2. Embryonic tissues remain extremely active in plants and result in what is termed unlimited growth; as tissue dies it remains in place and the young, active tissue grows away from it Thus each apex of the root or shoot system consists of an aggregation of embryonic cells, an apical meristem, which persists throughout the life of the plant unless it changes into a reproductive cone or flower, or is destroyed by accident or disease; in some higher plants, especially treelike forms, lateral meristems (vascular and cork cambia) produce a growth in girth (see Tissues below). A mature animal, however. usually attains a maximum size and a characteristic form, that is, it has a limited growth pattern.

3. Almost all plants have cells whose walls contain cellulose and are, therefore, more or less rigid. Animal cells generally lack cellulose, and their cell walls are usually elastic.

4. Higher plants are anchored to the soil or to some other solid surface from which they cannot move by their own power. Most animals, on the other hand, are capable of considerable movement and make rather rapid changes to new locations when this is necessary.

Of course there exist plantlike animals such as the sessile marine corals, graptolites, anemones, sponges; and there exist also animallike plants such as bacteria, fungi and certain stages of algae and of higher plants. Nevertheless, when all characteristics are considered, it is relatively easy to determine whether an organism should be listed as a plant or as an animal. For the really difficult cases—slime molds, euglenoids, chlamydomonads, etc.—some biologists have advocated a separate kingdom, the protista (see PROTOZOA).

This article is divided into the following sections:

- B. Transpiration
  1. Physiology of Stomates
  2. Environmental Influences on Transpiration
  3. Significance of Transpiration
  4. Guttation
- C. Translocation of Water
  1. Mechanics of Water Movement
  2. Absorption of Water
- D. Metabolism
  1. Carbohydrate Metabolism
  2. Photosynthesis
  3. Fat Metabolism
  4. Mineral Metabolism
  5. Nitrogen Metabolism
- E. Translocation of Solutes
  1. Organic Solutes
  2. Mineral Salts
- F. Respiration
  1. Aerobic Respiration
  2. Fermentation
- G. Growth
  1. Hormones
  2. Factors Influencing Growth
- H. Plant Movements
  1. Tropisms
  2. Nastic Movements and Nutations
  3. Turgor Movements

V. Plant Ecology
- A. Environment and Species (Autecology)
  1. Habitat and Structure
  2. Plant Adjustments
- B. Regional Floras (Floristics)
  1. Pattern of Distribution
  2. Factors Influencing Distribution
- C. Ecological Plant Geography
  1. Major Communities (Biomes)
- D. Plant Sociology (Synecology)
  1. Community Structure and Evolution
  2. Changes in the Landscape (Physiographic Change)
  3. Soil Development
  4. Biological' Interaction
- E. Nonliving Factors of the Environment
  1. Ecological Measurement, or Habitat Analysis
  2. Limiting Factors
- F. Applied Plant Ecology

I. CLASSIFICATION OF PLANTS

A census of living things indicates that there exist today more than 300,000 species of plants and more than 1,000,000 species of animals. In the evolutionary sequence of the rise and fall of living things. many more have had their golden ages, and whole groups have either disappeared or exist today only as minor elements of the earth's flora and fauna. Knowledge of these relict or extinct groups of organisms is limited either to studies of the few representatives remaining or to the discovery of fossils.

Man has always been curious about his environment. History points to his efforts at identifying, naming and using the living things around him for his own ends. As man's knowledge grew, he has devised numerous systems of classification. The early systems for classifying plants are now little more than historically important (see BOTANY). With the general acceptance of the doctrine of evolution another point of view was added to the classification of organisms, namely, the understanding of relationships and origins of plants and plant groups as well as animals and animal groups. Clearly the evolutionary system is a natural system in that it occurred in nature over geological time; it contrasts with the artificial systems set up for identifications only.

Man, appearing late in the evolutionary system, has had to rebuild the natural system for himself from available evidence. Certainly an understanding of this system has become a major end of classification for both plants and animals. Here the accumulative evidence from comparative morphology and comparative anatomy; the contributions from embryology; the findings from paleobotany; the results from experimental studies in genetics, cytogenetics and morphogenesis; and the more recent additions from comparative physiology and biochemistry have helped clarify the issues and have pointed up the problems inherent in any attempt to duplicate the natural system. As a result certain areas of evolutionary relationship are now established. Many areas, however, remain conjectural and controversial. The present objective of investigators in diverse fields of botany is to narrow down or fill in these controversial gaps of knowledge.

Efforts at artificial classifications of plants need not concern us in detail here except insofar as terms employed in them have been carried over into present usage. The major divisions of the plant kingdom in the artificial system set up by Linnaeus (1754) were Cryptogamia and Phanerogamia, terms derived from the Greek meaning hidden marriage and visible marriage.

The phanerogams include what we know as flowering plants, or, as conceived then, seed plants. These have seemingly visible sexual organs in the flower. The cryptogams encompassed the nonflowering plants with inconspicuous sexual cells. It is now known that the plants in each group were misunderstood by Linnaeus and his followers. Actually the cryptogams, though their sexual cells are not advertised by showy flowers and are therefore not immediately evident, have the more obvious sexual reproduction on closer examination; the phanerogams, with their flowers making known the presence of sexual cells within, do by this device conceal them, rendering it difficult to detect and understand the details of sexual reproduction. Even though the Linnaean system has been superseded, the term phanerogam is still sometimes employed to cover all plants which reproduce by seeds, and cryptogam is frequently used for those that do not. The term vascular cryptogam is often used in current writings to indicate those vascular plants that do not bear seeds: the spore-producing clubmosses, horsetails and ferns.

After the artificial system of Linnaeus, classification turned in the direction of a natural system, one such system being that largely attributed to Eichler (1886). Under this system, the plant kingdom was considered to consist of four divisions:

1. Thallophyta, the algae and fungi.
2. Bryophyta, the liverworts and mosses.
3. Pteriodophyta, the clubmossrs, horsetails and ferns.
4. Spermatophyta, the seed plants (gymnosperms and angiosperms).

Until recently, the Eichler system had persisted generally; at the present time, however, it is largely replaced by a more natural arrangement (see the outline below). The tremendous strides made during the first half of the 20th century in paleobotanical investigations of Devonian and even Silurian fossils have produced a picture of an early, apparently world-wide flora of vascular plants with considerable diversification. While their beginnings are not clear, the different phyletic lines (lines of descent) already established in this flora by the mid-Devonian must have originated at a much earlier geological period.

Available evidence supports the premise of an origin for vascular plants from the green algae (Chlorophyta), but whether they descended from one line of green algae (monophyletic) or from more than one line (polyphyletic) is not clear. In the face of this irresolution, it has seemed wise for the present to hold to the conservative premise of a monophyletic origin for vascular plants. Pending further information, the phylum, or division, Tracheophyta is maintained for all vascular plants, and supersedes the divisions Pteridophyta and Spermatophyta of the Eichler system. This classification of the vascular plants, foretold by E. C. Jeffrey (1899–1910), took firmer form during the period 1917–1930; since 1930 it has slowly replaced the Eichler system.

With regard to Eichler's Thallophyta, students of algae (algologists) and of fungi (mycologists) have demonstrated it to be a cover-all group, including numerous phyletic lines. The number of these lines in the algae is generally agreed upon. By contrast, in the Eumycota, or true fungi, current opinion tends to favour a single origin directly from colourless flagellate organisms rather than multiple origins from algal groups, as advocated earlier.

Another body of opinion deserves mention: that both algae and fungi descended from colourless flagellate ancestors termed Protista initially by Haeckel in 1866. The term has been extended by adherents of this thesis beyond the limits set up by Haeckel until it includes all flagellated groups and their presumed early evolutionary progenitors. Therefore the Protista is presently conceived of as the first kingdom, ancestral to all living beings.

An increasing tendency among mycologists to question the grouping of the fungi with green plants must be considered.

These students, who doubt that fungi and green plants were ever related, conclude that fungi may well have arisen directly from the colourless Protista. The whole outlook of these mycologists depends upon an ecological and physiological approach; they base the classification of living beings upon nutritional modes of life. By this viewpoint the Protista are considered as having given origin to (1) a producing group of organisms that live by manufacturing their own food through photosynthesis — the plant kingdom; (2) an ingesting group that live by devouring organisms — the animal kingdom; and (3) an absorbing group that live by absorbing nourishment from either living or dead organisms — the fungal kingdom (R. H. Whittaker, 1959).

The place of the bacteria is as yet unresolved. It may be within the fungal groups or, in close alliance with the blue-green algae, either in the Protista or in a separate phyletic line from the supposed colourless flagellated ancestors. Preponderant opinion among bacteriologists separates the bacteria from the fungi.

The outline provided below attempts to produce an approach to the natural system of classification of plants; certain portions appear sound from the available facts and other portions are tentatively set forth as reasonable evaluations of data in hand. Since each scheme results from the interpretations of evidence by one man, or at most a few men, differences of opinion are to be expected. It is even more to be expected that the system of classification as set forth in this article will be changed as more information becomes available. The present offering is conservative and, with only minor variations, currently in wide use.

KINGDOM PLANTAE

Current System — Phylum or Division | Eichler System — Class | Phylum or Division

1. Chlorophyta* -- green algae
   Chlamydomonas, Oedagonium, Ulva, Spirogyra, etc.
2. Euglenophyta — euglenoid algae
   Euglena, etc.
3. Chrysophyta — yellow-green algae, golden-brown algae and diatoms
   Tribonema, Dinobryon, Navicula, etc.
4. Pyrrhophyta — dinoflagellates, desmokonts
   Peridinium, Ceratium, etc.
5. Phaeophyta — brown algae
   Ectocarpus, Lanzinaria, Fucus, etc.
6. Cyanophyta — blue-green algae
   Anacystis (= *Chroococcus*), *Oscillatoria, Nostoc,* etc.
7. Rhodophyta — red algae
   Nemalion, Polysiphonia, Corallina, etc

Algae

8. Schizomycota — bacteria†
   Streptococcus, Bacillus, Spirillum, etc.
9. Myxomycota — slime molds
   Physarum, Stemonitis, Dictyostelium, etc.
10. Eumycota — true fungi
    Class Phycomycetes — algal fungi
    Mucor, Pythium, Phytophora, etc.
    Class Ascomycetes — sac fungi
    Saccharomyces, Aspergillus, Neurospora, etc.
    Class Basidiomycetes — club fungi
    Puccinia, Amanita, Polyporus, etc.
    Fungi Imperfecti

Fungi

Thallophyta

11. Bryophyta
    Class Hepaticae — true liverworts
    Class Anthocerotae — horned liverworts
    Class Musci — mosses

Bryophyta

12. Tracheophyta
    Class Psilopsida
    Order Psilophytales
    Psilophyton, Rhynia, Asteroxylon, etc.
    Order Psilotales
    Psilotum and *Tmesipteris*
    Class Lycopsida
    Order Lycopodiales — club mosses
    Lycopodium and *Phylloglossum*
    Order Selaginellales — little club mosses
    Selaginella
    Order Lepidodendrales — tree club mosses
    Lepidodendron, Sigillaria, Bothrodendron, etc.
    Order Pleuromeiales
    Pleuromeia
    Order Isoetales — quillworts
    Isoetes
    Class Sphenopsida
    Order Hyeniales
    Hyenia, Calamophyton, etc.
    Order Sphenophyllales
    Sphenophyllum, etc.
    Order Equisetales — horsetails
    Equisetum, Calamites, etc.
    Class Pteropsida
    Subclass Filicinidae — ferns
    Order Coenopteridales — early fossil ferns
    Botryopteris, etc.
    Order Marattiales
    Marattia, Danaea, Angiopteris, etc.
    Order Ophioglossales
    Ophioglossum, Botrychium, Helminthostachys
    Order Filicales — "true" ferns
    Osmunda, Gleichenia, Dryopteris, Pteris, etc.

Pteridophyta (Continued)

    Subclass Gymnospermidae — gymnosperms
    Order Cycadofilicales — pteridosperms, or seed ferns
    Order Bennettitales — fossil cycads
    Williamsoniella, Wielandiella, Cycadeoidea, etc.
    Order Cycadales — cycads
    Cycas, Zamia, Dioon, Bowenia, etc.
    Order Ginkgoales — ginkgo, maidenhair tree
    Ginkgo
    Order Cordaitales
    Cordaites, etc.
    Order Voltziales — early fossil conifers
    Lebarhia, Walchia, Pseudovoltzia, etc.
    Order Coniferales — conifers
    Pinus, Sequoia, Taxodium, Thuja, Araucaria, etc.
    Order Gnetales‡
    Ephedra, Welwitschia and Gnetum

Gymnospermae

    Subclass Angiospermidae
    Dicotyledones — 44 orders, with over 250 families §
    Ranunculus, Quercus, Rosa, Malus, Taraxacum, etc.
    Monocotyledones — 11 orders, with 45 families §
    Triticum, Avena, Lilium, Musa, Cocos, etc.

Angiospermae

Spermatophyta

II. MORPHOLOGY OF PLANTS

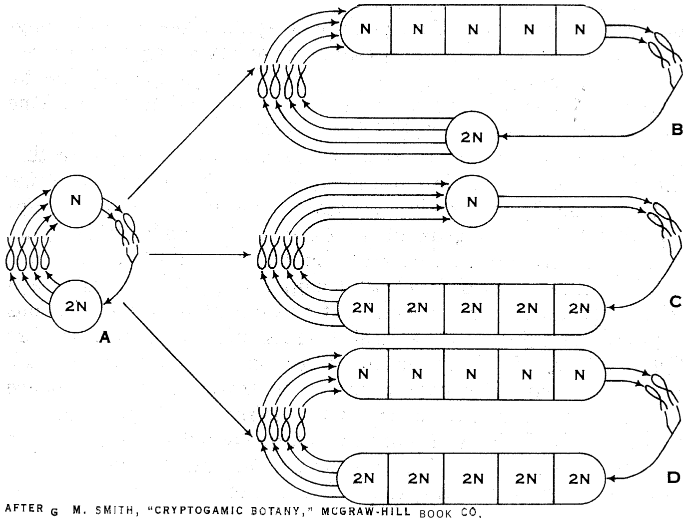
Plant morphology is concerned with the form and structure of plants and of their parts, and with the relation of parts to one another and to the whole, Morphology is thus fundamentally descriptive. A morphological study may be merely the determination of the facts of the history of an organism through all stages of development and reproduction; that is, it may be a purely descriptive life history study. As commonly understood, however, morphology has a broader basis: its object is to trace the underlying similarities in form between various plant groups; it is comparative in its nature, and its comparisons are considered in the light of evolutionary modification and development. Morphology thus conceived aids in the establishment of a natural classification of plants and in the reconstruction of their evolutionary history (phylogeny).

The methods used in morphological studies are: (1) comparison of adult forms of living plants; (2) comparison of living plants with fossils of ancient extinct forms (paleobotany) ; (3) observations on development of the individual (ontogeny). Morphology is generally subdivided into external morphology which deals with the external form, and anatomy, the study of the external and internal structure of plants. Cytology, study of the cell. arose as a subdivision of morphology concerned nith internal structure, but it has become an independent branch of biological science. A morphological study may assume a somewhat specialized aspect. Thus it may deal with the early development of an individual (embryogeny) ; with the causes that determine form and structure (morphogenesis); or with plant parts considered as organs carrying out certain distinct functions (organography).

1. Alternation of Generations. — The phenomenon of alternation of generations is so prominent and important a feature of the morphology of plants that for many years it has been one of the main objects of morphological studies. The term alternation of generations is used to designate the occurrence of two distinct phases in the life history of the plant, each of which produces the other. One is the sexual phase, the gametophyte, that bears male and female organs (gametangia) and gametes (sperms and eggs) and in which fertilization (syngamy) is effected The fertilized egg (zygote) develops into a nonsexual phase. the sporophyte. which produces a large number of single-celled spores. The latter develop directly into new gametophytes. The two phases of the life cycle are commonly referred to as generations. though actually they are two phases of one generation if the latter concept is used in the same sense as in zoology.

At fertilization the number of chromosomes is doubled through the union of two gametes. At some other point of the life cycle this number is again halved through reduction divisions (meiosis) (see FERTILIZATION; CYTOLOGY). The phase of the life cycle in which all cells have a double complement of chromosomes (diploid) and which begins with the fertilization and ends nith the reduction divisions is the sporophyte. The phase characterized by a single complement of chromosomes (haploid), from reduction division to fertilization, is the gametophyte. The character and relative extent of these two phases differ considerably in different groups and show great variability in the lower plants. .In many of the thallophytes (algae and fungi) almost the entire life cycle is gametophyte, since the first divisions of the zygote are meiotic; in others it is almost all sporophyte. Still others show varying degrees of relative development of these two phases, and often both are vegetative plants entirely similar in everything except the method of reproduction.

The diagrams give examples of different types of life cycles. The simplest possible life cycle occurs in the unicellular green alga *Chlamydomonas* (phylum Chlorophyta). It consists of an alternation of a one-celled haploid phase with a one-celled diploid phase (fig. 1[A]). In the somewhat higher Chlorophyta vegetative cell divisions occur in one or the other or in both phases. In the haplont type, as seen in the green algae *Spirogyra* and



AFTER G. M. SMITH, "CRYPTOGAMIC BOTANY," MCGRAW-HILL BOOK CO.

FIG. 1.—VARIOUS TYPES OF LIFE CYCLE AMONG THE CHLOROPHYCEAE (GREEN ALGAE)

(A) chlamydomonad; (B) haplontic; (C) diplontic; (D) diplohaplontic

Oedogonium, a multicellular haploid phase alternates with a unicellular diploid one (fig. 1[B]). In the diplonts, the green alga *Codium,* the life cycle consists of an alternation of a diploid coenocyte (the morphological equivalent of a multicellular diploid generation) with a unicellular haploid phase (fig. 1[C]). Certain other green algae, *e.g., Ulva,* are diplohaplonts and have an alternation of a many-celled haploid generation with a many-celled diploid generation (fig. 1[D] j (see also ALGAE).

The gametophyte is the dominant phase or "the plant" of the mosses (Bryophyta), whereas the sporophyte is merely a spore-bearing structure that develops from the zygote and remains attached to the gametophyte (fig. 2). In contrast. the vascular plants (Tracheophyta) have a large and conspicuous sporophyte with roots, stems and leaves and predominates in the life history. The fern sporophyte bears the spores on the backs of its leaves. Each spore may develop into a small but independent generation, the gametophyte or prothallus. on which the sex organs are borne (fig. 3). In the conifers and their allies (gymnosperms) and in the flowering plants (angiosperms) the gametophyte generation is extremely reduced. The spore (megaspore) producing the female gametophyte (megagametophyte) remains attached to the sporophyte after germination. Other spores (microspores) germinate to form the male gametophytes (pollen grains), which are liberated and carried (by wind, rain or insects) to or near an ovule containing the female gametophyte. One of the two male gametes (sperms) produced by the male gametophyte fertilizes the egg. The zygote grows at once into the embryo (fig. 4).

Two theories have long existed concerning the nature and origin of the sporophyte of vascular plants: the antithetic theory and the homologous theory. The first assumes that the two phases are essentially distinct, that the sporophyte is a new phase introduced into the life cycle of vascular plants in relation to life in air. It is supposed to have evolved from the zygote of an ancestral algal form through a stage in which it was merely a spore-bearing structure wholly dependent upon the gametophyte.

According to the homologous theory (which is supported by modern morphological and paleobotanical studies), the sporophyte and gametophyte are fundamentally alike in nature; they are correlative phases in the life cycle of plants that have arisen by modification of an original single sexual phase. In several interpretations the homologous theory places the differentiation of the gametophyte and sporophyte in ancient algal stocks and assumes the origin of land-living independent sporophytes directly from independent aquatic sporophytes.

2. Plant Body.—In the simplest plants the body consists of a single cell nithin which all life activities are carried on. According to the evolutionary concept, the simple cells united into colonies forming at first a loose, later a more intimate. union. until a multicellular plant arose. With the advent of "division of labour" between the different parts of the multicellular body, a morphologic differentiation of these subdivisions occurred, so that a very complex plant body appears in the higher plant groups. In the lowest plants any part may perform all functions. whereas in the highest the various functions have organs devoted to their performance, and in these the cells are grouped in definite and very specialized tissues. The lower plants (Thallophyta) show various degrees of complexity of form and structure. Certain groups of red and brown algae somewhat resemble the higher plants in the formation and arrangement of the members of their bodies. The progressive differentiation of the thallus of the liverworts and mosses (Bryophyta) presents an even closer parallel to the organization of the higher plants. Some of these have stemlike and leaflike body parts resembling organs of the most highly organized plants. True roots, stems and leaves, honever, do not occur in either thallophytes or bryophytes. These are characteristic organs of the vascular plants (Tracheophyta). According to a modern concept, these organs evolved with the invasion of the dry land by plants that formerly inhabited only the sea.

The nature of the plant body and its parts in vascular plants has long been a basic morphological problem. As was shown in the preceding section, it is the body of the sporophyte that is so complex in the higher plants. The gametophyte is extremely simple. In early days of morphological study the sporophyte body was looked upon as constituted of organs that were of different fundamental nature The number of these organs was at first large; for example, stem, root, leaf, ovule, sporangium. sporangiophore, emergence, hair. With the development of the concept of homologies, the interrelation of parts of a plant body began to be recognized. Comparative and developmental studies suggested that differently appearing parts may bear the same relation to the whole plant body, that. in other words, they may be homologous. For example, the floner appeared homologous with the shoot. the floral members with leaves. In contrast, if parts differ in their relation to the whole, but are similar in function and structure. they are analogous. Thus the flattened green stems of many plants of dry habitats are analogous with leaves. With increase in comprehension of the relationship between parts. the units of structure became reduced to three: stem. leaf and root.

The later discoveries of early land plants and studies in development have indicated that even these three categories of parts are not absolute, but are results of evolutionary development and cannot be clearly separated morphologically. The general nature of the plant body seems to be that of an axis. Under this interpretation there are no fundamental parts Roots and leaves, as elaborated organs. are secondary structures that differentiated on an originally primitive axis. The leaf may have arisen in two ways: (1) as a lateral emergence of the axis; and (2) as a branch system that became flattened and expanded. nith a webbing of tissue uniting the branches into one. The view upon the relation of the angiospermous flower to the other plant parts is also in a state of flux. The concept of the flower as a modified shoot. and particularly that of the homology between the leaf and the carpel, is being contested. The complex problem of the nature of the plant organs is still anaiting its final clarification. A judicial use of data on ontogeny. vascular anatomy. paleobotany and comparative morphology should eventually bring about such clarification. See ROOT; LEAF; STEM; FLOWER.

III. ANATOMY OF PLANTS

Anatomy deals with structure, gross and minute. external and internal. A special field of anatomy is histology, nhich is concerned nith the minute structure of organisms. If an anatomical study deals nith the structure of cells. particularly nith the protoplast, it enters the field of cytology. Thus anatomy merges with cytology and only an arbitrary limit may be set up between the two.

A. MINUTE STRUCTURE

1. The Cell.—An account of the anatomy of plants naturally begins nith the cell. which is the smallest physiological unit of organisms The cell is essentially an integral mass of protoplasm, of small dimensions and containing many specialized structures, chief among which is the nucleus. Other protoplasmic bodies. knonn as plastids. and inanimate matter. are present. The different living bodies and nonliving inclusions are dispersed within the more or less fluid living substance called cytoplasm. Among the nonliving inclusions are starch grains, crystals of various shapes and compositions, oil globules, tannins and food masses of different sorts. Much of the inanimate matter occurs in a n atery solution forming the cell sap. All cells that are permanent tissue

elements of the plant body possess a more or less rigid limiting membrane or cell wall, consisting primarily of cellulose or some allied substance excreted by the living cell body. As mentioned above, the presence of plastids in the protoplasm and the existence of the cell wall are the two main characteristics that differentiate plant cells from those of animals.

The walls of adjacent cells are cemented together so that the cells are united into more or less coherent masses or tissues. Upon the characters of constitution, thickness and sculpture of the cell walls, the qualities of a plant tissue largely depend. The life of all the cells in a plant body may be prolonged, or a number of the cells may die and their protoplasm be removed. Thus a tissue may consist of living cells combined with an inanimate framework of cell walls, enclosing in their cavities solely liquids and gases. In such cases the characters of the adult tissue largely depend on the proportion and distribution, the size, form and contents of the living and dead units, and on the nature of their walls.

In all but the simplest forms the plant body is composed of cells associated in more or less definite ways. In the higher or more complicated plants the cells differ greatly among themselves so that the adult body is composed of definite systems of units, the tissue systems. Each system has its own characteristic structure, depending partly on the characters of the component cells and partly on the method of association.

For a detailed consideration of the structure and development of the plant cell with regard to the protoplasm and the nucleus, see **CYTOLOGY**.

Plastids.—The plastids are portions of the protoplasm that have become specialized for the performance of certain functions. They are readily distinguished in the adult cell by their size and definite form, and they are often conspicuously coloured. Leucoplasts are colourless and occur in the cells of the deeper lying tissues where light cannot penetrate—if exposed to light they often become green. They are frequently concerned with the formation of starch grains. Chromoplasts are colour-carrying bodies giving red and yellow colours to the petals of flowers, ripe fruits, etc.; they contain yellow and red pigments such as xanthophyll and carotin. The most important of all the plastids, however, are the green chloroplasts. These contain chlorophyll and are of universal occurrence throughout the plant kingdom with the exception of the important groups of fungi and bacteria. By means of this pigment the plastids are enabled in the presence of light to form carbohydrates from water and carbon dioxide. The chloroplasts are extremely variable in shape, particularly in the algae. In the higher plants the chloroplast is disc-shaped and, according to the prevalent view, consists of a mass of somewhat dense colourless cytoplasm, the stroma, and of granules containing chlorophyll. Chloroplasts frequently contain starch grains.

The differentiated plastids seen in mature tissues may be traced back to plastid primordia, or proplastids, in the youngest tissues (meristems) or embryo. The proplastids appear in the cytoplasm of the young cells as minute bodies grading off to the limit of visibility. At all stages of development from proplastids, and at maturity, the plastids may divide by simple constriction. These divisions are sufficiently numerous to account for the large numbers of plastids in mature cells. It has not been disproved, however, that plastids arise also anew (de novo) in the cytoplasm. The problem of individuality of the plastid is mainly one of determining whether they are continuous or not through the critical stages in the life cycle, the gametes and spores. They have been shown to be present in the gametes and spores of some plants and are, in these instances, apparently passed on'from one generation to another.

Mitochondria.—In addition to the plastids there are other bodies in the cytoplasm which are very minute and appear as tiny granules, rods or threads and whose nature and function are not well understood. They are called chondriosomes or mitochondria. According to one opinion. mitochondria are the bodies from which plastids develop; according to another, the proplastids and mitochondria are distinct structures. Mitochondria are thought to be concerned with respiration and accumulation of certain substances.

Cell Sap.—All living cells in plants contain variable amounts of nonliving materials that are collectively designated as inclusions or ergastic substances. They include storage products, waste material, or by-products of protoplasmic activity. One of the commonest examples of ergastic substances is the cell sap, which occurs nithin cavities or vacuoles of the cell. One or more vacuoles may be present in a cell, their number and shape varying from time to time in the same cell. The total vacuolar system of a cell or other protoplasmic mass, whether this system consists of one or more vacuoles, is called the vacuome. The cell sap is water in which are dissolved substances of various kinds, some being food materials, others products of the metabolism of the protoplasm. Its composition is constantly changing, but among the substances of constant occurrence are inorganic salts, carbohydrates such as the sugars and soluble nitrogenous compounds.

Vacuoles appear to be universally present in living plant cells. In the youngest or meristematic cells, which by continual division form the tissues and organs of the plant body, the vacuoles are rather numerous, small, spherical or drawn out into other shapes by the streaming cytoplasm in which they are dispersed. As the meristematic cells multiply, the vacuoles are distributed. with or without division, to the daughter cells. During the enlargement and maturation of the cell the vacuoles increase in size and eventually coalesce to form one large central vacuole, and the cytoplasm thus becomes displaced to a comparatively thin layer closely applied to the cell wall.

Cell Wall.—The cell wall in young, active cells (meristematic cells) is thin and extremely delicate; however, upon completion of the growth of the cell, the cell wall becomes thicker and may undergo considerable modification. It is commonly regarded as a secretion of the protoplasm and is, in living cells, in intimate relation with the protoplasm which may interpenetrate the particles of its substance. This close relation can be readily appreciated when the process by which the wall is first laid down is considered From the beginning of the plant's existence as a single cell, all new cell formation consists in the division of a pre-existing cell into two halves by the formation of a dividing wall. In this process the cytoplasmic spindle, which functioned in the preceding nuclear division (see CYTOLOGY), plays an important part. The new wall begins with the appearance of a cell plate dividing the spindle in two halves. If the spindle does not reach to the side walls of the dividing cell, new fibres arise on its periphery and extend the cell plate to the side walls. The cell plate is a fluid layer appearing first as minute droplets that unite to form a continuous layer. Some interpret these small units as droplets of pectic substances. The fluid cell plate apparently soon solidifies and becomes part of the wall. The two daughter protoplasts that resulted from the division of the original cell secrete additional wall substances. These are deposited among the existing particles (intussusception) and also over the inner surface of the new wall (apposition). The amount of wall material deposited varies in different kinds of cells. One extreme is cells with walls that are a little thicker than those of the meristematic cells from which they arose; the other, cells nhose interior spaces (lumina) are almost filled nith wall material.

Commonly the wall does not appear homogeneous, but shows layering. The layers may differ in origin, in appearance when viewed in polarized light. and in chemical and physical structure. Three main types of layers exist: intercellular substance, prrmary wall and secondary wall. The intercellular substance is composed of pectic substances and is isotropic (i e., dark or nonrefringent when viewed under polarized light). This substance acts as a cementing material binding together the walls of adjacent cells. Some regard it as being derived from the cell plate formed during cell division.

The primary wall consists largely of cellulose and pectic substances and is anisotropic (i e., bright or refringent when viewed under polarized light). It occurs next to the intercellular substance. Many thin-walled tissues contain only primary malls. In other tissues, however, these primary walls may be comparatively thick. They are formed while the cell is still enlarging during differentiation from a meristematic cell.

The secondary wall is extremely complex, physically and chemically, and strongly anisotropic Cellulose is its basic component and it is formed after the cell attains its final size and shape. The secondary wall of plant cells is rarely continuous over the entire surface of the underlying primary wall It may develop as separate rings. spirals, bars. or as complex network or mesh; or it may cover most of the primary wall except for small interruptions or cavities called pits (fig. 5). All three uall layers may become modified by impregnation with a variety of inorganic and organic substances, notably lignin, which renders the walls firm and hard.

The anisotropy of the primary and secondary walls indicates that they are crystalline in nature. The crystalline properties are imparted to the wall by cellulose, a carbohydrate with the general formula $(C_6H_{10}O_5)n$. The units $C_6H_{10}O_5$ (anhydrous glucose residues) are combined into long chains—the cellulose molecules.

These chain molecules occur in bundles, the microfibrils, in parts of which the molecules are arranged parallel to one another with characteristic spacings betneen the chains. The molecules and their aggregations are too small to be seen through a light microscope and are studied by the use of X-rays, polarized light and electron microscope.

The microfibrils appear to overlap each other and form a coherent system perforated by a continuous system of spaces. Within these spaces substances other than cellulose (e g , lignin, fatty substances, water) are deposited. As seen through the light microscope the cellulose wall also appears as a continuous system of fibrils, the macrofibrils, interpenetrated by a system of porosities. The macrofibrils are aggregations of submicroscopic microfibrils.

Many conspicuous differences in the optical and mechanical properties of cell walls are correlated with variations in the orientation of the microfibrils. If the microfibrils are oriented parallel to the long axis of the cell, the wall or layer in which they occur does not contract longitudinally in drying. The opposite is true if the walls have transversally oriented microfibrils. Various intermediate conditions occur in walls whose microfibrils are oriented in a spiral in relation to the long axis of the cell. To further complicate the system microfibrils may be differently oriented in

FIG. 4.—LIFE CYCLE OF WHEAT (TRITICUM)

the various wall layers of the same cell.

Plasmodesmata.—The living cell in a complex multicellular plant body is not a completely independent unit, and its functions are conditioned by, and related to, the activities of the organism as a whole. This must involve a close connection between the living protoplasm of neighbouring cells, and this is effected by delicate connecting strands, the plasmodesmata. which traverse the walls. The connecting strands may be scattered singly throughout a wall or may be aggregated in thinner places of the wall, the pit areas. Plasmodesmata may represent the persistence of the original continuity of the protoplasm of two sister cells, but also are established after growth is completed. These delicate connections seem to occur universally in the higher plants. They play a part in the correlation of the functions of the cells and may also provide the means by which stimuli can be conveyed through long tracts of tissue.

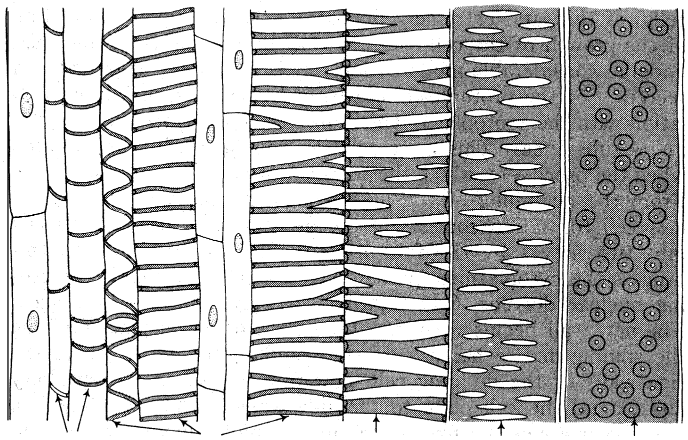
2. Cell Types **and** Tissues.—As plants increased in complexity the component cells also came to differ greatly among themselves. Plant cells may vary in size, shape, contents and wall structure. and may be highly specialized with regard to function.

Parenchyma. — Parenchyma cells are commonly more or less isodiametric in form, have thin walls and active protoplasts. A certain degree of variation in characteristics occurs with relation to the functions performed by parenchyma. Thus the parenchyma cells of the photosynthetic tissue of a leaf are rich in chloroplasts and may be considerably elongated or lobed; the parenchyma cell of a potato tuber contains leucoplasts that store starch; the parenchyma cells within the water-conducting tissue (xylem) may have thick secondary walls. The retention at maturity of living protoplasts is one of the most important characteristics of parenchyma cells. These cells are regarded as the least differentiated, the least specialized, and they make up the entire plant bodies of most of the Thallophyta (algae and fungi).

Collenchyma.—Collenchyma cells occur in layers or strands in the subsurface region of many stems. petioles and ribs of leaves where they serve as a supporting tissue. Like the parenchyma, this tissue retains living protoplasts at maturity. The shape of the cell varies from nearly isodiametric to a very much elongated (prosenchymatous). The principal characteristic is the thick cellulose wall, the thickening being irregular and massive. The thickenings occur in strips along most walls, or the tangential walls or only in the corners. The walls are very strong but plastic, and do not hinder the elongation of the growing organs in which collenchyma is the chief supporting tissue.

Sclerenchyma.—Sclereids and fibres are often treated as elements of one type of tissue called sclerenchyma (mechanical or supporting tissue), because both have thick walls, lack protoplasts and serve for support. Sclereids show similar variations in shape as the parenchyma cells but have very thick lignified walls with tubular pits. The protoplasts are usually lacking at maturity. One of the best-known examples of a sclereid is the stone cell that is a common component of the flesh of the pear fruit. The hard shell of the walnut is made up largely of sclereids. Fibres are elongated cells, sometimes very much so, with thick pitted secondary walls which may be of cellulose or lignified cellulose. The protoplasts usually die when the cells mature. The two main groups of fibres are those that occur in the wood tissue, the xylem fibres, and those located in various parts of the plant outside the xylem, the bast fibres. The xylem fibres are usually lignified and are chiefly responsible for the rigidity and hardness of the wood. Some bast fibres are lignified, others have unmodified cellulose walls. The latter kinds of fibres are valued commercially and occur in such well-known fibre plants as flax, hemp and ramie.

Conducting Elements.—Tracheary elements are water conductors located in the xylem or wood. The vascular plants are called Tracheophyta because they contain tracheary elements. Two principal types of tracheary elements occur in plants: tracheids (fig. 6[A]) and vessel elements (fig. 6[B], 6[C]). Both of these are commonly prosenchymatous with oblique or transverse end walls. They have secondary walls of lignified cellulose that are deposited as rings, spiral bands, bars, a network, or as pitted layers upon the thin primary wall. At maturity the protoplasts are lacking.



AFTER E. W. SINNOTT, "BOTANY PRINCIPLES AND PROBLEMS," MCGRAW-HILL BOOK CO.

FIG. 5.—CELL WALL TYPES IN PRIMARY XYLEM SHOWN IN A LONGITUDINAL SECTION OF VASCULAR BUNDLE IN A STEM

The principal distinction between the two types of tracheary elements is that the tracheid is an imperforate cell with a continuous primary wall, whereas a vessel element has openings or perforations usually located in the end walls of the cell. The vessel elements are combined into longitudinal pipelike units, the vessels, in which water passes freely through perforations from element to element. Water moving through tracheids passes from one cell into the other through places where the secondary wall is discontinuous but the primary wall is present. Often these places are very restricted and are then called pits. The water passes through the exposed part of the primary wall of the pit, the pit membrane.

In the wood of gymnosperms (firs and their allies) the pits show very elaborate structure. The pit membrane has small but numerous perforations and is reinforced by a primary thickening, the torus, in the middle. The secondary wall overhangs the pit cavity as a border (hence bordered pit), leaving a small opening (pit mouth) at the entrance into the pit cavity (fig. 6[D]). The pit membrane is flexible and can bulge one way or the other within the cavity formed by two communicating bordered pits of the adjacent cells. The torus may become appressed to the mouth of one or the other pit, obstructing the entry into the pit cavity. Thus, apparently by changes in the position of the pit membranes of bordered pits, some control is exercised over the passage of fluids in the xylem.

Sieve cells (fig. 6[G]) and sieve-tube elements (fig. 6[F]) are the characteristic components of the phloem, a tissue outside the xylem and concerned with the conduction of food (chiefly sugars and protein) manufactured in the leaves. The sieve-tube elements occur in the angiosperms (plants having their seeds enclosed in an ovary), whereas sieve cells are typical of gymnosperms and ferns. The sieve-tube elements have specially modified walls or portions of walls called sieve plates (fig. 6[E]). The essential feature of a sieve plate is the presence of perforations (sieve-plate pores) in the wall through which the protoplasts of two adjacent or superposed elements are continuous. These connecting strands are comparable with plasmodesmata but tend to be thicker than ordinary plasmodesmata.

In the sieve plate a special kind of carbohydrate, callose. surrounds each strand. In other words. each strand is enclosed in a tube or cylinder of callose, the callose cylinder. As the sieve tube ages, the callose becomes more massive. Since each callose cylinder thickens, the strands are constricted and, furthermore, callose bulges and spreads over the surface of the plate until the latter appears completely buried within the callose. The bulging callose masses on both sides of the sieve plate are referred to as callose plugs, though it is not known whether they actually plug the sieve plate. The appearance of the callose plugs indicates that the sieve-tube element has ceased to function. Therefore, the final callose masses developed at the end of the active period of the conducting element are also called definitive callose.

As it matures the protoplast of the sieve-tube element loses its nucleus. but the cytoplasm is retained until the cell ceases to function. Some studies indicate that this cytoplasm is peculiar: it appears to be very fragile. The contents of the vacuole are often slimy and readily coagulate when the tissue is killed. The so-called slime plugs often seen on sieve plates result from such coagulation. The sieve-tube elements of the angiosperms tend to have their sieve plates on the end walls. The sieve plate may cover the wall uniformly or may be broken up into more or less clearly defined sieve areas. The lateral walls show similar sieve areas, but with thinner strands (fig. 6[F]).

Series of sieve-tube elements are combined into longitudinal series, the sieve tubes. Each sieve-tube element is closely associated aith one or more slender parenchyma cells called companion cells (fig. 6[F]). These arise by division from the same mother cell as the sieve-tube element. The sieve cell of the gymnosperms and ferns shows no differences betneen end and lateral walls. All bear sieve areas of similar nature with rather thin connecting strands. Furthermore, sieve cells are not arranged in vertical superposed series and have no companion cells. Otherwise the sieve cell resembles the sieve-tube element in having callose associated with the connecting strands of the sieve areas and containing no nucleus in the mature protoplast.

Tissues.—The different types of cells characteristic of the plant body are combined into tissues in various manners. For example, only one kind of cell may form a tissue, as in parenchyma or collenchyma tissues. The fibres also may be aggregated into a simple mechanical or supporting tissue. These are simple tissues. In other instances many different kinds of cells are combined to make a complex tissue. The best examples of complex tissues are the xylem and phloem, which together constitute the vascular or conducting tissues. The xylem is concerned principally with the conduction of water and inorganic solutes and contains vessels and tracheids (or only tracheids), xylem fibres of different kinds, xylem parenchyma, and ray parenchyma in different proportions and combinations. The phloem translocates various organic solutes and contains sieve tubes and companion cells (or sieve cells), phloem parenchyma, ray parenchyma and bast fibres. The vascular tissues. notably the xylem, function also as supporting tissues because of the presence of fibres. The parenchyma that occurs in these tissues commonly serves for storage of different ergastic substances, particularly starch. The vascular tissues together form an elaborate system, the vascular system. Parenchyma is the principal tissue that surrounds and interpenetrates the vascular system. It may be spoken of as ground tissue.

B. Organization of the Plant Body

1. Nonvascular Plants.—The reader is referred to special articles on the anatomy of the lower plants (Thallophyta: ALGAE and FUNGI; and BRYOPHYTA: mosses and liverworts) in which the tissues are rather undifferentiated. Suffice it here to mention that both algae and fungi range from the simplest unicellular forms with no external differentiation of the body to forms of larger size and greater complexity of organization. The progress in complexity is closely associated with division of physiological labour among the component cells and with the adaptation of the multicellular organism to its environment. But whatever are the various states attained by individual genera, the majority of the cells of the adult bodies of both algae and fungi remain alive and the tissues are essentially parenchymatous.

In accordance with the greater complexity in the conditions of life on land for self-supporting plants, considerably more advanced tissue differentiation is exhibited by the mosses, liverworts. etc. (Bryophyta). which are mainly terrestrial plants. In a general way this greater complexity consists (1) in the restriction of regular absorption of nater to those parts of the plant body which are in close contact with the soil; and (2) in the more regular evaporation of water from the parts exposed to the air. In the higher vascular plants these two principles find their full expression, whereas in the bryophytes water is still absorbed (as, for example, from rain or dew) by the general plant surface.

The lowest liverworts have an extremely simple vegetative structure comparable to that of many of the simpler algae. Since their bodies are small and normally live in damp air, the demands of terrestrial life on them are at a minimum. Their bodies consist of true parenchyma, and the vast majority of the component cells remain alive. Rooting and absorbing threadlike cells (rhizoids) universally occur on their lower surfaces in contact with the soil. and considerable tissue differentiation may occur within the body. Thus some possess a distinct assimilative system consisting of branched chains of thin-walled cells packed with chloroplasts and arising from the bases of large cavities directed toward their upper illuminated surfaces (fig. 7). These cavities are completely roofed by a layer of surface cells pierced by pores through nhich aeration and evaporation are freely maintained. In certain forms in which the body consists of thick midribs and delicate lateral leaflike appendages, strands or bundles of long thick-walled fibrelike prosenchymatous cells with pointed ends are arranged longitudinally within the midribs. which are devoid of special assimilative tissue. The walls of these cells are strongly lignified and are irregularly thick and thin so as to be closely studded by simple pits The latter are usually arranged in spirals and are often elongated in the direction of the spiral There is much variety of detail in the differentiation of the tissues of the liverworts, but the general plan of construction resembles that characteristic of the leaves of higher plants.

FIG. 7.— SECTION OF THALLUS OF A LIVERWORT (MARCHANTIA)

In the mosses the plant body is generally more elaborate. There is a radially organized supporting and conducting axis (stem) bearing laterally through most of its length thin, flat assimilating and transpiring appendages (leaves). Branched rhizoids are attached to the base of the stem or to parts in contact with the soil. In some instances the stem possesses a special surface or epidermal layer of cells, but usually all the outer layers of the stem (the outer cortex) are composed of brown, thick-walled, lignified. prosenchymatous. fibrelike cells forming a peripheral sclerenchyma (fig. 8). This passes gradually into the thinner walled parenchyma of the inner cortex. The entire cortex is generally alive, and its cells often contain reserve foods in the form of starch. The centre of the stem. in the forms which live on soil, is composed of a strand of narrow, elongated. thin-walled, unlignified, dead cells, which are commonly interpreted as water-conducting elements (hydroids). This hydrom strand has in most cases no connection with the leaves, but forms a straight column in the stem and branches locally below the reproductive organs. In the aquatic and semiaquatic forms, and in those mosses which live under conditions of extreme drought, the entire plant surface absorbs water. In all such forms the hydrom strand is either slightly developed or altogether absent. The leaves of most mosses are flat plates, each consisting of a single layer of square or oblong assimilating cells containing chloroplasts. The marginal cells of the plates are frequently produced as teeth, and their walls are thick. The centre of the leaf is often occupied by a midrib consisting of several layers of parenchymatous cells elongated in the direction of the long axis of the leaf and poor in chloroplasts. This midrib is usually considered a primitive conductive foliar strand or leaf bundle. Hydroids, like those of the central strand of the stem, are frequently associated with this conducting parenchyma, and in some instances are continued into the cortex of the stem as a leaf trace bundle (the anatomically demonstrable trace of the leaf in the stem) (fig. 8). In several forms the leaf trace extends vertically downward for some distance in the outer cortex and ends blindly in a fan-shaped expansion; in others it joins the central hydrom strand so that a connected system is established between stem and leaf.

Further differentiation of tissues characterizes the highest family of mosses, the Polytrichaceae. In these, elongated, living, nucleated cells with a thin lining of protoplasm surround the dead central strand and form the phloemlike tissue, commonly called leptom. Between the hydrom and leptom is a cylinder of cell layers that may serve for the temporary storage and distribution of carbohydrates, since they sometimes contain an abundance of starch. The underground portion of the stem (rhizome) bears rhizoids and simple scales. The aerial parts bear leaves, each nith a simple midrib several cells thick and with a strong band of sclerenchyma above, and below a bundle of leptom, hydrom and starch cells, all of which join the central cylinder of the stem. Each midrib bears two wings, one cell thick, while above the midrib is a series of closely set, vertical, longitudinally arranged plates of green assimilative cells.

2. Vascular Plants. — The greatest anatomical complexity occurs in the vascular plants, which comprise the psilopsids, lycopods, horsetails. ferns and seed plants. The vascular plants are not exactly comparable with the bryophytes for while the body of the latter bears the sexual organs and is called a gametophyte, the vascular plant is a sporophyte. Nevertheless the gametophytic brpophyte and the sporophytic vascular plant have similar physiological needs and are both fixed to the soil. The chief new feature in external conformation of the body of a vascular plant compared with that of a bryophyte is the presence of "true" roots, the first formed of which is the downward prolongation of the primary axis of the plant. From this and from various parts of the shoot system, other roots originate. The roots of ferns are structurally simple and uniform compared with those of seed plants, but all manifest a primary plan of construction in direct relation to their normally subterranean life and fixative and absorptive functions; they differ from aerial stems in the characters of their surface tissues, in the absence of the green assimilative pigment chlorophyll, in the arrangement of their vascular systems, and in their mode of apical gronth. Great variety in stem and leaf form and structure is shown by the vascular plants.

Evolutionary Trend. — In spite of the many differences of detail betneen ferns and seed plants, we can trace, alike in root, stem and leaf. a threefold division of tissue systems, already indicated among the bryophytes, and expressive of the fundamental conditions of evolution of the bulky body of a land plant. Thus there is (1) a specialization of a surface layer of cells that regulates the immediate relations of the plant with its surroundings, while varying in expression in the subterranean and aerial parts. In the former the surface layer is pre-eminently absorptive whereas in the latter it is protective and is concerned with the gaseous interchange of oxygen and carbon dioxide involved in respiration, and in such vital functions as assimilation and transpiration. This surface layer is known as the epidermis. Then there is (2) an internal differentiation of conductive tissue, presaged in the bryophytes, and collectively known in the vascular plants as the vascular system. The vascular structures are imbedded in (3) fundamental or ground tissue. The latter may show differtnt distribution and may be combined with other types of tissue. Thus in the axis a cortex appears betneen the epidermis and the vascular tissues and, in the stem, a pith usually occurs enclosed by the vascular tissues. In the root the pith is usually absent. In leaves the vascular system is imbedded in parenchyma which is called mesophyll. The mesophyll is especially adapted for photosynthesis.

Besides absorption, assimilation, conduction and protection, plant tissues serve for support and the storage of food. Thus locally in the cortex, mesophyll and vascular system, special supporting tissues (sclerenchyma) may be developed, and living cells of both the ground tissue and the vascular system may serve for temporary storage of foods and are specialized accordingly. The functions of aeration. assimilation and transpiration are maintained by an extensive system of intercellular spaces communicating with the external air.

C. Tissues

1. Meristems.—The different types of cells characteristic of the body of higher plants are alike at the beginning of their existence. They arise together from meristems, and only through subsequent differentiation in development become unlike. A meristem is best defined as a specific region in the plant body where cells are engaged chiefly in division and enlargement Meristems can be conveniently classified according to position as apical

The apex or growing point of the root or shoot illustrates the former type, the vascular and cork cambia the second. The localization of the regions of cell formation in the plant body distinguishes the plants from the animals, whose parts grow through their whole extent. Also. unlike animals, the higher plants have a continuous formation of new tissues and organs throughout the life of the individual. A meristem is described as undifferentiated embryonic tissue exhibiting juvenile characteristics in contrast with the differentiated or mature tissues that arise from it. Meristems. however, differ morphologically and physiologically from each other and are not sharply separated from those differentiated tissues that retain protoplasts at maturity, particularly the parenchyma tissue. The living mature tissues are potentially meristematic. and resume meristematic activities when appropriately stimulated. Furthermore, cells of a given meristematic region may vary among themselves in many features.

Apical *Meristems*.—These meristems are usually composed of approximately isodiametric cells with prominent nuclei. The cytoplasm is often dense but may be also conspicuously vacuolated. The dense cells have many small vacuoles dispersed in the cytoplasm. The walls are commonly thin, and the cells are closely packed without intercellular spaces among them. The architecture of the apical meristems varies in different groups of plants. In most ferns, in the horsetails and in some other vascular plants, all tissues of the stem and root are derived from single apical cells located at the apices of these organs. The apical cell, which may be termed also initial cell, is usually tetrahedral in shape. Its base occupies the surface of the apical mound of tissue, and the apex points inward. By definite and regular divisions of such a cell, a mass of still undifferentiated cells is produced immediately below the apex that is continuously occupied by a residual apical cell. From these undifferentiated cells the different tissues sooner or later arise by further growth, divisions and differentiation. In the seed plants a few to many cells at the apex of shoot and root initiate the body tissues, and these cells function in different manners. In angiospermous shoots one or more superficial layers and a central core of the apical mound have independent initials. The peripheral layers (tunica) are characterized by surface growth, that is, anticlinal divisions predominate. The underlying core (corpus) shows divisions in all planes and thus grows in volume. The two zones are interdependent and their extent and behaviour fluctuate. They are not at all specific as to the tissues that originate from them. The peripheral zone may be concerned with the production of the epidermis only, or it may give rise to one or more of the underlying regions. Similarly, the central zone may produce pith only or also the vascular tissues and even the cortex. In the gymnosperms a peripheral and central zone may also be distinguished but here they appear to be more interdependent than in the angiosperms: a superficial group of initials divide anticlinally and periclinally and give rise to both the external and the internal cells of the apical mound.

The root and shoot apices differ from each other in several fundamental features. The shoot apex is concerned with the production of the lateral organs of the stem axis, that is, the leaves; the root apex produces no lateral organs: the lateral roots arise some distance from the apex and not superficially (like the leaves) but in the deeper layers of the axis. Thus the lateral roots have an endogenous origin in contrast to the leaves, whose origin is described as exogenous. The shoot apex is exposed to the outside and cuts off cells only toward the axis. The root apex is covered with a protective tissue. the root cap. produced by cells that are cut off away from the axis of the root. Thus, strictly speaking, the apical meristem of the root is subterminal, whereas that of the shoot is terminal. The initial cells of the root apex of angiosperms are commonly arranged in two or more tiers. One tier may form the root cap, epidermis and cortex, the other the central cylinder containing the vascular tissues. In other species the root cap arises from a separate initial layer (calyptrogen). the cortex and epidermis from another, the central cylinder from a third; or the epidermis and root cap have common origin. Sometimes all four root regions arise from separate sets of initials. In some roots the apical meristem appears generalized and shows no distinct tiers of initials. The study of a root having separate initials for the various regions of the root axis might give the impression that the regions are predetermined in the apical meristem. Such a view has been actually held and the supposedly independent meristematic regions, the histogens, have received special names: dermatogen. periblem and plerome, the precursors of the epidermis, cortex and central cylinder, respectively. Since in some roots. and apparently in all shoots, the regions of the axis cannot be traced back to separate sets of initials, the deterministic scheme of apical structure cannot be accepted.

2. The Primary **Plant** Body.—The apical meristem of shoot and root produce a complete plant body with all its vegetative and reproductive organs. This body is spoken of as the primary body. and the tissues composing it as primary tissues in distinction from the secondary body or secondary tissues that are later added to the primary body by the two lateral meristems, the vascular cambium and the cork cambium. The primary tissues result from progressive differentiation of the cell masses produced by the apical meristems, and the latter may be traced back to the embryo and the zygote. As previously stated, the various tissues or regions of the plant body do not appear to be predetermined in the initial regions of the apical meristems. The first certain evidence of tissue differentiation occurs in the subapical regions. There some cell masses show speeded up vacuolation of their protoplasts, others remain dense somewhat longer, but divide largely by longitudinal walls and soon become longer than wide. The more highly vacuolated parts of the subapical meristem later differentiate into the cortex and pith (if the latter is present) and are termed the ground meristem; the meristem part composed of the dense elongated cells is the precursor of the primary vascular system called procambium. It forms the primary xylem and primary phloem. A young plant organ, or part of it, composed of these partly differentiated but still meristematic tissues, is covered on the outside by a discrete meristematic layer, the protoderm, which later matures into the epidermis. These three meristems, the ground meristem, the procambium, and the protoderm, as well as the apical meristems, are the primary meristems whereas the two cambia are secondary meristems.

3. Epidermis.—The epidermis of the aerial stems and leaves is primarily a covering layer which protects against harm from loss of water and against mechanical injury. It usually consists of a single layer of living cells devoid of chloroplasts, and with thickened and waterproofed (cuticularized) outer walls. At intervals the epidermis is interrupted by small pores (stomata or stomates) leading from the outer air to the system of intercellular spaces in the underlying tissues, and serving for gaseous interchange between these tissues and the outer air. Each stoma or stomate is surrounded by a pair of peculiarly modified epidermal cells called guard cells. which possess chlorophyll and open and close the pore in accordance with the changes in water content (turgidity). The stomates of leaves are generally much more numerous in the lower epidermis than in the upper, and even may be absent in the upper epidermis. They are often situated at the bottom of pits in the leaf surface. Thus loss of water (transpiration) is checked by the creation of a still atmosphere in the pit above the pore. Such an arrangement of the stomates is found especially in plants adapted to gron th in regions where the supply of available water is deficient. In some angiosperms the epidermis is doubled or trebled by tangential divisions in the original layer, resulting in a multiple epidermis, which functions as a water-storage tissue. In many vascular plants epidermal organs, known as hydathodes, are developed, especially on foliage leaves, and serve for excretion of water in liquid form.

Hairs *and* Scales.—The epidermis of many species of vascular plants bears hairs or scales of varied form and function. The simplest hairs consist of single elongated cells projecting above the general surface of the epidermis, whereas others consist of simple or branched cell chains. The more complex scales are flat plates of cells commonly inserted on mounds or stalks, and may be placed parallel to the leaf surface or projecting directly from it. In other instances the hairs are glandular and excrete volatile oils, or they may be stinging, as in the common stinging nettle, in which the top of the hair is brittle, and when touched penetrates the skin, breaks and injects a poisonous liquid into the wound thus formed. In many plants both hairs and scales are shed before the stems and leaves are mature; in others they are retained throughout the life of the plant.

Epidermis of Root.—The epidermis of the root is different from that of the stem or the leaf. In relation to its normal function of water absorption its cell walls are not conspicuously cuticularized. and usually remain thin. The absorbing surface is increased because many of the cells expand their outer walls into tortuous, delicate, one-celled tubes (root hairs) which aid in anchoring the root, and readily absorb the surface films of water from the soil particles. A root hair thus corresponds in function with a rhizoid of a moss. The hairs are normally definitely restricted to a more or less definite zone of the root a little removed from the growing root tip. At the lower limit of this zone hairs are constantly being formed as the root advances in the soil, while at the upper limit they have passed maturity, are dying and are being destroyed. Thus beyond the zone which at any moment bears living absorbing hairs the epidermis is extensively or completely destroyed, and its place is taken by the immediately subjacent cortical layer, which is not absorptive, but becomes protective like the epidermis of the stein or leaf.

4. Cortex.—The cortex consists primarily of living parenchyma, but its differentiation may be extremely varied, and in the complex bodies of vascular plants its functions also are varied and may be modified. The cortex of a young stem is usually green—for its cells possess chloroplasts—and a fine system of intercellular spaces communicates with the external air through stomates. With age the inner cortical layers may lose their chlorophyll and become merely storage tissue, and the outer layers may be extensively modified. In many ferns and lower vascular plants the mature outer cortical layers of the stem and root are hard sclerenchyma with thick brown walls, but in flowering plants, while the stems are still slender, the cells of the outer cortical layers elongate and become cylindrical or spindle-shaped and develop localized cellulose thickenings; that is, this part of the cortex differentiates as collenchyma. It provides peripheral support for the growing stem, and as its cells are alive, is open to later modifications with changing conditions in stems that undergo annual increase in girth. On the other hand sclerenchyma is commonly dead, and provides a more rigid but usually unmodifiable supporting tissue. Its adequacy will be evident for stems such as those of modern ferns, which do not increase annually in girth. Less commonly, scattered cells or cell groups which increase little in length may become stone cells. with irregularly but inordinately thickened hard walls. Various secretory cells may occur in the cortex, usually lining cavities or canals which arise through a breakdown of certain cells (oil cavities in a citrus stem or fruit) or through enlargement of intercellular spaces (resin canal in pine stem). The cortex of the stem shows more modifications than that of the root. In the dicotyledons the root cortex commonly remains entirely parenchymatous and is early shed in connection with secondary growth, whereas in the monocotyledons and in the ferns it is more or less sclerified at maturity.

Endodermis.—The innermost layer of the living cortex investing the centrally located vascular system of the axis may be early and peculiarly modified as a continuous cylinder called the endodermis. Throughout its extent the endodermal cells are in close contact, so that the system of intercellular spaces in the cortex is not continued into the central cylinder of conductive tissue. In the absorbing region of angiospermous roots the endodermis shows a very characteristic structure. A band of wall material impregnated with fatty substances and lignin extends completely about the inner surface of the lateral longitudinal and end walls of each cell. These bandlike thickenings of the wall are known as Casparian strips. This kind of endodermis is thought to play a role in the regulation of the transfer of solutes from the cortex into the vascular system: the presence of the fatty substances in the Casparian strip and the firm connection between the strip and the cytoplasm of the cell apparently force the soil solution to move through the cytoplasm and be subjected to the protoplasmic control of the endodermal cells. In older roots that cease to absorb the endodermis may develop thick lignified walls; or it is torn and shed because of secondary increase in thickness of the central vascular cylinder.

The stems of seed plants rarely show peculiar morphologic characteristics in the innermost layer of the cortex. In the youngest part of the stem this layer is commonly differentiated as a starch sheath, which may be regarded as an equivalent of the endodermis. It is rich in starch and forms a continuous layer around the vascular system. In the more mature regions of the stem starch is absent. In most ferns the endodermis appears as a morphologically distinct layer throughout the stem and the root. Casparian strips and more generally corky (suberized) endodermal cells have been observed in this group of plants.

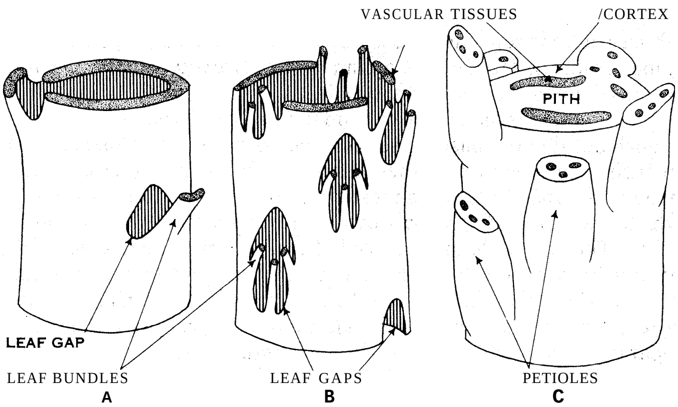
5. **Mesophyll.**—The mesophyll of the leaf is primarily concerned with the fundamental function of manufacture of carbohydrates (carbon assimilation), and to the active performance of this function the maximum exposure of living parenchymatous tissue containing chloroplasts is necessary. Thus the mesophyll is essentially a green expanse of thin-walled parenchyma and is penetrated by a large and elaborate system of intercellular spaces which serve at one and the same time for the promotion of transpiration and respiration. The pathways for the gases between the mesophyll and the outer air are the stomates which are in direct communication with the ample system of intercellular spaces in the mesophyll. The lower layers of the mesophyll are loosely arranged as spongy tissue with extensive intercellular spaces. This is the main transpiring tissue of the leaf, and in it chloroplasts may be comparatively few. It is protected from direct illumination and is at the same time liable to overevaporation. The main assimilating tissue, on the other hand, is under the upper epidermis and it is well illuminated; its cells are densely packed with chloroplasts, and are commonly oblong, with their long axes perpendicular to the leaf surface. The intercellular spaces in this upper epidermis are narrow, as between sticks in a bundle, and are in open communication with the intercellular spaces in the spongy tissue below. By reason of its resemblance to the boards in a fence, when viewed in a transverse section of the leaf, this portion of the mesophyll is called the palisade tissue. Leaves with blades held in a vertical position commonly possess palisade tissue on both sides or have little or no distinction in the form and arrangement of the cells of the mesophyll, since there is no difference in the illumination or other external conditions, while cylindrical or approximately cylindrical leaves may have palisade tissue all around. The leaves of shade plants have little or no differentiation of the palisade tissue. In fleshy leaves, which contain a great bulk of tissue in relation to their chlorophyll content, the central mesophyll contains little or no chlorophyll and may consist of water-storage tissue. while locally a layer or mass of subepidermal cells may be thick-walled and fibrous.

The cortex of the leaf stalk or petiole is transitional in structure to that of the stem and leaf blade. The petiole is traversed by one or more vascular strands connected below to the central conductive system of the stem, and leading forward in the leaf blade to a complex system of minor strands which ramify in the mesophyll where the spongy and palisade tissues meet. The layer of mesophyll immediately investing each bundle (bundle sheath) usually has the form of a special parenchymatous sheath of elongated cells. In dicotyledons the sheath cells commonly have fewer chloroplasts than the rest of the mesophyll. The bundle sheaths are considered important in the conduction of carbohydrates from the manufacturing (assimilative) cells to the conductive strands and in the supply of water from the latter for transpiration. Their function is thus considered in some measure comparable with that of the endodermis.

6. Vascular System.—Among the most striking characters of vascular plants is the possession of a double (xylem-phloem) conducting system, such as has been presaged in the higher mosses, but with more sharply defined and specialized features. This is the vascular system, and associated with it are other tis-

sues consisting of parenchyma and sclerenchyma. The primary vascular system together with the associated tissues is known as the stelar system (from the way in which in its simpler forms it traverses the whole axis of the plant as a column). When it is remembered that the moss plant is a gametophyte while the vascular plant is a sporophyte, it will be realized that the vascular system of the latter is not the result of elaboration of the conductive system of the former, but that these vascular systems are most readily interpreted as somewhat similar products of differentiation in plants adapted to life on land.

Arrangement of the Vascular System.—In the vascular system the xylem and phloem are nearly always found in close association in strands or bundles, but as is to be expected the arrangement of such bundles is by no means stereotyped either in the given plant group or in the different parts or members of the plant body. A connected vascular system penetrates, however, the entire body. When the vascular system of the axis appears in the form of a solid central rod. with a core of xylem ensheathed by phloem, it is termed protostele. Usually a discrete parenchymatous layer, the so-called pericycle, surrounds the phloem and lies directly beneath the endodermis. The evidence from comparative anatomy and paleobotany indicates that protostele is the primitive type of vascular system. It occurs in both the stem and root of many lower vascular plants, but is restricted to the root of seed plants. In the advanced ferns the vascular system of the juvenile stem is a solid protostele, but that of the more bulky portions of the adult plant shows a somewhat different arrangement.



AFTER Y. OGURA, IN LINSBAUER'S "HANDBUCH DER PFLANZENANATOMIE." GEBR. BORNTRAEGER

FIG. 9.—TYPES OF VASCULAR SYSTEM IN HIGHER PLANTS

(A) Siphonostele; (B) dictyostele; (C) tissues other than the vascular in connection with a dictyostele

If the xylem core is not solid but contains parenchyma (pith or medulla), the stele becomes a medullated protostele or siphonostele (fig. 9[A]). In the protosteles the vascular system is not interrupted, at least not markedly so, where a vascular bundle, the leaf trace, diverges to a leaf. Siphonosteles usually show breaks in the continuity of the vascular tissues above the departure of a leaf trace, these breaks being called leaf gaps. The gaps are filled with parenchyma, which connects the pith with the cortex. In cross sections of internodes such a stele appears as a continuous circle but shows breaks in the nodal region. If the leaf gaps overlap in their longitudinal extent in a siphonostelic vascular system, the stele is a dictyostele which, in cross section of both nodes and internodes, appears composed of several portions (fig. 9[B]). This kind of dictyostele may be found, for example, among ferns. In a dictyostele breaks other than leaf gaps—the parenchymatous medullary rays—may be present. A stele of this type should be visualized as a tubular network, the meshes representing the vertical leaf gaps and parenchymatous rays. The stems of seed plants usually have similar steles. Thus the vascular system of the axis (root and stem) commonly has the shape of a solid rod or a tube with or without perforations.

The leaves, if small as in the lower Tracheophyta (*e.g.*, *Selaginella*, Equisetum) or the conifers (*e.g.*, firs), have a very simple system which typically consists of one unbranched vein. The large-leaved ferns have complex systems of bundles in the petioles and rachises (extension of petioles to end of leaf) with branches given off into the leaflets (pinnae). The flowering plants (angiosperms) commonly have rather large leaves with complex vascular systems (see below. Vascular System of Leaf). The xylem and phloem show two types of arrangement in siphonosteles. If the phloem appears only on the outside of the xylem the stele is ectophloic, if on both sides, amphiphloic. If the ectophloic stele is a much dissected siphonostele the individual strands making up such a stele are collateral bundles, having xylem on one side, phloem on the other. The component parts of an amphiphloic siphonostele are bicollateral bundles having phloem on both sides of the xylem.

The Vascular System in the Stem of Seed Plants.—In this group of plants distinct vascular bundles traverse the axis and connect or anastomose with each other (very much dissected siphonostele). At certain intervals one or more bundles diverge into a leaf, and it appears that all bundles of the stem are directly or indirectly related to the leaf bundles. In other words, the vascular system may be regarded as made up of leaf traces and their fusions. The number of leaf traces to a given leaf varies. Common numbers are one, three and many. If the trace is single only one leaf gap or lacuna is associated with the given leaf and the node is called unilacunar. If there is more than one trace the node may be trilacunar (three gaps) or multilacunar (more than three gaps). The unilacunar node associated with two leaf traces to one leaf is primitive in the angiosperms. The development of axillary buds further complicates the vascular anatomy of the node. The vascular bundles connecting the bud with the vascular system of the main axis are known as branch traces, which are usually two in number. Branch gaps or parenchymatous areas in the vascular system of the main axis occur above the divergence of the branch traces.

In the gymnosperms and dicotyledons the vascular bundles are usually arranged in one circle, with parenchymatous rays separating the bundles from each other. The monocotyledons typically possess large leaves with broad sheathing bases containing numerous bundles. Therefore the number of bundles present at any given level of the stem is high. They are arranged in more than one circle or are scattered in a definite, though not superficially obvious, order throughout the cross sectional area of the stem so that the delimitation of cortex and stele is difficult or impossible. The bundles are surrounded by large-celled ground tissue and around each bundle there is a fibrous investment or sheath.

Vascular System of Root.—The stele of the primary root of a gymnosperm or angiosperm is of radial structure. There are usually two or more xylem strands radially alternating with as many phloem strands, and the first formed xylem groups (protoxylem) are peripheral. Depending on the number of the xylem strands, the root is called diarch, triarch, tetrarch or polyarch. The centre of the stele is either solid xylem or is pithed, and sclerotic cells are in the ground tissue. Thus the vascular system of the root in seed plants is much simpler than in the stem. It forms a protostele, though not of the most primitive kind: the phloem does not completely ensheath the xylem but appears in strands alternating with the protoxylem groups.

Vascular System of Leaf.—In the leaf of the average seed plant the vascular tissue appears as a number of branching or approximately parallel, and usually anastomosing, strands. Above and below the larger strands the leaf parenchyma is raised so as to produce the so-called veins. The vein system is typically very elaborate, and the bundle system is concentrated in the petiole as the tributaries of a river are massed in the main stream. The leaf bundles are usually collateral (the phloem being turned downward and the xylem upward), and the whole bundle may be protected above and below by fibrous cells. As the bundles are followed toward their blind endings in the mesophyll the fibres first disappear, the sieve tubes are replaced by narrow elongated parenchyma cells which disappear before the end of the bundle is reached. The bundles usually end in short or long spiral or reticulate tracheids covered by the bundle sheath.

Ontogeny of the Vascular System.—The primary vascular system in the various organs of the plant is first delimited in the form of a meristem called procambium. The procambium assumes similar aspect as the mature vascular system with its continuities and interruptions. gaps, traces. bundles and other details. But all parts of the procambial system are short. The elongation of these parts is one of the phases in the maturation of the procambium into the vascular system. In a given transverse section of the procambium the vascular elements differentiate not all at once. but gradually. The first primary xylem elements (protoxylem) may appear on the periphery of the xylem system, and the subsequent primary elements (metaxylem) toward the centre. Such order of differentiation is spoken of as centripetal and the xylem of this kind is exarch; or the protoxylem occupies the innermost position in the xylem system and the further xylem differentiates centrifugally. Such primary xylem is endarch.

The first phloem is termed protophloem; then follows the metaphloem. The phloem located on the outside of the xylem differentiates centripetally. The internal phloem, as in an amphiphloic siphonostele, differentiates centrifugally.

A good example of exarch xylem is found in the roots of seed plants. Here the starting points of xylem differentiation. the protoxylem poles. occur on the periphery of the stele and alternate with the protophloem poles. Both metaxylem and metaphloem differentiate toward the centre of the root, but the phloem remains essentially peripheral, whereas the metaxylem frequently reaches the centre. The xylem in the stems of seed plants is typically endarch. The protoxylem occurs on the periphery of the pith in each major subdivision of the dictyostele. Opposite each protoxylem strand on the periphery of the stele is the protophloem bundle. The metaxylem and metaphloem differentiate toward each other, that is, the xylem shows a centrifugal, the phloem a centripetal order of development. The leaf bundles commonly show the same order of differentiation as the stem bundles.

The longitudinal course of differentiation in the root is from the more mature toward the younger parts of the root. that is, the differentiation is acropetal. In the stem, however, xylem and phloem, as far as known, differ from each other in their initial course. The phloem differentiates acropetally from the lower regions of the axis toward the apex and into the leaf primordia, whereas the xylem is initiated at the base of the leaves or in the leaves and then differentiates toward the apex of the elongating leaf and downward (basipetally) into the axis toward the junction with the mature xylem below.

The primary xylem is simpler in structure than the secondary. The protoxylem contains only one or two kinds of tracheids or vessels (commonly with annular and spiral secondary thickenings) and some parenchyma. The metaxylem shows greater variety of elements and often contains fibres. The primary phloem also is simpler than the secondary. The protoxylem and protophloem mature before the organ in which they occur completes its elongation.

Since the water-conducting elements are dead at maturity and the sieve tubes or sieve cells have enucleate protoplasts. these vascular elements cannot respond with growth to the continued division and elongation of the adjacent tissues. For a while the protoxylem and protophloem elements, which have no rigid walls, are passively stretched, then they are torn and more or less completely obliterated while new conducting elements differentiate to take the place of the old ones. Consequently in mature plant organs the protophloem and protoxylem may appear much modified as compared with their original state. This is particularly true of the protophloem in which fibres (bast fibres) or collenchymalike cells often differentiate after the obliteration of the conducting elements. The fibrous or collenchymatous protophloem appears like a region very distinct from the rest of the phloem and has often been called the pericycle The metaxylem and metaphloem remain longer intact, though they too become functionless when secondary vascular tissues are formed. In plants having no secondary growth, the metaxylem and metaphloem are the main conducting tissues of the mature plant.

7. Laticiferous Tissue.—In certain families of angiosperms there are peculiar tissues that do not occur in the ferns and their more primitive relatives. Such, for example, is the laticiferous tissue found in many composites (Compositae) and spurges (Euphorbiaceae). nhich appears in the form of long, usually branched tubes penetrating the other tissues of the plant in a general longitudinal direction. The tubes possess a delicate layer of protoplasm with numerous nuclei lining the walls, whereas the interior of the tube (corresponding with the cell vacuole or cavity) contains a fluid called latex. consisting of an emulsion of fine granules and drops of various substances, suspended in a watery medium, in which other substances (salts, sugars, rubber producers, tannins, alkaloids and various enzymes) are dissolved. Of the suspended substances, grains of caoutchouc. drops of resin and oil, proteid crystals and starch grains may be mentioned. Of this varied mixture of substances some are undoubtedly plastic (*i.e.*, of use in constructing new plant tissue), while others are apparently endproducts of metabolism, secreted within the plant body. The latex may be milky in appearance or nearly colourless. The use of certain plants as rubber producers (notably Hevea *brasiliensis*, the Para rubber tree). depends on the property of coagulation of the latex. The trees are regularly tapped and the coagulated latex which exudes is collected and worked up into rubber. Opium is obtained from the latex of the opium poppy (*Papaver somniferum*), which contains the alkaloid morphine.

Laticiferous tissue is of two kinds: (1) laticiferous cells, which branch but do not anastomose, and the apexes of which keep pace in their gronth with the other tissues of the plant, as seen in dog bane (Xpocynaceae) and in most spurges; (2) laticiferous vessels, which are formed from rows of actively dividing (meristematic) cells. The end walls of these cells break down so that a network of laticiferous tubes arises (Papaveraceae. Hevea). In some plants, as in onion (*Allium*) and in morning glories (Convolvulaceae) roms of cells with latexlike contents occur. but the walls separating the individual cells do not break down.

8. Cambium and Secondary Growth.—Most of the modern ferns. horsetails and herbaceous monocotyledons, and many of the annual dicotyledons, are composed of primary tissues only. The gymnosperms and many dicotyledons, particularly the treelike forms (arborescent). have, in roots and stems, large amounts of secondary vascular tissues added to the primary so that the axis becomes many times thicker than it was in the primary state. These tissues are formed by the vascular cambium. In the stems this merrstem arises partly from the procambial cells that remain in meristematic state after the primary xylem and phloem of the bundles mature, and partly from the ray and gap parenchyma cells located between the bundles. Because of this double origin it is customary to speak of fascicular cambium, if it arises within the bundle, and interfascicular, if it is formed between the bundles. The tno, however, form one continuous meristem, circular in cross section In the roots, the cambium arises first on the inside of the phloem strands. Then these strips of cambium become connected with each other by cambial cells that arise within the parts of pericycle located outside the protoxylem poles. Thus in both the stem and root a continuous cambial cylinder is formed, which produces secondary xylem toward the centre of the axis, secondary phloem toward the periphery.

It is difficult to indicate precisely when procambium becomes cambium. Generally, one might say that the procambium exists and produces the primary vascular tissues as long as the primary organ is still elongating by continued cell division and cell enlargement. After this gron th ceases, the remaining vascular meristem assumes the characteristics of the cambium. The latter thus functions in the part of the body that attained its final length. Therefore, if the elements produced by the cambium elongate, they do so not in harmony with the adjacent tissues but by a kind of sliding gronth in ahich the elongating cell intrudes among other cells.

In a wide range of dicotyledons and gymnosperms the vascular cambium shows certain common characteristics. It is composed of two kinds of initials: (1) the elongated, prosenchymatous, sometimes spindle-shaped, fusiform initials. and (2) the prismatic parenchymatous ray initials. Both kinds of initials are highly vacuolate. The fusiform initials form such elements as tracheids, vessels, fibres. wood parenchyma and sieve tubes, that is, vascular elements that are disposed vertically in the axis of the plant. The ray initials are points of origin and propagation of the radially disposed xylem and phloem rays. There is only one layer of initials around the circumference of the axis but the immediate products of this layer cannot be distinguished anatomically from the initials. The initials and their nearest products (the xylem and phloem mother cells) together form a few layered cylinder of thin-walled vacuolate cells between the xylem and the phloem.

Through secondary growth the primary xylem is buried in the centre of the stem or root, while the primary phloem is pushed outward. The cambial cylinder itself moves outward because of the accumulation of secondary xylem inside of it. As it does so, it also increases in circumference. The divisions that add to the xylem and phloem are tangential, but those that cause the increase in girth of the cambial cylinder are either radial longitudinal (anticlinal) or oblique radial divisions, followed by such elongation of the daughter cells that they appear to slip past each other and eventually lie side by side, at least part of their length.

9. Secondary Vascular Tissues.—The secondary xylem and phloem are highly complex tissues composed of many kinds of cells. As in the cambium, two systems of cells may be distinguished in the secondary tissues, the radial or transverse formed by rays. and the vertical or longitudinal made up of various cells having their long axes parallel with the axis of the organ (fig. 10). The xylem and phloem rays are usually parenchymatous, but may contain ray tracheids in the xylem of gymnosperms. The longitudinal system of the phloem contains sieve cells, phloem parenchyma and fibres in the gymnosperms; sieve tubes with companion cells, phloem parenchyma and fibres in the dicotyledons. The vertical system of the xylem in gymnosperms may contain only tracheids or also fibres and xylem parenchyma. The dicotyledons have a more complex longitudinal system, the complexity varying in different groups. Vessels, tracheids, several kinds of fibres. and xylem parenchyma are common components. The patterns of distribution of the different elements of the secondary phloem and xylem vary greatly and serve as useful criteria in the recognition of relationships among plants.

The secondary vascular tissues in roots and stems are fundamentally similar, but often the root contains a higher proportion of storage parenchyma. The fascicular and interfascicular cambium portions of stems may produce essentially the same kinds of tissues, as in most trees; or the interfascicular cambium forms only ray parenchyma, as in woody vines. In the former case the secondary xylem and phloem form continuous cylinders; in the second the vascular system is broken up into blocks or large strands, each associated with a primary xylem strand next to the pith. Similarly in the roots, the cambium arising in the pericycle may form parenchyma only; or the cambium produces a continuous vascular cylinder.

Annual Rings.—In those plants whose annual activity is interrupted by a regular winter or dry season the limit of each year's increase of secondary wood is marked by a more or less distinct line which is produced by the sharp contrast between the elements formed in the late summer of one year and those produced in the spring of the next. Frequently large vessels are produced by the cambium in the spring. while as summer advances the vessels formed are narrower, and then fibres with greatly reduced cavities arise. In gymnosperms containing no vessels the tracheids formed in the spring have much thinner walls and wider interiors (lumina) than those produced during the summer. Thus in a single season of cambial activity a rough outward progression may be traced in the secondary wood of that season from wide vessels or tracheids to narrow fibres, beyond which the transition to the wide vessels or tracheids of the succeeding spring is sudden. Each zone thus recognized in a cross section of the stem is called an annual ring, and the lines of separation of successive rings mark the temporary cessation of cambial activity at the end of successive seasons.

Sapwood and Heartwood.—The older wood of large trees, forming a cylinder in the centre of the trunk, frequently undergoes marked changes in character. The wood parenchyma and medullary rays die, and the walls of all the cells often become greatly hardened, because of the deposit in them of special substances. Wood thus altered is called heartwood or duramen, as distinguished from the younger sapwood or alburnum, which is nearer the cambium, carries on the active function of conduction, and retains its parenchymatous cells in life. The heartwood ceases to be of any use to the tree except as a support.

10. Phellogen and **Periderm.**—The secondary increase of xylem and phloem involves an outward movement of the primary phloem and of all the elements which surround the latter. The cortex, and particularly the epidermis, must accommodate for this movement, either yielding passively to a limit and being injured or destroyed by the outward pressure, or being to some extent modified so as to persist. Mostly the epidermis is unable to maintain the active radial division of its cells necessary for such expansion, is soon stretched to its limit, dies and is destroyed. Extensive radial division in the cortical cells is progressively less essential as the inner cortex is followed inward, and as a rule, by a combination of radial and tangential divisions, the integrity of the cortex is maintained. Toward the periphery of the cortex, and commonly by modification of its outer layer, a secondary meristem arises and produces external and internal secondary tissues. This meristem is the cork cambium or phellogen, and the whole of the tissue it gives rise to is known as periderm.

Cork and Bark.—The phellogen is simple in structure as compared with the vascular cambium; it is composed of one kind of cell which is rather short and prismatic. The external product of this meristem is the characteristic tissue known as cork. This consists typically of closely fitting layers of cells which quickly die, and when mature, have completely suberized walls. The cork serves to replace the epidermis as an external protective layer when the former is ruptured. The outer layers of the cork are constantly being destroyed, but new layers are in progress of formation within. The internal tissue sometimes formed by the phellogen is known as phelloderm; it augments the cortex, and typically consists of living parenchymatous cells to some extent capable of further division. Indeed, an inward succession of phellogens may arise in the phelloderm and in even more deeply seated living layers. The phellogens arising deeply may cut off parts of cortex and even phloem. These tissue parts then die and together with the cork form the rough bark on the surface of the tree. In certain plants the epidermis becomes the phellogen. To the great activity of the phellogen, and to the power of formation of a series of phellogens in deep layers, the value of the cork oak as a source of cork is due. Certain regions of the periderm show loosely arranged cells whose walls are not suberized. These regions are the lenticels through which gaseous interchange between the stem tissues and the outside air is possible.

IV. PLANT PHYSIOLOGY

Plant physiology is the division of botanical science which comprises knowledge of the processes occurring in plants and the influence of environmental conditions on those processes. Since experimental analysis of plant processes has invariably shown that each such process can be resolved into a number of relatively simpler physical and chemical processes. it is customary for the plant physiologist to regard a plant as essentially a complex living mechanism. Adoption of this viewpoint has led to notable advances in our knowledge of the material and energy transformations which occur within plants, and no exception has ever been found in which plant processes do not operate in accord with the fundamental principles of the physical sciences. Given a plant of known heredity. and of known previous history, it is possible by applying the principles of plant physiology to predict with considerable certainty the physiological reactions which will be evoked in that plant upon its exposure to a given complex of environmental conditions.

The following discussion is largely restricted to the physiology of seed plants.

A. Physiology of the Plant Cell

Although from one point of view all plant physiology is cellular physiology, most plant processes are considered in relation to larger structural units such as tissues, organs or the entire plant body. Certain topics. however, can most conveniently be discussed under the above heading.

1. Organization of the Plant Cell.—Essential to the discussion that follows is a review of cell structure as given earlier in the *Anatomy* section. The typical mature plant cell is a tiny many-sided compartment enclosed by a cell mall. Lining the inside of the wall is a thin layer of protoplasm. which is the seat of physiological processes. Present as a part of the protoplasm of each cell is a more or less spheroidal body called the nucleus, which appears to exert a controlling influence on the processes of the cell. The remainder of the protoplasmic layer is called the cytoplasm. Within the cytoplasm are present other organized bodies, smaller than the nucleus. The most important of these are the plastids. The great bulk of the cell cavity or lumen is the vacuole, which contains a complex watery (aqueous) solution called the cell sap. Present as solutes in the cell sap are sugars, salts and many other compounds.

Plant cells of higher plants vary greatly in size and configuration. Some are essentially spheroid (isodiametric), others are considerably or greatly elongate. They range in size from $\frac{1}{250}$ to $\frac{1}{2,500}$ in in rough diameter; a cubic centimetre of compact plant tissue may contain 1.000.000 or more cells. The protoplasts of individual cells are not entirely isolated from each other by the imprisoning walls, but are interconnected by minute strands of cytoplasm called plasmodesmata, which extend from protoplast to protoplast through pores in the separating wall.

The cell wall between two adjacent cells consists of tno or more layers: (1) the middle lamella; (2) the primary cell wall of each cell; and (3) secondary layers which are not present in all cells. The middle lamella is the first cell wall layer formed in the process of cell division and is bounded on each side by the primary walls of tno adjacent cells. This layer is composed of pectic compounds of mhich calcium pectate is one of the more important. The primary cell wall, mhich also develops largely during and immediately subsequent to cell division, is composed of cellulose and pectic compounds which are water-saturated. The basic structural framework of such walls is composed of long chainlike cellulose molecules, which. in portions of the wall at least. are bound together into bundles (micelles) of 100 to 170 parallel molecules. The pectic compounds in the primary wall apparently occupy only the irregular spaces between the micelles. In some kinds of cells a secondary wall may be formed on the inner surface of the primary wall. Unlike primary cell walls, secondary walls lack elasticity, and fail to manifest reversible changes in thickness which are characteristic of many primary walls. Secondary cell walls often contain a smaller proportion of pectic compounds to cellulose than primary cell walls. A number of other constituents are also found in plant cell walls. The most important of these are lignin, suberin and cutin. Lignin, the characteristic constituent of the walls of the cells of woody tissues, is a brownish substance whose exact chemical composition is unknown. It occurs in the intermicellular spaces of the cellulose-containing wall. Suberin is a fatlike substance which is the characteristic constituent of cork cells; cutin is another fatlike substance which occurs as a thin "varnish" over the epidermis of most aerial plant organs.

2. Protoplasm.—As observed at high magnification in an ordinary optical microscope protoplasm appears as a clear fluid in mhich are suspended numerous granules or droplets of insoluble materials. This visible gross structure of the protoplasm does not, however, represent the physical organization which accounts for its unique properties. Portions of the protoplasm mhich contain no suspended granules exhibit all of its fundamental properties. Hence the ultimate structure with which most of the distinctive properties of protoplasm are associated is beyond the limit of the optical microscope: it is ultramicroscopic and resides in the hyaline. optically empty fluid which is its basic constituent.

Chemical analyses of protoplasm tell us no more of its organization than the analysis of a ground-up match would tell us of its mechanical construction. The protoplasmic system is destroyed the moment it is subjected to chemical analysis. Nevertheless such analyses do yield the best available information on the proportionate amounts of various ingredients present in protoplasm. Water is the chief component of the protoplasm of all active cells, usually constituting 90% or more of its total weight. Most detailed chemical analyses of protoplasm have been made upon the formless ameboid bodies (plasmodia) of slime molds. These are inconspicuous naked masses of flowing protoplasm often found creeping imperceptibly over rotting logs in damp woods. Because of the absence of cell wall material, and because the protoplasm can be collected in relatively large quantities. such plasmodia have been favourite materials for chemical analyses of protoplasm. Analysis of such a plasmodium shows that proteins and chemically related substances constitute about 67%, lipids about 11%, minerals about 4%, and sugars about 14% of the total dry weight. The sugars, however, appear to be entirely restricted to the vacuoles. as is also true of a part of the minerals and some of the nitrogenous compounds, especially the amino acids.

The properties of protoplasm are clearly as much a function of its ultimate physicochemical organization as of the specific compounds of which it is composed. A number of the properties of protoplasm are similar to those of gelatin, agar and other water-absorbing colloids (hydrophilic colloids). Among these are its elasticity. its variable viscosity, its capacity to absorb water, its capacity for reversible gelation, and the fact that its physical state may be markedly influenced by mechanical disturbances, high or low temperatures, or certain concentrations of various salts (electrolytes). Although protoplasm appears to have the organization of a hydrophilic colloid, its structural and dynamic complexity far transcends that of nonliving hydrophilic systems such as agar or gelatin sols or gels. William Seifriz and others postulated that protoplasm has a basically fibrillar structure, the submicroscopic fibrils (composed largely or entirely of complex proteins) overlapping and interlocking through molecular side chains within an aqueous medium. Electrolytes, carbohydrates, lipids and other constituents of the system may be dissolved or dispersed in the aqueous medium, dissolved in water held within the fibrils, or adsorbed at interfaces within the system. For a detailed treatment of the physics and chemistry of protoplasm see PROTOPLASM.

Protoplasmic Streaming. — In many plant cells the protoplasm is in active motion, the exact mechanism of which is unknown. In the simplest cases this movement consists of a rotation around the inner surface of the cell wall. Rates of streaming may range up to at least 19 in. per hour. Cyclosis is accelerated by increases in temperature up to the point at which injury occurs, and is retarded at lower temperatures, ceasing just above freezing. Protoplasmic streaming also ceases in the absence of oxygen.

3. Permeability. — Unlike the cell walls, which in most living cells are quite freely permeable to water and solutes, the cytoplasmic layer is more permeable to some substances than to others. In other words, cytoplasm is differentially permeable. This property of differential permeability resides largely in the surface layer of the cytoplasm in contact with the cell wall (plasmalemma), and the surface layer in contact with the vacuole (tonoplast). The cytoplasmic layers are usually relatively permeable to water and to certain solutes such as dissolved gases, and to some types of organic compounds. On the other hand, they are usually much less permeable to sugars and mineral salts. The permeability of the cytoplasmic membranes is a variable property, however, and under certain conditions solutes which ordinarily penetrate through these membranes slowly or not at all may enter or leave cells very rapidly.

4. Osmotic Relations. — If a flabby or flaccid plant cell (*i.e.,* one in which the cell sap exerts no pressure against the encompassing protoplasmic layer and cell wall), is immersed in pure water, inward diffusion of water (osmosis) occurs into the cell sap. Diffusion of the water takes place because the diffusion pressure of the water in the cell sap is less than that of the surrounding pure water by the amount of its osmotic pressure. If the osmotic pressure of the cell sap is 12 atm. (atmospheres, each of which is equivalent to a pressure of 14.7 lb. per square inch or 14.7 lb./inch^2) the diffusion pressure of the water in the cell sap is 12 atm. less than that of pure water at the same temperature and under the same pressure. The lo er diffusion pressure of the water in the cell sap results from the presence of solutes. As water enters the cell it exerts a turgor pressure against the protoplasm and cell wall, a pressure which also prevails throughout the mass of water within the cell. If the cell wall is elastic, as it usually is, some expansion will occur in the volume of the cell. As diffusion of water into the cell continues, turgor pressure gradually increases until eventually it is equal to the final osmotic pressure of the cell sap. At this point of dynamic equilibrium the diffusion pressures of the water in the cell sap and the surrounding water are equal, and the number of molecules entering the cell exactly equals the number passing out of the cell per unit of time. Subjection of water to an imposed pressure increases its diffusion pressure by the amount of the imposed pressure. In this example, disregarding the usually small effect of sap dilution as the cell expands, the diffusion pressure of the water in the cell sap is reduced 12 atm. because of the presence of solutes (the osmotic pressure is the index of this effect) and raised 12 atm. by the turgor pressure; hence its equilibrium diffusion pressure is the same as that of the pure water bathing the cell. If the same cell in a flaccid condition is immersed in a solution with an osmotic pressure of 5 atm., inward diffusion of water occurs but does not continue as long as in the preceding example.

Disregarding dilution, dynamic equilibrium is attained when a turgor pressure of 7 atm. prevails within the cell, because at that point the diffusion pressure of the water in the cell sap and that of the water in the solution are equal. As exemplified in the preceding examples, the effective physical quantity determining the direction of osmotic movement of water from cell to cell in plants or between a cell and an external solution is the diffusion pressure deficit of the water. This value is equal to the osmotic pressure of the contained water (which tends to hold the water in) less the turgor pressure to which it is subjected (tending to push the water out). In an unconfined solution (no membranes) the diffusion pressure deficit is equal to its osmotic pressure, since there is no turgor pressure. In a fully swollen or turgid cell the diffusion pressure deficit is zero, and the turgor pressure equals the osmotic pressure, and as much water leaves the cell as enters it; in a fully flaccid cell the turgor pressure is zero. and the diffusion pressure deficit is equal to the osmotic pressure; therefore much more water diffuses into the cell than goes out.

The osmotic pressures of plant cell saps mostly lie within a range of 5–40 atm. Much higher values occur in some halophytes, the maximum on record being 202.5 atm. in the leaf cells of saltbush (Atriplex confertifolia). The osmotic pressures of the cells of a given plant tissue may vary considerably with environmental conditions and the metabolic status of the cells; more or less regular diurnal or seasonal variations in osmotic pressure occur in the cells of many tissues.

In some kinds of cells water may, under certain conditions, pass into a state of tension (negative pressure). In such cells the diffusion pressure deficit is equal to the osmotic pressure plus the tension imposed on the water, and sometimes far exceeds the osmotic pressure of the cell sap. Osmotic movement of water always occurs from the cell of lower to the cell of greater diffusion pressure deficit unless some interfering or offsetting condition or mechanism prevents or counteracts such movement. Movement of water in plant tissues commonly occurs from cell to cell along diffusion pressure deficit gradients. The osmotic pressure, diffusion pressure deficit and turgor pressure are called the osmotic quantities of plant cells; all three of these physical quantities are necessary in any critical evaluation of the water relations of cells.

5. **Plasmolysis.**—If a partially turgid plant cell is immersed in a solution with a higher osmotic pressure than the cell sap, a slow shrinkage in the total volume of the cell ensues; *i.e*, water moves from the cell sap to the surrounding solution. When the lower limit of elasticity of the rigid cell wall is reached the protoplasmic layer begins to recede from the wall because of continued loss of water from the cell sap. This recession often continues until the protoplasm has shrunk to a more or less rounded sack in the centre of the cell, the space between the wall and the protoplasm becoming filled with the external solution. This phenomenon is called plasmolysis. Since immersion of a cell in a solution with an osmotic pressure just barely exceeding that of the cell sap should just initiate withdra al of the protoplasm from the cell wall, this phenomenon is the basis for one of the methods of measuring the osmotic pressure of plant cells.

6. Enzymes. — Numerous kinds of chemical transformations are constantly occurring in physiologically active plant cells. Many of these chemical reactions can be accomplished artificially, if at all, only by subjecting the reactants to drastic conditions such as high temperatures or extreme degrees of acidity or alkalinity. Yet these reactions occur efficiently and rapidly at ordinary temperatures in a protoplasmic medium which is neither strongly acid nor strongly alkaline. This is possible because of the accelerating effect of certain organic catalysts called enzymes, which are synthetic products of the protoplasm.

Two principal groups of enzymes occur in plants. Hydrolytic enzymes catalyze certain hydrolytic decomposition reactions such as digestive processes and also condensation reactions in certain synthetic processes. Desmolyzing enzymes catalyze various kinds of reactions such as those that involve breaking the bonds between carbon atoms, adding or removing atoms or atomic groups, and shifting atoms or groups of atoms from one part of a molecule to another. The enzymes participating in the various chemical steps of respiration are of the desmolyzing type (see below, *Respiration*). A very small amount of an enzyme can catalyze the transformation of an enormous quantity of substrate. The enzyme sucrase, for example, can catalyze the hydrolysis of 1,000,000 times its own weight of sucrose into glucose and fructose and still retain its catalytic properties.

Many enzymes catalyze the same reaction in both directions, but this is not true of all of them. Most enzymes are thermolabile and in a liquid medium are chemically destroyed at temperatures between 140° and 158° F. Some enzymes appear to consist solely of protein molecules; others of protein molecules to which some nonprotein (prosthetic) group is attached. The prosthetic groups of some enzymes appear to exist in the protoplasm apart from the protein fraction, in which case they are called coenzymes. Some coenzymes are related chemically to the vitamins. See also ENZYMES.

B. TRANSPIRATION

In spite of the indispensability of water for their growth and metabolism. most kinds of land plants—excepting only certain species native to arid habitats—are extremely inefficient in their utilization of water. An overwhelmingly large proportion of the water absorbed from the soil is not retained within the plant or used in metabolic processes but escapes in the process of transpiration. essentially a modified kind of evaporation. Although loss of water vapour, at least in limited amounts, can occur from any part of the plant exposed to the atmosphere, in general most transpiration occurs from the leaves. Leaf transpiration is of two types: (1) stomatal transpiration, in which water vapour loss occurs through the stomates; and (2) cuticular transpiration, in which evaporation of water takes place directly from the surface of epidermal cells through the cuticular layer which, although relatively impervious to water, does permit the passage of limited quantities. In most species stomatal transpiration accounts for 90% or more of the water vapour loss from leaves. Through the investigations of Stephen Hales, in 1i27, transpiration was the first major plant process studied from essentially a modern experimental viewpoint.

1. Physiology of **Stomates.**—The stomates are minute, elliptical pores which occur in the epidermis of plants, being most abundant in leaves. Every stomate is surrounded by two distinctive epidermal cells called guard cells. Open stomates are the principal pathways through which gaseous exchanges occur between a leaf and the atmosphere.

The principal gases which diffuse into or out of a leaf through the stomates are water vapour, carbon dioxide and oxygen. When the stomates are closed all gaseous exchanges between a leaf and its environment are greatly retarded. The size of a fully open stomate varies greatly according to species. Among the largest knoan stomates are those of Zebrina *pendula* whose axial dimensions average $31 \times 12\mu$ ($1\mu =$ ——— in.). The number of stomates may range from a few thousand per square centimetre of leaf surface in some species to over a hundred thousand per square centimetre in others. In many kinds of plants stomates occur in both the upper and lower epidermis, usually being more abundant in the lower. In numerous other species, especially trees and shrubs, they are present only in the lower epidermis. In aquatic plants with floating leaves stomates occur only in the upper epidermis.

The total combined area of the fully open stomates is only 1%–3% of the total leaf area. Despite this fact, rates of stomatal transpiration are often 50%, and sometimes more, of the evaporation from a free water surface under comparable conditions. Much more important is the fact that the rate of diffusion of carbon dioxide, essential in photosynthesis (see below), into the leaf through the stomates is much greater than through an equivalent portion of the area of a fully exposed carbon dioxide absorbing surface. H. T. Brown and F. Escombe in 1900 showed that the high diffusive capacity of stomates in proportion to their area is in accord with the principles of the diffusion of gases through multiperforate septa. Diffusion rates through small openings vary as the perimeter, not the area; therefore. the smaller the aperture the greater its diffusive capacity relative to its area. As a result a gas may diffuse nearly as rapidly through a septum pierced with a number of small apertures. whose combined area represents only a small proportion of the septum area, as through an open surface equal in area to the septum. Since diffusion of gases through stomates is proportional to the perimeter of the pore, diffusion rates through a partially open stomate are almost as great as when the stomate is fully open.

Increase in the turgidity of the guard cells results in opening of the stomates; decrease in their turgidity results in their closure. In general stomates are open in the daytime and closed at night. although there are many exceptions. The mechanism whereby stomates open in the light and close in its absence seems to be principally an osmotic one. Upon illumination the hydrogen ion concentration of the guard cells decreases. This favours the conversion of insoluble starch in the guard cells into soluble glucose-1-phosphate by the enzyme phosphorylase. The resulting increase in the osmotic pressure of the guard cells causes an increase in their diffusion pressure deficit. Osmotic movement of water from adjacent epidermal cells, in which there is no appreciable daily variation in osmotic pressure, takes place in the guard cells. A thicker ridge of cell wall occurs on the stomate side of the guard cells, and as the turgor of the guard cells increases the cells "buckle" and part, thus opening the stomate. With the advent of darkness or even of a markedly reduced light intensity. the reverse train of processes is induced in the guard cells, leading to stomatal closure. Since light of low intensity is relatively less effective in inducing stomatal opening, stomates usually do not open as wide on cloudy as on clear days and often do not remain open for as much of the daylight period. Deficiency of water within the plant induces partial to complete closure of the stomates. During periods of drought stomates therefore remain closed much or all of the time regardless of the light intensity to which the plant is exposed. Stomatal opening does not occur in most species at temperatures approaching 32° F. Therefore in cold or even cool weather stomates may remain closed even when other environmental conditions favour their opening. Nocturnal opening occurs at times in some species, but the conditions resulting in such stomatal behaviour have not been adequately investigated.

Dynamics of Stomatal Transpiration.—In most kinds of plants the cells of the mesophyll do not fit together tightly and the intercellular spaces between them are occupied by air. A labyrinth of these air-filled spaces is thus present in a leaf, bounded by the water-saturated cell walls of the mesophyll. Evaporation of water takes place from the wet cell walls into the intercellular spaces. If the stomates are closed the only effect of this evaporation is the saturation of the intercellular spaces nith water vapour. When the stomates are open, homever, diffusion of water vapour may occur through them into the outside atmosphere. Such diffusion always takes place unless the atmosphere has a vapour pressure equal to or greater than that within the intercellular spaces. an uncommon condition during the daylight hours of clear days. The physical processes of evaporation of water from wet mesophyll cell malls and its subsequent diffusion from the intercellular spaces through the stomates into the atmosphere are, therefore. the tno main steps in stomatal transpiration.

2. Environmental Influences on Transpiration.—Because of its usually controlling influence on the opening and closing of stomates, light is a factor of prime importance in influencing the rate of transpiration. Stomatal transpiration is largely restricted to the daylight hours; hence daytime transpiration is usually many times greater than nighttime transpiration, which is largely or entirely cuticular. Light also has a secondary effect on transpiration through its influence on leaf temperatures, since leaves in direct sunlight usually have temperatures one to several degrees higher than that of the surrounding atmosphere.

The rate of diffusion of water vapour through open stomates depends upon the steepness of the vapour pressure gradient betneen the intercellular spaces and the atmosphere. Assuming open stomates. therefore, the greater the atmospheric humidity (vapour pressure) for any given vapour pressure just below the stomatal pores in the intercellular spaces. the less the rate of transpiration. Temperature affects the rate of transpiration principally because of its differential effect upon the vapour pressures in the intercellular spaces and the atmosphere.

Although leaf temperatures do not follow atmospheric temperatures exactly, in general, increase of atmospheric temperature results in a rise of leaf temperature. Assuming a warm, clear day and an adequate soil water supply, increase in temperature results in an increase in the vapour pressure in the intercellular spaces. Such a rise in vapour pressure occurs because the vapour pressure necessary to saturate air increases with rise in temperature, and the extensive evaporating surfaces of the cell walls bounding the intercellular spaces make it possible for the intercellular spaces to be maintained in an approximately saturated condition most of the time. Rise in temperature ordinarily has little or no effect on the vapour pressure of the atmosphere. Consequently the vapour pressure gradient through the stomates is steepened and the rate of outward diffusion of water vapour increases.

Transpiration rates on windy days are usually greater than on otherwise comparable but quiet days. A gentle breeze is relatively more effective in increasing the transpiration rate than winds of greater velocity. In very quiet air local regions of relatively high humidity may build up in the vicinity of transpiring leaf surfaces. Such localized zones of relatively high vapour pressure retard transpiration unless the air movement is adequate to prevent such an accumulation of water vapour molecules. The bending. twisting and fluttering of leaf blades, and the swaying of branches in a wind also contribute to increasing the transpiration rate.

Soil water conditions also influence the rate of transpiration. Whenever soil conditions are such that the rate of absorption of water is retarded, a corresponding diminution in transpiration rate soon follows.

3. Significance of Transpiration. — Transpiration rates of temperate zone plants may range up to values of about 5 g. per square decimeter (about $15\frac{1}{2}$ sq.in.) of leaf area per hour. Considerable interest also attaches to the quantities of water transpired per acre of crops. grassland or forest. An acre of corn, for example, transpires water equivalent to 15 acre-inches in a growing season. Tremendous variations occur in such values from season to season, however. depending upon climatic conditions. The quantities of water vapour transpired by vegetation-covered areas of the earth's surface are often of sufficient magnitude to have important effects on meteorological conditions.

Much fruitless discussion has raged over the question of whether transpiration is detrimental or beneficial to plants. The extreme viewpoints are (1) that the process is an unavoidable evil; and (2) that it is a physiological necessity. Some of the incidental effects of transpiration are advantageous to the plant, but none is indispensable for its survival or even for its normal physiological operation. Likenise, some of the incidental effects of transpiration are detrimental to the plant, but plants have transpired and survived for untold centuries.

Transpiration is a necessary consequence of the relation of water to plant structure. Terrestrial green plants cannot survive unless they obtain carbon dioxide from the atmosphere. Whatever course the evolution of green plants might follow, their structure must always remain such that carbon dioxide can reach interior cells of the leaf. The principal carbon dioxide absorbing surfaces of terrestrial vascular plants are the moist mesophyll cell walls bounding the intercellular spaces of the leaves. Ingress of carbon dioxide to these spaces occurs almost entirely through open stomates. When the stomates are open. outward diffusion of water vapour is unavoidable, and this process of stomatal transpiration accounts for most of the loss of water by plants. Transpiration is, therefore, in itself an incidental phenomenon. Despite this fact it often has marked indirect effects on other physiological processes occurring in the plant, especially photosynthesis and gronth, because of its influence on the internal water relations of the plant.

4. Guttation. — The exudation of drops of water at the tips or margins of the leaves of many species of herbaceous plants can often be observed, especially in the early morning on a spring day. This phenomenon, called guttation, also occurs in some woody plants. The exuded water is not pure but contains traces of sugars and other solutes. Guttation occurs from special glands called hydathodes, which resemble enlarged stomates. In most species water loss by guttation is negligible compared with water loss by transpiration.

C. Translocation of Water

In land plants the water absorbed from the soil moves to all living parts of the plant. The most striking examples of upward translocation of water occur in trees. One of the tallest known living trees is a specimen of coast redwood (Sequoia sempervirens) which has attained a height of 364 ft. In this tree water ascends to an elevation of nearly 400 ft., since the roots extend for at least several feet into the soil. Many other individual trees of this species and of several others exceed 300 ft. in height. The mechanism of the ascent of sap in plants, and especially in tall trees, has long been one of the classical problems of plant physiology.

1. Mechanics of Water Movement. — The upward movement of water in plants occurs in the xylem, which in the stems of trees and shrubs is identical with the wood. In the trunks and larger branches of a tree, however, sap movement is restricted to a few of the outermost annual layers of wood. For this reason hollow trees, in which most of the central core of heartwood has disintegrated, can remain alive indefinitely. The xylem of any plant constitutes a unit system which extends from just back of every root tip through all the intervening root and stem branches to the mesophyll of the leaves. In angiosperms most translocation of water occurs through vessels. which are elongated tubelike structures in which cross walls are of relatively infrequent occurrence. In gymnosperms movement of water occurs solely through spindle-shaped cells called tracheids, which may be as much as five millimetres in length. Small. often rounded, thin areas occur in the malls of vessels and tracheids which are contiguous with other vessels or cells; these pits are structurally of several types but all of them appear to facilitate passage of water from one xylem element to adjacent ones.

Root Pressure. — If the stem of an herbaceous plant is cut off, a slow exudation of sap often occurs from the xylem tissues at the cut surface of the stump. A similar phenomenon occurs in many woody plants, such as the maple, birch, currant and grape, especially in the spring. A vigorous grapevine often loses a quart or more of sap per day after spring pruning. The exudation of sap results from a pressure originating in the roots, called root pressure. There are several reasons, however, why root pressure cannot be the principal mechanism operating in the upward transport of water in plants: (1) there are many species in which this phenomenon — the exudation of sap — does not occur; (2) the magnitude of measured root pressures seldom exceeds 2 atm. (about 30 lb. per square inch), which could not motivate a rise of water for more than about 60 ft.; (3) known rates of flow under the influence of root pressure are inadequate to compensate for known rates of transpiration; (4) root pressures are usually present in woody plants only in the early spring; during the summer period when transpiration rates, and therefore rates of sap transport, are greatest, root pressures are negligible or nonexistent. Root pressure does account for some upward movement of water in certain species of plants at some seasons, but it represents only a secondary mechanism of water transport.

Ascent of Sap. — Molecules of water, although ceaselessly in motion, are also strongly attracted to each other. This property of a liquid is called cohesion. The cohesion of water is the cornerstone of an important theory of the ascent of sap in plants. The postulated mechanism is relatively simple. Evaporation of water from the walls of the mesophyll cells of leaves results in an increase in the diffusion pressure deficit of the mesophyll cells. Resulting intercellular movements of water cause an increase in the diffusion pressure deficit even of those mesophyll cells not directly exposed to the intercellular spaces. The increased diffusion pressure deficit of the cells abutting directly upon xylem elements in the veinlets of the leaf induces movement of water from the vessels or tracheids into the adjacent cells. Whenever transpiration is occurring at appreciable rates, water does not enter the lower ends of the xylem conduits in the roots as rapidly as it passes out of the xylem vessels or tracheids into mesophyll *cells at the upper end of the* water-conductive *system, consequently the* water *in the xylem ducts is stretched into taut threads; i.e., passes into a state of tension. Each column of* water *behaves like a tiny steel wire which is stretched. Because of their saturated condition, cross* walls *in the xylem do not interfere* with *the continuity of the water. The tension is propagated along the entire length of the water columns to their terminations just back of the root tips, causing entry of water from adjacent root cells (see below. Absorption of Water). The tension can be sustained by the water threads because of the cohesion between the water molecules, operating in conjunction with adhesion of the boundary layers of* water *molecules to the walls of the xylem ducts. The existence of* water *under tension in vessels and tracheids has been confirmed by direct microscopic observation and in other ways. Conservative calculations indicate that a cohesion of 30 to 50 atm. would be adequate to allow conduction of water to the topmost leaf of the tallest known tree. However, under conditions of internal water deficiency, tensions considerably in excess of 50 atm. probably prevail in the water columns of many plants. Actual measurements of the cohesion of water in physical systems indicate* with *a high degree of probability that tensions of this magnitude can develop in the water columns of plants.*

2. *Absorption of Water.* — *Soil Water Conditions.*—Since *soil particles never fit together tightly, there is a certain amount of space betneen them. This pore space varies from about 30% of the soil volume in sandy soils to about 50% in clay soils. The pore space may be occupied entirely by air, as in dried soils, or entirely by* water. *as in saturated soils. but is commonly occupied partly by air and partly by* water. *In a soil in which the mater table lies relatively close to the surface, considerable quantities of water may rise into its upper layers and become available to plants. In many soils, especially in arid regions. there is no water table, and in many others. even in humid regions, the* water *table is continuously or intermittently too far below the soil surface to be an appreciable source of water for most plants. In such soils the only water available to plants comes through natural precipitation or artificial irrigation.*

If rain falls on a dry, homogeneous soil the water will become rapidly distributed to a depth which will depend on the amount of water which falls per unit area and the type of soil. After several days, further deepening of the moist blanket of soil extending down from the ground surface will virtually cease because downward *capillary movement of water has become extremely slow* or *negligible. The boundary between the moist layer of soil and the drier zone underneath will be quite sharp. At this equilibrium condition the water content of the moist soil layer is essentially uniform throughout. The water content of a soil in* this condition *is termed the field capacity. A soil at its field capacity, although relatively moist, is also well aerated; hence soil water contents in the vicinity of the field capacity are the most favourable for the development of most kinds of plants.*

A considerable proportion of the water in any soil is unavailable to plants. The permanent wilting *percentage, an index of the soil water unavailable in growth, is measured by* allowing *a plant to develop with its roots in soil enclosed in a waterproof pot until the plant passes into a state of permanent wilting. The water content of the soil at this point is its permanent wilting percentage. The range of permanent wilting percentages is from* less *than 5% in very sandy soils to about 20% in clay loams. Therefore, sandy soil gives up a greater portion of its moisture; only about 5% of its total moisture content is unavailable to plants. The permanent* wilting *percentage of a given soil is about the same, regardless of the kind of test plant used.*

The diffusion pressure deficit of the water in soils varies with the soil water content. In most soils it is virtually zero at saturation, less than 1 atm. at the field *capacity, and about* 15 *atm. at the permanent wilting percentage. As the water content of a soil drops below its permanent wilting percentage, its diffusion pressure deficit increases at an accelerating rate, soon attaining a value of hundreds of atmospheres; it is for this reason that the permanent wilting percentage is an index of the soil water which is unavailable in plant growth.*

Relation of Root Growth to Water Absorption. — *The successively smaller branches of the root system of a plant ultimately terminate in the root tips, of which there may be thousands or millions on a single plant. The term root tip refers to the region extending back from the actual termination of the root for a distance of several to many centimetres. The terminal zone of a root tip is the dome-shaped root cap, just back of which are the regions of cell division and elongation (see below, Growth). Just back of these regions, in most species. is the root hair zone. Each root hair is a projection from an epidermal cell of which it remains an integral part. A single root tip may bear thousands of root hairs, each of* which *may be from a few millimetres to a* centimetre *or more in length. A root hair is generally a short-lived structure. but* new *ones are constantly developing as the root advances through the soil.*

Most absorption of water occurs at the root tips, especially in the root hair zone. since the older portions of roots become covered with *cutinized or suberized layers which are virtually impermeable to water. Whenever the diffusion pressure deficit of root hairs and other peripheral cells of the root tip exceeds that of the soil water, movement of water into the root cells occurs. If the soil is above the field capacity, water may move from more remote portions of the soil by capillarity toward the region of absorption; the supply of* water *to root tips is largely or entirely maintained in this* way. *Elongation of the root tips, although slower in most species in relatively wet soils. also helps maintain their contact with untapped portions of the soil water. Many plants* grow *for a great part of the time in soils* with *a water content* between *the field capacity and the permanent wilting percentage. In this range of soil* water *contents, capillary movement of mater is too* slow *to maintain an adequate supply of* water *to rapidly absorbing root tips, and after most of the nater on the soil particles in contact with a root tip is absorbed, it cannot be replaced in significant quantities. In such soils it is the continued elongation of the root tips which maintains their contact with available soil water. The numerous root tips may be pictured as slowly progressing through the soil, absorbing* water *from the particles* with *which they come in contact. The aggregate increase in length of the root system of a rye plant averages 3.1 mi. per day. Calculations show that daily root growth of this plant would permit sufficient absorption of water from soils at the field capacity to compensate for daily transpirational water loss.*

Mechanism of Water Absorption.—The *tension generated in the* water *columns of a plant as an indirect result of transpiration is propagated to the terminations of the xylem ducts in the root* tips. *As soon as the tension in the* water *columns exceeds the diffusion pressure deficit of adjacent cells in the root tip, water passes from those cells into the xylem. This engenders further cell to cell movement of water in a lateral direction across the root tip* with *the presumable result that a gradient of diffusion pressure deficits. consistently increasing from the epidermal cells to the root xylem, is established. As soon as the diffusion pressure deficit of the peripheral cells of the root exceeds that of the soil* water. *entrance of mater from the soil begins. Essentially, the long chain of* water *molecules is "drawn" upward by transpiration in the leaves, and water from the soil is "taken in" through the root hairs.*

The process just described accounts for most of the absorption of water by plants. The phenomenon of root pressure, previously described, involves an absorption mechanism which is localized in the roots. Absorption of this type occurs only when transpiration is low *and the soil is relatively moist. Although xylem sap is relatively dilute, its osmotic pressure is often greater than the diffusion pressure deficit of the soil water. This leads to the establishment of a gradient of diffusion pressure deficits across the cortex and other tissues of the root tip along which water moves from the soil to the xylem.*

Environmental Factors *Influencing* Water Absorption. — *Because of their reciprocal relation any factor* which *influences the rate of transpiration influences the rate of absorption; the converse is also true. In addition the rate of absorption is also influenced by* certain soil conditions. Within limits the greater the available soil water supply the greater the possible rate of absorption. Extremely high soil water contents decrease absorption rates in many species because of deficient soil aeration. Low soil temperatures retard the rate of absorption of water by many species. The rate of water absorption by sunflower plants, for example. is rapidly reduced as the soil temperature drops below 55° F. Deficient aeration. characteristic of wet soils, retards water absorption in many species. In such soils the oxygen concentration is lower and the carbon dioxide concentration is higher than in the atmosphere. This retarding effect on water absorption is correlated with a retardation in the rate of root respiration. The presence of solutes in appreciable concentrations in the soil solution also retards or checks water absorption by roots. In most soils the solute concentration is too low to have any appreciable effect on water absorption, but in saline or alkaline soils the influence of this factor may be so pronounced that only a few species of plants are able to survive.

Relative Rates of Water Absorption and Transpiration.—On a clear, warm day, when transpiration rates are high, the rate of water absorption usually lags behind the rate of transpiration, largely because of the resistance of the root cells to the passage of water. As a result there is a gradual increase in the tension in the water columns and a gradual diminution in the water content of the plant, especially of the leaves, during the day. This leads to the partial loss of turgor pressure by the leaf cells, a condition called incipient wilting. Sometimes, especially on clear, hot summer afternoons, the decrease in water content of the leaves is sufficient to induce visible wilting. If the soil water supply is adequate, absorption of water during the night exceeds nocturnal transpiration loss, and the leaf cells gradually regain their turgor. Visible wilting caused by a temporary excess of transpiration over absorption is called temporary wilting, which is distinguished from permanent wilting, caused by a soil water deficiency. Plants automatically recover from temporary wilting during the night, but will not recover from permanent wilting unless the soil water supply is replenished.

D. Metabolism

1. Carbohydrate Metabolism.— The dry matter content of a plant tissue can be determined by drying it at 212° F. The dry residue remaining after the evaporation of water can be further separated into two fractions by incinerating it at about 1,100" F. The bulk of the dry matter, representing combustible organic constituents, disappears, leaving only a small mineral residue called the ash, which is derived from mineral salts absorbed from the soil.

An adequate explanation of the origin of the bulk of the dry matter of plants long eluded students of plant life. As a result of the investigations of Joseph Priestley, Jean Senebier, Jan Ingen-Housz, N. T. de Saussure and others in the late 18th and early 19th centuries, the gaseous exchanges between green plants and the atmosphere were first clearly envisaged. Green parts of plants, exposed to light, were found to utilize carbon dioxide and release oxygen. Nongreen parts, whether in light or dark, and green parts in the dark were found, like animals, to release carbon dioxide and consume oxygen. These gaseous exchanges are the external manifestations of the processes now known as photosynthesis and respiration, respectively. Photosynthesis occurs only in green plant organs exposed to light. Respiration occurs in all living plant tissues, green or nongreen, in light or dark. The fact that green plants usually lose oxygen and use carbon dioxide in the light does not mean that no respiration occurs in such organs in the light, but merely that the rate of photosynthesis exceeds the rate of respiration. Although De Saussure in 1804 recognized that utilization of carbon dioxide by plants contributed to their increase in dry weight, it was not until Julius von Sachs, in 1862, discovered the appearance of starch in the chloroplasts of leaf cells as an accompaniment of the consumption of carbon dioxide that the relation of the gaseous exchanges of plants to their carbohydrate metabolism began to be adequately realized.

2. Photosynthesis.— In the process of photosynthesis certain carbohydrates are synthesized from carbon dioxide and water in the chloroplasts of living plant cells, oxygen also being a product, and light the source of energy. The summary chemical equation for the process is:

$$6CO_2 + 6H_2O + 673 \text{ kg.cal. of radiant energy} \longrightarrow C_6H_{12}O_6 + 6O_2$$

A hexose sugar is conventionally considered to be the basic carbohydrate product of photosynthesis, although in actuality the situation is much more complex. Most of the carbon dioxide used diffuses into the leaf through the stomates and dissolves in wet cell walls bordering the intercellular spaces, from where it diffuses in solution to the chloroplasts. In most species less than 1% of the water absorbed is used in photosynthesis. Most of the oxygen liberated passes out of solution into the intercellular spaces, from where it diffuses through the stomates into the atmosphere. For details of the synthesis of carbohydrates see PHOTOSYNTHESIS.

Plant *Pigments.*—In the higher plants photosynthesis occurs only in the chloroplasts, which are green ellipsoidal bodies about 5 μ in diameter. A single mesophyll cell may contain hundreds of chloroplasts. The green colour of chloroplasts and of leaves is because of the presence in the plastids of chlorophyll, of which there are two kinds: chlorophyll a ($C_{55}H_{72}O_5N_4Mg$) and chlorophyll b ($C_{55}H_{70}O_6N_4Mg$). Most leaves contain from two to three times as much chlorophyll a as chlorophyll b. Both chlorophylls have been extracted in pure form from the leaves of over 200 species. The structural formulas of the chlorophylls were determined in 1936 by H. Fischer and S. Breitner. In the angiosperms chlorophyll is, with rare exceptions, synthesized only in the light; in plants of all other groups it can be made either in light or dark. Among the substances which must be present in the cells for normal chlorophyll synthesis are oxygen, carbohydrates, nitrogen, magnesium, iron and water.

The role of chlorophyll seems to be a twofold one: it absorbs light of certain wave lengths, principally in the blue-violet and short red regions of the spectrum. which is used as a source of energy in photosynthesis, and it is a transitory participant in some step of the reaction, presumably acting as a catalyst (see also CHLOROPHYLL, CHEMISTRY OF).

The chloroplasts also contain the yellow pigments carotene ($C_{40}H_{56}$), and the xanthophylls (mostly $C_{40}H_{56}O_2$). The leaves of any angiosperm which have developed in the dark are yellow as a result of the presence of these pigments. Carotene is the precursor of vitamin A. one molecule of carotene being split into two molecules of vitamin A by a simple hydrolysis reaction. Carotene, the xanthophylls and certain other chemically related red and yellow pigments are collectively called the carotinoids. In some plant organs, such as carrot roots, carotinoid pigments occur in the amorphous or crystalline state. The cell sap anthocyanins constitute the other principal group of plant pigments; they are responsible for most of the red, blue and purple colorations of flowers, fruits and other plant parts. Both the carotinoids and anthocyanins play a prominent part in the autumnal coloration of leaves (see ANTHOCYANINS AND ANTHOXANTHINS; PLANT COLORATION).

Factors *Influencing the* Rate of *Photosynthesis.*—F. F. Blackman's (1905) "principle of limiting factors" has assisted materially in the interpretation of the effects of various factors on the rate of photosynthesis. This principle was stated by its author as follows: "When a process is conditioned as to its rapidity by a number of separate factors, the rate of the process is limited by the pace of the 'slowest' factor." This principle, which also holds for other physiological processes, does not admit of too rigorous an application, but in general the concept is valid that the rate of a physiological process is largely controlled by the factor present in relative minimum, the so-called "limiting factor."

Carbon dioxide constitutes only 0.03% by volume of the atmosphere. marked deviations from this value seldom occurring. In the air stratum just above the suriace of rich forest or agricultural soils, however, concentrations several times the usual one sometimes occur, as a result of the upward diffusion of carbon dioxide released in the respiration of soil organisms. With increase in the carbon dioxide concentration of the atmosphere, the rate of photosynthesis increases until some other factor becomes limiting. If the natural concentration of carbon dioxide in the atmosphere were higher than 0.03%. most plants, much of the time, would photosynthesize at a more rapid rate than they do. Very high concentrations of carbon dioxide (15% or more), however, cause a retardation in photosynthesis.

Photosynthesis can occur in visible light from any source, provided its intensity is sufficiently great. The minimum light intensity at which sufficient photosynthesis occurs during an average day's length to be in excess of the consumption of carbohydrates in respiration during 24 hours—no plant can long survive at intensities less than this—differs according to species. In tree seedlings this minimum light intensity ranges from about 1% of full sunlight intensity in some shade species to about 5% in some sun species; in larger plants the minima are probably greater. For measurements made on a leaf or group of leaves, all of which are well exposed to light, the rate of photosynthesis rises with increase in light intensity until some other factor becomes limiting. At the atmospheric concentration of carbon dioxide, maximum rates of photosynthesis in single leaves are attained in many species at one-fourth to one-third of full sunlight intensity, and in some shade species at still lower values. Very high light intensities cause a retardation in photosynthesis, a phenomenon termed solarization.

The rate of photosynthesis for an entire tree, or for a plot of vegetation, increases consistently with increase in light up to the maximum sunlight intensity, which at noon on a clear summer's day in mid-temperate latitudes approximates 1.3 g.cal. per square centimeter per minute (equivalent to about 9,000 foot-candles). Even in full sunlight many interior leaves of an apple tree, for example, cannot photosynthesize at their maximum capacities because they are shaded by peripheral leaves. The lower the light intensity, the greater the proportion of the leaves of which this will be true. Hence the greater the intensity of the light, the greater the average photosynthesis per unit of leaf area and the greater the total photosynthesis per tree up to the limits of sunlight intensity. All wave lengths of light are not equally effective in photosynthesis. For equal intensities of light incident on the leaf, maximum photosynthesis occurs in the orange—short red region, with a secondary maximum in the blue. Rates in the green and yellow regions are lower, but still very appreciable.

The daily rate of photosynthesis is also influenced by the daily duration of the light period (photoperiod). One reason certain crops can develop to maturity during the short growing seasons of high latitudes is that more sugar can be synthesized during the long photoperiods than during the shorter photoperiods of lower latitudes (see below, *Photoperiodism*).

Photosynthesis occurs over a wide range of temperatures, but in temperate zone plants this process takes place at relatively rapid rates in the temperature range 50°–95° F. Increase in temperature. in general, results in an increase in the rate of photosynthesis, if no other factors are limiting the process. In nature, however, the effect of an increase in temperature on the rate of photosynthesis is often not fully realized because of the limiting effect of some other factor. Very commonly the factor which prevents a temperature rise from being fully effective in increasing the rate of photosynthesis is the carbon dioxide concentration of the atmosphere. but low light intensity and low water supply also often act as limiting factors.

Reduction in the water content of a plant causes a retardation in the rate of photosynthesis. This effect is not primarily a result of a deficiency of water as a raw material used in photosynthesis, but of certain indirect effects such as a reduction in the diffusive capacity of the stomates, and a decrease in the hydration of the protoplasm. In young apple trees marked diminution in the rate of photosynthesis occurs long before wilting is apparent, although even in wilted leaves some photosynthesis continues. When uater is applied to the soil, wilted apple leaves recover their turgidity in a few hours, but the original rate of photosynthesis is not regained for several days (G. W. Schneider and N. F. Childers, 1941).

Conditions within the plant also affect the rate of photosynthesis. Among the internal factors which may influence photosynthesis are peculiarities of leaf anatomy, chlorophyll content of the cells, hydration of protoplasm, other "protoplasmic factors," and the accumulation of carbohydrates within the cells.

Mechanism of Photosynthesis.—From the standpoint of fundamental chemistry photosynthesis is, in essence, an oxidation-reduction reaction between carbon dioxide and water. The carbon dioxide is reduced and the water is oxidized, largely as a result of the transfer of hydrogen atoms from water to carbon dioxide. Because the energy content of the products (carbohydrates and oxygen) is greater than that of the reactants (carbon dioxide and water), energy must be supplied from an outside source. In actuality the energy source is light, and the process is thus a photochemical one. As is true of many metabolic processes, photosynthesis is a complex process, embracing numerous sub-reactions, and is by no means entirely understood. Three major sub-reactions which are generally recognized are: (1) photolysis (splitting by light) of water; (2) photosynthetic phosphorylation; and (3) carbon dioxide fixation. All three of these reactions occur in the chloroplasts (D. I. Arnon, 1958).

Substantial evidence exists that the light energy is used in splitting the water molecules and that chlorophylls play a role in this stage of photosynthesis. R. Hill (1937) showed that illumination of a suspension of chloroplasts in water in the presence of certain hydrogen acceptors results in the evolution of oxygen. This phenomenon, now generally called the Hill reaction, can be represented chemically as follows, *A* representing a hydrogen acceptor:

$$2H_2O + 2A \xrightarrow[\text{chloroplasts}]{\text{light}} 2A\ H_2 + O_2$$

The Hill reaction has also been shown to occur in suspensions of grana from disintegrated chloroplasts, as well as in suspensions of intact chloroplasts. It has been shown experimentally that the oxygen released in this reaction comes from the water molecules. The Hill reaction appears to represent, in essence, the photolysis of water stage of photosynthesis.

Photosynthetic phosphorylation is a process in which adenosine diphosphate is converted into adenosine triphosphate in the chloroplasts. This compound and triphosphopyridine nucleotide, which is reduced simultaneously with the synthesis of adenosine triphosphate, provide the necessary "assimilatory power" used in the final step in photosynthesis, which is the fixation of carbon dioxide. M. Calvin and A. A. Benson (1949) and others consider that the compound phosphoglyceric acid is a key intermediate compound in the fixation of carbon dioxide stage of photosynthesis. (See PHOTOSYNTHESIS.)

Biologzcal Significance of *Photosynthesis*.—World-wide cessation of photosynthesis would soon result in the disappearance of all plants and animals, including man, with the negligible exception of a few species of autotrophic bacteria, because this process provides both the energy and organic substance capital of the biological world. Directly or indirectly, all plants and animals, with the minor exception just noted, obtain from green plants oxidizable carbon compounds ("food"). which alone can be used as a source of energy (see below, Respiration) by living organisms in growth, movement and the accomplishment of metabolic processes. All such oxidizable carbon compounds are the direct or derivative products of photosynthesis. Carbohydrates, fats and proteins all are synthesized by chains of chemical transformation from the hexose sugars produced in photosynthesis, and retain within their molecules chemical energy primarily incorporated in hexose molecules by the transformation of radiant energy from the sun. In some food chains carnivorous animals prey upon smaller or weaker carnivorous animals, which in turn prey upon smaller or weaker animals, but ultimately all such chains always lead to animals which obtain their food from green plants. Photosynthesis not only supplies the energy upon which living organisms operate, but all of the organic substance out of which bodies of plants and animals are constructed consists of the direct or derivative products of photosynthesis.

Magnitude and *Efficiency* of *Photosynthesis*.—Under favourable conditions rates of photosynthesis often approximate 10–15 mg. of hexose per square decimeter of leaf surface per hour. Corn plants yielding 100 bu to the acre synthesize about 8,700 kg. (nearly 10 tons) of sugar in a growing season. This represents the transformation of about 33,000,000 kg cal. of radiant energy into chemical energy Nearly one-fourth of this is oxidized in respiration and most of the rest has been transformed into starch, cellulose and other compounds before the plants are mature. The world production of sugar by land plants has been estimated by H. Schroeder (1919) at 4×10^{13} kg. annually which represents the transformation of 1.6×10^{17} kg.cal. of radiant energy into chemical energy.

Despite the utter dependence of the entire organic world upon photosynthesis, only a relatively small percentage of the light incident on plants is used in the process. Of the radiant energy falling on the acre of corn mentioned above only 1.6% is utilized in photosynthesis. Under certain conditions, particularly nhen the light intensity is low, the efficiency of the process in utilizing incident light may be as high as 5%, but rarely, if ever, is greater than that under natural conditions. From a theoretical standpoint the quantum yield of photosynthesis is of considerable significance, but this question has not been settled with finality. Results of various investigators are not in agreement on the magnitude of this quantity, values ranging from 0.1 to 0 25 molecule of carbon dioxide reduced per quantum of light absorbed having been recorded.

Synthesis of Other *Carbohydrates*.—Sucrose is universally present in plants, and is the most abundant of plant sugars. In some plant tissues (sugar cane, sugar beet) it may constitute as much as 20% of the fresh weight, but its concentration is usually lower. Upon hydrolysis sucrose yields an equal number of glucose and fructose molecules, both hexose sugars. In rapidly photosynthesizing leaves the sucrose content usually increases during the daytime; during the night hours the concentration decreases because of its continued translocation out of leaves to other parts of the plant.

Starch is a complex, insoluble carbohydrate which is synthesized in many, but not all, species of plants. In green leaves starch synthesis occurs in the chloroplasts and apparently is initiated whenever the concentration of hexoses exceeds a certain critical value. Starch is a long chainlike carbohydrate molecule composed of hundreds of α D-glucose residues. It is synthesized in plant cells from glucose-1-phosphate by a specific enzyme Considerable quantities of starch accumulate in green leaves during the occurrence of photosynthesis, but most of it is converted into soluble carbohydrates and translocated out of the leaves at night. Starch is also synthesized in many other organs of plants, as for example in potato tubers, from soluble carbohydrates translocated from the leaves. In the nongreen organs of plants, starch synthesis occurs in the colorless leucoplasts. Starch usually occurs in plant cells as microscopically visible starch grains.

Cellulose, the importance of nhich as a cell wall constituent has already been mentioned, is also synthesized from glucose. Cellulose molecules are long chainlike molecules built up from hundreds of β D-glucose molecules. Cellulose is the most abundant organic compound present on the earth. Among the other more important carbohydrates synthesized in plants are pentosans, dextrins, inulin, hemicelluloses, pectic compounds, gums, mucilages, glycosides and tannins.

3. Fat Metabolism.— Fats and fatlike substances, collectively called lipids, are universal constituents of plant cells. All lipids contain the elements carbon, hydrogen and oxygen; some of the more complex ones, the phosphatides, also contain phosphorus and nitrogen. Phosphatides and perhaps other lipids are essential ingredients of the protoplasm. Fats (called oils in the liquid state) accumulate in various organs of plants, especially in seeds and fruits, in which they constitute a reserve supply of food. Upon germination of fatty seeds the oils are digested and used in the processes of respiration and assimilation. Many vegetable oils are important items of commerce; among these are castor bean, rape, sunflower, linseed, peanut, corn, cotton, coconut, palm and olive oils. Lipids apparently can be synthesized in any living plant cell.

Only the synthesis of the fats is well enough understood to warrant discussion. There are three main steps in this process: (1) synthesis of glycerol from carbohydrates; (2) synthesis of fatty acids from carbohydrates; and (3) condensation of glycerol and fatty acid molecules. The detailed chemistry of the first two steps is not known, except that in both there is a chemical reduction with the result that both glycerol and fatty acids contain more energy than the carbohydrates from which they are made. This energy is derived from respiration. The condensation of fatty acids and glycerol to form a fat, using palmitic acid as an example, proceeds as follows under the influence of the enzyme lipase:

$$\underset{\text{palmitic acid}}{3C_{15}H_{31}COOH} + \underset{\text{glycerol}}{C_3H_5(OH)_3} \longrightarrow \underset{\text{palmitin}}{(C_{15}H_{31}COO)_3C_3H_5} + 3H_2O.$$

In this condensation reaction there is very little energy change, but because of the endothermic nature of the reactions by which fatty acids and glycerol are made, a fat contains about $2\frac{1}{4}$ times as much energy as an equal weight of carbohydrate.

4. Mineral Metabolism.— Although many other chemical elements are constituents of plants, only 15 are definitely known to be necessary in chemically detectable quantities for most kinds of plants. These are: carbon, oxygen, hydrogen, nitrogen, magnesium, potassium, calcium, phosphorus, sulfur, iron, boron, manganese, zinc, copper and molybdenum. The first three of these elements are obtained by plants from atmospheric gases or soil water. The remainder are obtained from mineral salts which are absorbed from the soil. The last six of the elements listed above are often called micrometabolic (or trace) elements because they constitute only a very small proportion of the necessary mineral ration of plants. In agricultural soils the elements most likely to be deficient are nitrogen, phosphorus and potassium; hence most commercial fertilizers consist of mixtures of compounds of these three elements. There are many soils, however, to which one or more of the other essential elements, including some of the micrometabolic ones, must be added if satisfactory growth of plants is to be obtained.

Absorption of Mineral Salts.— A part of the mineral salts used by plants is absorbed from the soil solution. Another and, at least for cations, more important source of mineral elements is the clay fraction of the soil. The clay particles are largely of colloidal dimensions and bear negative charges, having associated with them certain cations in large numbers, the commonest of nhich are hydrogen, calcium, magnesium, potassium and sodium ions. Of all these cations the hydrogen ion is held most tenaciously by the clay particles. As a result of respiration, carbon dioxide is continuously being generated in root cells. Part of this carbon dioxide reacts with water, forming carbonic acid, which in turn dissociates, forming hydrogen ions. If a root hair or root epidermal cell is in intimate contact with a clay particle, hydrogen ions from the cell exchange places with cations associated with the clay particles. This process of cation exchange is one of the mechanisms of absorption of ions by the roots of plants. Similar cation exchanges often occur following the addition of a fertilizer to a soil, the displaced cations passing into the soil solution.

Some of the absorption of mineral salts from the soil solution undoubtedly occurs by a simple diffusion, but a larger proportion of the absorption results from the operation of a more complex mechanism, called accumulation of salts. Many of the kinds of ions in the cell sap of large-celled species of submersed water plants such as *Nitella*, *Chara* and *Valonia* are present in a much greater concentration than in the water in which the plants live. A similar situation appears to exist in cells of root tips, which contain various kinds of ions — apparently in a freely dissolved state — each in a concentration much greater than in the medium from which they have been absorbed. Many kinds of plant cells, including those of root tips, appear to possess such a capacity of accumulating salts, *i.e.*, in causing their net movement from a medium of their lesser concentration to one of their greater concentration, which is directly opposite to the direction in which they would move if simple diffusion were the mechanism of movement. Furthermore. such cells possess the capacity of retaining accumulated salts in the cell sap in a higher concentration than in the surrounding medium. In this process, unlike the cation exchange process, both the anions and cations of a salt usually pass into a cell in electrostatically equivalent quantities. The accumulation of salts and their retention in the cell in a higher concentration than in the surrounding medium is correlated with an adequate rate of aerobic respiration within the cells. Presumably energy released in respiration is utilized in the process. Absorption of water and absorption of mineral salts both occur principally through the root tips although the mechanisms of the two processes are entirely different. Continued growth of the root tips through the soil is an important factor in the absorption of mineral salts. particularly in soils at water contents below the field capacity.

Roles of Mineral *Elements* in Plants.—Plants absorb many kinds of ions which are not necessary for their development, and commonly absorb necessary ions in quantities greater than are utilized in the metabolism of the plant. Absorption of ions, therefore, is not necessarily followed by their utilization. Generally speaking, however, most of the ions of essential elements which are absorbed are utilized in one manner or another in metabolic processes, or else have important influences upon physiological conditions within the plant. Many of the mineral elements are important constituents of protoplasm, cell walls or accumulated foods within the plant. The osmotic pressure, hydrogen ion concentration, buffer action and permeability of plant cells are all influenced by mineral salts or their constituent ions. Some mineral elements act as catalysts in the plant. Others have, in certain concentrations. toxic effects which often may be offset by the presence of other ions, a phenomenon known as antagonism. Examples of specific roles of most of the essential mineral elements are given at other places in this article.

Absence or deficiency of any of the essential mineral elements sooner or later becomes apparent in the plant as aberrations in growth or pigmentation. Characteristic visible symptoms of the deficiency of each of the essential elements have been recognized for a number of kinds of plants. Ability to identify such symptoms is of value in diagnosing developmental disorders in plants under natural or cultural conditions.

Hydroponics.—J. von Sachs in 1860 and W. Knop in 1863 were the first to use the method of water culture (solution culture) for studying the mineral salt relations of plants. In this method the plants are grown with their roots immersed in dilute solutions containing dissolved salts (so-called nutrient solutions). An alternative procedure is to grow plants with their roots in pure quartz sand or gravel which is kept moist with the solutions. By comparing the development of plants in solutions containing different kinds and proportions of ions, or the growth reactions of plants in a solution markedly deficient in one of the necessary elements with its growth in a complete solution (one containing all necessary elements) many important facts concerning the mineral nutrition and metabolism of plants have been discovered.

Solution and sand cultures have been used by plant physiologists as a laboratory technique for many years, but it was not until about 1936 that the extension of these methods to the commercial culture of plants in large tanks was attempted, a procedure for which the name hydroponics has been proposed. In one such method plants are supported in a matrix of peat, excelsior or some similar material on a wire screen with their roots projecting into a tank of solution below. Provision for adequate aeration of the solution is necessary if suitable development of the plants is to be insured. In another method the plants are rooted in a medium of coarse sand. gravel or haydite (fused shale) contained in large shallow tanks into which the solution is automatically pumped at intervals from a reservoir. to which it drains back after each cycle of pumping. Considerable success in the culture of certain greenhouse crops by these methods has been reported by commercial growers. The principal salts used in preparing solutions suitable for use in soilless plant culture are potassium dihydrogen phosphate, calcium nitrate, potassium nitrate, magnesium sulfate, ammonium sulfate and iron tartrate. (See HYDROPONICS.)

5. Nitrogen Metabolism.—Proteins, as already noted, are, next to water, the most abundant constituent of protoplasm. Proteins also accumulate in certain plant organs in considerable quantities, especially in the seeds of legumes. Upon germination of such seeds the proteins present are digested and utilized in the processes of assimilation and respiration. All molecules of plant proteins contain the elements carbon, hydrogen, oxygen and nitrogen. Sulfur also appears always to be a constituent, although present in relatively small quantities. Phosphorus is also a component of certain plant proteins.

In spite of the fact that nitrogen gas constitutes about 79% of the atmosphere, green plants are not able to utilize nitrogen from this source. Leguminous plants. an apparent exception to this statement, obtain atmospheric nitrogen indirectly through metabolic activities of symbiotic bacteria living in nodules on their roots. The well-known influence of legumes in enhancing the nitrogen content of soils is dependent upon the action of these bacteria. Most green plants obtain their nitrogen as a constituent of the nitrates or ammonium compounds which they absorb from the soil.

Protein molecules are synthesized by the condensation of large numbers of molecules of amino acids. More than 15 different amino acids occur in plants. The simplest amino acid is glycine:
$$\begin{array}{l} CH_2.COOH \\ | \\ NH_2 \end{array}$$
Most amino acids have a more complex molecular structure; at least one plant amino acid (cystine) also contains sulfur. Amino acids are apparently synthesized from organic acids derived from carbohydrates and from the nitrogen absorbed as nitrates or ammonium compounds. The sulfur present in cystine and possibly other amino acids is absorbed by the plant as sulfates. In some species of plants (apple, asparagus, certain grasses) synthesis of amino acids occurs principally in the roots, while in others (pea, soybean, tomato) it occurs principally in the aerial parts. The principal regions of protein synthesis do not necessarily correspond with the principal regions of amino acid synthesis. Amino acids may be made in one part of a plant, translocated to other parts. and used there in protein synthesis. Condensation of amino acids resulting in the formation of proteins occurs chiefly in the meristems and in certain storage tissues, especially in seeds. The condensation of amino acid molecules occurs mainly by their union through the peptide linkage. Using two glycine molecules for illustration, this process occurs as follows:

$$\begin{array}{l} CH_2-COOH \\ | \\ NH_2 \end{array} + \begin{array}{l} CH_2-COOH \\ | \\ NH_2 \end{array} \longrightarrow \begin{array}{l} \qquad\qquad\quad CH_2-COOH \\ \qquad\qquad\quad | \\ CH_2-CO-NH \\ | \\ NH_2 \end{array} + H_2O.$$

By the linking together of at least several hundred amino acid residues in this fashion the long, complex molecular chains characteristic of proteins are built up. A number of different kinds of amino acids enter into the constitution of each protein molecule; these are not arranged in a haphazard manner, but according to definite linear sequences, which are different and characteristic in each kind of protein. Many of the proteins found in the nuclei of plant cells contain phosphorus. Such proteins are complex compounds formed by the combination of proteins and the phosphorus-containing nucleic acids. Among the compounds important in the protein metabolism of plants are asparagine and glutamine. chemically very closely related to aspartic acid and glutamic acid, respectively, both of which are important plant amino acids. Organic nitrogen is often translocated from one part of the plant to another as asparagine, and this compound also commonly occurs as a temporary storage food. Alkaloids, complex nitrogen-containing compounds. very different in chemical constitution from the proteins, occur in some species of plants. Examples are nicotine, quinine, strychnine and morphine. These compounds are apparently only incidental products of plant metabolism; many of them, however, are important in therapeutics.

E. Translocation of Solutes

1. Organic **Solutes.**—*Downward* Translocation.—Organic solutes, principally carbohydrates synthesized in the leaves, are translocated in a downward direction in plants to the tissues of stems and roots through the phloem. In the stems of noody plants downward translocation occurs only in the youngest layers of phloem. corresponding roughly to the inner bark adjacent to the cambium. In tall trees the carbohydrates entering the root tips may have moved hundreds of feet through the continuous phloem from the leaf cells in which they were made. Most of the translocation of solutes through the phloem occurs in the sieve tubes, which consist of linear series of elongate cells joined together end to end. The exact mechanism of the downward translocation of solutes through the phloem is not knoun. One theory is that it is accomplished by cyclical streaming of the cytoplasm in the sieve tube cells, the solutes passing from one cell to the next by diffusion. Another theory is that there is a mass flow of solution in a downward direction through the phloem, movement from cell to cell being assumed to occur through the interconnecting cytoplasmic strands. There are a number of objections to both of these theories. one of the most serious being that neither of them can account for the rapidity with which translocation occurs in some plants. There are indications that the movement of solute molecules is in some manner greatly accelerated by the metabolic activity of the phloem cells through which translocation occurs, and that energy is actually expended in the accomplishment of solute movement (H. F. Clements, 1940).

Upward *Translocation.*—Under certain conditions considerable quantities of carbohydrates and other soluble foods are translocated in an upward direction through plants. This occurs, for example, in the stems of woody species when the buds resume growth in the spring. The tissues of the shoots formed shortly after initiation of growth are constructed largely from foods nhich move in an upward direction from storage tissues of the older stems. Translocation of foods in an upward direction also occurs toward developing flowers or fruits located in a terminal position, in seedlings as food moves from the endosperm or cotyledons toward the apical growing regions, and during the earlier stages in the development of leaves or shoots from bulbs. corms, rhizomes and tubers. Upward translocation of organic solutes occurs largely in the phloem. It is not certain nhether solutes can move simultaneously in the phloem in both directions or can only move in an upward direction under certain conditions and in a downward direction under others. The comments previously made regarding lack of knonledge of the mechanism of downward translocation apply equally well to upward translocation of organic solutes.

2. Mineral Salts.—The mineral salts absorbed from the soil by the roots are mostly translocated in an upward direction in plants, a large proportion of them ultimately reaching the leaves. Considerable controversy has flourished over whether upward movement of the mineral salts occurs principally in the xylem or principally in the phloem, but the preponderance of the evidence at present indicates that the xylem is the chief tissue through which mineral salt transport occurs (P. R. Stout and D. R. Hoagland. 1939). The dissolved mineral salts. generally in very low concentration, are passively carried in an upward direction through the ascending streamlets of water in the xylem ducts. The possibility of some upward movement of certain mineral elements in the phloem. particularly if in organic combination, cannot, however, be entirely excluded. Not all of the mineral salts translocated into a leaf or other lateral organ of a plant necessarily remain in that organ permanently. Re-translocation of certain mineral elements either as ions or as constituents of organic compounds out of the leaf and their subsequent distribution to other organs, often younger leaves, is of frequent occurrence in plants. Just prior to the abscission of leaves or floral parts a considerable proportion of the nitrogen, phosphorus, potassium, sulfur and magnesium present is translocated back into the stems. Such movements of minerals out of leaves occur through the phloem. There are also indications of a periodic daily "circulation" of at least certain of the minerals in the plant. Mobile phosphorus compounds, for example, apparently can move from root to leaf through the xylem, and from leaf to root through the phloem within a 24-hour period (O. Biddulph, 1941).

F. Respiration

The gaseous exchanges—consumption of oxygen and release of carbon dioxide—accompanying respiration are only external manifestations of this process.

1. Aerobic Respiration.—The essential and only invariable feature of respiration in green plants is that this process results in the oxidation of foods in living cells. The summary equation for the most usual course of respiration is:

$$C_6H_{12}O_6 + 6O_2 \rightarrow 6CO_2 + 6H_2O + 673 \text{ kg.cal.}$$

This process is often termed aerobic respiration because it proceeds only in the presence of atmospheric oxygen. Hexose sugars are most commonly the substrate of respiration and the equation given above, representing their complete oxidation, is the exact opposite of the photosynthetic equation. Fats and proteins can also be oxidized in plant cells after conversion into soluble hydrolytic products. Oxidation of fats usually is not initiated until the soluble carbohydrates in the cell are exhausted. Oxidation of proteins apparently seldom occurs until the cells have been depleted of both carbohydrates and fats. The respiratory ratio (ratio of volume of carbon dioxide released to volume of oxygen consumed) of a plant tissue depends upon the type of substrate being oxidized. Oxidation of carbohydrates results in a respiratory ratio of approximately 1, of fats a ratio of about 0.8, of proteins about 0.9, and of certain organic acids, such as oxalic and malic acids, a ratio of more than 1. The occurrence of anaerobic respiration in a tissue also results in a respiratory ratio greater than 1. That heat energy is released in respiration can be demonstrated by placing a mass of germinating seeds in a calorimeter and measuring the rise in temperature with a thermometer. The energy which escapes as heat is entirely lost to the plant. An important fraction of the energy released is not transformed into heat, but is used in endothermic synthetic processes, in various translocation phenomena. in protoplasmic streaming, in the accumulation of ions or molecules by plant cells, in various stages of growth and in other ways. All of the energy made available by respiration represents radiant energy previously entrapped in the process of photosynthesis.

Factors *Influencing the* Rate of Respiration.—In general, young meristematic tissues, relatively rich in protoplasm, have higher rates of respiration than older tissues in which the proportion of cell walls and dead cells is greater. Opening leaf or flower buds, growing root tips and germinating seeds all have relatively high rates of respiration. Germinating poppy seeds at 61" F. may lose 122 cc. of CO_2 per gram of dry weight in 24 hours. The respiration rates of meristematic plant tissues are of the same order of magnitude as the rates in warm-blooded animals. Rates in dormant seeds or other dormant organs, and mature or senescent leaves. fruits or other organs are much lower. Within a temperature range of about 32"–113" F., increase in temperature usually causes an increase in respiration rate (an approximate doubling for each 18° F. rise in temperature), although at the higher temperatures the increased rate often diminishes with time. Starved plant cells respire relatively slowly, and in general, with increase in the soluble carbohydrate content of the cells there is an increase in the rate of respiration up to the point at which some other factor becomes limiting. Very high oxygen contents of the atmosphere result in increased rates of respiration, very low ones result in decreased rates. The oxygen content of the atmosphere can, however. deviate considerably from the usual atmospheric concentration without any pronounced effect on the rate of respiration. An increased carbon dioxide content of the atmosphere results in a decrease in the rate of respiration of some plant tissues and an increase in others. The effect of a shift in the hydration of the tissues on the rate of respiration is exhibited most clearly in seeds. The respiration rate of dry seeds is often vanishingly small. but immediately upon the imbibition of water, the first step in germination, it increases markedly.

Influence oj Respiration Rafe on Net Rate of Photosynthesis.—The average quantity of hexose produced in photosynthesis by a corn plant during its life history is about 9 g. per photoperiod, while the average amount of hexose consumed in respiration during its life history by the entire plant is about 2 g. per 24-hour day. The difference between these two quantities is the net daily rate of photosynthesis and represents the amount of hexose which can be utilized by the plant in assimilation or which may accumulate as unused food. The average net daily rate of photosynthesis is an important consideration in evaluating the survival and development of plants, as, in general, the greater this quantity the larger the plant can grow and the more food that can accumulate. Temperature has an important effect on net daily photosynthesis because of its differential influence on the rates of respiration and photosynthesis.

In many and perhaps all species the temperature optimum for respiration is higher than the optimum for photosynthesis. In the potato, for example, the temperature optimum for photosynthesis, under otherwise favourable conditions, is about 68° F.. while the optimum for respiration, at least of the leaves, is about 95° F. Hence, the higher the temperature above the photosynthetic optimum, the greater the proportion of the photosynthate which is consumed in respiration in one part of the plant or another. and the smaller the daily net photosynthesis. At relatively high temperatures, therefore, there is relatively less food which can be used in the construction of new tissues and which can accumulate in the tubers or other organs. This is the explanation of the well-known fact that the potato is a cool climate crop. The same principle also applies to other species, although the temperature which results in maximum daily rates of net photosynthesis varies with other environmental factors and with the species, being in general higher in species indigenous to warm climates than to those indigenous to cool climates. Analysis of this effect of temperature on plants is complicated by the fact that plants in nature are exposed to a daily cycle of temperature variations, the general pattern of which varies from season to season and habitat to habitat.

2. Fermentation.— When a dilute sugar solution becomes inoculated with yeast cells the process of alcoholic fermentation ensues:

$$\underset{\text{hexose}}{C_6H_{12}O_6} \longrightarrow \underset{\text{ethanol}}{2C_2H_5OH} + 25 \text{ kg.cal.}$$

This process proceeds as a series of sub-reactions, each catalyzed by a specific enzyme. The over-all series of reactions in which the compound pyruvic acid is formed from a phosphorylated hexose sugar is called glycolysis. Although an oxidation reaction, glycolysis can occur in the complete absence of atmospheric oxygen; *i.e.,* it is anaerobic. The further steps in the conversion of pyruvic acid to ethanol are also anaerobic. Even when oxygen is present yeast cells carry on very little aerobic respiration, still obtaining most of their energy from the relatively less efficient process of fermentation.

A process identical with or at least very similar to alcoholic fermentation occurs in the tissues of green plants under certain conditions. If kept in an atmosphere devoid of oxygen many plant tissues continue to release carbon dioxide while ethanol or other chemically related compounds accumulate in them. In some plant organs such anaerobic respiration occurs even in the presence of oxygen. This is true in the earlier stages in the germination of some kinds of seeds and grains (pea, oat, sunflower) because of the virtual impermeability of the coats to oxygen. The skin of the grape and some other fruits is also highly impermeable to oxygen, and considerable anaerobic respiration undoubtedly occurs in such organs. Many tissues of higher plants are soon injured by prolonged anaerobiosis. Within a day signs of injury appear in corn seedlings which have been deprived of oxygen. The injurious effect of anaerobic respiration on many plant tissues is undoubtedly in part a result of the low-energy output of this process and in part a result of the accumulation of ethanol or other toxic products within the cells. Some aging (senescent) plant tissues, on the other hand, such as apple and pear fruits, continue to release carbon dioxide and remain uninjured for months when stored in pure nitrogen or hydrogen.

Mechanism of Respiration.—Like fermentation. the process of aerobic respiration proceeds as a complex series of sub-reactions. The earlier steps in fermentation and respiration appear to be identical. By means of the glycolytic series of reactions pyruvic acid is formed in the cells of plants. Glycolysis may occur either in the presence or absence of oxygen. In the presence of oxygen fermentation is usually inhibited and the further aerobic oxidation of the pyruvic acid to water and carbon dioxide takes place through another complex series of reactions known as the Krebs cycle. Most of these reactions in this cycle are catalyzed by specific enzymes. Energy transfers from molecule to molecule during respiration are accomplished through the intermediation of certain complex molecules of which adenosine triphosphate is the best known. Compounds formed during the intermediate steps of respiration are the starting points for many metabolically important chains of reactions. The biochemical pathway along which respiration proceeds appears to be the same or very similar in most kinds of plant and animal cells.

G. Growth

The co-ordinated development of plant organs and tissues is just as clearly a type of physiological activity as relatively simpler processes such as photosynthesis and respiration. The tissues and their constituent cells resulting from the complex of physiological processes referred to as growth in turn become factors influencing subsequently occurring physiological processes in those tissues. Growth of plants occurs primarily in meristems, which are tissues in which the cells retain a capacity for cell division. The principal meristems of a vascular plant are the apical stem meristems, the apical root meristerns and the cambium (not present in ferns or monocots). An embryo plant has only one apical stem meristem. but with the development of the branching stem system there comes to be such a meristem at every growing stem tip and in every bud. Hence there may be thousands of apical stem meristems on any plant with an extensive system of branching. Likewise there is only one apical root meristem on an embryo plant, but with the branching of the root system the number of such meristems on a single plant may exceed many thousands or even millions, since one is present at every root tip.

Growth of any meristem proceeds by successive microscopically visible stages of cell division, cell enlargement and cell maturation. which are the three principal morphological phases of gronth. The terms for the first two stages of growth are self-explanatory. Cell maturation refers to the final stage in growth during which most of the distinctive structural and chemical differences in the walls of the various kinds of cells develop. It is also the stage in which the protoplasm disappears from many kinds of cells as, for example, most cells of the xylem. An actively growing meristem is a centre of intense assimilatory activity, assimilation being the term used to refer to the construction of new cell walls and protoplasm from foods. Protoplasmic proteins are made by the condensation of amino acids, principally during the cell division stage of growth. Cellulose, pectic compounds and other cell wall constituents are synthesized by the condensation of soluble carbohydrates, principally during the cell division and cell enlargement phases of growth. Water is incorporated into the cells in considerable quantities during both cell division and cell enlargement, some entering into the hydration of newly formed cell walls and protoplasm, and larger quantities entering into the expanding vacuoles, particularly during cell enlargement. Translocation of water and soluble foods is, therefore, constantly in progress toward growing meristems. Translocation of essential minerals, as soluble compounds of one kind or another, is also continually occurring toward growing meristems. Certain growth substances must also be present if growth is to occur. Regions of cell division and cell enlargement are also centres of intense respiratory activity, considerable quantities of carbohydrates being oxidized in such cells, much of the resulting energy being utilized in various dynamic and metabolic processes which are integral phases of growth. Respiration rates during the maturation phase are distinctly lower than during the tno preceding stages of the growth process.

(A) intact coleoptile; (B) tip severed and replaced; (C) tip removed. At right, differences in subsequent elongation of coleoptiles treated as shown at left

Growth from primary meristems is called primary growth and results in all increase in the Itngth of stems and roots. in the development of their branching system, in the development of the primary tissues of such organs, and in the production of all lateral appendages. such as leaves, floral parts and root hairs. Primary growth of plants is not a continuous but a periodic phenomenon, periods of growth having in general a correlation with favourable seasons. but varying greatly from one species of plant to another. The periodicity of root growth in a given species is usually different from the periodicity of stem growth often beginning earlier in the season than stem growth and continuing after the latter has ceased. Most of the secondary growth of plants is initiated in the cambium. which is a uniseriate layer of cells located between the xylem and phloem. In most plants in which it occurs the cambium is present as an almost continuous layer of cells extending from just back of every root tip to just below every stem apex. As a result of secondary gronth in a lateral direction xylem cells (secondary xylem) are formed on the inner side of the cambium and phloem cells (secondary phloem) on its outer side (the first layers of these tno tissues. primary xylem and primary phloem develop during primary growth). In woody perennials secondary tissues may develop from the cambium for hundreds of years cambial activity being resumed periodically nith the advent of each growing season The diameter of the woody cylinder is thus increased from growing season to growing season, and commonly each season's layer of xylem (wood) can be distinguished in cross sections of the wood as a definite annual ring As new layers of phloem form adjacent to the cambium, the older phloem is displaced outward and in most woody species, becomes part of the bark. which eventually sloughs off.

Leaves develop from the leaf primordia, small protuberances of meristematic cells nhich originate laterally in apical meristemi. The zone of attachment of a leaf to a stem is called a node; in most kinds of plants the !eaves become more or less regularly spaced along the stem axis by elongation of the internodes In the axil of each leaf an offshoot of the terminal meristem develops which in turn becomes a terminal meristem Such meristems are essentially rudimentary side branches and are called lateral buds, usually being covered nith bud scales in woody species. The branching stem system of the plant is a result of the development of the lateral buds into side branches. Branch roots, on the other hand, develop from meristems ahich originate in interior pericycle tissue. In many woody plants scale-enclosed terminal buds form annually at the tip of each stem axis In the woody plants of temperate regions resumption of growth from the terminal buds and from some of the lateral buds occurs each spring. continuing for a few weeks to several months, depending upon the species of plant and

the environmental conditions. In most species of plants some of the apical stem meristems sooner or later become differentiated into flower primordia from which develop flowers and, ultimately, fruits and seeds.

1. Hormones. — Hormones are substances synthesized within an organism which, in very minute concentrations: exert profound effects on its metabolism or growth, often after translocation to parts or organs remote from their centre of production. Although the existence of such substances in plants had been suspected for many years. the first convincingly clear demonstration of the presence of growth hormones (growth substances) in plants was not made until the investigations of F. W. R'ent in 1928.

The auxins have been the most thoroughly studied of the plant hormones. Their action has been investigated mostly in the coleoptile of the oat, which is the first part of the plant that emerges above the ground in germination. This is a cylindrical structure several centimetres in height, which encloses the first leaf. If the tip of an oat coleoptile is removed, elongation of the stump is greatly retarded as compared with an intact coleoptile. If the cut off tip is replaced on the coleoptile. nearly the original rate of elongation may be regained (fig. 11). Furthermore. if the cut off tip be placed with its cut surface in contact with a small block of agar gel for about an hour. and the agar block then be affixed on the cut surface of a detipped coleoptile, that coleoptile will elongate at nearly its usual rate. No such effect will be obtained if a block of pure agar is used (fig. 12). Cell divisions cease very early in the development of coleoptiles and their elongation in length is restricted to the basal portion. The facts just cited indicate that the tip exerts a controlling influence on the elongation of basal cells of the coleoptile and, furthermore, as shown by the agar block experiment, this controlling influence must be ascribed to some diffusible substance or substances which move from the tip toward the base through the coleoptile. These substances are called auxins. If an agar block containing auxins from one source or another is affixed one-sidedly on a detipped coleoptile. cell elongation is found to be more rapid on a side of the coleoptile below the portion of the tip on which the block is located, resulting in curvature of the coleoptile (fig. 13). Translocation of the auxin is almost strictly longitudinal, the elongating cells on the side of the coleoptile below the block receiving much more than cells on the opposite side, with a corresponding differential effect on growth. Within limits of 0° to 20°, curvature resulting from the eccentric attachment of agar blocks containing auxin to detipped coleoptiles is proportional to the concentration of auxin in the blocks. This proportionality between auxin concentration and coleoptile curvature has made it possible to use the bending of oat coleoptiles as the basis for a quantitative and extremely sensitive biological test for auxins. Auxins are essential for the occurrence of cell elongation in all plant cells. In their absence elongation ceases; in their presence elongation occurs if no other factors are limiting, and within limits, elongation is proportional to auxin concentration. Relatively high concentrations of auxins inhibit cell elongatipn. and the concentration most favourable for elongation is different in different tissues. being, for example, much higher in stems and coleoptiles than in roots. The only auxin definitely known to occur in the tissues of higher plants is the compound indole-3-acetic acid. although the presence of others, probably chemically similar. is suspected. A number of synthetic compounds, not known to occur in plants, have been discovered to have many of the same effects on plants as the naturally occurring auxins.

Within limits, this curvature is proportional to the concentration of auxin in the agar block

More roots form on cuttings of many kinds of plants if they are first treated with an auxin. Some of the synthetic auxins, notably indole-butyric acid and a-naphthalene acetic acid, are especially effective in inducing root formation. The hormone may be applied in solution. in a paste, as a vapour or in a powder. Detailed information on the rooting of cuttings of many species by treatment with auxins is given by G. S. Avery, *et al.* (see Bibliography, below).

The detachment of leaves, fruits and certain other parts of plants from stems usually occurs by the process of abscission. The first step in the abscission of leaves or fruits is the formation of an absciss layer across the base of the petiole of the leaf or the peduncle of the fruit. The absciss layer is a transverse zone consisting of several layers of parenchymatous cells. It may form weeks or months before detachment of the leaf or fruit occurs. Abscission proper, which in the leaves of deciduous trees of temperate regions occurs principally in the autumn, takes place as a result of dissolution of the middle lamella between layers of cells in the absciss layer. Artificial introduction of auxin into leaf petioles at a time when they would ordinarily abscise within a short period materially delays the time of abscission. A practical application of this discovery is to spray apples with a solution of a-naphthaleneacetic acid shortly before harvest in the fall. Aplication of such a spray delays abscission of the fruits and makes it more likely that they can be picked before they fall to the ground and deteriorate in quality.

Usually fruit development ensues only after pollination and subsequent fertilization have occurred. *If*, however, pollination is prevented and any one of several of the auxins is introduced into the pistil by a suitable technique, development of the fruit will occur (F. G. Gustafson, 1936). Such parthenocarpic fruits are seedless.

One of the seemingly paradoxical developments from the study of auxins which. in general, are growth hormones par excellence. is that some of them also exert such toxic effects on plants that they are widely used as weed killers. The best known of such auxins is 2.4-dichlorophenoxy-acetic acid (2,4-D). Such auxins exert their toxic effects only when employed at considerably higher concentrations than those at which they exert growth-promoting effects.

Other growth reactions of plants which are influenced by auxins include cambial activity, abscission, initiation of flowers, gromth correlations and tropisms.

The auxins are by no means the only hormones which occur in plants. Many vitamins of the so-called B-complex appear to operate as hormones in plants. Thiamin, for example, is synthesized principally in the leaves! whence it is translocated to other parts of the plant (J. Bonner. 1942). The same situation appears to prevail with respect to some of the other B vitamins.

The kinins constitute another group of plant hormones. These compounds are purine derivatives, the most thoroughly investigated of which is 6-furfurylaminopurine (C. O. Miller, et *al.*, 1956). The kinins were originally considered to be primarily cell division promoting hormones, but have also been found to favour certain other growth reactions of plants such as expansion of leaf blades.

The gibberellins constitute still another group of plant hormones. the best known of which is gibberellic acid. This compound has the molecular formula of $C_{19}H_{22}O_{11}$ and has the basic ring structure of the compound fluorene. One of the principal effects of the gibberellins is that of promoting elongation of various plant organs. In this respect they resemble the auxins, but they are not to be classed with the auxins because their effects on many plant growth reactions are quite different from those of the auxins. Among other growth reactions of plants influenced by gibberellins are induction of flowering in certain species. shifting the growth cycle of some biennials to annuals. induction of parthenocarpy. enhancing cambial activity, and overcoming the dwarf habit of growth in some species (B. B. Stowe and T. Yamaki, 1957)

2. Factors Influencing Growth. — The process of growth is so complex that it is impossible to characterize it by any single index. Quantitative measurements may readily be made of such aspects as increase in lengths of stems or roots, increase in diameter of a stem, increase in volume of a fruit, or increase in dry or fresh weight of a plant organ. However! qualitative differences in growth are often of greater significance than quantitative differences. The relative development of vegetative and reproductive growth, for example, or whether the vegetative growth is soft and succulent or hard and woody are often of greater import from a physiological or practical standpoint than the absolute development of any plant organ or organs, measured as length or weight. Such developmental differences must be characterized largely in descriptive terms rather than in quantitative measurements.

The growth and reactions of a plant are the result of the coordinated interplay of its hereditary factors and the environmental conditions to which it is exposed upon its internal physiological processes. Genetic factors have as much influence on the development of a plant as environmental factors, but a detailed consideration of their effects cannot come within the scope of this article. The environment of plants is too complex to be subjected to any completely logical analysis, but the following are the principal factors of the physical environnient which have effects upon the rate and type of growth of plants: radiant energy (intensity, quality, duration). temperature of air and soil, atmospheric humidity, soil water supply, soil aeration, supply of available minerals in the soil, concentration of gases in the atmosphere, gravity and atmospheric pressure. Since an individual factor can vary in more than one way, since various interrelations exist among the different factors, and since each factor can induce various chains of reactions in a plant, interpretation of the effects of an individual environmental factor on the growth of plants is usually a complex problem. The principle of limiting factors can be applied in the approximate analysis of many growth phenomena. In this epitomized discussion the influence of only a few of these environmental conditions can be considered in detail.

Photoperiodism.—The reaction of plants to the length of the daily period of illumination is called photoperiodism. The daily length of the photoperiod varies from latitude to latitude and from season to season in the same latitude. In the tropics, seasonal variations in the photoperiod are small, day lengths approximating 12 hours the year round. In mid-temperate regions, photoperiods vary in length from 8 or 9 hours in December to 15 or 16 hours in June. In arctic regions the photoperiod drops to a zero value in December, and is of a 24-hour duration in June. Although the length of the photoperiod has certain effects on the vegetative development of plants, its most noteworthy influence is upon reproductive development. The foundations of our knowledge of photoperiodism in plants were laid by W. W. Garner and H. A. Allard, beginning in 1920. Originally four categories of plants, in terms of their photoperiodic reaction, were recognized: short-day plants, long-day plants, indeterminate plants and intermediate plants. Further investigations have shown that all plants belong basically to the two categories of long-day plants and short-day plants. Long-day plants require a certain minimum length of photoperiod (which varies considerably from one species or even variety of plant to another) out of each 24-hour day for the induction of flowering, but flower under any longer photoperiod, up to and including continuous light. Short-day plants, on the other hand, require an alternation between a dark period and a light period during each 24-hour day if flowers are to be induced. The dark period must be of a certain minimum length (which varies considerably from one species or even variety of plant to another) but flowering also occurs under dark periods which are considerably longer than the minimum. In the Biloxi soybean, for example, a dark period at least 11 hours (but which may be considerably longer) must alternate with photoperiods which may be from 4 to 18, but optionally from 10 to 12 hours in length if flowers are to be initiated (K. C. Hamner. 1940).

Examples of short-day plants include: cocklebur. salvia, aster, dahlia, poinsettia, chrysanthemum and violet; examples of long-day plants include spinach. radish, dill. lettuce, grains, timothy and hibiscus. Spring-flowering plants of temperate zones are mostly of the short-day type, the flower primordia having been formed during the shortening days of the preceding late summer and autumn. Temperate zone autumn flonering plants mostly fall into the same category, except that flowers are initiated during the current instead of the preceding season. Most summer-blooming plants are of the long-day type.

The daily length of the photoperiod is an important factor influencing the distribution of crop plants and of plants in nature. Species of the pronounced long-day type cannot survive in nature in the tropics. Similarly species of the pronounced short-day type cannot survive under natural conditions in more northern latitudes, excepting only those nhich are maintained by vegetative propagation. Short-day Biloxi soybeans, for example, fruit readily in the gulf states of the United States. but not in the latitude of Washington. D C. In the latter region days short enough to induce flowering come so late in the season that fruits are killed by frost before they can ripen. Long-day species with a short critical photoperiod (indeterminate plants) can complete their life cycle over such a nide range of day lengths that their ecological distribution and season of blooming are controlled by factors other than length of the photoperiod.

When the leaves of short-day Biloxi soybean are exposed to short photoperiods while the apical growing regions are kept under long photoperiods or in total darkness. initiation of flower primordia occurs. If the growing tip of the plant is exposed to short photoperiods and the leaves to long photoperiods, no such initiation occurs (H. A. Borthwick and M. W. Parker. 1938). Similar results have been obtained with other short-day species and also with long-day species. These facts indicate that the leaves are the loci of the reactions which lead to the flowering of plants, and that the effects of processes which occur in the leaves are transmitted to the apical meristems, causing them to differentiate into flower primordia. Under the influence of photoperiods of the proper duration it seems likely that a substance (or substances) is made in the leaves. whence it is translocated to the terminal meristems. inducing floner formation. The name florigen has been proposed for this postulated flower-inducing hormone.

It is not necessary for plants to be exposed continuously to photoperiods of the proper length for the initiation of flowers to occur. Short-day Biloxi soybeans, nhich have been growing under long days, will initiate flower primordia after exposure to only two short-day cycles and a return to long days. Similarly four long-day cycles are sufficient to initiate flowering in long-day dill plants which are kept under short days before and after exposure to long days. The existence of this phenomenon of photoperiodic induction has also been demonstrated in a number of other species of both long-day and short-day types.

When a typical short-day plant is kept under a distinctly short-day cycle, such as 8 hours of light alternating with 16 hours of dark, initiation of flowers soon ensues. If. however. the dark period is interrupted at somewhere near its mid point by a short period of relatively low-intensity light flowering is inhibited. When a long-day plant is kept under such a short-day cycle flowering does not occur. If, however. the dark period to which such a plant is exposed is interrupted at approximately its mid-point by a short period of relatively low-intensity light, flowering is induced. In both short-day and long-day plants the usual photoperiodic reaction is reversed by such a treatment. The same effect can be achieved by folloning the 8-hour photoperiod, which must be of relatively high light intensity, with a 6- to 8-hour exposure to low-intensity light.

This low-intensity light reaction of photoperiodism (which must be distinguished from the "high intensity" reaction of the photoperiod proper) has been investigated from the standpoint of the relative effectiveness of different spectral bands of light. A narrow band in the red vicinity of 6500 Å (1 Å or Angstrom unit = $\frac{1}{10,000,000}$ mm.) wave length has been found to operate most effectively in the low-intensity light reaction. Furthermore. a closely adjacent band in the far red, at about 7.300 Å wave length reverses the effect of the red band. This reversible far red reaction affects a number of other growth phenomena in plants in addition to the photoperiodic reaction. These include germination of seeds, elongation of stems, expansion of leaves, germination of fern spores and the formation of certain pigments. Many of these growth reactions apparently can be reversed an indefinite number of times by alternately exposing the plant first to the effective red band, then to the effective far red band of light.

Temperature Effects on Growth—Within limits a rise in temperature favours increased rates of elongation or enlargement of plant organs. The range of temperatures within which this occurs is usually higher in tropical than in temperate zone species, and higher in plants of the latter group than in subarctic species. In temperate zone species, the temperature range over which such an effect occurs approximates 40°–95° F. With further rise in temperature above the optimum. elongation or enlargement rates decrease. falling to zero at about 105°–115° F. The temperature most favourable for one stage of development of a plant is often not the most favourable for another stage.

Relatively low temperatures favour initiation of flowers in some species relatively high temperatures favour floner initiation in other species, and dowers are initiated in still other species over a wide range of temperatures (H. C. Thompson, 1939). Celery plants which have been exposed to a temperature range of 40°–50° F. or 50°–60° F. for 10–15 days will develop flowers, fruits and seeds if subsequently grown at 60°–70° F., a range of temperatures too high for the initiation of flowering. On the other hand, lettuce plants (White Boston) develop flowers, fruits and seeds without forming heads if grown at 70°–80° F Similar plants grown at 60°–70° F first form heads and subsequently go to seed. Other species for which exposure to a relatively low temperature seems essential to induction of flowering include rutabaga, onion, cosmos and stock; other species for which exposure to a relatively high temperature seems essential to induction of flonering include pepper, phlox and cleome.

Growth Correlations—The influence of one part of a plant upon the development of another part of the same plant is called a growth correlation. The harmonious development of the plant body as a whole is controlled by correlative influences operating reciprocally from organ to organ, tissue to tissue, and cell to cell. Innumerable examples of growth correlations can be cited. A familiar one is the phenomenon of apical dominance. 4s long as the terminal bud on a woody stem remains intact or continues to gron, development of lateral buds, at least on the current season's shoots. fails to occur. If the terminal bud is injured or destroyed, however, development of the lateral buds usually ensues. Obviously the terminal bud has some sort of an influence on the lateral buds which prevents their development. Apical dominance also occurs in the groaing shoots of herbaceous plants. When the terminal bud is removed from a broad bean and replaced with a biock of agar gel containing auxin *b* or heteroauxin, inhibition of lateral bud development continues just as if the terminal bud remains intact. If the terminal bud is replaced with a block of plain agar, however. lateral buds begin to develop immediately. It is obvious that auxins play a role in apical dominance. but the exact mechanism of their action has not been worked out. Many, but not all correlative influences of one plant organ on another result from the action of growth substances. One part of a plant often has an influence on the relative quantities of certain foods, of mineral compounds, or of water which reach other parts of the plant. and correlative influences on growth often result from such effects. For example, if the nitrate supply is low, the root system of a plant is large in nroportion to its top. Under such conditions absorbed nitrates are largely used in the synthesis of amino acids in the roots and these amino acids are used in protein synthesis accompanying root growth. Only small quantities of nitrogenous compounds escape utilization in the roots and are translocated to the tops. Hence the growth of the tops is checked by a deficiency of nitrates or amino acids, even though they may contain an abundance of carbohydrates, some of which are translocated downward and used in amino acid synthesis and other processes in the roots. If the supply of nitrates is more abundant, however, more nitrogenous compounds are translocated to the tops, where most of them are used in the synthesis of protoplasmic proteins. The resulting enhanced vegetative growth of the tops results in a greater proportionate development of the aerial portions of the plant as compared with the roots than occurs when the nitrogen supply is deficient.

Dormancy.—Many kinds of seeds. apparently mature, fail to sprout even when brought under environmental conditions favourable for germination. This state of internally inhibited growth of seeds or other plant organs is called dormancy. The following are the main causes of dormancy in seeds: (1) seed coats impermeable to water; (2) seed coats mechanically so strong that they cannot be ruptured by swelling of the embryo; (3) seed coats impermeable to oxygen; (4) seed coats containing a specific chemical inhibitor of germination; (5) embryos in a rudimentary state at the time seeds are shed; (6) embryos fully formed at seed maturity but in such a physiological condition that they will not develop further until they have passed through a period of "after-ripening." More than one of these conditions is present in some kinds of seeds. Methods of "breaking" the dormancy, or at least shortening the period of dormancy, have been devised for a number of kinds of seeds and are of considerable practical utility. The method used with a given kind of seed depends upon the cause of dormancy in that particular seed.

The phenomenon of dormancy is also exhibited by buds. The buds on stems of woody temperate zone species ordinarily do not develop during the summer in which they are formed. even under favourable environmental conditions. This condition of dormancy is maintained in most such species until the following autumn or winter. Exposing stems to vapours of ether, ethylene chlorohydrin or ethylene dichlorid is an effective method of breaking bud dormancy in many woody species. The buds of many kinds of tubers, rhizomes, corms and bulbs likewise may remain dormant for a considerable period. Freshly harvested potato tubers, for example, ordinarily do not sprout at once because of bud dormancy. The duration of dormancy in potato tubers can be greatly curtailed by treatment uith certain chemicals

Vernalization.—This term refers to a low-temperature treatment given seeds before sowing which results in shortening the time until flowering of plants that develop from them. Less commonly, it is also applied to treatment of seeds at relatively high temperatures, or to temperature treatments of plant organs other than seeds (H. H. McKinney, 1930). Although seeds of a number of kinds of plants can be vernalized. this technique is employed principally with cereals, and especially with winter wheats. Vernalization of the grains of a winter wheat so speeds up the completion of its life cycle that it can be grown as a spring wheat. Grains of the Turkey Red variety of winter wheat, for example, are vernalized by soaking to a moisture content of about 60%, which just permits initiation of germination, holding them at approximately that water content, and exposing them to a temperature of 33°–37° F. for 9–10 weeks before sowing. The plants developing from these seeds reach the heading stage in 110–120 days from the beginning of the cold treatment. Unvernalized seeds of the same variety require 150 days from sowing to attain the same stage of development in the same environment. This effect of low temperature treatments on pre-germinated seed, now called vernalization, has been known for many years, but gained new prominence beginning about 1930 because of its advocacy as a practical measure by Russian agriculturalists. Because of the particular climatic conditions prevailing over large portions of the U.S.S.R., the vernalization of winter wheats has proved an advantageous agricultural procedure in some parts of that country. In other parts of the world, however, vernalization has not proved to be a practice of commercial value.

H. Plant Movements

The existence of autonomous movements in plants usually escapes notice because most of them occur too slowly to permit their detection by casual observation. That movements of plant organs actually do occur can be readily confirmed by a series of observations of certain plant organs under suitable conditions. The reality and vigour of plant movements can also be demonstrated strikingly by time lapse motion-picture technique in which pictures of the moving plant organs are taken at relatively long intervals and the resulting film projected at such a speed that the movements are greatly accelerated. Most movements in the vascular plants may be classified into growth movements or turgor movements.

Growth movements, many of them curvatures of plant organs, result from differential rates of growth. Growth movements may be classed as tropic movements. nastic movements and nutations.

1. Tropisms.—Tropic movements such as phototropism and geotropism occur under the influence of an environmental factor acting with greater intensity from one direction than another.

Phototropism—When a plant. such as a potted plant on a window sill, is illuminated more strongly on one side than on others, the stems usually bend toward the brighter light. Two mechanisms of this phenomenon of phototropism have been recognized. One is a retarding effect of light on the elongation of the cells. Hence the cells on the more brightly illuminated side of the stem elongate less than cells on the opposite side, and the stem bends toward the light. The other mechanism of phototropism has been studied principally in the coleoptiles of grasses. Charles Darwin showed many years ago that, although bending occurs in the basal portions of a coleoptile, shading its tip with a tin-foil cap prevents curvature of the coleoptile when unilaterally illuminated. Detipped coleoptiles likewise evince little or no phototropic reaction. Bending of the basal portions of the coleoptile is, therefore, subject to a controlling influence of the tip. Subsequently it was shown that auxin in the tip of an oat coleoptile migrates laterally across the tip from the more strongly illuminated to the shaded side. Some inactivation of auxin on the illuminated side may also occur. Since downward translocation of the auxin is almost strictly longitudinal. the cells on the shaded side of the coleoptile receive more auxin than those on the lighted side. The cells on the shaded side therefore elongate more than those on the illuminated side, and the coleoptile bends toward the light.

Geotropism.—If a potted plant be placed in a horizontal position, the stem bends upuard away from, and the root bends downward toward, the force of gravity. These are examples of negative and positive geotropism, respectively. In a horizontally oriented oat coleoptile, auxin migrates from the upper to the lower side of the tip and thence longitudinally in the usual manner. The greater concentration of auxin on the lower than on the upper side induces greater elongation of cells on the former. and the coleoptile bends upward. In a horizontally oriented root tip, auxin also migrates from its upper to its lower side. Elongation of root cells is favoured by much lower concentrations of auxins than favour elongation of coleoptile cells, and root cell elongation is retarded at all higher concentration. A relatively high auxin concentration on the lower side of the root therefore results in a smaller elongation rate of the cells on the lower as compared with the upper side, and a downward bending of the root results.

2. Nastic Movements and **Nutations.**—Nastic movements are those in which the direction of the movement is limited by the structural symmetry of the plant organ. The more rapid growth of the upper side of a plant organ such as a leaf or flower part is called epinasty; the more rapid growth of its lower side hyponasty. Opening of flowers is caused by epinastic movements of the sepals and petals; closing of flowers, such as occurs in some species at night or at low temperatures, results from hyponastic movements of the floral parts. Careful observation of a growing stem tip reveals that it does not grow straight ahead through space, but moves in an irregular spiral pathway as it elongates. Such growth movements are called nutations.

3. Turgor Movements.—Turgor movements are those caused by reversible changes in cell volume. Many such movements result from turgor changes in structures called pulvini, located at the base of the blade or petiole, or both in some kinds of plants. The well-known and spectacular reactions of the sensitive plant result from turgor changes in cells of pulvini located at the base of the petiole and the base of each leaflet.

V. PLANT ECOLOGY

Plant ecology is the science which deals with the interrelationships between plant life and environment. It is a segment of general ecology, the empirical basis of which lies in the common observation that living organisms vary with environment. and whose deeper foundations rest upon the fact that life and environment are inseparable parts of a greater whole. Other aspects of general ecology are animal ecology, human ecology and bioecology. which is defined provisionally as the ecology of plant and animal interrelations. Actually, plants, animals and men are so intimately associated that it is seldom possible for the ecologist to confine his attention to any one of them, although each special field has its own core of knowledge and technique.

This last statement can be emphasized by noting the following subdivisions or facets of plant ecology: (1) autecology, the relation of the individual species or plant to its environment: (2) floristics, the distribution in time and space of the various kinds (*i.e.*, species, genera, etc.) of plants; (3) ecological plant geography, the distribution of plant communities; (4) plant sociology, or synecology, the characteristics of plant communities; (5) ecological measurement or habitat analysis, the analysis of the nonliving environment; (6) applied plant ecology.

Throughout the following discussion of these phases of ecology it should be kept in mind that earth, atmosphere, individual organism and communities of organisms all represent dynamic systems, or processes, whose mutual interplay is the concern of the ecologist.

A. Environment and Species (Autecology)

This subject deals with the types of plant structure and behaviour characteristic of different habitats, and the capacity of plants to adjust themselves to various conditions. These are problems of structure and behaviour as well as of ecology, hence they involve the techniques of morphology and physiology. Genetics is also involved, since the attributes in question depend upon the inherited make-up of the individual.

1. Habitat and Structure. — It is a matter of common observation that plants of arid regions are gray, thick-leaved or leafless, succulent and often thorny. in contrast to those of humid regions nhich have delicate, bright green, abundant foliage. Every gardener is familiar with the fine texture of lettuce or tobacco leaves grown in moderate light, as against the woody, coarse leaves produced in strong sunlight. Travelers have also noted the rapid decrease in height of nheat and corn in passing from Iowa to Colorado In a given field of alfalfa, some plants will be killed by winter temperatures which leave others unharmed, partly through local differences in soil moisture, etc., but also in part through inherited differences in different individuals. A field of cabbage or flax may be swept by disease which kills some plants, leaves others unharmed. Such are a few of the countless problems with which autecology must deal.

Every species of plant inherits certain potentialities of adjustment to external conditions. The range of tolerance may be nide or narrow, and differs as regards different factors. The dandelion. which occurs under a nide range of temperature and moisture conditions, has been observed to bloom during ten months of the year at Lincoln, Neb. But along the shore of Lake Michigan it thrives only on clay or where lime-bearing clays are mixed with beach sand.

Within the species are to be found varieties with special limits of tolerance. Upon these, as upon the species. environment may act selectively, eliminating in one place, sustaining in another.

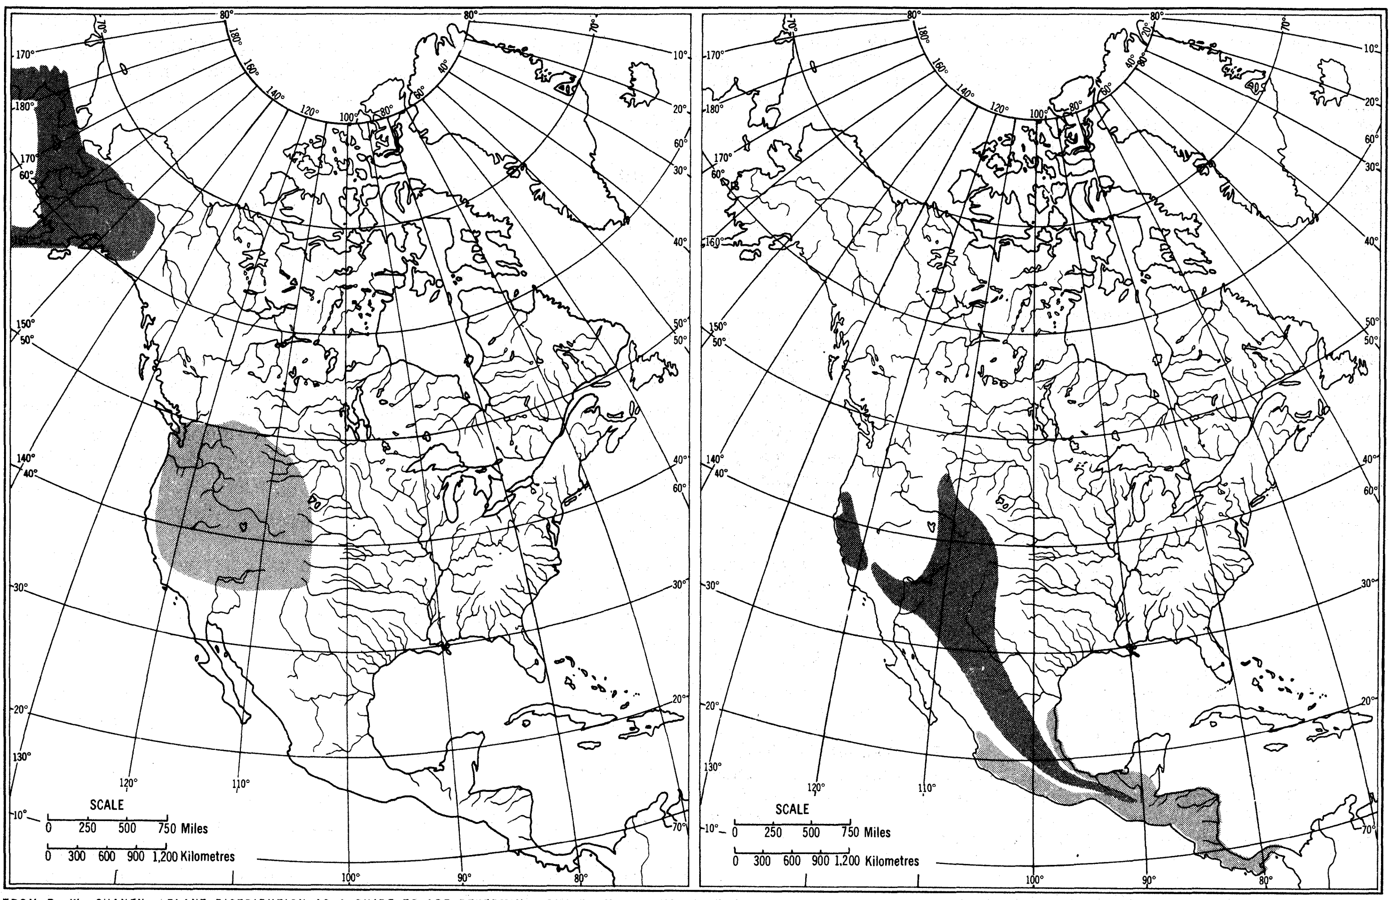
A given factor, such as temperature or moisture. does not always act in absolute fashion. The reaction of a plant with respect to it may vary nith other conditions. Thus by regulating water supply, etc., a plant may be hardened to resist cold.

2. Plant **Adjustments.**—Autecology also considers the numerous specialized adjustments of behaviour between different species of plants, or between plant and animal species. Into this category fall such problems as insect pollination, parasitism and mutual relations between legumes and nitrogen-fixing bacteria.

The course of organic evolution has led not merely to increased specialization of animals and plants, but to increasingly specialized relations between and among species of both. Thus the class of insects. although older than flowering plants, has developed to its present amazing complexity (over 500.000 species) along with the flowering plants, with which insects sustain a wide variety of intimate, often mutual relationships. Unquestionably the development of the flowering plants has been, in its turn, profoundly affected by the activities of these invertebrates. Similarly, the rise of hoofed grazing animals mas conditioned by the evolution of grasses and the consequent origin of great continental steppes. The grasses, in turn, have become adjusted to grazing as a factor in their normal environment.

Among the interrelations of plants none is more important than competition. The consequences of competition are evident in all plant communities, but the source and means of competition are a part of the subject matter of autecology. The general principle involved is that the intensity of competition increases as requirements become more nearly alike. This implies that competition should be most intense between individuals of the same species, which have practically identical requirements. Especially is this true of plants, since mutual benefit within the species does not appear so clearly among plants as among animals. Some measure of the intensity of competition can be seen in any normal woodland by comparing the density of seedlings, saplings and mature trees of any species. A single mature tree is likely to be the sole survivor of many thousand seedlings. Since the most critical competition is for light, water and soil nutrients, the ultimate adjustment among individual plants is attained through spacing, both of roots and tops. Secondary species commonly root at shallower depths and branch at lower levels than dominant forms.

The absence of mutual aid within the plant species is compensated for in part by the usually prodigious output of reproductive bodies, e.g , seeds, and by the development of often highly specialized means of dissemination, whose study is an important phase of autecology. Seed transport by wind, water and animals is a phenomenon familiar to anyone with the slightest knowledge of



FROM R. W. CHANEY, "PLANT DISTRIBUTION AS A GUIDE TO AGE DETERMINATION" FROM "JOURNAL OF THE WASHINGTON ACADEMY OF SCIENCES"

FIG. 14 — DISTRIBUTIONOF SUBTROPICAL AND TEMPERATE FOREST UNITS DURING THE CENOZOIC ERA OF WESTERN AMERICA (BEGINNING ABOUT 70.000,-000 YEARS AGO)

(Left) Eocene epoch; (right) recent epoch. In both maps, the lighter area indicates a subtropical, and the darker area a temperate forest

plants, and often attains great effectiveness. Hard seeds of edible fruits not only pass through the digestive tract of animals without injury, but may actually germinate better for doing so. The eccentrically weighted fruit of maple acquires in falling a spin which may project it to a considerable distance from the parent tree. The coconut, although it cannot germinate after prolonged immersion in salt water, appears to have been transported, by means of ocean currents, to every oceanic isle capable of growing it.

The term adaptation is frequently used with respect to autecological adjustments. It should be employed. however, in such a way as not to confuse (1) the fitness of plants which have become adjusted by selection to a given environment; and (2) the plastic adjustments which a given species can make to variations within an environment to which it has long since been generally fitted by selection.

Autecology has numerous practical applications; *e.g.,* in the selection of drought-, frost-, and disease-resistant varieties of economic plants. It is also of value in diagnosing the character of a habitat under conditions where instrumental studies are not available. Commercial use has been made of it in selecting sweet corn strains with very tight husks through which the larvae of the European corn borer cannot penetrate to the tender grains within.

B. Regional Floras (Floristics)

With the possible exception of certain microscopic plants, every species has a limited and characteristic range, although there is wide variation among species in extent and continuity of their range. The same statement may be made of larger groups, the genera and, to a considerable degree, of families. Groups with greatly restricted range, such as the genus *Sequoia* which is confined to California, are known as endemic. The opposite extreme is represented by cosmopolitan forms such as the common dandelion.

1. Pattern of Distribution. — The pattern of distribution of plant families and their subdivisions finds its explanation in terms of organic evolution and subsequent migration. This migration, in turn, has been subject to changing conditions of earth, climate and biological influence. Theoretically, the older a group. the more extensive should be its distribution; but this principle is subject to so many modifications that every instance has to be investigated on its merits. For example, the present genus *Sequoia* referred to above was once widespread.

Thus a study of floristic patterns must take account of the past as well as the present. It draws upon geology and climatoiogy for explanations, and in turn is a source of valuable clues to students of these subjects by suggesting the position, in time and space, of pathways and barriers. These latter are dependent upon changes of land and water area, changes in land elevation, and shifts in climatic centres.

The term continental pairing is sometimes employed to describe the rather frequent appearance of a genus. or even a species, on two continents. Thus closely related forms are to be found in eastern Asia and in North America — a fact correlated with the existence of a land bridge in the Bering region and a uniform, favourable circumpolar climate. Similar relationships exist between the floras of Europe and North America and those of Asia and Africa.

On the other hand, members of families common to Africa and South America, or to Australia and other continents of the southern hemisphere, exhibit more distant relationship and hence point to more remote opportunities for migration and to barriers of greater antiquity. These facts are parallel nith data obtained from animal distribution — for example. the relatively ancient separation of old and new world marsupials and primates.

2. Factors Influencing Distribution. — The most obvious climatic influence on plant distribution is that of temperature. Few species of seaweeds, if any, have a zone of distribution exceeding a difference of ten degrees in mean annual isotherm. Land species are subject to similar limitations, plus those caused by differences in supply of available moisture. Hence continental desert areas may form barriers as effective as mountain ranges or seas.

Numerous biological factors also influence migration of plant species. Apparently the Yucca (*q.v.*) will tolerate a wider range of conditions than the *Pronuba* moth which is essential to its pollination and seed formation. Thus its natural range is limited to that of the symbiotic insect. Again, the evolutionary development of more efficient species will drive older, less efficient species from areas to which they are well adjusted, and hinder their return. This is exemplified in the relation between conifers and deciduous trees in the humid temperate parts of the northern hemisphere. The former, though quite capable of growing in such regions, have been relegated to the less productive margins. Also, the presence of lethal parasites may exterminate a particular species throughout a portion of its natural range especially favourable to the parasite. and thus establish a lacuna or barrier.

The reciprocal relation between human cultures and plant species is of extreme importance. The three great centres of primitive agriculture — eastern Asia. Asia Minor and Central America — are correlated with the original location of three grasses — rice, wheat and maize. respectively. In the subsequent migrations of these and other economic plants, and of numerous ruderals, is to be found much of the record of the shifting of human cultures.

While the subject of floristics deals with the distribution of all species of the plant realm, the greatest interest attaches to seed plants, which are the dominant forms of modern plant life. Considerably more than half the known families are represented within the tropics. which have afforded more or less continuous refuge during periods of climatic stress in more temperate regions. Flowering plants, well established during the Cretaceous, evolved into a wealth of species during the ensuing Tertiary and became widely distributed during that period of comparatively widespread favourable climate. Present patterns of distribution of this great group and the somewhat older conifers are largely the result of the impact of glacial Pleistocene conditions upon this Tertiary pattern.

Pleistocene glaciation involved at least four major advances of continental ice sheets, with three more or less prolonged interglacial periods. The comparatively brief time since the last retreat (about 15,000 years). although usually referred to as postglacial, has exhibited some of the qualities of an interglacial period, and at no time since the Tertiary have the mild conditions of that period been attained.

During the Tertiary a remarkably rich temperate flora had become diffused to high latitudes in both hemispheres and may properly be described as circumpolar. This flora was compelled to retreat toward the tropics by the advance of Pleistocene ice. With each glacial recession some of the lost territory was reoccupied. to be lost again with successive advances of the ice. The effect of this upon the Tertiary flora was less disastrous in North America than in Europe, where southerly retreat encountered obstacles, and where now the deciduous forest flora is relatively poor in species.

Glaciated portions of the northern hemisphere exhibit three groups of disjunct species of great interest: (1) boreal species in now temperate southerly regions; (2) southern plants occurring in isolated stations north of their present main range; and (3) continental steppe or grassland species in more humid or oceanic regions than they normally occupy. The boreal species, notably bog plants, are now usually regarded as true relicts left behind following the last glacial retreat. The northern outliers of southern plants are still a subject of controversy. One school holds that they represent vegetation which persisted in place on nonglaciated elevations or nunataks throughout glaciation. Critics of this belief hold that this was impossible, questioning the nunatak nature of the areas in question and also the ability of southern plants to survive the glacial climate. Both botanists and geologists are divided in opinion.

In view of this problem, the third group of disjunct species takes on considerable interest. There is a growing belief that they represent relicts from a postglacial time that was warmer and drier than the present — a so-called xerothermic period or periods. Given such climatic conditions and a suitable pathway for migration — for example, the formerly elevated but now submerged Atlantic coastal shelf — southern plants may well have moved northward, leaving relicts behind them during the subsequent cooling and subsidence. At any rate evidence is accumulating from a variety of sources, including modern glaciers and microfossils in peat deposits. to substantiate the existence of postglacial xerothermic conditions.

While the chief contributions to floristics are made by students of plant classification (taxonomy), the knowledge itself is an essential segment of ecology. For example, composite maps of the ranges of characteristic plants of great formations reveal with clarity the dynamic centres of climate and plant distribution in such regions as the eastern deciduous forests and tall-grass prairies of North America and the Mediterranean zone of Europe.

Moreover the Danish botanist C. Raunkiaer has developed a method of climatic analysis through floristic lists of any region. He has classified plants according to the depth of burial or height of exposure of their delicate perennial growing points. Each species falls into a definite category according to the degree of exposure or protection, and the percentage of species in each category constitutes what he calls the "biological spectrum" of a given regional flora. By comparison with a standard spectrum which he devised, inferences may be drawn concerning the climatic characteristics of a region whose flora has been thus analyzed.

C. Ecological Plant Geography

Much that has been said concerning the distribution in space and time of species will apply to communities of plants as well. For a discussion of the nature of communities, see Plant Sociology (Synecology) below.

1. Major Communities. — The major communities of the earth can be grouped roughly as follows: (1) tundra, or treeless, largely moss and lichen vegetation found in the arctic and above timberline on mountains; (2) taiga, or coniferous evergreen forest, ranging from sparse and stunted to dense and thrifty, characteristic of cool regions bordering the tundra; (3) forests of other types, including temperate-deciduous and evergreen forests, tropical rain forest and tropical monsoon (deciduous) forest; (4) grassland, including subhumid and dry steppe or prairie and shortgrass; (5) scrub, or woody, semiarid shrub vegetation; (6) desert. Transitions of course are common — for example, savanna between forest and prairie.

The major communities are known as formations. They are regarded, with reason. as expressions of major climatic types. Allowance must be made, however, for variations caused by physiographic conditions which modify the impact of the general climate, thus producing microclimatic differences, and for soil (edaphic) conditions which modify the availability of water and nutrients or impose unusual chemical limitations.

For such reasons, the actual boundaries between formations are seldom smooth and unbroken. Rather they are lobed and interdigitated, resembling peninsulas and chains of islands. As Asa Gray put it, there must be debatable borders between regions where slight incidents will throw the balance either way. Climates fluctuate in the intensity of their expression from year to year. and consequently in their marginal effects.

Rapid increases in elevation result in a telescoping of climates within comparatively small areas. Thus in ascending a mountain one may pass through plant communities expressing climates which on level terrain might encompass many hundreds of miles.

Any map of world formations must be generalized to a high degree, yet inspection of such a map reveals the transitions from extreme oceanic to extreme continental climates except in circumpolar regions where temperature becomes the limiting factor. The failure of such maps, in temperate and tropical regions, to correlate more exactly with conventional rainfall maps is caused by evaporation, a quantity not generally measured by the meteorologist, but one of critical importance to vegetation.

Ecological plant geography is a subject of the highest utility in its bearing upon world resources and industries and in its indication of proper types of land use and management. It is likewise a factor in military strategy.

D. Plant Sociology (Synecology)

In its broad sense this term is equivalent to synecology, or the study of vegetation rather than the individual plant, or the physical factors of the environment. It is sometimes employed to indicate particular techniques of statistical study. Whereas flora represents the sum total of plant species, vegetation refers to the aggregate of plant life in terms of the communities into which it is organized. Beginning with the great formations already referred to, vegetation may be subdivided into communities of descending rank and of distinctive character at each level.

Difficult problems of nomenclature and classification are involved here, including the old Aristotelian problem of the specific thing and the form which it represents. The deciduous forest of eastern North America may be designated as the oak-beech formation, which in turn includes the maple-beech, oak-hickory, and oak-chestnut associations. These associations again may be divided into faciations (white oak–black oak), consociations (bur oak), and these latter into societies of subordinate species. More formal systems, involving Latinized terms, are also employed. In general the more refined a subdivision, the more homogeneous its character.

1. Community Structure and Evolution. — The attributes of a plant community are structure (the growth forms present—*e.g.*, trees, shrubs, grasses — and their relative arrangement), composition (the species present), and development (life history or succession). Thus a forest is dominated by trees of one or more species, the individuals exhibiting definite spatial relations to each other. In the environment thus controlled, characteristic undershrubs, seedlings, vines and herbs occupy suitable niches. Equally essential, although less conspicuous, are the fungi and bacteria which utilize the materials formed by the dominant vegetation and by decay return these materials for re-use by green plants. Characteristic parasites and symbionts are also part of the community structure, and so are its animals as well. Such a structure may vary greatly in Aoristic composition, depending upon the species present in the region. The deserts of Asia and North America are similar in structure, but composed of different plant families.

One of the most fruitful discoveries in connection with plant communities is the fact of succession or development. This can be simply illustrated by the changes which occur on an abandoned field, a bare rock surface, or a sand dune from the first invading pioneers to the final stabilized forest or prairie. Succession involves change in both structure and composition and moves toward a condition of relative equilibrium characterized by little change in either respect, and known as a climax community. The test of a climax community lies in the ability of the species composing it to reproduce themselves under the conditions which they so largely determine. Pioneer and subclimax species do not have this power. In principle a climax community, once established, maintains itself unless disturbed by physiographic, climatic, or biological (biotic) change. Such disturbance for example would result from serious erosion, uplift or depression, shift in available moisture or temperature patterns. evolution or immigration of new species, fire, clearing, drainage, disease, etc.

Succession represents a process of increasing integration between life and environment. It apparently tends to follow the principle of Le Chatelier as developed by Bancroft; *i.e.*, heterogeneous systems tend progressively toward a condition of minimum disturbance by external forces and internal stresses. So far as the somewhat limited evidence goes, succession also tends toward a progressively more efficient use of energy. The climax community is a close-knit and delicately balanced system which stores and uses solar energy. So intimately adjusted are the nutrient and reproductive cycles of its constituent organisms that the minimum of useful energy is wasted in the chain of metabolic relationships. Thus the climax community represents the maximum in organic economy, as contrasted with the extreme of energy waste in a bare area which receives solar energy only to dissipate it into space without benefit to living organisms.

Representing thus the maximum capacity of a landscape for sustained production, the climax community affords a scientific norm of great value to man in the planning of land use and management and. by analogy at least, in the organization of his own communities. For this reason, quite as much as for sentimental and aesthetic considerations, it is important that in civilized and heavily populated areas substantial remnants of natural vegetation should be set aside, preserved and permanently protected from disturbance. Such reserves or nature sanctuaries are to be distinguished from parks set aside for recreation, and from public forests managed for economic yield.

There is, unfortunately, some difficulty among ecologists in arriving at an agreement regarding the exact meaning of the word climax. For practical purposes the climax plant community might be regarded as the limit toward which the vegetation of a given climatic area and a given evolutionary composition tends. This definition is chiefly convenient because the changes in climate and evolution are slow in terms of human experience. Against them as a background, succession involves the operation of three other dynamic processes: (1) changes in the landscape; (2) soil development; and (3) biological interaction.

2. Changes in the Landscape. — The youthful landscape is typically marked by strong contrasts of elevation, which for a time are increased by the rapid downcutting of narrow stream valleys. This tends to diversify the effect of climatic conditions. producing extremes of shelter in ravines and depressions, of exposure on uplands, and marked differences in available soil moisture throughout. As topography matures, valleys widen, depressions fill and uplands are lowered, thus lessening the initial contrasts. The limit of this process is represented by the peneplain, a generally uniform physiographic system over which local modifications of climate are at a minimum. Until this mature stage of topography is reached, the stability of any community within the landscape is provisional, and its climax character is relative, subject to completion of the erosion cycle.

Actually the peneplain condition is not often attained. Tilting, warping and uplift often interrupt the orderly progress of the erosion cycle, rejuvenating the landscape and interrupting the course of plant succession. Morever, the rate of erosion and deposition is significantly modified by the presence of vegetation. This can be observed by comparing the sharp and rugged topography of a thinly clad desert or semiarid terrain with the gently rounded hills of a heavily vegetated humid region. By removing natural vegetation and substituting clean-tilled fields, man has become a prime agent of geological change, inducing as much erosion in a few decades as might occur in a millennium under natural conditions.

3. Soil Development. — Soil represents not merely the finely divided rock of the earth's surface, but the underground extension of community action and influence. This activity results in a physical, chemical and biological organization of the soil of which the structural expression is the soil profile. The soil profile is studied by means of trenches, or along road and stream cuts, and accurately records the character of the particular climate and vegetation. Thus a forest soil profile is characterized by a thin, very rich and acid surface layer of black humus formed by the fungus decay of fallen leaves and other organic debris. Beneath is a light layer from which the acids have leached soluble mineral material, and below that the layer occupied by tree roots, from which they draw mineral nutrients that are subsequently dropped on the surface by falling leaves, branches, fruits, etc. By comparison, a grassland soil profile exhibits a dark humus layer often 36 in, or more in thickness, measuring the depth of penetration of the abundant fibrous roots and the accompanying microorganisms and fauna. In consequence of these differences cleared woodland soil quickly loses its shallow, rich surface layer with careless handling, while prairie soil can endure longer periods of exploitation. The latter, on every continent, is particularly suited to cereal production, and from it comes the bulk of such staple foodstuffs.

Thus the soil profile is an expression of the energy which activates the living community, and the organization of the profile indicates the capacity of the area to sustain life under current conditions. It should be noted that this organization represents an accumulation of solar energy, inanifesting itself in the accumulation and mobilization of materials, and facilitating the work of living organisms. The accumulated energy in soil is analogous not so much to the power which runs a factory, as to the energy used in its construction and equipment. Soil development is clearly a most important phase of community succession. And in the same way that physiographic processes tend to minimize the initial differences of a given climatic area: soil development tends toward uniformity throughout such an area.

4. Biological Interaction. — The influences of vegetation and habitat are mutual and continuous. Yet it may be said that the influence of the physical environment is at a maximum under pioneer conditions, while that of vegetation is greatest at climax. The pioneers in a new or raw habitat usually encounter extremes of physical and chemical conditions, and frequently violent fluctuations in those conditions. For example, successful pioneer plants must be adapted to withstand high intensities of light usually characteristic of such habitats. But these plants produce shade, which is unfavourable to their own seedlings, and they are replaced by species more tolerant of shading.

Pioneer habitats likewise often present extremes of moisture or dryness. The growth of pioneer plants, adjusted to such extremes, increases humus and modifies the local water balance, a circumstance which operates in favour of plants which, while less hardy than the pioneers, are much more efficient than their predecessors under the new conditions which those predecessors have brought about.

An exceedingly important aspect of this process is the role played by animals and microorganisms, through competition and through the mutual adjustments between dominant and secondary species belonging to the same stage of succession. Like the processes of physiographic change and soil development, biological interaction is convergent in character, leading from initial heterogeneity to ultimate homogeneity. Thus, in the north central states, such varied habitats as dunes, ponds, bare rock and clay ridges have their distinctive pioneer vegetation. Each passes through a characteristic sequence beyond this stage, approaching in structure and composition the beech-sugar maple forest—a relatively stable and self-perpetuating community. Numerous instances are on record of beech-maple climax forests which have deveioped on each of these types of initial areas; on the other hand a lag in physiographic change or soil development may arrest the sequence for a long period at some subclimax level. Thus the moist shaded northern face of a steep hill may reach the climax condition while the hot dry southern exposure remains covered with the subclimax oak and hickory.

Problems of technique in the field of plant sociology have been quite as troublesome as those of nomenclature. Mapping, both topographic and two-dimensional, is of course essential. Aerial photograph>·has been an invaluable aid.

Within the community itself the problem of expressing quantitatively the relationships which exist is extremely complicated. In addition to relative abundance of various species, their cubic magnitude, both above and below ground, may bc significant. Typical concepts used are frequency, coverage, constancy, presence. Since the end of quantitative study is always a qualitative judgment, the choice of particular techniques of counting and measuring varies widely with workers and with the nature of the communities studied. Thus in grassland and herbaceous communities the use of standard quadrats, or squares of uniform size for sampling and comparison, has been extensively developed. In forest regions quadrats of larger size are necessary to give adequate sampling.

Since plant succession is at best a slow process, it must ordinarily be demonstrated by a combination of more or less indirect and inferential methods. Prevalence of vigorous juveniles of species different from the existing dominants is strong evidence of the direction of succession. The zonal distribution of plants, as, for example, about a senescent lake, often indicates the sequence of advance of land vegetation into the lake bed. Comparison of numerous related communities in different stages of development is also a fruitful method. Records, whether paleobotanical, archaeological, or historical, often afiord valuable clues. Direct proof is increasingly afforded by the growing length of scientific records.

E. Nonliving Factors of the Environment

1. Ecological Measurement, or Habitat Analysis. — These terms are employed in the absence of better ones to designate evaluation of the nonliving factors of the environment. The ecologist here depends upon techniques borrowed from sciences which deal with earth and atmosphere. Not infrequently he contributes to these sciences in return, as is evidenced by the groming attention given to evaporation by meteorologists.

It is an axiom that the living community is the most perfect expression or integration of the physical environment. This has led to considerable use of plant communities as indicators of conditions which cannot conveniently be measured otherwise, as for instance, depth of water table. Individual species are also used as indicators.

It is essential, however, that the physical environment be understood as accurately and completely as possible. This is well exemplified by the problem of the Korth American prairie. For a century able scientific men had propounded explanations as to the absence of trees on the prairie. More than a score of theories were advanced, including such suggestions as fire and soil. It was not until after 1910, and then as a result of patient instrumental studies, that proof was obtained that the lack of available moisture is the limiting factor for tree growth in the main body of the grassland. This had been frequently surmised, but never before established.

For the greatest value, ecological measurements should be continuous and inclusive. Light. humidity, precipitation, temperature, evaporation, wind movement and direction are the atmospheric factors most important. Moisture, temperature, texture and chemical composition are the corresponding soil properties. Automatic recording instruments, such as the hygrothermograph, must be employed, supplemented by frequent determinations for such factors as are not adapted to automatic measurements.

The earlier ecological methods of studying light only measured the intensity of actinic rays. improved means are now available which measure both intensity and quality for a wide range of the effective spectrum. Also important is the photoperiod, or relative length of day and night. Measurements for evaporation have until recently given only relative figures, which could not be integrated with rainfall data. Improvements under way promise to give means for direct and absolute determination of the evaporating power of the air.

2. Limiting Factors. — In the study of environment the principle of limiting factors must constantly be borne in mind. It is empirically expressed in the proverb "a chain is no stronger than its weakest link," and was recognized by Baron Justus von Liebig in his study of soil fertility by his "law of the minimum." In 1905 it was placed upon precise experimental basis for plant metabolism by F. F. Blackman, who stated that the rate of photosynthesis mas conditional upon the least favourable of the several factors necessary. Depending upon local conditions, moisture, acidity, nutrients, temperature, light. etc., may be the controlling or limiting factor in a given habitat for given plants. The object of much ecological measurement is to determine limiting factors.

Ecological measurement has been sufficiently perfected to give material aid in predicting the hazards to be encountered in critical areas under various types of land use and management. This technique can be of the greatest economic importance in semiarid regions, such as the high plains of Korth America.

F. Applied Plant Ecology

Illustrations of the economic uses of ecology have been given in the preceding sections. With few exceptions, however, such applications have been sporadic. At the first Imperial Botanical conference, held in London in 1924, systematic plans were laid for the employment of ecology in developing new parts of the empire. With the encouragement of Gen. Jan Smuts, this conference has borne fruit in Africa. The Russians have made intelligent use of ecology. although there is reason to believe that parts of the steppe area have suffered unduly from exploitation. The Gnited States department of agriculture, including the soil conservation service organized in 1935, is making increasing use of ecology.

Yet it is probably fair to say that among public men, and among the general population, there is yet little realization of the basic importance of this subject in establishing permanent and healthful relations between landscape and population.

In the problems of land use and management, ecology occupies a role analogous to that of physics and chemistry in modern industry. Such problems must increasingly be solved by the rigorous application of the principles of ecological science.

Man is the beneficiary not only of a prolonged process of organic evolution which has provided him a great variety of useful plants and animals, but of prolonged and continuous activity by plant and animal communities. This has resulted in the development of fertile soil, as well as in forests and grasslands whose products are no less essential to man than those of his cultivated fields. Moreover, natural vegetation maintains a cover which stabilizes the earth beneath him and retards the violent action of erosion.

Natural communities are characterized by a positive or favourable energy budget. Many, perhaps most, areas controlled by man are exploited, resulting in a negative energy budget, the final mark of which is unproductiveness and abandonment. The fundamental problem of applied ecology therefore is to assay various landscapes occupied by man and determine whether they are registering a net loss or gain in efficiency. The simple criterion of cash returns cannot be applied here. The next problem of the ecologist is to assist in devising methods of land use suited to the character of the locality so that a favourable energy budget may be maintained or restored.

Because of the character of our political system and our long habit of using science chiefly where immediate problems of health or profit are involved. the fundamental application of ecology cannot be hastily achieved. In practice, however, growing numbers of civil servants — foresters, county agents, agricultural engineers, entomologists. etc.—are acquiring some understanding of ecology. The same thing is true to a lesser extent of farmers and farm owners. As this knowledge becomes more general, it will materially affect practice and planning, and has in fact already done so in favoured localities.

In the field of land management, or actual operation, ecology also has important functions, some of which have been suggested in preceding sections.

PLANUDES, MAXIMUS (c. 1260–1330), Byzantine grammarian and theologian who flourished during the reigns of Michael VIII and Andronicus II Palaeologi, spent the greater part of his life as a monk in Constantinople On entering the monastery he changed his original name Manuel to Maximus. Possessing a knowledge of Latin remarkable for his time he was sent by Andronicus II in 1327 on an embassy to remonstrate with the Venetians for their attack upon the Genoese settlement in Pera. Planudes, especially by his translations, paved the way for the introduction of the Greek language and literature into the west.

He is the author of a Greek grammar, a biography of Aesop and a prose version of his fables, certain scholia, various original poems. His numerous translations from the Latin included Cicero's *Somnium Scipionis* with the commentary of Macrobius: Caesar's *Gallic War;* Ovid's *Heroides* and *Metamorphoses;* Boetius, *De consolatione philosophiae;* Augustine, *De trinitate.* He also edited a supplement to the Anthology known as *Appendix Planudea*

PLASKETT, JOHN STANLEY (1865–1941), Canadian astronomer, discoverer of the dual star known as "Plaskett's twins," was born Nov. 17, 1865, near Woodstock, Ont. Me graduated from the University of Toronto in 1899. In 1905 he was made astronomer of the Dominion observatory at Ottawa, and remained in that position until 1917, nhen he was placed in charge of the Dominion Astrophysical observatory in Victoria, B C. After his retirement in 1935, he supervised the grinding and polishing of the 82-in mirror for the telescope of the McDonald observatory of the University of Texas.

Plaskett was one of the most noted astronomers of his time Of his many important discoveries, one of the first came in 1922 when he found that what had for years been considered a large single star was actually two stars. The stars, although clearly visible to the naked eye, had not been identified as tuins until Plaskett studied them through the Dominion observatory's 72-in. telescope. which he had been instrumental in persuading the government to install.

The stars were subsequently given his name and are known as "Plaskett's tnins" He also made valuable studies on the motions of stars, on the Milky Way and its movements and on the rotation of the galaxy.

Of his numerous papers. the most important include *Star Image in Spectroscopic Work; Design of Spectroscopes; The Rotation of the Galaxy; Diffuse Matter in Interstellar Space;* and several on the 0-type stars.

He was the recipient of a number of honorary degrees and awards for his distinguished services to astronomy. He died at Esquimault. B C., Oct. 17. 1941.

PLASSEY (PALASI), a village of Bengal, scene of Robert Clive's victory on June 23, 1757, over the forces of the nawab Suraj-ud-Dowlah. Clive, with a force of about 3,000 men and 8 fieldpieces, took the field against the nawab, who had about 60,000 men, 53 heavy guns and some French artillery under St Frais. Only the Bhagirathi river separated Clive's force from the entrenched camp of the enemy, when the English leader, for once undecided. called a council of war. Clive and the majority were against fighting; Maj. Eyre Coote, of the 39th foot, and a few others were for action. Coote's soldierly advice powerfully impressed Clive, and after deep consideration he altered his mind and issued orders to cross the river. After a fatiguing march, the force bivouacked in a grove near Plassey early on June 23. The nawab's host came out of its lines and was drawn up in a huge semicircle almost enclosing the little force in the grove. and St. Frais's French gunners on the right wing opened fire. Clive replied and was soon subjected to the converging fire of 50 heavy guns. For hours the unequal fight was maintained, until a rainstorm stopped it. The English covered up their guns, but the enemy took no such precaution.

Mir Mudin, the only loyal general of the nawab's army, thinking that Clive's guns nere as useless as his own, made a disastrous cavalry charge upon them; he lost his own life, and his colleagues then had the game in their hands. Mir Jafar persuaded the nawab to retire into the entrenchments.

But the rank and file of the Indians, ignorant of the treachery of

Mir Jafar, who went over to Clive, made a furious sortie. Clive, noticing that Mir Jafar's division in his rear made no move against him, led his troops straight against the works.

After a short resistance, made chiefly by St. Frais, the whole camp fell into Clive's hands. At a cost of 22 killed and 50 wounded this day's work decided the fate of Bengal. Although the historic grove has disappeared, a monument has been erected to commemorate the victory.

PLASTERING is one of the most ancient building techniques. Evidence indicates that primitive peoples plastered their reed or sapling shelters with mud, thus developing more durable structures and more effective screens against vermin and inclement weather. More lasting and sightly materials in time replaced mud. Some of the earliest extant plastering is of a quality that compares to that used in modern times. The pyramids of Egypt contain plasterwork executed at least 4,000 years ago which is still hard and durable. The principal tools of the plasterer of that time were in design and purpose like those used today. For their finest work the Egyptians used a plaster made from calcined gypsum which is identical with plaster of paris. In other respects also the materials and the procedures used by the Egyptians 4,000 years ago were identical with those of today.

Very early in the history of Greek architecture (*e.g.*, at Mycenae) plaster of a fine white lime stucco mas used. The art of plastering reached a high degree of perfection in Greece more than five centuries before Christ, and plaster was frequently used to cover temples externally (stucco) and internally, in some cases even when the building was made of marble. The stucco and the plaster of the interior provided an excellent ground for decorative painting. The temple of Apollo at Bassae, built of yellow limestone about 450–420 B.C., is an excellent example of Grecian skill and artistry in the use of decoration on stucco and plaster. The ornamental plaster ceilings of England during the reigns of Henry VIII, Elizabeth I and James I still are admired. Earlier extant specimens of the plasterers' skill in England are the pargeted and ornamented fronts of half-timber houses. Plaster as a medium of artistic expression waned by the 19th century, when imitation and mechanical reproduction all but displaced this creative art. As a surface material for interior walls and ceilings and to a lesser degree for exterior walls, plaster has become common. It facilitates cleanliness and sanitation in building and is a retardant to the spread of fire.

Base.—A surface is usually prepared for plastering by first providing a base to which the lath is applied. The base may be an integral part of the structure or a separate framework attached to the walls and ceilings. The purpose of the base is to correct minor deviations from a true surface that may be present in the structure and to provide additional attachment for the lath. In wood-frame structures the walls are usually constructed so as to provide a true surface while the ceilings for the most part require a base. On masonry walls the base also provides a necessary air space and a separation between the plaster and the dampness which might penetrate the masonry. Furring may consist of strips of wood or light steel structural shapes fastened to the walls or ceilings of masonry or wood-frame buildings.

Wood Furring.—Wood furring consists of strips of wood usually surfaced on one or both faces to a thickness of $\frac{3}{4}$ in. and having a width of two or three inches. The strips are spdced 12 or 16 in. on centres to conform with the dimensions of the lath which are 48 in. or a multiple of 48 in. in length. Wood furring strips on exterior masonry walls are placed vertically and are securely attached with galvanized nails driven into the mortar joints or into plugs provided for that purpose. On wood floor joists and rafters the furring strips (or strapping) are run crosswise to the direction of the joists and nailed securely to the underside of each joist.

Steel Furring.—Steel furring, consisting of light channel sections or rods, may be used on exterior masonry walls. The channels or rods should be galvanized or painted as a protection from corrosion and securely attached with galvanized staples driven into galvanized metal plugs set in the mortar joints of the wall. In fireproof construction, where plastered ceilings are installed, steel furring may be suspended from the flanges of the beams or soffits of the floor construction by means of clips or metal hangers.

Grounds.—Grounds are strips of soft wood surfaced to a uniform thickness corresponding to the combined thickness of the lath and plaster. These strips surround all openings in the plastered areas and provide a stop at the boundaries of the plasterwork. They must be set accurately for line, and they must be level and plumb, since they serve as guides for the finished plaster surface. The grounds must be set carefully with respect to the interior finish so that they are covered by the door casings, the window trim, the baseboards and all other interior finish. At the intersection of plastered surfaces forming an external angle, a metal corner bead serves as a ground and a protection for the otherwise exposed plaster. In fireproof construction where interior partitions are masonry or steel stud walls the grounds may be an integral part of the metal frames. The thickness of the ground varies with the type of lath and the number of coats of plaster required. With metal lath and three coats of plaster the grounds are $\frac{3}{4}$ in, thick; with gypsum lath and two coats of plaster the same thickness is required and with wood lath and three coats of plaster $\frac{7}{8}$ in. thickness is required.

Lathing.—Lathing provides the structural base or reinforcement for the plaster and is the means of attaching it to the wall and ceiling furring. The plaster may be keyed to the lath and held mechanically, as it is when used with wood lath or it may be bonded to a surface by adhesion as it is when used with gypsum lath.

Until the end of World War I wood lath was extensively used in the U.S., but it has largely been displaced by plasterboards and metal lath.

Wood lath is usually sawn, straight grain spruce, free of bark and live knots and measuring $1\frac{1}{2}$ in. wide by $\frac{1}{4}$ in. thick and 48 in. long. In wood-frame buildings having studs spaced 12 or 16 in. on centres the laths are nailed on the walls in parallel horizontal rows with their edges not less than $\frac{3}{8}$ in. apart so that the mortar may be pressed through to form a key which clinches it to the lath. The laths are laid with end joints meeting on the supports, but should not be permitted to butt or overlap, nor should continuous joints occur on one support. The joints of every eight or ten laths should fall on alternate supports in order to avoid a line of weakness where the plaster might crack from shrinkage. The wood laths are secured to the studs or furring with a threepenny large-headed nail at each end of the lath and at each intermediate stud or furring strip.

Metal lath is usually some form of expanded metal or woven wire mesh which is protected against corrosion by galvanizing or painting. The expanded metal lath is available in standard lengths of 8 ft. and widths of 24 in., and the wire mesh is available in rolls of 100 ft. or more and in various widths. Because of their fireproofing quality metal laths are used extensively in all types of buildings. Expanded metal lath should be applied to the walls with the long dimension running horizontally, starting at the bottom, with each successive sheet overlapping the one below. The end joints should also be lapped and securely stapled or wired to the supporting furring or studs. Additional ties should be provided between supports along the overlapped edges so as to prevent sagging nhen the weight of the wet plaster is applied.

Gypsum lath consists of a sheet of gypsum plaster enveloped in a protective paper covering and available in units 16 in. wide by $\frac{3}{8}$ in. thick and 4 ft. long. These units are nailed to the base with joints breaking on alternate furring strips or studs. To protect against cracks caused by shrinkage narrow strips of metal lath may be applied at the intersection of the ceiling and walls as well as at the interior corners. As a substitute for wood lath this type of lath requires less plaster and has a somewhat better insulating value.

Plaster.—Plaster materials used in the composition of plastering mortars include a cementing agent, an aggregate and a binder. The aggregates and binders are inert materials while the cementing agent, in the form of a paste, has the property of setting or hardening. 4 properly proportioned mixture of these components results in a workable mortar which sets and hardens. Mortar is usually designated according to its cementing material, such as lime, gypsum or cement mortar. The aggregate most commonly used is a fine-grained, sharp and angular sand, clean and free of all traces of clay, loam or organic matter. The binder may be long, clean cattle hair or jute fibre in two- to three-inch lengths. For interior work lime or gypsum plasters are most commonly used.

Lime.—Lime is made by heating limestone at a sufficiently high temperature to eliminate the carbonic acid and water. At this temperature the limestone is said to be calcined. The resulting white product is called quicklime or lump lime.

Lime in this form must be slaked and reduced to a paste before being mixed with the aggregate to form a mortar. Slaking takes place when water is sprayed on the quicklime. causing it to generate heat as a result of a chemical action. The lime swells to about two and one-half times its original bulk and breaks down into a powder at first and later into a paste. This process is usually carried out at the place of manufacture, and the product appears on the market in the form of a fine powder called hydrated lime. Two grades of hydrated lime are available. One, known as mason's lime. is gray-white; the other, finishing lime, is snow-white and has a finer texture.

Gypsum.—When gypsum rock is heated to a sufficiently high temperature its water of crystallization is expelled. leaving a white powder. This powder, plaster of paris, hardens rapidly after it is mixed with water into a paste. In order to use this material as a cementing agent, a retarder is mixed with the powder to control the time of hardening. With further preparations and additions, including jute fibre, it is known as prepared gypsum cement. This cementing agent. with its aggregate, known as gypsum plaster, is used extensively in the U.S. for interior plasterwork. Because it is soluble in water it cannot be used for exterior work.

Application.— Plasterwork is designed according to the number of applications or coats involved. such as one-coat. two-coat and three-coat work. Two-coat and three-coat work, finished to a thickness. including the lath, of $\frac{3}{4}$ in. is commonly specified for interior work. Three-coat work is usually applied to wood and metal lath and two-coat work is applied to gypsum lath.

Scratch Coat.—The first coat or scratch coat is applied to wood and metal lath, but omitted on the gypsum lath. The mortar for the scratch coat is rich in cementing material and binder using one part by weight of prepared gypsum cement to two parts of sand mixed dry to a uniform colour before the water is added. The mortar should be plastic enough to be worked through the openings to form a key when laid on with some pressure. The scratch coat should be as thin as possible (not over $\frac{1}{4}$ in.) but sufficiently strong to serve as a foundation for the subsequent coats. It is laid on with a steel trowel starting as the grounds near the floor and working upward with overlapping diagonal applications of mortar. When the mortar is set and somewhat hardened the surface is thoroughly scored to provide an adequate bond for the second coat.

Brown Coat.—The second coat, called the brown coat in the U.S. and the floating coat in England, is less rich in cementing material. The proportion of cementing material to aggregate by weight is about one to three when prepared gypsum and sand are used. The cement and sand are thoroughly mixed to a uniform colour in a dry state; water is added to the mixture, and the whole is worked to the desired consistency. Because of the greater proportion of sand in the brown-coat mortar: there is less danger of excessive shrinkage and resultant cracks in the finished plaster surface. The brown coat should not be less than $\frac{1}{4}$ in. thick. It should be laid onto a straight, smooth surface, using the grounds as the guides for establishing the true surface. When the area to be brown coated is large, additional guides may be established by setting points of reference from the grounds. These points of referende, called dots, are used in establishing vertical and horizontal bands of mortar that are six to eight inches wide. These bands, called screeds, divide the area into panels which are then filled in with mortar and brought to a true surface with a straight edge. using the screeds and grounds as the guides. After this operation, which is known as rodding, the surface is smoothed with a two-handed float, called a darby, and further packed and smoothed with a small wooden float. A well-packed and relatively smooth surface is essential to a satisfactory brown coat. When properly packed and smoothed the surface should be scored to provide a bond for the hard finish or white coat.

White Coat.—The third coat consists of a lime paste into which plaster of paris is worked at the time of application. In its preparation hydrated lime is mixed with sufficient water to bring the mixture to a thin paste consistency. It is then permitted to stand for a few days for complete soaking. At the end of this period the paste is mixed with plaster of paris and applied to the brown coat, which should be firm and nearly dry. The mixture of lime and plaster of paris, called gauged stuff, should be applied at once. The gauged stuff may be prepared by the plasterer in small batches to avoid the danger of setting due to the presence of plaster of paris.

The final coat is applied in three operations starting with a thin coat applied with a steel trowel and well bonded to the brown coat. This operation. called scratching in, is followed by a second coat, called doubling-up, that brings the finish surface to its final true plane. The third operation consists in working over the surface with a steel trowel and damp brush correcting minor inequalities and producing a smooth polished surface.

Ornamental Plaster.—Ceiling ornaments and cornices constitute the major part of ornamental plasterwork. Cornices are usually run in place using a metal molding tool which is a reverse profile of the desired cornice. The molding tool is guided by running rods attached for their temporary use to the ceiling and wall. Gauged stuff, consisting of lime paste and plaster of paris, is laid on to meet the profile which is worked to and fro until the cornice is formed. The miters at the corners have to be formed by hand and decorative elements such as egg and dart, rope moldings and other decorative elements are precast and stuck in place with plaster of paris.

Stucco.—Plaster coating of exterior walls is commonly known as stucco. Since the stucco surfaces are exposed to the inclemencies of the weather the choice of cementing material is of great importance, especially in areas where the climate is rigorous. Strength, durability and weather resistance are essential qualities. Mortars with portland cement and other admixtures that improve its workability and reduce its porosity are most commonly used. Stucco may be applied directly to concrete, brick, tile and other masonry malls, or it may be applied to a supporting metal lath base. When the mortar is applied directly to masonry walls the surfaces should be sufficiently rough to form a key for the plaster and properly wetted to prevent excessive absorption. When metal lath is used as a supporting base, the procedures are essentially the same as those used for interior work. Various types of finish. including colours and textures, may be incorporated or applied to the finish coat. White portland cement used with white sand provides a durable surface with a fine texture resembling stone. Splatter dash and pebble dash are textured surfaces resulting from throwing mortar or pebbles with some force on the finish coat while it is still soft. When skillfully done these methods produce interesting variegated surfaces. Colour pigments and finishing techniques may be incorporated in the finish coat with pleasing effects. One of the oldest techniques for decorative plasterwork used for interior and exterior embellishment is sgraffito. Colour coats are applied to the area to be decorated, which is finished with a skim coat of fine cement. The outer coat or coats are scratched away, exposing the coloured layers that make up the decoration.

Plaster Substitutes.—After World War I many composition boards and sheets became available as substitutes for plaster. These substitutes have many desirable characteristics such as insulation, sound absorption, durability as well as ease of application. To this might be added the advantages of a dry construction. which permits an uninterrupted building program and reduces building costs. The disadvantages stem from the inherent difficulties with joints and with application to nonplanar surfaces. Much improvement has been made in dealing with the joints. Most of the sheets manufactured in the U.S. have standard widths of four feet and lengths of eight feet (with some exceptions). Some of the compositions available include wood products, pressed or laminated, asbestos-cement, gypsum and variations under many trade designations.

PLASTER OF PARIS (GYPSUM PLASTER), $2CaSO_4.H_2O$, a hemihydrate of calcium sulfate made by heating gypsum. When mixed with water it quickly sets to a mass of gypsum crystals with an increase in volume. It is used in making molds, casts and finishing plaster. See CEMENT; SCULPTURE TECHNIQUE.

(J. B. Ps.)

PLASTICS. The term plastic, derived from the Greek *plastikos,* appears to have been used first as a suffix implying growing, developing and forming. Later it was used as an adjective meaning capable of being formed. The manufacture of pottery and earthenware depends on the plastic qualities of the clay; the making of glass and plastics and the use of putty. asphalt and cement are all dependent upon the plasticity of the product. Properly speaking, all these products should be considered in any description of plastics and the plastics industry, but the term is much more highly restricted. Today it is used to describe a product of synthetic origin which is capable of being shaped by flow in some stage of manufacture and which is not rubber, wood, leather or metal.

Before the introduction of manufactured plastics, almost any material was pressed into service, especially those materials which could be cut easily and which would take on a high lustre on polishing. Among the products found useful were ivory, coral. tortoise shell. mother-of-pearl, amber, bone and horn. Numerous intricate carvings aere made out of ivory during all periods of history. Ivory lends itself readily to the manufacture of handles for cutlery, for brushes, combs, balls, toys and models. Amber was used in the form of beads and turned into ornaments and holders of various types. Buttons and handles were made out of bone; and combs, handles, drinking cups, powder horns and musical instruments were fabricated out of horn. Although these natural products do not require plasticity in their fabrication, they are consciously or otherwise classed with plastics; they may possess a type of residual plasticity or thermoplasticity which enables them to flow slightly from the heat generated during the polishing operation.

While the designation "plastic" is broader generically than the word "resin" (*q.v.*), both terms are used indiscriminately with respect to synthetic products. It is worthy of note, however, that general usage refers to cellulose derivatives as plastics and not as resins; and conversely, the synthetic resinous products, particularly those entering into the surface-coating field, are referred to as resins and not plastics. Doubtlessly, this distinction is again based on usage, since products of the resin class were primarily employed in the surface-coating field and the plastic characteristics were achieved by solution rather than by heat. The articles called plastics generally require shaping by heat during their fabrication by moulding or extrusion. Since the newer synthetic products can frequently be used interchangeably as coatings or as mouldings, the distinction between resins and plastics becomes less pronounced. Moreover, modern technology shows that the materials which are designated as rubber, fibres, resins and plastics are of a similar molecular structure, and by appropriate chemical and physical treatment it is possible to interconvert any one of these materials. It follows that certain structural features are common to all these products, and, being common, they relate to similarity in physical properties between materials which are not necessarily chemically related.

It might be argued that rubber is a plastic, since it can be fabricated by procedures similar to those employed in moulding plastics, but rubber is not generally considered to be a part of the plastics industry. Moreover, synthetic rubber is in a similar category, even though the preparation of the polymeric rubber molecule employs many of the processes developed for the preparation of resinous polymers. Similarly, the fibre industry is considered to be independent of the plastics industry, and here again the same raw materials, polyamides (nylon), cellulose and cellulose acetate are used by both industries. Plastics are also divorced from the self-supporting type of film production such as the manufacture of photographic film and cellophane. The term plastic, therefore, is essentially a commercial classification to which no strictly scientific definition can be applied.

HISTORY OF DEVELOPMENT

The modern plastics industry is an integration of many different and unrelated bodies of knowledge. One part of the development is derived from the fundamental investigations which were made into the chemistry, physics and biology of such high-molecular-weight natural products as natural resins, rubber, gutta-percha, cotton, cellulose, ramie, pectins, chitin, starch, glycogen, wool, silk and hair. Initially, optical methods were used in order to investigate the nature of these products, and later ultramicroscopy was brought into play. Somewhat later colloidal chemical methods were developed and used in the study of the gross morphology of these substances. X-rays indicated that some of these natural products. such as cellulose, gutta-percha and silk, were crystalline; other materials were amorphous; and still others were both crystalline and amorphous depending on the state of the product. Natural rubber (hevea) in the unstretched state was amorphous when examined by X-ray diffraction methods but it became crystalline when in the stretched state. As new technological tools were developed, they were also brought into use, and among the more powerful of these methods were the measurements of viscosity and the sedimentation of the products when they were subjected to extremely high centrifugal forces such as those developed by the ultracentrifuge. The idea grew that the natural products must of necessity be of a very high molecular weight.

Causes of **Resinification.**—In the preparation and synthesis of new compounds, materials would often resinify through unknown and uncontrollable reactions either during the course of the preparation or spontaneously after the product was formed and isolated. Other compounds were made where the transformation to the resinous and polymeric state could be followed and the various stages studied.

J. J. Berzelius in an article in the *Jahresbericht* of 1833 introduced the term "polymer." Naturally the definition which Berzelius presented underwent some later change. Initially, a polymer indicated the presence of the same atoms in the same proportion in compounds having different molecular weight. These conditions satisfy many compounds which are no longer considered polymers. The term "high polymer" is now restricted to high-molecular-weight compounds which are composed of simple molecules while the term "polymerization" (*q.v.*) relates to the process by which large molecules are synthesized from smaller ones.

In the same year (1833), nitrocellulose was prepared; H. Regnault in 1838 noted that vinyl chloride polymerized in sunlight and in the following year E. Simon polymerized styrene; J. Redtenbacher prepared acrylic acid in 1843; W. Caspary and B. Tollens in 1873 synthesized the methyl, ethyl and allyl esters, whereas G. W. A. Kahlbaum prepared the polymer of methyl acrylate in 1880. It is known that isoprene was prepared by G. Williams in 1860, and that it was polymerized by G. Bouchardat in 1879. R. Anshutz prepared polymers of itaconic-acid esters in 1881, and E. Frankland and B. F. Duppa discovered a method of making ethyl methacrylate from hydroxyisobutyric esters in 1865. Many condensation-type resins were also discovered during this interval, and many polyesters were also prepared, particularly those derived from glycerol and dibasic acids (*see* RESINS). The transformation of ethylene oxide from monomer to polymer was studied by M. A. von Lourenço, who showed that the boiling point and the viscosity increased progressively with molecular weight of the polymer. I. Ostromislensky maintained that there was a stepwise synthesis of rubberlike substances. Similarly it was observed that when glycine was condensed, there was obtained a series of products in which there was a regular change in the physical properties. The classical work of Emil Fischer in synthesizing numerous polypeptides out of simple amino acids is well known. Although Fischer showed that his synthetic product possessed many of the properties of the hydrolytic products of naturally occurring proteins, it was generally considered that the natural products such as proteins, cellulose and rubber possessed unique properties of their own and one that was not shared by the products of the laboratory. The so-called "association theory" was advanced to account for the behaviour of the natural products.

Part of the dilemma of the different behaviour shown by natural and synthetic products was resolved by Hermann Staudinger in **1926.** He demonstrated the inter-relationship existing between the structure as determined physically by X-rays and the size and structure of the polymer as determined chemically from analysis, as well as the size of the molecule determined by the nature and number of end groups existing in the high-molecular-weight compound. These various ideas were consolidated by Staudinger in his book which has now become a classic, *Die hochmolekularen organischen Verbindungen-Kautsckuk und Cellulose.* In this treatise he shows the similarities which exist between polystyrene, a synthetic substance, and rubber (*Kautschuk*) and between the polyoxymethylenes and naturally occurring cellulose. He demonstrated that the products of the laboratory have many properties in common with the natural products and that the synthetic materials can be used as prototypes in evaluating the natural materials.

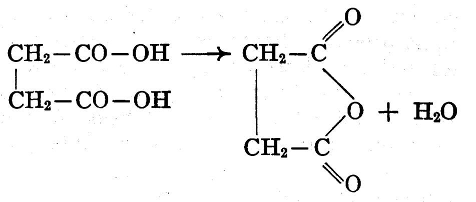
The causes of resinification of organic compounds remained obscure for a long time. The chemical reactions which led to resinification were unknown and the development was empirical. It was recognized very early that unsaturated compounds yielded resins and when the phenol-formaldehyde resins were first introduced, the same unsaturation hypothesis was advanced. The resin formation of phenol-formaldehyde resins was attributed to the polymerization of methylene quinones. Somewhat later the concept of "resinophoric" groupings (*e.g.*, azomethine$-C{=}N-$, carbodiimide $-N{=}C{=}N-$, conjugate unsaturation $-CH{=}CH-CH{=}CH-$, $-CH{=}CH-CHO$) was introduced by W. Herzog and I. Kreidl, and although the theory was shown to be untenable, it focused attention on the relationship of structure and it led to studies which revealed that there were essentially two chemical reactions responsible for resinification: one involving a condensation reaction, where the polymer differs from the starting material by the elements eliminated in the condensation; and a second involving a polymerization reaction, where the polymer and starting material have the same chemical composition. *(See* **POLYMERIZATION.)**

About the same time that Staudinger was conducting his investigations in Europe, studies were being made in the United States on various condensation-type resins, and the foundation was laid for the so-called functionality concepts which enabled a clear distinction to be made between the chemistry of the thermoplastic resins and the behaviour of the thermosetting type of product. Synthetic products made by W. H. Carothers using condensation reactions yielded fibrelike materials which possessed many of the crystalline properties which had been associated only with natural products.

In order that a chemical compound can be made to condense to a material of high molecular weight, it is necessary that each molecule of that compound contain two or more functional groups which can react with one another. When a compound contains molecules possessing only one functional group, these molecules on interaction will yield a product which can be, at best, twice as large as the molecules of the starting material. When a compound possesses molecules containing more than two functional groups, then each molecule can be joined to two other molecules. Preferably these functional groups should be at the ends of the molecule or at least so situated sterically that cyclization or intramolecular reaction cannot occur. These important steric or spatial configuration factors were first thoroughly evaluated by Carothers. When all of these requirements are met, it is possible for the functional groups to react with one another intermolecularly, leading to a reaction product containing long chains. These long chains are molecules of high molecular weight. When the product contains molecules having more than two functional groups, the reaction product which is formed by condensation leads to the formation of complex structures. It is such complex molecules which are responsible for the industrially valuable physical properties found in plastics.

The functional groups referred to above are simply any chemical groups which can react with others. For example, two organic acid molecules can react to form an anhydride (1, below). If the original starting molecule contains two acid groups and these groups are so situated sterically that ring formation can occur, then ring formation takes place without the formation of a high-molecular-weight compound; for example, succinic acid dehydrates to an anhydride (2). If, on the other hand, the acid groups are situated sufficiently far apart to preclude cyclization, such as are found in sebacic acid, polymeric, high-molecular-weight, linear anhydrides are formed (3).

$$2R-COOH \longrightarrow R-CO-O-CO-R + H_2O \qquad (1)$$



(2)

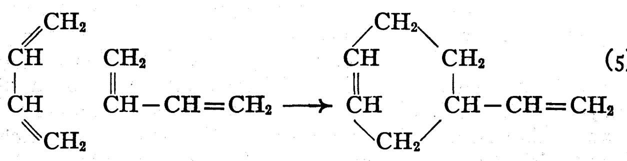
$$\begin{gathered} HOOC-(CH_2)_8-COOH \longrightarrow \\ HO-CO-(CH_2)_8-CO-O-CO-(CH_2)_8-COOH \end{gathered} \qquad (3)$$

Likewise, an alcohol and acid can react to form an ester. If a simple organic molecule contains an acidic group on one end and an alcoholic group on another, the initial condensation product that is formed still possesses a hydroxyl group and a carboxyl group which can react similarly to the starting materials (4).

$$\begin{gathered} HO-R-COOH + HO-R-COOH \longrightarrow \\ HO-R-CO-O-R-COOH \end{gathered} \qquad (4)$$

Such a condensation can proceed to yield a high-molecular-weight pclymer. The unreacted end groups left over at the ends of such large molecules are referred to as "end groups."

A similar situation exists with respect to polymerization products. Under these conditions, cyclization to a low-molecular-weight compound can occur (5); or if the conditions are properly selected, a polymer of high molecular weight may result (6).



(5)

$$CH_2{=}CH-CH{=}CH_2 \longrightarrow (-CH_2-CH{=}CH-CH_2-) \qquad (6)$$

Later studies gave some insight into the molecular size and structure of the large molecules that are found in plastic materials. Minor changes during the preparation, and the addition of small amounts of other chemicals, may markedly change both the proportion and the distribution of the molecular species with the result that a new product of differing physical properties may be formed. Moreover, the same materials may under different chemical processing yield resins and polymers of widely different physical characteristics. By means of these two procedures innumerable types of resinous compositions can be produced. Since most of the plastic products depend on the chemical industry as their source of raw materials, it follows that as soon as a new chemical is developed it is immediately tested by plastic manufacturers to determine whether this new material may serve as a partial or a total replacement for the material now employed. The new materials are quickly introduced into the plastics industry, allowing the preparation of new products with different structures and different handling characteristics.

FABRICATING TECHNOLOGY

The development of moulding technology parallels the study of resinification, since it was only by fabricating the synthetic laboratory products that these materials could be turned into articles of commerce. The art of moulding developed following Charles Goodyear's discovery of the vulcanization of rubber about 1839; this involved the use of a simple hand type hydraulic press. This type of press came into use for all types of moulding operations where the mould is sufficiently light to warrant manual handling. With the development of phenolic resins, larger objects could be moulded, and this necessitated the improvement of compression moulding in order to increase the output of any individual mould. Automatic presses were developed and pins were incorporated into the mould itself to permit automatic ejection of the pieces from the mould. Where metallic inserts had to be introduced into the specimen during moulding, semiautomatic presses were constructed, enabling the introduction of inserts in an efficient manner. To eliminate error further and to speed production, automatic presses were fashioned which can measure the charge, preheat the charge, load it into the cavity, close the mould, mould the object, open the mould and eject the final piece. Still greater mould efficiencies are achieved by electronic preheating of the plastic prior to its introduction into the mould.

The conventional type of compression moulding is both awkward and expensive when applied to thermoplastic materials. Where compression moulding is used on thermosetting materials the mould can be kept at a uniform and constant temperature. During the moulding and curing operations chemical reaction occurs, causing the plasticity to decrease, with the result that the product is sufficiently rigid while hot to be ejected from the mould. Thermoplastic resins, on the other hand, do not undergo any chemical change, and after fabrication of the piece it is necessary to cool the mould in order to decrease the plasticity to the point where the object can be taken out as a single entity. The idea arose that if it were possible to inject the hot plastic into a cool mould, utilizing the procedure used in the die-casting of metals, it would obviate the periodic heating and cooling of the mould. It is of interest to note that the first experiments directed toward injection moulding were made by John and Isaiah Hyatt, who were also instrumental in first commercializing nitrocellulose (see below); but they abandoned the work. Later the technique of injection moulding was again revived, this time in Germany. The first presses had an injection capacity of from about 0.5 oz. to 1.5 oz. per cycle and were useful only for the manufacture of small objects such as buttons, combs and costume jewellery. Once the value of these presses was demonstrated and a suitable plastic composition developed, larger and larger presses were designed until it became possible to inject 32 oz. of plastic into a mould in a single cycle.

The advent of the injection type of equipment speeded up the production of thermoplastic resins, and in order to increase the mould capacity of the thermosetting resins a type of injection moulding was developed for the thermosetting type of material. This is known as transfer moulding. Since thermosetting resins remain plastic for only a very short time, they cannot be preheated in the manner employed for thermoplastic resins; the heating chamber must be loaded afresh for each cycle and the heated charge forced into a hot mould. Not only does transfer moulding decrease the time of moulding of certain objects, but it allows the introduction of inserts which sometimes cannot be introduced into conventional compression mouldings. The plastic enters the mould in a highly fluid state and will not displace or break such fragile inserts as glass and fine metal parts. Moreover, the separation of resin and filler are minimized by this type of moulding, and the resulting moulded objects are stronger, of more uniform density and freer of gas pockets.

A third type of moulding is the so-called extrusion type, which was used for many years in the rubber industry before it was applied to thermoplastic resins. The resin is fed from a hopper, thence to a screw conveyor where the resin is heated, whereupon it emerges from a die in a continuous strip in the form of the die opening. In order to minimize distortion, the heated plastic is frequently caught on a belt which travels at the same rate as the extruded object. By this means rods and tubing of various sizes and shapes can be produced efficiently.

Still another type of plastic fabrication is the process known as "pulp-preforming." By means of this procedure, resin and filler are deposited on suitable forms prior to moulding.

CELLULOSE PLASTICS

Nitrocellulose. — In 1833 Henri Braconnot, a professor of chemistry at Nancy, described the preparation of a "xyloidine," which he considered similar to lignin, by treating starch, sawdust and cotton with nitric acid. He found that this material was soluble in wood vinegar and attempted to make coatings. films and shaped articles of it. For those who are concerned with origins, it is in these early experiments that one can see the beginnings of both the plastics and the lacquer-coating industry. Somewhat later, in 1846, C. F. Schoenbein nitrated cotton, using for this purpose a mixture of nitric and sulphuric acids. He also found that he could dissolve the nitrocellulose in a mixture of ether and ethyl alcohol and this solution came to be called "ether glue." At the time, Schoenbein made the prediction that this nitrated cotton or explosive cotton wool would make a substitute for gunpowder. The explosive nature of this product attracted the attention of militarists all over Europe, and many governments and private individuals started extensive tests to adapt this smokeless powder to explosive use since, unlike ordinary gunpowder, it left no black smudge after firing. Because crude preparatory methods were employed, disastrous explosions occurred in many countries, with the result that the manufacture of the product began to be looked upon with disfavour.

These explosions had a salutary effect, however, in that the pressure and stimulus were removed from production and allowed leisurely scientific research into processes and means of stabilizing the product.

Investigations into various methods of conducting nitration indicated that several types of nitrated cotton might be made. The nitrocellulose possessing the highest degree of nitration where the nitrogen content was more than 13%, was referred to as guncotton or explosive cotton; where the nitrogen content was from 12.6% to 12.8%, the material was referred to as pyrocollodion and where the nitrogen content was from 11.5% to 12% the materials were known as pyroxylin, collodion or photocotton. The nitration reaction is a very complicated one, involving a heterogeneous system of cellulose, nitric and sulphuric acids and water. Each constituent may play several roles which are both physical and chemical in nature, the reagents swelling as well as reacting with the cellulose.

While some attempts had been made to prepare coating compositions out of collodion, the first successful plastic was made by a young U.S. printer, John W. Hyatt. So great was the demand for ivory that the great elephant herds were being slaughtered in an attempt to supply the market. It was in 1863 that Phelan and Collander, manufacturers of ivory billiard balls, offered a $10,000 reward to anyone who might develop an adequate substitute for natural ivory. Working with his brother, Isaiah, John Hyatt prepared satisfactory billiard balls. Somewhat later the Hyatt brothers were granted a patent which described the process of dissolving nitrocellulose under pressure. Since very volatile liquids were employed as solvents, a great economy of materials resulted. Procedures for mixing the pyroxylin and camphor were disclosed in patents issued to the Hyatts between 1870 and 1872. Subsequently, 75 patents were taken out on various procedures for plasticizing nitrocellulose in order to produce the plastic. In 1870 the Albany Dental Plate company was organized by Hyatt and in 1871 the Celluloid Manufacturing company mas formed. The immediate use of this material was for dental plate blanks; later the plastic was used in sheet form for automobile side curtains as well as the well-known celluloid collars Toughness flexibility and good appearance were the properties which enabled the material to be used for a wide variety of items such as combs, brush handles, spectacle frames and various novelty and decorative items.

In 1884 Count Hilaire de Chardonnet, a pupil of Louis Pasteur, deposited with the French Academy of Sciences a document entitled. "Artificial Textile Material Resembling Silk." The paper, which was opened in 1887, described the method of transforming guncotton into fibrous. silklike material. At the Paris exposition in 1899 he was awarded the grand prize for his discovery. The fibre left much to be desired inasmuch as it was highly inflammable, but it focused attention on the possibility of manufacturing synthetic filaments from a vegetable source.

As noted above, it was possible to dissolve nitrocellulose in ether and alcohol. and such collodion solutions could be cast into films. In the early days of photography, it was necessary to prepare the plate prior to exposure. Many descriptions have been given of the methods employed by the early photographers using their so-called "wet" collodion plates. The solvent combination was extremely volatile. making it difficult to secure uniform films free from "blushing." After the development of the dry-process plate, the next logical step was the elimination of the glass support for the nitrocellulose. Such a nitrocellulose film was demonstrated at a photographic exhibition held in Paris in 1881.

The discovery by John H. Stevens that amyl acetate could be used as a solvent for nitrocellulose was made in 1882. This solvent proved to be far superior to anything used previously and enabled uniform films to be formed without haze. The first successful attempt to secure transparent flexible film for photographic purposes was made by H. Goodwin of Newark, S.J., during the years 1887–98. A somewhat similar process was developed independently by H. Reichenbach in 1889. Further work resulted in processes which allowed the nitrocellulose to be fabricated in continuous fashion, enabling the production of suitable base for both still and motion-picture photography. Another important use for nitrocellulose in sheet form was in safety glass. Sheet nitrocellulose was laminated between glass sheets forming a glass-plastic sandwich. The nitrocellulose film discoloured rapidly. however, and was eventually superseded by other, more light-stable plastics; but it served as an invaluable guide and established the importance of safety glass in the automotive industry.

Prior to World War I. Russia supplied the largest volume of fusel oil. This oil. remaining after the distillation of grain alcohol, was the raw material used in the synthesis of amyl acetate. Following the loss of this source of supply during the Russian Revolution. and with the loss of additional supplies caused by the enactment of the U.S. prohibition laws. the amount of this potential lacquer solvent became vanishingly small. New solvents for nitrocellulose were being developed rapidly, however. During 1920–23 the butyl-alcohol process was perfected by Chaim R'eizmann, and about the same time anhydrous ethyl acetate made its appearance. Moreover, other plasticizers than camphor were being developed. Tricresyl phosphate was prepared in 1920 and triacetin in 1921, and both materials weakened the grip of the camphor monopoly which had been notorious in manipulating the price of the product.

Since the theoretical nitrogen content for mono-, di- and trinitrated forms of cellulose are 6.77%, 11.3% and 14.16%, respectively, it can readily be seen from the nature of the manufactured products that the most valuable nitrocellulose plastic compositions contain from two to three nitrate groups per glucose residue in the cellulose molecule. Explosives are made from those materials having from 12.2% to 13.8% of nitrogen; lacquers and films from 11.5% to 12.2% and plastics from 10.5% to 11.5%. The properties of the nitrocellulose thus secured are dependent not only upon the degree of nitration but also on the uniformity of nitration of the cellulose molecule. Moreover, the length of the chain of the nitrocellulose molecule is very important since the longer the chain — that is. the larger the x in the equation below — the more viscous the solution of nitrocellulose in organic liquids. The reaction leading to cellulose trinitrate may be expressed by the equation:

$$[C_6H_7O_2(OH)_3]_x + 3x\ HNO_3 \longrightarrow [C_6H_7O_2(ONO_2)_3]_x + 3x\ H_2O. \qquad (7)$$

For coating applications high-viscosity lacquers are a disadvantage since only thin films can be deposited, and large and excessive amounts of solvent are required. The viscosity of the nitrocellulose can be controlled to some extent by selecting the source of the cellulose and by modifying the nature of the nitration. The most important means of controlling the viscosity of the nitrocotton, however, is by chemical treatment; and while it had been observed that certain materials such as ammonia and metallic salts had the property of decreasing the viscosity of nitrocellulose, it was found that the most certain method for securing a low-viscosity nitrocellulose was by treating the product with water under pressure.

Several factors contributed to the greatly expanded use of nitrocellulose immediately following World War I. Some idea of the expansion can be seen from the fact that the consumption of these materials jumped from 1,000,000 lb. in 1922 to more than 20.000,000 lb. in 1929. These developments could be traced to: (1) the availability of desirable solvents at relatively low cost; (2) the large quantities of nitrocellulose on hand following termination of the war; (3) the development of a method for preparing lacquers possessing a high solids content with relatively low viscosity; and (4) the tremendous demand for rapid-drying finishes by the rapidly expanding automotive industry. Through the use of a combination of nitrocellulose with alkyd resins, it was possible to decrease the time of finishing of an automobile body from weeks to a matter of hours.

For plastic manufacture, the nitrocellulose or pyroxylin is admixed with alcohol together with camphor, either natural or artificial, and kneaded into a doughlike mass. Colouring matter is added, either in the form of dyes for ,transparent colours, or as pigments for opaque colours. The coloured masses are rolled to discharge some of the volatile solvent, sheeted and pressed into blocks. After seasoning, the blocks are sliced; then they are either further fabricated, or the process is repeated for various mottled and variegated effects. The sheets may be moulded and when sufficiently soft may be fashioned by "blow moulding" into hollow objects. Rods and tubes are fabricated by extrusion, Artificial leather is made by painting fabrics with nitrocellulose solutions and then stamping or embossing the surface after discharge of the solvent.

Despite its obvious disadvantages of inflammability, discoloration on aging and limited tolerance to heat and to strong organic solvents such as alcohols, ketones and esters, the nitrocellulose plastic is colourful, tough! flexible, of good appearance and resistant to wear, water and humidity. It is easy to fabricate into many diverse forms and finds wide acceptance for billiard balls, piano keys, mirror and spectacle frames, combs, brush handles, machine keys, radio dials and various novelty and decorative items.

The various developments of nitrocellulose in fibres, films, coatings and plastics paved the way for further advances for newer materials which did not possess the disadvantages enumerated above, and the technology used in nitrocellulose was a useful guide in the processing of new products. Most important, the success of nitrocellulose indicated that a market existed for plastic products.

Cellulose Acetate. — The deficiency inherent in nitrocellulose for plastic use brought up the possibility of adapting other esters of cellulose, particularly the esters of organic acids. Paul Schutzenberger acetylated cellulose in 186j and A. Franchimont in 1879 found that the esterification reaction could be catalyzed by sulphuric acid. In 1894 C. F. Cross 'and E. J. Bevan, working in England, patented a process for preparing a chloroform-soluble type of cellulose acetate. The most important commercial development was made by G. W. Miles in 1903–05 with the discovery that if the highly acetylated cellulose was subjected to hydrolysis, it became transformed to a less highly acetylated compound which was soluble in cheap organic solvents such as acetone. In 1911 Henry Dreyfus perfected a manufacturing process for the preparation of the acetylated compound and its hydrolysis. The same basic process is employed in the manufacture of the cellulose acetate as that employed in the manufacture of a nitrate with the exception that the anhydride is used as the esterification reagent with the net result that acetic acid is the by-product rather than water.

$$[C_6H_7O_2(OH)_3]_x + 3x\ (CH_3CO)_2O \longrightarrow [C_6H_7O_2(OCOCH_3)_3]_x + 3x\ CH_3COOH. \quad (8)$$

The cellulose acetate with an acetate content of about 62.5% is then hydrolyzed, precipitated, washed and dried. This process of hydrolysis can be conducted on the acetate in the fibrous form or in solution. In order to bring out the full toughness of the product, the fibrous acetate is colloidized with plasticizers. These are high-boiling liquids possessing a low vapour pressure and having solvent or gelling action on the plastic. Among the more useful plasticizers are such materials as dimethylphthalate, diethylphthalate and dimethoxyethylphthalate. Depending on its ultimate use as a film, moulding powder or safety glass, different quantities, amounts and types of plasticizers are employed, allowing one type of polymer to fill many diverse applications.

The first use of this material was in the so-called "safety film" for photographic use. The acetone-soluble cellulose acetate found extensive use in World War I as the "dope" for coating aircraft wings because it was much less inflammable than nitrocellulose. After the war the excess plant capacity found a ready market for cellulose acetate as an acetate rayon. However, another very important development, the new procedure for moulding thermoplastic resins mentioned above, was occurring simultaneously. It was found that the acetate was particularly amenable to being moulded by injection, and the cellulose-acetate plastic was given a new impetus by this rapid and efficient means of fabrication. The acetate was preferred since the nitrate could not be subjected to the same temperature conditions required in injection moulding. Cellulose acetate became widely used in the automotive industry because of its mechanical strength, toughness, wear-resistance, transparency and ease of mouldability. The high resistance to impact made it a desirable material for protective goggles, tool handles. oil gauges and the like.

Since the cellulose acetate did not discolour as did the nitrate on exposure to light. it was far more suitable for safety-glass manufacture; and, while its resistance to water was not all that could be desired, the laminated safety glass found favour, especially when precautions were taken to edge-seal the assembly in order to prevent access to moisture. Such safety glass became accepted and in time definitely made the public safety conscious.

Cellulose Acetobutyrate and Other Esters.—Since one of the more serious limitations of cellulose acetate lies in its poor resistance to moisture and weathering. attempts were made to use longer, less water-soluble organic acids for esterification purposes. The use of mixed acids was not overlooked, with the result that it was found that a mixture of butyric and acetic acids (as anhydrides) yielded mixed esters which were very similar in properties to the acetate but possessed much better moisture resistance, better weathering and superior adhesion. When moulded by injection. cellulose acetobutyrate required somewhat less pressure than acetate and yielded better welded joints.

Other cellulose esters were prepared commercially. During World War II processes for the manufacture of propionic acid (and anhydride) were developed, and cellulose esters made from this acid appeared on the market. Since propionic acid contains three carbon atoms, it is intermediate between acetic and butyric acids. It follows that the cellulose propionate possesses many excellent properties similar to those exhibited by the acetobutyrate as well as many characteristics of its own, particularly a shorter moulding cycle and easier machining qualities. Cellulose benzoate was manufactured in Germany but the material did not find a market in the U.S.

Cellulose Ethers.—Since cellulose is a polyhydric alcohol, it can be made to undergo etherification reactions as well as the esterification reactions mentioned above. Ether linkages cannot be saponified; so it is not surprising to find that the cellulose ethers are among the more stable of the cellulose derivatives. The idea of ethylating cellulose was first conceived by W. von Suida in 1905 with the primary object of changing the affinity of cellulose for dyestuffs. The cellulose ethers were studied simultaneously by Leon Lilienfeld in Austria, Otto Leuchs in Germany and Henry Dreyfus in France. It was found that the cellulose ethers and in particular ethyl cellulose were soluble in organic liquids and possessed potentialities in plastic as well as in lacquer and in rayon applications.

Ethyl cellulose was first produced commercially in Germany and it was not until 1935 that large-scale production was undertaken in the U.S. The alkali cellulose—a mixture of cellulose and caustic soda—is reacted with either ethyl chloride or with ethyl sulphate until the desired ethoxy content is secured. While it is possible to introduce three ethoxy groups into each glucose segment in the cellulose molecule, it has been found that only those products which contain from 43.5% to 49.5% ethoxy content are of commercial interest. This degree of ethylation amounts to from 2.15 to 2.58 ethoxy groups per glucose residue. Those ethylcellulose derivatives possessing from 47.5% to 50% ethoxy content exhibit the greatest solubility in organic liquids as well as the best compatibility with other film-forming materials. However, ethyl cellulose possessing somewhat lower ethoxy content (from 45.0% to 47.5%) yields harder films and plastics which have less tendency to flow at elevated temperatures. The chief uses of ethyl cellulose are in coating, in adhesives and as plastics possessing a high degree of toughness over a wide temperature range.

Many other cellulose ethers are known. The methyl cellulose, glycol cellulose and cellulose glycolic acid prepared respectively from methyl sulphate (or chloride), from ethylene oxide (or chlorohydrin) and from sodium monochloroacetate are dispersible in water and have found use as sizing and finishing agents in the textile industry.

OTHER NATURAL PRODUCTS AS PLASTIC MATERIALS

Casein Plastics.—Casein (the protein derived from milk) was condensed with formaldehyde by A. Spitteler and W. Krische to form a tough, insoluble mass which could be fabricated readily. Production of this plastic was begun shortly after 1900 in Germany and France and in 1914 in England under the name of Galalith (milk stone). When the monopoly was broken during World War I, manufacture was undertaken in the U.S. in 1919. At the time the casein plastic came into prominence it possessed an immediate advantage over the competitive products inasmuch as it was much less inflammable than nitrocellulose and could be fabricated into objects of lighter colour than was possible with the phenolic resins. When an attempt was made to introduce the casein plastic into the United States, the limitations of the material became apparent, especially under the extremes of humidity encountered. The result was that the product was wholly unsuited for electrical fixtures and other applications requiring some degree of dimensional tolerance. The limitation of the composition, and the advent of synthetic resins which could be handled more rapidly and did not possess the limitations inherent in the protein plastic, gradually restricted the use of casein plastic until the only large outlet for the product was in the manufacture of buttons from alum-hardened casein.

Shellac.—This natural resin finds some use in the manufacture of moulding compositions. In many respects shellac is an ideal plastic binder for certain types of electrical equipment and for communication instruments. The resin is often used by itself as well as in combination with such fillers as flaked mica and asbestos.

SYNTHETIC RESIN PLASTICS

Synthetic resins can be grouped into many different arrangements but one generally accepted classification involves the designation "thermoplastic" and "thermosetting" types of resins. The thermoplastic resins are characterized by their ability to remain plastic after numerous heating treatments. while the thermosetting or thermocuring resins are not susceptible to repeated heating cycles and, once heated, are converted to a cured or infusible form which cannot be fused again without serious chemical degradation. From the molecular structural standpoint, the thermoplastic resins are characterized by molecules which are essentially linear or threadlike in form, while the thermocuring resins consist of molecules which are considered to be linked three-dimensionally into a network arrangement. Resins may also be classified by the chemical means employed to effect reaction. Certain resins formed without the elimination of volatile components are generally referred to as the polymerization type. Where volatile ingredients such as water and alcohol are formed during the resin preparation, this type of product can be considered a condensation resin. When the chemical and physical types are superimposed, it is possible to have the grouping:

1. Thermoplastic condensation resins
2. Thermoplastic polymerization resins
3. Thermocuring condensation resins
4. Thermocuring polymerization resins

The equations leading to the formation of these various types may be written schematically as follows:

$$2n\ H{-}R{-}OH \longrightarrow H{-}[R{-}O{-}R]_n{-}OH + n\ H_2O$$

Linear polymer formed by condensation reaction

$$n\ CH_2{=}\overset{R}{\underset{R_1}{C}} \longrightarrow -CH_2-\overset{R}{\underset{R_1}{C}}\left[-CH_2-\overset{R}{\underset{R_1}{C}}\right]_{n-2}-CH_2-\overset{R}{\underset{R_1}{C}}$$

Linear polymer formed by loss of unsaturation

$$2n\ \begin{array}{c}H-R-OH\\ | \\ H-R_1-OH\end{array} \longrightarrow \begin{array}{c}H-\\ \\ H-\end{array}\left[\begin{array}{c}R-O-R\\ |\qquad | \\ R_1-O-R\end{array}\right]\begin{array}{c}-OH\\ \\ -OH\end{array} + 2n\ H_2O$$

Ketwork polymer formed by condensation reaction

$$n\ \begin{array}{l}CH=CH_2\\ | \\ R\\ | \\ CH=CH_2\end{array} \longrightarrow \left[\begin{array}{l}-CH-CH_2-\\ \quad | \\ \quad R \\ \quad | \\ -CH-CH_2-\end{array}\right]_n$$

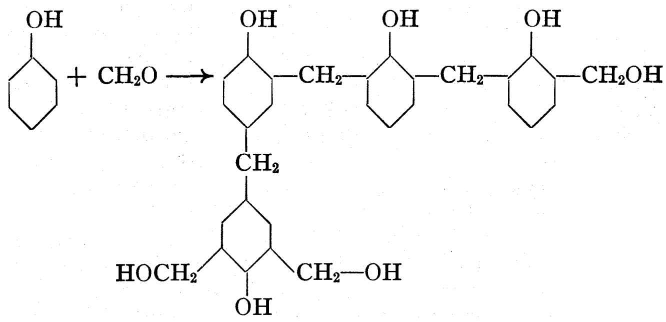
Network polymer formed by loss of unsaturation

Generally the thermocuring resins will tolerate substantial quantities of inert fillers such as cellulose flock, wood flour, asbestos and the like, whereas the thermoplastic resins are fabricated clear or when fillers or opacifiers are used, the quantity employed is much less than with the thermosetting type of resin. Different methods of iabrication are utilized with thermoplastic and thermosetting resins since chemical changes occur during the moulding of thermocuring resins, whereas physical changes predominate in the moulding and extruding of thermoplastic resins.

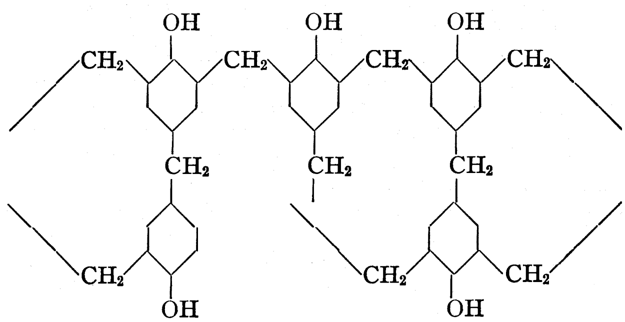
Thermosetting Resins.— Phenol-Formaldehyde Resins.— When Leo *H.* Baekeland offered the phenol-formaldehyde resins in 1909, the value of nitrocellulose plastics sold annually in the U.S. was more than $5,500,000. Irrespective of the fact that the pyroxylin plastic was well established, this new material found a ready market because, unlike the nitrocellulose product, the phenol-formaldehyde resin could be made insoluble and infusible. Moreover, unlike the thermoplastic material, the thermosetting phenolic condensation product would tolerate considerable amounts of inert ingredients or fillers and, in much the same manner that the thermoplastic materials could be changed by the incorporation of various plasticizers, the thermosetting resins could be modified through the incorporation of various fillers.

In some respects, this resin-filler combination was being exploited prior to Baekeland's entrance into the plastic moulding field. Various coal-tar residues were mixed with asbestos and silica and these resins were moulded under pressure and subsequently heated outside the mould to further the reaction. Since a great deal of curing does not occur, the strength of such cold-moulding compositions was not very high. When the phenolic binder became available, however, and when it was substituted for the bituminous binder, the moulded piece took on a much better finish and possessed increased strength.

In making phenolic moulding powders, phenol and formaldehyde are heated in the presence of suitable catalysts, generally acids. and the condensation is conducted to the stage where the water separates. The viscous phenolic condensation product on cooling to room temperature becomes hard and brittle. The resin at this stage is soluble and can be dissolved in various organic liquids; such solutions are employed for laminating and impregnating purposes. The structure can be represented schematically as follows:



Intermediate condensation product



Cross-linked

In order to make the moulding compound, the resin is ground and mixed with appropriate filler, lubricants and dyes. To render the combination as homogeneous as possible, the mixture is milled and then ground. For general use, wood flour is the preferred filler, but where heat resistance, impact strength or electrical characteristics are involved, other fillers such as cotton flock, asbestos and chopped fabric are used. The resin, because of its excellent insulating characteristics, enters into the manufacture of radio parts such as sockets, binding parts, knobs and dials, and into the electrical system of the automobile as distributor heads, coil parts, switches, magnetos, instrument-housing panels, etc.

Where the resin is to be cast, the initial condensation of the phenol and formaldehyde is heated with alkaline catalysts in such a way as to hold the water which is formed in the condensation as a suspension in the resin. The reaction mixture is subjected to reduced pressure whereby the water of condensation is removed without phase separation. Where opaque castings are desired, the viscous resin is poured directly into moulds made of either rubber or lead. Hardening is allowed to take place from one to two days at moderately elevated temperatures. During curing of the resin, the water which is evolved forms droplets which are large enough to interfere with the transmission of light. Where clear castings are required, suitable modifiers are added to the resin prior to the introduction into the mould. These modifiers cause the water which is formed in the final cure to assume a size smaller than the wave length of light and, being of such dimensions, the particles do not interfere with the transmission of light. Such castings are clear. Mottled effects can be secured by appropriate mixing of coloured viscous resins prior to the introduction into the mould. The castings are machined and polished to objects possessing a high degree of lustre and brilliance.

Certain developments in the foundry industry have involved utilization of phenolic resins. In powdered form they have been used to cement sand for making the so-called shell moulds. A large volume of resin was projected for this application, but the automatic or semi-automatic manufacture of shell moulding on any substantial scale remains in the future. Present indications are that resin-coated sand may prove more useful in larger scale applications of this process.

For laminated structures, the resin in alcoholic solution is used to impregnate either paper or fabric. After impregnation the sheets are dried, consolidated and subsequently heated under pressure to form a rigid, tough assembly of high strength and good electrical properties which can be machined and fabricated. Power transformers, timing gears, cams, clutches, fan belts and many other materials can be made from such structures. When fabric is substituted for the paper, similar laminated compositions are made which can be machined to form gears and bearings.

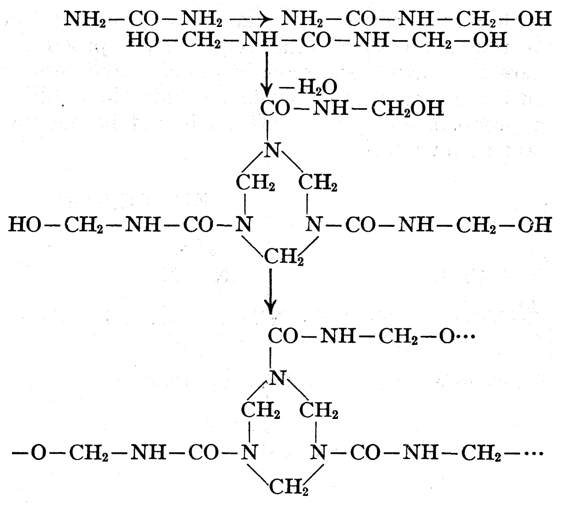
Lignin, which is the bonding agent of wood and other cellulosic derivatives. has been isolated from certain intermediates from paper manufacturing. The lignin resins have been used as extenders for phenolic resins. particularly those entering into varnishes, moulding resins and adhesives.

Phenol-Furfural Resins.—Furfural is an aldehyde which is derived from waste farm products such as the hulls of oats, rice and cottonseed and corn husks. This aldehyde will condense with phenol to produce a resin similar to that secured from phenol and formaldehyde. The plastic properties of the two compositions differ. however, in that the furfural product possesses a long period of flow at low temperatures; this property enables it to be used in certain types of intricate mouldings.

Urea-Fornzaldehyde Resins.—The resins derived from urea and formaldehyde have been considered truly synthetic materials inasmuch as all the basic materials are derived from gases. These gases are ammonia, carbon dioxide, carbon monoxide and hydrogen. Reaction of ammonia and carbon dioxide under pressure yields urea, whereas the reduction of carbon monoxide results in the formation of formaldehyde. Condensation of urea with commercial formalin (aqueous solution of formaldehyde) yields the water-soluble intermediate condensation products known as mono- and dimethylolurea, which on further reaction form water-soluble, resinous condensation products.

The intermediate water-soluble resins are starting materials for the production of resin, adhesives. surface coatings and moulding powders. Initially, glass-clear products were produced and extensively investigated as substitutes for glass and were often referred to as "organic glass." While the initial products were clear and brilliant, they quickly deteriorated on aging. Part of the difficulty resided in the ability of the plastic to absorb water from a humid atmosphere and then to release the water when the moisture content of the atmosphere decreased. This "breathing" of the plastic resulted in some loss of transparency and glasslike clarity. Furthermore, on prolonged standing, cracks and fissures developed in the surface of the resin, probably arising from liberation of water and formaldehyde through further condensation occurring in the colloidal mass; these fissures further decreased the transparency and limited the strength of the product since, on impact, the surface fracture acted as a focal point for the transmission of energy into the interior of the specimen. The glasslike product was extensively investigated by Hanns John and by Heiner Ramstetter and by Fritz Pollak and Kurt Ripper during the decade following World War I, but attempts to commercialize the product were unsuccessful.

The combination of the urea-formaldehyde resin with various fillers was investigated by many chemists, but the combination of cellulose and resin has been generally associated with the development work of Carleton Ellis in the U.S. A parallel development occurred in England, however. where because of lack of timber, Norwegian pulp was imported and used. The introduction of fillers destroyed the transparency of the product but the resin-filler combination. when suitably compounded with flow promoters, plasticizers, lubricants, accelerators and catalysts, could then be moulded in steel dies under heat and pressure to insoluble and infusible products possessing a wide utility. Manufacture of one of these materials began in the U.S. in 1929. The plastic can be produced in any colour, from translucent and colourless to ivory and pure white. through pastels and brilliant hues to jet black. In thin sections the natural uncoloured combination of urea and cellulose transmits light in a highly diffused state, and



Preparation of urea-formaldehyde resin

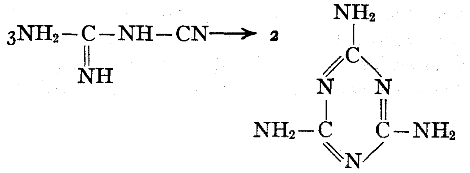
by altering the thickness and pigmentation, the reflection and transmission can be modified at will. Among the widespread uses of the moulded product. aside from its value in luminaries, are in the manufacture of closures, buttons, wall plates, instrument dials, display boxes, dress accessories and housings of all types.

The resin in solution form possesses many other applications aside from impregnating filler to make moulding compositions. The resin solutions are used in the preparation of cements which can be hardened hot or, through the proper addition of catalysts, may be set cold. When the water-soluble resin is suitably dispersed in organic solvents, it forms the basis of a very important class of resin finishes and enamels for metal coating. As an impregnant for wood veneer, the water-soluble condensation products serve both as a binder and a protective coating. Since the resin is colourless, the cured resin materially enhances the beauty of the wood. The solutions are also used to treat textiles in order to control their shrinkage and render them crease or crush resistant.

In the manufacture of laminated stock, sheets of absorbent paper are impregnated, dried and assembled to appropriate thickness and then heated between platens to yield a sheet stock which has found utility in lighting reflectors, signs, wall panels, table tops and decorative murals.

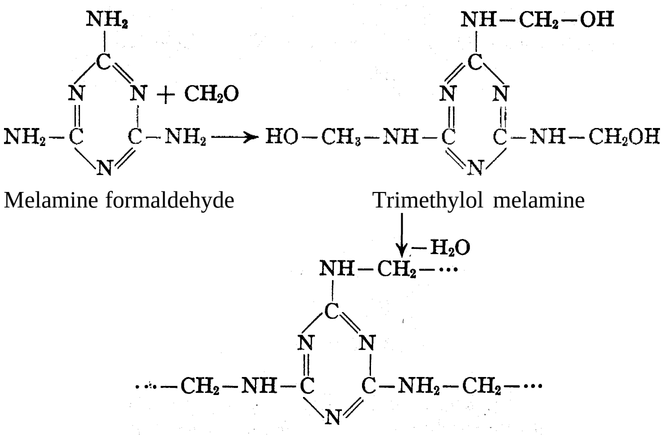
Melamine-Formaldehyde Resins.—Prior to 1939 melamine was practically an unobtainable rare chemical compound which could be secured only in limited amounts at $40 a pound. Although the compound was rare, it was not new and unknown. It had been known and characterized for more than 100 years and had been first prepared in 1834 by the famous chemist Justus von Liebig. After 1939, melamine became a commercial article made in ton quantities. and like urea it is secured from the air. Combination of the nitrogen in the air with calcium carbide yields calcium cyanamide, which can be hydrolyzed to cyanamide and dimerized to dicyandiamide. Under high temperature and pressure dicyandiamide is transformed to melamine, an extremely stable substance containing only carbon, hydrogen and nitrogen in its chemical structure. These reactions can be represented by the following chemical equations:

$$CaC_2 + N_2 \longrightarrow CaCN_2 + C$$
$$CaCN_2 + 2H_2O \longrightarrow Ca(OH)_2 + NH_2{-}CN$$
$$2NH_2{-}CN \longrightarrow NH_2{-}C({=}NH){-}NH{-}CN$$



Preparation of melamine from calcium cyanamide

Condensed with formaldehyde, melamine forms products which in superficial respects resemble the condensation products of urea but, where only mono- and dimethylolureas have been prepared, a much wider number of the initial melamine-formaldehyde condensation products are known. Di-, tri- and hexamethylol melamines have been prepared.



Network condensation of melamine with formaldehyde

The melamine resin is not so sensitive to alkalies and can tolerate fillers which cannot be used with the urea condensation product. One of these fillers is the mineral asbestos. Because of their excellent heat and arc resistance, good dielectric strength and low water pickup, mineral-filled melamines suitably modified with other resins were used in ignition systems, particularly in the large distributor heads in military aircraft where, under the reduced pressures at high altitude, flash-over and tracking are especially troublesome. The mineral-filled materials may also be used where other unusual performance characteristics are required such as in the automotive ignition parts of trucks, tractors and automobiles.

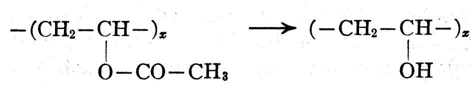
Cellulose-filled melamine plastics have been used in many of the applications already discussed for the urea resins. but since the melamine resin is more resistant to high temperatures, to boiling water and to more alkaline solutions, and since it does not retain food odours, it is particularly useful in tableware. The melamine resin possesses extreme hardness and this, together with its good colour and abrasion resistance, makes it an invaluable material for surfacing of laminated assemblies. Translucent mouldings may be made and are applied to button manufacture.

Anhydrous Thermosetting Resins.—The thermosetting resins used for laminating and moulding depend on the loss of water to effect insolubilization. In order that this water content be as small as possible, the resin is carried to an advanced stage of condensation where considerable heat and pressure must be utilized to cause the resin to flow sufficiently to fill the mould. During World War II, new types of products appeared which did not involve the loss of water to bring about insolubility and infusibility of the resin. These compositions have been referred to as anhydrous thermosetting resins and solventless varnishes, while the process has been called low-pressure or contact moulding. They belong to the class of thermocuring polymerization type of resins. Irrespective of the name, all of these resins have one characteristic in common: the polymerizable molecules possess a plurality of unsaturated groups and undergo reaction to insolubility quickly and exothermically without the evolution of low-molecular-condensation residues. The unsaturation can be introduced into the initial molecule by the incorporation of either unsaturated acid residue or unsaturated alcohol residues or both. The polymerization is generally catalyzed by peroxides. The physical state of the anhydrous thermosetting resins can be varied within wide limits; some are thin fluids, others viscous liquids. whereas still others are solid or greaselike in consistency. Since only low pressure is required in fabrication, comparatively inexpensive moulds can be utilized. In many instances, the fluid-moulding technique may be employed for making complex shapes; this procedure depends on delivering pressure uniformly over a large area through the use of rubber bags, and by such means large structural parts of aeroplanes and boats have been built. The most spectacular development in this field is the fibrous glass reinforced automobile body. In certain respects the high strength and the low weight of the plastic combined with its ability to recover practically undamaged from impacts and its higher resistance to corrosive atmospheres and moisture penetration have been assets. In large-scale production, however, the assembly could not compete with steel construction. Some efforts have been directed to the use of these reinforced resins as reinforcing agents in the manufacture of plastic pipe and in the manufacture of equipment for use in the chemical process industries. Here again the outstanding advantage arises from corrosion resistance. When such rigid sheets of plastics are laminated into a cellular or honeycomb core, highly rigid and lightweight combinations can be produced which possess good strength and insulating characteristics.

The anhydrous thermosetting products are frequently referred to as polyester resins. Structurally ester groups are present in the molecule. Another product designated as a polyester is the polyethylene glycol terephthalate. Again. ester linkages are present in the molecular pattern but the physical properties of the polymer are very different. Being of much higher molecular weight and crystalline in structure the product can be oriented into fibres and into sheet stock of exceptional clarity and strength.

Thermoplastic **Resins.**—*Vinyl Resins.*—As noted above, acetic anhydride is required in the manufacture of cellulose acetate. Following World War I various methods were investigated for processes which might be used to convert the acid to the anhydride since it was anticipated that large quantities of this cellulose plastic would be required in the manufacture of fibre, film and safety glass. Among the methods investigated for the manufacture of acetic anhydride was the reaction of acetic acid with acetylene to form ethylidene diaceiate, which in turn could be decomposed to acetic anhydride. In conducting the reaction between acetylene and acetic acid, investigators obtained substantial quantities of an organic liquid which was too low boiling to be the desired product. This liquid was monomeric vinyl acetate. Although the investigation was directed primarily to the preparation of an acetylating agent. vinyl acetate was in time destined to be the basis of the manufacture of most of the plastic for use in safety glass.

Polyvinyl Acetate Resins.—The transformation of vinyl acetate ($CH_2 = CH—O—CO—CH_3$) to a safety glass interlayer did not occur all at once, however. Manufacture of the early product was difficult because little was known concerning the chemistry of transformation of a vinyl monomer to its polymer. Moreover, the early development was hazardous from a commercial standpoint since there were no uses for such a resinous product. It was first investigated as a shellac substitute. but its remarkable adhesive properties, when hot, made it invaluable for uniting many diverse materials such as cloth, paper, leather. wood and glass. Compounded with fillers, glycerine, sugar and flavouring, polyvinyl acetate makes an acceptable chicle substitute in the manufacture of chewing gum. Hydrolysis of the polyvinyl acetate causes cleavage of the ester grouping resulting in the formation of polyvinyl alcohol,



a resinous polymeric alcohol that forms viscous solutions in water and finds some utility as a thickening agent for emulsions and in the preparation of plastics which, although sensitive to water. are highly resistant to oils. Polyvinyl alcohol can be spun into a fibre, and although the fibre is soluble in water, special uses can be made of this solubility in the weaving of sheer laces; fibres of polyvinyl alcohol and any other fibre can be woven and the synthetic water-soluble fibre dissolved, leaving a sheer fabric which would be difficult to approach by mechanical means alone. There have been a number of developments in Japan whereby polyvinyl alcohol has been cured with formaldehyde to yield a fibre material possessing excellent fibre characteristics. The major shortcoming appears to be in the heat resistance. On the other hand, the dry tenacity of the product is outstanding.

Many chemical transformations of polyvinyl alcohol are possible. It can be condensed with other low-molecular compounds, particularly aldehydes, to form new resinous materials. Condensation with, formaldehyde, acetaldehyde and butyraldehyde results, respectively, in polyvinyl formal, polyvinyl acetal and polyvinyl butyral. The polyvinyl formal finds use as a coating resin for electrical insulation; the acetal possesses potentialities as a photographic film base and as an injection-moulding material; but it is the butyral which possesses the most outstanding utility, and as much as 100,000,000 sq.ft. have been produced annually for safety-glass manufacture. The resin when suitably plasticized yields a tough, high-impact film which maintains its properties at low temperature, and when laminated between glass yields a composite assembly which possesses little tendency to yield flying splinters on impact.

Polyvinyl Chloride Resins.—Vinyl chloride is a gas at room temperature and can readily be prepared from either ethylene or acetylene. Addition of hydrogen chloride directly to acetylene yields the monomer, or ethylene can be chlorinated and dehydrohalogenated to vinyl chloride. The polymerization was extensively studied by Ostromislensky, who sought to dehalogenate the polymer to a rubberlike substance. Polyvinyl chloride was transformed to a rubber substitute about 20 years after these basic investigations but by an entirely different procedure.

Polymeric vinyl chloride, $—(CH_2—CHCl)_x—$, is practically infusible and for a long time proved to be a rather intractable substance. In efforts to plasticize the product it was milled and compounded with polyvinyl acetate, mentioned above, but with no great degree of success until it was found that by mixing the ingredients prior to polymerization and then chemically combining the two materials into a polymeric structure, it was possible to achieve in this conjoint polymer or copolymer a new type of product which was easier to handle and one which could be further flexibilized through the addition of high boiling liquids and plasticizers. By varying the ratio of acetate to chloride, resins of varying plasticity and stiffness can be secured.

Intensive investigations were made into the nature of plasticization methods and techniques of direct plasticization of vinyl chloride without the necessity of copolymerization. It was generally conceded, however, that the copolymer is amenable to plasticization by a larger number of widely diverse liquids than is the unmodified polymer. Both types, however, have found extensive use as sheet stock and as wire insulating compounds and as substitutes and replacements for rubber. Since these polymers possess considerable amounts of chlorine, they will not support combustion and they therefore possess distinct advantages in wiring where noninflammability is of importance. The halogen, however, is labile and when the resin is exposed to heat or to ultra-violet light, loss of hydrogen halide occurs, resulting in discoloration.

By the dry spinning of the vinyl chloride-acetate copolymer, it is possible to produce filaments which can be woven into chemically resistant fabric. In Germany fibres were fabricated directly from polyvinyl chloride and were known as PC-fibres.

Polyvinylidene Chloride Resins.—By doubling the amount of chlorine in vinyl chloride, a new chemical entity. vinylidene chloride, is obtained. Because of the symmetrical arrangement of the chlorine atoms in polyvinylidene chloride. $—(CH_2—CCl_2)_x—$, the polymer is crystalline. and advantage can be taken of this crystalline characteristic to form oriented filaments and tubing. Such oriented forms have the molecules arranged in an ordered manner with the result that in the direction of orientation the product is very strong. Extruded, quenched and drawn, the polyvinylidene chloride makes an excellent substitute for reed and rattan and a corrosion-resistant substitute for insect screening; in the form of tubing, the resin can be used to pipe many corrosive chemicals.

Acrylic Resins.—The term acrylic resin covers not only the acrylic esters but also the polymerizable derivatives of both acrylic and methacrylic acids as well as the acid chlorides, nitriles, amides and substituted amides. Acrylic derivatives generally involve cyanide in their synthesis, but investigations indicate that, at least in the case of the acrylic acid derivative, there inay be an alternative procedure involving carbon monoxide (in the form of a metallic carbonyl) and acetylene. Considerable investigation was also undertaken in an attempt to prepare acrylic esters from natural lactic acid derived from milk. but it remained to be demonstrated nhether the natural lactic acid could compete with the synthetic product. The names of Otto Rohm and Rowland Hill were associated with the preparation and polymerization of acrylic and methacrylic esters, respectively.

From the standpoint of plastic use of the methacrylic esters are preferred, since they are harder and more rigid than the corresponding acrylic esters. By changing the type of alcohol which is used in esterification of the original monomeric ester, it is possible to modify the hardness of the resulting polymer. Polymethyl acrylate is tough and rubbery; polyethyl acrylate is softer and more rubbery; polybutyl acrylate is sticky. If one continues up the homologous series of alcohol esters, the polymers become softer and more plastic until at polyoctyl acrylate, it is found that the polymer is almost liquid in consistency.

Polymethyl methacrylate,

$$\begin{array}{c} \quad CH_3 \\ \quad | \\ (—CH_2—\underset{|}{C}— \quad)_x, \\ \quad COOCH_3 \end{array}$$

is the hardest ester in the methacrylate series and. as in acrylates, introduction of alcohols possessing longer chains into the ester lowers the softening point of the plastic. Some idea of the relative hardness is seen in the fact that polyamyl methacrylate is about as hard as polymethyl acrylate. While polymethyl methacrylate is the preferred resin for injeciion moulding and plastic applications, it was found that cyclohexyl methacrylate was superior for lens casting, since this liquid undergoes less shrinkage during polymerization than does the methyl ester. Cyclohexyl methacrylate polymer, together nith styrene resin, was used in combination in the preparation of plastic achromatic lenses.

Without doubt the largest single outlet for the methyl methacrylate resin has been in sheet form for windows in aircraft, particularly in military aircraft. The resin was cast in moulds made of glass and the finished sheet could then be "post-formed" to a uide variety of shapes necessary for blisters, noses. cockpits, windshields and canopies of aircraft. The high clarity of these plastics. as well as the ability to transmit or "pipe" light, also favoured their use in surgical instruments, highway reflectors and edge-lighted advertising displays.

Whereas styrene was copolymerized with butadiene to form a general-purpose rubber, acrylonitrile, the nitrile of acrylic acid (CH, = CH—CN) was copolymerized with butadiene to yield a special 011-resistant rubber extensively used where rubber of necessity had to be in contact nith gasoline and other hydrocarbon liquids. Acrylonitrile forms conjoint polymers with many other vinyl compounds such as acrylic esters and styrene, but from all indications it promised to play its most important role as a polymer in the form of a synthetic fibre.

Polyamides.—By the condensation of diamines and dibasic acid. linear condensation products may be formed and by varying the nature of the acid and the amine, it is possible to produce products which are hard and tough or soft and rubbery. These linear condensation products are referred to as polyamides $[—NH—(R)—NH—CO—R'—CO—]_x$. Polyamides are most generally knonn in the form of fine and coarse filaments in such articles as hosiery, parachutes. bristles and brushes. As has been pointed out, however, high-molecular-weight organic resinous cornpounds of certain types can be converted into fibres. The polyamides were first offered commercially in the form of filaments but were later directed to the moulding trade. particularly toward the injection-moulding field where their toughness and ability to flow around complicated inserts are prime considerations. Polyamides, particularly those derived from primary *amines, are characterized by a high degree of crystallinity whether in the form of filaments or as mouldings. Under stress, orientation of molecules begins to occur and this orientation continues until the specimen is drawn to about four times its initial size; although this property is of outstanding importance in filaments, it is of more limited utility in moulded articles. The resin exhibits a sharp melting point, and on melting is more liquid and plastic than conventional resinous materials. The fluidity is both an advantage and a disadvantage: the high fluidity necessitates the use of specialized equipment but on moulding there is no need of using excessive pressure in injection moulding, since the liquid resin transmits its pressure on the moulded specimen hydrostatically.*

Inasmuch as adipic acid and hexamethylene diamine are the ingredients most often used in nylon synthesis, and since both of these ingredients contain six carbon atoms, this particular product has been referred to as Nylon-6,6. *There is another variety of nylon which can be made from amino caproic acid; this polymer is referred to as Nylon-6. However, a much easier and efficient preparation of Sylon-6 can be effected through the use of* caprolactam. *Extensive facilities are available both in Europe and in the United States for the manufacture of this polymer from this ingredient.*

Caprolactam is a 7-membered heterocyclic ring. More recently a 5-membered ring has been polymerized to a high-molecular-weight substance, polypyrrolidone, or in the alternative designation, Nylon-4.

A product somewhat similar to the polyamides, manufactured in Germany during World *War* II, *utilized isocyanates, particularly the diisocyanates. Reaction of these unsaturated compounds* with *glycols yielded polyurethanes* $[-NH-R-NH-CO-O-R'-O-]_x$ *which could be iabricated into bristles. A wide variety of other urethane products have been derived from isocyanates. When reacted* with *the appropriate alkyds, foamed resins are produced which have wide utility in the manufacture of laminates, upholstery, and in insulation. Reacted with another variety of alkyd resins, these same isocyanates yield synthetic rubbers having unusual abrasion resistance. Other uses for these isocyanate products are being discovered.*

Polymers From Cycloctabutanes.—From *pentaerythritol a cyclic monomeric chlorinated ether can be prepared which can be polymerized to a high-molecular-weight plastic containing a fair proportion of halogen. Because of the position of the chlorine in the polymer molecule, it is difficultto remove and consequently the product possesses unusual stability. Inasmuch as the groups are symmetrically positioned in the polymer, the product is crystalline and capable of being drawn.*

Polystyrene Resins.— That styrene or vinyl benzene would polymerize has been known for a long time. The designation "vinyl benzene" $(CH_2 = CH-C_6H_5)$ *immediately relates it to the other polymerizable vinyl compounds, such as vinyl chloride, fluoride and acetate. The designation "styrene" arose from the fact that this liquid was first prepared by heating the natural resin* storax. *The first patents on the possible uses of styrene were taken out by F. E.* Matthews *in 1911.* Monomeric *styrene is present in the light oils of coal-tar manufacture and in the drip oils condensed during the preparation of illuminating gas, and although extensive investigations were undertaken to remove styrene from this source, the processes proved too costly and could not compete economically* with *the synthetic methods. In order to secure a satisfactory plastic out of styrene, it is necessary that a highly purified product be subject to polymerization Where the monomeric styrene is of inferior quality, the resulting resin is too brittle and on aging the surface of the plastic becomes covered with fine hair lines similar in appearance to those appearing in an unfilled urea-formaldehyde resin. By using a reaction discovered by* M. *Berthelot in 1869. it was found that by dehydrogenating ethyl benzene catalytically at elevated temperatures and fractionating the resulting mixture, it is possible to secure a product which on polymerization under appropriate conditions yields a polymer possessing valuable chemical and physical properties. Chemically, the resin is highly resistant to both* weak *and strong acids, although oxidizing types of acids may lead to some discoloration. Alkalies and the lower alcohols do not attack the polymer, and the water absorption of the resin is extremely small. The resin can be dissolved in coal tar and in chlorinated solvents. In electrical characteristics, the plastic possesses an extremely low* power *(or loss) factor and,* when *the resin is properly prepared, this power factor remains substantially unchanged over a wide range of frequency. The low power factor combined* with *the low* water *absorption makes polystyrene an ideal material for various electrical and electronic applications. The presence of a multiplicity of aromatic rings in the polymer renders the product responsive to temperature, with the result that the resin can be handled expediently by the injection-moulding technique. Among the* noteworthy *applications of this plastic is the fabrication of battery boxes, ranging in size from those employed in a small automobile to the type that is ordinarily used in portable radio sets. It has found utility in manufacture of condensers, tube sockets, coil forms and switch plates. Since styrene was one of the components entering into the synthetic rubber GR–S. large facilities exist for the manufacture of the monomer. Some idea of the expansion that took place can be seen from the fact that the amount of polystyrene used rose from about 750,000* lb. *per month in 1937 to more than 20,000,000 lb. per month in 1951. During this period progress was made on the commercial casting of styrene in several forms. As a copolymer with divinyl benzene, the resin was employed for certain radar applications which involved operating temperatures higher than could be tolerated with polystyrene. The monomer was also cast directly for certain optical parts such as prisms and lenses.*

Since polystyrene possesses a high dispersion value, it could be combined with polycyclohexylmethacrylate *to make corrected plastic achromatic lenses.*

One of the limitations of polystyrene for many applications is its inability to tolerate excessive heat; and although the modification with divinyl benzene increases its resistance to heat distortion, it does so at the expense of mouldability. In order to increase the heat resistance of polystyrene and maintain mouldability, the monomer has been copolymerized with various nitrogen-containing compounds such as acrylonitrile, fumaric nitrile *and vinyl* carbazole. *The increase in softening point is attained at the sacrifice of colour. Consequently, extensive investigation was carried out in the direction of introducing various groups into the styrene nucleus in an attempt to improve the heat distortion directly. One of the methods that proved successful involves the introduction of multiple halogens into the aromatic nucleus. Another method of securing styrenelike plastics having softening points above that of boiling* water *involves the use of ring-substituted methyl groups in the monomer. Through the introduction of methyl groups into the benzene nucleus of the monomer one can, on polymerization, modify the properties of the resulting resin. Two syntheses based on alternative isomers are now being employed commercially. One procedure, based on the conventional dehydrogenation of the appropriate methyl ethyl benzene, yields a meta para mixture; the other process involves the decomposition of* diaryl *ethanes permitting the formation of* ortho *methyl styrenes.*

The presence of a methyl group. ortho *to the vinyl. imparts important heat resistant characteristics to the finished polymer; the composition comprising 67% of para and 33% of* ortho *yields derivatives* which, *on injection moulding, remain stable in boiling water.*

Isotaxic Polymers. — *Still another development having far reaching implications in the manufacture of plastic products is the observation made by Guilio Natta at Milan university that entirely new physical properties can be built into vinyl polymers through the use of their so-called heterogeneous catalysts.* When *these heterogeneous catalysts are utilized with styrene, propylene, and butylene the polymerization becomes directed in the sense that it permits arrangement of the monomer units in an ordered fashion in the chain.*

Through the use of these novel catalysts, one secures through the positioning a symmetry with a result that the new *products possess much higher melting points.*

Also, these catalysts have been utilized with diolefins yielding, under polymerization conditions, a different type of symmetry in the diene polymer. With isoprene it is now possible utilizing these more unusual catalysts, to arrange a very large proportion of the double bonds in a cis position yielding a synthetic rubber which closely simulates the physical and chemical properties of the natural *Hevea brasiliensis*.

Polyvinyl Carbazole Resins.—Reaction of acetylene with carbazole yields vinyl carbazole $\left[\begin{array}{l} CH_2=CH \\ \quad\ | \\ \quad\ N-C_{12}H_8 \end{array}\right]$, which can be converted to a plastic possessing high heat resistance and excellent electrical properties; but the brittleness of the product limits its uses to specialized industrial applications.

Polyethylene Resins.—Although ethylene is the simplest unsaturated compound, it proved to be one of the most difficult to convert into a high-molecular-weight polymer. The polymerization requires extremely high pressures and moderately high temperatures to effect conversion. As might be predicted from its structure, polyethylene, $-(CH_2-CH_2)_x-$, is completely nonpolar and possesses a low power factor and a low dielectric constant. Being highly symmetrical, it is also crystalline; and in common with other crystalline polymers, thin sheets of the resin exhibit high resistance to penetration by water vapour.

At ordinary temperatures the resin is highly resistant to attack by organic and inorganic reagents. At moderate temperatures, the resin can be dissolved in certain organic liquids and such solutions can be applied as a coating, but satisfactory results are obtained only by keeping the object coated in a heated condition until the solvent has evaporated. Polyethylene, however, can be applied more easily directly by extrusion of the molten plastic. It proved suitable for insulating high-frequency and high-voltage circuits. Because of its low water permeability, extensive tests were carried out with a view of using the resin in submarine cables.

A new type of polyethylene which takes on characteristics of a rigid plastic has created considerable interest in both industrial and in scientific quarters. It has been referred to as "linear polyethylene," "high density polyethylene" or "low pressure polyethylene." The term "low pressure" appears undesirable inasmuch as investigations have demonstrated that a high-density rigid polyethylene can be prepared utilizing high-pressure techniques. The term "linear polyethylene" appears to be most appropriate in that it refers to the fundamental architecture of the molecule. Perhaps the most important technical advantage from the standpoint of the consumer is that this linear polyethylene possesses a higher softening point permitting sterilization—a procedure which was impossible with the earlier type. Another advantage of the high-pressure linear polyethylene resides in the absence of a catalyst which, in certain highly selective electrical applications of polyethylene, may lead to difficulties.

Polyisobutylene Resins.—Isobutylene is a hydrocarbon boiling at about $-5°$ C., and when dimerized it can be converted by reduction to iso-octane. By conducting the polymerization at very low temperatures, using boron fluoride as a catalyst, a high-molecular-weight product is formed $\left[\begin{array}{c} \quad\ CH_3 \\ \quad\ | \\ -CH_2-C- \\ \quad\ | \\ \quad\ CH_3 \end{array}\right]_x$. This polymer is rubberlike but inasmuch as the material is saturated, it cannot be vulcanized. By conducting the polymerization of isobutylene along with a diene such as butadiene, isoprene or dimethyl butadiene, unsaturated residues are introduced into the polymer. These residues can act as nuclei for vulcanization with sulphur.

Polyvinylpyrrolidone.—The polymer secured from 1-vinyl 2-pyrrolidone is a water-soluble product, possessing many unusual characteristics and having a wide variety of pharmaceutical applications including that of blood plasma extender. It was used as a blood plasma substitute by the German army during World War II. The product is being manufactured in the U.S. chiefly for use in hair-spray lacquers and in detergents. The polymer has a high affinity for many dyestuffs and in many cases will prevent the bleeding of migrant colours from one garment to another. When hair is placed in contact with aqueous solutions of polyvinylpyrrolidone a certain amount of polymer enters into the hair shaft. Subsequent rinsing will not remove all of the polymer, leaving the hair with an improved appearance both from the standpoint of clarity and of natural colour. A number of preparations employ PVP as a retardant vehicle for drugs since it permits the drug to remain in the body for a longer period. The success of the pyrrolidone polymer as a blood plasma extender has stimulated research in other products possessing similar characteristics. One derivative which has found some interest is Dextran, a polymer of glucose.

Polyvinyl methyl ether.—Another high polymer possessing water-soluble characteristics and simultaneously dispersible in a number of organic liquids is the polymer secured from vinyl ether. Like PVP it is a derivative of the high-pressure synthesis of acetylene. The direct addition of methanol to acetylene under pressure using appropriate catalysts yields a monomer. When alcohols other than methyl are used with acetylene similar vinylization occurs yielding ethyl vinyl ether. Vinyl isobutyl ether and, if the alcohol is long enough, such as octadecyl alcohol, no excessive pressure is required to carry out the reaction. These vinyl ethers will polymerize among themselves or with other vinyl materials. One product possessing extensive uses as a water-soluble colloid is the copolymer of vinyl methyl ether with maleic anhydride, which has been designated as PVM/MA. Inasmuch as there are acidic groups still present in the polymer a number of esters may be prepared which vary widely in physical characteristics.

Polyacrylamide.—Still another polymer possessing water solubility in its resinous plastic form is polyacrylamide. The amide linkage is capable of reaction with formaldehyde yielding the intermediate which can undergo further condensation reactions.

Perhalogenated Plastics.—Several references can be found in the patent literature to the preparation of polymeric materials which possess only carbon and halogen in their molecular structure. One of the perhalogenated products, polytrifluorochloroethylene, $-(CF_2-CF-Cl)_x-$, is described in a patent issued to F. Schloffer and O. Scherer (1934), while another patent, that of R. J. Plunkett in 1941, refers to tetrafluoroethylene polymer $-(CF_2-CF)_x-$. The latter product was produced commercially in limited quantities and found its chief utility in the preparation of corrosion-resistant gaskets. Polymeric tetrafluoroethylene is a remarkably stable substance and is insensitive to all organic and inorganic liquids. As would be expected from its symmetrical structure, the polymer is crystalline and the resin on heating undergoes a phase transition at about 327° C., where the mouldings become transparent and the tensile strength decreases markedly.

Trade Names.—Plastics are known and sold commercially under various trade names. A single resin may be sold under a multiplicity of names arising from the fact that the resin manufacturer sells the resin under his own trade name while the moulder may offer this resin in its moulded form to the public under his own distinctive brand name. Moreover, the same chemical composition may frequently be offered to several different consuming industries under several different individual names. As knowledge gradually accumulates concerning the chemical nature and constitution of resins and plastic materials, the custom is becoming established of associating, directly or indirectly, the trade name along with the chemical constitution.

PLASTIC SURGERY is that specialty of surgery which concerns itself principally with the improvement in appearance or function of the external tissues of the body. It is a formative or constructive discipline making use of the readjustment of local tissues or the transfer of tissues from a distance to effect a desired change for the better appearance of parts of the body. Early in its development, plastic surgery was limited to correction of facial deformities, but its scope has been expanded to include correction of defects of all external parts and, in a more limited fashion, restoration of function, as of the hands, not necessarily associated with abnormal appearance.

History.—Probably the earliest use of the term plastic surgery was that by Edward Zeis, author of the *Handbuch der Plastischen Chirurgie* (1838). But some of the techniques employed had their origin long before the publication of Zeis's book. As early as or earlier than 800 B.C. the Hindus restored missing facial features. For instance, the caste of potters advanced the tissues of one or both cheeks toward the midline of the face for the reconstruction of the nose; the need for this arose from the practice of slicing off the nose as punishment for various offenses. Some discussion of the same general type of surgery as that used by the Hindus was contained in Celsus' description of plastic procedures in his *De re medica* (1st century A.D.). Galen (2nd century A.D.) also was acquainted with these procedures. Thereafter, it was not until the middle of the 15th century and the work of Branca in Sicily that further development of plastic surgery occurred. Instead of using facial tissues for reconstructing the nose, Branca substituted the use of skin and fat from the arm. In 1597 Gaspar Tagliacozzi prepared a systematic treatise on plastic surgery. Then its development ceased again until the 19th century.

The first half of the 19th century mas marked by development and refinement of the established principles underlying the transfer of tissue still partially supplied with blood (pedicled flaps); the second half was marked by expansion of the newly evolved technique of transplantation of skin and other tissues completely separated from their original blood supply (grafts). One of the earliest descriptions of the use of 'grafts was that by J. Mason Warren of Boston in 1843. In fairly rapid succession, Jacques Louis Reverdin (1869), L. L. X. E. Ollier (1872), J. R. Wolfe (1876), Karl Thiersch (1886) and Wilhelm Krause (1893) elaborated and refined the principles involved in the free and unattached transfer of skin grafts, so that by 'the beginning of the 20th century grafting mas a well-recognized plastic surgical procedure. With the development of the Padgett dermatome, a mechanical device for cutting thin pieces of skin from a large area; in 1939, it became possible for surgeons to make use of skin grafts readily.

Techniques. — Autografting — The use of pedicled flaps and of free grafts has as its main purpose the addition of tissues to the region undergoing repair. Sometimes there is no need to supply new tissue; rearrangement of what is already there may be sufficient. The Z-plasty is one such local rearranging technique. In this, width may have to be sacrificed for length, but by so doing an improvement in appearance or function may be attained. Sometimes simple removal of tissue may be all that is needed to provide the desired effect. Very commonly the plastic surgeon employs two, three or all four of these major techniques.

The employment of a free graft entails relatively less surgical manipulation than that of a pedicled flap, for the tissue is simply removed from one part of the body and then reinserted into or applied upon another. The tissue of a pedicled flap, on the other hand, usually must be prepared for severance from its donor site by a series of incisions which progressively all but encompass the tissue and cause it to become wholly dependent upon the blood supply entering from one retained attachment or pedicle. In this manner a relatively great bulk of tissue can be made to live upon a relatively narrow stalk, and it becomes possible to move one extremity of the flap to a new site while the flap continues to be nourished through its stalk. Once the transplanted portion has healed to the margins of the defect to which it has been transferred. the sustaining pedicle can be divided and the tissue will live from the blood carried into it from the vessels of the recipient area.

The skin employed for grafting may include the entire thickness of the two layers of skin, the external epithelium and the deeper corium, or the skin may be reduced in thickness by inclusion of only part of the corium with the epithelium. The full-thickness graft does not have so good a chance for survival as the partial-thickness graft. but when it survives it retains more normally its original characteristics such as colour and texture and is not so subject to reduction in area. Split-thickness grafts, which have a better chance for survival, undergo more shrinkage and alteration of their original texture and colour. Full-thickness grafts find their principal use in the replacement of skin of, the face. where texture and match of colour with the surrounding normal skin are of paramount importance; partial-thickness grafts are employed on other parts of the body, particularly when extensive areas of skin are needed.

Homografting.—For many years efforts have been made to understand the physiological basis for the maintenance of survival of tissues transplanted from one human being into or upon another. Such tissues, called homografts (as opposed to autografts, or transplants from one part to another of the patient's own body), could be very useful. as for the skin grafting of extensive defects when the patient, for one reason or another, is unable to supply donor skin for himself. Permanent hoinografting of skin must await elucidation of the means whereby the graft can be induced to remain alive. In spite of their frailty, however, homografts of skin do survive for periods of several weeks. and this makes it possible to apply them, as a purely temporary measure, upon extensive burn wounds merely to obtain provisional coverage while the general condition of the patient improves.

Foreign Bodies as *Replacements* for Living Tissue. — Although the body usually can provide its own replacements, such as cartilage or bone, for the reconstruction of skeletal defects, there are times when the patient is unwilling to submit to the extra operation necessary for the removal of the graft. Homografts of cartilage or bone can be used, with less chance of success than with autografts, or foreign materials such as various plastics (polyethylene) may be employed. The indications for the use of foreign bodies are relatively few, because the chance for permanent retention is not great. On the other hand, foreign bodies do find a wide application as external prostheses. Whereas the reconstruction of a major defect of the face from living tissue may be indicated when the patient's life expectancy is considerable, an external prosthesis may be desirable for older persons who might not be willing to devote the time needed for the multiple operative stages necessary to rebuild a complicated anatomical part such as a nose or ear.

Deformities **and** Defects. — Congenital *Malformations.*— These constitute a very important segment of plastic surgical practice. Two of the commonest are harelip and cleft palate. Repair of harelip generally is carried out within the first few months of life, not only to restore an abnormal appearance toward normal but also to improve the sucking function. Harelip deformity may be seen as a notching of the vermilion border or may be present as a complete cleft of the upper lip. usually on the left side, but occasionally bilateral or on the right side alone. Both harelip and cleft palate may occur in the same patient, or only one may be present. The time for repair of the cleft palate is often said to be about the age of 18 months, but sometimes it is desirable to wait for several years, in which instance an artificial device may be provided to help separate the nasal and buccal cavities. The aim of surgical repair is to accomplish such separation by eradicating the longitudinal gap in the roof of the mouth, and so to aid in the development of better speech, the control of escape of ingested food via the nostrils, and the reduction of upper respiratory infections. For the maximal benefit from repair of harelip and cleft palate. in some instances a series of operative procedures must be performed.

Burns. — Although minor burns (*q.v.*) can be treated successfully by all surgeons, the techniques of skin grafting play such an important role in the treatment of major burns that plastic surgeons are frequently called upon to care for patients following destruction of extensive areas of skin. Burns usually are classified as first. second or third degree. In third-degree burns the entire depth of skin is lost, and unaided healing can occur only by the slow advance over the wound of skin from the margins of the defect. This process may take weeks, months or even years to be completed, depending upon the extent of the burned area. The patient's immediate welfare may be improved by the application of partial-thickness skin grafts, which also reduce the time required for wound healing as well as the amount of residual scarring.

After an interval of many years (approximately 10–40), the scars resulting from unaided healing of large third-degree burns may undergo chronic ulceration, perhaps related to an inadequate blood supply. Such unstable scars are subject to skin cancer. As a consequence, even though third-degree burns may have healed without skin grafting. the plastic surgeon may be called upon years later to excise ulcerated, unstable scars down to normal tissue and to cover the new wound with grafts or even with pedicled flaps.

Another complication of the healing of some third-degree burns is development of contractures. Virtually all scars gradually decrease in length over a period of months or years. This may, in effect, lead to the limitation of motion of joints over which the skin must be able alternately to increase and decrease in length. The inelasticity of a short contracted scar over a joint may very well limit the range of motion of the joint and so interfere with normal usefulness. Seldom is simple excision of the scar sufficient for restoration of function; it is frequently necessary not only to remove the scar but also to add new skin.

Keloids—excessive overgrowths of scarlike tissue at the site of destruction of skin—may follow any deep skin injury, but are most prone to follow third-degree burns in those persons who have the inherent tendency to develop them. Little is known of the underlying reasons for the excessive overgrowth of scar, but the end results can be improved in some cases by plastic surgery combined with the therapeutic influence of X-rays or some other means for lessening the amount of new scar formation.

Psychologic Implications of Plastic Surgery.—In many instances, the deformity or abnormality which is being subjected to plastic surgical repair is gross and obvious to everyone, but in many others deviation from an accepted norm is so slight that an observer might wonder why the patient calls for correction. In addition to the patient's simple displeasure with his appearance, there may of course be economic or sociologic implications when the patient believes that an abnormality is preventing him from securing or holding a specific position or gaining the affection of a specially desirable mate. Many persons, for example, ask for such operations as "face-lifting" so that they may continue to hold jobs in which the appearance of old age is considered undesirable. Under such circumstances as these, recourse to plastic surgery may save the patient much unhappiness.

Although patients may occasionally request alteration of almost any part of the body, the majority of cosmetic surgical procedures are carried out for remodeling of the nose, ears and breasts, and for the removal of wrinkles from the aging face. Sometimes the amount of surgical alteration, as in cosmetic rhinoplasty, may involve the addition or removal of a very small amount of tissue, yet result in a striking change in the patient's appearance.

The Specialty of Plastic Surgery.—Although some of the techniques of plastic surgery are used by many different types of surgeons, surgeons who devote all their time to this type of surgery in the United States usually take the examination of the American Board of Plastic Surgery after a prolonged period of study and hospital training. For the dissemination of new information, the Society of Plastic and Reconstructive Surgery publishes a monthly journal. See also TRANSPLANTS, TISSUE AND ORGAN.

PLATA, RÍO DE LA (PLATE **RIVER**), has two meanings: in the most limited sense, it is a broad estuary, approximately 171 mi. long, located between Argentina and Uruguay and flowing southeast into the South Atlantic; in a more comprehensive sense, it is the mouth of an enormous drainage basin which includes the Paraguay, Paraná and Uruguay rivers and numerous smaller rivers and streams. This basin drains the southern portion of South America, as the Orinoco and Amazon drain the northern. The area covered, 1,679,535 sq.mi., includes the whole of Paraguay, southeastern Bolivia, most of Uruguay and large portions of Brazil and Argentina, thereby ranking this river system fourth in the world by size. The rate of discharge, however. estimated at 2,800,000 cu.ft. per second, makes this system second only to the Amazon in volume.

The Estuary.—At its upper extremity, where this estuary receives the waters from the great river systems of the Paraná and the Uruguay, the width is 19 mi. The Argentine island of Martin Garcia is located near this extremity and provides a control point for navigation. The estuary gradually widens to 63 mi. at Montevideo and then fans out to 140 mi. at its mouth. Despite the enormous amount of water discharged into the ocean, the Rio de la Plata is relatively shallow. The depth of the main channel above Montevideo is 36 ft. The average depth outside the main channel is 10 to 20 ft. Seasonal rates of flow, winds and tide have a considerable effect on the depth. Constant dredging is necessary to keep a 20 mi. side channel, 31 ft. deep, open to the port of Buenos Aires, and to clear other parts of the main channel. Consequently, ships, after entering the Rio de la Plata, are restricted to prescribed courses. The bottom is composed of sand and silt. The expanse of low plain or pampas on the southern or Argentine side, permits violent winds, known as *pamperos* to build up and whip the waters of the estuary into violent storms at certain times of the year.

Upper **Paraná and Affluents.**—The Paraná, meaning "mother of the sea" in the Guarani language. is the larger and'more important of the two river systems which flow into the Rio de la Plata estuary. About 1,400 mi of its estimated 2,347-mi. length is above its juncture with the Paraguay river and is known as the Upper Paraná (Alto Paraná). The Paraná is formed by the union of the Paranaiba and Grande rivers at 20° S.. these tno rivers having traced the western and southern borders of the state of Minas Gerais. Brazil, in their previous course. The Paranaiba originates a few miles from the headwaters of the Sho Francisco river, but flows in the opposite direction, at first west and then southwest. By the time it joins the Grande, it has already received eight sizable tributaries. The Grande originates in the Serra da Mantiqueira, almost within sight of Rio de Janeiro, Braz , and descends in many falls and rapids for about 845 mi. to its juncture with the Paranaiba.

A number of Brazilian rivers from the states of Mato Grosso, São Paulo and Paraná empty into the Paraná as it flows generally southwest Most of these tributaries, such as the Sucurih, Verde, Pardo, Ivinheima, Amambai and Iquatemi on the west and the Tieté, rising within 35 mi. of the city of São Paulo. the Peixe. Ivai, Pequiri on the east. are navigable only for short stretches by canoes or small launches and are broken by frequent waterfalls and rapids. The largest of the eastern tributaries is the Paranapanema, which descends 559 mi. from the Serra Paranapiacaba overlooking the Atlantic ocean.

Small river boats can navigate the upper reaches of the Paraná river in Brazil for 400 mi. between the falls of Urubu-Pungá and the falls of Guairá (or Sete Quedas). At this latter point, the river has torn a 2-mi. gorge through the red sandstone of the Serra de Maracaju (Serra do Mbaracayú.) The result is a stupendous although not well-known sight. The river. which widens to a 3-mi, lagoon, suddenly becomes constricted between canyon walls only 300 ft. apart. As a result the water boils in deafening crescendo, which can be heard for 20 mi. through several channels and some 18 cataracts in a total descent of approximately 300 ft. There the Paraná becomes an international boundary and serves to divide Brazil and Paraguay for a distance of 130 mi. until joined by the Iguaçú (Iguassu) river.

Iguaçu.—This river, the most spectacular of the Paraná's affluents, also rises in the Brazilian coastal range, the Serra do Mar, and flows nearly directly west for 430 mi. For its last 75 mi. it divides the Argentine province of Misiones from Brazil. About 15 mi, before it joins the Paraná, the river plunges over an escarpment, which is 23 mi. in width. The resultant cataracts are among the most famous falls in the world, often compared with the Niagara or the Victoria on the Zambezi. Although most of the escarpment is broken into two descents of approximately 100 ft. each, one mass of water roars 269 ft. down the Garganta del Diablo or Devil's Throat. As many as 275 separate waterfalls have been counted in the dry season, while at flood stage the volume exceeds that of Niagara. (See IGUAÇU.)

From the mouth of the Iguaçu to the juncture with the Paraguay, 420 mi. further on, the Paraná serves as the boundary between Paraguay and Argentina. There are no important tributaries which join the river in this stretch. Near the capital of the province of Misiones, Posadas. 27° 22' S., the Paranb turns westward. The relatively narrow river, 1.500 ft. in width. has cut several channels between high rocky banks, creating large islands in its course, such as Yaciretá, ApipC Grande and ApipC Chica, and Talavera. The current in these channels is strong and the passage is made difficult by rapids such as those of the ApipC. Shortly after these rapids. however, the Paranb escapes from its red sandstone bed, and its flow becomes more leisurely as the river widens. The banks of the river are lower and the bottom is sandy.

Paraguay.—This main affluent of the Paraná is 1,584 mi. long.

It rises in the Brazilian state of Mato Grosso, near the town of Diamantino, 14° 24′ S., not far from the headwaters of the Tapajós and the Xingu, tributaries of the Amazon. It flows first southwest and then south into the morass of Xarayes, which expands into still vaster swamps as the river grows in size. Few streams feed the Paraguay from the west with the exception of the Jaurú. There are, however, a number of large shallow lakes to the west of the Paraguay which receive overflow from the morass of Xarayes. Several important affluents swell the Paraguay from the east and drain a vast area of Mato Grosso. These Brazilian rivers, north to south, are the Cuiabá and São Lorenzo, the Taquari, Miranda and Apa. the last serving as a boundary between Mato Grosso and northern Paraguay. In this northern area, the Paraguay is a shallow, sluggish river. During the rainy season, it spreads out for hundreds of miles from each bank. turning the vast swampland between 17° and 20° S., into great lakes. In this Corumbá territory of Brazil, as much as 30,000 sq.mi. have been inundated.

South of the mouth of the Apa river, the Paraguay flows through Paraguayan territory. On the west, the vast Chaco jungle and morass is only imperfectly drained by the Pilcomayo and Bermejo rivers and by innumerable smaller streams. Much of the east bank of the Paraguay, in particular, the lowland between Concepción and Asuncion, is also subject to seasonal flooding. About 250 mi. south of Asunción, the Paraguay merges its slow moving mass (140 ft. above sea level) with the Parana river.

Pilcomayo, Bermejo and **Salado.**—These three rivers, north to south, rise in the Andes and flow southeast in parallel courses. The Pilcomayo, '(river of the birds" in Guarani language. descends from its source north of Potosi, Bolivia, 8,000 ft. in 350 mi. to the Chaco plains. The course of the river then loses itself in the Chaco morass and finally wanders in three separate branches to its juncture with the Paraguay opposite Asunción. The main channel, such as it is, marks the boundary between Argentina and Paraguay.

The Bermejo rises on the Bolivian-Argentine frontier. After a rapid plunge to the Chaco lowlands, the river flows in a sinuous course around islands and sandbars which make any estimate of depth meaningless. The current is stronger than that of the Pilcomayo. Much silt is carried in suspension thus originating its name to describe the reddish colour. It has been estimated that this river alone carries off 6,400,000 cu.yd. of soil from the Chaco each year.

The Salado is formed by several rivers which drain the Argentine province of Salta and emerge on the Chaco lowlands. Like the Pilcomayo and Bermejo. the Salado follows no prescribed channel but wanders in a braided pattern across the countryside, particularly at floodtime. The Indian use of such alluvial croplands has been imitated by settlers growing maize, wheat, flax and cotton, although permanent or continuous use of the land is, at best, difficult when irrigated only by such annual floods.

Lower **Paraná.**—After its juncture with the Paraguay, the Paraná flows slightly southwest until it reaches the city of Santa Fe and is joined by the Salado river. Then it curves in a gradual arc until at Rosario it is flowing southeast to join the Rio de la Plata. The Lower Paraná is entirely within Argentine territory, passing through some of the richest agricultural land in the world. On the east lie the pastoral provinces of Corrientes and Entre Rios. while on the west is the breadbasket of Santa Fe and northern Buenos Aires.

The Paraná becomes a truly imposing river after it joins forces with the Paraguay. Even at low water, its 800-mi. course to the Rio de la Plata is from 2 to 4 mi. wide. Unlike the clear waters of its Brazilian sources, however, it is now tremendously burdened with silt. The Paraguay brings soil from Mato Grosso, while the Pilcomayo, Bermejo and Salado, eating away at the Andes, add tons of alluvium. The western bank of the lower Paraná is a high bluff of red clay rising 25–75 ft. above the river level and is constantly undermined by the current.

The amounts of silt lend themselves to a building as well as a tearing away process. Unlike the high rocky islands of the Upper Paraná, the Lower Paraná is dotted with large, low, often forested islands. During flood season, however, the Paraná may widen to 10 mi. and, in places, even 30 mi. burying islands and overfloaing into marginal swamps. The periodic floods as well as the seasonal rise and fall of the water level naturally wreak havoc with islands and channels. Below Rosario, the islands and the main channel are more stable, because the total rise, even of flood waters, is distributed over a wider area and consequently is not as great. The mouth of the Paraná river or the head of the Rio de la Plata estuary, until a recent geological period, must have been located much further inland, perhaps as far as 32" S., near the present town of Diamante in Entre Rios. Subsequently, silt has built up island structures from the sandy bottom. The clustering of these islands form a huge delta, 40 mi. wide and 100 mi. long, at the mouth of the Paraná.

The lower Paraná finds its may through the Paraná delta in 11 outlets and several canals. The two principal channels which are used by ocean vessels are the Paraná Bravo with a depth of 36 ft. and the Paraná Guazú with a depth of 20 ft. The depths of the other channels and connecting canals used by coasting craft vary greatly but are announced periodically. Constant dredging is naturally required to keep these channels open for navigation.

Uruguay and Its Affluent%— Thisis the second major system, 1,000 mi. in length, which flows into the Rio de la Plata. Like the Upper Paraná and the Paraguay, the Uruguay originates in Brazil, formed by several small streams which rise on the western slopes of the Serra do Mar, at 27° 09' S. From the south it is joined by the Pelotas, the two rivers serving to divide the states of Rio Grande do Sul and Santa Catarina. After floning west, the Uruguay turns southwest at its juncture with the Pepiri Guaçu, the first sizable affluent to join it from the north. For most of its course, the fast flowing Pepiri Guaçu marks the boundary between the Argentine province of Misiones and Brazil. Now the Uruguay serves to divide Brazil and Argentina. A few miles beyond the juncture with the Pepiri Guaçu, the river is constricted between rocky walls in the Salto Grande de Misiones. a 2 mi. stretch of rapids with a total descent of 26 ft. in 8 mi. At the cataracts, the river narrows suddenly from 1,500 ft. to an extreme of 70 ft.

Several small rivers join the Uruguay from the west and are navigable in their lower reaches by canoes and small boats. The principal of these, from north to south, are the Xguaypey. Mirinay, Mocoretá, which divides Entre Rios and Corrientes, and Gualeguaychú. The important affluents of the Uruguay, however, come from the east. The Ijuí, Ibicui and the Quarai (Cuareim) are short rivers but of considerable volume; the last forms part of the boundary between Brazil and Uruguay. At the mouth of the Quarai, the Uruguay becomes the boundary line between Argentina and Uruguay, and the river flons almost directly south. The Negro river, 300 mi. long and the Uruguay's largest tributary, joins the latter only 60 mi. from the estuary of the Río de la Plata. The Negro rises on the Brazilian border in Rio Grande do Sul and flows westward through the middle of the Republic of Uruguay. Sizable river craft can reach Mercedes, 32 mi. from its mouth. Like the Upper Paraná, the Uruguay is generally clear and carries little silt except in the seasonal floods. After its juncture with the Negro, the Uruguay broadens sharply to a width of 4 to 6 mi., and becomes a virtual extension of the Rio de la Plata estuary.

Navigation and Economic Importance.— The economic usefulness of these river systems is not commensurate with the area which they drain. A principal problem is that of navigation. A large portion of the rivers cannot be used at all or only by very shallow draught vessels. Elsewhere navigation can only be maintained by constant dredging and renovation of port facilities. The other economic uses to which these rivers might lend themselves, such as irrigation or hydroelectric power, are equally difficult to achieve. The swamps of Xarayes and the Chaco make agriculture a virtual impossibility in these areas, while under present conditions the potential electric power represented by the falls of Guairá or Iguaçu is too remote from any centres to be harnessed.

Buenos Aires is one of the principal seaports of the world and the main port of Argentina. Vessels approach it from the main estuary channel by one of two side channels which are clearly marked and dredged to depths of 31 ft. Ocean vessels can travel up the Paraná river as far as Santa Fe or Paraná. The channel depth from the mouth of the Paraná to Rosario is dredged to 21 ft., from Rosario to Paranb to 19 ft. Ocean trade can also reach Concepción del Uruguay directly by the Uruguay river where the dredged depth of the channel is 19 ft.

Commerce further upstream on these river systems operate under conditions which fluctuate considerably. Passage of vessels depends to a large extent on seasonal variations in depth. A 6-ft. depth is assured from Paraná to Corrientes and usually to Posada, although vessels of deeper draught can often pass Long fleets of barges carry the bulk of the river freight. The current, narrowness, and curves above Corrientes on the Upper Paraná, however, rule out such barge transport. Several rapids on the Upper Paraná can only be passed with the use of winches to pull the vessels. Narrowness of the river, whirlpools and the increased speed of the current to 5 m.p.h. make navigation more dangerous as the mouth of the Iguaçu is approached. The absolute head of navigation is located at Pôrto Mendes below the Guairá falls in Brazil. A railroad, 38 mi. long, circumvents the falls to the town of Guairá, and opens up another 400 mi. of navigable river further up the Paraná. Beyond, stretches of the Paranb and of tributaries are navigable only by launches or canoes.

On the Paraguay river, vessels drawing 7 ft. and displacing 2,000 tons are able to reach Corumbá in Brazil at all seasons. The most traveled stretch of this river is the 250 mi. from Corrientes to Asunción which is accessible to vessels of 10 ft. draught. Although Corumbá is considered as the head of navigation on the Paraguay, the Bolivian town of Puerto Suárez, 10 mi. away, was built to provide this landlocked nation with a port. Vessels can reach it from Corumbk during the flood season, March to Sept., but its population of 1,154 (1950) indicates that it is hardly a major commercial centre.

Some ocean vessels with a draught of 15 ft. can go 25 mi. beyond Concepción del Uruguay on the Uruguay river to Fábrica Colón. A 9 ft. depth is assured as far as Concordia and 6 ft. as far as Salto. Ships of deeper draught reach these river ports in flood time. Above Salto, there are few ports and no measurement of depths is taken. A considerable commerce and movement, however, is carried on by small launches, rafts and canoes.

Navigation of the Pilcomayo, Bermejo and Salado is negligible, because of shifting channels, sandbars and shallowness. Vessels of 3 ft. draught can ascend the Pilcomayo for the first 120 mi. to Fontana, although in a straight line this means only 45 mi. Barges and motorboats on the Bermejo reach Presidencia Rosa, 160 mi. from the mouth, on a regular schedule, although the depth in the shallows is reduced to 2 ft. in the dry season. During high water, November to April, small vessels can ascend the Bermejo 400 mi. from its mouth. Only very shallow draught vessels can use stretches of the Salado.

The value of these river systems as a commercial artery is, therefore, concentrated on the lower reaches. A large volume of ocean shipping reaches Rosario and Concepción del Uruguay, although the major seaports are Buenos Aires and Montevideo. The great bulk of river transport is concentrated within the limits of Asunción on the Paraguay, Corrientes on the Paranb, and Salto on the Uruguay. The Argentine Flota Fluvial del Estado, the Lloyd Brasileiro and the Compañía Uruguaya de Navegación, however, provide regular passenger and freight service to all navigable parts of these river systems. Rafts, canoes and motorboats provide irregular although important service on the tributaries and upper reaches of these rivers.

A lack of population, remoteness of markets and difficulty of transport are partial reasons for the failure to develop other uses from these river systems. Seasonal rainfall with consequent flooding of large areas may provide a very crude basis for agriculture along the Salado, but it prevents agriculture in vast areas of the Chaco and Mato Grosso. The same remoteness has prevented any effective harnessing of the rivers' power. One exception is the headwaters of the Tieté which, pumped across an intervening range, provide water for a hydroelectric plant near São Paulo.

History. — The Rio de la Plata was discovered by Juan Díaz de Solís, chief navigator of Spain, in 1516, as a result of efforts to find a route to the Pacific. The estuary was temporarily named in his memory after his death on its shores at the hands of unfriendly Charrua Indians. Magellan touched at the estuary in 1520 during his circumnavigation of the globe. In 1526, Sebastian Cabot ascended the rivers as far as the present city of Asunción and obtained silver trinkets in barter with the Guarani Indians. Spanish dreams gave the estuary its permanent name, Rio de la Plata, in the hope that it might indeed become a river of silver. The major Spanish expedition which settled near the present location of Buenos Aires in 1536 under Pedro de Mendoza proved a fiasco. After much misfortune the survivors moved upstream to the surroundings of the more docile Guarani Indians at Asunción. Buenos Aires was not refounded until 1580, and throughout the Spanish colonial era, the Rio de la Plata remained a backwash of the empire. The estuary was virtually closed to legal commerce until the end of the 18th century. Spain only renewed its interest in the area when Portuguese and English ambitions threatened to expand into the Rio de la Plata in the 1760s.

Navigation of the river systems became a problem when the national states of Argentina, Uruguay, Paraguay, Brazil and Bolivia emerged on its courses. Territorial conflicts and restrictions on navigation caused several wars, culminating in the titanic struggle by Francisco Solano López's Paraguay against Brazil, Uruguay and Argentina from 1864 to 1870. In the 20th century, similar conflicts sharpened by rumoured oil wealth resulted in the Chaco war between Paraguay and Bolivia.

The development of agricultural wealth, particularly in Argentina, resulted in greater appreciation of the commercial value of these river systems after the mid-19th century. Wheat, beef, wool and hides entered the river and world trade in increasing quantities from Argentina and Uruguay, while from Brazil and Paraguay came forest and tropical products and yerba mate or Paraguayan tea. Port construction and dredging made Buenos Aires more valuable as a seaport, and by 1902 similar improvements had been completed at Rosario. Marking of channels, soundings, dredging and other aids to navigation became a responsibility of all the riparian states. See also SOUTH AMERICA; BRAZIL; ARGENTINA; PARAGUAY; URUGUAY. (Js. R. S.)

PLATAEA (PLATAEAE), an ancient Greek city of Boeotia, situated close under Mt. Cithaeron near the passes leading from Peloponnesus and Attica to Thebes and separated from the latter city's territory by the Asopus river. Though one of the smallest Boeotian towns, it stubbornly resisted the centralizing policy of Thebes. In 519 B.C. it invoked Sparta's help against its powerful neighbour, but was referred by King Cleomenes to Athens (for the date, see Grote's History of Greece, ed. 1907, p. 82, note 4). The Athenians secured Plataea's independence and thus secured its enduring friendship. In 490 the Plataeans sent their full levy to the assistance of the Athenians at Marathon, and during the invasion of Xerxes they joined eagerly in the national defense. At Artemisium they volunteered to man several Athenian ships, and subsequently abandoned their town to be burned by Xerxes. In 479 they fought against the Persians under Mardonius in the decisive battle which bears the name of the city. (For an account of the battle see GRAECO-PERSIAN WARS.) Their great victory was celebrated by annual sacrifices and a festival of liberation (Eleutheria) in every fourth year at Plataea, whose territory, moreover, was declared inviolate.

In spite of this guarantee Plataea was attacked by Thebes at the beginning of the Peloponnesian War (431) and formally besieged by the Peloponnesians (429–27). The garrison after capitulating was put to death. and the city razed by the Thebans. The remaining Plataeans received a qualified franchise in Athens, and in 421 were settled on the territory of Scione. Expelled by Lysander in 404 they returned to Athens, until in 387 Sparta restored them in their native town as a check upon Thebes. The city was again destroyed by Thebes in 373 and the inhabitants once more became citizens of Athens. Plataea was rebuilt by Philip and Alexander of Macedon, and during the rest of antiquity enjoyed a safe but obscure existence. It continued to flourish in Byzantine and Frankish times. The walls of the town, which at various periods occupied different portions of the triangular ledge on which it stood, remain partly visible. Modern excavations discovered the Heraeum, but the temple of Athena the Warlike. built from the Persian spoils and adorned by the most famous artists, was not identified.

PLATE GLASS: *see* GLASS.

PLATEN-HALLERMÜNDE, AUGUST, GRAF VON (1796–1835), German poet and dramatist who opposed romanticism and in his own work aimed at classical purity of style, was born Oct. 24, 1796, at Ansbach. He entered the Bavarian life guards in 1814, and took part in the campaign in France in 1815. After a tour in Switzerland and the Bavarian Alps: he entered the University of Wurzburg in 1818 as a student of philosophy and philology. In 1819 he moved to Erlangen, where he studied under the philosopher of romanticism; F. W. von Schelling, and made the acquaintance of Jean Paul, Jacob Grimm. the oriental scholar and poet Friedrich Riickert, Goethe and Ludwig Chland. He became a first-rate scholar and as a result of his oriental studies he published a little volume of poems. *Ghnselen* (1821). in which he imitated the style of Ruckert. This was followed by *Lyrische Blatter* (1821), *Spiegel der Hafis* (1822), *Vermischte Schriften* (1822) and *Neue Ghaselen* (1823).

Though Platen was at first influenced as a dramatist by the romantics and particularly by Spanish models, the plays he wrote while at Erlangen (*Der glaserne Pantoffel, Der Schatz des Rhampsinit, Berengar, Treue um Treue, Der Turm mit sieben Pforten*) show a clearness of plot and expression foreign to the romantic style. His antagonism to romanticism became more pronounced. and he attacked its extravagances, particularly the *Schicksaldrama*, or fate drama, in the witty "Aristophanic" comedies *Die verhangnisvolle Gabel* (1826) and *Der romantische Oedipus* (1829). *Der romantische Oedipus* earned him the enmity of Karl Immermann, whose work was ridiculed in it, and of Heinrich Heine, a close friend of Immermann, but he had many admirers, who delighted in the classical purity of his plays and their polished form and diction. After 1826 he lived in Italy, and his last play, *Die Ligu von Cambrai* (1833), and the epic fairy tale *Die Abbassiden* (1834), were written at Naples. He died at Syracuse, Dec. 5, 183j. Platen's odes and sonnets, and his *Polenlieder* (1831) expressing sympathy for the Poles in their rising against the tsar's rule, are among the best classical poems of their time.

Platen's *Gesammelte Werke* were published in one volume in 1839. There is a critical edition in 12 vol. by M. Koch and E. Petzet (1910). His *Tagebücher* (1813–3j) were edited by G. von Laubmann and L. von Scheffler, 2 vol. (1896–1900); his correspondence by L. von Scheffler and P. Bornstein, 4 vol. (1911–31).

See R. Schlosser, *August Graf von Platen*, 2 vol. (1910–13); F. Redenbacher, *Platen-Bibliographie* (1926). (A. Gs.)

PLATERESQUE, the earliest of the styles of Spanish Renaissance, so called either because the Renaissance found its first popular Spanish expression in silverware (*platero*, "silversmith") or because its rich and delicate ornament resembled silversmith work. It is characterized by the application to structurally simple forms of extremely rich ornament, distantly based on Italian Renaissance forms, using pilasters, entablatures, carved rectangular panels, shallow niches, much heraldic ornament and richly pierced. scrolled cresting. Its courtyards, usually with two or more openings on the upper floor, above a single opening below, are famous for their decorated columns, sometimes simulating balusters, their bracketed capitals and their graceful delicacy. As a result of Moorish influence there is a common tendency to carry the decoration around the door over the full height of the wall above. Decorative ironwork. as in the church *rejerias* or open metal screens, was highly developed. The style embraces, generally, the first half of the 16th century, but its decorative ideals influenced not only the classic period which followed but the baroque as well. Characteristic examples are the hospital of Santa Cruz, Toledo, by Enrique de Egas (1504–16), the college at Alcalá de Henares, the university and Irish college at Salamanca. the Casa de las Conchas at Salamanca and the Infantada at Guadalajara. *See* RENAISSANCE ARCHITECTURE. (T. F. H.)

PLATE RIVER: *see* PLATA, RÍO DE LA.

PLATFORM TENNIS is a combination of tennis and squash invented in 1928 by Fessenden Blanchard and James Cogswell at Scarsdale. N.Y. The game is played on specially constructed 60 × 30 ft. wooden platforms. The platform is surrounded by back and side stops of tightly strung wire which are 12 ft. high. The actual court measures 44 × 20 ft. and the net is 2 ft. 10 in. at centre. The paddles or bats, which are used instead of racquets. are oval plywood, metal-bound and perforated, and have short handles. Balls are made of sponge rubber. The rules are the same as tennis with two principal exceptions: balls may be taken off wires. after first striking inside the proper court, and only one serve is allowed.

Since its inception it has gained considerable popularity in the United States. (F. S. BD.)

PLATINUM is a chemical element which is a very heavy precious silver-white metal. It is the best known and most widely used of the six platinum metals. (*See* PLATINUM METALS and the articles on individual elements, IRIDIUM, OSMIUM, PALLADIUM, RHODIUM and RUTHENIUM.) The chemical symbol for platinum is Pt, atomic number 78 and atomic weight 195.09. The usefulness of this metal is due to its resistance to corrosion or chemical attack and to its high melting point of 1,773° C. For example, when brought to a white heat in air, it retains its bright surface. It is scarcely attacked by simple acids but does dissolve readily in aqua regia ($HCl;HNO_3$). With such a high melting point platinum is not easily fused or cast. In the fabrication of metal a sponge is commonly prepared by decomposition of its compounds. The sponge can be hammered and welded at a white heat into massive sheets and various objects. The massive metal has the very high specific gravity of 21.46. However, it is soft and ductile, and thereby unsuited for many purposes. Small amounts of iridium are commonly added to give a harder, stronger alloy which retains the advantages of the platinum. The boiling point of platinum is estimated to be 4,500° C., but the loss of weight of the solid by volatilization above 1,000° C. is very gradual but detectable.

Platinum did not receive general recognition in ancient times. Large deposits as heavy river sands were uncovered in the 16th-century Spanish conquest of South America. The Spaniards called the new metal *Platina del Pinto* after the Rio Pinto, from which its present name was taken. Samples of the element received the general attention of European scientists in the latter 18th century. Platinum occurs in native alloys which frequently contain smaller amounts of other platinum metals. It is recovered as a by-product in a number of metallurgical operations for the production of copper, nickel, lead and other metals.

Uses.—Platinum and its alloys are indispensable in the chemical laboratory for crucibles and dishes in which materials can be heated to high temperatures. However, some caution must be used, for it is attacked and alloyed by carbon, phosphorus, silicon and some low-melting metals such as lead, arsenic and antimony. Besides these metals it alloys readily with other platinum metals and with copper, gold and silver. Caustic alkalis at high temperature must be avoided, although alkali carbonates may be fused in platinum ware.

Platinum is used in the preparation of electrical contacts and sparking points because it resists the high temperature and chemical attack of electric arcs. The manufacture of jewelry and dental alloys consumes large amounts of the metal. The prototype international standard metre of length and standard kilogram of mass together with several national copies have been made from the alloy, 90% platinum and 10% iridium. Fine laboratory weights are frequently electroplated with platinum. Platinum electrodes are used in the important electrolytic preparation of hydrogen peroxide, strongly oxidizing salts and acids which corrode other metals. Electrodes of platinum also serve for quantitative electroplating operations in chemical analyses.

The electrical resistance and its temperature coefficient for platinum are relatively high for a metal, and the resistance of coils of exceptionally pure platinum wire therefore gives a precise measure of temperature. The international temperature scale from − 190° C. to 660° C. is defined in terms of such a platinum resistance thermometer. At higher temperatures, from 660° C. to 1,063° C. (the melting point of gold), the international temperature scale is defined by the electromotive force of a thermocouple with a wire of pure platinum against another of the alloy, 90% platinum and 10% rhodium. The coefficient of thermal expansion of platinum is low for a metal and near to those of soft glasses, so that thin electrical leads of the metal can be conveniently sealed through glass walls.

Platinum metal surfaces are exceptionally good catalysts for many chemical reactions, especially for reactions which involve the gases hydrogen or oxygen. For this purpose thin deposits of the metal may be formed on an inert supporting material, or fine gauze may be utilized. Also, very finely divided platinum black can be prepared by the reduction of solutions of its compounds or may be deposited by electrolysis on platinum sheet. Large quantities of platinum, which were used to catalyze the oxidation of sulfur dioxide in the manufacture of sulfuric acid, have been mostly replaced by vanadium oxide and other materials; but platinum gauzes serve as catalyst when ammonia is burned in air to yield nitric oxide in the manufacture of nitric acid. Vapours of hydrocarbons or alcohols in air ignite spontaneously, sometimes explosively, on these surfaces. The platinum catalysts can be used in the laboratory for hydrogenation or reduction of organic compounds. The catalytic properties of a platinum-black electrode allows the reversible oxidation of hydrogen gas. and the resultant hydrogen electrode serves as the standard reference electrode for potentials in electrochemistry. Bright platinum wires in ionic solutions function as reversible electrodes for a number of oxidation-reduction systems.

Platinum Compounds.— Platinum forms important series of compounds with the oxidation states of + 2 and + 4. Many of these compounds contain co-ordination complexes in which chloride, ammonia or other groups are bonded covalently to a central platinum atom. There are bonds from a platinum atom to six groups arranged symmetrically around it toward the corners of an octahedron for the + 4 state. For compounds of + 2 platinum, four bonds are commonly directed toward the corners of a square, a geometrical arrangement which can occur in chemical systems only under special circumstances of electronic configuration. Complexes of both oxidation states are kinetically inert in that groups are replaced slowly. The preparation of numerous isomers (complex compounds with the same composition, for example, Peyrone's chloride, *cis*-$[Pt(NH_3)_2Cl_2]$, Reiset's second chloride, trans-$[Pt(NH_3)_2Cl_2]$, and Magnus' green salt, $[Pt(NH_3)_4]$-$[PtCl_4]$), provided an important stimulus to the evolution of theories concerning structural arrangements of atoms (stereochemistry). All the compounds of platinum are readily decomposed or reduced to the metal. Many of their aqueous solutions decompose with an appreciable rate below boiling temperature.

When platinum dissolves in aqua regia, hexachloroplatinic (IV) acid, H_2PtCl_6, is formed. The slightly soluble yellow potassium and ammonium hexachloroplatinate (IV) are readily precipitated and are useful in analysis. Pure sponge metal is usually prepared by ignition of $(NH_4)_2PtCl_6$. Heated with sodium hydroxide, hexachloroplatinic (IV) acid gives soluble $Na_2Pt(OH)_6$ which yields yellow hydrous hydroxide when neutralized with weak acid. The hydroxide can be dehydrated to give black PtO_2. Electrolysis of the alkaline solutions gives a hydrous oxide corresponding to a higher oxidation state. Hydrates of hexachloroplatinic (IV) acid can be crystallized; and if the crystals are heated to 300° C. in an atmosphere of chlorine, a reddish-brown $PtCl_4$ is formed,

$PtCl_4$, heated to above 360° C., yields a green-brown platinum (II) chloride, $PtCl_2$, which is insoluble in water but dissolves very slowly in HCl solutions to give the red solution of tetrachloroplatinic (II) acid, H_2PtCl_4. This acid is readily prepared by the reduction of H_2PtCl_6 with sulfur dioxide. When alkali is added to a solution of a tetrachloroplatinate (II), a hydrous black platinum (II) hydroxide is precipitated. It can be dehydrated to gray PtO with some decomposition to metal. Hydrogen sulfide precipitates a black sulfide, PtS. (D. S. MN.)

PLATINUM METALS are a group of six chemical elements, including platinum, which are generally found together in nature with varying proportions in the metallic form. The elements are listed in the accompanying table together with their important atomic and physical properties.

The group is naturally divided into light and heavy triads of three elements each. For each light element there is a heavy element whose atomic number is greater by 32. The two elements in each such pair belong to the same family of the periodic table of elements so that three families are represented. As is normally the case, elements of the same family have strikingly similar chemical and physical properties. Although some similarities are noted among the entire group, there are wide differences in the chemical behaviour between different families. The six platinum metals are included together with iron, cobalt and nickel as Group VIII of the periodic table of elements.

Each of the individual elements is a silver-white metal. Although none melt below a white heat, there is still a wide range in the melting points. With such high melting points they are difficult to fuse or cast. Their boiling points can only be estimated roughly from extrapolations of vapour pressure measurements. The specific gravities of the light triad fall in the narrow range of 12.0–12.5; the heavy triad are exceptionally dense.

Osmium and iridium, whose densities are equal within the experimental accuracy, are the densest terrestrial materials known. Platinum and palladium are soft, ductile and easily worked; the other members are hard and difficult to work in the cold. However iridium and rhodium can be worked at a white heat. An important common property of the group is the instability of their chemical compounds which are readily decomposed or reduced to yield the free elements in the form of a metal sponge or powder. Chemists accordingly classify all members of the group as noble metals.

History and Occurrence.— None of the platinum metals received widespread recognition in ancient times, although artifacts containing platinum have been uncovered occasionally by archaeologists. Large deposits of platinum were first recognized in South America during the 16th-century Spanish conquest. The Spanish government originally held a low regard for the metal because its high density permitted the preparation of counterfeits for gold which were difficult to detect. The new metal came to the general attention of European scientists in the late 18th century. Within the two-year period 1803–04 the discoveries of four new elements from crude platinum were announced in England—palladium and rhodium by William Wollaston and osmium and iridium by Smithson Tennant. Although other elements were thought to be contained in crude platinum at times, Carl Claus in Russia demonstrated the existence of the remaining rare metal of the platinum group in 1844. He chose for it the name ruthenium, which G. W. Osann had suggested earlier.

Since compounds of all the platinum elements are readily decomposed to give dense metals, it is not surprising that the six elements have been concentrated together as native alloys by geological processes. The earliest deposits to be worked were heavy river sands which had been concentrated by gravity. Primary deposits of the metals dispersed in basic and ulrrabasic igneous rocks have since been productive. They are normally accompanied by other elements such as gold, and compounds of iron and nickel. Platinum metals are sometimes included in sulfide deposits and are recovered as by-products in the metallurgical operations for copper, nickel and other metals. The earliest workings of platinum were in Colombia and Brazil. In 1819 platinum was discovered in the Ural mountains. and since about 1825 Russia has been a dominant producer of the metals. For a period, 1828–41, coins were minted from a platinum-iridium alloy in Russia. Limited occurrences have been found in many areas of the world. Ores

Atomic and Physical Properties of the Platinum Metals

Metal	Ruthenium	Rhodium	Palladium	Osmium	Iridium	Platinum
Symbol	Ru	Rh	Pd	Os	Ir	Pt
Atomic number	44	45	46	76	77	78
Atomic weight	101.1	102.91	106.7	190.2	192.2	195.09
Mass number of stable isotopes	96, 98, 99, 100, 101, 102, 104	103	102, 104, 105, 106, 108, 110	184, 186, 187, 188, 189, 190, 192	191, 193	190*, 192, 194, 195, 196, 198
Outer electron configuration	$4d^7 5s^1$	$4d^8 5s^1$	$4d^{10}$	$5d^6 6s^2$	$5d^9$	$5d^9 6s^1$
Ionization energy (electron volts)	7.5	7.7	8.33	8.7	[illegible]	8.96
Structure	hexagonal close-packed	cubic close-packed	cubic close-packed	hexagonal close-packed	cubic close-packed	cubic close-packed
Density (g./cm.^{3} at 20° C.)	12.38	12.42	12.03	22.56	22.56	21.46
Metallic radius (C.N. 12) (angstroms)	1.34	1.34	1.37	1.35	1.36	1.39
Melting point (° C.)	2,450	1,980	1,550	2,700	2,450	1,773
Boiling point (° C.)	>2,700	>2,500	>2,500	>5,300	>4,800	>[illegible]
Specific heat (cal/g.deg. C.)	0.0551	0.0589	0.05838	0.0310	0.0307	[illegible]

*Possibly radioactive.

from the Union of South Africa and the nickel ores of the Sudbury, Ont., area have given especially high continued yields. Because sources of the elements are limited, the metals command high prices which have fluctuated widely.

In atomic energy reactors isotopes of the light triad are formed together with more than 30 other elements as products of the nuclear fission of uranium, plutonium or thorium. It is necessary to eifect their removal from the fissionable materials and sometimes from other fission products under difficult conditions imposed by the radiation hazards for large-scale applications of atomic energy.

Uses; — Platinum is the most readily available and widely used of the metals in the group. Its utility depends mostly upon its high melting point and its resistance to chemical attack by the atmosphere and by many chemical agents. The metals are used in the electrical industry for resistors, contacts and sparking points. In the chemical industry and laboratory they are used for dishes, crucibles, electrodes, nozzles and other objects which must resist corrosion. Also large quantities are consumed for dental alloys and decorative purposes in jewelry. The surfaces of these metals are extremely active catalysts for a number of chemical reactions. Therefore they are widely used in the laboratory and in industry to accelerate chemical reactions despite their high cost. However, unless wastage is very small, cheaper materials, which may be less effective catalysts, are frequently used.

Chemical Properties. — Platinum can be heated to a white heat in air without losing its bright surface. It k not attacked by simple acids but does dissolve readily in aqua regia. None of the metals in the massive form is appreciably oxidized by the atmosphere at room temperature. However, when heated in air osmium is converted to the tetraoxide, OsO_4, a volatile poisonous compound (boiling point 131° C.) with an unpleasant odour; and ruthenium oxidizes to give RuO_2. The other elements oxidize only superficially in the air. Palladium slowly dissolves in concentrated nitric or sulfuric acid, and osmium forms OsO_4 with fuming nitric acid. Even aqua regia scarcely attacks ruthenium, rhodium or iridium. A fused mixture of sodium hydroxide and sodium nitrate is an effective agent which will oxidize all of the elements.

A few examples suffice to show the wide differences in chemical properties among the group. Osmium and ruthenium are alone among all known elements in forming a few well-characterized compounds with the +8 oxidation state, for example RuO_4, OsO_4, OsF_8 and $KOsO_3N$. The volatility of the tetraoxides permits convenient, efficient and rapid separation of these two elements.

All the platinum metals can form compounds with more than one oxidation state. For ruthenium there is evidence for compounds in every oxidation state from +1 through +8. However both ruthenium and osmium are normally encountered in the states +3, +4, +6 or +8. In contrast, rhodium is limited with a few exceptions to the +3 oxidation state, whereas iridium forms important compounds for the +3 and +4 states. Palladium and platinum compounds are largely confined to the +2 and +4 states, the latter being very unstable for palladium.

All the platinum elements are characterized by a tendency to form co-ordination complexes in which chloride, ammonia, water or other groups are bonded covalently to the central metal ion. Replacements of one group by another, especially in the complexes of the heavy triad, are frequently slow.

Separation.—Processes for the recovery of the metals from the ores remain somewhat as trade secrets of individual firms and depend partly upon the composition and nature of metallurgical concentrates which must be handled. Commonly, at one step a mixture of the metals is dissolved in aqua regia. However, the mineral osmiridium, an alloy rich in osmium and iridium, is not dissolved by aqua regia. If it is heated with zinc it yields an alloy which is acid-soluble. The osmium distils away from the aqua regia solution as OsO_4 upon boiling. NH_4Cl added to an HCl solution of the remaining elements precipitates $(NH_4)_2PtCl_6$ and $(NH_4)_2IrCl_6$. These two compounds can be separated by repeated fractional crystallizations of the less soluble platinum compound. After platinum and iridium are removed, a precipitate of $[Pd(NH_3)_2Cl_2]$ can be formed by the addition of aqueous ammonia followed by HCl. If the remaining material in solution is reduced to metal and treated with fused potassium hydrogen sulfate. the rhodium is recovered as a soluble complex sulfate. $K_3Rh(SO_4)_3$. A ruthenium concentrate which remains can best be dissolved by a potassium hydroxide-potassium nitrate fusion and purified by a distillation procedure.

(D. S. MN.)

PLATO (428/427–348/347 B.C.), Greek philosopher whose influence on thought has been continuous for more than 2,400 years. was the son of Ariston and Perictione. His family was, on both sides. one of the most distinguished of Athens. Ariston is said to have traced his descent through Codrus to the god Poseidon; on the mother's side. the family. that was related to Solon, goes back to Dropides, archon of the year 644 B C. Perictione apparently married as her second husband her uncle Pyrilampes (*Parmenides* 126 *b*) a prominent supporter of Pericles. and Plato was probably chiefly brought up in his house: Critias and Charmides, leading men among the extremists of the oligarchic terror of 404, were respectively cousin and brother of Perictione; both were old friends of Socrates, and through them Plato must have known the philosopher from boyhood

His own early ambitions as he tells us in the *Epistle* vii. 324 *b*–326 *b*, were political The reactionaries urged him to enter public life under their auspices—at the age of 24—but he wisely held back until their policy should declare itself. He was soon repelled by their violences, particularly by their attempt to implicate Socrates in the illegal execution of their victim Leon. He hoped better things from the restored democracy, but its condemnation of Socrates finally convinced him that there was no place for a man of conscience in active politics. Hermodorus, an immediate disciple. is the authority for the statement that, on the execution of Socrates in 399 B.C., Plato and other Socratic men took temporary refuge with Eucleides at hlegara. The later biographies represent the next few years as spent in extensive travels in Greece, in Egypt and in Italy. Plato's own statement is only that he visited Italy and Sicily at the age of 40 and was disgusted by the gross sensuality of life there, but found a kindred spirit in Dion, brother-in-law of Dionysius I of Syracuse.

The Academy and Sicily. — About or soon after 387, Plato founded the Academy as an institute for the systematic pursuit of philosophical and scientific research. He presided over it for the rest of his life, making it the recognized authority alike in mathematics and in jurisprudence. From the allusions of Aristotle we gather that Plato lectured without manuscript, and we know that "problems" were propounded for solution by the joint researches of students. On the political side there are traces of tension between the Academy and the rival school of Isocrates.

The one outstanding event in Plato's later life is his intervention in Syracusan politics. On the death of Dionysius I in 367, Dion conceived the idea of bringing Plato to Syracuse as tutor to his successor, whose education had been neglected. Plato himself was not sanguine of results, but as both Dion and the philosopher-statesman Archytas of Tarentum thought the prospect promising, he felt bound in honour to risk the adventure The project was by training Dionysius II in severe science to fit him for the position of a constitutional king who might hold Carthaginian encroachment in Sicily at bay. The scheme was crushed by his natural jealousy of the stronger Dion, whom he drove into virtual banishment. Plato paid a second and longer visit to Syracuse in 361–360, in the hope of still eifecting an accommodation, but failed, not without some personal danger. When Dion captured Syracuse by a *coup de main* in 357, Plato wrote him a short letter of congratulation and warning against his own lack of tact and graciousness. After the murder of Dion in 354 the philosopher drew up his important *Epistles* vii and viii. reviewing and justifying the policy of Dion and himself and making proposals, unsuccessfully, for a conciliation of Sicilian parties.

The prejudice which led students in the 19th century to discredit the *Epistles,* in spite of the favourable opinion of scholars such as Richard Bentley, C. G. Cobet, George Grote, F. Blass and E. Meyer, worked havoc with their accounts of Plato's life. It is safe to say that the two letters of chief biographical importance, vii and viii, have the best claim to authenticity, i and xii the weakest.

To us Plato naturally is important primarily as one of the greatest of philosophical writers, but to himself the foundation and organization of the Academy must have appeared his chief work. In *Epistle* vii, 341 *b–e,* 344 *c,* he utters on his own account the same comparatively unfavourable verdict on written works, in contrast with the contact of living minds, as a vehicle of "philosophy," which he ascribes to Socrates in the *Phaedrus.* It can hardly be doubted that he regarded his dialogues as intended in the main to interest an educated outside world in the more serious and arduous labours of his "school."

All the most important mathematical work of the 4th century was done by friends or pupils of Plato. Theaetetus, the founder of solid geometry, was a member of the Academy, as were also the first students of the conic sections. Eudoxus of Cnidus, author of the doctrine of proportion expounded in Euclid's *Elements,* inventor of the method of finding the areas and volumes of curvilinear figures by exhaustion and propounder of the astronomical scheme of concentric spheres adopted and altered by Aristotle, removed his school from Cyzicus to Athens for the purpose of cooperation with Plato. Archytas, the inventor of mechanical science. was a friend and correspondent. The Xcademy is thus the link between the mathematics of the 5th-century Pythagoreans and those of the geometers and arithmeticians of Alexandria.

Nor were other sciences neglected. Speusippus, Plato's nephew and successor, was a voluminous writer on natural history; Aristotle's biological works have been shown to belong largely to the early period in his career immediately after Piato's death, before the breach between the younger philosopher and the Xcademy. The comic poets found matter for mirth in the attention of the school to botanical classification. The Academy was particularly active in jurisprudence and practical legislation. "Plato sent Aristonymus to the Arcadians, Phormion to Elis, Menedemus to Pyrrha. Eudoxus and Aristotle wrote laws for Cnidus and Stageirus. Alexander asked Xenocrates for advice about kingship; the man who was sent to Alexander by the Asiatic Greeks and did most to incite him to his war on the barbarians was Delius of Ephesus, an associate of Plato." (Plutsrch. *Adversus Coloten,* i126 *c–d).* The creation of the Academy as a permanent society for the prosecution of both exact and humane sciences was, in fact, the first establishment of a university. *(See* ACADEMY, GREEK.)

Formative Influences.—The most important formative influence to which the young Plato's mind was exposed was that of Socrates. But it does not appear that Plato. whose first ambitions were political. belonged to the innermost circle of the old man's intimates. or regarded himself as a "disciple." In *Epistle* vii he is careful to speak of Socrates not as a "master" but as an older "friend" *(hetairos)* for whose character he had a profound respect; and he has recorded his own absence (through indisposition) from the death scene of the *Phaedo.* It would seem that his own vocation to philosophy dawned on him only afterward, as he reflected on the moral to be learned from the treatment of Socrates by the democratic leaders. Aristotle incidentally ascribes to him an early familiarity with the Heraclitean Cratylus, a younger man than Socrates and apparently an admirer of the philosopher. This may be only Aristotle's inference from the existence of the dialogue *Cratylus.* It is more important to remember Plato's connection with Pyrilampes and Critias. Pyrilampes was a Periclean politician, and Critias was known as a democrat until his moral balance was upset by the collapse of the Periclean system in 404. Early upbringing in a family of Periclean politics having connection with Solon may explain why Plato's own estimate of democracy in the *Politicus* and *Laws* is much less unfavourable than that which he ascribes to Socrates in the *Gorgias* and *Republic.*

Beyond this, we can say only that Plato in early life must have been exposed to the same influences as his contemporaries. His early experiences covered the disastrous years of the Deceleian War, the shattering of the Athenian empire and the fierce civil strife of oligarchs and democrats in the year of anarchy 404–403. He was too young to have known anything by experience of the imperial democracy of Pericles and Cleon, or of the full tide of the sophistic movement. It is not from memory that he depicts Protagoras, or even Alcibiades, as they were in their great days.

THE DIALOGUES

The fixing of the canon and text of Plato has often been attributed to two scholars, Dercylides and Thrasylus, either shortly before or shortly after the Christian era (but *see* ACADEMY, GREEK). Thrasylus is uncertainly identified with Thrasylus of Mende and generally assumed to have been astrologer to and friend of Tiberius. By reckoning the *Epistles* as one item, the list was made to consist of 36 works, arranged in nine tetralogies, or groups of four. (Aristophanes of Byzantium had already attempted an arrangement in trilogies, or groups of three, which, however, he did not carry through.)

No genuine work of Plato has been lost, but there is a general agreement of modern scholars to reject a number of small items from the text. Their verdict may be said to have gone definitely against the following: *Alcibiades* I, *Alcibiades II* (suspected by some even in ancient times), *Theages, Erastae, Clitophon, Hipparchus, Minos.* Most or all of these are probably early Academic work, and possibly not all later in date than Plato's death. Most, though not all, contemporary scholars also regard the *Epinomis*—in the present writer's opinion wrongly—as an appendix to the *Laws* added *de suo* by the mathematician Philippus of Opus, who is recorded by Diogenes Laertius (iii, 37) to have transcribed the work for circulation. The *Hippias Major* and the *Menexenus* are still regarded as doubtful by some, though Aristotle used both in a way which seems to prove that he regarded them as Platonic (he expressly quotes the *Menexenus*). Plato's will, preserved by the same Diogenes (iii. 41–43), is pretty certainly authentic. Some of the 32 epigrams ascribed to him in the *Anthology* may conceivably be genuine.

Order of **Composition.**—Plato's literary career extended over the greater part of a long life. The *Apology* must have been written while the memory of Socrates' appearance before his judges was still fresh; the *Laws* is confessedly the work of an old man with a long experience of life behind him, and the state of its text fully bears out the tradition, preserved by Proclus, that its aged author never lived to give it final revision. Half a century or more must have elapsed between Plato's last and his earliest composition.

This of itself would prove that F. Schleiermacher, with whom modern critical study of Plato begins, went astray in assuming that Plato started his career with a ready-made complete "system' to be disclosed. We must expect to find in his writings evidence of the development of his mind. But if we are to read the development aright we must have some trustworthy way of determining the order of the dialogues. Plato himself has given us only the scantiest indications of the order. He has linked the *Sophistes* and the *Politicus* externally with the *Theaetetus* as continuations of the conversation reported in that dialogue; he has also, as most students recognize, linked up the *Timaeus* in the same way with the *Republic*. Aristotle adds one other piece of information, that the *Laws* were written after the *Republic*.

Further investigation of the problem opens in 1867 with L. Campbell's edition of the *Sophistes* and the *Politicus*, and the work thus begun was continued by others, notably W. Dittenberger, M. Schanz, C. Ritter, H. Arnim and W. Lutoslawski.

By consideration of independent stylistic criteria, it has been definitely established that the dialogues *Sophistes, Politicus, Philebus, Timaeus* (with its fragmentary sequel *Critias)* and *Laws* form a distinct linguistic group, which must belong to the later years of Plato's life, as we might have presumed from the consideration that Socrates, the central figure of other dialogues, becomes, in those of this group (with a solitary exception for the *Philebus*, the one member of the group which is wholly preoccupied with ethics), a secondary personage, and disappears altogether from the *Laws*. The whole group must therefore be later than the *Sophistes*, which professes to be a sequel to the *Theaetetus*. Now the *Theaetetus* can be dated with some accuracy, since it commemorates the recent death of the eminent mathematician after whom it is named from disease and injury contracted in a campaign before Corinth, which, as elaborately proved by Eva Sachs *(De Theaeteto Atheniensi,* 1914), must be that of 369 B.C. The dialogue may thus be safely ascribed to 368–367, the eve of Plato's departure for Syracuse, and the marked change of style visible in the *Sophistes* is best explained by the supposition that there was a break in Plato's literary activity during the years 367–360 when he was specially occupied with Sicilian affairs. So much may be regarded as fairly certain.

It is not so easy to reach conclusions about the order of composition of the earlier group of dialogues. It is generally recognized, on linguistic and other grounds, that the series ends uith the *Theaetetzrs* and the closely related *Parmenides*. Ritter, Lutoslawski and others tried to determine the internal order of the group on linguistic evidence, but there are obvious reasons for doubting whether the methods which proved successful in establishing the distinction between the two great groups of earlier and of later dialogues can be applied with the same confidence to works belonging to the same general period of their author's life and composed probably at no great distance of time from one another.

In point of fact, there is no complete agreement between the arrangements proposed by different "stylometrists," and their advocates have usually eked out the strictly philological argument by more or less dubious assumptions about the development of Plato's thought, though it is very questionable whether any real development can be traced before the *Theaetetus* and the *Parmenides*. Perhaps all that can be said with certainty is that the great outstanding dialogues, *Symposium, Phaedo, Republic* (and perhaps also *Protagoras),* in which Plato's dramatic power is at its highest, mark the culmination of this first period of literary activity. The comparative decline of dramatic power, accompanied by compensating maturity of critical acumen, is the most striking contrast between the dialogues of the second and those of the first period. A good account of the work done by the "stylometrists" is to be found in H. Raeder, *Platons philosophische Entwickelung* (1905), another in an article by C. Ritter in *Bursians Jahresbericht,* vol. 187, i (1921).

The Persons of the Dialogues. — The great initial difficulty which besets the modern student of Platonic philosophy is that created by the dramatic form of Plato's writings. Since Plato never introduces himself into his own dialogues, he is not formally committed to anything which is taught in them. The speakers who are formally bound by the utterances of the dialogues are their protagonists, Socrates, Parmenides, the Pythagorean Timaeus, and all these are real historical persons. The question thus arises, with what right do we assume that Plato means us to accept as his own the doctrines put into the mouths of these characters? Is his purpose dogmatic and didactic, or may it be that it is mainly dramatic? Are we more at liberty to hold Plato responsible for what is said by his dramatis personae than we should be to treat a poet like Browning in the same fashion?

It is tempting to evade this formidable issue in one of two mays. One is that of Grote, who held that Plato allows himself freely to develop in a dialogue any view which interests him for the moment, uithout pledging himself to its truth or considering its compatibility with other positions assumed elsewhere in his writings. Thus, according to this theory, Plato can make Socrates tolerate hedonistic utilitarianism in the *Protagoras* and denounce it in the *Gorgias,* or can assert the so-called ideal theory through the mouth of Socrates in the *Phaedo* and refute it in the character of Parmenides in the dialogue of that name, with equal gusto and without pledging himself to any view. His championships are purely dramatic, or, at most, reflect his passing mood at the moment of composition.

The more common assumption of the 19th century was that some of Plato's characters. notably Socrates and Timaeus, are "mouthpieces" through whom he inculcates tenets of his own, without concern for dramatic or historical propriety. Thus it was and often still is held that the most famous philosophical doctrines of the *Phaedo* and *Republic,* the "ideal theory." the doctrine of "recollection" and of the tripartite soul, were actually originated by Plato after the death of Socrates (to whom these speculations were supposed to be entirely unknown) and consciously fathered on the older philosopher by a mystification too glaring to deceive any one seriously. Careful study of the dialogues should satisfy us that neither of these two extreme views is tenable.

The Thought of the Earlier and Later Dialogues. — There is undeniably a real difference between the thought of the dialogues which are later than the *Theaetetus* and those which are earlier, and this difference will have to be accounted for. But there are no serious discrepancies of doctrine between the individual dialogues of the same period.

Now Plato seems to announce his own personal conviction of certain doctrines of the second group of dialogues by a striking dramatic device. In the *Sophistes* and *Politicus* the leading part is taken by an Eleatic and in the *Laws* by an Athenian who are the only anonymous, indeed almost certainly the only imaginary, personages in the whole of Plato's writings (except the two minor personages of the *Laws*, a Spartan and a Cretan, who have really nothing to do except to say "Yes," "No," in the appropriate places). It can hardly be doubted that the reason why these two characters have been left anonymous is precisely that the writer may be free to use them as "mouthpieces" for his own teaching. Plato thus takes on himself the responsibility for the logic and epistemology of the *Sophistes* and of the *Politicnrs* and for the ethics and educational and political theory of the *Politicus* and of the *Laws* in a specially marked way, and by doing so compels us to face the question how far he means the utterances of Socrates in his earlier dialogues to be taken as expressions of a philosophy of his own.

Forms. — It may be regarded as an established result of the inquiries of Henry Jackson and others that there is a definite philosophical doctrine running through the earlier dialogues which has as its main features the theory of "Forms" (the ideal theory; *see* FORM), the theory that knowledge is "recollection" and the theory of the "tripartite soul." In the dialogues of the second period these tenets, as we have learned to know them from the earlier dialogues, appear only in the mouth of Timaeus, a 5th-century Pythagorean older than Socrates; and the most important of them all, the theory of "Forms" is actually made the object of what looks like a refutation in the *Parmenides*.

The problem is to find an explanation of this puzzling fact. Are we to distinguish two philosophies, both originated by Plato after the death of Socrates, an earlier and a later? Or are we to suppose that in the main the object of the first group of Plato's dialogues is to preserve the memory of Socrates and that the philosophy expounded is in the main what it professes to be, the thought of Socrates, coloured, no doubt, unconsciously but not consciously distorted, in its passage through the mind of Plato? On the second view we should have to say that, strictly speaking, Plato had no distinctive Platonic philosophy until a late period in his life, much as we can say that, though Kant mas all through his life a prolific writer on philosophy, there was no distinctive Kantian philosophy before the *Critique of Pure Reason.* Most Platonic scholars are still unwilling to accept this interpretation of the facts, though there are weighty considerations which plead strongly for it.

Socrates and **Plato.**—It is significant that the only dialogue not earlier than the *Theaetetus* in which Socrates takes a leading part is the *Philebus*, the one member of the second group which deals exclusively with those ethical problems on which the thought of the historical Socrates had been specially concentrated. This is most naturally explained by supposing that Plato, from regard to fact, was unwilling to make Socrates the exponent of doctrines which he knew to be his own property, though it is hard to understand his misgivings if he had already for years been employing him in 'that very capacity. (If, as is most probable, *Epistle* ii is authentic, the question would be definitely settled by the sentence of the latter [314 *c]* "there is not, and never will be, a work of Plato; the works which now go by that name belong to Socrates embellished and rejuvenated.")

It is notable, too, that Aristotle apparently knew nothing of an earlier and a later version of Platonism. He attributes a definite doctrine to Plato which is quite unlike anything to be found in the first great group of dialogues, and seems to be known to him from oral communications in the Academy, though something similar to it can, by looking hard, be read between the lines in the *Philebus*. It was also the view of Neoplatonic scholars such as Proclus that the ideal theory expounded in the great earlier dialogues really originated with Socrates and that something of the same kind was also held by contemporary Pythagoreans in Italy (Proclus, *Commentarii in Parmenidem,* edited by G. Stallbaum [1839], 562, 610), and the fact that Proclus does not find it necessary to argue the point seems to show that this had been the standing tradition of the Academy. Similarly Galen, early in the 3rd century A.D., cites the definite statement of the learned Stoic Poseidonius that the doctrine of the "tripartite soul," often said in modern times to be another invention of Plato's, is as old as Pythagoras *(De Placitis Hippocratis et Platorzis, 425, 478).*

Moreover, as J. Burnet argued, it is hard to believe that any writer would introduce a far-reaching novel speculation of his own to the world in the curious fashion which Plato is supposed to have adopted in the *Phaedo,* where Socrates is made to describe the ideal theory as something quite familiar which he has for years constantly canvassed with his intimates (nearly all, if not all, of whom, were certainly living when the *Phaedo* was circulated). It is not necessary here to determine the historical question. We may be content to turn to the Platonic dialogues, carefully distinguishing the successors of the *Theaetetus* from its predecessors, and attempt a summary of their contents. The general doctrine of the first period will be described without any more or less arbitrary attempt to say how much of it may be actually Socratic. We may then consider how far this doctrine is modified in later dialogues, or in the version of Platonism presupposed by Aristotle's criticisms.

No attempt will be made here to describe the personality or temperament of Plato which is, in fact, as elusive as that of Shakespeare and for the same reason. He is often credited with a strongly "mystical" and "erotic" temperament. He does ascribe such a temperament to Socrates, but it is puerile to treat his picture of Socrates as evidence about himself, though the mistake is constantly committed.

It should therefore be noted that the "mysticism" is confined to dialogues of the first period, in which Socrates is its exponent, and that the "erotic" language in which Plato's Socrates speaks of his devotion to his young friends was also used by the Socrates of Aeschines to describe his relations with Alcibiades (fragment 4, edited by H. Krauss, 1911). There is no evidence that Plato personally ever fired the imagination of gifted boys as Socrates did. Apart from the *Epistles*, the most valuable light we possess on Plato's personality is afforded by Aristotle's description of him as a man "whom it is blasphemy in the base even to praise."

The Earlier Dialogues

In the *Republic,* the greatest of all the dialogues which precede the *Theaetetus,* there may be said to be three main strands of argument deftly combined into a consummate artistic whole, the ethical and political, the aesthetic and mystical and the metaphysical. Other major dialogues belonging to this period give special prominence to some one of these three lines of thought; the *Phaedo* to the metaphysical theme, the *Pvotagoras* and the *Gorgias* to the ethical and political. the *Symposium* and the *Phaedrus* to the aesthetic and mystical, though in none does Plato make an artificially rigid separation of any one of the great ideal interests of human life from the rest.

The shorter dialogues deal with more special problems, usually of an ethical character, and mostly conform to a common type. A problem in moral science, often that of the right definition of a virtue, is propounded, a number of tentative solutions are considered and are all found to be vitiated by difficulties which we cannot dispel; we are thus left, at the end of the conversation, aware of our discreditable ignorance of the very things it is most imperative for man to know. We have formally learned nothing but have been made alive to the worthlessness of what we had hitherto been content to take for knowledge and the need of seeking further enlightenment.

The effect of these dialogues of search is thus to put us in tune with the spirit of Socrates, who had said that the one respect in which he was wiser than other men was just his keen appreciation of his own ignorance of the most important matters. We learn the meaning of his ruling principle that the supreme business of life is to "tend!' the soul (to make it as good as possible) and his conviction that "goodness of soul" means first and foremost, *knowledge* of good and evil. The three dialogues directly concerned with the trial of Socrates have manifestly a further purpose. They are intended to explain to a puzzled public why Socrates thought it stuff of the conscience neither to withdraw from danger before trial, nor to make a conciliatory defense, nor, finally, to avail himself of the opportunity of flight after conviction. Even well-wishers such as Xenophon, as we know, were puzzled by what had seemed his wilfully defiant attitude; it was therefore a debt of honour to his memory to put the matter in the true light. In the remarks which follow, we will consider these shorter dialogues in an order adopted simply for purposes of convenience.

Hippias I and 11.—In these dialogues Socrates has as respondent the well-known polymath Hippias of Elis, whose self-complacency is sharply satirized. In the *Hippias Major* the question propounded is "What is the fine" (*kalon*)? "Fine" is a predicate by which we are constantly expressing both aesthetic and moral approval; do we really know what we mean by it? We discover that we do not, though incidentally me also learn that "fine" or "beautiful" is certainly not a synonym for either "useful" or "pleasant." *Hippias Minor* deals directly with the famous Socratic paradox that "wrong-doing is involuntary." It is commonly held that it is much worse to tell a willful untruth than to blunder into an unintentional false statement. Yet the analogy of the arts and professions seems to show that the man who errs intentionally, if there is such a person, is a better man than he who errs unintentionally. (The suggested thought, of course, is that there is no such person. The man who knows what is good will always aim at this and at nothing else,—the familiar doctrine of Socrates.)

Ion, Menexenus.— Both these are occasional works. Socrates had said that he found the poets, who as a class are commonly reckoned "wise," quite unable to explain to him how they came to say their best things, or what they meant by them. *(Apology*

22 a–c.) The *Ion* develops this thought into the theory that neither the poet, nor his interpreter the rhapsode, produces his effects "by science," that is, as a result of conscious artistry; the effect in both cases is due to a nonrational inspiration, or, as we now say. native genius. (The importance of this is that it rules out appeal to the poets as specially competent authorities on the conduct of life.)

The *Menexenus,* which professes to repeat a funeral oration learned from the famous Aspasia, is apparently meant as a satire on patriotic distortion of history. Apparently the discourses satirized are those of Pericles in Thucydides, Lysias *(Oratio* ii) and Isocrates (the *Panegyricus*). The singular anachronism by which Socrates (and Aspasia) are represented as commenting on the events of the Corinthian War down to the year 387 must be intentional, whatever its object.

Charmides, Laches, **Lysis.**—These are typical dialogues of search. The question of the *Charrnides,* which contains a particularly delightful picture of the way of Socrates with a promising lad, is what is meant by *sophrosyne,* the virtue which is shown alike in graceful and easy command of one's appetites and passions, in dutiful behaviour to parents, elders, official "superiors." in balance and sanity amid the ups and downs of fortune. We seem to be in a fair way to identify this virtue with "knowledge of self"—the self-knowledge Socrates had valued so highly—when we are confronted with an ambiguity. Self-knowledge might be taken to mean a knowledge which has knowledge itself for its object, in fact for epistemology. But it is hard to be sure that there is any such science as the knowledge of knowledge and harder still to see how such knowledge could be directive of conduct.

In the *Laches* we are concerned with valour, the soldier's virtue. Here again we are on the point of defining the virtue as knowledge of what is and what is not really to be dreaded. But this is tantamount to saying the true knowledge of evil and good, and the resultant definition "valour is knowledge of good," would identify valour with the whole goodness of man. That is, the definition is only possible if we can meet the popular objections to the Socratic thesis of the unity of virtue.

The *Lysis* examines in the same tentative way, friendship, the relation in which self-forgetting devotion most conspicuously displays itself. The crux of the problem is that after many false starts, we seem to have reached a promising result in the vien that each friend is really "a part of" the other in "soul or temper or body," and yet it is hard to reconcile this position with the facts which seem to show that "unlikeness" is a potent source of attraction. Aristotle has taken up and discussed the issues raised in the dialogue in his own treatment of the same subject (*Nicomachean Ethics,* viii–ix).

Cratylus.—The question here, one much agitated in the age of Socrates, is whether names are significant by nature or convention. Is there some special appropriateness of the sounds of names to the objects called by them, or is there no bond between the thing and its name but that of the "usage of the community"? The absurdity of attempts to get metaphysics out of etymologies is humorously exposed by shoning that the method can be used at pleasure to prove either that the "giver of names" agreed with Heraclitus that motion is the sole reality or that he held, with Parmenides. that motion is an illusion. Yet there are real analogies between "vocal gestures" and the things signified by them, which are pointed out with a good deal of insight. The main purpose of Plato, however, is to dwell on the point that language is an instrument of thought; the test of its rightness is not mere social usage, but its capacity to express true thought accurately.

Euthydemus.—The dialogue is, in large part, broad satire on "eristics" nho misapply the logic of Zeno for the purpose of entangling anyone who commits himself to any assertion in fallacies because of the ambiguity of language. (Aristotle has drawn freely upon it in his essay on fallacies, the De *Sophisticis Elenchis.)* Its more serious purpose is to contrast this futile contradiction mongering with the "protreptic" of Socrates. The lad Clinias is simply bewildered by the questions of the two professors of "eristic"; those of Socrates have the purpose of convincing him that the happiness we all desire is not guaranteed by the *possession* of the things the world accounts good, but depends on our making the right *use* of them. If we would attain happiness we must "tend" our "souls." and that means that we must acquire the "royal" science which ensures that we shall make the right use of all the gifts of mind, body and fortune, in other words, the knowledge of true and absolute good.

Gorgias.—The *Gorgias* is a greater as well as a much longer work than any of those hitherto considered. Beginning ostensibly as an inquiry into the nature and worth of rhetoric, the art of advocacy professed by Gorgias, it develops into a plea of sustained eloquence and logical power for absolute right, as against expediency, as the sovereign rule of life private and public, and ends with an imaginative picture, on Orphic lines, of the eternal destinies of the righteous and of the unrighteous soul. Literature has no more impressive presentation of the claim of conscience to unqualified obedience and the impossibility of divorcing the politically from the morally right.

Gorgias holds that "rhetoric" is an "art." the application of knowledge to practice, and the queen of all "arts," since it gives its possessor the object of man's highest ambition, power to enforce his will on society. The statesman, who is the man of men, is just a consummate advocate speaking from a brief. If he is clever enough he will, though a layman, carry the day with an audience of laymen, even against the expert specialist. To his audience he will seem, though he is not, the superior of the real expert Socrates declares that "rhetoric" is not an "art," a matter of native principles, but a mere "empiric knack" of humouring the prejudices and pleasing the tastes of an audience. It is a subspecies of parasitism.

There are two genuine arts conducive to the health of the body, those of the trainer and of the physician; each has its parasitic counterfeit, the one in the profession of the beautifier, the other in that of the confectioner. So there are two arts conducive to health of soul, those of the legislator, who lays down the rule of morally sane life, and of the judge, who corrects moral disorders. The sophist counterfeits the first, as the rhetorician the second, by taking the pleasant instead of the good as his standard The rhetorician is thus not the wise physician of the body politic but its toady.

This severe judgment is disputed by Polus, the ardent admirer of Gorgias, on the ground that the successful rhetorician is virtually the autocrat of the community. every man's life and property are at his mercy. To be such an autocrat is the summit of human happiness; even if, like Archelaus of Macedonia, the aspirant only reaches the position by a series of shocking crimes, he is the most enviable of mankind. because he is above law and can do whatever he likes.

Socrates rejects this view. The autocrat always does "as he pleases," and for that reason never does "what he wishes"; as all mankind, he wishes for true happiness or good. but no act which is immoral ("unjust") ever leads to happiness. To suffer a wrong is an evil, but to inflict one is much worse. And if a man has committed a wrong, it is much worse for him to go unpunished than to be cured of his moral malady by the sharp but wholesome medicine of punishment. If rhetoric is of real service to men, it should be most of all serviceable to an offender. If he knew his own interest, he would employ all his powers of persuasion to move the authorities to inflict the penalties for which the state of his soul calls. Polus is unable to meet this reasoning. because he had at least conceded to current morality that it is more disgraceful, though not more evil. to inflict wrong than to suffer it.

This is denied by Callicles of Xcharnae, an otherwise unknown politician, who proceeds recklessly to develop the doctrine of the "will to power." It may be a convention of the herd that unscrupulous aggression is discreditable and wrong, but "nature's convention" (a phrase which appears here for the first time in literature) is that the strong are justified in using their strength as they please, while the weak "go to the wall." Callicles and Socrates thus appear as champions of two contrasted moralities of private and public life. Callicles stands for self-assertion in ethics and aggressive imperialism in politics. Socrates opposes both. In his judgment the creators of the imperialistic Athenian democracy were no true statesmen, because they were content to give Athens a navy and a commerce without creating a morally sound national character. They may have been capable domestic servants of the democracy for whose tastes they catered; they were not its physicians. The one true statesman of the past was the just Aristides; in the present, Socrates himself is the one man who shows a statesmanlike mind, though it is perfectly true that he might at any moment have to pay with his life for refusing to call that good which pleases the public fancy. It is not true, as Callicles supposes it to be, that the secret of happiness is to have strong and vehement passions and be able to gratify them to the full. That would be a condition like that of the fabled sinners who are punished in Hades by being set to spend eternity in filling leaking pitchers. The truly happy life is that of measure in which the gratification of desire is strictly regulated by regard for justice and *sophrosyne*. If we may believe the Orphic doctrine of judgment to come, the votary of passion and injustice has a heavy reckoning to await hereafter.

Meno.—The *Meno* is nominally concerned with the question of what virtue is and whether it can be taught, but it is further interesting for two reasons. It states clearly the doctrine, which me have not met so far, that knowledge is "recollection"; it also introduces as a character the democratic politician Anytus, the main author of the prosecution of Socrates. It seems plain that Plato wishes to indicate his opinion that it was Socrates' severe criticism of the great figures of the history of Athenian democracy which led to the prosecution.

Can virtue be taught or learned (as must be the case, if the professional sophists can really do what they profess)? That depends on what virtue is. We are on the way to define it as "ability to secure good things by honest means," when we reflect that honesty itself is a "good thing," and the definition consequently is circular. This reminds us of the current dilemma that all such inquiries are futile because it is idle to inquire into what you already know, useless to inquire into what you do not know (since you could not recognize the unknown, even if you found it). This difficulty would vanish if it were true that the soul is immortal and has long ago learned all truth, so that it needs now only to be reminded by sense-experiences of truths which it once knew and has forgotten. This (Orphic) doctrine seems to be supported by the experience that a lad who has never studied geometry can be brought to recognize mathematical truths by merely showing him a diagram and asking him appropriate questions about it. He produces the right answer "out of himself." (The point thus is the presence of an a priori element in mathematical truth.)

In any case, we may say that if "virtue" is knowledge, it can be taught; if it is not knowledge, it cannot. But is it knowledge? If it is, one would suppose that there must be professional teachers of it. But Anytus assures us vehemently that the sophists, who claim to be such professionals, are mischievous impostors, and we can be sure that the ordinary decent citizen cannot "teach virtue," as Anytus maintains, since the "best men" of the democracy, Themistocles and the rest. have been unable to teach it to their own sons. Perhaps, then, we must say that the "best men" of Athens have no genuine knowledge of good; their successes have been due not to knowledge, but to mere correct opinions. Still, for practical purposes a correct opinion will serve as well as knowledge. The trouble is that you cannot depend on its permanency unless you fasten it down by thinking out the reason why of it. Then it becomes knonledge. If a man should arise who could actually teach statesmanship to others, he would be one who really *knew* what good is; the virtue of such a scientific statesman would be to that of other men as substance is to shadow.

Protagoras. — This finely dramatic dialogue gives us the most complete presentation to be found in Plato of the main principles of the Socratic morality and is the direct source of Aristotle's statements about the teaching of Socrates in the *Nicomachean Ethics*.

Socrates meets, in the house of Callias, the eminent sophist Protagoras, who is attractively drawn and represented as a great admirer of the younger man's ability. Protagoras explains that his profession is the "teaching of goodness," and that by "goodness" he means the art of making a success of one's own life, of one's household and of one's city. (Thus he teaches the conduct of life. private and public. and has done so for years with success.) Socrates urges that there are two considerations which make it look doubtful whether this art can be taught. The Athenians have a high reputation for intelligence, but it is notorious that their assembly requires no evidence of expert knowledge in a speaker who discusses the morality of a proposed course of action.

Also the eminent democratic statesmen have never taught their own "goodness" to their sons. Public opinion and the practice of the eminent few alike suggest that the conduct of life is not teachable. Protagoras, to be sure, thinks that the absence of special teachers only proves that every citizen of a civilized city can, in his degree, act as teacher, exactly as he can teach his children his native language or his trade. Goodness depends on the sense of right and conscience, and the whole of life in a civilized society is a process of education in these. His exposition at once raises the problem of the unity of virtue. Are the various commonly recognized virtues really different, so that a man may be strong in one but weak in another? Protagoras is at first inclined to say that they are, but on reconsideration is ready to identify all of them but one with wisdom or sound judgment.

An exception must be made for courage, a virtue which is popularly regarded as having something conspicuously nonrational about it. The dialogue culminates in an argument by which Socrates attempts to show that there is no need to make this exception. The general public, the party which insists so much on the nonrational character of courage, mould be ready to accept the identification of the good and the pleasant and to grant that the goodness of courage means that by facing pain and danger one escapes worse pain or danger. On their own theory, then, courage and the rest of virtue can be reduced to prudent computation of pleasures and of pains. The humour of the situation is that Socrates and Protagoras have thus changed places. Socrates, who had raised a difficulty about the teachability of virtue, is left satisfied that virtue must be knowledge; Protagoras, who claimed to be able to teach it, ends by declaring that, whatever virtue may be. it cannot be knowledge. It is important to observe that the dialogue does not teach hedonism. The equation *good = pleasant* is advanced only as one which would be accepted by the mass of men, and should forbid them to find a paradox in the identification of virtue with knowledge; it is expressly repudiated by Protagoras as unworthy of a man of high character.

All that Socrates asserts is that virtue is knowledge and wrongdoing consequently involuntary. There is no disagreement in moral principle between the *Protagoras* and the *Phaedo* or the *Gorgias*. If the mass of men are ready to accept the hedonist formula, that is because they are votaries of the body-loving life; this is why we are told in the *Phaedo* that "popular" virtue is illusory. The true explanation of Socrates' doubts is that. though he holds that true virtue, being knowledge, is teachable, he does not believe that what Protagoras is trying to teach is true virtue. Success depends on personal tact and tact cannot be learned from an instructor.

Euthyphro, Apology, **Crito.**—The main purpose of these three works, which deal with the bearing of Socrates before, during and after his trial, is to obviate possible serious misunderstandings of his position and motives; the theme of all three may be said to be the true meaning and importance of care or tending of the soul.

The problem of the *Euthyphro* is what is religion. The respondent Euthyphron is certainly meant to be a kind of Orphic sectary, not, as has been fancied, a representative of ordinary Athenian belief and practice. Socrates had associated with such men and was known to hold unusual beliefs about the soul; hence it was important to make it plain that he was something different from a fanatic. The dialogue. interesting also from its well-developed logical terminology, enables Socrates to repudiate immoral mythology and to reject the conception of "religious duty" as fulfilment of purely arbitrary commands. Its central thought, which, honever, is not formally asserted as a conclusion, is that the service of God which in religion means co-operation with God and under God in the production of a noble work, the nature of which is not further defined, though it is sufficiently clear that the "work" meant is the "tending of the soul."

Consideration of the Apology and Crito in detail belongs rather to the study of Socrates (*q.v.*) than to that of Plato. Of the Apology we must be content to say here that the real defense of Socrates is contained in the pages which explain that the mainspring of his life has been his conviction that he has a mission from God to spend his life in "philosophy," the endeavour to "make his own soul as good as possible," and to incite mankind to do the same; to this mission it is his duty to be strictly faithful, even if faithfulness means condemnation as a traitor by the democracy. The Apology thus depicts Socrates as carrying out in his own practice the ethical program of the Gorgias. The actual accusation is treated with contempt and satirical humour. (See SOCRATES.)

The point of the Crito, though simple, is often missed. Was Socrates wantonly throwing away a valuable life by refusing to escape from prison? Why did he make this refusal? Because, though the conviction was materially iniquitous, it was the verdict of a legitimate court, which could not be disregarded without real disloyalty. Socrates has been wronged not by the law, but by politicians who have abused the law. If he disregarded the conviction, he would be directly doing a wrong against the whole social system.

Foundation of Plato's Doctrine.—In the works so far considered we have the foundation of a moral and political doctrine based on Socratic principles, from which Plato never departed. The main underlying thought is that the great concern of man, a concern not limited to this earthly life, is the development of a rational moral personality (the tending of the soul). Our felicity depends wholly on our success in this task (to use J. Butler's language, on "our conduct," not on "our condition"). And this success, again, depends on rational insight into the true scale of good. It is not because they do not desire it that men fail to attain felicity: on the contrary, no man ever really desires anything else. The reason why men forfeit felicity is that they mistake apparent good for real, the conditionally for the absolutely good. If a man ever knew with assurance what absolute good is, he would in practice never pursue anything else. It is in this sense that "all virtue is knowledge" and that "all wrong-doing is involuntary" (*i.e.,* consists in the pursuit of what is falsely supposed to be good).

"Popular morality" is confused in theory and unreliable in practice because it does not rest on any assured insight into absolute good; "philosophic morality," just because it does rest on such certain insight, is a morality of absolute and unconditional obedience to conscience, such as Socrates had shown. Since the task of the statesman is simply the task of tending the soul extended to the national soul as its object, the philosophical moralist is also the only true statesman. True statesmanship means the promotion of national character as the one thing which matters, and is therefore simply the application, on the grand scale, of the principles of absolute morality; what falls short of this is opportunism masquerading as statesmanship.

These convictions clearly imply a far-reaching metaphysic as their foundation and justification. The principles of this metaphysic, though they are frequently hinted at in passages of dialogues already reviewed, are put before us more explicitly in those which we have now to consider; in connection with them we shall also observe an explicit theory of knowledge and scientific method.

Phaedo.—The Phaedo is often treated as though its object were to provide a demonstration of the immortality of the soul. It does not really profess to do this. The object is to justify faith in immortality as a rational faith by showing that it follows naturally from a fundamental metaphysical doctrine (the ideal theory or doctrine of forms), which seems to afford a rational clue to the structure of the universe, though it is expressly said at the end of the whole discussion that this doctrine itself still requires further examination. At the same time, it is made fully clear that the writer accepts this metaphysical doctrine, with the reservation just mentioned, and is passionately sincere in the faith in "personal immortality" which he brings into connection with it. To be strictly accurate, indeed, we ought to say that the faith to be defended goes beyond belief in immortality. What is being maintained is the divinity of the soul; its survival of death is a consequence of this inherent divinity.

The argument is briefly as follows: A true philosopher may naturally look forward to death without dismay. For death is the separation of soul from body, and the philosopher's whole life has been spent in trying to liberate the soul from dependence on her body. In life, the body is always interfering with the soul's activity. Its appetites and passion interrupt our pursuit of wisdom and goodness; its infirmities are perpetually hindering our thinking. Even in our scientific work, we only attain exact and certain truth in proportion as we detach ourselves from reliance on sense-perception and learn to depend on pure thinking.

Death, then, only completes a liberation which the philosopher has been "rehearsing" all through life—if, that is, the soul continues to exist after death, as there are reasons for thinking. For:

1. There is a belief that the soul has a succession of many lives and that, when it is born into this world, it has come back from another; and there are two considerations to be urged on behalf of this belief. In the first place, the processes of nature in general are cyclical: the hot becomes cold, the cold hot; the waking go to sleep, the sleeping wake. It is reasonable to suppose that this applies to the case of dying and coming to life, so that the dead return to life, just as the living die. If this were not so, if the process of dying were not reversible, life would ultimately vanish from the universe. Secondly, we may appeal to the doctrine that what we call "learning" is really "recollection," being reminded of something. This certainly seems to be the case, for in all our science we are perpetually being put in mind of precise ideal standards, mathematical or moral, with mhich sense or experience never presents us. We must therefore have become acquainted with them before we were confined to our bodies. and therefore must have existed before our birth. These two considerations together would prove what we want to prove, the soul's survival of death, though our dread of the dark makes us demand a more convincing argument.

2. We may consider the antithesis between the divine and eternal and the temporal and mutable, which runs through the universe. The body is certainly temporal and mutable. The soul is relatively immutable, like the fixed ideal standards or norms which she contemplates in her scientific thinking, Her thought is concerned with eternal objects and she herself has the likeness of that which she contemplates. If, then, some constituents of the body are nearly indestructible how much more should one expect the divine element in us, the soul. to resist destruction, as the traditions about rebirth assert that it does.

There are two grave "scientific" difficulties still to face. It may be argued: (1) that the soul is an epiphenomenon, the tune (*harmonia*) given out by the body, and if so, its superior divinity will not protect it from vanishing when the instrument which makes the music is broken; (2) that though the soul actually makes its own body, and perhaps can make a long succession of bodies, it cannot do so without expending energy, so that a time will come when it can no longer make a fresh body, and then it will itself disappear. We must not be driven into misology, antipathy to science, by this apparent clash betneen science and a faith to which we are attached.

The answer to (1) is that there are good souls and bad ones, and the good soul is more in tune than the bad one. But that which can be more or less in tune is clearly not itself a tune. And if the soul were the tune resulting from the functioning of the body, its character at any moment mould be a resultant of the condition of the body. How then could we have the experience, characteristic of the moral life, of the conflict betneen the soul with its aspirations and the body with its carnalities? The answer to (2) can only be given as part of a whole theory of the causes of "coming into being and passing out of being." Socrates had been led, early in life, to frame a tentative theory of the matter in consequence of his dissatisfaction with the chaotic state of physical speculation and in particular with the failure of Anaxagoras to make any satisfactory use of his apparently teleological principle that "mind is the cause of all order and structure." He fell back on the method of "hypothesis."

What distinguishes this method from all others is that it begins by making an undemonstrated postulate *(hypothesis)*. It then proceeds from this point to consider the truth or falsehood of the consequences which follow logically, from the initial postulate; the question of the truth of the postulate is, for the present, left unasked. Socrates' own fundamental unproved postulate has always been that usually, but loosely, called the theory of ideas. The postulate is that there really is a single determinate and immutable something answering to every significant general term and apprehended only by pure thought. The sensible things of which we predicate general terms temporarily partake in or communicate with the idea or form *(idea, eidos)*. When we say that a thing becomes beautiful, what we mean is that the form "beauty" begins to be present to that thing, the thing begins to partake of the form. When we say that a thing ceases to be beautiful, we mean that this relation of presence, participation, communication is dissolved. This is the true account of the cause of "coming into and passing out of being," and if we accept it, we may proceed to our final argument for immortality.

3. There are forms which are mutually incompatible, such as warmth and cold. Heat is never cool, and cold is never warm. But there are also certain sensible things of which it is an essential character to partake of a given form. Such things will never admit an incompatible form. Thus it is an essential character of snow to partake of cold. It mill never, therefore, partake of the form heat. Similarly it is an essential character of a soul to be alive, to partake of the form life It refuses to partake of the form death. At the approach of death. the soul must either retire or be annihilated (the metaphors are military). What we have said of its divinity forbids us to think that it is annihilated; we must therefore assume that it retires to some other region. The proof of immortality is thus hypothetical; it is shown to be involved as a consequence by the doctrine of forms. This doctrine has been stated as a fundamental unproved postulate and it is admitted that it demands fuller consideration.

But our inquiry has at least satisfied us that the hope of immortality is a reasonable one. (To distrust it would be to call the foundation of our whole philosophy into question.) The discourse ends with an imaginative cosmological myth depicting the future of the just and the unjust, respectively.

In this statement of the theory of forms we may note the following points: (1) The doctrine is a piece of realist metaphysics in so far as it is assumed that a universally predicated general term denotes or stands for an individual reality, apprehensible by thought, though not by sense; (2) there are a plurality of such forms, standing in various logical relations with one another (whether they constitute a system with a definite structure the *Phaedo* does not tell us); (3) they are at once the objects known in all genuine science and the formal causes of all the temporal processes of the sensible world; (4) the sensible things which have the same names as forms are said to owe their character to their participation of the forms, or, equivalently, to the presence or communication of the forms to them. though the precise character of this relation of participation is admitted to need further explanation (so far as the language of the *Phaedo* goes, a sensible thing would seem to be thought of as a temporary complex or meeting place of universal characters and as nothing more).

Symposium, **Phaedrus.**—It is by no means clear that these two dialogues are closely connected in point of date, but they may be considered together as both presenting the forms in a special light, as objects of mystical contemplation and excitant of mystical emotion.

The argument of the *Symposium* cannot be reproduced here as a a-hole. The immediate object of the dialogue, which professes to record the discourses made in eulogy of Eros by a group of eminent speakers at a banquet in honour of the tragic poet Agathon, in the year 416–415, is to find the highest manifestation of the love which controls the world in the mystic aspiration after union with the eternal and supercosmic beauty; to depict Socrates as the type of the aspirant who has reached the goal of union; and to set in sharp opposition to him the figure of Alcibiades, who has sold his spiritual birthright for the pleasures and ambitions of the world. The centre of philosophical interest lies in the discourse of Socrates, which he professes to have learned a quarter of a century ago from the priestess Diotima of Mantinea.

The mairi argument may be summarized thus: Eros, desirous love, in all its forms. is a reaching out of the soul to a good to which it aspires but has not yet in possession. The desirous soul is not yet in fruition of good. It is on the way to fruition, just as the "philosopher" is not yet in possession of wisdom but is reaching out after it. The object which awakens this desirous love in all its forms is beauty, and beauty is eternal. In its crudest form, love for a beautiful person is really a passion to beget offspring by that person and so to attain, by the perpetuation of one's stock, the *succedaneum* for immortality which is all the body can achieve. A more spiritual form of the same craving for eternity is the aspiration to win immortal fame by combining with a kindred soul to give birth to sound institutions and rules of life. Still more spiritual is the endeavour, in association with chosen minds, to enrich philosophy and science with noble discourses and thoughts.

But the goal still lies far ahead. When a man has followed the pilgrimage so far, he suddenly descries a supreme beauty that is the cause and source of all the beauties discerned by him so far. The true achievement of immortality is finally effected only by union with this. The philosopher's path thus culminates in a supreme beatific vision. It is clear that the object of this vision, the beauty sole and eternal of the dialogue, means what the *Republic* calls "the good" or "form of good" which by its presence actually causes the goodness of everything else to which the name of good can be given. The forms are thus thought of as a hierarchy with a supreme form at their head, though no attempt is made at a rational theory of the way in which the supreme form unites the rest into the system.

The immediate subject of the *Phaedrus* is the principles of rhetoric or, as we should say, prose composition. The *Gorgias* had told us that rhetoric as commonly practised is not a matter of rational principles at all, but a mere empirical trick of adapting one's tone to the prejudices of an audience. The *Phaedrus* aims at showing hon a really scientific rhetoric might be built on the double foundation of logical method and scientific study of human passions. Plato contrives, however, by making a real or supposed "erotic" composition of Lysias the starting point of his criticisms, to unite nith this topic a discussion of the psychology of love. and this, as in the *Symposium,* leads him to speak of the forms as the objects of transcendental emotion. The soul is immortal, because it has within itself a native source of spontaneous movement. (This is the argument for immortality to which Plato trusts in the *Laws* It is not specially mentioned in the *Phaedo,* but this can hardly mean that Plato had not yet discovered it, since it is, in fact, taken from Alcmaeon of Crotona. a medical man of the beginning of the 5th century) In its disembodied state it shared the life of the gods and could enjoy the direct contemplation of unbodied reality — that is. of the forms. It has suffered an antenatal fall into an embodied condition in which it is blind to everything nhich does not come in at the avenues of sense.

Now our senses only suggest few and faint images of such forms as justice and temperance, but they can suggest beauty in a much more impressive and startling way. To fall in love is to come under the influence of such sudden and arresting suggestions of beauty; the unreason and madness of the lover mean that he is being awakened to realities which other men ignore. The wings of his soul are beginning to grow again, and his experience, rightly used, will be the first step in the soul's return to its high estate. This section of the *Phaedrus* is the *locus classicus* in Plato for the forms as objects of mystical contemplation.

Republic. — The philosophy presupposed in all these dialogues receives its fullest exposition in the *Republic.* Here the immediate problem is strictly ethical. What is justice? Can it be shown that justice is always a boon, injustice a curse. to its possessor, apart from all consideration of consequences in this life or another? That is, is there a rational principle at the root of moral distinctions, and does the principle carry with itself its own intrinsic and indefeasible authority?

Plato's answer is that there is such a principle; each of us, in virtue of his special endowments and aptitudes, has a specific work or vocation; there is some special contribution which he, and no other, can make most effectively to the life of a rational society. Morality, justice, is to discharge that vocation to the height and with a single mind. To live thus is to be in spiritual health; to live otherwise is to be spiritually diseased. The obligation is thus intrinsic and absolute. This position has to be made good against the incoherencies of a morality of uncriticized traditional maxims, as well as against the inmoralism of advanced thought (represented by Thrasymachus in book i, expounded more intelligently by Glaucon in book ii).

This leads us to consider what would be the general type of life in a society where the principle of justice had power as well as manifest authority, and how it might acquire that power. Hence the need for a sketch (books ii–iii) of the institutions of the reformed society, and particularly of its moral and religious education. We have next to satisfy ourselves that the principles which regulate the public life of the morally healthy society are also recognizably the principles of the great virtues of private life. For this purpose, we need a psychology of voluntary action which is provided (book iv) by the doctrine of the tripartite soul. This is not, indeed, a scientific psychology, but proves adequate to describe the moral life of the ordinary good citizen of such a society as we have conceived. The foundation of all this moral excellence is thus laid in absolute loyalty to a sound moral tradition enforced by education.

To ensure that the tradition shall be thoroughly sound, we must stipulate that the authorities who create it do not themselves depend on tradition for their convictions about good and evil; they must not opine, but know, by personal insight. The statesmen at the head of the community must be "philosophers" as well as kings (book vi).

But the vision of "the good" will only dawn on them if they have been prepared for it by an intellectual discipline in hard thinking which leads them through the curriculum of the exact sciences to the critical study of the metaphysical principles involved in science (book vii). The central books of the Republic thus present us with an outline of metaphysics and a philosophy of the sciences. We now turn back to consider the various stages of degeneration through which national and personal character pass when the true moral ideal is allowed to fall more and more completely out of view. As we pass them in review, we are increasingly confirmed in our conviction that, in respect of happiness, the life of regard for right is immeasurably superior to that of sating one's cupidities or gratifying one's personal ambitions (books viii and ix), and this conclusion is finally clinched (book x) by reaffirmation of the immortality of the soul. Since the soul is immortal, the issue which hangs upon our choice to live well or ill is one of infinite moment.

The ethical scheme of the Republic, like that of the Gorgias and Phaedo, is dominated by the conception of the "three lives," ascribed by Heraclides Ponticus to Pythagoras. The "lives" are those of the philosopher, of the man of action and of the votary of enjoyment. The end of the first is wisdom, of the second, distinction, of the third, the gratification of appetite. Distinction is a worthier end than mere satisfaction of appetite; the supremely worthy end is wisdom. In a well-lived life, then, the attainment of wisdom will be the paramount end, and ambition and appetite will be allowed only such gratification as is compatible with loyalty to the pursuit of that paramount end. The psychological foundation of this doctrine is the theory of the tripartite soul, expounded fully in book iv. Analysis of familiar experience reveals three elements or active principles within us: (1) considered rational judgment of good; (2) a multitude of clamant appetites for particular gratifications, which may be in violent conflict with our own considered judgment of good; (3) a factor of spirit higher ideal emotion, which manifests itself as resentment against both the infringement of our just rights by others and the rebellion of our own appetites against our judgment.

The same distinctions reappear in the structure of society. A society naturally falls into three divisions: the statesmen, who direct the public life; the general civilian population, who carry on the business of providing for material needs; and the executive force (army and police), whose function is, in a rightly ordered society, to give effect to the counsels of the statesmen by repressing attacks from without and rebellion from within.

These three orders are thus respectively, the judgment, the appetitive element and the spirited element in the national soul. On this basis, we can proceed to work out an ethical and political theory. In ethics we can define the great types of goodness, the quadrilateral, later known as the cardinal virtues. Wisdom is the excellence of the thinking part, clear and assured knowledge of the good; courage, the fighting man's virtue, is the excellence of the spirited part, unswerving loyalty, unshaken by pain, by danger, by the seductions of pleasure, to the rule of life laid down by judgment; temperance, the special excellence of the appetitive part, is the contented acquiescence of the nonrational elements in the soul in the plan of life prescribed by judgment; justice is just the state in which each of the elements is vigorously executing its own function and confining itself within the limits of that function. In the rightly ordered society, the national wisdom has the statesmen as its organ, the national courage the executive force; the national temperance is shown in the loyal contentment of each class in the community with its prescribed place and its duties.

Such a society is a true aristocracy, or rule of the best. Timocracy, the military state, in the better sense of that phrase, arises when the mere man of action, only competent to fill the part of a good soldier, takes the place which rightly belongs to the thinker as directing statesman. Oligarchy (*e.g.*, the dominance of merchant princes, plutocracy) is a further deviation from the ideal, which arises when political power is bestowed on property as such. A still worse system is democracy, in which no attempt is made to connect political power with any special qualifications. Worst of all is tyranny, exercise of irresponsible po er by the positively disqualified, the man of criminal will. The psychological scheme on which this construction is based is not given by Plato as a piece of strict science. We are carefully warned that exact truth is not to be reached by such an analysis of prima facie facts of social life (435 d) and reminded later on that this apparent triplicity of the soul may prove to be only a temporary consequence of its conjunction with the body (611 b). The tripartite psychology, it is meant, enables us to give an account of the moral life, as it actually appears in a good citizen, which will fairly describe the facts. It is good popular psychology, useful for the moralist, but it is no more.

Hence it is improbable that the analysis originated with Plato himself. More probably it was, as the Stoic Poseidonius asserted, a piece of earlier Pythagorean doctrine, as is also suggested by the constant recurrence, throughout the section of the Republic in which the analysis is offered, of analogies from the specially Pythagorean science of harmonics; and by the fact that the same doctrine is taught by the Pythagorean speaker in the *Timaeus*. Plato has, however, worked the theory into his ethics so completely that through him it has actually become a part of the psychology of Thomism, where it has to be squared, not quite satisfactorily, with the radically divergent psychological scheme of Aristotle.

In point of fact, the tripartite schema proves inadequate in the Republic itself when we advance in book vi to the consideration of the moral life of the philosopher-king, whose virtue is founded on a personal knowledge of good. A higher level of moral goodness is demanded of him than of other citizens even of the ideal state; his courage, for example, is declared to be no mere loyalty to right opinions inculcated by early education, but a high serenity arising from the knowledge of the relative insignificance of a brief individual life in the great universe which lies open to his contemplation. This has an important bearing on the teaching of the Republic about the unity of virtue.

In the ideal state itself, virtue does not appear as a complete unity. The leading types of moral excellence receive their several definitions. It is recognized that a special demand may be made on a particular section of the society in respect of a particular virtue of which it is, so to say, the public organ, as the fighting force is of the valour of the whole society. This is because, even in the ideal state, the moral convictions of citizens, other than the men of superlative intelligence and character who become kings, are not supposed to arise from personal insight. They rest on opinions implanted by education and are thus taken on trust. The good civilian or soldier, after all, is not living by a knowledge which is his own. But the rulers, by whose knowledge the rest of the community lives, must not. of course, themselves take their convictions on trust. They must know with a personal knowledge. The foundation of their virtue must be insight into a system of absolute values embodied in the very structure of the universe. In virtue of this deeper foundation the virtues in them are. so to say, transubstantiated and can no longer be distinguished from one another. They will fuse in knowledge of the good, as, in the Christian saints, they are fused in knowledge and love of God. It is in this form that the Socratic doctrine, "all virtue is one thing, knowledge" reappears in the *Republic* as the foundation of a society in which mankind has at last "escaped from its wretchedness," because knowledge rules.

In the *Republic,* as in the *Phaedo,* the forms appear in the double character of objects of all genuine science and formal causes of the world of events and processes. It is expressly denied that there can be knowledge, in the proper sense of the word, of the temporal and mutable. In the scheme laid down for the intellectual training of the philosophic rulers, ten years, from the age of 20 to that of 30, are assigned for systematic study of the exact sciences in the order: arithmetic, plane geometry, solid geometry, astronomy and harmonics. Special stress is laid on the points that the object of these studies is not practical applications but the familiarizing of the mind with relations between terms which can only be apprehended by thought. and that diagrams and models are to be treated merely as incidental aids to imagination. Five years are then further to be given to the still severer study which Plato calls dialectic, a study which avails itself of no sensible aids to imagination. It proceeds "by means of forms, through forms, to forms" (511 b). It is, in fact, what we should call a critical metaphysic of the sciences. It examines the *hypotheses* or unproved postulates, of the various sciences, and its object is to destroy their character as unproved ultimate postulates (533 *c*) by discovering some still more ultimate really self-evident principle (511 *b*) from which they follow as consequences.

There can be no doubt that this most ultimate principle which is more than a postulate means the good or form of good which is said to be the source at once of the reality and the knowability of all that is real and knowable. though it is itself neither knowledge nor being, but transcendent of both (509 *b*). On the methodological side the *Republic* thus completes the teaching of the *Phaedo* by providing the answer to the question then left open. when a postulate may be regarded as finally established. It may be so regarded when it is seen to follow itself from the good, which is the principle at once of existence and of value.

Socrates is made to confess (506 *d-e)* that he can give no positive account of this supreme metaphysical principle; he can only indicate its nature by an analogy. It is to the whole system of forms what the sun is to the system of visible things, the source at once of their existence and of the light by which they are apprehended. The good is thus thought of, to use scholastic terminology, as a transcendent reality which can be apprehended but never fully comprehended. The comparison with the sun and the free employment of the metaphor of vision indicate that the thought of the *Republic* is here the same as that of the *Symposium:* the good is no other than the supreme beauty which was there said to dawn suddenly upon the pilgrim of love as he draws near to the goal of the journey. R. L. Nettleship rightly says that it holds the place taken in later philosophies by God, when God is thought of as the "Light of the world." But it would be deforming Plato's thought to call the good of the *Republic* God. The *Republic* is permeated by religious faith, but theism as a principle of metaphysical explanation only makes its appearance in Plato's latest dialogues, and there as the solution of a problem which can hardly be said to have been adequately faced in the dialogues so far considered.

How the good gives systematic structure to the plurality of forms. the *Republic* does not tell us.

Development of the Doctrine of Forms.—So far we have been presented with a body of thought nhich has remained recognizably the same without serious modification throughout its various expositions. When me come to the two works which there is reason to regard as directly preluding to the dialogues of Plato's old age, the *Parmenides* and *Tkeaetetus,* we are struck by a remarkable difference of tone. With Plato, as with Kant, the middle years of life were clearly a period of fruitful critical reconstruction. There is an obvious motive for each reconstruction suggested by the *Phardo* and *Republic* themselves.

The theory there expounded does not allow enough reality to the sensible world. It is quite false to say that even the *Phaedo* teaches an absolute dualism of two disconnected worlds, a realm of genuine being which never appears and a realm of sensible appearances which are merely unreal. What is true is that both *Phaedo* and *Republic* leave us with an unsolved problem. They tell us that a sensible thing is a complex or meeting place of a plurality of forms. What else, or what more, it is they do not tell us. And yet it is clear that a thing is not simply a bundle of universal predicates.

Or, to put the point rather differently, according to the *Phaedo* a thing becomes for a while beautiful because beauty "becomes present to it." But why does beauty become present to this particular thing at just this particular moment? Clearly the relation between a thing and a form which has been called participation needs further elucidation. Again the simple epistemological formula that knowledge is confined to forms and their relations, while me can only have shifting opinions about temporal facts does less than justice to our scientific knowledge of the natural world; truths of fact have not yet come by their rights. Finally, if the forms constitute a rationally ordered system, there must be definite principles of interrelation between forms themselves as well as between forms and sensible things and these principles demand investigation. (If the good is what the *Republic* says it is, not only will things "participate" in forms; forms also will "participate" in it.) Here are internal motives for active re-examination of the whole system.

It is clear that there was also an external motive. The *Parmenides,* the *Theaetetus* and the *Sophistes* all reveal a special interest in the Eleatic philosophy, and the first and third show an anxiety on Plato's part to maintain that, in spite of important divergences, he, and not the professed Eleatics, is the true spiritual heir of Parmenides. This is easily explained when we remember that Plato was personally a friend of the chief representative of Eleaticism among the Socratic circle. Eucleides of Megara. while Polyxenus of Megara, an associate of Eucleides, was a hostile critic of the doctrine of participation. The doctrine of Eucleides, like that of Parmenides was that sensible appearances are illusions with no reality at all. Against criticism from this quarter, it mould be necessary for Plato to show that the *Phaedo* itself does not allow too much reality to the sensible; the attempt to prove this point would inevitably show that it had conceded too little. Continued reflection on the same problem of the worth of propositions about sensible fact leads straight to the discussion of the meaning of the copula. and the significance of denial, which is the subject of the *Sophistes.*

Parmenides.—Formally the dialogue conducts to an impasse. In its first half the youthful Socrates expounds the doctrine of the participation of things in forms to the Eleatic philosophers Parmenides and Zeno as the solution of the problem of the one and the many. Parmenides raises what appear to be insoluble objections to the conception of participation, though he admits that dialectic would be impossible if the existence of forms were denied: he hints that the helplessness of Socrates under his criticism arises from insufficient training in logic.

In the second and longer half, Parmenides gives an example of the logical training he recommends. He takes for examination his onn thesis, the one is. and constructs an elaborate set of antinomies after the fashion of Zeno, apparently proving that whether this thesis be affirmed or denied, in either case we are compelled either to affirm simultaneously or to deny simultaneously a series of contradictory predicates. alike of the one and of the many. The conclusion is patently ironical, and we are left to divine the author's purpose, if we can.

The objections to participation, which is formulated precisely as in the Pizaedo, are directed not against the existence of forms, but against the possibility that sensible things should participate in them. From the point of view of this criticism Socrates' error is that he attributes some sort of secondary reality to the sensible. The main arguments are two. First, the doctrine does not really reconcile unity with plurality, since it leads to a perpetual regress. It says that the many things which have a common predicate participate in or imitate a single form. But the form itself also admits of the common predicate, and there must therefore be a second form. participated or imitated alike by the sensible things and the first form, and so on endlessly. We could not escape by the suggestion that the form exists only in our minds, since that would mean that a form is a thought, and it would follow that things are made of thoughts. But if so, either everything thinks, or there are thoughts which do not think, and both alternatives are absurd. Secondly, a graver difficulty is that if there are two realms, a realm of forms artd a realm of sensible things, the relations between forms must belong to the realm of forms, those between sensible things to the realm of things. We ourselves belong to the second. and therefore all our knowledge belongs to it too; we know nothing of the true realities, the forms: if anyone knows them, it is God, but God's knowledge, being knowledge of realities, will not extend to our world, the sensible. The purpose of the objections is thus to suggest that the manifold of sense has not even a derivative reality; it is mere illusion.

This is precisely the position of the Eleatics and their Megarian continuators. The inference is that Plato is reproducing Megarian criticisms of the doctrine ascribed by himself to Socrates, an inference confirmed by the notice preserved by Alexander of Aphrodisias (on *Metaphysics* 990 b 15) of the "third man" argument of the Megarian Polyxenus against participation. Plato does not indicate his own opinion of the cogency of the reasoning, which is, in fact. fallacious, as was properly pointed out by Proclus. (For a detailed discussion of it, see A. E. Taylor, "Parmenides, Zeno and Socrates." in *Proceedings* of the Aristotelian Society for *the Systematic Study of Philosophy,* vol. xvi, pp. 234 ff.)

The purpose of the antinomies which follow has been differently understood. It seems possible that they may be deliberate parody, the object being to show that the methods of the Megarian logicians are even more damaging to their own fundamental metaphysical tenet than they are to the doctrine of participation. Megarian logic is a double-edged weapon, and Plato, if he chooses, can apply it even more dexterously than its inventors.

Theaetetus.—Except for a magnificent interlude in praise of the contemplative life. the dialogue is a straightforward discussion of the question how knowledge should be defined. It naturally ends negatively. None of the proposed definitions will stand examination (the reason is that we are really trying to define truth and truth is an ultimate). But the incidental results of the discussion are of the first importance. We learn (1) that knowledge cannot be identified with sensation nor with any formless simple apprehension; (2) that pure relativism is as impossible in epistemology as in metaphysics. We have the beginning of a doctrine of the categories which is further developed in the *Sophistes.*

The increasing value which Plato is coming to put upon natural knowledge is marked by the use of the word doxa (which in earlier dialogues had commonly meant mere uncertain opinion) in the new sense of "judgment" which it retains in Plato's subsequent work. The most striking negative feature of the *Theaetetus* is that it discusses knowledge at length without making any reference to the forms or to the mythology of recollection. It remains to this day the best of introductions to the problem of knowledge. The main argument may be briefly summarized as follows:

1. It seems plausibie at first to say that knowledge (*episteme*) is sensation (aisthesis). This sounds like the proposition of Protagoras. "what seems to me is so to me; what seems to you is so to you." We might base such a thoroughgoing doctrine of the relativity of all knowledge on a still more ultimate metaphysical theory, if we said—it is implied that Protagoras himself said nothing of the kind—that. within us and without us, the only reality is motion. Organ and environment are both motions; when these motions impinge on one another, they give rise to the twin product. felt sensation–sensible quality.

Both the sensation and the quality sensed will therefore be affected by any difference in the pair of slower motions which cause them (the organ and its environment), and each percipient, therefore, is confined to his strictly private world, which exists only for him. There is no common perceived world, and therefore no standard of truth or reality other than the individual percipient. A teacher does not aim, any more than a physician, at convincing his pupil of the falsity of his judgments, but at giving him useful or healthy convictions in place of harmful or diseased convictions.

The full discussion of such a theory would demand a thorough study both of the Heraclitean philosophy, which says that there is nothing but motion, and the Eleatic philosophy which says that motion is an illusion. But for our immediate purpose, a more summary argument is sufficient. It is certain that even the relativists, who hold that each man is the one infallible measure of his present perceptions, do not hold that he is the only and inerrant measure of his future sensations. A physician can often judge better than his patient whether the patient is going to have, say, the sensations of an ague. A man's own opinion whether a certain course will be expedient or good for him is often far from being the soundest. We must distinguish carefully between what the soul perceives through bodily organs—the data of sense—and what she apprehends by herself without organs. The latter class includes number, sameness. difference, likeness, unlikeness, being, good, bad, right, wrong; *i.e.*, the great universal categories of fact and value. These are apprehended not by sense, but by thinking, and as they are the formal element in all knowledge, knowledge must be found not in our sensations, but in the judgment (syllogismos) of the mind upon them.

2. Is knowledge, then, true judgment? The statement implies that me know nhat we mean by false judgment, error. But is this the case? Error must not be confused with mere false recognition, misinterpretation of present sensation, since there are purely intellectual errors, and we find ourselves unable to explain the nature of this kind of error. And, in fact, it is clear that persuasive rhetoric may produce in the hearer judgments which are true, but have no claim to be called knowledge.

3. Finally, is knowledge "true judgment accompanied by discourse true judgment for which we can give grounds"? This would distinguish knowledge from simple apprehension and would harmonize with the theory of those who hold that knowledge is always of complexes, never of their simple constituents. But this doctrine has difficulties of its own, and, in any case, if we say that knowledge is true judgment + discourse, the discourse meant must be a statement of the logical differentia of the object of which I have knowledge. The proposed definition therefore amounts to saying that knowledge is true judgment about an object + knowledge of the *differentia* of that object and so is circular.

Later Dialogues

Sophistes **and** Politicus.—Formally these two important dialogues are closely connected. They are made to appear as a sequel to the *Theaetetus,* and a further connection is afforded between them by the fact that both are ostensibly concerned with a problem of definition. which is treated by the characteristic Platonic method of repeatedly subdividing a *genus* until we obtain the *definiendum* as a subspecies. The real purpose of the *Sophistes* is logical or metaphysical; it aims at explaining the true nature of negative predication and so as to dispose of the Eleatic thesis that the temporal and sensible realm, containing, as it does, a negative moment, must be mere unreal illusion. The object of the Politicus is to consider the respective merits of two contrasted forms of government, personal rule and constitutionalism, and to recommend the second, particularly in the form of limited monarchy, as most suitable to the actual condition of mankind. The Sophistes lays the foundations of all subsequent logic, the Politicus those of all constitutionalism.

A more temporary purpose in both dialogues is to illustrate the value of careful classification as a basis for scientific definition. In both dialogues Socrates is almost silent; his place as chief speaker is taken by an unnamed and very unorthodox Eleatic, who seems to be a purely fictitious character. Plato is, in fact, claiming that he, and not the formal logicians of Megara, is the continuator of Parmenides, much as Aristotle in his polemic against Xenocrates claims to be the true successor of Plato.

In the Sophistes the main discussion is led up to through a definition of the "sophist" as an "illusionist," a person who, by abuse of logic. produces the illusion, or false appearance, that nature and human life are alike riddled by insoluble contradictions. (This shows that the persons aimed at under the name sophist are the Megarian controversialists who make an illegitimate use of the dialectic of Zeno and Socrates). Now the sophist himself would retort that this definition is senseless, for there can be no such thing as a false statement or a false impression. For the false means "what is not," and "what is not" is nothing at all and can neither be uttered nor thought. To refute him we need to correct the fundamental thesis of so venerable a thinker as Parmenides. Either we must admit that there can be no false statements, or we must be prepared to maintain that "what is not, in some sense also is," and "what is, in some sense is not" (*i.e.*, me must explain what is the meaning of a significant negative proposition). In our theory of being we have to meet at once Parmenides and two different types of pluralist opponents of Parmenides, (1) the corporealists who say that the real. "what is." is just visible and tangible body and (2) certain friends of forms who maintain that the real is a multitude of incorporeal forms, denying that sense-perception gives us any apprehension of it. The corporealist is sufficiently refuted by the consideration that he himself cannot deny the reality of force (*dynamis*) and that force is not a body. The incorporealist friends of forms cannot be met in this way. They regard force, or activity itself as belonging to the unreal realm of becoming. We meet them by urging that knowing is itself an activity and that we cannot deny intelligence and knowledge to the supreme reality. This means that it has a "soul" and is alive. But if life is real, movement and repose from movement must be real too.[1]

This leaves us free to attack the Parmenidean monism itself. That is refuted by drawing the distinction between absolute and relative nonbeing. A significant denial, A is ***not*** B, does not mean that A is nothing, but that ***A*** is other than B. Every one of the great categorical features of reality is other than every other, and the true business of dialectic is to study the various possible combinations of these universal categories. The dialogue mentions five of them, being, identity, difference, motion and rest. (Though it is not said that this is a complete list of categories, it was treated as such by the Neoplatonists.)

The important result is thus that we have learned to think of forms themselves as an interrelated system, with relations of compatibility and incompatibility among themselves. Negation is a moment in the system of intelligible reality, and therefore its presence in the sensible realm does not stamp that realm as illusion. This is the ontological position which interests Plato; the recognition of the function of the logical copula is a consequence.

The Politicus has as its main result the conclusion that government by the personal direction of a benevolent dictator is not suitable to the conditions of human life, where the direction is necessarily that of a fallible man, not of a god. In an actual human society, the surrogate for personal direction by a god is the impersonal supremacy of inviolable law. Where there is such a recognized sovereign law, monarchy is the most satisfactory type of constitution, democracy the least satisfactory. but where there is no fundamental law, this situation is inverted. A sovereign democracy is preferable to an irresponsible autocrat. The dialogue is rich in thoughts which have passed into the substance of Aristotle's ethics and politics. Aristotle took directly from it the conception of politics as the architectonic practical science to which all others are subordinate; the formula of the right mean comes from it together with the Philebus.

Philebus.—The subject of the dialogue is a strictly ethical one. and this, no doubt, explains why it is the only dialogue after the *Theaetetus* in which Socrates is the principal speaker. The issue propounded is the question whether the good is pleasurable feeling or whether it is thought, the exercise of intelligence.

Comparison with the notices of Aristotle in the Nicomachean Ethics shows that this was the subject of a sharp division in the Academy. the hedonist party being led by the mathematician and astronomer Eudoxus, the antihedonists by Speusippus. Under the guidance of Socrates the question is narrowed down to a consideration of the good for man in particular, and a mediating conclusion is reached. The best life for man contains both elements but intelligence is the predominant partner.

All forms of knowledge find a place in it, but only those pleasures which are compatible with wisdom and virtue; *i.e.*, those which are "unmixed" (not preceded by a sense of want or craving) and those of the "mixed" pleasures (the satisfactions of appetite) which are innocent and moderate. The *Philebus* contains Plato's ripest moral psychology; it is the immediate source of the famous doctrine of the mean.

Philosophically the most important feature of the dialogue is a classification adopted with a view to determining the formal character of the two claimants to recognition as the good. All components of the actual belong to one of four classes, (1) the infinite or unbounded (*apeiron*), (2) the limit (*peras*), (3) the mixture or combination of infinite and limit, (4) the cause of the mixture. (Infinite and limit are just the two fundamental opposites of Pythagoreanism.) All the good things of life belong to the third class, that is. they are produced by the introduction of definite limit or ratio into an indeterminate continuum. (This is precisely the doctrine of the mean.) The establishment of such a ratio is a genesis into being, a process resulting in a stable being, and it is indicated that the cause or agent in such a process is always intelligence. human or divine.

There has been much discussion of the question in which of these classes the forms should be placed. The only tenable alternatives would be to put them into the class of limit or into that of the mixture (a view suggested both by the teaching of the *Sophistes* and by Aristotle's express statement that Plato distinguished two constituents within the form and advocated ably by H. Jackson). The truth seems to be that the particular classification in the *Philebus* is devised for a special purpose and that it is not intended to apply to anything but the things and processes of the sensible realm. In that case, though there is a close correspondence between what the *Philebus* teaches about stable being in the sensible realm and what. as we know from Aristotle; Plato taught about the forms, it will be a mistake to look for any actual exposition of the metaphysic of the forms in the Philebus.

Timaem. — The *Timaeus* is an exposition of cosmology, physics and biology put into the mouth of the astronomer Timaeus of Locri. Though Plato avoids expressly describing the speaker as, a Pythagorean. his doctrine is revealed by attentive analysis as an attempt to combine the mathematics and astronomy of the Pythagorean~with the biology of Empedocles, the real founder of Sicilian medicine. The discussion is introduced by the famous narrative of the gallantry of the prehistoric Athenians who defeated the kings of the imaginary Atlantis in their ambitious attempt to become masters of the world. The story was to have been told more in detail in the unfinished *Critias*.

Timaeus opens his discussion by drawing a distinction between

[1]It is still a much agitated question who are the logical atomists described in the *Sophistes* as the friends of forms. The view that they are adherents of the philosophy of the *Phaedo* and *Republic* is deservedly dead. They are still often supposed to be Megarians, but this seems inconsistent with the way in which they are carefully distinguished from the followers of Parmenides as belonging to the other side at 245 *e* Proclus (*Commentarii in Parmenidem*, 562) says positively, as though it u-ere the only view known to him, that they are Italian Pgthagoreans, and this is probably correct, since, the Eleatic of the dialogue refers to them as persons with whom he is familiar. It is Important to remark that the identification of being with force is given merely as a consequence which would follow from, and contradict, the corporealist hypothesis. The implication of the passage is rather that the identification is false than that it is true.

eternal being and temporal becoming and by insisting on the point that it is only of the former that we can have exact and final knowledge. All accounts of the temporal can be only tentative and liable to repeated revision. Cosmology, then, at best, is not exact science. The visible world, being mutable and temporal, is a copy of a model which is eternal, and the copy is the work of God. The reason why there is a copy at all is the unceasingly active and generous goodness of God. (In the sequel Timaeus speaks of the forms which God had before Him as His model in much the same language as the *Phaedo,* except that he uses the Pythagorean word imitation, not participation, to describe the relation of sensible things to forms.)

The world, then, had a beginning. (The Academic tradition from the first was that this is not to be understood literally; Aristotle insists on taking it literally.) God first formed its soul out of three constituents, identity. difference, being. Its body was made later from the four Empedoclean elements. The world soul was placed in the circles of the sidereal equator and ecliptic the latter being split into seven lesser circles, those of the planets, and the two were animated with movements in opposite senses. Subsequently were formed the various subordinate gods and the souls of human beings, that is the immortal and rational element in the human soul, which come straight from the hands of God Himself. The formation of the human body and of the two lower mortal components of the human soul was effected through the intermediacy of the "created gods" (i e., the stars). The most important question of detail arising from this part of the dialogue is that debated between A. Boeckh and G. Grote. Does Timaeus ascribe a motion to the earth? The restoration of the correct text at 40 c ("going up and down on the path about the axis of the universe") proves definitely that he does, but it is not a diurnal revolution, as Grote supposed; it must be rectilinear displacement of unknown period.

The contact is made between Pythagorean geometry and the Empedoclean biology which mill be needed for the physiology and medicine of the dialogue by a mathematical construction of the elements. Starting with two primitive triangles, the isosceles right-angled, and .the right-angled scalene in which the hypotenuse is double the shortest side, Timaeus constructs four of the regular solids, cube, tetrahedron, octahedron, icosahedron, and these are assumed to be the shapes of the corpuscles of earth, fire, air, water. These four in their turn are the immediate constituents of all organic and inorganic compounds.

The important features of the dialogue are not the particular tentative scientific hypotheses but its leading methodological principles. We should note the introduction of God as the intelligent efficient cause of all order and structure in the world of becoming, which preludes to the natural theology of the *Laws,* and the emphatic recognition of the essentially tentative and therefore progressive, character of natural science. It is also noticeable that though Plato's scientific ideal is a mathematical corpuscular physics — his influence in creating this ideal has been much more important than that of the ancient atomists — he constructs his physical world without matter as a metaphysical substrate. The place of matter is taken in his analysis, as Aristotle complained, by *chora,* space, as in the *Principia* of Descartes, a point of view to which physical speculation seems to be returning. He analyzes the passage of nature into three factors: being (a form). space and happening (genesis) much as A. N. Whitehead analyzes it into objects, events and the ingredients of object into event.

It is a fundamental point that the presence of space as a factor makes it necessary to recognize over and above God or mind a subordinate element of ananke, "necessity," in events. Since necessity is also called the errant cause, *planomene* aitia (with an allusion to the name of the planets or tramp-stars) the word clearly does not mean conformity to law. It is rather a name for the fact that there is always in the actual an irreducible remainder of brute datum, "conjunctions" in Hume's phrase, which we cannot rationalize completely into intelligible connections. Thus ananke is not a rebel or evil principle in the constitution of things; its function is everywhere to be instrumental to the intelligent and beneficent purpose of mind or God. There are many facts which we have to be content to accept simply as facts without seeing their reason why. We do not know and may never know, why it is "best" that they should be as they are (*e.g.,* why it is "best" that we should live on a moving earth) but we may be sure that, since it is the fact, it is in some way best that it should be so. This seems to be what is meant by the statement that God or mind (*nous*) persuades ananke. It is the expression of a rational faith in Providence and the supremacy of the moral order. The details of the cosmology, physiology and psychophysics of the dialogue are of great importance for the history of science, but metaphysically of secondary interest.

Laws and Epinomis.—The Laws, Plato's longest, is also his most intensely practical work and contains his ripest utterances on ethics, education and jurisprudence, as well as his one entirely nonmythical exposition of theology. The immediate object is to meet a practical need by providing a model of constitution making and legislation for members of the Academy who may be called on to assist his advisers in the actual founding or refounding of cities.

Plato's attempt to do work of this kind himself at Syracuse had borne no immediate fruit but had given the Academy a recognized standing as a school of scientific politics and jurisprudence. The work of constitution making and legislation was going on in many quarters at the end of his life, and his experience might be made fruitful in sage counsels to younger men. The practical character of the subject explains some novelties in the outward form of the work. As the dialogue is assumed to be dealing with the actual present, Socrates has disappeared and his place is taken by an unnamed Athenian who is, to all intents, Plato himself.

The scene is laid in Crete; the imagined situation is that the Cretans are about to found a settlement on the site of a long deserted city. The chief commissioner for the project is walking out to inspect the proposed site with a Spartan friend. when they meet the Athenian and, being favourably impressed by his conversation invite him to join them as an expert adviser.

The problem thus differs from that of the Republic; the question is not the construction of an ideal state, but the framing of a constitution and code which might be successfully adopted by a society of average Greeks in the middle of the 4th century. Hence the demands made on average human nature, though exacting, are not pitched too high; the communism of the *Republic* is dropped. And for the same reason it is assumed all through that the regulations are carefully adapted to the particular economic and geographical conditions, though it is said that these conditions will not really suit any actual Cretan locality. If so, we must suppose that Plato. under a transparent disguise, is contemplating the actual conditions in quarters from which the Academy was more likely to receive appeals for help.

The special purpose of the work also explains why purely speculative philosophy and science are excluded from its purview. The metaphysical interest is introduced only so far as to provide a basis for a moral theology; the one matter of first-rate scientific importance touched on is the diurnal motion of the earth, and this is only hinted in connection with the practical problem of the construction of the calendar. In compensation. the *Laws* is exceptionally rich in political and juristic wisdom and appears, indirectly, through its influence on the law of the Hellenistic age, to have left its mark on the great system of Roman jurisprudence.

It is impossible to do more than to call attention to a few of the striking features of this great work. The ethical ideal is still that familiar from earlier dialogues. It is interesting that the demand is expressly made that all unnatural vices shall be completely suppressed and that the rule of sexual life is to be monogamous marriage with strict chastity, outside the limits of marriage, for both sexes. In politics, Plato declares himself definitely in favour of a mixed constitution; a good government demands a balance betneen two principles, *eleutheria,* "popular control," and *monarchia,* "personal authority." Persia is an illustration of the mischief of unqualified autocracy, Athens of the evils which come from elimination of the authoritarian principle, and considerable care is taken in the suggested system of magistracies to secure both genuine popular representation and the proper regard for personal qualifications. The basis of society is to be agriculture, not commerce, the citizens are to be peasant proprietors — communism is regretfully abandoned as impracticable in a society of ordinary human beings. But the patrimony of each household is to be strictly inalienable, and differences in personal property are to be kept within strict bounds by what amounts to a supertax of 100% on incomes beyond the statutory limits. Education, as in the Republic, is regarded as the most important of all the functions of government; it is placed under the control of a minister who is the premier. As far as possible, the distinction between the sexes is, as in the *Republic,* to be treated as irrelevant to the educational program.

The most striking features of the scheme are the careful attention paid to the problems of the physical training of children in their earliest infancy and to the right utilization of the child's instinct for play and the demand, made now for the first time, that in adolescence, the young shall be taught in institutions where expert instruction in all the various subjects is co-ordinated. It is from this proposal that the grammar school, or secondary school, has taken its origin. Though we hear no more of philosopher-kings the demand is still made that the members of the "nocturnal council," the supreme council of the state, which is always in permanent session, and exercises a general control over administration, shall be thoroughly trained, not only in the exact sciences, but in the supreme science, which "sees the one in the many and the many in the one"; that is, they are to be dialecticians.

The work is full of suggestions for the practical application of science, such, for example, as that of the necessity of strictly standardizing all weights and measures, or that of basing the calendar on a solar year (of 363' days). The object of the apparently arbitrary selection of the number of patrimonies and the scheme of subdivision of the whole society into smaller groups appears to be the practical one of making it easy to determine exactly what quotum each subdivision may justly be called on to contribute to the revenue or the defenses.

At least two fundamental improvements are made on the Attic jurisprudence which Plato has adopted as the foundation of his own code. One great blot on the heliastic system is removed by the regulations which ensure that trials for serious offenses shall take place before a court which contains highly qualified magistrates, and shall proceed with due deliberation and that there shall be provision for appeals from the primary tribunal to a court of cassation. It is even more important, perhaps, that Laws ix by drawing a clear distinction between blabe, "detriment," and adikia, "infringement," of rights, lays the foundation for the discrimination between civil and criminal actions at law.

An incidental passage in the Laws (822 a-b) and another in the *Epinomis* (987 b) definitely show that Theophrastus was right in crediting Plato with belief in the earth's motion. In the Laws it is said that the real orbit of each planet is a single closed curve, in the *Epinomis* the view that the circle of the stars communicates its motion to those of the planets is called that of men "who know but little of the subject." The allusion is to the famous theory of the celestial motions put forward by Plato's friend and associate, the great mathematician Eudoxus.

According to this, the first great geocentric theory in scientific astronomy, the movements of each planet can be analyzed into a combination of circular revolutions, the unmoved earth being taken as the common centre of all. What Plato asserts is that each planet has only one proper revolution, the remaining revolutions are apparent, not real. The implication is that these apparent revolutions of the planet must be real motions of the earth from which we make our observations. The earth is thus a planet, though not a satellite of the sun. The language of the *Epinomis*—which may be safely regarded as at least true to Plato's thought — definitely makes the sun, itself, one of the planets. We have, therefore, to think of the earth as also a planet revolving with the rest round an unseen centre. We may infer from the words of Theophrastus that Plato, like some of the Pythagoreans, held that there is a luminary, the "central fire," at this centre. The period of the earth's revolution would certainly be taken to be the natural day, so that the motion ascribed to the earth is equivalent to the diurnal rotation, though from Plato's point of view it is not a rotation on an axis, but a revolution round a centre. It follows that the alternation of day and night is no longer accounted for by a rotation of the heaven of the fixed stars. This outermost circle is still credited in the *Epinomis* with a revolution in the sense east to west, but its period is not specified. We need not suppose either that Plato could have specified the period or that he used it to explain any special appearances. It has nothing to do with precession of the equinoxes. being in the wrong sense for that purpose.

What is to Plato's credit is that he has the insight to see that, with all its attractions, the scheme of Eudoxus starts from a wrong presupposition, a stationary earth.

In Laws x Plato. for a practical purpose, creates natural theology. There are three false beliefs which are fatal to moral character, atheism, denial of the moral government of the world, the belief that divine judgment can be bought off by offerings. Plato holds that he can disprove them all. The refutation of atheism turns on the identification of the soul with the "movement which can move itself," already used in the *Phaedrus.* All motion is either communicated from without or self-initiated, and the ultimate source of all communicated motion must be self-initiated motion. The only thing which can move itself is a soul. It follows that all motion throughout the universe is ultimately initiated by souls. It is then inferred from the regular character of the great cosmic motions and their systematic unity, that the souls which originate them form a hierarchy with a best soul, God, at their head. Disorderly and irregular motions are equally due to souls, but to bad and disordered souls, and from the fact that there are disorderly motions, it is inferred that the best soul cannot be the only soul.

There is no suggestion that there is a worst soul, a devil or evil world-soul; all that is said is that there must be one soul which is not the best, and may be more. This is Plato's way of excluding pantheism, as incompatible with the reality of evil. The argument thus establishes at once the immortality of the soul and the existence of God. The other two heresies can now be disposed of. It is inconsistent with the goodness of the best soul to be indifferent to our conduct, and still more so to be venal. The moral government of the world is, in fact, assured by the establishment of the single principle that every soul gravitates into the society of its desires and consequently does and has done to it what it befits such a soul to do and have done to it. Plato thus becomes the originator of the view that there are certain theological truths which can be strictly demonstrated by reason.

It is these demonstrable truths which are subsequently named by M. Terentius Varro natural or philosophical theology in contradistinction to the poetical theology, the myths related by the poets, and the civil theology. the ritual cultus instituted by politicians. From Varro the distinction of three theologies passed to St. Augustine and thus in the end became the foundation of the scholastic distinction between natural theology, those truths about God which can be ascertained independently of any specific revelation, and revealed theology, the further truths which are only made accessible by the Christian revelation. Since Plato's object in demonstrating his three propositions is an ethical one, he goes on to enact that the denial of any of them shall be a grave crime to be visited by the state with penalties ranging from a minimum of five years' solitary confinement, and with death on a second conviction. Plato is thus the inventor, so far as European society is concerned, of the proposal to make an official creed for the state and to treat dissent from it as criminal, an innovation foreign to the spirit of the Hellenic cities, in which religion was a matter not of beliefs but of cultures. Plato's last word, then, on the problem how the sensible comes to partake of form is that it does so through the agency of divine goodness and wisdom. God molds the sensible upon the pattern of the intelligible. The obvious question, how God, who is a soul not a form, is related to the good which is the supreme form never receives discussion or solution. To answer that question was to be the main business of Plotinus.

PLATONISM AFTER PLATO

Aristotle's Account of Platonism. — Since Plato refused to write any formal exposition of his own metaphysic. our knowledge of its final shape has to be derived from the statements of Aristotle. nhich are confirmed by scanty remains of the earliest Platonists preserved in the Neoplatonist commentaries on Aristotle. These statements can, unfortunately, only be interpreted conjecturally. According to Aristotle (*Metaphysics* i, 987 *b* 18–25) Plato's doctrine of forms was, in its general character, not different from Pythagoreanism. the forms being actually called numbers. The two points on which Aristotle regards Plato as disagreeing with the Pythagoreans are (1) that whereas the Pythagoreans said that numbers have as their constituents, the unlimited and the limit, Plato taught that the forms have as constituents the one and the great and small; and (2) that whereas the Pythagoreans had said that things are numbers. Plato intercalated between his forms (or numbers) and sensible things an intermediate class of mathematicals. It is curious, that in connection with the former difference Aristotle dwells mainly on the substitution of the "duality of the great and small" for the "unlimited." not on the much more significant point that the one, which the Pythagoreans regarded as the simplest complex of unlimited and limit, is treated by Plato as itself the element of limit. He further adds that the "great and small" is, in his own technical terminology, the matter, the one, the formal constituent, in a number.

If we could be sure how much of the polemic against number-forms in *Metaphysics* xiii–xiv is aimed directly at Plato. we might add considerably to this bald statement of his doctrine, but unluckily it is certain that much of the polemic is concerned nith the teaching of Speusippus and Xenocrates. It is not safe. therefore, to ascribe to Plato statements other than those with which Aristotle explicitly credits him. We have then to interpret, if we can, two main statements: (1) the statement that the forms are numbers; (2) the statement that the constituents of a number are the great and small and the one.

Light is thrown on the first statement if me recall the corpuscular physics of the *Timaeus* and the mixture of the *Philebus.* In the *Timaeus,* in particular, the behaviour of bodies is explained by the geometrical structure of their corpuscles. and the corpuscles themselves are analyzed into complexes built up out of two types of elementary triangle, which are the simplest elements of the narrative of Timaeus. Now a triangle, being determined in everything but absolute magnitude by the numbers nhich express the ratio of its sides, may be regarded as a triplet of numbers. If we remember then, that the triangles determine the character of bodies and are, themselves, determined by numbers, we may see why the ultimate forms on which the character of nature depends should be said to be numbers, and also what is meant by the mathematicals intermediate between the forms and sensible things. According to Aristotle, these mathematicals differ from forms because they are many, whereas the form is one, from sensible things in being unchanging. This is exactly how the geometer's figure differs at once from the type it embodies and from a visible thing. There is, for example, only one type of triangle whose sides have the ratios 3:4:5, but there may be as many pure instances of the type as there are triplets of numbers exhibiting these ratios; and again. the geometrical triangles which are such pure instances of the type, unlike sensible three sided figures, embody the type exactly and unchangingly. A mathematical physicist may thus readily be led to what seems to be Plato's view that the relations of numbers are the key to the whole mystery of nature, as is actually said in the *Epinomis* (990 *e*).

We can now, perhaps, see the motive for the further departure from Pythagoreanism. It is clear that the Pythagorean parallelism between geometry and arithmetic rested upon the thought that the point is to spatial magnitude what the number 1 is to number. Numbers were thought of as collections of units, and volumes, in like fashion, as collections of points; that is, the point was conceived as a minimum volume. As the criticisms of Zeno showed, this conception was fatal to the specially Pythagorean science of geometry itself, since it makes it impossible to assert the continuity of spatial magnitude. (This, no doubt, is why Plato, as Aristotle tells us, rejected the notion of a point as a fiction.)

There is also a difficulty about the notion of a number as a collection of units, nhich must have been forced on Plato's attention by the interest in irrationals which is shown by repeated allusions in the dialogues, as well as by the later anecdotes which represent him as busied with the problem of doubling the cube or finding two mean proportionals. Irrational square and cube roots cannot possibly be reached by any process of forming collections of units, and yet it is a problem in mathematics to determine them, and their determination is required for physics (*Epinomis* 990 *c*–991 *b*).

This is sufficient to explain why it is necessary to regard the numbers which are the physicist's determinants as themselves determinations of a continuum (a great and small), by a limit and why, at the same time the one can no longer be regarded as a blend of unlimited and limit but must be, itself, the factor of limit. (If it were the first result of the blending, it would reappear in all the further blends; all numbers would be collections of one and there would be no place for the irrationals.) There is no doubt that Plato's thought proceeded on these general lines. Aristotle tells us that he said that numbers are not really addible (*Metaphysics* xiii. 1083 *a* 34). that is, that the integer series is not really made by successive additions of 1; and the *Epinomis* is emphatic on the point that contrary to the accepted opinion. surds are just as much numbers as integers. The underlying thought is that numbers are to be thought of as generated in a way which will permit the inclusion of rationals and irrationals in the same series. In point of fact there are logical difficulties which make it impossible to solve the problem precisely on these lines. It is true that mathematics requires a sound logical theory of irrational numbers and. again, that an integer is not a collection of units; it is not true that rational integers and real numbers form a single series.

The Platonic number theory was inspired by thoughts which have since borne fruit abundantly but was itself premature. We learn partly from Aristotle, partly from notices preserved by his commentators, that in the derivation of the integer series, the even numbers were supposed to be generated by the dyad which doubles nhatever it lays hold of, the odd numbers in some way by the one which limits or equalizes, but the interpretation of these statements is, at best, conjectural. In the statement about the dyad there seems to be some confusion between the number 2 and the indeterminate dyad, another name for the continuum also called the great and small, and it is not clear whether this confusion was inherent in the theory itself, or has been caused by Aristotle's misapprehension.

Nor, again, is it at all certain exactly what is meant by the operation of equalizing ascribed to the one. It would be improper here to propound conjectures which our space will not allow us to discuss. A collection and examination of the available evidence is given by L. Robin in his *Thdovie platonicienne des idées et des nombres d'après Aristote* (1908), and an admirable exposition of the significance of the problem of the irrational for Plato's philosophy by G. Milhaud in *Les Philosophes-géomètres de la Grèce, Platon et ses prédécesseurs,* new ed. (1934). For a conjectural interpretation *see* A. E. Taylor, "Forms and Numbers." in *Mind,* new series, 140, 141.

The Academy After **Plato.**—Plato's Academy continued to exist as a corporate body down to A.D. 529 when the emperor Justinian, in his zeal for Christian orthodoxy, closed the schools of Athens and appropriated their emoluments (*see* ACADEMY, GREEK). Plato's greatest scholar. Aristotle, had finally gone his own way and organized a school of his own in the Lyceum, claiming that he was preserving the essential spirit of Platonism, while rejecting the difficult doctrine of the forms. The place of official head of the Academy was filled first by Speusippus, Plato's nephew (*c.* 347–339 B.C.), then by Xenocrates (*c.* 339–314 B.C.). Under Arcesilaus (c. 276–241 B.C.) the Academy began its long-continued polemic against the sensationalist dogmatism of the Stoics, which accounts both for the tradition of later antiquity which dates the rise of a New (some said Middle) and purely skeptical Academy from Arcesilaus and for the 18th-century associations of the phrase "academic philosophy."

In the 1st century B.C. the most interesting episode in the history of the school is the quarrel between its president Philo of Larissa and his scholar Antiochus of Ascalon, of which Cicero's *Academica* is the literary record. Antiochus, who had embraced Stoic tenets, alleged that Plato had really held views indistinguishable from those of Zeno of Citium and that Arcesilaus had corrupted the doctrine of the Academy in a skeptical sense. Philo denied this. The gradual *rapprochement* between Stoicism and the Academy is illustrated from the other side by the work of Stoic scholars such as Panaetius of Rhodes and Poseidonius of Apamea, who commented on Platonic dialogues and modified the doctrines of their school in a Platonic sense.

The history of the Academy after Philo is obscure, but since the late 1st century A.D. we meet with a popular literary Platonism of which the writings of Plutarch are the best example. This popular Platonism insists on the value of religion, in opposition to Epicureanism, and on the freedom of the will and the reality of human initiative, in opposition to the Stoic determinism; a further characteristic feature, wholly incompatible with the genuine doctrine of Plato, is the notion that matter is inherently evil and the source of moral evil.

Genuine Platonism was revived in the 3rd century A.D., in Rome, and independently of the Academy, by Plotinus. His Neoplatonism (*q.v.*) represents a real effort to do justice to the whole thought of Plato. Two aspects of Plato's thought, however, in the changed conditions inevitably fell into the background, the mathematical physics and the politics. The 3rd century A.D. had no understanding for the former, and the Roman empire under a succession of military chiefs no place for the latter. The doctrine of Plotinus is Platonism seen through the personal temperament of a saintly mystic, and with the *Symposium* and the teaching of the *Republic* about the form of good always in the foreground. Plotinus lived in an atmosphere too pure for sectarian polemic, but in the hands of his successors, Neoplatonism was developed in conscious opposition to Christianity. Porphyry, his disciple and biographer, was the most formidable of the anti-Christian controversialists; in the next century, "Platonists" were among the allies and counsellors of the emperor Julian in his attempts to invent an Hellenic counterpart to Christianity.

Early in the 5th century. Neoplatonism flourished for a short time in Alexandria (which disgraced itself by the murder of Hypatia in 415) and captured the Athenian Academy itself, where its last great representative was the acute Proclus (A.D. 410–485). The latest members of the Academy, under Justinian, occupied themselves chiefly with learned commentaries on Aristotle, of which, those of Simplicius are the most valuable. The doctrine of the school itself ends in Damascius with mystical agnosticism.

Influence on Christian Thought.— Traces of Plato are probably to be detected in the Alexandrian *Wisdom of Solomon;* the thought of the Alexandrian Jewish philosopher and theologian Philo, in the 1st century A.D., is at least as much Platonic as Stoic. There are, perhaps, no certain marks of Platonic influence in the New Testament, but the earliest apologists (Justin, Athenagoras) appealed to the witness of Plato against the puerilities and indecencies of mythology. In the 3rd century Clement of Alexandria and after him, Origen made Platonism the metaphysical foundation of what aas intended to be a definitely Christian philosophy. The church could not, in the end, conciliate Platonist eschatology with the dogmas of the resurrection of the flesh and the final judgment, but in a less extreme form the platonizing tendency was continued in the next century by the Cappadocians, notably St. Gregory Nyssa and passed from them to St. Ambrose of Milan. The main sources of the Platonism which dominated the philosophy of western Christian theologians through the earlier middle ages, were, however, Augustine, the greatest thinker among the western fathers, who had been profoundly influenced by Plotinus read in a Latin version, before his conversion to Christianity; and Boethius, whose wholly Platonist vindication of the ways of Providence in his *De Consolatione Philosophiae* was the favourite serious book of the middle ages.

A further powerful influence was exerted by the writings of the so-called Dionysius the Areopagite (*q.v.*), which laid down the main lines of medieval mystical theology and angelology. These works are, in fact, an imperfectly Christianized version of the speculations of Proclus and cannot date before the end of the 5th century A.D. at the earliest, but they enjoyed an immense authority based on their attribution to an immediate convert of St. Paul. After their translation into Latin in the 9th century by Johannes Scotus Erigena, they became popular in the west.

Apart from this theological influence, Plato dominated the thought of the earlier Renaissance which dates from the time of Charlemagne in another way. Since the west possessed the philosophical writings of Cicero, with the Neoplatonic comment of Macrobius on the *Somnium Scipionis,* as well as the Latin translation of the first two-thirds of the *Timaeus* by Chalcidius, with his commentary on the text, and versions, also, at least of the *Phaedo* and of the *Meno,* whereas nothing was known of the works of Aristotle except Latin versions of some of the logical treatises, the middle age, between Charlemagne and the beginning of the 13th century, when the recovery of Aristotle's physics and metaphysics from Moors, Persians and Jews began, was much better informed about Plato than about Aristotle; in particular, in the various encyclopaedias of this period, it is the *Timaeus* which forms the regular background.

The 13th century saw a change. Aristotle came to displace Plato as the philosopher, partly in consequence of the immediately perceived value of his strictly scientific works as a storehouse of well-digested natural facts, partly from the brilliant success of the enterprise carried through by St. Thomas Aquinas, the reconstruction of philosophical theology on an Aristotelian basis. Plato is, however, by no means supplanted in the Thomist system; the impress of Augustine on western thought has been far too deep for that. Augustine's "exemplarism," that is, the doctrine of forms in the version, ultimately derived from Philo of Alexandria, which makes the forms creative thoughts of God, is an integral part of the Thomist metaphysics, though it is now denied that the'exemplars are themselves cognizable by the human intellect, which has to collect its forms, as best it can, from the data of sense.

Directly or through Augustine, the influence of Plato, not only on strictly philosophic thought but on popular ethics and religion, has repeatedly come to the front in ages of general spiritual requickening and shows no signs of being on the wane.

Two revivals in particular are famous. The first is that of the 16th century, marked by the Latin translation of Marsilio Ficino and the foundation of Lorenzo dei Medici's fantastic Florentine Academy. What was revived then was not so much the spirit of Plato as that of the least sober of the Neoplatonists; the influence of the revival was felt more in literature than in philosophy or morals, but in literature its importance may be measured by the mere mention of such names as Michelangelo, Sir Philip Sidney and Edmund Spenser.

In the 17th century, Plato, seen chiefly through the medium of Plotinus, supplied the inspiration of a group of noble thinkers who were vindicating a more inward morality and religion against the unspiritual secularism and Erastianism of Hobbes: namely the so-called Cambridge Platonists, Benjamin Whichcote, Henry More, Ralph Cudworth and John Smith. In the 20th century, on the one hand A. N. Whitehead tried to work out a philosophy of the sciences which confessedly connected itself with the ideas of the *Timaeus;* and on the other the rise of totalitarian governments produced a number of publications confronting Plato with the theories (Communist, Fascist, etc.) inherent in their policies.

See also Index references under "Plato" in the Index volume.

BIBLIOGRAPHY.—The works of Plato are conveniently arranged in nine tetralogies as follows: (1) *Euthyphro, Apology, Crito, Phaedo;* (2) *Cratylus, Theaetetus, Sophistes, Politicus;* (3) *Parmenides, Philebus, Symposium, Phaedrus;* (4) *Alcibiades I, Alcibiades 11, Hipparchus, Erastae;* (5) *Theages, Charmides, Laches, Lysis;* (6) *Euthydemus, Protagoras, Gorgias, Meno;* (7) *Hippias I (major), Hippias II (minor), Ion, Menexenus;* (8) *Clitophon, Republic, Timaeus, Critias;* and (9)

Minos, Laws, Epinomis, Epistles. Of the manuscript codices, none of which are earlier than the 9th century A.D., the most important are the Bodleianus-Clarkianus (containing the first six tetralogies), the Parisinus 1807 A (containing the eighth and the ninth) and the Venetus (containing the first seven and part of the eighth). Since the end of the 19th century papyrus fragments have been found; on these, *see* H. Leisegang, "Platon" (1950), in Pauly-Wissowa, *Real-Encyclopädie der Classischen Altertumswissenschaft.* On the text and the canon *see:* H. Alline, *Histoire du texte de Platon* (1915); L. A. Post, *The Vatican Plato and Its Relations* (1935); G. Jachmann, "Der Platontext" in *Nachrichten der Akademie der Wissenschaften in Göttingen, Phil.-hist. Klasse 1941* (1942); E. Bickel, "Das Platonische Schriftenkorpus . . ." and "Geschichte und Recensio des Platontextes," in *Rheinisches Museum,* 92 (1943).

Modern editions of Plato refer to the pagination of the edition by (J. Serranus and) H. Stephanus, 3 vol., with Lat. trans. (1578), which is used also in the foregoing text of this article. The standard edition is that by J. Burnet, 5 vol. (1899–1907), containing not only all the 36 works of the nine tetralogies but also the *spuria* (*Definitions, On Justice, On Virtue, Demodocus, Sisyphus, Halcyon, Eryxias* and *Axiochus*). Earlier editions deserving mention are those of G. Stallbaum, 12 vol. (1827–42), improved edition with extensive commentary in Latin; and of K. F. Hermann, 6 vol. (1851–53), rev. by M. Wohlrab (1884–87), containing not only Plato's works and the *spuria* but also the Pseudo-Timaeus Locrus *On the World Soul,* two writings by Albinus, the biography by Olympiodorus, the scholia, an index of names, etc. There is a collected edition in Greek and English by W. R. M. Lamb, H. N. Fowler *et al.* (1914 *et seq.*); and another in Greek and French by A. Croiset *et al.* (1920 *et seq.*). The Eng. trans. by B. Jowett, 4th ed., rev. by D. J. Allan and H. E. Dale (1953), omits *Alcibiades II, Hipparchus, Erastae, Theages, Clitophon, Minos, Epinomis* and *Epistles.* Among translations into other languages are those into German by H. Müller, 8 vol. (1850–66) and by O. Apelt, 25 vol. (1912–22; with rich bibliographies and index); into French by L. Robin and J. Moreau, 2 vol. (1940 *et seq.*); and into Italian by E. Turolla, 3 vol. (1953).

For individual works, the following editions, annotated translations and commentaries may be recommended: *Hippias I,* ed. by D. Tarrant (1928); *Ion,* ed. by St. G. Stock (1909); *Menexenus,* ed. by J. A. Shawyer (1906); *Laches,* ed. by G. Ammendola (1933); *Euthydemus,* ed. by E. H. Gifford (1905); *Gorgias,* ed. by W. H. Thompson (1894); *Meno,* 3rd ed. by St. G. Stock, 2 parts (1955); *Protagoras,* ed. by J. Adam (1893; reissue 1940) and 7th ed. by W. Nestle (1931); *Euthyphro, Apology and Crito* (1924) and *Phaedo* (1911), both ed. by J. Burnet, as well as *Apology,* ed. by J. Riddell (1867) and *Phaedo,* trans. by R. S. Bluck (1955) and by R. Hackforth (1955); *Symposium,* 2nd ed. by R. G. Bury (1932); *Phaedrus,* trans. by R. Hackforth (1952) and by J. B. Skemp (1952); *Republic,* ed. by J. Adam, vol. i, 4th ed. (1926), vol. ii, 3rd ed. (1921) and trans. by F. M. Cornford (1941); *Parmenides,* trans. by F. M. Cornford, *Plato and Parmenides* (1939; reprinted, 1950); *Theaetetus* and *Sophistes,* trans. by F. M. Cornford, *Plato's Theory of Knowledge* (1935; 1957); *Theaetetus,* 2nd ed. by L. Campbell (1883); *Politicus,* trans. by J. B. Skemp, *Plato's Statesman* (1952; new ed., 1957); *Philebus,* ed. by R. B. Bury (1897) and trans. by R. Hackforth, *Plato's Examination of Pleasure* (1945); *Timaeus,* ed. and trans. by R. Archer-Hind (1888) and trans. by F. M. Cornford, *Plato's Cosmology* (1937; reprinted 1957), commentary by A. E. Taylor (1928); *Laws,* commentary by C. Ritter (1896) and ed. by E. B. England, 2 vol. (1921); *Epinomis,* trans. by J. Harward (1928); with *Philebus,* trans. by A. E. Taylor (1956); *Epistles,* ed. by G. Pasquali (1938) and by A. Maddalena (1948) and trans. by L. A. Post (1925), by J. Harward (1932) and by G. R. Morrow (1935). The standard edition of the *Scholia Platonica* is ed. by W. C. Greene *et al.* (1939). *See* also A. Diès, *Autour de Platon: essais de critique et d'histoire,* 2 vol. (1927); R. Schaerer, *La Question platonicienne* (1938); M. Pohlenz, *Aus Platos Werdezeit* (1913); H. Arnim, *Platons Jugenddialogue und die Entstehungszeit des Phaidros* (1914); and R. Hackforth, *The Composition of Plato's Apology* (1933).

Comprehensive presentations are to be found in J. Burnet, *Greek Philosophy,* part 1 (1914); in E. Zeller, *Die Philosophie der Griechen,* vol. ii, part 2, 4th ed. (1921); in T. Gomperz, *Griechische Denker,* vol. ii, 4th ed. (1925); in F. Ueberweg, 12th ed. by K. Praechter, *Die Philosophie des Altertums* (1926); and in J. Geffcken, *Griechische Literaturgeschichte,* vol. ii (1934). Separate studies are: C. Ritter, *Platon,* 2 vol. (1910–23); U. von Wilamowitz-Moellendorff, *Platon,* 2 vol., 3rd ed. rev. by B. PLATO (fl. *c.* 400 B.C.), Greek poet, was a writer of Old Comedy. His earliest play was probably produced in 427 B.C., his last in 387. Of his 28 comedies most were on political themes. He attacked Hyperbolus in his *Perialges* ("The Sufferer"; 420?), Dieitrephes in the *Heortai* ("The Festivals"; 414?) and Peisander and Cleophon in the so-named plays. Mythological burlesques are represented by such plays as the *Adonis,* the *Daidalos,* the *Phaon,* etc., and social (= Middle) comedy by the *Sophistai,* for example.

Antiquity admired the elegance of his style.

PLATONIC LOVE, a locution used in two senses, with allusion in both cases to Plato's account of love in his *Symposium* (*see* PLATO: *The Earlier Dialogues*).

1. In common speech, platonic love means a supremely affectionate relationship between human beings in which sexual intercourse is neither desired nor practised. In this sense, it most often refers to a heterosexual relationship. By extension, it may be used to cover that stage of chivalrous or courtly love in which sexual intercourse is indefinitely postponed.

2. From the Renaissance to the end of the 19th century platonic love was used as an occasional euphemism for homosexual love, in view of the comparatively tolerant attitude to such love discernible in Plato as well as in other Greek authors.

PLATOON, a tactical subdivision of a military company. It is customarily a lieutenant's command and consists of from 25 to 50 men.

In the 17th century the term referred to a small body of musketeers who fired together in a volley, alternately with another platoon. In the 18th century battalions were often organized for tactical purposes into 16 platoons of about 24 men each, plus two or four platoons of grenadiers or light infantry. Since then the term has been applied to various tactical subdivisions of a company of infantry, cavalry or artillery.

The term "platoon" has been used in American manuals since 1779, and throughout the 19th century meant half a company. It has always retained some sense of systematic alternate employment. Hence "platoon fire" meant a regulated fire of alternating platoon volleys, and "platoon" sometimes meant the volley itself. The "platoon system" in municipal police and U.S football organizations signifies teams or shifts of comparable strength that alternate on duty.

The platoon was reintroduced into the British service in 1913 and became the name of the tactical subdivision of a company in most modern armies, being in turn subdivided into sections or squads.

See also COMPANY, MILITARY. (F. P. T.)

PLATT, CHARLES ADAMS (1861–1933), U.S. architect and landscape gardener, whose work showed the marked influence of Italian form, was born in New Tork, N.Y., on Oct. 16, 1861, and educated in the National Academy of Design and in Paris under Gustave Boulanger and Jules J. Lefebre. After a visit to Italy he nrote a book. *Italian Gardens* (1892). He designed many private houses and gardens in addition to public buildings, among the latter being the Maxwell Memorial library, Rockville, Conn. (1917); the Freer Gallery of Art, Washington, D.C. (1918); the library. Connecticut College for Women, New London (1922); the agricultural building, University of Illinois, Urbana (1923); and the Lowell Memorial fountain, New York, N.Y.

See *Monograph of the Work of Charles A. Platt,* with an introduction by Royal Cortissoz (1913).

PLATT, THOMAS COLLIER (1833–1910), U.S. politician, born in On-ego, N.Y., July 15, 1833, studied at Yale university, New Haven, Conn., 1849–52. He became a banker and speculated in lumber. In the 1860s Platt was chairman of the Tioga county (N.Y.) Republican committee, and in 1877, after having been elected for two terms to the U.S. house of representatives, he became chairman of the state Republican convention. Elected to the U.S. senate in Jan. 1881, Platt soon resigned, and within ten years he became the Republican boss of the state. Although he again served in the U.S. senate, his political power waned steadily after about 1903. He died in New York city, March 6, 1910.

PLATT AMENDMENT, an amendment to the U.S. army appropriation bill of March 1901, offered by Sen. Orville H. Platt of Connecticut and adopted by congress, which defined the conditions on which the United States was willing to end the military occupation of Cuba that had followed the Spanish-American War of 1898. Elihu Root, secretary of war, had previously formulated the terms on which the United States would withdraw and leave the government of Cuba to the Cubans. It was the Root formulation that Platt offered in the senate, with the proviso that the conditions must be embodied in the new Cuban constitution and also in a permanent treaty with the United States. The Cuban Constitutional convention reluctantly accepted the amendment. In so doing, it agreed that Cuba would validate the acts, and carry out the sanitary program, of the U.S. military government; that it would not impair Cuban independence by treaty with, or cession of territory to, any "foreign" power, or contract any debt beyond the capacity of the ordinary revenues to pay. It conceded to the United States the right to a naval base in Cuban territory and waters (later fixed at Guantbnamo bay) and gave the United States the right to intervene in Cuba for the preservation of orderly government or of Cuban independence — a right the Cnited States exercised repeatedly during the next 30 years. The Cubans never liked the Platt amendment, for they regarded it as an infringement of their sovereignty. In 1934 the United States negotiated a new treaty with Cuba that abrogated all provisions of the Platt amendment except the right to the naval base at Guantánamo bay.

PLATTE, a river system of the western United States, tributary to the Missouri river. The Platte river, 310 mi. long, is formed at Korth Platte, Neb., where the North Platte, 618 mi. long, and the South Platte, 424 mi. long, flow together. The North Platte river rises in the Medicine Bow and Park ranges and the Rabbit Ears mountains of north-central Colorado. It flows north into Wyoming and bends east-southeast at Casper, Wyo., flowing into western Nebraska. In eastern Wyoming the North Platte valley is one to ten miles wide and from 100 to 300 ft. below the surrounding uplands. On the Wyoming-Nebraska boundary the North Platte flows through the Goshen Hole'where the valley has widened to 50 mi. in places and the bordering bluffs are 400 ft. high. Torrington, Wyo., and Scottsbluff, Neb., mark the western and eastern extremities of the Goshen Hole. On the North Platte there are three large reservoirs used for irrigation and power: Pathfinder reservoir near Alcova, Wyo., completed in April 1909, with storage capacity of 1,016,000 ac.ft.; Seminoe reservoir near Leo, Wyo., completed in March 1939, capacity 1,012,000 ac.ft. and Alcova reservoir at Alcova completed in Jan. 1938, capacity 190,400 ac.ft.

The South Platte river rises in Park county on the Mosquito range of central Colorado and flows southeast across South Park. West of Divide, Colo., the river turns sharply northeast, flows through the Front range via the Platte River canyon and emerges on the flat land of the Colorado piedmont southeast of Denver. Continuing its northeast course, it flows through Denver to Greeley, Colo., where it bends eastward to North Platte. From Greeley east the valley of the South Platte is from two to ten miles wide. The river bed is filled with sandbars and the stream channel is often braided. Cheesman, Eleven Mile Canyon, and Antero reservoirs on the upper South Platte are storage units for Denver's water supply.

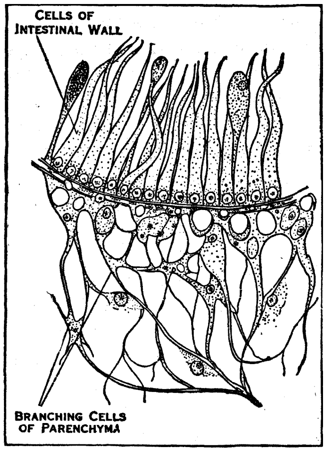
From North Platte the Platte river flows southeast into a big bend at Kearney, Neb., turns northeast and empties into the Missouri at Plattsmouth, Neb. During the spring runoff the Platte river is a mile wide in many places and almost dry the remainder of the year. Important tributaries of the North Platte are the Sweetwater and Laramie rivers and Medicine Bow creek. South Platte tributaries are Clear creek and Boulder creek and the Big Thompson, St. Vrain and Cache La Poudre rivers. The Loup river is the largest tributary of the Platte. The vast quantities of water diverted for irrigation agriculture and for municipal use are the most significant aspects of the Platte river system.

(M. J. L.)

PLATTSBURGH, a city of Clinton county, N.Y., U.S., on the west shore of Lake Champlain. Plattsburgh is surrounded by beautiful scenery: the broad island-studded lake in front, the Green mountains beyond, and on the southern horizon the distant Adirondacks. South of the city is Plattsburgh air base, a unit of the U.S. Strategic Air Command. Part of the base occupies the site of an army post established in 1815 where reserve officers were trained during World War I. After World War II the first university for U.S. veterans was established there; it later became a unit of the State University of New York and was eventually disbanded. Lccated in the centre of Plattsburgh is a college of education which originated in 1889 as a normal and training school and which became a unit of the State University of New Tork in 1949. Plattsburgh is a recreational area and marketing and manufacturing centre of pulp, paper and allied products. The city was founded by Zephaniah Platt (1740–1807), who brought a colony from Long Island. Recognized as a town April 4, 1785, it was incorporated as a city in 1902. The opening naval engagement of the American Revolution (a victory for the British) took place at Valcour Island 5 mi. S.E. of Plattsburgh on Oct. 11, 1776. In the War of 1812 the city was the headquarters of the U.S. army on the northern frontier. In Sept. 1814, the village was besieged in what was planned to be a joint attack by sea and by land; on Sept. 11, Commodore Thomas Macdonough and the U.S. forces defeated the invading British fleet and the British army, deprived of naval support, retreated. See WAR OF 1812. For comparative population figures *see* table in *NEW* YORK: *Population.* (*G. L. F.*)

PLATYHELMINTHES or PLATODARIA, a phylum of invertebrate animals, containing soft-bodied creatures which are bilaterally symmetrical and usually somewhat flattened in shape, and in which there is no true "coelom" or perivisceral cavity and no true (metameric) segmentation. The animals contained in this group (flatworms) are the simplest and probably the most primitive of those in which the tissues and organs of the body are developed from three, instead of two, original embryonic layers.

The external covering of the body is typically a cellular or syncytial epidermis providedwith vibratile cilia. These serve partly for locomotion and partly for creating currents to be tested by the sense organs. In the adults of certain parasitic groups, the epidermis is replaced by a smooth or spiny cuticle. Pigment is commonly present beneath the epidermis in free-living forms, but is usually absent in those which are parasitic. The spaces between the internal organs are for the most part filled up with a kind of loose connective tissue called the parenchyma. A coelom is absent. The musculature of the body is mainly peripheral, consisting of layers of transverse, longitudinal and often also oblique muscle-fibres running beneath the epidermis.

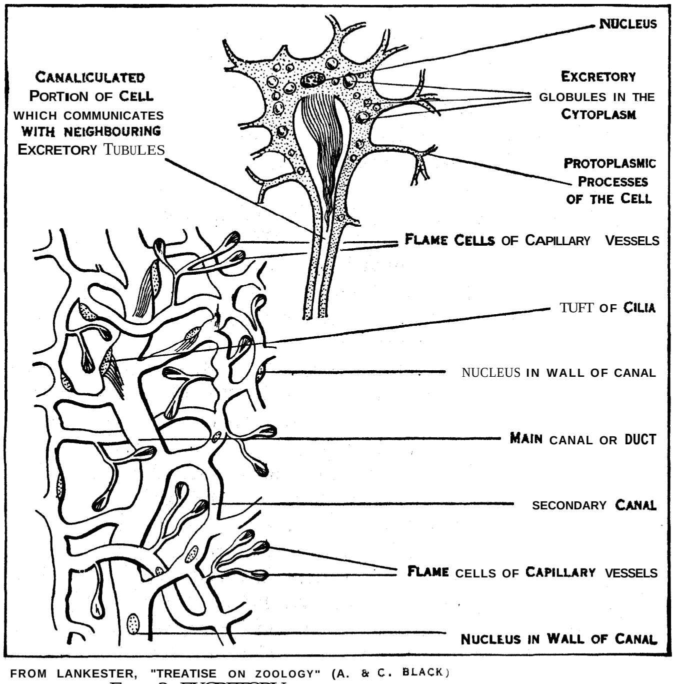


AFTER KERBERT, IN "ARCHIV FUR MIKROSKOPISCHEN ANATOMIE" (FRIEDRICH COHEN)

FIG. 1.—SECTIONAL PORTION THROUGH THE BODY OF A TREMATODE (PARAGONIMUS), SHOWING STRUCTURE OF TISSUES

These muscles render the body capable of extreme elongation and contraction, and often of surprising variability in shape.

Anterior and posterior ends of the body can usually be distinguished, the animals having a definite direction of locomotion, accompanied by a greater degree of specialization of the anterior extremity. Dorsal and ventral surfaces are also generally distinguishable, the latter being that on which the animal creeps, and on which the oral and genital apertures are commonly situated. In the parasitic flatworms special clinging organs are generally developed, in the form of muscular suckers, often supplemented by cuticularized hooks or spines.



FROM LANKESTER, "TREATISE ON ZOOLOGY" (A. & C. BLACK)

FIG. 2—EXCRETORY SYSTEM OF A PLATYHELMINTH

Below, diagram of a portion of the excretory system showing branching ducts ending in flame cells. Above, a single flame cell more highly magnified

An alimentary canal may or may not be differentiated. When present, it may either be a simple saclike organ or may be variously branched. With very few exceptions, its only aperture is the mouth, which may be situated subterminally, near the anterior end, or much further back, sometimes even behind the middle of the body. The mouth may be surrounded by an oral sucker, and usually a highly muscular, often protrusible pharynx intervenes between mouth and intestine.

The main ganglia of the nervous system (the "brain") and the chief sense organs are generally concentrated towards the anterior end. In addition to tactile papillae or special sensory cilia, "eye-spots" or ocelli are frequently present in free-living forms, and sometimes in the free-living larval stages of parasitic forms. In certain free-living flatworms *statocysts* (saclike organs containing minute calcareous nodules or *statoliths*) and ciliated pits, probably sensory in function, also occur.

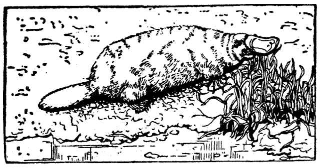
There is no blood-vascular system or haemocoele. The excretory organs consist of a branching system of canals ending internally in "flame-cells." These are minute pyriform structures containing cilia which keep up a constant flickering movement. The main collecting vessels of the system open to the exterior by one, two or many pores.

The Platyhelminthes are, with rare exceptions, hermaphroditic animals, each individual being functionally both male and female. The reproductive system is usually very complex. The male organs consist essentially of one or more (often very numerous) testes, whose ducts are usually connected with a protrusible intromittent organ (penis or cirrus). The essential organs of the female apparatus are an ovary (sometimes multiple ovaries) and a tubular duct communicating with the exterior. The arrangement of the parts of the female system is subject to great variation in different groups. In some cases (most cestodes) the only communication with the exterior is a vagina, which is connected internally with an oviduct leading from the ovary to a saclike uterus! but does not serve for the expulsion of eggs. In such forms the eggs are either shed only by the dehiscence of the wall of the uterus and of the body wall, or by a special (temporary or permanent) birth-pore. In almost all flatworms there is a yolk gland or vitellarium (often multiple vitellaria), producing yolk cells which form nutritive material for the developing embryos. There is also usually a "shell gland," which usually secretes adhesive material for iastening eggs together or to a substratum. The ducts of these glands open into the oviduct or into a specialized portion of it called the ootype. The external apertures of the male and female ducts are sometimes separate, but frequently both ducts open into a common "genital atrium," which is often muscular. Not infrequently a special duct and pore for copulatory purposes are present.

The Platyhelminthes are extremely widely distributed, free-living forms occurring in almost every kind of environment—in shallow or deep water, both fresh and marine, and on land—while parasitic forms occur on or in animals of almost every class. The free-living forms usually feed actively on small animals or plants. The parasitic forms show various degrees of modification in habits, some being external parasites and feeding on mucus or other matter derived from the skin of their hosts, while others are internal parasites and feed on partly digested food or on body fluids. Among the latter class some are without special digestive organs and can only feed by the absorption of liquid nourishment.

The phylum is usually considered to include three main divisions or classes: (1) Turbcllaria (including Temnocephalidea), the majority of which are free-living, but some parasitic. This group is probably nearest to the primitive ancestral form. (2) Trematoda (flukes), all of which are wholly or partly parasitic either upon or within other animals. (3) Cestoda (tapeworms), all of which are wholly endoparasitic. *See* TAPEWORMS, TREMATODES, TURBELLARIA. (H. A. B.; X.)

PLATYPUS, a remarkable Australian aquatic mammal belonging to the primitive subclass Monotremata (*q.v.*). The duckbilled platypus (*Ornithorhynchus anatinus*), the only species, is oviparous; two eggs, $\frac{3}{4}$ in. long and $\frac{1}{2}$ in. wide, each enclosed in a strong, flexible, white shell, are produced at a time. The animal shows many primitive features; there are no true teats in the female, the milk glands being probably modified sweat glands; the body temperature is relatively low. The platypus inhabits the streams and rivers of southeast Australia and Tasmania. About 20 in. long, it is clad in short, dense fur of a deep brown above, paler below. There are no teeth in the adult, their purpose being served by horny prominences, two on each side of each jaw. The broad horny muzzle is very beaklike. In the cheek are capacious pouches. The limbs are short and strong, each with five claw-bearing toes. In the forefeet, the web extends far beyond the ends of the claws, but it can be folded back on the palm when the animal comes out on to the land. On the heel of the male is a movable horny spur, perforated by a canal which communicates with a poison-gland. The platypus forms deep burrows in the banks, in which it sleeps and brings up its young, the entrance being under water. The food consists of aquatic insects, Crustacea and worms. The animal is nocturnal.



PLATYPUS (ORNITHORHYNCHUS ANATINUS), AN EGG-LAYING MAMMAL

See H. Burrell, *Platypus* (1927); D. Fleay, *Animal Kingdom (1944)*.

PLATYRRHINA, the name applied, in contradistinction to Catarrhine (*q.v.*), to the new world monkeys. The name (New Lat. platys, "wide'!; Gr. rhinos, "nose") refers to the broad septum between the nostrils.

See PRIMATES.

PLAUEN, a town of Germany, in the district of Karl-Marx-Stadt. Pop. (1950) 84,438. Plauen, probably founded by the Slavs, is first mentioned in 1122. It passed under the authority of Bohemia in 132i and came to Saxony in 1466, remaining united with the electorate after 1569. The manufacture of white goods was introduced by Swabian, or Swiss, immigrants about 1570.

It was formerly the capital of Vogtland, or Voigtland. a territory governed by the imperial vogt, or bailiff, and this name clings to the district. The fine Gothic church of St. John, with twin spires, was restored in 1886. The town hall dates from about 1550; and the old castle, Hradschin, is now a law court. Plauen manufactures embroidered white goods and makes lace. It manufactures much of the machinery used in the town and it has a trade in coal, yarn and cattle.

PLAUTUS (fl. late 3rd and probably early 2nd century B.C.) was the great comic dramatist of ancient Rome. Twenty-one plays (Amphitruo, Asinaria, Aulularia, Baechides, *Captivi*, Casinu, Cistellaria, Curculio, Epidicus, Menaechmi, Mercator, Miles Gloriosus, Mostellaria, Persa, Poenulus, Pseudolus, Rudens, Stichus, Trinummus, *Truculentus* and the fragmentary Vidularia) ascribed to Plautus have survived in the manuscripts (*i.e.,* the 4th-century Ambrosian palimpsest, known as "A," and various manuscripts of the 10th century and later, known as the "Palatine" family). According to Festus and Jerome he was born at Sarsina, in Umbria: his death occurred in 184 B.C. according to Cicero; in 200, according to Jerome. The two *didascaliae* (notes in the form of a preface) preserved in "A' are usually regarded as firm evidence that the *Stichus* was produced in 200 and the *Pseudolus* in 191; but see H. B. Mattingly, "The Plautine 'Didascaliae,"' Athenaeum (nuova serie), xxxv, pp. 78–88 (1957). According to Cicero, Plautus in his old age took great pleasure in his Pseudolus and Truculentus. This may be invention, indicating merely that these were popular plays in Cicero's day; but on it is founded the usual view that Plautus was born about 250 B.C. The only extant record as to his life is that of Aulus Gellius (based on Varro), the historical character of which is questioned by Friedrich Leo in his Plautinische *Forschungen* (2nd ed.; 1912). It is probably invention or mistaken inference, but the record may be near the truth in stating that from an early age Plautus was connected with the theatre (perhaps as an actor). The prologue to the *Asinaria* gives the author's name as Maccus; the prologue to the Mercator gives it (in the genitive) as mactici (Macci *Titi*?); at the end of the Casinu in "A" it is given (in the genitive) as T. Macci *Plauti.* The poet Accius, however, seems to have distinguished between Plautus and Titus Maccus. It will be remembered that Maccus was the clown in the Atellanue *fabulae* (*q.v.*) and that Plautus is said by Festus to mean *planis pedibus* (cf. *planipes,* "mime"). The other prologues which give the name give it as "Plautus."

There is no certain evidence as to the dates of the plays. *Cistellaria* (201 ff.) refers to approaching victory over the Carthaginians. The supposed reference in Miles Gloriosus (211 ff.) to the imprisonment of the poet Naevius is perhaps itself the source of that story. Evidently Plautus' plays were popular and were revived after his death (see the post-Plautine prologue to the Casinu). The works of other dramatists came to be attributed to him; by Varro's day the number of his plays had risen to 130. Varro made out a list of 21 (evidently those now known) which he said were universally agreed to be genuine (perhaps on grounds of style); others he himself accepted on grounds of style but did not include in the 21; still others he rejected. He can scarcely have been right in excluding the Commorientes (attested as Plautine by Terence and Accius) and, perhaps, the *Colax,* mentioned by Terence as either partly or doubtfully Plautine.

Attempts to arrange the plays in chronological order, on the evidence of topical allusions, metrical development, etc., must be regarded as speculative. What one scholar thinks a topical allusion by Plautus another will ascribe to the Greek original and yet another to a post-Plautine hand. Metrical variety is indeed characteristic of Plautus; but the prominence of the so-called "lyrical" metres might just as plausibly be attributed to the poet's youth as to his age. (*See,* however, W. B. Sedgwick, "The Origin and Development of Roman Comic Metres," *Classica* et *Mediaevalia*, 10, pp. 171–181, 1949).

Indebtedness and Originality. — The plays of Plautus are based on Greek originals of the New Comedy, of which original examples are to be found in the fragments of Menander (including the Dyscolus, discovered in 1956). But Plautus was not a mere translator. This was shown by K. M. Westaway (The Original Element in Plautus, 1917) and Eduard Fraenkel (Plautinisches *im* Plautus, 1922); later, Italian scholars pointed to the vitality and verve which pervade all his work. On the other hand, there are passages in which he does not hesitate to take over allusions which can hardly have been intelligible to a Roman audience; *e.g.,* the reference in the Rudens to Stratonicus, a musician of the time of Alexander the Great. Terence refers twice to Plautus' "carelessness" as a translator, says that he omitted a scene from Diphilus' *Synapothnescontes* in his Commorientes and implies that he himself is following Plautus' example in his own practice of borrowing from a second original. Of large-scale remodeling there is no evidence; Aulus Gellius speaks rather of difference for the worse in style. Are the prologues mainly Greek, or Plautine, or post-Plautine? The romanization of the plays by way of allusions to towns in Italy, to the streets, gates and markets of Rome, to Roman magistrates and their duties and to Roman laws and the business of Roman law courts, banks, comitia and senate. etc., still leaves the structure Greek. Frank inconsistency is shown by his use, side by side, of the contemptuous expressions *barbarus* (applied to the Romans) and pergraecari, "to play the Greek" (applied to the Greeks). Frequently, as in passages in the *Aulularia,* the Poenulus and the Pseudolus, he seems to take delight in casting dramatic illusion to the winds.

But as an adapter for the Roman stage Plautus is nothing less than masterly. His command of Latin is such that his plays read like original works. Some of his characters stand out so vividly from his canvas that they have ever since served as representatives of certain types of humanity; *e.g.,* Euclio in the Aulularia, the model of Molière's miser. Alliteration, assonance, deft use of metre for dramatic effect, plays upon words and happy coinages of new terms give his plays a charm of their own. "To read Plautus is to be once for all disabused of the impression that Latin is a dry and uninteresting language," wrote Franz Skutsch in *Die Cultur der Gegenwart* (1905). It is a mistake to regard the Latin of Plautus as "vulgar" Latin. It is essentially a literary idiom. based upon the language of Roman society in his day.

Characters and Plots.—The characters in his plays are the stock characters of New Comedy (though there may well be a suspicion that he has heightened the farcical element, perhaps under the influence of native Italian farce). The finer insight into human nature and the delicate touch in character drawing which 'Terence presents in his reproductions of Menander may be missing. but there is wonderful life and vigour and considerable variety in Plautus' characters. Their language is often downright and sometimes obscene, but, as has been well said, "the coarseness of Plautus' plays is not as great as is sometimes supposed" (John N. Hough, "Miscellanea Plautina," *Transactions of the American Philological Association,"* 71, p. 186, 1940). The careful reader will take note of occasional touches of serious thought, examples of which are to be found in the *Pseudolus* (683 ff.); the *Stichus* (124); the *Rudens* (1235–1248), etc. The *Captivi* is the story of the heroic self-sacrifice of a slave; the *Amphitruo* is a mythological burlesque; the *Rudens* tells of shipwreck and treasure trove. But most of his plays depend for their main interest on intrigue. In the *Menaechmi* and *Amphitruo* and as a subordinate element in the *Bacchides* the theme of mistaken identity is to be found.

Metres.—In the metrical structure of his plays Plautus (no doubt following the earlier Latin dramatists) made an important change from the Greek model. The New Comedy had confined itself for the most part to the metre of dialogue (the six-foot iambic trimeter), occasionally relieved in moments of excitement by the trochaic tetrameter catalectic (seven and a half feet), which latter was accompanied by the pipe. Plautus greatly developed this trochaic metre in its Latin form (trochaic septenarius); it is actually more common than the iambic senarius (six-foot line), the only metre not accompanied by the pipe. But he used many other metres as well, all accompanied by the pipe; in fact the senarius or metre of unaccompanied speech (*diuerbium*) is only about half as common as the metre (whatever its form) of *canticum*, or declamation supported by the pipe. The *cantica* are not mere inserts or accessories, like the songs introduced in the Shakespearean drama; they comprise two-thirds of the text. The effect was probably not that of full song but rather that of the recitative "patter" of W. S. Gilbert, in which the words and rhythm are important and the music simply supports the rhythm. In *Stichus* (758 ff.) the piper (*tibicen*) is given a drink, and while he is drinking the metre changes for seven lines to iambic senarius. The *tibicen* was on the stage throughout the play; in *Pseudolus* (573a) he is asked to supply a solo.

The origin of the *cantica* has been much debated. Leo put forward the view that Plautus derived their metrical structure from contemporary Hellenistic music-hall songs; Fraenkel suggested that some earlier Latin dramatist had endeavoured to enliven comedy by introducing the metrical variety which he found in Creek tragedy; A. M. G. Little and others have sought the origin in Italian popular comedy (see *Harvard Studies in Classical Philology*, 49, p. 226, 1938). The individual metres employed were not indeed invented by Plautus; they are adapted from Greek and are common to Roman tragedy and Roman comedy, however, Plautus handled them with peculiar literary and dramatic skill.

Reputation.—Plautus held the stage until the end of the republic. Aelius Stilo, Cicero's teacher, praised his Latinity. Cicero. though in the *Orator* he found fault with the iambics of the Latin comedians generally as *abiecti* ("slovenly"), admired Plautus' type of wit as *elegans, urbanum, ingeniosum, facetum.* Varro ranked him above all other Latin comic dramatists for dialogue. Horace in the *Ars Poetica* is a more severe critic: he is impatient with the taste of an earlier age which had admired Plautus' command of rhythm and jest, and in *Epistles* ii he accuses Plautus of carelessness in character drawing and indifference to everything except box-ofice success. The mime seetns to have driven Plautus off the stage during the empire (though a ticket has been found at Pompeii giving admission to a performance of the *Casina*, and Arnobius says that the *Amphitruo* was performed in the reign of Diocletian). But he was still read; Aulus Gellius praises his style; Sidonius Apollinaris ranked him above the Greeks in wit; Jerome, after a night of weeping over his own sins, would console himself by reading Plautus; Eusebius praised him. In the middle ages he seems to have been best known as the supposed author of the *Querolus* (5th century A.D.?). Only the first eight of his plays were known to Petrarch and other scholars at the beginning of the Renaissance: but in 1429 Nicolaus Cusanus brought to Rome a manuscript containing the 12 later plays; this event gave a strong impulse to the study of Plautus, who took rank as one of the great dramatists of antiquity.

Influence on Modern Literature.—Carl von Reinhardstoettner in his *Spätere Bearbeitzrngen plautinischer Lustspiele* (1886) deals at length with the influence of Plautus on modern literatures. In the 15th century Italian scholars were producing Plautus' plays, new Latin plays and new Italian comedies (the *commedia erudita*) based on Plautus and Terence. In 1484 the *Aulularia* was presented on the Quirinal. An important play on the theme of the *Menaechmi* was *Gl'Ingannati*, by the members of the Sienese Academy; this was translated into Spanish as *Los Enganados* by Lope de Rueda. In the 16th century Plautine influence was strong in Germany. Holland and France. In England the *Menaechmi* was performed by the boys of St. Paul's school in 1527. Nicholas Udall's *Ralph Roister Doister*, the first English comedy. was written about 1552; it is based on the *Miles Gloriosus*. Shakespeare's *Comedy of Errors* (about 1591), based upon the *Menaechmi*, with additional material from the *Amphitruo*, is thought to reflect the poet's Latin studies at school; his Falstaff and Parolles and Ben Jonson's Captain Bobadil owe much to the Plautine braggart warrior; the *Taming of the Shrew* has been influenced by the *Mostellaria*. In *Hamlet* II, ii. 377–382, Polonius says "The best actors in the world . . . Seneca cannot be too heavy nor Plautus too light." Ben Jonson's *The Case is Alterd* (1609) is adapted from the *Captivi* and the *Aulularia*. Thomas Heywood adapted the *Amphitruo* in his *Silver Age* (1613), the *Rudens* in his *Captives* (1624) and the *Mostellaria* in his *English Traveller* (1633) John Dryden's *Amphitryon* (1690) is based partly on the Latin *Amphitruo* but chiefly on Molière's adaptation. Henry Fielding's *Miser* (acted 1732) rests on Moliere's *L'Avare* rather than on the *Aulularia*. In 1929 Jean Giraudoux scored a resounding success with his *Amphitryon 38*, based on the *Amphitruo*.

PLAY: *see* DRAMA; *THEATRE*.

PLAY, ANIMAL. At the beginning of any discussion of play in animals it is necessary to emphasize the fact that understanding " the subject is extremely limited. The factual evidence consists exclusively of descriptions of a wide variety of responses that have been lumped arbitrarily together in the category of play. The explanations and interpretations are speculative, deductively derived and untested. Some of the theories purporting to elucidate the causes and results of play are emotionally appealing but scientifically unsound; others appear plausible and may be valid, but none has been subjected to objective verification.

Characteristics of Play.—The general characteristics of playful behaviour in animals as set forth by most students of the subject can be stated briefly: (1) It is almost universally agreed that in animals, as in men, playful responses carry an emotional element of pleasure. (2) Play is characteristic of the immature animal rather than of the adult; mature individuals sometimes play, but it is generally believed that they do so less frequently than juvenile members of their species. (3) The majority of students concur in the belief that play differs from nonplayful activities in having no immediate, utilitarian result affecting the continued existence of the individual. (4) The type of play is characteristic of the species; furthermore, the nature and amount of play exhibited by members of a particular species vary according to evolutionary position. (5) Play is more common, occurs during a greater portion of the life span and appears in more diversified form in the higher animals than in the lower.

These generalizations refer to the commonly accepted characteristics of play. They are descriptive rather than analytical; and they cannot be used as explanations or interpretations.

Types of Behaviour Regarded as Play.—General Bodily Activity.——Young children take delight in racing about a room at top speed, stamping violently upon the floor, shouting loudly in utter abandon. Many young animals display similar behaviour. Colts, calves, kids, puppies and kittens expend vast amounts of energy in vigorous locomotor activity to no apparent biologically useful end. They gallop, run, bound and gambol to the point of apparent exhaustion. Many observers regard this behaviour as a form of play. It is assumed to constitute an outlet for surplus energy, to bring pleasure to the performer and to lack any practical purpose.

Youthful Practice of Adult Activities.—The African lion cub lies in hiding and creeps forth, belly close to the ground, to stalk and leap upon an unsuspecting brother or sister. Two puppies wrestle and roll in mock combat, sinking tiny teeth into thick fur and uttering infantile growls. Twin lambs face each other with heads lowered and forefeet pawing the earth; charging forward, they meet head-on and tumble awkwardly on the grass. The common element in such activities lies in their resemblance to similar behaviour patterns the animal will display in somewhat different form later in life.

There are, however, several significant differences between the behaviour of the young and the adult individual. These responses, when they appear during infancy, do not terminate in the same result they will achieve in the adult stage. The kitten's chase of a ball or a blowing leaf mirrors the cat's pursuit of a mouse; but in one instance food is obtained and in the other it is not. The puppy's battle with his brother reflects the adult dog's combat with other grown animals; but in the infant's struggle no damage is inflicted. The young animal's performance is often imperfect and incomplete; whereas that of the adult is relatively polished and well integrated. From such observations it was deduced by Karl Groos arid others that this type of play serves to prepare the animal for a more efficient adult life. It is thought that incomplete and imperfect instincts are modified, strengthened or suppressed during the practice period of youthful play. C. Lloyd Morgan suggested that the play period of infancy permits the practice of vital responses under conditions in which error and incompleteness are not fatal. The perfection of essential reactions is thus held to take place before the animal is subjected to the exigencies of an independent existence, wherein the forces of natural selection are constantly operating to weed out inefficiency and the penalty for error may be sudden death.

It seems probable that this theory may hold good for the play of certain higher mammals. The chimpanzee, for example, passes through a lengthy period of infancy and childhood during which a number of highly imporrant reactions are exercised and possibly organized into biologically effective form. There is, however, no proof that the generalization may correctly be extended to include all examples of this type of behaviour. The kitten's play with small, moving objects may indeed improve its abilities as a mouser, but there is no factual evidence to prove or disprove the assumption. In some cases youthful practice is demonstrably unnecessary. It is certain, for example, that the common sex play of some animals, such as the immature rat, has no demonstrable effect upon the efficiency of adult mating performance. The existence of a preparatory function of play can be established only by direct test of each activity in each species.

Exploration and Experimentation.—Young animals often peck, scratch, claw, pull and bite at objects in their environment, and such activities are sometimes classified as experimental play. The puppy's destructive attentions to a book or pillow are interpreted as play that serves to acquaint the animal with the properties and potentialities of the object thus investigated. Similarly, certain reactions of the young animal to its companions can be listed under the heading of exploratory or experimental play. An eventually practical outcome of such behaviour is held to lie in its tendencies to promote the development of new modes of conduct and to inhibit biologically dangerous reactions. Although this assumed function of exploratory play is based chiefly upon a priori reasoning, there are some instances in which it can be shown to exist. Wolfgang Kohler reported that captive chimpanzees given stout sticks or poles soon devised a crude form of vaulting or jumping, using the pole as a sort of crutch. Originally this response was apparently indulged in as a form of amusement and nas not used as a means of achieving any secondary objective. Although further test and observation would be necessary to establish the point, it seems probable that the pole vaulting response was a form of play and the outgrowth of experimentation with the stick. Later, however, when the chimpanzees were confronted with the problem of obtaining a banana suspended above their reach, they quickly turned the vaulting technique to good use, employing it as a means of getting the fruit.

Social Play.—Young British warblers are describec! as engaging in "tilting matches," during which each bird commands a perch and attempts to dislodge other birds from theirs. African lion cubs play "king of the mountain." When one assumes possession of a high spot of ground or climbs on top some low object, all others try to force him off and take his place. "Follow the leader" games occur in the repertory of several mammalian species. Otters have been observed sliding down muddy banks into the water, one after the other in quick succession, and then climbing out to repeat the performance time and again.

Young monkeys in the jungle often swing single file through the branches, each copying roughly the actions of the animal ahead of him.

The group play of chimpanzees is highly diversified, anti often resembles certain human activities. Kohler's description of "dancing" is illustrative. Several chimpanzees start to march in single file around a box or post. Gradually their pace quickens, and they trot, often with emphasis upon one foot, so that a primitive kind of rhythm emerges; and as they trot and stamp the animals wag their heads in time with the rhythm. Other kinds of social play occur in this species; and 0. L. Tinklepaugh suggested that this type of behaviour early in life enhances the individual's adaptability and co-operativeness, both of which are essential characteristics of the chimpanzee.

Play Between Species.—Although young animals of one species may investigate those of a foreign species, they do not often play together. Exceptions to this generalization sometimes occur when two domesticated animals are reared together.

Thus a dog and a goat may engage in mock battles if they have been associated long enough to establish friendly relations, so tc speak.

The outstanding type of interspecies play is that which occurs between man and his pets. If any of the criteria of play that have been accorded common use are to be accepted, it must be agreed that the dog frequently plays with his master. The dog may enter into mock chases or battles with a man much as he would mith another dog. On the other hand, he will with equal willingness participate in a learned game such as fetching the ball or performing tricks without any material reward. It is significant that the animal may initiate the play and in many different ways signalize his desire to stimulate playful relations with the human partner.

Explanations of Play.—Several theories have been formulated in an attempt to elucidate the causes of playful behaviour. None is completely satisfactory although several are partially serviceable.

Surplus Energy Theory.—This holds that play is a safety valve, providing an outlet for unused vigour. This interpretation has little to recommend it. Energy is not stored up in the organism like water in a reservoir. Animals are either completely rested and ready to react quickly to stimuli from the environment, or they are tired and sluggish in their responses. All types of behaviour occur more promptly and persist longer in the rested individual.

The energy expended in play differs in no way from that used in nonplayful pursuits.

Joie-de-Vivre Theory.—A second attempt to explain play is found in the *joie-de-vivre* theory, which interprets play as the expression of a general exuberance, an overflowing enthusiasm for life itself. A serious objection to explanations of this type is that they add nothing to basic understanding of natural phenomena; they explain nothing. They involve merely the substitution of one word or phrase for another, although the meaning or significance of the new term is no more precise nor illuminating than the old.

Instinctive Theory.—The instinctive theory of play in animals was championed by Karl Groos, who interpreted all play as responses based upon inherited tendencies or predispositions. However, to label an act as "instinctive" is not to explain it; and although the form that play takes in various animal species is unquestionably influenced by hereditary constitution, the serious student of behaviour is still faced with the responsibility for determining the stimuli that evoke playful responses, identifying the physiological and psychological processes that mediate the behaviour, and describing in objective terms the eventual effects and results.

Future Theories.—Although no completely satisfactory explanation for the occurrence of play in animals is available, it is possible to predict with reasonable certainty the form which such a theory must assume.

1. In the first place it is obvious that no single hypothesis can be formulated to explain all forms of play in every animal species The types of activity that have been labeled "play" are so variable in form and complexity that a different interpretation is indicated for each major category.

2. It must be recognized that playful behaviour differs from nonplayful pursuits in subtle and often elusive fashion. There is no sharp border line between play and work for animals or for man. The two types of activity merge insensibly one into the other, and some complex responses may be partly play and partly work. Therefore, any acceptable definition of play must be based upon a list of predominating characteristics that combine to set it off from nonplayful behaviour, and cannot be derived from adherence to a single, rigid criterion such as nonutilitarianism or imperfect, juvenile performance. It is, for example, permissible to state that playful reactions as a class tend to lack the immediate. biologically practical results that normally accompany nonplayful responses, but it is not permissible to set up as an inflexible rule the dictum that no activity is play if it achieves a useful end.

3. Play must be explained in purely objective terms. A small start in this direction was made by workers such as J. B. Cooper, who suggested that the playful execution of certain behaviour patterns is characterized by the absence of the consummatory phase and by the rapid shift from one element of the pattern to another. Cooper noted that the play of lions is more prevalent on cool days, and tends to occur most frequently following a major change in the environmental situation (such as release of the animals from an indoor cage, the introduction of new lions into the pride, or the sudden appearance of the keeper). Much more extended analysis along lines such as these will provide the basis for an interpretation of play that is biologically significant and subject to direct test and verification.

The play of human beings is no more clearly understood than is that of lower forms, and the careful study of animal play offers potentially important results in the increased understanding of similar behaviour in man See also ANIMAL BEHAVIOUR; PSYCHOLOGY, COMPARATIVE.

PLAYER-PIANO, a piano equipped with a mechanical device for automatically playing written music or for reproducing the playing of a pianist. All types of player-piano mechanism are operated by utilizing the difference between external and internal air pressures. In fig. 1, the tracker-bar, T, with its 88 holes, is represented as being closed by the paper roll, R, which lies closely against it. Some of the air has been extracted from the duct, D, and from the chamber, C, by means of an air-exhaust to which they are connected. These is a very tiny vent, V, which allows air from the tracker duct to leak into the chamber. A disk, K, closes the chamber from the outer air, being held down because the air in C, is at a lower pressure than normal. The pneumatic, B, is full of air at normal atmospheric pressure and is open to the external air by means of the port, A.

Should a hole in the paper come into line with any hole in the tracker-bar, the external air rushes into the duct and lifts the pouch, P, which is simply a circular piece of soft kid about $\frac{3}{4}$in. in diameter, and bigger than K. Hence it lifts K, connecting the pneumatic with the partial vacuum, C, and disconnecting it from the external air by closing the port A. The air in B spreads to C and, the external pressure on the surface, S, being greater than the reduced pressure inside, the pneumatic collapses suddenly, the movable leaf rising and lifting with it the pilot, L, which operates the piano action.

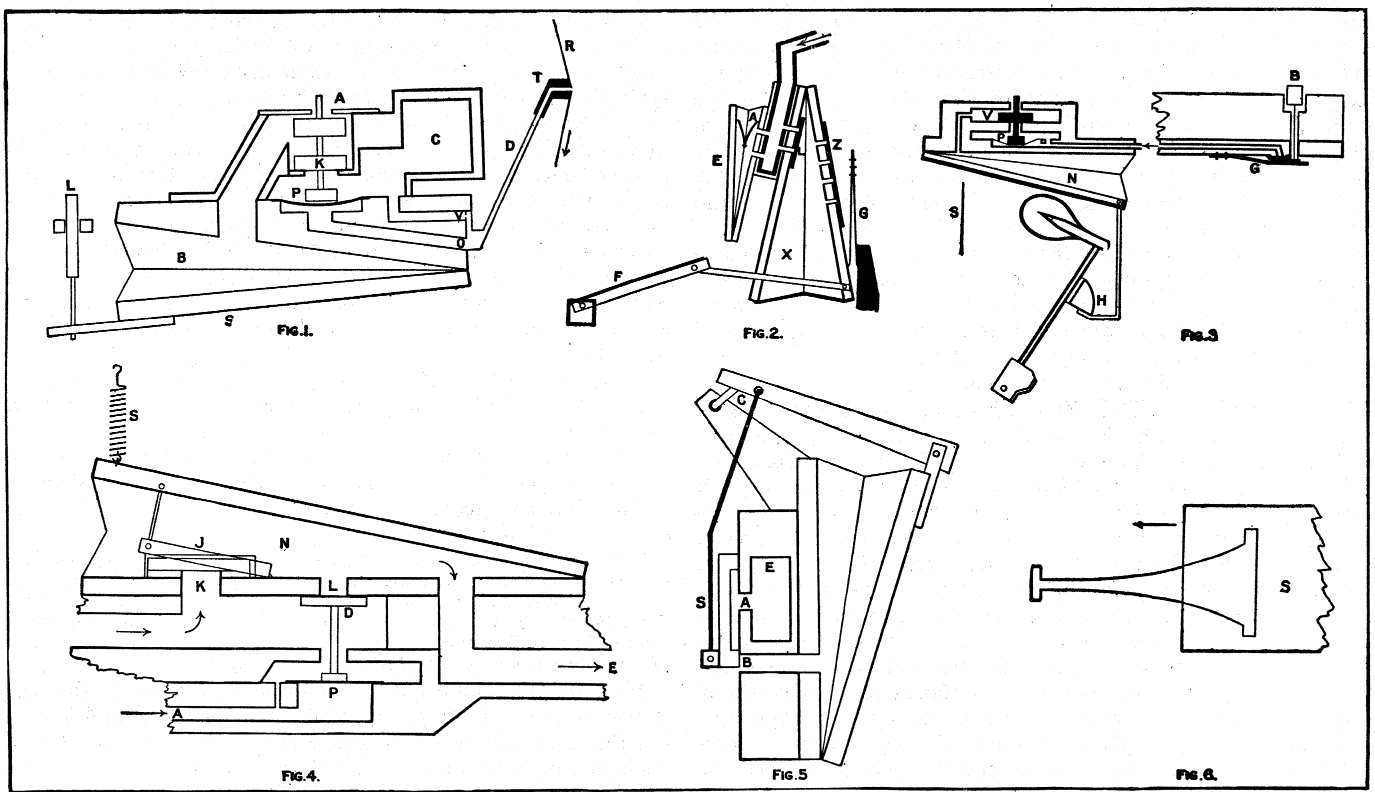
The pneumatic remains collapsed until paper again blocks the hole in the tracker-bar. The air in D then leaks through into C and can no longer hold up the pouch, which falls back into position and allows K to close the chamber C again, at the same time opening the pneumatic to the external air at A. The external and internal pressure on S now being the same, the pneumatic reinflates and allows the pilot to drop back into position.

In the days of heavy and clumsy valves it was difficult to provide the necessary power to lift them rapidly without hard pedalling and consequent loud tone. To overcome this defect the more expensive player action was provided with an additional (or primary) valve of light construction, easily lifted by the inrush of air when a hole was opened on the tracker-bar. Its lifting admitted air to the other and heavier valve, through the port O, operating the striking pneumatic as previously described. Both single and double valve systems are still in use.

The interior of the player action is maintained. in a steady state of reduced pressure by forcing the pedal, F, to open the exhaust, X (fig. 2). This allows all the interior air to spread itself into X past L, a flat strip of well-tanned leather, lying over holes. A fan spring, G (about 12lb. in strength), then closes the exhaust, expelling the air via another flap valve, Z. A strong spring, A, is always trying to open the equalizer, E, but is prevented from so doing when the external air pressure is much greater than the reduced pressure inside. When, however, there is not much difference between the external and internal pressures, the spring can open and in so doing allows air to spread into it from the interior. The effect is to reduce the internal pressure once more to such an extent that the equalizer begins to collapse. Its constant to-and-fro motion enables a steady amount of reduced pressure to be mairtained in the interior channels, despite unsteady working of the pedals.

Controls.—The simplest method of operating the "soft" and "sustaining" pedals is to connect the ordinary mechanism of the piano, by suitable levers, to finger controls in front of the keyboard. Many manufacturers prefer to control the distance from the hammers from the strings as shown in fig. 3. A button, B, opens a gate, G, when pressed down. This admits air to a pouch, P, which lifts the valve lying above it, and puts the pneumatic, N, into communication with a partial vacuum, V, thus collapsing it and causing it to lift the hammer rail, H, which softens the tone by giving the hammerhead less distance to travel towards the string, S.

A similar device withdraws all the dampers from the strings. This being a heavier task than shifting the hammers, a larger



MECHANISM OF THE PLAYER-PIANO. THE FIGURES AND LETTERS ARE EXPLAINED IN THE TEXT

pneumatic has to be employed, and two valves instead of one. Music rolls are provided with an additional hole at the left-hand edge, which works the lifting of the dampers, if desired.

Change of power, in addition to the means above described, is provided by varying the strength of the blow given to the hammer. Fig. 4 shows how the normal amount of reduced air is altered by interposing a pneumatic, N, between the main exhaust, E, and the small playing pneumatics. Pressing a button (as in fig. 3), air is allowed to enter at A, the pressure from which lifts the pouch, P, and with it the valve, D. This closes the large hole, L, and leaves only the aperture, K, over which lies a knife-cutter valve, J, so called because it closes like the blade of a pen-knife. The spring, S, is of such strength that it governs the amount of air passing through to the bellows, hard pumping closing N and therefore closing the aperture K and preventing loud playing.

A slight alteration of fig. 4 would give a fair representation of the automatic Accenting Device, which is worked from marginal perforations in the music roll. The valve disk, D, is moved to the other side of the hole, L, keeping it normally closed and softening the tone until a marginal perforation allows air to rush towards P. The pouch lifts the valve, opens L and accents the note.

The pedals also provide sufficient power to work the spool which draws the music roll over the tracker-bar. Five pneumatics of the type shown in fig. 5 are fixed at equal angular distances upon a crank-shaft, C, each one collapsing in turn and so driving the shaft round steadily. Collapse is effected when the hollow slide, S, is covering both of the ports A and B, for the pneumatic is then in direct communication with the main exhaust, through E. As the crank-shaft is thus moved round, the slide is raised, and no longer covers both ports. External air is admitted to the pneumatic, and the collapse of one of its neighbours provides the power to lower its slide and again get into communication with the main exhaust.

All communication between motor and exhaust is by way of a governor pneumatic; powerful pedalling tends to collapse it, but directly this happens a knife-valve partly closes the passage-way (as in fig. 4), and thus prevents the motor from "racing." Variation in tempo is secured by deliberately altering the size of the passage-way within an enclosure known as the Tempo Box. The shape of the slot is usually as shown in fig. 6, over which passes a slide, S. When half the area of the slot is covered, the speed of the motor is half its maximum, and so on, the slide being worked mechanically from the control board.

The holes in the paper roll being so close together, it is essential that they should track correctly, despite the effects of wear and weather. Correct tracking is controlled in ways which vary in detail, but usually depends upon the action of two pneumatics, kept under exhaust. Holes in the tracker-bar are so placed as to be uncovered when (and only when) the roll goes to one side, letting air into one of the pneumatics and causing it to open slightly, taking with it either tracker-bar or spool.

Reproducing Pianos.—The "reproducing" instruments are in a separate class, designed to reproduce faithfully all the shades of tempo and expression made by well-known pianists. All control is rightly withdrawn from the operator when using the specially cut rolls, but the same instrument may be used for ordinary rolls by putting the reproducing mechanism out of action. Additions to the normal player mechanism are mostly for the purpose of controlling more completely the comparative loudness or softness of individual notes. To do this effectively it is necessary to have as many grades of power as possible, to include smooth crescendo as well as sforzando effects.

The Ampico mechanism alters the size of the main passage-way (and hence the power) by means of a regulator valve, which is attached to a lever, controlled by a set of pneumatics under vacuum (three small "intensity" pneumatics above, balanced by a large "spring" pneumatic beneath). When marginal perforations connect up to the valves of the "intensity" pneumatics, these lift and allow the pneumatics to fill with air, thus exerting an up-push on the lever, raising the regulator valve and increasing the size of the passage-way. As these pneumatics lie along the lever, their lifting power depends upon position, those furthest from the fulcrum end being the most effective. When it is necessary for an intensity pneumatic to collapse again, another marginal perforation, connecting up to a "cancel" valve, admits air and allows this to happen. Further marginal perforations are provided, one for slow crescendo, and the other for fast crescendo, each connecting up to the same crescendo pneumatic, but in the latter case two ways are open for the air to escape, making the pneumatic collapse quickly. For "brilliant" or extra powerful performance, the Ampico can be switched over so as to close the slight "in-leak" provided on one of the three pumpers of the power mechanism. The whole system then works at maximum power. For subdued performance the main passage-way is blocked by a disk, operated pneumatically from a switch in the spool-box.

The Duo-Art (Aeolian Company) is essentially a theme and accompaniment expression arrangement, the former being at a higher dynamic power than the other. Each has a knife-valve control of the passage-way, operated by a set of four pneumatics, varying in their amount of possible collapse. In this way sixteen variants of power are obtained. There is also an "in-leak," closed by another knife-valve so as to get maximum power when the passage-way is already nearly full open. (S. A. H.)

PLAYFAIR, LYON PLAYFAIR, 1ST BARON (1818–1898), was born at Chunar, Bengal province, on May 21, 1818, and educated at St. Andrews, Glasgow, Edinburgh, University College, London, and under Liebig at Giessen, where he took his doctor's degree. Playfair translated into English Liebig's *Chemistry of Agriculture.* From 1841–42, he was chemical manager of the Primrose print-works at Clitheroe, and in 1843 was elected honorary professor of chemistry to the Royal Institution of Manchester. Soon after he was appointed a member of the Royal Commission on the Health of Towns, a body whose investigations may be said to have laid the foundations of modern sanitation. In 1845 he was appointed professor in the new School of Mines, and chemist to the geological survey, and thenceforward was constantly employed by the public departments in matters of sanitary and chemical inspection. For his services as special commissioner of the 1851 Exhibition, he was made C.B. From 1856 to 1869 he was proiessor of chemistry at Edinburgh University. In 1868 he was elected to represent the universities of Edinburgh and St. Andrews in parliament, and retained his seat till 1885, from which date until 1892 he sat as member for Leeds. In 1873 he was made postmaster-general, and in the following year, after the dissolution of parliament, was made president of a commission to inquire into the working of the civil service. Its report established a completely new system, known as the "Playfair scheme." From 1880, when Gladstone returned to power, till 1883, Playfair acted as chairman of committees. In 1892 he received a peerage, and in 1895 the G.C.B. He died in London, on May 29, 1898, and was buried at St. Andrews.

PLAYFORD, JOHN (1623–*c.* 1686), English musical publisher, was born at Norwich. From 1653 he was clerk to the Temple church, and from his shop in the Inner Temple issued most of the English music of his day. Of his own compositions the chief are numerous psalm tunes, the popular *Introduction to the Skill of Musick* (1654, 19 ed. 1730) and *The English Dancing-Master* (1651), a collection of airs for the violin used for country dances. which constitute a treasury of English national tunes.

See F. Kidson, *British Music Publishers.*

PLEADING, that branch of the law which governs the successive formal papers in which litigants in the opening stages of a lawsuit set forth the facts upon which they claim legal relief or challenge the claims of their opponents to such relief. *See* PRACTICE AND PROCEDURE. (C. E. CL.)

PLEASURE: *see* FEELING, PSYCHOLOGY OF; HEDONISM; ETHICS.

PLEBISCITE, a term borrowed from the French for a vote of all the electors in a country or given area, taken on some specific question. The most familiar example for the use of the plebiscite in French history was in 1852, when the *coup d'état* of 1851 was confirmed and the title of emperor was given to Napoleon III. Its essential characteristic, as distinguished from the referendum (*q.v.*), is this: a plebiscitary vote decides a specific question, *ad hoc* and *pro hac vice.* It is not, as in the case of the referendum, a normal method or procedure of voting applied on a general system to certain classes of legislation. In Europe its use has been almost wholly political and national.

As a means of settling the destination of populations and territories, this method was first used in the French Revolution to defend the wholesale annexations of territory made by the conquering French republic, and subsequently by Napoleon I. It was revived by Napoleon III and applied (successfully for him) in the case of Nice and Savoy, and (successfully for Victor Emmanuel) in the duchies of north Italy during the years 1859–60. The peace conference of 1919 proposed the taking of 17 plebiscites to settle difficult national questions, of which 8 were actually held. Of these the Turkish plebiscite in Transcaucasia was a farce, Others, which decided the fate of Allenstein Marienwerder, of the Burgenland, the attribution of the northern and southern zones of Schleswig, the partition of Upper Silesia, the fate of Klagenfurt and the economic destiny of Luxembourg had substantial and important results.

By a plebiscite of Jan. 14, 1935, the Saar, which had been administered by the League of Nations since 1920, voted to return to Germany.

Another plebiscite in 1947 favoured France but on Oct. 23, 1955, a third plebiscite rejected a Europeanization proposal leading to a Franco-German agreement on July 4, 1956, to reunite the Saar with Germany on Jan. 1, 1957.

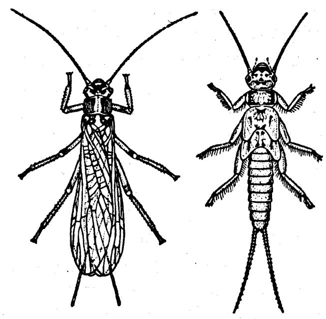
PLEBS, the "multitude." or unprivileged class, in the early Roman state (cf. Latin *plenus,* "full"; Gr. *plethos,* "multitude"). For the origin and history of this order *see* PATRICIANS. Its disqualifications were originally based on descent, but after the political equalization of the two orders these ceased.

PLECOPTERA (Gr. *plekos,* "plaited"; *pteron,* "wing") is the order of insects known as stone flies. The immature stages are aquatic, living in streams and rocky lake margins. The female lays several thousand eggs, discharging them in masses into the water. The nymphs are active and elongate, have long antennae and a pair of long "tails." Some forms have gills, but most do not. They feed on microorganisms, decaying organic matter or other insects. Nymphs may be found in clumps of rotted leaves, masses of debris or beneath submerged logs and stones. When mature, the nymph crawls out of the water and attaches itself firmly by its claws to a rock or tree trunk. The nymphal skin then bursts along the back and the adult emerges.



BY COURTESY OF THE ILLINOIS STATE NATURAL HISTORY SURVEY

STONE FLY (ISOPERLA CLIO)

(Left) adult, length about 0.8 in.; (right) nymph, length about 0.6 in.

The adults are soft-bodied and range in length from $\frac{1}{8}$ to $1\frac{1}{2}$ in., plus the tails. They have long, many-segmented antennae; a pair of "tails" (minute in some forms); and usually two pairs of membranous wings folded flat over the back. In a few species the wings are mere stubs. Most species are black or dark brown, but some are bright yellow or leaf green and others may be marked with orange or red. Stone flies fly rather slowly, but run actively. They are found on stones. foliage or tree trunks along the edge of a stream, or hiding in crevices of bridges or bark. Most species emerge from the water in spring, but there is a fairly large group of winter species, and a few in summer and autumn. Most adults do not feed, but some species eat algae, pollen and bud exudates. All forms are important as fish food and in general stream ecology. Both adults and nymphs are best collected in 80% alcohol.

The order Plecoptera contains about 1,200 species classified in nine families, distributed throughout the world. There are about 450 species in North America, 34 in the British Isles. Australia and New Zealand contain many primitive forms.

Fossil stone flies appear first in the Permian period, but are reasonably common only in the middle Tertiary amber of the Baltic region of Europe.

PLEDGE or **PAWN,** in law, a "bailment of goods by a debtor to his creditor to be kept till the debt is discharged" (Jones on Bailments). The term is also used to denote the property which constitutes the security. Pledge is the *pignus* of Roman law from which most of the modern law on the subject is derived. It differs from hypothecation and from the more usual kind of mortgage in being confined to personal property, and also in that the pledge is in the possession of the pledgee. A mortgage of personal property, in the majority of instances, takes the name and form of a bill of sale (*q.v.*). In the case of a pledge, it is held that a special property passes to the pledgee, sufficient to enable him to maintain an action against a wrongdoer, but the general property, *i.e.*, the property subject to the pledge, remains in the pledgor. As the pledge is for the benefit of both parties, the pledgee is bound to exercise only ordinary care over the pledge. He must, however, insure against loss by fire (3 5/36 Vict. ch. 93, s.36). The pledgee has the right of selling the pledge if the pledgor makes default in payment at the stipulated time.

The law of Scotland as to pledge generally agrees with that of England, as does also that of the United States. The main difference is that in Scotland and in Louisiana a pledge cannot be sold unless with judicial authority. Chattel mortgages, which differ from pledges in that the owner retains possession of the article, are uniformly required to be recorded in order to be valid against third parties, but except for a few States and aside from the Factors acts, a pledge, for the validity of which possession must be transferred to the pledgee, will be enforcible against third parties without being recorded. (See also FACTOR and PAWNBROKING.)

PLEDGE OF ALLEGIANCE TO THE U.S. FLAG. This pledge was first published in the juvenile periodical *The Youth's Companion* on Sept. 8, 1892, in the following form: "I pledge allegiance to my Flag and the Republic for which it stands: one nation indivisible, with liberty and Justice for all." The words "the Flag of the United States of America" were substituted for "my Flag" in 1924, and the pledge was officially recognized by the C.S. in 1942. In 1954 "under God" was added, making it read: "I pledge allegiance to the fag of the United States of America and to the Republic for which it stands, one Nation under God, indivisible, with liberty and justice for all." A controversy arose concerning the authorship of the pledge of 1892. Claims were made on behalf of both James B. Cpham, one of the editors of The *Youth's* Companion, and Francis Bellamy, an assistant editor. In 1939 a committee of the U.S. Flag association ruled in favour of Bellamy, however, and a detailed report issued by the Library of Congress on July 18, 1957, concluded that "the Bellamy claim to authorship rests upon the more solid ground."

See also LOYALTY.

PLEHVE, VIATSCHESLAF KONSTANTINOVICH (1846–1904), Russian statesman, was born of Lithuanian stock in 1846. He was educated at Warsaw and at the university of St. Petersburg (Leningrad) before he entered the department of justice, in which he rose rapidly to be assistant solicitor-general in Warsaw, then solicitor-general in St. Petersburg, and in 1881 director of the state police. As assistant to the minister of the interior he attracted the attention of Alexander III. by the skill he showed in investigating the circumstances of the assassination of Alexander II. He received the title of secretary of state in 1894, became a member of the council of the empire, and in 1902 succeeded Sipiaguine as minister bf the interior. Plehve carried out the "russification" of the alien provinces within the Russian Empire, and earned bitter hatred in Poland, in Lithuania and especially in Finland. He despoiled the Armenian Church, and oppressed the Armenians of the Caucasus. He certainly did nothing to discourage pogroms against the Jews, and he was credited with being accessory to the Kishinev massacres. His logical mind and determined support of the autocratic principle gained the tsar's entire confidence. He opposed commercial development on ordinary European lines on the ground that it involved the existence both of a dangerous proletariat and of a prosperous middle class equally inimical to autocracy. He was a determined and successful opponent of Witte's policy. An attempt was made on his life early in 1904, and he was assassinated on July 28 of the same year by a bomb thrown under his carriage as he was on his way to Peterhof to make his report to the tsar; the assassin, Sasonov, was a member of the socialist revolutionary party.

PLEIAD, in Greek literature, the name given (by analogy from PLEIADES) by the Alexandrian critics to seven tragic poets who flourished during the reign of Ptolemy Philadelphus (285–247 B c.). In French literature, in addition to the Pleiad of Charlemagne, there were two famous groups of the kind. The first, during the reign of Henri III. (1574–89), the chief member of which was Pierre de Ronsard, sought to improve the French language and literature by enthusiastic imitation of the classics; the second, under Louis XIII. (1610–43), consisted of authors who excelled in the composition of Latin verse.

PLEIADES, an asterism, or star cluster; in mythology the seven daughters of Atlas and Pleione, and sisters of the Hyades (*q v.*). Because of their grief at the death of their sisters or at the sufferings of their father, they were changed into stars. In another account, the Pleiades and their mother met the amorous hunter Orion (*q.v.*) in Boeotia; for five years he pursued them through the noods. until Zeus translated them all—Pleione and her daughters, Orion and his dog—to the sky. This is one of the few myths really astronomical in origin, for it is based on the relative positions of the constellations in the sky. The names of the sisters are Xlcyone, Asterope, Electra. Celaeno. Maia, Merope and Taygeta; one is always dim or invisible, because she is Electra mourning for Troy, or Merope, who is ashamed of having wedded a mortal. Sisyphus. All the Pleiades became the ancestresses of divine or heroic families. The early winter rising and spring setting of the Pleiades (Lat. Vergiliae) are important dates to the farmer.

See H. J. Rose, *Handbook of Greek Mythology,* 5th ed rev. (1953).

The stars are situated in the constellation Taurus (*q.v.*). They are referred to in the Old Testament (Job ix, 9; xxxviii. 31). The brightest star is Alcyone (η Tauri), of the third magnitude. This group is physically connected, being distinguished from the background stars by community of proper motion. Photographs show a faint nebulosity filling the whole region; there is little doubt that this is rarefied matter made luminous by stimulation of the radiation of the hot stars comprised in it. The distance of the Pleiades from the solar system is estimated at 100 parsecs (300 light-years), but is not very certainly known.

Alcyone and the other bright stars are of the hottest type of spectrum (Type B) and give out several hundred times as much light as the sun.

PLEISTOCENE EPOCH. This is the sixth of the seven epochs that constitute the Cenozoic era (*q.v.*) of geological history (if, as is indicated on the accompanying geologic time chart, the Recent is taken as the seventh and the Pleistocene is not separated as the Quaternary era). By recommendation of the commission, 18th International Geological congress, the nonglacial Pleistocene (Greek *pleistos,* most, and *kainos,* recent) is defined on the basis of its fauna and separated from the preceding Pliocene by this means. Broadly speaking, however, it is thought to coincide with a period when glacial and interglacial conditions alternated over a large part of the earth's surface and because of this it is often known as the Glacial epoch or the Great Ice Age. During the glacial ages, widespread continental ice sheets repeatedly covered large areas in the northern hemisphere and alpine glaciers were more numerous and extensive in both the northern and southern hemispheres. During the interglacial ages, the climate seems to have been as warm or warmer than the present. The glaciated areas were reclothed with vegetation and repopulated with animal life and soils were formed. This epoch, the major part of the Quaternary period, is believed to have lasted several hundreds of thousands of years. It is generally regarded as having been terminated by the melting away of the latest of the great ice sheets, but at the same time it is also recognized that the Recent epoch of warm climate is not dissimilar to the interglacial ages, though shorter, and therefore the conditions of the Pleistocene glacial epoch have continued uninterruptedly to the present day.

This article is divided into sections and subsections dealing with various aspects of the epoch. The general geology of the period is considered under QUATERNARY. In addition to the cross references to related articles given under the several headings in this article *see* also ARCHAEOLOGY: *Prehistory;* GLACIER; MAN, EVOLUTION OF; PALAEOBOTANY; PALAEONTOLOGY.

- VI. The Glacial Climates
  - 1. Character
  - 2. Causes

I. THE GLACIAL CONCEPT

The concept of an ice age, when climates were colder and glaciers were far more extensive than they are at present, was first advanced by A. Bernhardi (1832) and Louis Agassiz (1837). Agassiz conceived the idea in Switzerland as the outgrowth of examining evidence earlier pointed out by scientific colleagues that certain glaciers in the Alps had formerly extended far down their valleys. He confirmed his views after a field study in Scotland in 1840. and extended them still further after he went to the United States in 1846 to spend the rest of his life.

Prior to the announcement of this glacial hypothesis naturalists commonly viewed the extensive glacial deposits and the widespread evidence of glacial erosion in the lowlands of both Europe and North America as the work of a cataclysmic flood (many believed it to have been the biblical deluge), or of a temporary submergence of the lands beneath the sea, with or without icebergs to help carry the large quantity of stones and boulders visible in the deposits. Not until about three decades after Agassiz' first announcement were the majority of scientific men on either side of the Atlantic convinced that glaciers rather than water had been responsible for these features. The term "drift," still applied to glacial deposits in general, dates from the time when the submergence hypothesis was widely accepted.

Geologic **Time** *Chart*

System and Period	Series and Epoch	Distinctive Records of Life	1,000 Years
CENOZOIC ERA			
Quaternary	Recent	Modern man	11
	Pleistocene	Early man	1,000
Tertiary	Pliocene	Large carnivores	
	Miocene	Whales, apes, grazing forms	
	Oligocene	Large browsing mammals	
	Eocene	Rise of flowering plants	
	Paleocene	First placental mammals	70,000

II. EXTENT OF GLACIATION

1. Areas of Continental Glaciation.— The convincing evidence of the former. much greater extent of glaciers is so generally accepted that it need not be presented here. The areas within the northern hemisphere that were formerly ice-covered are shown in the accompanying maps (the less extensive glaciers in the southern hemisphere are not illustrated). The mountainous western part of North America was occupied by a vast complex of glaciers which throughout most of the Canadian sector formed a nearly continuous covering of ice. The vast area from the Atlantic to the Rocky mountains. Canada and the northern part of the United States (as far south as New York city. Cincinnati. O., Carbondale, Ill., St. Louis, Mo., Kansas City. Mo., and Pierre, S.D.) were buried beneath an ice sheet (the Laurentide ice sheet) that had its source in Canada and also reached north to the Arctic ocean. The Laurentide ice sheet overtopped the White mountains in New Hampshire and so was at least 5.000 ft. thick in that region. This is the greatest minimum thickness that is shown by direct evidence, but it is considered probable that this ice sheet was 5,000 to 10,000 ft. thick throughout the greater part of its extent.

Greenland and Iceland were almost entirely ice-covered. Nearly half of Europe—from the North Cape off the north coast of Norway south to Kiev on the banks of the Dnieper—was covered by a single vast ice sheet (the Scandinavian ice sheet) which is believed to have attained a maximum thickness of 10.000 ft. Much of Siberia was overspread by mountain glaciers and by a great ice sheet (the Siberian ice sheet) on its northwestern plain. The Alps, the Caucasus and the Pyrenees in Europe and most of the high mountains on other continents carried glaciers of varying dimensions. The antarctic continent was even more nearly completely ice-covered than now. and the glaciers of the southern Andes spread westward to tidewater in Chile and eastward onto the pampas of Argentina. The highest mountains of Hawaii, Japan and New Guinea were marked by glaciers.

At present about 5,800,000 sq.mi (about 10.4% of the land area of the globe) are covered by glacier ice. but 98% of this ice is in the distant higher latitudes of Antarctica and Greenland. In contrast, when glaciers were at their maximum they extended into temperate latitudes now the sites of highly organized civilizations and abundant agricultural and manufacturing production.

2. Source-Areas of Glacial Radiation.— During the early part of the last glacial age, the Wisconsin, the great Laurentide ice sheet over Canada had two primary areas of glacial radiation, one known as the Labradorean area located over the highlands of Labrador and eastern Quebec, and the other known as the Keewatin area located on the plains of Manitoba and adjacent territory of Ontario and Hudson bay. Later there was another area of almost equal importance, the Patrician. which developed south of Hudson bay and sent ice lobes southward through the Lake Michigan basin to form the moraines around the southern end of that basin and westward and southwestward through the Lake Superior basin into northern Wisconsin and northeastern Minnesota. The Keewatin ice lobe was crowded westward by it but even so the Keewatin ice received sufficient snowfall and possessed the energy to advance nearly as far south as Des Moines. Ia. Over the Cordilleras of western Canada the excessive snowfall, though much greater than today's, failed to form a continuous ice cap because of the rapid movement of the valley glaciers. especially on the west side, and the calving of icebergs into the sea.

The Scandinavian ice sheet had its origin on the high divide between Norway and Sweden. The Siberian ice sheet possibly began as small glaciers on three separate highlands: the Putorana mountains. the Byrranga ridge on the Taimyr peninsula and the

Severnaya Zemlya archipelago.

A consideration of these ice fields makes it appear that they were all in response to a changing glacial atmospheric organization measurably different from the present; some ice fields began on plains, some on highlands, all necessarily being in the paths of maritime air masses charged with moisture. These ice fields varied in relative importance from age to age. During the Nebraskan age the Keewatin was the dominant field. During the following Kansan both fields were important. During the Illinoian, the third glacial age, the Labradorean area of radiation was preponderant and the Keewatin played a minor role.

This history emphasizes the fact that the nature of the atmospheric organization is unpredictable. The facts lie in the stratigraphic record.

(See also *The Glacial Climates,* below.)

III. REVOLUTIONARY EFFECTS OF GLACIATION

1. Effect **of** the Continental Glaciers.—The northern part of North America and of Eurasia as well suffered profound changes from continental glaciation. The features of the latest glacier are indeed climactic. In North America the Great Lakes—the greatest fresh-water bodies on earth—are due more to glacial scour on a grand scale of former lowlands than to glacial deposition and later crustal deformation that followed the unloading of the earth's crust by the melting of the continental ice sheet. The moraines of glacial drift that lie beyond the basins are in large part the debris resulting from the glacial scour. The lake floors have irregular contours due to both glacial scour and deposition. However, the present outlines of the Great Lakes were assumed when crustal deformation tipped the land southward and helped to fix the present outlets. Northern Lake Michigan is more than

100 ft. shallower than when the glacier scoured it, and the northern part of Lake Huron and Georgian bay is something like 600 ft. shallower.

The lakes, muskegs, embossed and striated rock and other features of the irregular topography of Canada, the 10,000 lakes of Minnesota and large portions of the terrain of North Dakota, South Dakota, Wisconsin and Michigan are mainly such as only the processes of a continental glacier can bring about. New England and areas adjacent to it show the beautiful flowing lines of glaciated hills once buried deeply beneath the great ice sheet that terminated in the Atlantic. The lake basins among the hills, the anomalous sources of streams, the setting of the lakes and the strewing of the countryside with boulders and stony deposits are also features that result from glaciation. Maine has its eskers (rounded ridges of sand and gravel) crossing hill and dale, marking for mile after mile the courses of subglacial streams.

To the south and southwest of Lake Michigan, westerly and southward from Lake Erie, southwest from Saginaw bay, and in northern Iowa and the eastern Dakotas, the spreading continental glacier made a plains country and left upon its retreat a successive series of moraines that fashioned the country into a rhythmic succession of ridge-and-plain topography remarkably suited to agriculture and transportation. This central interior lowland, however, is not all glacial. The glaciers left within it a driftless area of some 10,000 sq.mi., a topographic "island" of rugged hills and valleys branching treelike (dendritic) in pattern and made only by running-water erosion, a relic of preglacial times left between the Keewatin and Patrician ice fields and unmodified by them. Regardless of the direction of his travel, the motorist can see in contrast these pristine erosional forms of the driftless area and the bordering, newer and higher glacial landscape which has beneath it the older stream-eroded topography.

Most of the ancient master streams that preceded the glacial invasion did not survive. The ancient Teays-Mahomet river which once had its source in the distant western fringe of Virginia and which flowed northwesterly and westerly, eventually crossing the present course of the Ohio river and traversing central Indiana and central Iliinois to Havana where it joined the ancient Mississippi, indeed formed one of the master valleys of the great interior of the continent. The Nebraskan and Kansan glaciers which crossed it transversely finished it off. This ancient valley was discovered only recently by a study of thousands of records of well drilling. The present course of the Ohio river along the southwestern boundary of Ohio is a consequence of this geological accident to the Teays-Mahomet valley, as is the upper portion of the Wabash river. One hundred fifty miles of the course of the present Mississippi river above the mouth of Illinois river is also an accident of continental glaciation, as is the Missouri river for 500 mi. in North and South Dakota.

These phenomena of the glacial age in North America are in a real sense duplicated in continental Europe — the glacial topography, lake regions. terminal and recessional moraines, buried valleys and other features — but there is no counterpart of the Great Lakes. A vast river flowed across northern Germany, along the southern part of the North sea floor and through the English channel because the normal drainage to the north was blocked by the Scandinavian ice sheet. (The English channel and much of the North sea floor were then dry land.) Capacious abandoned valleys excavated by the previous drainage are present in the north German plain. Where the land surface sloped toward the ice sheet, there were formed large temporary lakes, one shore of which was against the glacier ice. Lakes of great extent, now drained, also originated in this way in Ontario, Manitoba and the Great Plains region of Canada.

The people of many other parts of the North American continent marvel at the fertile soils of the north central states. It is common to refer to them as glacial. In the main, however, they are not derived from glacial drift but from loess, a silt picked up, carried and deposited by terrific glacial winds. The greatest thickness of loess in the middle west is along the east or southeasterly side of wide valleys containing silty glacial outwash and along the margin of the Iowan drift sheet, where the loess mantle averages 50 ft. or more and extends over the adjacent uplands in decreasing thickness, fineness and lime content. The shells of air-breathing snails, forms whose habitat is commonly the open woodland, make up the chief fossil fauna. In central Illinois some 10 ft. of the loess occurs under the Tazewell or Middle Wisconsin drift which has protected it from oxidation. Here peaty and woody remains of the original vegetation still occur in the loess, some in layers, thus recording pauses in the deposition. Beyond the terminal moraine and the protective cover of the Tazewell there are no plant remains, merely thin layers of orange-coloured iron oxide representing the iron residue of the former plant layers.

Niagara falls, one of the natural wonders of the world, is a product of the glacial age. It was initiated when the melting of the ice uncovered the cliff at Lewiston. N.Y., and opened a lower outlet for the waters of Lake Erie. That this occurred fairly late in geological times is shown by the fact that the falls have receded only about seven miles at a rate that is measurable.

The fertile Red river valley of the north is the former bed of Lake Agassiz whose natural outlet to Hudson bay was blocked until the Laurentide ice sheet was virtually melted. Its maximum area far exceeded the combined area of the Great Lakes. It had two histories, Lake Agassiz I and Lake Agassiz II. the first following the melting of the Mankato ice, the second the melting of the Valders ice. Its outlet was of great volume, flowing like a torrent down the Minnesota and Mississippi rivers, widening their valleys, steepening the bluffs and truncating the headlands.

The basin of Lake Agassiz 1 was entirely overridden by the advance of the Valders glacier which built the Big Stone moraine at Ortonville, Minn. When the Valders ice retreated, the waters of Lake Agassiz II were obliged to cut a new outlet, narrow and gorgelike compared to the wide Minnesota river valley below Ortonville. Though of shorter duration than Lake Agassiz I, Lake Agassiz II lasted long enough to form beaches and a smooth floor out of a moderately undulating ground moraine topography, but the gravel of the beaches show little water wear. Upon the complete melting of the glacier the lake, from its very south end, drained into Hudson bay, thus beheading the Minnesota river and forming a new river system, the Red river. The area today is an important wheat-growing region.

Lake Winnipeg and other water bodies in Manitoba are relicts of ancient Lake Agassiz II. A similar water body formed in the Baltic sea basin of northwestern Europe and over the adjacent coasts of Sweden and Finland, its overflow being through the submerged channel between Denmark and Sweden. A lake of similar origin is reported in the headwater region of Irtysh river, western Siberia. Obstructed by the Siberian ice sheet the lake overflowed southward into the ancient Aral sea, at that time probably a part of the Caspian sea-Black sea-Mediterranean water body.

The various outlets of the glacial Great Lakes, which were also held back by the ice sheet, hold interest too because of their great size. Among these overflow routes may be mentioned: (1) from Chicago to the Illinois river valley and thence to the Mississippi river; (2) from Fort Wayne, Ind., via the Maumee and Wabash river valleys to the Ohio river; (3) from Lake Erie via the Mohawk river valley to the Hudson river; (4) from North Bay, Ont., via the Ottawa river valley to the St. Lawrence river. The old lake shores are variously marked by distinct cliffs, beaches and bars, many of which later served the early Indian as travel routes and still later were adopted in part for highways.

In the course of early geological investigations the students of glacial geology were amazed to find that some of the later beaches, which have a northward trend, rise higher and higher to the north, the oldest one reaching 600 ft. higher at North Bay than farther south. Thus was born the concept that the ice load had depressed the earth's crust and that removal of the ice permitted it to rise. The response was tardy but still continues, as accurate and refined measurements prove. Similar and equally striking phenomena occur in northeastern North America and northwestern Europe. The first-formed beach in the Baltic, following the shrinkage of the Scandinavian ice sheet, is now found in places as much as 700 ft. above sea level (see also Warping of the Earth's Crust, below).

The valley glaciers of the Cordilleras, the Alps, Carpathians and other high mountains in both the northern and southern hemispheres deepened and widened the pre-existing valleys, steepened the valley sides and excavated basins in the bedrock of the valley floors.

Farther down the valleys glaciers built up side ridges with the rock debris that they had acquired, in many cases hundreds of feet high (lateral moraines), and made ridges across the valleys from side to side (end moraines). Some lateral moraines consist partly of debris washed and avalanched onto the sides of valley glaciers from the steep slopes above. Melt-water streams coursing away from the glaciers spread boulders, gravel and sand over the valley floors. in some cases scores of miles beyond the farthest positions reached by the glaciers themselves. Far up in the mountains, ridge crests were sharpened to serrate forms by intense frostwork at those altitudes.

The world-famous, deep, steep-sided fiords of the coasts of Norway, Greenland, Alaska, Chile and parts of New Zealand were glacially carved from pre-existing valleys, and deepened far below sea level.

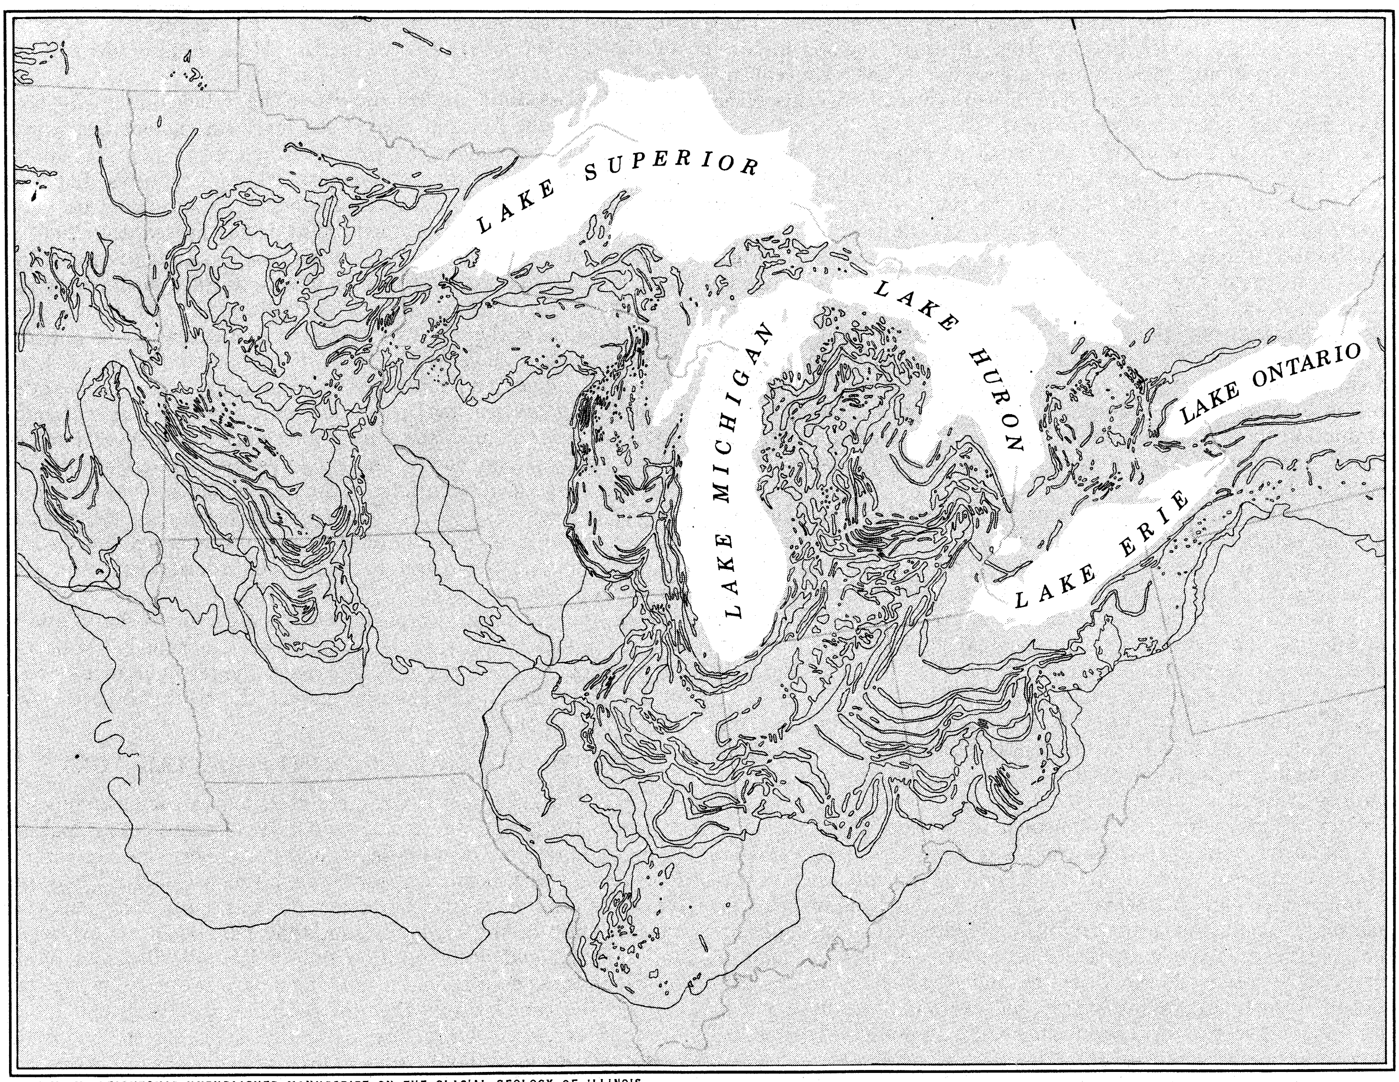
2. Effects Beyond the Glaciated Area.—The effects of the glacial climate and continental ice sheets extended far beyond the limits of glaciation. Rivers like the Mississippi and its strikingly spaced tributaries, the Ohio and the Missouri, and the Susquehanna and Columbia were greatly augmented by glacial melt water and overloaded with glacial sediment which they deposited as valley-train outwash all of the way to their receiving embayments. Sea levels were lower than they are at present and the extension of the Mississippi delta was controlled by such levels, only to become platforms upon which the later delta deposits were laid. Other river systems of the earth were affected similarly, the Volga, Don and Dnieper of eastern Europe being among those that are better known.

Mixed with some of the glacial sediment were ice-rafted boulders that reached the sea.

The valley trains that came from the glaciers of the Rocky mountains down the Missouri. the Platte and other rivers were sources of silt for winds to whip up and deposit as loess on the adjacent uplands. These valley-train sediments joined those from the upper Mississippi, so that loess in great thicknesses is found on the eastern bluffs of that valley as far south as Natchez, Miss., and beyond.

In the dry regions in low and middle latitudes on all continents there is impressive evidence both of former lakes where none now exist and of the former much larger size of existing lakes These phenomena show that in these regions there were repeated times of greater precipitation and smaller evaporation than now occur. In at least two cases (Lake Bonneville in Utah and Mono lake in California) a close time relationship has been established between the shore lines of the expanded lakes and glacial moraines. It is widely believed that the times of greater precipitation and less evaporation coincided nith the glacial ages, and that the times of low water or even desiccation coincided with the interglacial periods.

The most widely studied of these dry regions is in the western United States, where no fewer than 68 former lakes have been



FROM M. M. LEIGHTON'S UNPUBLISHED MANUSCRIPT ON THE GLACIAL GEOLOGY OF ILLINOIS

OUTLINES OF GLACIAL MORAINES AROUND THE DISTAL ENDS OF THE GREAT LAKES SHOWING THE LOBATE ORGANIZATION OF THE LAST ICE SHEET identified by their abandoned shore lines and sediments. The largest of these lakes was Lake Bonneville which filled a number of coalescent intermontane basins in Utah, Nevada and Idaho and had a maximum area of more than 20,000 sq.mi. and a maximum depth of more than 1,000 ft. Since the last glacial age this enormous fresh-water body has been shrunken by evaporation to Great Salt lake, Provo lake and Sevier lake. Second only to Bonneville in size was Lake Lahontan, which had a maximum area of **8,422** sq.mi. in Nevada, Oregon and California. Pyramid lake, Winnemucca lake, the Carson lakes and Walker lake are its reduced successors. Some of the **68** basins, studied in detail, have yielded evidence of two and even three high-water stages separated by stages of partial or complete desiccation.

In Eurasia a similar record has been recognized. The Caspian sea and the Aral sea east of it had at least three expansions separated by drier times. Both basins filled and overflowed. Similar though less fully determined records have been reported from the larger undrained basins of central Asia. According to Max Blanckenhorn the Dead sea of biblical fame filled, at least once, to four times its present length and to a height nearly 1,400 ft. above its present surface.

In northern, eastern and southern Africa the record of former lakes is closely similar. This repeated expansion and desiccation form the basis for a Pleistocene sequence for that continent.

The low temperatures responsible for the formation of glaciers in higher latitudes are believed to have been the basic cause of the lake expansions. Decreased evaporation directly resulted. As the ice sheets formed, they became the sites of high atmospheric pressure, which in turn pushed the principal middle-latitude belts of moving cyclones south of where they presently lie. These cyclones brought added precipitation to broad regions in lower latitudes that in nonglacial times were semiarid. As a consequence of increased precipitation and diminished evaporation, lakes either came into existence or were enlarged.

Because they were in part the result of increased rainfall, the high-lake stages are termed pluvial stages. The lakes appear to have reached their maxima at about the times when the ice sheets were at their maxima. Thus the glacial ages and the pluvial ages are thought to have been coincident and closely related in origin.

A conspicuous effect of the glacial climates in regions that lay a short distance beyond the ice sheets is the effect of frost heaving and solifluction. Solifluction is the slow creeping of superficial soil, even on very gentle slopes, as a result of freezing and thawing of the ground. It takes place today in arctic and antarctic regions and on high mountain summits in lower latitudes. The effects of solifluction in producing contortion of stratification and the patterned arrangements of stones resulting from frost-heaving of the soil are distinctive.

These effects also have been observed in regions never glaciated, such as southern England and northern France, and where the ground does not freeze today. They have been found also in various parts of the United States, even on the older drift sheets that extend beyond the younger. The inference is that during the glacial ages the temperatures in the regions surrounding the ice sheets were reduced enough to cause the ground to freeze and thaw vigorously, with resulting solifluction.

3. Warping of the Earth's Crust.—The building of large glaciers on the earth's surface during the glacial ages had two direct effects which in some places conditioned and resulted in greater changes than those attributable to erosion and deposition by the glaciers. These effects were conspicuous fluctuations of sea level and extensive warping of the earth's crust. The crust yields to excessive loading such as that induced by the great ice sheets. In the substratum below the rocky crust plastic flow transfers rock material outward away from the weighted area causing basin-like subsidence. When the ice sheet begins to melt the load on the crust is reduced, the direction of plastic flow in the substratum is reversed, the rocky crust bulges up very slowly in dome-like fashion and not until some time after the ice has disappeared are conditions restored to normal.

Along the seacoast and in regions of large glacial lakes extensive areas were submerged as they were uncovered by the melting ice. Waves and currents fashioned cliffs and beaches along the shores. The delayed updoming of the crust gradually caused the water to recede and at the same time warped the shore lines out of their original horizontal positions. Where there are several successive shore lines it has been possible to reconstruct the general form and progress of updoming. Doming movements related to the latest glacial age began so recently that they are still in progress, at least in eastern North America and in northwestern Europe. In the latter region the warping is concentric to an area in east-central Sweden. From this fact it is inferred that the Scandinavian ice sheet was thickest over that area. It is estimated that when the warping movement has been completed, thousands of years in the future, most of the floor of the Gulf of Bothnia will have become dry land.

In North America updoming is evident throughout the northern part of the vast region uncovered by melting of the Laurentide ice sheet. The great system of temporary glacial lakes, now extinct, that extended from Montana and the Great Plains of Canada on the west to northern New York and northern Ontario on the east left an array of shore lines whose measurements have yielded much information about the progress of updoming of the crust as the ice sheet disappeared. The thickest part of this ice sheet—at least during its later history—is inferred to have stood over the Hudson bay region because the warped shore lines are generally concentric to that region. Farther east along the St. Lawrence. in the maritime provinces of Canada and in Newfoundland, well-developed marine strand lines record submergence beneath the sea as the ice melted, followed by slow upwarping toward the northwest. This movement is still continuing throughout much of the region. It is predicted that the future completion of the doming movement will cause Hudson bay virtually to disappear.

4. Fluctuations of Sea Level.—The other direct effect of glaciation is the fall and rise of sea level throughout the world. As was correctly deduced by Charles Maclaren in **1842,** the building of large glaciers when none existed before requires that vast quantities of atmospheric moisture be precipitated in the form of snow. As this moisture must come from the sea, the result is lowering of the sea level. Under warming climates the existing glaciers melt and large volumes of melt water are returned to the sea, thereby raising its level. The alternation of glacial and interglacial ages therefore has resulted in fluctuation of the sea level through a range of hundreds of feet, including levels both somewhat higher and much lower than today. It is generally thought that the sea level has stood, during glacial ages, perhaps 400 ft. lower than now, and during interglacial age's several scores of feet higher than now. These figures are arrived at by two methods: (1) calculation from estimated volumes of present and former glaciers; (2) measurement of the heights of interglacial marine deposits and shore lines above present sea level; and (3) ascertaining the depth to which shoreward sediments and submerged channels occur.

Measurements made throughout the past century have established the fact that the sea level is rising at a rate of about 2.5 in. per century. This rise may be largely the result in many areas of the shrinkage of glaciers throughout the world, in others of subsidence of the earth's crust.

IV. THE GLACIAL AND INTERGLACIAL AGES

The U.S. middle west is the great classic area for clear records of successive glacial and interglacial ages of many thousands of years of duration. A mere layer of humus between deposits is looked upon with skepticism for representing a long time because humus can accumulate within a few decades. But when the soil zone includes deep leaching of limestone pebbles, deep oxidation and staining, and decomposition of granites, diorites and other silicate rocks as deep and intense as in modem soils on the younger drifts in the same latitude, then the record of an interglacial age is regarded as clear. Drift sheets of adjacent areas may also be compared in age by the relative degree of erosion which they exhibit under comparable conditions—the older the drift sheet the better developed the drainage pattern and the greater the erosion.

A weathered drift beneath an unweathered drift is a reliable basis for recognizing the lower drift as much older than the upper. Along the sea coast if two drift sheets exposed in a sea cliff are separated by marine sediments containing warm-water fossils, the difference in age is apparent. Other means of differ'entiating drift sheets and the problems involved will not be discussed in this brief article. It should be noted. however. that the wood of buried soils is commonly coniferous even in such latitudes as central Illinois. The soil zone may be interglacial but it is questionable if the wood is. It is probably from the new forest that migrated southward in response to the oncoming glacial climate.

In North America the following sequence of glacial and interglacial stages (and ages) is recognized, the oldest at the bottom:

Wisconsin glacial
Sangamon interglacial
Illinois glacial
Yarmouth interglacial
Kansan glacial
Aftonian interglacial
Kebraskan glacial

All of these names originated in the upper Mississippi valley states where the type areas or sections occur. Certain correlations have been made with the Atlantic coast and with the Cordilleras. The Kansan is the surface drift over a large part of southern, western and eastern Iowa, northern Missouri, northeastern Kansas and eastern Nebraska. It also extends north into Minnesota and South Dakota. The Nebraskan is exposed beneath the Kansan at a great many places, rather commonly with a deep weathered zone preserved. For many years northeastern Iowa as far south as Dubuque was regarded as driftless, but patches of Kebraskan have been found on the upland ridges, making it quite certain that the Nebraskan ice sheet covered all of Iowa. A deposit of old weathered drift which some believe to be Nebraskan occurs on a high rock terrace in the mouth of the Wisconsin river valley. The Illinoian drift covers a large portion of Illinois and parts of southern Indiana and southwestern and eastern Ohio. and in places a fringe extends eastward beyond the Wisconsin. The Kansan seems to extend almost as far south in Indiana and Ohio as the Illinoian. Naturally the Wisconsin drift, being the youngest, is the surface drift over a much greater territory than the older drift sheets.

In the western mountains glacial deposits of at least three different ages have been found. The youngest is probably of Wisconsin age; the older ones have not been confidently correlated. Deposits as old as the Kansan, which in the middle states has been greatly eroded with only small ground moraine remnants remaining, are probably the oldest that can be positively identified in the mountains.

For many years the following classification of glacial deposits in the Alps by A. Penck and E. Bruckner has been recognized:

Würm glacial
Riss-Wdrm interglacial
Riss glacial
Mindel-Riss interglacial
Mindel glacial
Günz-Mindel interglacial
Gunz glacial

Though some would add to this a suggested older deposit, the Donau. this classification seems to stand. In the area of continental drift in northern Germany and Denmark three stages are recognized. They are:

Weichsel glacial (includes Brandenburg)
Eem interglacial (marine)
Saale glacial (Warthe, an upper member)
Holstein interglacial (marine)
Elster glacial

As in the case of North American geological literature the European literature is replete with suggested revisions, concerning the merit of which only the test of further investigations will tell. The fact. ho ever, is patent that the effects of the glacial period were world-wide and it comprised a series of glacial and interglacial equivalents. Much research remains to be done to perfect the record. See also QUATERNARY.

1. Subdivisions of the Latest Glacial Age.—Because there is much hidden history of the older glaciations the Wisconsin offers the best opportunity to learn the nature of a glacial stage and from some standpoints the substages of the Wisconsin glacial stage hold greater interest than the older glacial stages. In North America the substages of the Wisconsin deposits are recognized from youngest to oldest as follows:

Valders
Mankato
Cary
Tazewell
Iowan
Farmdale

The Farmdale and the Iowan lobes are somewhat similar in that both ice sheets had their axial directions of movement diagonal to the succeeding stages; they were of short duration; and, like the fall season, they preceded the greater and more intense glaciation of the Tazewell. The Tazewell marks the "winter" of the glacial age. The ice sheet was bulkier, more persistent and extended farther than any other substage of the Wisconsin. It was inferred that the temperature reached its lowest point and snowfall was heaviest. The Cary marks a late resurge of low temperature and heavy precipitation but it did not last long. The Mankato and Valders have the earmarks of late pulsations that were brief and portended another interglacial summer.

Some geologists are inclined to regard the Recent epoch as beginning when the Valders ice began to melt back. Others regard the Cochrane minor advance which terminated at Cochrane, Ont.—less than 200 mi. south of James bay—as the last substage. The former group of geologists thinks of the Cochrane as minor in degree and insignificant in the role of geologic processes that characterized the Recent.

In Europe as in North America, the last glacier did not steadily wane after the maximum advance, but there were climatic pulsations, each less severe and shorter than the preceding, resulting in glacial and intraglacial substages. International correlations of some of the interstadial intraglacial deposits have received much attention.

2. Nonglaciated Regions.—Southeastern California, now a very arid region, had a chain of large lakes, hundreds of feet in depth, of which the dry floor of Searle's lake is a successor. Radiocarbon dates of the upper part of the sediments agree closely with dates of the Wisconsin drift in Illinois. The overlying beds of salts and carbonates, which are 65 ft. to 100 ft. thick, are the result of evaporation in postglacial time. It does not seem too much to anticipate that an alternating series of salts and clays and silts will be found to match the older interglacial and glacial climates.

3. Duration of the Glacial Epoch.—The method of carbon dating back to the beginning of the Wisconsin (Wiirm) rapidly came into use after 1949. W. F. Libby and J. R. Arnold developed the radiocarbon method by which discretely selected samples of wood, charcoal and certain other organic remains from deposits younger than 20,000 years could be dated. Radiocarbon C^{14}, a radioisotope of carbon with the mass number of 14 produced in the upper atmosphere by the bombardrnent of nitrogen by cosmic-ray neutrons, reacts with oxygen to form carbon dioxide. In that form it enters into all organic matter and all material exchangeable with atmospheric carbon dioxide, including carbonate in sea water. Upon death of any organism the radiocarbon diminishes by its own radioactive disintegration at a known rate. Therefore, by determining accurately the loss that has taken place from wood, for example, since its burial. the age of the wood, *i.e.*, the time since burial, can be computed. The method of determination has been improved to include specimens somewhat older than 30,000 years. (See GEOCHRONOLOGY.) According to this method wood from the Farmdale loess, the oldest known Wisconsin deposit. is from 25 000 to 29,000 years old. This does not take into account the time required for the development of the Laurentide ice sheet, for its movement into the drainage basin of the upper reaches of the Mississippi and for development of the valley train from which the loess was blown. The date of wood in the Iowan loess is 21,000 to 23,000 years; in Tazewell sediments, 15,000 to 19,000 *years; Cary, 13,000 to 14,000 years; Mankato about 12,200 years; and Valders advance, 11,400 years, all before the present time. E. Antevs, on the basis of varves and other geological evidence, disagrees. He calculates the date for the Mankato substage at about 19,000 years. In the early 1940s G. F. Kay estimated the retreat of the Mankato to have been about 25,000 years ago.*

It is seen that radiocarbon dating allows only about one-half of the time permitted by the older estimates. In the second half of the 20th century research was being conducted to determine whether microorganisms of decay and other factors affect dating. Minute shells associated with low temperatures have been recovered from deep sea cores taken from the Caribbean and mid-Atlantic. Some C^{14} measurements have been made of them which show an age range from 10,000 to about 55,000 years. Those that record the lowest temperatures are about 15,000 years old, which is the latter part of the Tazewell. The feeling of conservative glacial geologists is that research should be pursued to acquire further and broader information. In the meantime respect is held for carefully documented stratigraphic work and sampling.

The extensive erosion of the Kansan drift and the prolonged exposure recorded by its zone of weathering are so impressive that it seems quite clear that the Kansan glacial stage was several hundred thousand years ago. The deep weathering of the Nebraskan before that drift sheet mas superseded by the Kansan ice sheet, together with the apparent extensive erosion of the Nebraskan in northeastern Iowa, make the Nebraskan antedate the Kansan by an interval many times the duration of the Recent epoch. Hence. the over-all age of the Glacial epoch is at least several hundreds of thousands of years.

Another method of age determination, which has been applied to the older stages, is the "per cent of equilibrium method for uranium, ionium and radium," worked out by W. D. Urry. This method, which relies on the analysis of radioactive disintegration products, has been applied to ocean-bottom sediments in areas where they indicate alternating warm and cold periods, as for example alternating layers of globigerina ooze (see FORAMINIFERA*) and red clay in the southeastern Pacific ocean. The dates obtained, according to Jack L. Hough, seem to correlate well with Pleistocene events on the North American continent, including six substages of the Wisconsin glacial stage (11,000, 15,000, 26,000, 37,000, 51,000 and 64,000 years ago), three substages of the Illinoian glacial stage (274,000, 310,000 and 330,000 years ago) and, by extrapolation, with the end of the Kansan glacial stage, about 700.000 years ago. The above data corroborate the former conclusions drawn from geologic study of the drift sheets that the Yarmouth interglacial, between Kansan and Illinoian times, was longer than the Sangamon interglacial between Illinoian and Wisconsin times, and that the interglacial ages were much longer than the glacial ages.*

One of the intriguing methods for studying the glacial history of the earth, also based on marine deposition but employing radiocarbon dating instead of the per cent of equilibrium method, is that of taking deep-sea cores some 60 ft. or more long where the rate of sea-floor sedimentation is slow. These cores bring up alternating layers of oozes of microorganisms and red clay. The fossil microorganisms include those that are sensitive to temperature changes (Foraminifera, diatoms) and thus they afford opportunity to study the ocean temperatures of the Pleistocene. These temperatures, based on carbon-isotope ratios and the C^{14} datings of the shells, provide comparison for this information from the ocean depth with the C^{14} datings of wood and other carbon remains from soils and peat beds of known geological positions on the land. This is a frontier of scientific investigation in glacial geology.

V. LIFE OF THE PLEISTOCENE EPOCH

The extent to which the plants and animals of the earth have become adapted to the new environment since the end of the glacial age is an indication of what can transpire in something like 10,000 years. The older glaciations, Illinoian, Kansan and Nebraskan, had similar effects on the life of those of the last ice age. Since the interglacial ages that followed are estimated to have had a duration of something like 100,000, 300,000 and 200,000 years respectively, it is to be inferred that the land surface from which the ice had retreated became completely reclothed with vegetation, and repopulated several times during the glacial period.

Mammalian life changed greatly both through extinctions and through the appearance of new forms. Among the new ones were zebrine horses, cattle, camels, certain elephants, rhinoceroses and a woolly mammoth, a distinctly cold climated form not known to have lived before the first glaciation. Horses and moose were immigrants near or at the close of the Kansan glaciation. The greatest number of the extinctions came in the period roughly from 5,000 to 10,000 years ago, and included all the camels, horses and ground sloths; two genera of musk oxen; peccaries; antelope-like ruminants; all but one species of bison; a giant beaver-like animal; a stag moose; and several kinds of cats, some of which were of lion size. The huge mammoths, larger than living elephants, which had become common throughout the United States also disappeared as did the forest dwellers, the mastodon and the woolly mammoth of tundra and level stretches. Their extinction in North America, as well as Europe, is credited to early man. Man's appearance in North America was rather sudden, probably taking place when there was a land bridge across the Bering strait.

1. North America.— There were forms that lived on the tundra close to the ice front— the woolly mammoth (Mammuthus primigenius) and the caribou; in the subarctic forest the mastodon, moose, stag moose, giant beaver (Castoroides), deer and bears; farther removed, the other elephants of the mammoth line, tapirs, peccaries and a variety of deer and carnivores; in the central Great Plains elephants, horses, bison, elk, antelope, ground sloths from South America and many small mammals. The late glacial forms that lived in Florida included the mastodon, elephant, camels, a huge bison, peccaries, deer, tapirs, horses, ground sloths, armadillos, several carnivores including a sabre-toothed cat (Smilodon), wolves and bears. In central Alaska the frozen ground of alluvial silt contains fossils of bears, wolves, foxes, badgers, wolverines, sabre-toothed cat, jaguar, lynx, woolly mammoth, mastodon, horses, camel, saiga antelope, four bisons, caribou, moose, stag moose, elk, sheep, musk ox, ground sloth and various rodents. It is suggested that this fauna may be interglacial.

Today the Bering strait separates Alaska from Siberia. The fossil record indicates that this was a land connection one or more times during the Pleistocene. The Japanese current probably gave it a mild climate and permitted the growth of long thick grass like that on the Alaska peninsula. The immigrants and emigrants appear to have been entirely cold-temperate or boreal forms. Not only may crustal warping have produced the bridge, but lowered sea level prevailed during the early and late parts of the different glacial ages when much sea water was still locked up in the ice sheets.

Immigration from South America is recorded in the ground sloths which came to live as far north as central Alaska. The North American horse and deer traversed the Isthmus of Panama to live in South America. (*R. F.* FT.; *M. M. L.*)

2. *Europe.— The Pleistocene mammal fauna went through a series of striking changes in Europe as it did in North America. Basically there was a steady change as certain species like the elephants, rhinoceroses and horses evolved, while at the same time other forms became extinct against the competition of immigrants from the east. Superimposed on this progression, however, was an oscillation due to a north-south shift of animal population as the glaciers waxed and waned, so that faunas which were very similar appeared at two or more different times, separated by a fauna of quite different character.*

The very earliest part of the Pleistocene (Villafranchian) produced some strange inhabitants of western Europe— lynx, several species of bear, a macaque monkey and the great sabre-toothed cat, Machairodus. The elephants included Mastodon arvernensis, but also the first of the true elephants, Elephas meridionalis. This fact, and the appearance of the true horses (in the form of Equus stenonis), is regarded by many as the criterion of the Pleistocene.

In the later part of the Lower Pleistocene (the Günz-Mindel interglacial stage, the Aftonian in North America, identified in *The Glacial and Interglacial Ages,* above), though the macaque monkey, sabre-toothed cat and *Elephas meridionalis* persisted, the latter was accompanied by a more advanced type, *trogontheri.* Two species of rhinoceros *(mercki* and *etruscus)* were present, *a* giant extinct beaver *(Trogontlzerium)* was found, and the red deer and hippopotamus made their appearance.

The Middle Pleistocene started with the Mindel-Riss, or Great Interglacial, with the macaque monkey and Merck's rhinoceros still lingering on. A deer, *Dama clactonianus,* was distinctive. For the first time the straight-tusked elephant (*antiquus*) appeared, with the great ox (the aurochs, *Bos primigenius*) and the bison and the modern species of horse; and most interesting of all, *Homo sapiens.* (Fossil specimens from Steinheim. Ger.. and Swanscombe, Kent. Eng., are discussed in MAN, EVOLUTION OF: *Antiquity of Homo Sapiens.)* As the climate changed to the Riss glaciation. a characteristic cold-climate fauna replaced that of the preceding interglacial. For the first time appeared the woolly mammoth (*Mammuthus primigenius*) and woolly rhinoceros *(Tichorhinus antiquitatus),* both extinct, the bison and animals like the reindeer and musk ox which are associated with the arctic tundra.

The Upper Pleistocene started with the Riss-Wurm, or Last Interglacial, and the fauna was once more "warm." with the hippopotamus, straight-tusked elephant, brown bear, beaver, lion. leopard. marmot, red deer and the giant elk (*Megaceros giganteus*). As the Würm glaciation developed, so a "cold" fauna very like that of the Riss glacial period once more migrated in—the woolly rhinoceros and mammoth, cave bear, lynx, arctic fox, bison, aurochs. musk ox. horse and arctic lemmings. After the vicissitudes of this last glaciation, the progress to the present-day climate included the extinction of the mammoth and woolly rhinoceros (whose frozen remains have been found in the Russian tundra), the elimination of the beaver and the driving to the far north of the reindeer and the musk ox. *See* F. E. Zeuner. *The Pleistocene Period* (1959). (F. W. SN.)

3. Early Man.—In the examination of the past for the physical and cultural records of man. the written record gives way to the archeological record of pottery, drawings and carvings on the walls of caves and pieces of ivory, and artifacts of stone and bone, the basic materials of the science of archeology. The physical anthropology of man—the family of Hominidae—goes back to near the beginning of the Ice Age in Europe. Heidelberg man, the first recognized species of the genus *Homo,* lived at approximately the close of the Mindel glacial stage (Kansan in North America). Nonhomo manlike species. Archanthropic, prophetic of man. appeared first during the Günz-Mindel interglacial stage (Aftonian). The last of these are not known to have lived after the Mindel-Riss interglacial stage (Yarmouth). Their genera in successive order have been identified as *Gigantopithecus, Meganthropus, Pithecanthropus* and *Sinanthropus.* However. the time span from the beginning of the first interglacial to near the end of the Mindel-Riss interglacial is much longer than all subsequent time. Extinct fossil species of the genus *Homo* (paleoanthropic man)—Heidelberg, Neanderthal, Rhodesian and Solo—cover the period from the close of the Mindel glacial to the early part of the Würm glacial (Wisconsin). *Homo sapiens,* the present world-wide species, has lived since the close of the Mindel-Riss interglacial. Cro-Magnon man. the modern erect man. was found in fossilized condition in the Cro-Magnon cave in Dordogne, France. His appearance is dated as in the fourth glacial.

The skeletal parts show that marked evolution took place during the 1,000,000-year stretch of Pleistocene time, particularly in the brain. which increased greatly in size. The artifacts show a general progressive increase in perfection and adaptability, which in turn record an increase in intelligence and skill among the people who made them. These increases. however, apparently took place at different rates in different regions; very different degrees of culture flourished at the same time in different parts of the world. This has been learned in part through dating the various groups of artifacts and skeletal remains, both by means of fossil mammals that have been preserved with them and by identification of the deposits in which some of the remains occur with deposits of known glacial or interglacial age. Radiocarbon C^{14} datings have made significant contributions.

The record in America does not extend as far back in time as that in the old world. No skeletons or artifacts dating from early in the Pleistocene have been found, but discoveries indicate that man may have come to America at about the close of the Sangamon interglacial or the beginning of the Wisconsin glacial.

VI. THE GLACIAL CLIMATES

1. Character.—At the height of the glacial ages at least 28% of the land area of the world was covered by glacial ice. At present more than 10% is so covered, but significantly this is in the higher latitudes. The same was probably true for the interglacial ages. Some differences between the present and one of the interglacial ages are apparent, however, from comparison of fossil faunas with the living forms.

Glacial cirques (theatrelike valley heads fashioned by the action of snow fields at the heads of individual glaciers in mountainous terrain) bear a rough general relation to the snow line or lower limit of perennial snow. Through measurements of the altitudes of cirques in many parts of the world the approximate position of the snow line at the height of the latest glacial age has been determined. Wherever measured, this former snow line is lower than the snow line of today—at the equator as well as in polar latitudes.

In order to determine the glacial-age climate of a coastal point **A,** a point B on the same coast is located by finding the place where the present snow line has the same altitude as the glacial-age snow line of A. The present climate of B is then taken as representative of the former climate of A. The method is rough. but over a wide region it gives consistent results. Coastal points such as A are seen to have received much greater precipitation than they do at present, and to have had mean annual temperatures of the order of 7° C. to 8° C lower than now, nhereas in interior regions the increase in precipitation and decrease in temperature, compared with present conditions mere less pronounced. In other words. the subpolar climate belts were shifted toward the equator during the glacial ages. This shift may have amounted to as much as 15° of latitude for the boreal, or northern. belt, less for the warmer belts.

The pluvial conditions of the dry regions of middle and low latitudes support this conclusion in that they appear to show equatoruard shifting of the middle-latitude belts of rain-bringing cyclonic storms. The evidence of fossil animals in the northern hemisphere likewise indicates southnard shifting of the cold northern climatic zone through many degrees of latitude.

On the other hand the evidence of fossil plants and animals indicates that during the interglacial ages the climatic zones uere shifted toward the poles, and that at least once these zones. in the northern hemisphere have been pushed north of the positions they occupy at present. It is generally believed though it has not been conclusively proved. that these climatic shifts were synchronous throughout the world In summary. the climatic changes were world-wide and apparently contemporaneous; the climatic belts were shifted alternately. equatornard and poleward; and changes in mean annual temperatures amounted to several degrees centigrade.

2. Causes.—The causes of these remarkable climatic changes have received the attention of geologists, astroncmers. physicists and meteorologists for a century Of the many hypotheses put forward, a fen may be mentioned only to be dismissed: (1) Changes in the amount of volcanic or cosmic dust in the earth's atmosphere, thereby varying the thermal insulating effect of the atmosphere. This hypothesis encounters many objections and is wholly inadequate to meet the facts (2) Displacement of all or part of the earth's crust relative to the earth's axis thus bringing different regions into the positions of the poles at various times. This hypothesis is negated by the consistent relative positions of the climatic zones throughout long periods of time and by the lack of independent geophysical evidence of crustal displacement. (3) Broad uplifts of continents and localized uplifts of mountain masses, thus reducing temperatures and creating conditions favourable for the formation of glaciers. This hypothesis, which usually also applies to shifts in ocean currents, was proposed before the fact of the interglacial ages was fully established, and fails because it demands frequently repeated crustal uplifts and subsidences of which there is no independent evidence.

The basis of a theory that has received wide adherence was suggested by J. Adhémar in 1832. It was extended by J. Croll in 1875, and much later was elaborated, with variations, by M. Milankovitch, R. Spitaler, W. Koppen and A. Wegener, W. Soergel and others. This theory, sometimes termed "the astronomical theory," is based on the periodic changes that affect the earth's motion in three different respects: (1) eccentricity of the orbit (period 91,800 years); (2) inclination of the axis to the ecliptic plane (period 40,000 years); (3) shifting of the perihelion (period 21,000 years). These changes affect the distribution of solar heat received by the earth's surface, though they do not affect its total amount. The results of these changes can be plotted as a curve showing variations in the amount of heat received during the summer at any selected latitude. Because the three periods differ, such curves are nonperiodic. They show irregularly spaced maxima and minima of heat, which are taken by the advocates of the theory to represent the interglacial and glacial ages respectively. Four pairs or groups of temperature minima (nine in all), held to indicate four principal glacial ages, are represented as having occurred within the past 600,000 years.

Four objections to this theory may be mentioned: (1) it demands that the cold times alternate between the two polar hemispheres, yet there is no geologic evidence that such was the case; (2) it requires that at the equator there be little or no heat fluctuation, yet there is clear evidence in the east African mountains, directly on the equator, that the snow line there fluctuated throughout more than 3,000 ft. between glacial and interglacial ages; (3) the heat-fluctuation curves deduced from the theory show nine minima; these do not agree with the geologic evidence, which records only four glacial ages.

Another group of theories is based on the premise that there is a considerable variation in the absolute quantity of radiant energy emitted by the sun, and holds that terrestrial climatic fluctuations take place in accordance with such variations. E. Huntington's version of this idea laid emphasis on a supposed connection between solar energy and the incidence of cyclonic storms on the earth. Sir G. Simpson's version deduced an elaborate and ingenious scheme in which glacial ages are offset in time with respect to the maxima and minima of solar radiation. It applies best to the antarctic region. A. Penck's version deduces a direct connection between reduced solar radiation, world-wide temperature reduction and glaciation. Although there is no proof whatever that large fluctuations in solar energy have occurred, the assumption that they have occurred appears to meet all the requirements for the causes of the glacial climates. *See* also GEOLOGY.

(R. F. FT.; M. M. L.)

PLEKHANOV, GEORGY VALENTINOVITCH (N. BELTMAN) (1857–1918), the founder and for many years the chief exponent of Russian philosophic Marxism, was born on Nov. 26. 1857, in the province of Tambov, of an old noble family. His father wished him to enter the army, but while a student he joined the Narodnist (populist) revolutionary movement. In 1876 he led the first great popular demonstration at St. Petersburg (Leningrad) in the Kazansky square. When the majority section of the Narodnists adopted terrorist methods in 1879, Plekhanov seceded, and with Deutsch, Axelrod, Vera Sassulitch and Ignatov, formed the Marxist "Liberation of Labour" group in Geneva (1883). He spent 40 years in exile, chiefly at Geneva, from which town he became the intellectual leader of the Russian Social-Democratic movement, in particular playing a large part in Lenin's early mental development. In the '90s and the early years of the 20th century the two men were closely associated. In Dec. 1900 was founded the S.D. journal *Iskra* ("The Spark") of which Plekhanov was joint editor with Lenin, Martov and others. In the first split of the Russian S.D. party in 1903 Plekhanov was largely on the side of the Bolsheviks, holding views closely akin to those of Lenin.

After the resignation of the Mensheviks from editorship of the *Iskra* Plekhanov and Lenin were joint editors, but some months later differences arose between them on the question of collaboration with the Mensheviks, and Lenin resigned. Thenceforth for several years Plekhanov worked with the Menshevik section of the party, but after 1907, while remaining a Menshevik, he took up an attitude on many issues, particularly on the question of participation in the state Duma and also on illegal activities, in agreement with that of the Bolsheviks. At the end of 1910 he again co-operated with the latter in contributing to the Bolshevik *Zviezda* ("The Star") but the alliance did not last long, and when the war broke out in 1914 Plekhanov was foremost in advocacy of the principle of "revolutionary defence" of the country against the Bolshevik policy of working for the defeat of the government. After the March revolution he returned to Russia and was invited to join the Provisional government. He refused, but actively supported the government against the Bolsheviks, and remained an opponent of the Bolshevik revolution until his death in Finland on May 30, 1918.

Plekhanov had an enormous influence on the development of the Socialist movement in Russia. The Moscow Marx-Engels institute published a complete edition of his works in 26 volumes. His biggest work is available in German: *Beitriige zur Geschichte des Materialismus.*

PLESIOSAURUS, technically the name of a genus of extinct reptiles of the group Sauropterygia; it is commonly used to apply to all the later members of that group. The typical plesiosaurs are completely adapted for a marine existence in the open sea. They first appear in the Rhaetic and are last seen in the Upper Cretaceous.

A typical plesiosaur has a small head with a large mouth and slender pointed teeth adapted to the catching of fish. The neck is long, often four times as long as the head. The body is relatively short, as is the tail. All four limbs are converted into paddles, no external trace of the fingers being visible.

From these forms two main evolutionary lines appeared. In one, the animals adopted the habit of living on large prey which they captured by their superior speed; in this line the head grew bigger and the neck shorter until it became no longer than the head. The body is comparatively long, the tail little more than the pointed hinder extremity of the body. The paddles become very large indeed, the hinder pair being bigger than the front ones. There are large members of this line in the European Jurassic, with skulls 5 or 6 ft. long and a body length of 16 ft. or more. The giant of the tribe was *Kronosaurus* of the Cretaceous of Australia, with dimensions nearly twice as great.

The other line consists of animals which fed on small quick-moving prey which they seem to have captured by sudden lateral movements of the head and neck. Its most recent member, *Elasmosaurus*, is found in the Upper Cretaceous of Kansas, England, Queensland and New Zealand. In it the head is about 18 in. in length, the neck with as many as 76 vertebrae may reach a length of 19 ft., and the total length of the animal about 30 ft. The paddles of such an animal were about 3 ft. in length. Some plesiosaurs had the habit of eating pebbles which were kept in the stomach to assist in grinding up food. Although the majority of plesiosaurs were marine, some few are always found in estuaries or fresh-water deposits. *See* REPTILES. (D. M. S. W.; X.)

PLEURA, DISEASES OF. The pleura is a continuous thin sheet which lines the interior of the thoracic cavity (parietal pleura) and is reflected at the root of each lung to cover the entire surface of the lung (visceral pleura).

Pleurisy. — Inflammation of the pleura, which may occur as an accompaniment to almost any major lung disease, is often called pleurisy or pleuritis. The word is sometimes used in a loose and inaccurate manner to indicate any type of thoracic pain. The pain of pleural inflammation is usually sharp in character, well localized and clearly related to breathing.

Pleural Effusion. — Accumulation of excess amounts of fluid between the visceral pleura and the parietal pleura (pleural effusion) frequently results from pleurai inflammation or circulatory congestion. The amount of fluid may be very great, even several pints, sufficient to prevent expansion of the lung and, hence, result in respiratory insufficiency. Small amounts are often difficult to detect except by X-ray examination. The fluid is usually clear and straw coloured but may be cloudy and occasionally tinged with blood.

Infection of the pleural space with tuberculosis, secondary to a tuberculous lesion in the lung, is a common cause of pleural effusion. The fluid is usually clear and straw coloured and contains moderate numbers of lymphocytes. It may contain tubercle bacilli, but often biopsy of a small portion of the pleura is necessary to establish the diagnosis. Often, but not always, it is possible to diagnose the associated tuberculosis of the lung by the usual methods.

Treatment of tuberculous pleural effusion is usually effective when the specific antituberculosis chemotherapeutic drugs are administered as for pulmonary tuberculosis. Cntreated tuberculous pleural effusions are often followed by manifestations of lung tuberculosis after an interval of several months or several years of good health, during which latent period there may be no X-ray evidence or other indication of the infection.

Acute inflammatory diseases of the lung, including pneumonia (*q.v.*), are sometimes associated with pleural pain and occasionally by accumulations of pleural fluid. The amount of such fluid is usually small. and it usually disappears promptly when the lung inflammation subsides.

Impaired circulation of blood in the lungs due to ineffectual heart action often leads to a seeping of fluid from the swollen and congested lungs into the pleural space. Treatment of the heart failure may relieve the congestion and permit resorption of the fluid. Often this requires the administration of diuretic drugs; limitation of sodium intake; rest; and administration of digitalis. Occasionally needle aspiration of the pleural fluid may accelerate improvement.

Empyema of the Thorax. — A collection of pus in the pleural space, known as empyema, is the result of severe and prolonged infection. Treatment is difficult and requires removal of the pus. either by repeated needle aspirations or by surgical drainage. Antibacterial drugs are selected which are active against the causative organism, hence bacteriologic examination of the pus is important. Surgical treatment sometimes requires the removal of large portions of the infected pleural membrane (decortication).

Tumours of the Pleura. — Most tumours which originate from the pleura can be classified as mesotheliomas. They may be either malignant or benign and may be either localized or extended over a large area of pleural surface. Diagnosis is rarely possible without microscopic examination, and that necessitates surgical biopsy in most circumstances.

Cancer of the lung (bronchogenic carcinoma) often extends peripherally to involve the pleura producing symptoms and findings similar to those of infection. Malignant implants on the pleura of tumours originating elsewhere in the body are rather common in the latter stages of widespread metastatic cancer. Such implants often lead to marked pleural effusion, and the fluid is often bloody. Diagnosis is established by X-ray examinations and sometimes by biopsy. Treatment is difficult, but radiation, using either X-ray or radioactive isotopes, and chemotherapy with tumour-inhibiting drugs may provide some temporary symptomatic relief. *(See* also CANCER; TUMOUR.)

Chylothorax.—Rupture of the thoracic duct, a channel which transmits lymph (chyle) from the abdominal cavity to the large veins of the upper thorax. may lead to accumulation of chyle within the pleural space. This material is recognized by its milky appearance and its high fat content. The t o commonest causes of chylolhorax are injury and metastatic malignancy.

Hemothorax. — Accumulation of blood in the pleural space may be a serious result of injury, especially when there has been damage to the larger blood vessels of the chest wall. Sometimes the rupture of adhesions between visceral and parietal pleura, occurring in association with pneumothorax, will lead to occult bleeding which may become serious before it can be recognized. It is possible for a patient to lose very large amounts of blood by this type of internal hemorrhage. Diagnosis often requires needle aspiration as well as X-ray examination, and treatment may or may not require open operation for repair.

Fibrothorax.—Pleural fluid may contain large amounts of fibrin, which may be deposited on the pleural surfaces eventually to be organized by formation of scar tissue. Sometimes this is sufficient to envelop all or a portion of the lung in a thick inelastic coating ahich limits lung expansion and impairs breathing ability. Surgical removal (decortication) may improve respiratory function in selected cases. Small localized collections of fibrin are frequent and of little or no significance.

For other diseases of the chest, *see* LUNG, DISEASES OF AND RESPIRATORY SYSTEM. DISEASES OF. (H. C. H.; H. C. Hw.)

PLEURONECTIDAE, one of the families of fishes to which the name "flatfish" is popularly applied. It includes the halibut, flounder, plaice and sole (*qq.v.*). *See* also FISHES.

PLEUROPNEUMONIA (LUNG PLAGUE) is a specific contagious disease of bovine animals usually terminating in a characteristic inflammation of the lungs and pleura (lining of the chest cavity). It is caused by a minute organism so small that it will pass through bacteriological filters. By magnifying at least 1,500 diameters. the organisms can be seen as small dots or coccoid bodies, spiral forms, branching and star-shaped figures, from which the name *Asterococcus mycoides* was given to the organism by Pierre Borrel. Although extremely small. it probably should not be classed as a truly ultramicroscopic virus.

The disease was once prevalent over much of Europe, having been recognized by Claude Bourgelat in 1769 in France and being known even earlier in Switzerland and Germany. It spread rapidly because of the traffic in breeding cattle, especially from the Netherlands and Switzerland, and caused such great losses that energetic steps of eradication had to be developed, including slaughter of diseased animals, quarantine and veterinary sanitation measures. It is reported that in Great Britain alone 187,000 cattle died of the disease in one year, 1860.

In the United States. contagious pleuropneumonia first appeared in Brooklyn in 1843, in New Jersey in 1847 and in Massachusetts in 1850, and then spread over most of the important cattle-raising states east of the Mississippi, causing the deaths of thousands of animals, particularly in Illinois. The disease was such a serious problem that the federal government finally intervened to set up an eradication program to supplement the efforts of the several states; this was a major factor in the establishment of the U.S. bureau of animal industry. The ultimate eradication of contagious pleuropneumonia in 1892 was the bureau's first great accomplishment; it did not appear afterward in the United States.

The disease was also eradicated or greatly reduced in most countries, but still occurred after the mid-20th century in parts of Asia. Africa. Australia and the U.S.S.R.

Natural infection usually takes place by contact of diseased animals with susceptible cattle. probably by inhalation of infective material. The incubation period is about two weeks, and the symptoms manifested are fever, loss of appetite, dry painful cough, accelerated pulse and respiration and the usual signs of acute pneumonia. Depending on the extent and severity of the infection, the disease may terminate fatally in a few days or run a more chronic course with apparent recovery. The disease may become active again because of focuses remaining in the affected lung tissues, however, and death often follows.

No effective treatment had been discovered by the 1960s, although immunization methods had had some success. Materials used for vaccination by inoculation in the tip of the tail include pleural exudate from naturally occurring cases and culture preparations made from the causative organism. Neither is entirely satisfactory, however, because a small percentage of vaccinates may die and many more lose their tails. The only effective method of dealing with the disease is by eradication. quarantine and other veterinary sanitation measures. Institution of such measures is preceded by a veterinarian's diagnosis through use of the complement-fixation test. A simple slide flocculation test also has been used with success by British workers, particularly in areas where it is not practical to employ the complement-fixation technique

A sidelight of possible public health interest is the expressed view of certain workers that bovine pleuropneumonialike organisms may be responsible for some of the obscure human illnesses of respiratory origin seen in the United States. (J. G. HH)

PLEVNA (Bulgarian PLEVEN), a city in Bulgaria on the Sofia-Varna railway (opened in 1899). Pop. (19j6) 57,758 A branch line, 25 mi. long, connects Plevna with Samovit on the Danube, where a port has been formed. After the events of 1877, it was almost entirely forsaken by the Turks, and most of the mosques have gone to ruin; but, peopled now mainly by Bulgarians, it has quite recovered its prosperity, and has a large commerce in cattle and wine (see RUSSO-TURKISH WARS).

Plevna, a small and unknown town uithout fortifications. became celebrated as the scene of Osman Pasha's exploits. He left Widin on July 13 with a column consisting of some 12.000 men and 54 guns. Hearing that he was too late to relieve Nikopol, he pushed on to Plevna, where there was a small garrison, and on July 19 he took up a position on the bare hills to the north and east. He was none too soon. General Schilder-Schuldner, commanding the 5th division of the 9th corps. uhich had just captured Nikopol, had been ordered to occupy Plevna, and his guns were already in action. On July 20, having made no preliminary reconnaissance, the Russian commander advanced his infantry in four separate columns. On the north flank they pressed into Bukova, and also succeeded in driving back the Turkish right wing; but in both cases Turkish counterattacks pressed back the Russians, with the result that by noon they were in full retreat.

Second Battle of **Plevna.**—In accordance with orders from the Russian headquarters at Tirnova, a fresh attack was made by Krudener on July 30. After a preliminary cannonade the infantry advanced at 3 P.M., as before, in widely spread columns The columns attacking from the north and northeast were repulsed with heavy loss. Shakovskoi temporarily occupied two redoubts, but a counterstroke by the Turkish reserves forced him back. The Russians retreated.

The Russians now concentrated all their available forces against Plevna and called in the aid of the Rumanians. By the end of August they had assembled a force of 74,000 infantry, 10,000 cavalry and 440 guns. On August 30 Osman moved out of Plevna, and on the 31st attacked the Russians about Pelishat. He returned to Plevna the same evening. The Turks lost 1,300 and the Russians 1,000 men. The Russians determined to occupy Lovcha, and so cut Osman's communications before again attacking Plevna. After three days' fighting this was accomplished by Skobelev, acting under Imeretinski, with a force of 20,000 men, on September 3. Osman moved out to the relief of the garrison that day with a strong column, but, finding he was too late, returned to Plevna on the 6th. The survivors from Lovcha were re-formed into 3 battalions, including which Osman had been reinforced to a strength of over 30,000, with 72 guns.

Third Battle of **Plevna.**—The Russians moved to their preliminary positions on the night of September 6–7. Their plan was to attack the north-east, south-east and south fronts simultaneously. An artillery bombardment began at 6 A.M. on September 7, and was carried on till 3 P.M. on the 11th, when the infantry advanced. The Rumanians took one Grivitza redoubt; Skobelev occupied two redoubts on the south front, but the centre attack on the Radischevo front failed. On the 12th the Turks recaptured the southern redoubts, the Rumanians remained in possession of the Grivitza redoubt, but the Russian losses already amounted to 18,000 and they withdrew, and entrenched themselves on a line Verbitza-Radischevo, with cavalry on either flank to the Vid. The Turkish losses totalled 5,000, of which only a few hundred were caused by the artillery fire of the first few days. There was no question of pursuit. The Russians were greatly superior in numbers and the Turks were completely exhausted.

Investment and Fall of **Plevna.**—This was the last open-force attack on Osman's lines. General Todleben, the defender of Sevastopol, was now entrusted with the conduct of the siege, and he determined to complete the investment, which was accomplished by October 24, Osman's request to retire from Plevna having been refused by Constantinople. Supplies eventually gave out and a sortie on the night of Dec. 9–10 failed, with the result that he and his army capitulated.

Plevna is a striking example of the futility of the purely passive defence, which is doomed to failure however tenaciously carried out. (J. H. V. C.; X.)

PLEYEL, IGNAZ (JOSEPH) (1757–1831), Austrian composer, conductor and publisher, and founder of one of the principal French firms of piano manufacturers. The 24th son of a schoolmaster, he was born at Ruppersthal, near Vienna, on June 1. 1757. He studied the piano in Vienna under J. B. Wanhal and, from 1774 to 1779, composition under Haydn. In 1776 he produced his puppet opera Die Fee Urgele on a libretto derived from Voltaire and Chaucer, at Esterhaz, and in 1780 his opera *Ifigenia* in *Aulide* was produced in Naples. He mas made deputy chapelmaster at Strasbourg cathedral in 1783 and principal chapelmaster in 1789. In 1792 he conducted symphonies by Haydn, Mozart and himself at the Professional concerts in London. In 1795 he opened a music shop in Paris where he sold his compositions. most of which were published between 1783 and 1793. In 1802 he published the first collected edition of Haydn's quartets. Having founded the Pleyel piano factory in Paris in 1807, developed b~ his son Camille Pleyel (1788–1855), he retired to his estate near Paris, where he died on Nov. 14, 1831. His instrumental works, written under the influence of Haydn, include 29 symphonies, eight concertos and numerous chamber works.

PLIMER, ANDREW (*c.* 1763–1837), English miniature painter, was the son of a clockmaker at Wellington. With his brother Nathaniel (1757–*c.* 1822), who also became a miniature painter, he joined a party of gypsies and wandered about with them, eventually reaching London, where in 1781 he was engaged by the miniaturist Maria Cosway as studio boy. Her husband. Richard Cosway, the leading miniature painter of the time, then received him into his own studio. In 1785 he set up for himself in Great Maddox street. He exhibited many times in the Royal Academy. His miniatures are of great brilliance and are in considerable demand among collectors. They are distinguished by the peculiar wiry treatment of the hair and by the large, expressive eyes that Plimer invariably gave to his female sitters. He died at Brighton in 1837 and was buried at Hove.

See G. C. Williamson, *Andrew and Nathaniel Plimer* (1903). (G. C. W.; X.)

PLIMSOLL, SAMUEL (1824–1898), British politician and social reformer, was born at Bristol on Feb. 10, 1824. His efforts for reform were directed more especially against "coffinships"—unseaworthy and overloaded vessels, often heavily insured, in which unscrupulous owners risked the lives of their crews. Plimsoll entered parliament as Liberal member for Derby in 1868, and failing to pass a bill dealing with the subject, he published a work entitled Our Seamen (1872), which made a great impression throughout the country. On Plimsoll's motion in 1873, a royal commission was appointed, and in 1875 a government bill was introduced, which Plimsoll, though regarding it as inadequate, resolved to accept. On July 22, when Disraeli, announced that the bill would be dropped, Plimsoll lost his self-control, applied the term "villains" to members of the house, and shook his fist in the Speaker's face.

Eventually Plimsoll apologised, but the country shared his view that the bill had been stifled by the pressure of the shipowners, and the popular agitation forced the government to pass a bill, which in the following year was amended into the Merchant Shipping Act. This gave stringent powers of inspection to the Board of Trade. The mark that indicates the limit to which a ship may be loaded is generally known as Plimsoll's mark. Plimsoll was re-elected for Derby at the general election of 1880, but gave up his seat to Sir W. Harcourt, in the belief that the latter, as home secretary, could advance the sailors' interests more effectively than any private member. Later on Plimsoll was estranged from the Liberal leaders by what he regarded as their breach of faith in neglecting the question of shipping reform. He became president of the Sailors' and Firemen's Union, and raised a further agitation about the horrors of the cattle-ships. Later he visited the United States with the object, in which he did good service, of securing the adoption of a less bitter tone towards England in the historical textbooks used in American schools. He died at Folkestone on June 3, 1898.

PLINY THE ELDER (GAIUS PLINIUS SECUNDUS) (A.D. 23 or 24–79), Roman savant and author of the celebrated *Natural History,* was born at Novum Comum (Como), in Transpadane Gaul. On this ground he claimed Catullus, a native of Verona in the same region, as a fellow countryman. His own writings and those of his nephew Pliny the Younger show that the date of his birth was in A.D. 23 or 24, that he must have come to Rome at an early age and that he practised for some time as an advocate. He saw military service in Germany. Under Vespasian, with whom he was on the most intimate terms, he served as procurator in Hispania Tarraconensis and elsewhere. He was in Africa, Gallia Narbonensis and Gallia Belgica and perhaps also in Judaea and Syria.

Finally Vespasian appointed him prefect of the Roman fleet at Misenum, in Campania, which Augustus had made one of the principal Roman naval stations. He was stationed at Misenum when, on Aug. 24, 79, there occurred the great eruption of Vesuvius which overwhelmed Herculaneum and Pompeii and cost Pliny his life. The circumstances are vividly told in a letter of the younger Pliny to the historian Tacitus. Pliny, wishing to assist those persons who were in danger, sailed from Misenum to his friend Pomponianus at Stabiae (Castellamare) on the southern shore of the Bay of Naples. There, in order to allay the fears of his friends, he dined, as his nephew says, "cheerfully, or what was equally splendid, with a pretence of cheerfulness!" and then retired to rest. In the middle of the night, when stones and ashes were already falling about the house and the house itself was rocking alarmingly, he was roused and he and his party determined to seek safety in the open, binding pillows about their heads as a protection against falling debris. "Now it was day elsewhere," runs his nephew's account. "but there night darker and denser than any night: alleviated a little by numerous torches and lights of various sorts. It was decided to go out upon the shore and see at close quarters whether the sea now offered any prospect of safety; it still continued wild and adverse. There Pliny lay down upon a cast-off linen cloth, and once and again he asked for cold water, which he drank. Then flames and a smell of sulfur announcing the approach of flames caused the others to take to flight and roused him. Supported by two slaves he got upon his feet, but immediately collapsed, his breathing, I gather, being obstructed by the thickening vapour which closed up his windpipe—naturally weak and narrow and frequently painful. When day returned—the third (in English reckoning the second, *i.e.,* Aug. 26) after the last day (Aug. 24) that he had seen—his body was found intact and uninjured: covered as he had been dressed. The appearance of the body suggested one sleeping rather than dead."

A list of Pliny's books in chronological order is given in a letter by his nephew: (1) *De iaculatione equestri unus* ("On Throwing the Javelin From Horseback, in One Book"), "written while he was serving as commander of a cavalry regiment with equal ability and care." (2) *De vita Pomponi Secundi duo* ("Life of Pomponius Secundus, in Two Books"), "the discharge, as it were, of a debt due to the memory of a friend who had entertained a singular affection for him." Pomponius, described by Tacitus as a man "of refined character and conspicuous ability" was a tragic poet who had also a military career of some distinction. (3) *Bellorurn Germaniae viginti* ("German Wars, in Twenty Books"), "in which he brought together all the wars waged between us and Germany. He began the work while he was serving in Germany, being admonished by a dream. The ghost of Drusus (stepson of Augustus and brother of Tiberius) who, having carried his conquest of Germany to the widest extent, died there, stood by him as he slept and commended to him his memory and entreated him to vindicate him from the injustice of oblivion." This work is cited by Tacitus, who probably used it in his *Germania.* (4) *Studiosi tres* ("The Student, in Three Books") "in which he instructs and perfects the orator from the cradle up." (5) *Dubii sermonis octo* ("Dubious Language, in Eight Books") "written in the last years of the reign of Nero when slavery had rendered dangerous every study of a free and elevated character." Fragments of the treatise were edited by J. W. Beck (1894). (6) *A fine Aufidi Bassi triginta unus* ("Continuation of the History of Aufidius Bassus, in Thirty-One Books"). The history of Bassus of which the terminal point is not known, Pliny continued down to his own day. (7) *Historiae Naturalis XXXVII* ("Natural History in Thirty-Seven Books"). This work alone is extant.

Pliny the Younger has given a description of his uncle's studious habits. He would call upon the emperor Vespasian before daybreak and then after performing his official duties return home and devote what time remained to study. After a light meal, if it were summer and he had leisure, he would often lie in the sun while a book was read and notes and extracts were made: he never read a book without making extracts, holding that no book was so bad as not to contain something good. Next he frequently had a cold bath, a snack and a short siesta, after which, "as if it were another day," he studied until dinnertime. During dinner a book was read and notes were made. He rose from the dinner table in summer before nightfall, in winter within the first hour of night. Thus at Rome; but in vacations no time was exempt from study, save bathtime, and even then he had something read to him or dictated something. while he was rubbed and dried. When traveling he was accompanied by a shorthand writer armed with book and notebook and in winter provided with gloves. To procure' time for study he was carried even in Rome and his nephew tells how he was once reproved by him for wasting valuable time in walking. R'hen he died Pliny bequeathed to his nephew 160 volumes of extracts *(electorurn cornmentarios)* "written on both sides and in the minutest hand." for which, uhen he was procurator in Spain and when the number of volumes was rather less, he had declined an offer from Larcius Licinus of 400,000 sesterces (c. £3,100).

The *Natural History,* which appeared with a dedication to Titus, son of Vespasian and his successor as emperor, two years before Pliny's death, is, as stated above, in 37 books. Book i has a general preface and contains a table of contents of the other books, to each being appended a list of the authors consulted. These lists contain the names of 146 Latin and 327 foreign authors. Book ii is devoted to a mathematico-physical description of the world and deals with the heavenly bodies—sun, moon, planets, fixed stars; various meteorological phenomena; the succession of the seasons; the earth's shape and surface phenomena—seas, rivers, springs and the like. The subject matter of this book affords Pliny an opportunity. of which he readily avails himself, to expound his own philosophic creed. which is a modified Stoicism. His view of nature is pantheistic. Books iii–vi are devoted to geography and ethnography. This is unscientific and uncritical but extremely valuable for the incidental facts which it presents. There is an interesting mention of maps of Armenia in book vi. 40.

Books vii–xi are occupied with zoology and are the most generally interesting section. The seventh book deals with man and is occupied less with the normal than with the marvelous and portentous, which the scientific creed of the author and his belief in the infinite power of *ingeniosa natura* enabled him to accept or at least not to reject outright. Thus there are tales such as would have charmed the ear of Desdemona--of men whose feet were turned the wrong way; of the Mouthless Men (Astomi) who subsisted upon the mere fragrance of flower and fruit; of the Umbrella-feet (Sciapodes) who used their extensive feet as parasols to protect them from the sun; of monstrous births; of precocity or exceptional development of physical strength or speed, sight or hearing, and mental powers; of men who were unconscionably long in dying. Incidentally, Pliny here declares his disbelief in immortality. Book viii treats of terrestrial animals other than man. Here again, amid much that is interesting in detail, there is an unfortunate absence of scientific arrangement and an excessive proneness to accept the marvelous, of which he was so unconscious that he expresses surprise at the credulity of the Greeks (*mirum est quo procedat Graeca credulitas*). Hence side by side with sound science, which comes mostly from Aristotle and, so far as concerns Africa, from Juba, there is a host of imaginary animals — winged horses, unicorns and like monstrosities. Book ix deals with aquatic animals and scientifically is the soundest of all the zoological books, which is no doubt due to the fact that Pliny's information is mainly derived, at least ultimately, from the *History of Animals* of Aristotle, who treats of aquatic animals with unusual fullness. The marvelous in this book is chiefly represented by Pliny's belief in Nereids and Tritons and the usual stories of the human sympathies of the dolphin. Book x treats of birds, commencing, according to Pliny's practice of beginning with the largest, with the ostrich. Such classifications as he makes of birds are of an empirical kind and based on very superficial observations. The first part of book xi is occupied with insects — the bee being treated with some fullness — and the latter part with what may be called comparative anatomy. Books xii–xix deal, generally speaking, with botany, including forestry and agriculture, the subject of book xviii, which is one of the most interesting in this section. Books xx–xxvii treat of medical botany or the medicines derived from plants. Books xxviii–xxxii deal with other than botanical *materia medica, i.e.*, with medicines derived from the bodies of man and other animals. The remaining books are occupied with mineralogy and with metals and metallic products, the precious metals, gold and silver, being discussed in book xxxiii; bronze, bronze statuary, iron and lead in book xxxiv; chiefly painting in book xxxv; stone, including its use in building and sculpture, in book xxxvi, gems and precious stones in book xxxvii.

Pliny's *Natural History* is a storehouse of ancient errors, but there are many branches of ancient manners and culture, such as sculpture and painting, concerning which he gives valuable information which can be found in no other extant writer. His style is sometimes dry and abrupt and sometimes slovenly, but at other times strongly rhetorical, pointed or mannered. The influence of his work on later times was great. Some three-quarters of the *Collectanea rerum memorabilium* of C. Julius Solinus (3rd century A.D.) were based on it, and on books xx–xxxii was based the *Medicina Plinii*, a compilation of the 4th century.

PLINY THE YOUNGER (GAIUS PLINIUS CAECILIUS SECUNDUS) (A.D. *61* or *62–c.* 113), Roman author and administrator, nephew and adopted son of the elder Pliny, who left a collection of private letters of great literary charm which intimately illustrate public and private life in the heyday of the Roman empire. His official correspondence as a provincial governor is a unique set of documents, and his career is characteristic of those concerned with the management of the peaceful areas of the Roman empire.

Born *c.* A.D. 61–62 of a wealthy family at Comum in north Italy, he was educated at Rome and began to practise law when aged 18. He made a reputation in the courts of civil law, and later was in demand in the political court that tried provincial officials on charges of extortion. His most notable success was in A.D. 100, when he secured the condemnation of the proconsular governor of Africa: and of a group of officials from southern Spain. Meanwhile he had reached the highest grades of the administration by securing the titular posts of praetor in 93 and of consul in 100, despite the fact that he was the first member of his family to become a Roman senator. In this he owed much to the influence of friends of his uncle. Pliny had financial ability, and was head successively of the military treasury (*aerarium militare*) and of the senatorial treasury (*aerarium Saturni*), (A.D. 94–100). After administering the drainage board of the city of Rome—*cura alvei Tiberis*— (*c.* A.D. 104–106) he was sent (c. A.D. 110) by the emperor Trajan on a special mission to investigate corruption in the municipal administration of Bithynia. He apparently died there in office about two years later. His military experience mas limited to a short commission on the staff of the governor of Syria at the beginning of his career, where his duties were financial. The details of his life are known from his letters: and from inscriptions set up in his honour at Comum.

Pliny, like his contemporary Tacitus was a conventional man who accepted the Roman empire, serving under "good" and "bad" emperors alike, and making in his writings the conventional complaints against the latter. He concealed the preferment which he secured from the hated Domitian, and even claimed, later, that he had been in political danger through his tenuous connection with the faction that had criticized Domitian and had suffered accordingly in a famous state trial in the year of Pliny's praetorship.

The Letters.— Publication and Chronology.— He published selections of his private letters in nine books, issued apparently in three or four groups at irregular intervals between 100—109. After essaying the state of the market with the first two volumes, possibly issued separately, since they contain no interconnecting links, he issued a series of five or six, in which the letters are arranged to a certain extent in interconnected series. The ninth volume contained a miscellany of mostly very short letters of uneven interest and uncertain date, which may well represent the residue of publishable material in his files before he left Italy for the governorship of Bithynia. The tenth book is a posthumous publication. The chronology of the letters has been much discussed. The material in the first eight books is chronologically coherent. Books i and ii overlap, covering events from after the death of Domitian in Oct. 97 to the early part of 100. Book iii touches events of the next three years. Thereafter books iv to vii inclusive (%-ith the exception of iv, 9, for a special reason) are confined each to the events of about a 12-monthly period from 104-105, to 107-108. The last two books cover much the same period as vii, but contain a few letters from earlier periods of the correspondence. This chronology depends not only upon a number of dated or datable historical references, and of obviously continuous groups of letters, but also on a series of subsidiary cross-references and interrelations in the subject matter which have not yet received sufficient attention.

Style and Content.— The letters are neither imaginary epistles in the style of Seneca nor unimproved copies of daily correspondence like those of Cicero. They are carefully written occasional letters. The topics are very diverse. Each letter contains an item of recent social, literary, political or domestic news or sometimes an account of an earlier but contemporary historical event, or else initiates moral discussion of a particular problem. Each has a single subject, and is written with considerable artifice in a style which mixes, in Pliny's terminology, the historical, the poetical and the oratorical manner, to fit the theme. Length depends on theme, but brevity is preferred. Pliny apologizes for the unusual length of certain letters. Whether they were all written as genuine letters is much discussed, but is the wrong question. Several are obvious literary revises of more practical originals, as nhen he discusses a new building with his agent, but omits its dimensions. Touches of revision can be detected in some of the longest historical letters that most resemble formal essays (*e* g., i, 5). The composition of these *litterae curiosius scriptae* ("letters written with special care") was a contemporary fashion which Pliny developed into a miniature art form. to uhich the closest parallel lies in the similar occasional verses of Martial. Pliny is a prose Martial. without the indecency. The form arose naturally in a wealthy and cultured class of interrelated families, lacking rapid communications.

There are letters of advice to young men, often illustrated by anecdotes short notes of greeting and inquiry to absent friends, descriptions of newly discovered scenes of natural beauty or of natural curiosities. There are compressed accounts of the lives and habits of famous men. Estate business is a frequent theme—crises in farming, famines, sales and floods. Forensic scenes play a large role; the longest letters describe the triumphs of Pliny in the political courts. Roman society is there in all its diversity—an aged and decrepit roué cheating his toadies in his last testament, or an octogenarian relict of the court of Nero maintaining bygone depravities in a more strait-laced age.

Pliny reveals himself as a successful and complacent, kindly man, patronizingly generous towards his juniors and inferiors. and smoothly tolerant of all but the most objectionable of his peers. His character is often unfavourably judged, but the model of the magnanimous man, mhich he consciously imitates, was honoured in antiquity as the highest pattern of human virtue.

Pliny was a shrewd man. who kept a careful eye on his landed estates, now discussing the pros and cons of a new purchase. now advising a friend how to prevent a municipality from wasting its endowments, now offering his wholesale buyer a price reduction when the grape market broke, with an eye to future deals, now modifying his system of rentals in order to keep the tenantry on his estates. Such letters reveal the abilities for which Trajan chose him to reorganize the municipal finances and local government of Bithynia. The tenth book of letters contains the minutes which he addressed to Trajan on sundry problems, and the emperor's replies. He consulted Trajan 42 times in a period of some 18 months. The topics include municipal expenditure on public works, the qualification of municipal councilors, the treatment of criminals and the prosecution of Christians.

Pliny has been criticized for lack of independent judgment and responsibility by those with little experience of modern bureaucracy, but it must be remembered that his province nas lacking in archives and permanent administrative staff. Official documents were known only from copies held by plaintiffs and petitioners. Many problems required an alteration of the basic law of the province, or the amendment of an imperial edict. Others involved the rights of Roman citizens, or the privileges of independent imperial officials. Pliny was also anxious that his decisions should be based on general rules approved by the central government instead of on *ad hoc* decisions. Hence he had good reasons for the submission of most of his inquiries to the emperor at Rome. who only once reproves him for writing needlessly.

On eight occasions Pliny seeks Trajan's approval for large public building operations — theatres. aqueducts. baths. sports stadium, and a canal; it seems that Trajan initiated a rule that required central sanction for new municipal expenditure of this sort. Pliny was also anxious to secure Roman engineers and architects to supervise these works for a reason which Trajan failed to understand — that he did not trust the local experts, who had been responsible for extensive jerry-building. Pliny's humanity was in several instances notably greater than that of the emperor. In the affair of the Christians his examination of prisoners led him to query the assumption that the new cult was associated with vicious practices. Though ready to execute Christians as members of a proscribed sect, he sought confirmation that this was the policy of the central government.

Pliny's letters introduce many of the leading figures of Roman society in the 12 years after the death of Domitian — men of letters, politicians, administrators, generals and rising young men of rank. They make possible the social reconstruction of an age for which there is otherwise no serious historical record. He was an adept at brief character sketches, less satirical, more kindly and possibly more complete than those of Tacitus. His portrait of the learned lawyer Titius Aristo is typical (i, 22, 1–3). He was also a devotee of literature. He has left a detailed picture of the amateur literary world of his time, and of the salons in which it was the custom to recite one's work and to seek critical revision from one's friends.

Pliny published his forensic and literary speeches with loving care, and late in life took to the contemporary fashion for light verse in the style of Martial, at which his samples show that he was no adept. Though fulsome in the praise' of contemporary writers, his judgment of the dead Statius was fair: "he was ever writing poems with greater pains than ability." His letters addressed to his fellow advocate Tacitus (*q.v.*), then occupied with his first major work. tell the little that is known about the date and circumstances of the composition of the *Historiae,* to which. Pliny contributed his famous account of the eruption of Vesuvius. The biographer Suetonius was among his *protégés.*

A seldom noticed aspect of Pliny's mentality is his semiscientific interest in natural phenomena, which he shared with his uncle, author of the *Naturalis Historia.* Four long letters describe with careful accuracy the peculiar behaviour of subterranean springs, the course of the Vesuvian eruption and the floating islets of the Vadimonian lake (iv, 30; vi, 16. 20; viii, 20). His speculations about their causes are rational. His discussion of dreams and visions has the same quality (vii, 27). His description of external scenery, whether natural or artificial, is remarkably precise, with an exact sense of detail, despite an elaborate literary style.

Style as an Orator.—Pliny's grand oratorical style is known from his panegyric. delivered in the senate when he entered office as consul. This is elaborately antithetical, colourful in ornament, inflated in substance, passionate and violent in tone, and contrasts with the deiicacy and balance of the letters. In it he contrasts the merits of the new emperor Trajan with the vices of Domitian, in a most partial manner. but still provides a valuable historical account of Trajan's succession and the first phase of his reign. Pliny's normal forensic manner was probably a great deal quieter and more argumentative, as in viii, 14. He debates the "battle of styles" in several letters.

BIBLIOGRAPHY.—The best modern editions of the letters and of the panegyric of Trajan are those in the "Teubner Series," by M. Schuster, 2nd ed. (1952) and in the "Budé Series," vol. i–iii, by A.-M. Guillemin (1927–43), vol. iv by M. Durry (1947). *See* the Eng. trans. by W. Melmoth, *The Letters of Pliny the Consul* (1746), rev. by W. M. Hutchinson, "Loeb Series," 2 vol. (1915). There are no modern general commentaries except E. G. Hardy, *Plinii epistulae ad Traianum* (1889); M. Durry, *Panégyrique de Trajan* (1938). *See* also (for Pliny's life and chronology) T. Mommsen, *Gesammelte Schriften,* vol. iv (1906), pp. 366 ff.; A. N. Sherwin-White, "Pliny's Praetorship Again," in *Journal of the Royal Society,* pp. 126 ff. (1937); R. Syme, *Tacitus,* ch. vii–viii (1938); (for Pliny and literature) **h.-M.** Guillemin, *Pline et la vie littéraire de son temps* (1929). (A. N. S.-W.)

PLIOCENE (from Gr. *pleion,* "more," and *kainos,* "recent"), the geological epoch immediately preceding the Glacial (Pleistocene) epoch as indicated on the accompanying geologic time chart. Many modern genera appeared before the epoch was over.

The name Pliocene was introduced by Sir Charles Lyell (1830, published 1833) for the youngest of his three divisions of the Tertiary (q *v.*) period of time. Lyell initially recognized a "Newer" and an "Older Pliocene." In 1839 he substituted the name "Pleistocene" for "Newer Pliocene." restricting the "Pliocene" to "the formations of Tuscany. and of the Subapennine hills in the north of Italy. as also the English Crag." In 1846 Edward Forbes redefined the Pleistocene, making it equivalent to the time interval of continental glaciation in Europe. This was considered to have begun somewhat later than was originally envisaged by Lyell and resulted in controversy as to the age of strata falling between the Pliocene as defined by Lyell and the Pleistocene as described by Forbes. During the 18th International Geological congress. in 1938, discussion of criteria for definition of the Pliocene-Pleistocene boundary indicated that the beginning of the

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	1,000 Years
CENOZOIC ERA			
Quaternary	Recent	Modern man	11
	Pleistocene	Early man	1,000
Tertiary	Pliocene	Large carnivores	
	Miocene	Whales, apes, grazing forms	
	Oligocene	Large browsing mammals	
	Eocene	Rise of flowering plants	
	Paleocene	First placental mammals	70,000
MESOZOIC ERA			
Cretaceous		Extinction of dinosaurs	130,000
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	160,000
Triassic		Appearance of dinosaurs	200,000
PALEOZOIC ERA			
Permian		Reptiles developed, conifers abundant	235,000
Carboniferous			
Upper (Pennsylvanian)		First reptiles, coal forests	260,000
Lower (Mississippian)		Sharks abundant	285,000
Devonian		Amphibians appeared, fishes abundant	320,000
Silurian		Earliest land plants and animals	350,000
Ordovician		First primitive fishes	400,000
Cambrian		Marine invertebrates	500,000
PRE-CAMBRIAN TIME			
		Few fossils	3,500,000–4,000,000

glacial epoch occurred earlier than previously recognized. The boundary has been placed at the original Lyell horizon.

Miocene-Pliocene Boundary.— Type sections of the Lyellian epochs do not occur in the same region. Deposits in many areas of the world cannot exactly be correlated with the Lyell units but are intermediate in position. The problem of the Miocene-Pliocene boundary, for example, has become complex. Vertebrate-bearing Sarmatian and Pontian strata of eastern Europe are not represented in the type sections of either epoch. Vertebrate paleontologists consider the advent of Hipparion, a primitive horse found in North America, Europe. Asia and Africa. as marking the beginning of the Pliocene. This genus first occurs in Pontian faunas; hence they are recognized as basal Pliocene. Correlative marine faunas are of distinctive Miocene aspect; invertebrate paleontologists assign the containing strata to the Upper Miocene (*q.v.*), which is the classification used in this article.

PHYSICAL HISTORY

The Miocene epoch closed with a widespread marine regression and consequent development of continental deposits. The expanded Black Sea and Caspian basins, cut off from the Tethyan (ancestral Mediterranean) sea, became brackish water bodies that persisted through the Pliocene. The marine life trapped in these basins underwent striking evolutionary changes.

The Pliocene began with a marine transgression and closed with a regression. In the Sub-Apennine area of Italy, considered as the type area of the epoch, the transgressive phase is represented by blue marls with offshore faunas. These pass upward into yellow sands with littoral faunas regarded as regressive deposits. Above are intertonguing marine (Calabrian) and nonmarine (Villafranchian) strata that, prior to 1948. were assigned to the Upper Pliocene. Much of Italy was flooded by Pliocene seas but small gulfs in the mouths of the larger river valleys characterize most of the Mediterranean Pliocene.

Embayments from the North sea covered Belgium and eastern England. Lower strata have a fauna of warm water affinities indicating a seaway opening toward the south. The deposits in England include the Coralline Crag (crag = shell sand) remarkable for the abundance of bryozoans. formerly identified as coral. The overlying Red Crag of Sussex has a cold water fauna suggesting that the southerly connection had closed.

In eastern Europe large fresh-water lakes formed. Most important were: (1) the Pannonian lake covering the Hungarian plains; (2) the Dacian lake. separated from the Pannonian by the Carpathian mountains. covering the lower Danubian plains; (3) the Aegean lake occupying the area of the Sea of Marmora, most of the Aegean sea, and parts of Greece and Thrace.

Marine Pliocene deposits in eastern North America are confined to peninsular Florida (Caloosahatchie formation) and coastal South Carolina and southern North Carolina (R'accama formation). The thickest known marine Pliocene, however: occurs in southern California where more than 13,000 ft. of sediments are found in the Ventura basin. Local embayments occurred from Lower California to Alaska.

Occasional mammalian teeth in the shallow water marine formations aid in correlating the marine and nonmarine strata of California. The Thousand Creek formation of Nevada and the Rattlesnake beds of Oregon are of Pliocene age, as is the upper part of the Ogallala group of the high plains; the lower part is correlated with the Pontian stage. These sandy deposits contain seeds of grasses and herbs, bones and teeth of grazing mammals, and leaves of poplar, willow, hackberry, elm and other trees that grew along stream valleys.

In Texas the first appearance of large ground sloths (*Megalonyx*), migrants from South America, testifies to the re-establishment of the connection between the two continents.

Pliocene deposits are not extensive in South America. In Argentina continental Hermoso beds of the Pampas, and the Tunuyan and Araucanian deposits of the Andean foothills yield mammalian remains. Marine faunas occur in the Mancora and Sechura formations of northwestern Peru.

In Japan, marine deposits are widespread but thin and discontinuous due to deposition in small gulfs. An exception occurs in the Vezo-Karafuto geosyncline bordering the Japan sea in northern Honshu island. Here a thick sequence of Miocene-Pliocene strata has no evidence of stratigraphic break between the two epochs. Elsewhere a major hiatus is evident.

Many Pacific islands show raised reefs and reef limestones that are believed to be of Pliocene age. There are also areas of local embayment, as in the Cagayan valley of northern Luzon and the Iloilo basin of Panay, in the Philippines, where clastic sediments represent marine transgressions. In New Zealand Pliocene sediments occur only along the coast of South Island, but an embayment or strait transected North Island in the Napier Bay-Wanganui area. Noteworthy is the fact that whereas the Lower Pliocene faunas are of colder water facies than those of the Miocene, the Upper Pliocene (Castlecliffian) Mollusca indicate warmer waters. This trend which continued into the Pleistocene is interpreted as resulting from the shifting of oceanic currents caused by Late Pliocene diastrophism in the Pacific basin.

Continental deposits of Pontian age are widely distributed in Asia; true Pliocene deposits, however, occur only in the Nagri and Dhok Pathan formations of the Siwalik series of northern India, and at a few poorly known localities in China.

Volcanism.—The volcanic Massif Central of France was initiated as early as Oligocene time, but the first well-dated flows are of Upper Miocene (Pontian) age. During the Pliocene, however, the great volcanoes of Cantal and Mont-Dore grew to elevations comparable to Mt. Etna. Ash and lava flows, 1,000 m. in thickness entomb Lower Pliocene plants and insects. Activity continuing into Villafranchian time culminated in basalt flows that form the present Massif surface.

Tertiary volcanism in North America occurred mainly during the Miocene epoch, but in many areas eruptions continued throughout Pliocene time.

PLIOCENE LIFE

Marine Life.—Marine mollusks show a predominance of recent species. Notable is the trend toward cooler water conditions than are evidenced by Miocene life. The only major exception is in New Zealand. Marine mammals reached their maximum development in the Miocene seas. Many genera became extinct at the end of that epoch, but nearly all families persisted, in reduced numbers. into the recent. Pliocene additions are the rorqual (Balaenopteridae) and the right whales (Balaenidae).

Continental Life.—The Pliocene mammalian fauna of the northern hemisphere is of modern aspect with the majority of the families represented still being extant. A limited amount of faunal exchange took place between Eurasia and North America during Pontian time at the end of the Miocene, but there is little to suggest a connection during the Pliocene itself. No representatives of the Bovidae (cattle, bison. antelope, etc.) or of the Cervidae (deer), families of Eurasian origin, were in the North American fauna. Their place was taken by antilocaprids, related to the pronghorn. Hypohippus, a long-necked. long-bodied. short-limbed. forest horse, and *Hipparion*, a three-toed horse, reached Europe during the Upper Miocene and are present in Eurasia and North America during the Pliocene; typical North American Pliocene horses including *Pliohippus*, ancestor of Equus, did not reach the old world. (See also EQUIDAE.)

Characteristic North American Pliocene mammals include camels (Pliauchenia, *Procamelus*); hornless rhinoceroses (*Aphelops*, Peraceras); short-legged, hip'popotamuslike rhinoceros. *Teleoceras;* beavers (Castor, *Dipoides*); large cats (Felis) and sabretooths (*Machairodus*); proboscideans, including *Tetralophodon*, shovel-tusked *Amebelodon*, and mastodons; and many others.

Eurasian faunas are strikingly like those of modern Africa. Bovids include cattle, bison, sheep and goatlike forms and many genera of antelopes. Deer, including Cervus, flourished, along with abundant suids and, in Asia, varied giraffids. Proboscideans include the peculiar *Dinotherium* with recurved lower jaw tusks, Stegodon, an ancestral elephant, and Mastodon. Among the Primates are the monkeys *Macacus* and Cercopithecus, and the apes Dryopithecus and Pliopithecus in Europe, and a larger number of genera in Asia.

Floras. — Pliocene floras are, generically, almost identical with those of today. Distributional differences reflect differing climatic conditions that obtained during the epoch. Unusual is the flora of England, dominated by a mixture of Japanese and North American forms with some Himalayan and Indo-Malayan types. See also PALAEOBOTANY; PALAEONTOLOGY.

PLOCK (PLOTSK), a town of Poland in the province of Warszawa. on the Vistula, 67 mi. by the Vistula W.N.W. of Warszawa. Pop. (1931) 32,777; (1950) 33,100. It has a cathedral dating from the 12th century, but restored in 1903, which contains tombs of Polish dukes and of Kings Wladyslaw and Boleslav (of the 11th and 12th centuries). There is considerable navigation at this point on the Vistula. Germany occupied Plock during World War II. It was returned to Poland in 1945.

PLOEȘTI, a city of Rumania, in the region of the same name, at the southern entrance of a valley among the Carpathian foothills. through which flows the Prahova river; it is at the junction of railways to Buzau, Bucharest and the Transylvanian system. Pop. (1956) 114,544. As the name Ploești (*pluviena*, "rainy") implies, the climate is moist. The surrounding hills are rich in petroleum, salt and lignite. Ploegti is the greatest centre of the Rumanian oil industry, and was severely bombed by the allies in World War II. There are cardboard factories, roperies and tanneries. Ploești possesses various schools. several banks and many churches, including the Orthodox church of St. Mary, built in 1640 by Matthew Bassarab.

PLOTINUS (A.D. 205–270) was the founder and incomparably the greatest philosopher of the Neoplatonist school. There is a good deal oi reliable information about his life, as his pupil and editor Porphyry wrote his master's biography as an introduction to his edition of the works of Plotinus, the Enneads (it appears at the beginning of all complete manuscripts of the Enneads and is printed in the same place in all editions). But Plotinus himself would never say anything about his family or birthplace, and it is not known for certain to what race or country he belonged, though it is generally assumed. on the strength of a statement of rather doubtful reliability in Eunapius, that he came from upper Egypt. He was certainly Greek by education and cultural background. He studied philosophy at Alexandria, where he could find no teacher to satisfy him till someone introduced him to the mysterious Ammonius Saccas (*q.v.*), with whom he remained for 11 years. He went east in 243 with the emperor Gordian III's expedition, in the hope of studying Persian and Indian philosophy. But Gordian was murdered in Mesopotamia in 244, and Plotinus escaped to Antioch without having made any contact with eastern thinkers. In the same year he went to Rome. where he spent the rest of his life teaching philosophy and, after ten years, began to write. This is the period when he is known best from Porphyry's biography, where he appears not only as a great teacher and spiritual director but also as a man of great charm and of far-reaching and efficient practical kindness. He died in his 66th year, after a long and painful illness (probably a form of leprosy) which he bore most bravely. His writings were collected and published by Porphyry in the rather artificial arrangement known as the Enneads; but Porphyry also kept and published in his biography a record of the chronological order in which they were written, which is followed in some modern editions.

The importance of Plotinus in the history of European thought is very great indeed. For more than two centuries before his time a revived Platonism, much influenced by Aristotelianism and by the Stoics, had been developing. But it was Plotinus, a philosophical genius of the first order and at the same time a man of deep contemplative religion and one of the world's greatest mystical writers, who made this new Platonism into one of the great religious philosophies. The success of Neoplatonism was rapid. Soon after Plotinus' death it came to dominate the Greek philosophical world completely. It deeply influenced, too. the new intellectual world of the great Christian thinkers. It is true that the beginnings of Christian Platonism go back behind Plotinus and that the great Christian Platonists were more original and independent — and indeed more thoroughly Christian — thinkers than has sometimes been supposed and so must not be represented as merely passive recipients of the influence of Plotinus and his school. Nevertheless that influence did go very deep with many of the Christian Fathers. notably with St. Augustine in the west and with the great Cappadocians, St. Basil and St. Gregory of Nyssa, in the east; and. later, the enigmatic but extremely influential Dionysius Xreopagiticus (*q.v.*) was much influenced by Neoplatonism. Plotinus, through these and other intermediaries, had a great indirect influence on the thought of the middle ages and both a direct (after the publication of Marsilio Ficino's Latin translation in 1492) and an indirect influence on the Renaissance; and his philosophy, still living and actual in the 20th century, seems likely to continue to be so, for his writings have in them an unusual power to inspire a new outlook on the world. to raise men's minds to the eternal and to encourage a moral virility very valuable in precarious times.

Philosophy. — Like other philosophers of the Hellenistic and Roman periods, Plotinus is a religious and moral teacher as well as a professional philosopher engaged in the critical interpretation of a long and complicated school tradition. He is an acute critic and a formidable arguer, with the intellectual honesty of a true philosopher; but philosophy for him is not primarily a matter of abstract speculation, or critical discussion of language or concepts, but a way of life in which, through an exacting intellectual and moral self-discipline and purification, those who are capable of the ascent can return to the source from which they came out. His philosophy is an account of how from the eternal creative act, at once spontaneous and necessary, of that transcendent source. the One or the Good, proceeds a world of living reality constituted by repeated double movements of outgoing and return in contemplation; and this account. showing the way for the human self, which can experience and be active on every level of being, to return to the One, is itself an exhortation to follow that way.

Plotinus always insists that the One or the Good is beyond the reach of thought or language; what he says about this supreme principle is only intended to point the mind along the way to it, not to describe or to define it. But though no adequate concept or positive definition of the Good is possible, it is certainly not for Plotinus a mere negation or ultimate void in attaining to which the human personality disintegrates into unconscious nothingness.

It is a positive reality of infinite richness and superabundant excellence. Plotinus often speaks of it in extremely negative language—largely inherited from the Platonic school tradition. But his object in doing so is to stress the inadequacy of all our ways of thinking and speaking to express this supreme reality, or to make clear the implications of saying that the Good is absolutely one and infinite and the source of all defined and limited realities.

The original creative act of the One produces the first great derived reality, *nous,* intellect or spirit; from this again comes soul, which forms, orders and maintains in being the material universe. It should be remembered that the generation of this ordered universe is timeless; *nous* is eternal, and time is the life of soul, and there was never a time when the material universe did not exist. Also we must remember that the "levels of being" are not spatially separate or cut off from each other. They are really distinct, but all intimately present in every part of the universe and in each one of us. To ascend through soul to intellect and from intellect to the One we do not have to travel in space to another world, but must wake to a new kind of awareness.

Intellect for Plotinus is both thought and object of thought; it is a mind which is perfectly one with its object. As object, it is the world of forms or ideas, the totality of real being in the Platonic sense. These forms are produced by intellect's apprehension in multiplicity of the rich unity of its principle, the One; and, being one with intellect, they are not merely static objects but living, thinking subjects, each not only itself but capable in contemplation of becoming the whole. They are archetypes and causes of the necessarily imperfect realities on lower levels, souls and the forms in body. We, at our highest, are intellects, or souls perfectly conformed to intellect; we become aware of our intellectual nature when, passing beyond not only sense perception but also the discursive reasoning characteristic of the life of soul. we attain to an intuitive contact and immediate possession of eternal realities.

Soul in Plotinus is very much what it is in Plato, the intermediary between the uorlds of intellect and sense and the representative of the former in the latter. It is produced by intellect, as intellect is by the One, by a double movement of outgoing and return in contemplation, but the relationship between the two is more intimate and the frontier less clearly defined. For Plotinus, as for Plato, the characteristic of the life of the soul is movement, and this soul movement is the cause of all other movements. Soul, unlike intellect. does not possess being as a whole, one with itself in immediate awareness; it is on the level, as already mentioned, of discursive thought which does not grasp its object immediately but has to seek it by a process of reasoning. The life of the soul in this movement is time, and on it all physical movement depends. Soul in relation to the material universe exists on two levels, a higher and a lower. The higher, in close and unbroken touch with intellect, forms and rules the material universe from above; the lower, which Plotinus often calls nature, acts as an immanent principle of life and growth and in its dreamlike contemplation, the last and lowest of contemplations, produces the immanent forms in body, which are noncontemplative and so sterile. Below these lies the darkness of matter, the absolute limit, the final absence of being at which the expansion of the universe from the One through diminishing degrees of reality and increasing degrees of multiplicity comes to an end. Because of its utter negativity, matter (at least the matter of the lower regions of the sense world) is for Plotinus the principle of evil; and his language about it has a strongly dualistic flavour. His real thought, however, does not seem to be genuinely dualistic, and he strongly maintained against the Gnostic dualists of his time the goodness and nobility of the physical universe as the best possible work of soul; in this he was faithful to the teaching of Plato in his later dialogues, as expressed most impressively and influentially in the Timaeus.

We, as souls in bodies, can exist on any level of the soul's experience and activity. (Our descent into bodies is for Plotinus, who has some difficulty in reconciling Plato's various statements on this point, both a fall and a necessary compliance with universal law.) We can ascend in spirit to the level of universal soul, become that whole which we already are potentially and, in soul, attain to intellect; or we can isolate ourselves on the lower level, shutting ourselves up in the experiences, desires and concerns of the lower nature to which we are attached and remaining ignorant of any higher kind of awareness than that of the senses. Philosophical conversion, the beginning of the ascent to the One, consists precisely in turning away from the life of the body, dominating and rising above its desires and "waking to another way of seeing. which everyone has but few use." This, Plotinus insists, is possible while we are still in an earthly body and without neglecting the duties of our embodied state. But the body and bodily life is something which weighs us down and hampers us in our ascent; Plotinus' language when speaking of it in this connection is strongly dualistic and other-worldly. In this he follows Plato in the *Phaedo,* but it is not impossible that he was unconsciously influenced by the Gnosticism that he consciously opposed.

The material universe for Plotinus is a living organic whole. Its organic wholeness is the best possible reflection on the material level of the living unity-in-diversity of the world of forms in intellect. It is held together in every part by a universal sympathy and harmony (a belief in which, deriving both from Stoic philosophy and from some very primitive conceptions, Plotinus shared with contemporary magicians and occultists). In this harmony external evil and suffering take their place as necessary elements in the great pattern, the great dance of the universe. Evil and suffering can affect our lower selves but cannot touch our true, higher selves and so cannot interfere with the real well-being of the philosopher who chooses to live on that higher level.

From what has been said so far something of the nature of Plotinus' religion should have become clear. It is essentially the effort to actualize in ourselves the great impulse of return to the Good which constitutes reality on all its levels. By a rigorous moral and intellectual self-discipline we awake from the alienation of our lower state and rediscover our true selves. We become intellect and then, when the One manifests to us his continual presence, we rise to the mystical union, carried on the surge of the current of the impulse of return in its strongest and final flow, the pure love of intellect for its source. There is no consciousness of duality in that union; we are not aware of ourselves; but we are not destroyed or dissolved into the One because even in the union we are still intellect, though intellect "out of itself," transcending its normal nature and activity. The mystical union was for Plotinus, in this life at any rate, a rare and transitory experience. He attained to it, Porphyry tells us, four times while Porphyry himself was a member of the school. But it was the goal of all his effort and the source of the continuing power of his teaching. Philosophy for him was the way to union with the Good through moral purification and intellectual enlightenment.

BIBLIOGRAPHY.—The Greek text of the Enneads was first printed by P. Perna (Basle, 1580), together with the Latin trans. by Marsilio Ficino, which had already appeared (Florence, 1492). The best 19th-century edition is by R. Creuzer and G. H. Moser (Oxford, 1835; text reprinted in the Didot ed., Paris, 1855); others are by A. Kirchhoff (Leipzig, 1856). by H. F. Miiller (Berlin, 1878–80) and by R. Volkmann (Leipzig, 1883–84). The edition of E. Bréhier (Paris, 1924–38), though the text is poor, is valuable for its admirable notes and introductions to the several treatises. A great critical edition, to supersede all others, was undertaken by P. Henry and H. R. Schwyzer (Paris and Brussels, 1951 ff.).

Plotinus has been translated into most modern European languages. In English there is a complete translation by S. MacKenna and B. S. Page, 2nd ed., rev. (London, 1957); also selections trans. with introduction and notes by A. H. Armstrong (London, 1953). The French translation by M. N. Bouillet (Paris. 1857–61) is still valuable for its vast and learned commentary; and there is a version by E. Bréhier (in his edition). The German translation by R. Harder (Leipzig, 1930–37; reissue, with text and commentary, Hamburg, 1956 ff.) and the Italian by V. Cilento (Bari, 1947–49) are accurate and scholarly.

For a complete bibliography of the vast literature on Plotinus, up to 1949, see B. Marien, *Bibliografia critica* degli studi plotiniani (Bari, 1949), published with the last volume of Cilento's trans. Only a few works can be mentioned individually here: W. R. Inge, ***The Philosophy***

of Plotinus (1918; reprint 1948); E. Bréhier, *La Philosophie de Plotin* (1928); A. H. Armstrong, *The Architecture of the Intelligible Universe in the Philosophy of Plotinus* (1940); J. Katz, *Plotinus' Search for the Good* (1950); H. R. Schwyzer, "Plotinos," in Pauly-Wissowa, *Real-Encyclopädie*, vol. xxi (1951); M. de Gandillac, *La Sagesse de Plotin* (1952); J. Trouillard, *La Procession plotinienne* and *La Purification plotinienne* (1955); H. Fischer, *Die Aktualitat Plotins* (1956).

PLOVER, the name given to an indefinite group of birds which, with the snipes and sandpipers, form the group *Limicolae* or "waders," although the plovers themselves rarely enter water. Perhaps the best entitled to the name are the golden plover (*Charadrius pluvialis*) and the gray plover (*Squatarola helvetica*). The latter is the larger and lacks the hind toe; otherwise the two forms are similar. The gray plover breeds in the far north of America, Asia and Europe, migrating south in the winter, when it reaches the Cape, Australia and Ceylon. The golden plover is more local but ranges from Iceland to Siberia, including the British Isles, as a breeding species. It also migrates south in winter. Both forms are exceedingly wary. In America occur two further golden plovers, breeding in the far north, where, in Alaska, their ranges are scarcely 100 mi. apart. But whereas the eastern form winters in Patagonia, which it reaches via Labrador. Newfoundland and the Antilles, returning by way of Panama. the Pacific bird widters in the Low Archipelago. Plovers are gregarious but monogamous birds, partial to mud flats and marshes and eating worms and small arthropods and mollusks. The legs are long, the bill shorter than in most waders.

The ringed plovers include the shore-haunting British bird of that name; killdeer (*q.v.*); and zick-zack (*Hoplopterus spinosus*). *Pluvianus aegyptius* (crocodile bird; *q.v.*), is celebrated for its connection with the crocodile, from the mouth of which it picks parasites. besides, from its wariness, acting as a sentinel to the reptile. The coursers, Cursorius and allied genera, to which the last belongs, are mainly desert forms from Africa and India. Other allies of the plovers are the stone curlews (*see* CURLEW), lapwings (*q.v.*), oyster catchers (*q.v.*), turnstones (*q.v.*) and avocets (*q.v.*). For "plovers' eggs" see LAPWING.

PLOW (PLOCGH): see TILLAGE MACHINERY.

PLUCKER, JULIUS (1801–1868), German mathematician and physicist, best known as an analytic geometer, but also carried out important research in magnetism and spectroscopy. He was born at Elberfeld on June 16, 1801. After studying at the universities of Bonn, Heidelberg and Berlin he went in 1823 to study in Paris, where he came under the influence of the great school of French geometers whose founder, Gaspard Monge, had only recently died. In 1825 he was received as Privatdozent (official but unpaid lecturer) at Bonn, and after three years he was made professor extraordinary. He then held the following posts: professor of mathematics at Friedrich Wilhelm's *Gymnasium,* Berlin (1833–34), professor of mathematics at Halle (1834–36), professor of mathematics (1836–47) and finally professor of physics (1847) at Bonn. He died at Bonn on May 22, 1868.

From his lectures at Bonn sprang his first great work, *Analytisch-geometrische* Entwickelungen, 2 vol. (1828–31), in which he introduced the abridged notation in analytical geometry. (See ANALYTIC GEOMETRY.) He applied this notation to the straight line, circle and conic sections, and he used it in his theory of cubic curves. Also he established the great principle of duality. He discovered the six equations known as "Plucker's equations" connecting the numbers of singularities in algebraical curves. (See CURVE.) Plucker communicated his formulas in the first place to *Crelle's* Journal, vol. xii (1834) and gave a further extension and complete account of his theory in his Theorie der algebraischen Curven (1839). In his System der analytischen Geometrie (1835) he introduced the use of linear functions in place of the ordinary co-ordinates; he also made the fullest use of the principles. of collineation and reciprocity. He discussed curves of the third order and gave a complete enumeration of them, including 219 species. In 1846 Plucker published his System der Geometrie des Raumes in *neuer* analytischer Behandlungsweise, but this contains merely a more systematic and polished rendering of his earlier results.

After his appointment as professor of physics at Bonn, Plücker began a series of researches in physics. His first physical memoir, published in J. C. Poggendorff's *Annalen der Physik und Chemie* (1847), deals with the behaviour of crystals in a magnetic field. Then followed a long series of researches, mostly published in the same journal, on the properties of magnetic and diamagnetic bodies, establishing results which are now part and parcel of our magnetic knowledge. This was followed by researches on the discharge tube; he investigated the deflection of the discharge by a magnet and the behaviour of the negative glow in a magnetic field. Plücker, first by himself and afterward in conjunction with J. W. Hittorf, made many important discoveries in the spectroscopy of gases. He anticipated R. Bunsen and G. R. Kirchhoff in announcing that the lines of the spectrum were characteristic of the chemical substance which emitted them and in indicating the value of this discovery in chemical analysis. According to Hittorf he was the first who saw the three lines of the hydrogen spectrum, which a few months after his death were recognized in the spectrum of the solar protuberances, and thus solved one of the mysteries of modern astronomy. Induced by his mathematical friends in England, Plücker in 1865 returned to "line geometry." His first memoir on the subject was published in the *Philosophical Transactions* of the Royal society in 1865. Plücker worked out the theory of complexes of the first and second order, introducing in his investigation of the latter the famous complex surfaces of which he caused those models to be constructed which are now well known to the student of higher mathematics. He left an uncompleted work on the subject which was so far advanced that his pupil and assistant, Felix Klein, was able to complete and publish it.

PLUM, the name of a fruit tree which belongs to the genus *Prunus* in the Rosaceae family. Like the peach and cherry, also members of the same genus and family, it is called a stone or drupe fruit. The fruit of the plum develops from a single ovary. As the fruit grows to maturity, the outer part of the ovary ripens into a fleshy, juicy exterior making up the edible part of the fruit and a hard interior called the stone or pit. The seed is enclosed within the stone. The fruits show a wide range of size, flavour, colour and texture.

The trees of some plum species are vigorous in growth with upright branches reaching a height of 20–30 ft., while others are much smaller; some are small shrubs with drooping branches, and some have great beauty as ornamental plants. The flower buds on most varieties and species are borne on short spurs or along the terminal shoots of the main branches. Each bud may contain from one to five flowers: two or three being most common; and where the buds are close together, they give an appearance of densely packed, showy flower clusters when the trees are in full bloom. Characteristic of the genus Prunus, the individual flower is made up of a receptacle forming a hollow cup bearing sepals, petals and stamens on the outer rim surrounding a single pistil attached at the bottom of the cup. After fertilization of the flower, the receptacle and attachments fall off and the style withers and drops off, leaving the enlarged basal portion of the pistil, the ovary, which develops into the fruit.

Native Habitat of Plum Species.—The common European plum, known botanically as Prunus domestica, appears to have originated somewhere in southeastern Europe or western Asia, probably in the region around the Caucasus and the Caspian sea. Although it is called the European plum, some botanists who have summarized the history of these stone fruits are doubtful that P. domestica is indigenous to Europe. According to the earliest writings in which this plum is mentioned, the species dates back about 2,000 years.

Another old world plum species, probably of European or Asiatic origin, is the damson plum (P. *insititia*). This species seems to antedate P. domestica, as is suggested by the finding of damson plum pits in ancient ruins. The ancient writings connect the early cultivation of these plums with the region around Damascus.

An important species native to China is the plum (P. *salicina*), which was domesticated in Japan and was introduced into the

United States about 1870.

Two less important species are the myrobalan plum *(P. cerasifera)*, a native of Europe, and the Simon or apricot plum *(P. simoni)*, a native of China. The myrobalan plum has been used a great deal in the United States as a rootstock. Varieties of *P. cerasifera* and *P. simoni* are noted for their ornamental foliage.

ROCHE

PLUM BLOSSOMS

Botanists have divided the native American plums into a number of species and subspecies. Many of them have numerous characteristics in common, so that they overlap somewhat in horticultural groups and classifications. *P. americana*, the most important of the native species, has a wide range of adaptation in the United States, extending from Maine to Florida. westward to Utah, and northwestward into Manitoba. The tree is small. not so vigorous as the European, and it has rough, shaggy, grayish bark. The fruit is red. reddish-yellow. or reddish-orange, possesses a pleasant flavour and is of good quality, but it has a thick. tough skin and the flesh clings to the pit. Desoto and Weaver are among the typical cultivated varieties of americanas.

Other American species of minor importance from a commercial standpoint but of interest to the fruit breeder are the native varieties of *P. hortulana*, the chickasaw plum *(P. angustifolia)*. and the wildgoose plum *(P. munsoniana)* of the southeastern and south central United States, of which Wildgoose and Robinson are important varieties.

Still other species of plums growing in North America are the Canada plum *(P. nigra)*, which is adapted to the north central United States and Canada; the small beach plum *(P. maritima)*, which grows along the eastern seacoast; and the western or Pacific plum *(P. subcordata)*, which grows east of the Coast range in southern Oregon and northern California.

Plum Culture in the United States.— Cultivated varieties of at least 12 species of plums are to be found in U.S. orchards or growing in the wild, but most of the important commercial varieties are confined to four of the species already mentioned, namely, *dornestica, insititia, salicina* and *americana.*

It is not known just when European plums were introduced into North America, but probably pits were brought over by the first colonists. It is reported that plums were planted by the Pilgrims in Massachusetts and importations were made by the French into Canada. These European plums have done remarkably well in the new world. and they constitute the most important group grown commercially for canning and drying.

The best known and most important of these groups are varieties of *Prunus domestica*, the European plums and prunes. These are vigorous-growing trees. upright spreading in habit. Unfortunately, they are not well adapted to regions with hot, dry summers or dry. cold winters. They are at home in the northeastern United States and in sheltered sections along the Great Lakes; but they are at their best in the irrigated regions of the intermountain and Pacific coast states, as is evidenced by the extensive production of fresh fruit and dried prunes in this region. The trees do well on medium heavy soils that are well drained. They blossom later than peaches and thus escape spring frosts. The European plums have been under domestication longest, and the fruits are notable for large size and attractive appearance. They vary in colour from the green and golden yellow of the Reine Claude (greengage) and Yellow Egg groups to the red and dark purple of the Lombard and Italian prune.

The damsons (P. *insititia)* of the old world are quite different from the domesticas. The trees are more upright, compact and dwarfish; the leaves and flowers are smaller; and the fruits are small, round and quite tart, so that they are especially suitable for preserves and jams. Varieties of this group are hardy, vigorous and productive, and the trees make good stocks for other species, being adapted to a wide range of conditions and thriving even when they are neglected. The Shropshire and the French are important blue damsons in the United States. while the yellow Mirabelles are popular in France. The demand for varieties of plums of this type is limited, and they are not planted as extensively as those varieties that can be consumed fresh, dried or canned.

The oriental plums *(P. salicina)* are relatively new to North America, but they were widely planted and became second to the domesticas in commercial production. The trees are more spreading in habit than the domesticas or damsons. and in leaf and fruit characters they are very different, resembling the native American plums. The fruits are very attractive and are characterized by a yellow ground colour overlaid by various shades of red. In some varieties the flesh colour is striking red, whereas fruit of the domesticas and damsons is green or yellow. Some newer hybrids of the salicina group show distinct superiority in flavour and in commercial possibilities over the early importations. Varieties of this group appear to be widely adapted in the United States except in the very coldest climates. While the quality is not equal to that of the best domesticas, and the commercial varieties are not so satisfactory for canning and drying, the fresh fruit is delicious in its blend of flavours. The varieties cross readily with one another and with the native americanas. Among the first so-called Japanese plums grown in the United States, Kelsey, Burbank, Abundance and Satsuma are typical. The trees are hardy and productive, and they tolerate a variety of soils as well as climatic conditions. The blossoms open earlier, hŏwever, than those of the domesticas and damsons and are frequently killed by spring frosts in the eastern part of the United States.

The native American plums were doubtless used for food by the Indians long before the white man set foot on the shores of North America. Reports of early explorers mention the finding of plums growing in abundance. According to the descriptions of the early settlers. these plums were inferior to the domesticas of the old world in quality, so that the colonists soon began importing varieties from Europe. As a result. European plums soon became predominant in home fruit gardens as well as commercial orchards in the northeastern United States. Varieties of native species, however, while not grown in commercial orchards, do fill a need in supplying fruit for the home garden in regions where the domesticas are not well adapted, as for example in the southwestern and south central United States. American varieties also have been selected for planting in the northern Great Plains where only cold hardy sorts can survive. Varieties like Xssiniboin and Cheney of the *P. nigra* group, and Wyant and Desoto of the americanas, survive in this region.

Hybrids produced by crossing American and oriental varieties have given larger fruited varieties of better quality, also adapted to the colder climates. Waneta and Underwood are two varieties that have been planted in home gardens. Furthermore, American species hybridize with the sand cherry *(P. pumila)*, and plant breeders have produced new varieties adapted to cold and dry conditions in the northern Great Plains. Important varieties are Opata, Sapa and Oka.

ROCHE

PLUMS (PRUNUS)

In the Gnited States, as well as in Europe, the plum has long been recognized as one of the most delicious of fruits, and among the stone fruits it ranks next to the peach in commercial production. Many of the varieties of plums cultivated in the United States have been introduced from elsewhere, and when these are added to thenative varieties they give plums the largest number and greatest diversity of kinds and species among the stone fruits.

Fortunately varieties can be selected that are adapted to a wide variety of soils and climatic conditions. Plums respond to good soil management practices. As trees come into bearing they do not require much pruning and in the home fruit garden can be grown satisfactorily if insects and diseases are controlled.

Insects and Diseases. — The fruit and tree of the plum are attacked by a number of troublesome insects and diseases that seriously limit production if not controlled by spraying. One of the most serious of the insect pests is the plum curculio, a small beetle that deposits its eggs in the fruit. As the larvae hatch and feed on the fruit, the affected fruits drop prematurely. Sometimes all of the fruits will drop off before harvest. This insect can be controlled by timely spraying with arsenate of lead or by the insecticide malathion.

Brown rot caused by a fungus that gains entrance through breaks in the skin or through punctures caused by the curculio may also be a serious menace. Fortunately this disease can be controlled by the timely application of fungicides of sulfur or copper. A bacterial leaf disease called bacterial spot, or shot hole, is serious in the more southern latitudes of the United States. Some varieties are quite resistant to this disease while others are susceptible. For the successful production of plums in any region a timely spray program must be followed to protect the fruit and foliage against these insect and disease pests.

Prunes. — Prune is a name given to a plum that can be dried without removing the pit into a firm long-keeping product. This term is frequently applied as a group name to plum varieties that have a sufficiently high sugar content and firm flesh so that they can be preserved by drying. The dried plum of commerce is, therefore, called a prune and only certain varieties have the qualities to make a good dried product. In California most of the plums are dried in the sun, while in Oregon and Washington drying is done in specially built dehydrators, where the drying is done with artificial heat. The growing of plums for the production of prunes in the United States is confined largely to the states of California, Oregon, Washington and Idaho. Agen or French, Italian, Sugar and Imperial Epineuse, all of European origin, are the principal varieties in the U.S.

Plums are the most widely distributed of the stone fruits. The fruit is also grown over a wide region in Europe from Italy on the south to Norway and Sweden on the north. Yugoslavia is the leading country with a tree potential of more than a million tons' production. A liqueur called *Slivovica* made from plums is an important article of commerce in Yugoslavia. Germany is the next largest producer of plums in Europe with a tree potential that in some years has equaled that of the U.S. in production. Turkey and Japan are leading countries in plum production in Asia.

PLUMBAGO: see GRAPHITE.

PLUMBING is the system of pipes and fixtures installed in a building for the distribution of potable (drinkable) water and the removal of water-borne waste materials. A plumbing system should perform in such a manner that the building's occupants are never endangered by contaminated drinking water or by contact with harmful wastes. Safe plumbing systems can only result from careful planning which takes account of 'the location of the building. the particular conditions arising from the design of the building and the activity taking place within it, the limitations of the municipal water and sewerage systems, and the plumbing standards enforced by the local, state or national governments. Properly designed, a plumbing system will maintain sanitary conditions over a broad range of both normal and abnormal operating conditions.

The piping system installed within a building is usually distinguished from the water and sewerage systems which serve a building, a group of buildings or a city.

The building plumbing system is usually considered to start at the point where the municipal water and sewerage lines cross the property lines of the building, or at some defined point just outside the building.

History. — One of the problems of every civilization in which the population has been centralized in cities and towns has been the development of adequate water and sewerage systems. In certain parts of Europe the complex aqueducts built by the Romans to supply their cities with potable water can still be seen. However, the early systems built for the disposal of human wastes were not quite so elaborate. Human wastes were often transported from the cities in carts or buckets or else discharged into an open, water-filled system of ditches which led from the city to a lake or stream.

Improvement in plumbing systems was very slow. Virtually no progress was made from the time of the Romans until the 19th century. The relatively primitive sanitation facilities were inadequate for the large, crowded population centres which sprang up during the Industrial Revolution, and outbreaks of typhoid fever and dysentery were often spread by the consumption of water contaminated with human wastes. Eventually these epidemics were curbed by the development of separate, underground water and sewage systems which eliminated open sewage ditches. In addition, plumbing fixtures — among them the lavatory basin, bathtub and water closet or toilet — were designed to handle potable water and water-borne wastes within buildings. However, these early fixtures often allowed sewer gases, bacteria and vermin to enter buildings through the open drain pipes with which they were connected to the sewer, and it was not until the latter part of the 19th century that the siphon water closet and the sanitary fixture trap were widely introduced, although the first patent for a water-sealed trap had been granted a century earlier.

Plumbing Fixtures and Materials. — The term plumbing fixture embraces not only showers, bathtubs, lavatory basins and water closets but also such devices as washing machines, garbage-disposal units, hot-water heaters, dishwashers and drinking fountains.

The materials used in a plumbing system must be strong, noncorrosive and durable enough to equal or exceed the expected life of the building in which they are installed. In addition, the materials used in fixtures that are exposed to view should be attractive and easy to clean.

Water closets, urinals and lavatories usually are made of stable porcelain or vitreous china, although they sometimes are made of glazed cast iron or steel or of stainless steel.

Ordinary water pipes usually are made of steel, copper, brass, lead, plastic or other nontoxic material, while the most common materials for sewerage pipes are cast iron, steel, copper, and asbestos cement.

Special fixtures — and entire plumbing systems of special design — are required for chemical laboratories and for plants manufacturing and processing chemicals and food products. Piping and fixtures for such applications may be made of glass, stainless steel, glass-lined metal, plastic, ceramics or special alloys. Drains often must be of special design to ensure proper disposal of corrosive or toxic materials, In the design of food-processing plants, the criterion is ease of cleaning equipment and piping.

Water-Supply Systems. — Usually only potable water is distributed in the water-supply system, but occasionally separate systems are installed for the distribution of nonpotable water used in industrial processes, fire-fighting equipment, or irrigation.

For towns and cities. municipally or privately owned water companies treat and purify water collected from wells, lakes, rivers and ponds and distribute it to individual buildings.

In rural areas water is commonly obtained directly from individual wells.

In most cities, water is forced through the distribution system by pumps, although in rare instances, when the source of water is located in mountains or hills above a city, the pressure generated by gravity is sufficient to distribute water throughout the system.

In other cases, water is pumped from the collection and purification facilities into elevated storage tanks and then allowed to flow throughout the system by gravity.

However, in most municipalities. water is pumped directly through the system; elevated storage tanks may also be provided to serve as pressure stabilization devices and as an auxiliary source in the event of pump failure or of a catastrophe, such as fire. that might require more water than the pumps or the water source are able to supply.

(See WATER SUPPLY AND PURIFICATION.)

The pressure developed in the water-supply system and the friction generated by the water moving through the pipes are the two factors which limit both the height to which water can be distributed and the maximum flow rate available at any point in the system. For example, if no water is drawn from the system in fig. 1. the pressure at any point in the building is equal to the pressure developed by the water tank less the pressure exerted by the column of water in the building below the point where the pressure is being measured.

If water is drawn from the system, the pressure at any point in the building will drop by an amount equal to the pressure required to overcome friction generated by the water moving in the pipes. As more and more fixtures draw water, the pressure will continue to drop, and eventually all the pressure developed by the water tank will be expended in overcoming friction and in pushing water up into the building against the force of gravity.

Subsequently, if more water is drawn by the fixtures on the lower floors of the building, the pressure used to overcome the increased friction will be balanced by a lowering of pressure on the upper floors, resulting in a decreased flow rate from the higher fixtures. In some instances, water may even stop flowing on the upper floors of a building.

Because friction losses increase approximately as the square of the velocity of the water flowing in the pipes, water pressure can be increased without decreasing the amount of water drawn from the pipes only by increasing the pipe diameter or providing booster pumps. Larger pipes can carry the same volume of water at lower velocities and, hence, with lower frictional pressure losses.

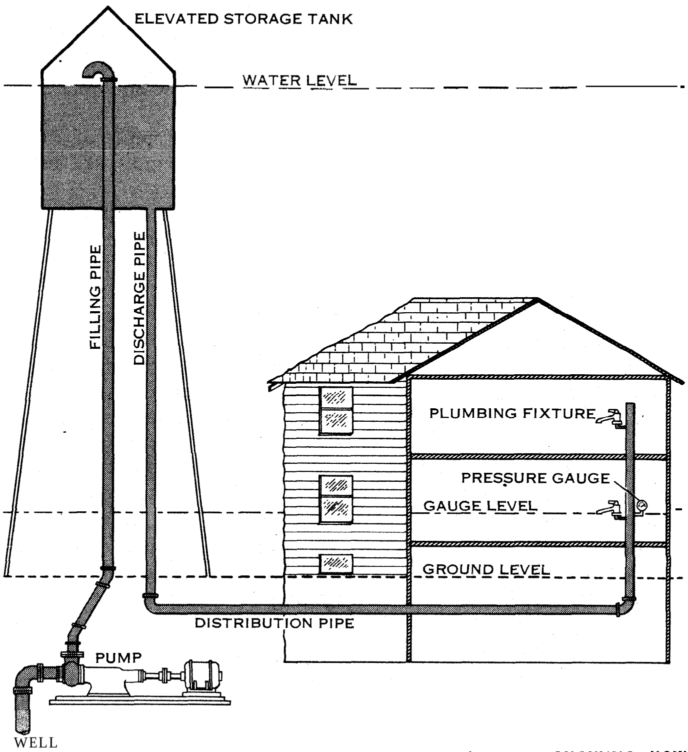

FIG. 1.— SIMPLIFICATION OF A WATER-SUPPLY SYSTEM, SHOWING HOW WATER PRESSURE AND HEIGHT ARE RELATED

Pressure losses are also caused by the formation of mineral deposits that decrease the effective diameter of the pipes and increase frictional pressure losses. For this reason, all pipes installed in a building should be large enough to allow for the restrictions caused by normal formation of mineral deposits during the life of the building.

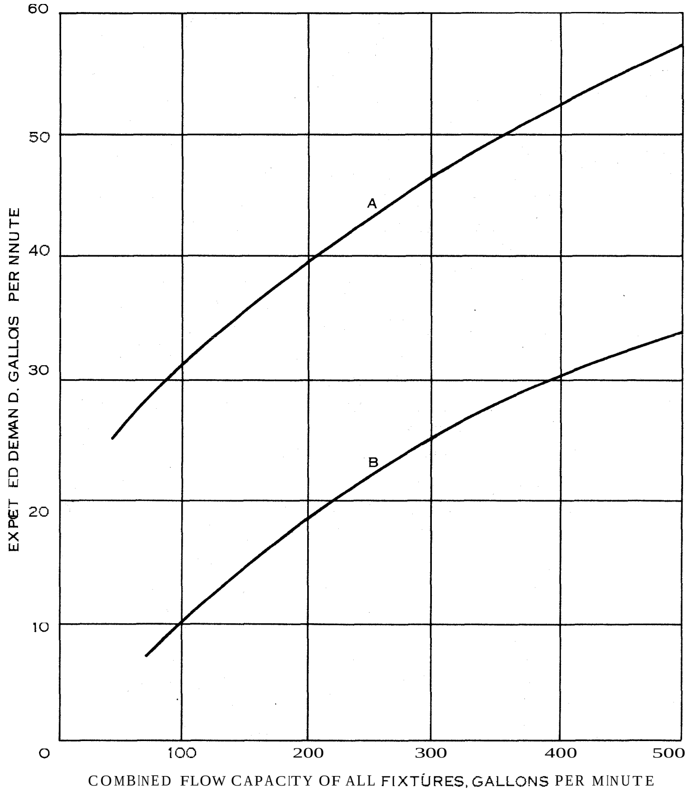

FIG. 2.— GRAPH SHOWING WATER DEMAND AS A FUNCTION OF TOTAL FIXTURE CAPACITY

Curve A is for buildings in which majority of toilets are flush-valve type. Curve B should be used if majority of toilets have flush tanks

Because it is extremely unlikely that all the fixtures in a building will be used at the same time. the pipe diameter selected by the plumbing designer is based on the frictional pressure losses caused by the maximum probable flow rate, not upon the maximum potential flow rate. Fig. 2 shows the relationship between the probable maximum demand for water and total potential flow capacities of the installed fixtures. To calculate the maximum probable flow rate for a new building, the plumbing designer refers to statistical tables which list the observed water demands of fixtures installed in buildings housing equivalent activities.

Pressures and Flow Rates for Common Plumbing Fixtures

Fixture	Recommended Pressure at Fixture (p.s.i.)	Ordinary Maximum Flow Rate (g.p.m.)
Lavatory basin	8	3.0
Bathtub	5	6.0
Shower	12	5.0
Water closet (with flush tank)	15	3.0
Water closet (with flush valve)	10 to 20	15 to 40

Recommended operating pressures and customary maximum flow rates for some common plumbing fixtures are shown in the accompanying table.

Booster pumps are sometimes installed in outlying areas of municipal water systems to offset the frictional head losses in long supply lines. Likewise, booster pumps are used in tall buildings when supply pipes of adequate size would be either too expensive or too bulky. The additional pressure supplied by the booster pump offsets the increased frictional losses of the smaller pipe and ensures that enough pressure will be available to maintain the flow of water to the upper floors during peak periods of consumption.

Sewerage System.—The sewerage system of a building consists of two parts: the drainage system and the venting system. The drainage portion comprises pipes leading from the various fixture drains to the central main, which is connected to the municipal or private sewerage system.

The venting system consists of pipes leading from an air inlet (usually located on the roof of the buildingj to various points within the drainage system; it protects the sanitary traps from siphoning or blowing by equalizing the pressure inside and outside the drainage system. Fig. 3 shows a typical arrangement of plumbing fixtures and drain and vent piping, with the drainage sections shaded.

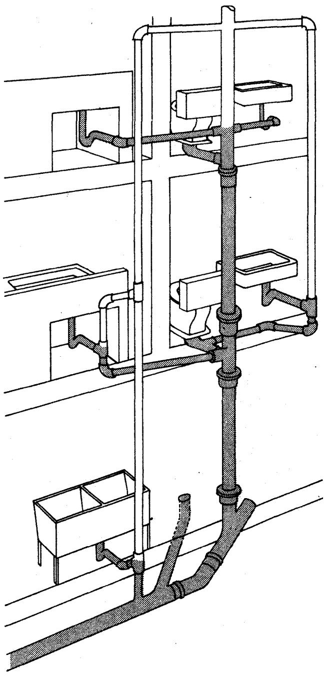

FIG. 3,— BUILDING DRAINAGE AND VENTING SYSTEM (DRAINAGE PIPING SHADED)

Sanitary fixture traps provide a water seal between the sewer pipes and the rooms in which plumbing fixtures are installed. The most commonly used sanitary trap is a U bend, or dip, installed in the drainpipe adjacent to the outlet of each fixture. A portion of the waste water discharged by the fixture is retained in the U, forming a seal which separates the fixture from the open drainpipes. Fig. 4 shows how water standing in the trap seals the pipe.

Sometimes the protection offered by sanitary traps is inadequate, and a device known as an indirect waste must be installed on the fixture to prevent sewage from backing up in a clogged drain pipe. Indirect wastes are designed so that liquids discharged from the fixture fall through an air gap into a receiver; this is connected through an ordinary sanitary trap to the sewer. If the section of pipe connected to the fixture drain ends at a level above that which wastes can reach in the receiver, the air gap between the fixture drain and the receiver top will prevent wastes from backing up into the fixture.

Plumbing regulations usually specify that indirect wastes be installed on restaurant coffee urns, automatic washing machines, dishwashers and other apparatus where great caution must be exercised to prevent contamination.

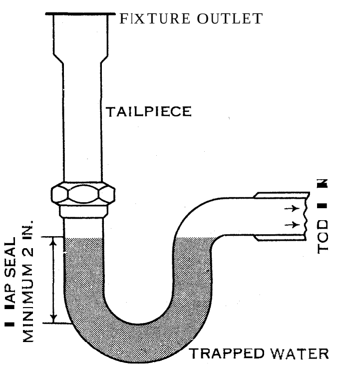

FIG. 4.—SANITARY FIXTURE TRAP SHOWING THE WATER COLUMN WHICH SEALS THE FIXTURE FROM SEWER GASES, BACTERIA AND VERMIN THAT ARE COMMONLY FOUND IN DRAINAGE SYSTEMS

In addition to sanitary traps and indirect wastes, fixture outlets are sometimes equipped with interceptors to separate and retain materials that should not be discharged into the sewerage system. For example, grease interceptors are often installed in restaurants to remove insoluble oils, fats and greases that, in large quantities, may impair the digestive action required for proper sewage treatment. (*See also* SEWER DESIGN AND CONSTRUCTION; SEWAGE DISPOSAL.)

Venting System.—If the drainage system is not vented, or if it is improperly vented. the air in the pipes will be evacuated by the flow of waste materials. For example. when the water discharged from a lavatory basin flows through the drainpipe, it pushes some of the air out of the pipe. If the waste water flows past openings where branch pipes join the system, air may be drawn from these branches by the suction created by the running water. If there were no sanitary traps at the fixture outlets, air drawn from the drainpipes by the flow of waste water would be replaced by air drawn into the pipes through the open drains on the fixtures.

However, the water retained in the sanitary traps blocks such a flow of air into the sewerage system just as it blocks the flow of sewer gases out of the system. Therefore, a partial vacuum may be formed inside an unvented drain, siphoning water from the sanitary trap and breaking the seal between the fixture and the sewer. Conversely, the water in the trap may be blown out through the fixture drain if the pressure within the drainage system should suddenly rise above atmospheric pressure. This could occur in an improperly vented system if air were trapped and forced into side branches by the flow of large quantities of water through the pipes.

In a small dwelling, where all the bathroom and kitchen fixtures can be located adjacent to a large vertical drainpipe, a separate venting system is usually not needed if the top of the vertical drain is open to the atmosphere. However, when this type of venting is used, the drainpipes must be large enough to handle peak waste loads without filling with water; otherwise, air will not be able to reach all parts of the system, and some of the traps may siphon or blow. If some fixtures are far enough from the central drainpipe so that they cannot be vented properly through the drainage system itself, separate air vents must be provided for them.

Water closets are usually provided with individual vents because the volume of water which they discharge makes it difficult to vent them properly through the drainpipes without using excessively large pipes.

Sanitation.— The central problem in the construction and repair of plumbing systems is the maintenance of sanitary conditions. Because both potable water and waste water are in close proximity in plumbing fixtures, such as water closets, lavatories and bathtubs, there is always danger of a cross connection which will allow contaminated water to enter the potable water pipes. Most cross connections are the result of faulty plumbing design and installation; they occur in leaking plumbing fixtures or through back siphonage in water-supply pipes. An example of a cross connection caused by leaking plumbing fixtures is an overhead sewerage pipe which drips sewage into an open laundry tub or sink. This could be eliminated by repairing the leak, but a better way would be to install the drainage pipes so that they never cross above open plumbing fixtures.

Another example of bad design which can lead to hazardous cross connections is a building in which both potable and nonpotable water are distributed in interlocked systems separated only by valves. If one of the interlocking valves fails or is inadvertently opened, the nonpotable water can contaminate the potable water.

Although the pressure in a water-supply system normally remains above atmospheric pressure, abnormal conditions may lower it sufficiently to induce back siphoning. The easiest way to safeguard fixtures against back siphoning is to install the water inlet well above the level of the waste water in the fixture. Most sinks and bathtubs are designed so that the inlet pipe is above the top of the overflow outlet. In these fixtures waste water cannot possibly submerge the inlet pipe and form a cross connection.

However, in some fixtures the space between the inlet pipe and the highest level of the waste water is so small that waste water could be sucked across the air gap and into the supply pipe under certain conditions.

Fixtures which have submerged inlets or improperly sized air gaps should never be installed unless they are safeguarded with vacuum breakers. Whenever the water pressure drops below atmospheric pressure, the vacuum breaker opens and allows air to flow into the water pipes, thus destroying the partial vacuum inside the pipes and eliminating the danger of back siphoning. Because vacuum breakers are mechanical devices subject to wear and corrosion! they should be checked from time to time to make sure that they are operating properly. In the case of the water closet, proper flushing action cannot be achieved unless the water inlet is submerged in the waste-water bowl, and thus plumbing codes specify that both flush-valve and flush-tank water-closets should be equipped with vacuum breakers.

PLUMER, HERBERT CHARLES ONSLOW PLUMER, 1st Viscount, of Messines, cr. 1929 (1857–1932), British field marshal, was born on March 13, 1857, and entered the army in 1876. He served on the Red sea littoral in 1884, and in 1896 commanded a mounted regiment in the Matabele campaign. Before the outbreak of the South African War (1899) he raised the Rhodesian field force, which he commanded during the early months of the contest. He was promoted major general on the conclusion of hostilities.

In May 1915 Sir Herbert Plumer was selected to lead the 2nd army on the western front. His army was not very actively engaged during the remainder of 1915, nor yet in 1916, but on June 7, 1917, Plumer gained a signal victory at Messines. (See Ypres, Battles of, 1915 and 1917.) In November he took charge of the British troops sent to the basin of the Po after the Italian defeat at Caporetto, and in the following March was recalled to Flanders to resume the leadership of the 2nd army just before the great German offensive started. In the general advance in August, his army took part in the operations for the recovery of Belgian Flanders. At the peace he received a peerage, promotion to field marshal and a grant of £30,000. He subsequently commanded the British forces on the Rhine for a short time. From 1919 to 1925 he was governor of Malta, and from 1925 to 1928 high commissioner for Palestine. He died July 16, 1932.

PLUM RAINS are the persistent precipitation of the "Bai-u" season in Japan and immediately adjacent areas. In Japan proper, particularly from Kyushu to northeastern Honshu, a period of considerable and rather steady precipitation extends from approximately early June to about the middle of July. This is the period when plums are ripening; hence, the popular name of these rains, which are also important to the rice economy.

The rains tend to be of the moderate, prolonged type, rather than the cloudburst type. The sky is overcast for many hours, and the weather is depressing. The phenomenon is much better developed on the east side of Japan than on the west. Tokyo, for example, has an average in June of 1 clear day, 9 partly cloudy and 20 cloudy days; bright sunshine is observed during only about a third of the daylight hours. Tokyo records measurable rainfall on an average of 16 days in June, and the average monthly total is about $6\frac{1}{2}$ in. The accompanying average maximum temperature is 68.5° F.; the average minimum is 62.2° F.

The beginning of the plum rains is earliest in low latitudes and later northward. In Formosa and the Ryukyus, precipitation begins to increase in the middle of May and continues heavy until early July. In northern Korea, the season begins in late June and lasts through July.

The rains are associated with eastward-moving cyclones, decelerated near Japan by the Pacific high-pressure area. Occasional failure of the rains to appear has resulted in damaging droughts. (W. A. Bm.)

PLUNKET, OLIVER (1629–1681), Irish Roman Catholic divine, was born at Loughcrew, County Meath. He was appointed archbishop of Armagh and primate of Ireland in July 1669 and in November he was consecrated at Ghent, reaching Ireland in March 1670. The measures following on the Test act bore hardly upon him, and in Dec. 1678 he was imprisoned in Dublin castle for six weeks. Accused of a share in the Irish branch of the "Popish Plot," he was brought to London, and in June 1681 arraigned in the King's Bench, charged with conspiring to bring a French army to Carlingford. He made a good defense, but on the most absurd of evidence the jury convicted him of treason, and on July 1 he was hanged, drawn and quartered at Tyburn.

PLUNKET, WILLIAM CONYNGHAM PLUNKET, 1st Baron (1764–1854), Irish lawyer, orator and statesman, was born in the county of Fermanagh in July 1764, the son of a Presbyterian minister, and studied at Trinity college, Dublin. Having entered Lincoln's Inn in 1784, Plunket was called to the Irish bar in 1787. He gradually obtained a considerable practice in equity and was made a king's counsel in 1797.

In 1798 he entered the Irish parliament as member for Charlemont. He was an anti-Jacobin Whig of the school of Burke, and a fervent Irish patriot. But he was a sincere admirer of the constitutional government of England as established in 1688; he even justified the ascendancy it had given to the Established Church, although he thought that the time had arrived for extending toleration to Roman Catholics and dissenters. To transfer it to Ireland as thus modified, and under an independent legislature, was the only reform he sought for his country; he opposed the union because he thought it incompatible with this object.

When Plunket entered the Irish parliament, the Irish Whig party was almost extinct, and Pitt was feeling his way to accomplish the union. In this he was seconded ably by Lord Castlereagh, by the panic caused by a wild insurrection, and by the secession of H. Grattan from politics. When, however, the measure was brought forward, among the ablest and fiercest of its adversaries was Plunket, whose powers as a great orator were now universally recognized. His speeches raised him immediately to the front rank of his party; and when Grattan re-entered the moribund senate he took his seat next to Plunket, thus significantly recognizing the place the latter had attained.

After the union Plunket returned to the practice of his profession, and became at once a leader of the equity bar. In 1803 he was selected as one of the Crown lawyers to prosecute R. Emmet. For his speech on this occasion he was exposed to much obloquy, and more especially to the abuse of W. Cobbett, against whom he brought a successful action for damages. In 1803, in Pitt's second administration, he became solicitor general, and in 1805 attorney general for Ireland; and he continued in office when Lord Grenville came into power in 1806. Plunket held a seat in the Imperial parliament during this period, and there made several able speeches in favour of Catholic emancipation, and of continuing the war with France; but when the Grenville cabinet was dissolved he returned once more to professional life.

In 1812 he re-entered parliament as member for Trinity college, and identified himself with the Grenville or anti-Gallican Whigs. He was soon acknowledged as one of the first orators, if not the first, of the house of commons. In 1822 Plunket was once more attorney general for Ireland, with Lord Wellesley as lord lieutenant. One of his first official acts was to prosecute for the "bottle riot," an attempt on his part to put down the Orange faction in Ireland. He strenuously opposed the Catholic Association, which about this time, under the guidance of D. O'Connell, began its agitation. In 1825 he made a powerful speech against it; thus the curious spectacle was seen of the ablest champion of an oppressed church doing all in his power to check its efforts to emancipate itself. In 1827 Plunket was made master of the rolls in England; but, owing to the professional jealousy of the bar, who regarded an Irishman as an intruder, he resigned in a few days. Soon afterward he became chief justice of the common pleas in Ireland, and was then created a peer of the United Kingdom. In 1830 he was appointed lord chancellor of Ireland, and held the office, with an interval of a few months only, until 1841, when he finally retired from public life. He died on Jan. 4, 1853, and was succeeded by his eldest son, Thomas Spen Plunket (1792–1866), bishop of Tuam, as 2nd baron.

See the *Life of the First Lord Plunket* (1869), by his grandson, David Robert Plunket.

PLUNKETT, SIR HORACE (CURZON) (1854–1932), K.C.V.O. (1903), son of the 16th Baron Dunsany, was born on Oct. 24, 1853 and educated at Eton and Oxford. After engaging in cattle ranching for ten years, his interest in agriculture led him to devote himself to the promotion of agricultural co-operation, and in 1894 he founded the Irish Agricultural Organization society. As a member of parliament from 1892 to 1900, he strongly advocated the cause of agriculture. and in 1899 he was appointed vice-president of the department of agriculture and technical instruction for Ireland. Two years later he became commissioner of the Congested Districts board in Ireland. He was elected F.R.S. in 1902, and in 1919 endowed a trust, known by his name, for the development of agriculture. He presided over the Irish convention of 1917-18, and was a senator (1922-23) of the Irish Free state. He died March 26. 1932.

His works include Ireland in the *New Century* (1904); The *Rural* Life Problem of C.S. (1910); *Some Tendencies* of Modern *Medicine* (1913); and *A Better Way* (1914).

PLURALISM AND MONISM are theories giving respectively the answers "many" and "one" to two quite distinct questions: first, how *many* things are there in the world?; and second, how *many kinds* of *things* are there in *the* world? Much confusion is engendered if this distinction is not clearly maintained. Pluralism and monism as theories of substance, answers to the first question, have no necessary connection with pluralism and monism as theories of kinds of substance, answers to the second question. Philosophers can be cited to exemplify the four possible combinations of views: Descartes is a pluralist and Hegel a monist in both senses. Spinoza is a monist of substance and a pluralist of kinds, Bertrand Russell a pluralist of substance and a monist of kinds. Such definitions as "monism attempts to explain the entire universe from a single principle" misleadingly suggest, by compounding the two questions, that Spinoza and Russell are guilty of some inconsistency from which the writings of Descartes and Hegel are free.

A theory of substance seeks to establish the nature of what it is that can properly be said to exist independently or in its own right, or, again. what are the ultimate subjects of discourse: "Substance is that which requires nothing but itself in order to exist" (Descartes). The existence of some subjects of discourse—complexes such as armies, men's characters, material objects—will be dependent on that of others—simples such as soldiers. actions, sense-experiences—in that what we know or believe about the complex will be an inference from, or a convenient paraphrase of, what we know or believe about the simple. An ultimate subject of discourse, then, a simple or substance proper, something that exists in its own right. is something whose existence we can discover directly and without having first to discover or assume the existence of something else. The natural answer to the question "how many simple things, existing and discoverable independently, are there in the world?" is "many." Monism of substance—the theory that the world as a whole is the only true thing, held by Parmenides, Spinoza and Hegel—being at odds with our common beliefs, requires substantiation by argument. The point requiring proof is that nothing but the world as a whole is really independent of anything else. This—the doctrine of internal relations—will be stated and examined below.

A theory of kinds. "ultimate" kinds, of substance seeks to establish how many irreducibly different kinds of knowledge or experience we must admit. Two things are of different kinds, in a very wide sense. if there is any feature that one has and the other lacks. And since, unless there were such a feature, they would not be distinct and thus not be two things at all (the identity of indiscernibles). everything is of a different kind from everything else. But we do not in practice use such a generous criterion of difference in kind. Only some features of things are relevant to answering the question "what kind of thing is that?"; *e.g.,* its being a chair or a tree or a house or a star. Other features are relevant to answering questions about what kind of chair. tree, house or star it may be. Others again are not relevant to answering any questions about kinds at all; *e.g.,* being two feet from the wall, being the property of Ring Farouk. The set of features determining "natural kinds." possible answers to the question "what kind of thing is that?" is wider than the set determining "ultimate kinds." Roughly. the latter set consists of various forms of occupancy of space—location, volume, solidity. Whatever occupies space can be discovered only and always by sensation. Whatever does not occupy space can be discovered only and always by self-consciousness and introspection ("reflection"). The natural answer to the question "how many ultimate kinds of thing, objects of distinct types of knowledge or experience. are there in the world?" is "many." Monism of kinds—the theory that there is only one fundamental type of knowledge or experience. held by Democritus. Berkeley and Russell—being nearly as much at odds with common beliefs as monism of substance, also requires substantiation by argument. The point requiring proof is that there is only one source of knowledge, only one type of experience.

Whether or not parts of the world are independent of one another and whether or not there is more than one source of knowledge are questions whose internal connection, if any, does not at once leap to the eye. Hence the importance of distinguishing the varieties of pluralism and monism to which the attempt to answer them gives rise.

THEORIES OF SUBSTANCE

The Eleatics.—Xenophanes is credited with the remark "All is One." but his main importance is rather as a critic of polytheism than as a philosopher. It is with Parmenides that the first significant statement appears of the view that only the world as a whole ("being") exists in its own right. The world confronts us as a theatre of change; but this becoming; of which the senses inform us, is unreal, an illusory appearance, no proper object of knowledge. Only "being," discovered by reason, is real and truly exists. Being does not change, it never came into existence, it will never pass away, it is timeless. For what could change it, how could it arise from or pass into not-being? It is also. incidentally, spatial, finite and spherical in shape. Since empty space is a contradictory notion, "being" is everywhere. This tinge of materialism, important for its influence on Democritus and the atomists, is hardly consistent with the view that only reason informs us about reality, and it was not taken over by Plato.

Zeno. Parmenides' disciple, reinforced his master's theory with famous arguments against plurality and motion. Of these the most influential and relevant to the present purpose concerns the size of a world of many things, which. Zeno argues, must be both infinitely large and infinitely small and is thus an impossibility: infinitely small, since its ultimate components must be indivisible and thus without size. and no collection. however large, of things without size has any size; infinitely large. since the world, being divisible, has size. and the parts into whichever has size is divided. however far the division is carried, must themselves have size, so that it must consist of an infinite number of parts with size. This is a much harder nut to crack than Parmenides' own arguments against pluralism and secured the attention of Hume, Kant and Russell.

Spinoza.—In Part I of Spinoza's Ethics the classical argument for monism of substance—the proof that only the world as a whole (Deus *sive Natura*—God or Nature) exists independently —is to be found. It depends ultimately on Spinoza's theory of explanation. To understand anything, to have knowledge of it, is to know its cause or explanation. Now the causes of most of the things with which we are familiar are external to them, the changes of state of other things. To have knowledge of something whose cause is external to it requires us. therefore, to look beyond the thing itself to whatever it is that is needed to explain it. A thing of this kind. then being essentially dependent on something other than itself. does not come up to Spinoza's somewhat exigent requirement for being a substance; viz.. "that, the conception of which can be formed independently of another thing." Now either this quest for causes must continue indefinitely or terminate in a thing which somehow explains itself. a *causa sui,* which will be a true substance. All its characteristics being essential or definitive parts of its inner nature. we will be able to deduce all the truths requisite to total "understanding" of it from the conception of the thing by itself.

Spinoza argues that if there is a plurality of things each must be limited by and thus dependent on the others. There can only be one truly independent, self-subsistent, self-explanatory thing, and it must be unlimited, infinite. It follows that the view that God transcends the world that He created is mistaken, a conclusion supported by such unhappy consequences of the creation theory as the problem of evil and the consequent imperfection, in respect of power or goodness, of God. God is therefore immanent in, indeed identical with, created Nature. they are not two things but the same thing viewed in different ways: as creating (*Natura naturans*) and as created (*Natura naturata*). Only the whole, then, is intelligible in itself. for the rather negative reason. it would seem, that it at any rate must be self-explanatory since the existence of anything external to it which could explain it is logically excluded.

Hegel.—It is one of the aims of Hegel to overcome the deficiency last mentioned. He attempts to produce a conception of the world as a whole, the absolute. which will provide a positive ground for thinking it to be self-explanatory and thus to exclude the possibility (compatible with Spinoza's view) that the world as a whole is a brute fact, neither self-explanatory nor to be explained by anything else. This attempt involves the distinction of cause from reason. The cause of something is merely externally connected with it, a mere concomitant happening. The reason for a thing, however, has an internal, logical connection with it, in this case there is real connection not just coincidence. But only thoughts stand in logical relationships to one another. So the absolute is a logically articulated system of thoughts. Hegel, like Spinoza. bases his version of monism on the unintelligibility on its own account of what is finite or limited (for the finite is necessarily limited by something else and so to that extent dependent on it). But his requirement that truly intelligible explanation must be rational or logical. a matter of the logical interrelation of thoughts, is a further development.

Internal Relations.—The monisms of Spinoza and Hegel are both variants of the doctrine of internal relations. Their fundamental thesis may be expressed in two ways: (1) nothing but the world as a whole is independent of everything else; and (2) everything in the world is in its real nature essentially related to everything else. For, it is argued. we do not fully understand anything until we know all of its relations to other things. As against the normal view that things. identified by the set of their defining or essential properties. stand in various external, contingent relations which are not part of their definition or essence, it is held that the true definition of a thing contains all its qualities and relations, everything that can truly be affirmed of it. This sets an ideal of understanding that cannot be attained, since it requires that to understand anything properly one must know everything about it, in effect everything whatever. To "understand" a thing. to know what it is, it is enough to be able to recognize or identify it: by picking out a set of qualities as a thing we obtain a reference point whose relations to other such reference points it is the business of empirical inquiry to establish. Not only is the theory of internal relations no account of our actual conception of things, it is not an account of any conception of things in which inquiry into the nature of the world remains possible, but rather a dream of the termination of science, of a way of thinking fit for an omniscient being.

THEORIES OF KINDS

The question "how many ultimate kinds of thing are there?" is, it has been seen, an inquiry into the number of sources of knowledge or forms of experience. In practice the philosophical debate on this issue has predominantly concerned itself with the nature of our experience of and knowledge about minds. Do we get to know about thoughts, decisions and feelings (our own and those of others) in the same way as we get to know about material. extended, spatially located things? Prima facie, we seem to have independent access to two quite distinct orders of things: by sensation to an outer world of material things and other persons. by introspection to an inner world of our own mental states. Monism of kinds denies this apparent independence and distinctness. Sensation and introspection are assimilated into experience simpliciter, the impassable frontier between inner and outer is dismantled. That there is some distinction. at least prima facie. between the mental and the material is not denied by any but the most ardent materialist. What is objected to is the view that this distinction, this "bifurcation of nature" as A. N. Whitehead calls it. is ultimate, that we are the inhabitants of two distinct worlds. at best contingently connected. For the theory of bifurcation has given rise to two historically obtrusive problems, that of the relation between mind and body and that of our knowledge of other minds (the latter problem, on a wide view, may be seen as a more modern version of the former).

Dualism.—The classical exponent of dualism is Descartes. On his view the created world is composed of two quite distinct kinds of substance. minds and bodies. to be distinguished by their "essential attributes" which are. respectively, thought and extension. In practice Descartes takes these essential attributes as constituting the whole essence of mind and body. so that he comes to hold that the mind is always active and thinking and that matter is extension and empty space an impossibility. Locke complements this account of things with an appropriate account of our knowledge of things when he declares that all knowledge is based on sensation and reflection. For Descartes the distinction of the two kinds of thing depends on his theory of self-knowledge. Our own existence. he holds, is self-evident. since. whatever we may doubt. we cannot doubt that we doubt and. therefore. exist. On the other hand our knowledge of the external world is mediate, indirect. Our natural propensity to infer external causes for our sensations is only to be indulged and trusted if we are assured of the existence of God. The essential feature of dualism. then, is its intuitive theory of self-knowledge which contrasts our immediate and infallible knowledge of our own minds with our more devious and fallible acquaintance with everything else.

The first difficulty to arise from this is the familiar mind-body problem. In human perception and action we are confronted with what seem to be clear cases of the interaction of these two quite distinct orders of things, mental and material. Now there are two grounds on which philosophers have refused to acknowledge this apparent interaction: first, the conservation principles of physics seem to exclude the irruption of mental causes into the physical order; second, it was held that effects must resemble their causes. This did not prevent Descartes from inconsistently accepting the interaction of mind and body. with the pineal gland as a medium of divine agency. But since, by the conservation principle. every physical event is already physically accounted for and. by the metaphysical principle. that cause must resemble effect, mental causes of physical events are impossible as well as superfluous. mental events can at best be occasions and not causes of physical ones. This result leads in Descartes' immediate successors to the view that there are two quite independent but divinely adjusted series of events within which, but not between which, causal relations obtain: on the one hand is the system of inner experiences, the felt, private order of states of mind; on the other is extended nature, a true causal system of material substances with merely geometrical, "primary" qualities. The triumphs of physics tend to degrade the mental world to a shadow play. an epiphenomenon, the view of materialism. The remote and unintelligible character of material substance conceived in purely geometrical terms leads to idealism.

Materialism.—This doctrine regards mental life as a more or less illusory exhalation of physiological processes, on its relation to which experienced mental life depends for such reality as it can be held to possess. Only that which can be mechanically explained is real. Mental life, as experienced, is a by-product, a mere symptom of mechanical transformations at the physiological level. The determination, which this theory evidences. to replace the obvious by the speculative in the interests of tidiness is still to be found among scientists and depends on laying down as universally to be followed in all spheres of inquiry a method notably successful in certain specialized investigations. Even the advances of contemporary neurophysiology do little to transform the speculative metaphysics of physiological materialism into a well-confirmed scientific theory.

Idealism.—Where materialism arises from the triumph of the material conception of cause, idealism is based on the paradox of the material conception of substance. Berkeley attacked the notion of material substance propounded by Descartes and Locke as unintelligible, a nonentity. It could not cause, or, a fortiori, resemble, the ideas of sensation on which all knowledge is based since ex hypothesi it could not be independently observed and compared with them. Material things are not distinct substances of a purely geometrical character on this view, for such things are unknowable, but are, rather, orderly and regular systems of sense experiences. Idealists of a Hegelian type argued that reality to be knowable must be mental in character, a system of ideas, which derives its objectivity for the observer not so much from being the beneficent contrivance of God as from being the logically necessary unfolding of the thoughts of an absolute mind (which is not perhaps very different).

Neutral Monism. — Idealists, while rejecting material substance, still distinguish mental substance, mind, from the ideas that it has. In Berkeley this leads to an uncomfortable and arbitrary proposal of a theory of notions to explain knowledge of mental substance, a theory required because we do not have any ideas of mind. But the "mental" character of ideas is based on their essential dependence on these somewhat feebly supported substances. Neutral monism reverses the relation by construing the ideas of sense as fundamental, the immediate objects of knowledge, and things, mental and material, as constructions out of these basic neutral elements. This view, developed by William James from some ideas of J. F. Herbart, became the foundation of Russell's theory of knowledge.

Other Minds. — The second major problem to which dualism gives rise is that of our knowledge of other minds. For, if dualism is correct, while we know about ourselves directly and infallibly we only find out about the mental life of others on the evidence of their behaviour and can never directly verify what we infer from this. Other minds are as unknowable in themselves, apart from their supposed effects! as the material substance attacked by Berkeley. Attempts have been made to identify our knowledge of self and others, to bridge the abyss exposed by criticism of the argument from analogy, by asserting that. we have direct, "intuitive" knowledge of the mental states of others or that we have to find out about our own mental states by a more or less prolonged, tentative and piecemeal procedure. "Telepathic" idealism comes to grief on the inescapable logical distinctness of your experience of your anger from my, telepathic, experience of your anger. Its diametrical opposite, G. Ryle's "dispositional" materialism, provides a valuable criticism of the Cartesian intuitive theory of self-knowledge in all departments of mental life. But the attempt to construe having pains, sensations and images as tendencies to behave in certain ways comes up against a mass of very ordinary conviction to the contrary. (A. M. Q.)

PLURALITY, a term applied particularly to the holding of two or more offices by the same person (called then a pluralist). In ecclesiastical law, plurality, or the holding of more than one benefice or preferment, was always discountenanced, and is now prohibited in England by the Pluralities Act, 1838, as amended by the Pluralities Act, 1850, and the Pluralities Acts Amendment Act 1885. By the latter act a provision was made that two benefices might be held together, by dispensation of the archbishop on the recommendation of the bishop, if the churches be within four miles of each other, and if the annual value of one does not exceed £200. (See BENEFICE.)

In the United States, the term is used in election law to denote the number of votes which a candidate has received for a public office in excess of the number received by any one of two or more other candidates.

PLURALITY OF CAUSES, in logic, is the view that one and the same kind of effect can be produced in different cases by different causes. This is quite distinct from the question whether the cause of an effect is as a rule a complex or multiplicity of several or many constituent or contributory factors or conditions. Assuming the complexity of each cause, there still remains the further question whether any one of several separate causes can produce the same kind of effect as another. In other words can one cause ever act vicariously for another? (Hence the alternative, and less ambiguous name, "vicarious causes.") J. S. Mill is the best known advocate of the doctrine of plurality of causes. Examples taken from daily experience seem to support the view. Many different causes can produce death for example. For most practical purposes the doctrine holds good. The whole system of substitutes, in peace and in war, is based on it. But for practical purposes many effects are sufficiently similar, although they are really very different when closely scrutinised. The total state called death is very different according as one cause or another led to it. The holding of coroner's inquests is based on the assumption that a close examination of the state of a dead body can help to determine the precise cause of death in each case. Similarly with all cases in which details matter. The total effect produced by one kind of cause is never precisely the same as that produced by any other. So that strictly speaking the doctrine of plurality of causes is not true. But where the interest is centred in broad kinds of effect, and differences of detail do not matter much, there the doctrine holds good for all practical purposes.

See J. S. Mill, *System of Logic* (1875 etc.); J. Venn, *Empirical Logic* (1889); J. Welton, *Manual of Logic* (1896).

PLUSH. Plush fabrics are characterized by a fur-like or velvet pile surface somewhat typical of the short hairy pelts of certain animals as, for example, the seal and otter. A plush pile surface is developed in woven fabrics by causing a series of tufts of pile to project more or less vertically from a foundation texture. The tufts of pile virtually consist of short lengths of warp threads usually of silk, artificial silk or mohair yarn interwoven with the foundation fabric in such a manner that the tufts of pile are looped under the picks of weft by which they are securely retained in the fabric.

PLUTARCH (Gr. Πλούταρχος) (c. A.D. 46–120), Greek biographer and miscellaneous writer, was born at Chaeronea in Boeotia. After having been trained in philosophy at Athens he travelled and stayed some time at Rome, where he lectured on philosophy and undertook the education of Hadrian. (There seems no authority for this statement earlier than the middle ages.) Trajan bestowed consular rank upon him, and Hadrian appointed him procurator of Greece. He died in his native town, where he was archon and priest of the Pythian Apollo. In the Consolation to his Wife on the loss of his young daughter, he tells us (§ 2) that they had brought up four sons besides, one of whom was called by the name of Plutarch's brother, Lamprias. We learn incidentally from this treatise (§ 10) that the writer had been initiated in the secret mysteries of Dionysus, which held that the soul was imperishable. He seems to have been an independent thinker rather than an adherent of any particular school of philosophy. His vast acquaintance with the literature of his time is everywhere apparent.

The celebrity of Plutarch, or at least his popularity, is mainly founded on his 46 Parallel *Lives*. He is thought to have written this work in his later years after his return to Chaeronea. His knowledge of Latin and of Roman history he must have partly derived from some years' residence in Rome and other parts of Italy (Demosth. § 2), though he says he was too much engaged in lecturing (doubtless in Greek, on philosophy) to turn his attention much to Roman literature during that period.

Plutarch's design in writing the *Parallel* Lives — for this is the title which he gives them in dedicating *Theseus* and Romulus to Sosius Senecio — appears to have been the publication, in successive books, of authentic biographies in pairs, taking together a Greek and a Roman. In the introduction to the *Theseus* he speaks of having already issued his Lycurgus and *Numa,* viewing them, no doubt, as bearing a resemblance to each other in their legislative character. Theseus and Romulus are compared as the legendary founders of States. In the opening sentence of the life of Alexander he says that "*in* this *book* he has written the lives of Alexander and Caesar" (Julius), and in his Demosthenes, where he again (§ 1) mentions his friend Sosius, he calls the life of this orator and Cicero the fifth book. (It is quite evident that the original order of the books has been altered in the series of *Lives* as we now have them.) It may, therefore, fairly be inferred that Plutarch's original idea was simply to set a Greek warrior, statesman, orator or legislator side by side with some noted Roman celebrated for the same qualities, or working under similar conditions. Nearly all the lives are in pairs; but the series concluded with single biographies of Artaxerxes, Aratus (of Sicyon), Galba and Otho. In the life of Aratus, not Sosius Senecio, but one Polycrates, is addressed.

The *Lives* are works of great learning and research, long lists of authorities are given, and they must for this very reason, as well as from their considerable length, have taken many years in compilation. It is true that many of the lives, especially of Romans, do not show such an extent of research. But Plutarch must have had access to a great store of books, and his diligence as an historian cannot be questioned, if his accuracy is in some points impeached. From the historian's point of view the weakness of the biographies is that their interest is primarily ethical. The author's sympathy with Doric characters and institutions is very evident; he delights to record the exploits, the maxims and virtues of Spartan kings and generals. This feeling is the key to his apparently unfair and virulent attack on Herodotus, who, as an Ionian, seemed to him to have exaggerated the prowess and the foresight of the Athenian leaders.

The voluminous and varied writings of Plutarch exclusive of the *Lives* are known under the common term *Opera moralia.* These consist of above 60 essays, some of them long and many of them rather difficult, some too of very doubtful genuineness. Their literary value is greatly enhanced by the large number of citations from lost Greek poems, especially verses of the dramatists, among whom Euripides holds by far the first place. The principal treatises in the *Opera moralia* are the following:—

On the Education of Children; How a Young Man Ought to Hear Poetry, on the moral aspect of Homer and the tragedians, with quotations *On the Right Way of Hearing* (Περὶ τοῦ ἀκόυειν) is another educational essay. Among the moral essays may be included: *How a Flatterer may be Distinguished from a Friend, How One May be Conscious of Progress in Goodness,* addressed to Sosius Senecio, consul under Nerva and Trajan; three short essays, *On Having many Friends, On Chance* and *On Virtue and Vice,* mainly valuable for quotations from poets otherwise lost; *Advice to the Married, On the Late Vengeance of the Deity, On the Genius of Socrates, On Superstition, On Exile,* a fine essay plentifully illustrated with quotations; *The Amorous Man,* and the *Gryllus,* an entertaining dialogue proving the moral superiority of many animals over man. The speakers are Circe, Odysseus, and a pig; the pig wins.

Another group includes some physical treatises such as *Precepts about Health,* which do not often coincide with modern ideas; *On the Face of the Moon's Disk,* which throws light on ancient astronomical theory; *Whether Land or Water Animals are the Cleverer; Whether Water or Fire is the More Useful; On Primary Cold; Questiones Naturales* and *On Flesh Eating.* The historical treatises include: *On the Fortune of the Romans,* two essays on the career of Alexander, *Whether the Athenians were More Renowned for War or for Wisdom,* and the famous *De Malignitate Herodoti,* charging Herodotus with unfair treatment of the non-Ionic States. There are also a purely metaphysical work, the *Platonic Questions,* and two political treatises, *Should a Man Engage in Politics when No Longer Young?* and *Political Precepts.* There are also two *Consolations,* one to Apollonius for his son, and one to his own wife for their daughter. There remains a group of his most valuable and interesting works, on archaeological questions generally, and especially religious history. These include *On Isis* and *Osiris, On the Cessation of Omcles, On the Pythian Responses* (an appendix to the last), and *On the E at Delphi,* of the exclusively ritual discussions; and two miscellaneous works, which contain a vast collection of information and discussions on points of almost every kind, the *Symposiaca* (9 books), and the *Quaestiones Romanae* and *Graecae,* which is of considerable importance to classical archaeology. There is also the collection of *Short Sayings,* divided into (1) of kings and commanders, (2) of Spartans, and (3) of Spartan women. Doubt is thrown on the validity of *Tlte Banquet of the Seven Wise Men, On Fate; Parallels; On Accepted Opinions and the Lives of the Ten Orators.*

BIBLIOGRAPHY.—Editio princeps, by H. Stephanus (1572); other complete editions by J. J. Reiske (1774–82), J. G. Hutten (1791–1804), T. Döhner and F. Dübner (1846–55). Of the *Lives,* there are editions by A. Coray (1809–14), C. Sintenis (1839–46; ed. min., 1874–81), and of many separate lives by Siefert-Blass, Sintenis-Fuhr, Holden, Hardy and others; Loeb ed., with trans. (11 vols. 1914–26). There are many English translations, of which the most popular is that by John and William Langhorne; also the old French version by Jacques Amyot (1559) from which Sir Thomas North's (1579) was made, newly edited by G. Wyndham (1895); many of the Roman lives have been translated, with notes, by George Long. The *Moralia* has been edited by D. Wyttenbach (1795–1830), and G. N. Bernardakes (1888–96) Loeb ed. with trans. (1927–). The old English translation by Philemon Holland (1603) has been revised by C. W. King and A. R. Shilleto in Bohn's *Classical Library* (1882–88), and a later translation by various hands (London, 1684–94), edited by W. W. Goodwin with introduction by R. W. Emerson, has been republished at Cambridge, Massachusetts (1874–78). Mention may also be made of P. Holland's *Roman Questions,* edited with introductory dissertations by F. B. Jevons (1892); *Roman Problems,* with essay on "Roman Worship and Belief," by G. C. Allen (1904); H. J. Rose, *The Roman Questions of Plutarch* (Text and Commentary, 1924); *De la Musique,* edit. H. Weil and Th. Reinach (1900); J. Oakesmith, *The Religion of Plutarch as expounded in his Ethics* (1902); Archbishop Trench, *A Popular Introduction to Plutarch* (1873); O. Gréard, *De la Morale de Plutarque* (1866); R. Volkmann, *Leben, Schriften und Philosophie des Plutarch* (1869); R. Hirzel, *Plutarch* (1912). The earlier literature of Plutarch is very extensive, for which W. Engelmann, *Scriptores graeci* (1881), may be consulted.

PLUTARCH OF ATHENS (4th–5th century A.D.), Greek philosopher. preceded Syrianus as head of the Platonic school at Athens and was one of the teachers of Proclus. He died at a good old age in A.D. 431/432. The commentaries that he wrote on a number of Platonic dialogues and on Aristotle's *De Anima* have not survived and are known to us only from allusions in later writers. The commentary on the *De Anima* had a particularly high reputation, ranking with that of Alexander of Aphrodisias. We know too little of Plutarch's teaching to be able to form any estimate of its importance or originality. What we are told by later writers does not suggest that it was notably different from that of other Athenian Neoplatonists, though perhaps he was more interested in and influenced by Aristotle's philosophy than some of them. (All Neoplatonists of course studied Aristotle and were to some extent influenced by him; he was in particular their principal authority in logic and natural philosophy.) Plutarch seems to have been particularly interested in Aristotle's psychology: we are told not only that he wrote a commentary on Aristotle's chief psychological work but that in his own teaching on the soul he combined the Platonic doctrine of recollection with the Aristotelian theory of the intellect. (A. H. AG.)

PLUTO, a euphemistic name for the Greek god of the lower world (Gr. Πλούτων), properly Hades, Aïdes or Aïdoneus, "the Unseen." He was the son of Cronus and Rhea, and brother of Zeus and Poseidon. Having deposed Cronus, the brothers cast lots for the kingdoms of the heaven, the sea, and the infernal regions. The last, "the house of Hades," sometimes loosely called Hades, fell to Pluto. Here he ruled with his wife, Persephone, over the other powers below and over the dead. He is stern and pitiless, deaf to prayer or flattery, and sacrifice to him is of no avail; only the music of Orpheus prevailed upon him to restore his wife Eurydice. His helmet, given him by the Cyclopes after their release from Tartarus, rendered him invisible (like the Tarn—or Nebelkappe of German mythology). Being feared, he is usually alluded to by euphemistic epithets: Polydectes (the receiver of many), Clymenus (the Illustrious), Eubulus (the giver of good counsel). But, perhaps by contamination with a god of the fertility of the earth, he is also Pluto, the "giver of wealth" (a name that first occurs in the Attic poets of the fifth century), and at most of the centres of his cult he was so worshipped; At Elis alone he was Hades, the god of the dead. The plants sacred to him were the cypress and narcissus; black victims were sacrificed to him. as to all underworld powers. In art he was represented like Zeus and Poseidon, but sterner; his attributes are a sceptre and Cerberus; he carries the key of the world below and is frequently in company with Persephone.

PLUTO is the outermost known major planet, ninth in order of distance from the sun. Its mean distance from the sun is 39.5 times that of the earth, but its orbit is so eccentric (e = 0 25) that at perihelion as in 1989, it comes closer to the sun than Neptune does. The inclination (17") and the orientation of its orbit (node to perihelion = 114°) are such that the orbits of Neptune and Pluto do not now intersect. Pluto's period of revolution is 248 years. Pluto is so faint, 15th magnitude, that a 20-in. telescope is necessary to see it. Its diameter has been measured as 3,700 mi., halfway between that of Mars and Mercury. This measurement is difficult because of Pluto's faintness and small angular diameter (0.″23). With a diameter of 3,700 mi., Pluto's volume is 0 1 that of the earth and its mass would probablv be about 0 1 that of the earth also, since it is not likely that its density exceeds that of the earth. Pluto's reflecting power derived from its apparent brightness and measured diameter is about what might be expected (albedo = 0.17). Its mass as derived from its attraction on Neptune is about that of the earth, but this value is also uncertain. If Pluto is as large as the earth, as indicated by its calculated mass, its reflectivity must be extreniely low. It therefore seems probable that Pluto's diameter is about one-half and its mass one-tenth that of the earth.

The brightness of Pluto varies about 10% in a period of 6.39 days, indicating that its surface is not uniformly bright and that the planet rotates on its axis in a period of 6.39 days.

Pluto mas discovered in a systematic search for a trans-Neptunian planet predicted by Percival Lowell on the basis of its attraction on Uranus (*Memoirs of the* Lowell Observatory, vol. i, 1915). William Henry Pickering, using discrepancies in the motion of Neptune. also predicted a trans-Neptunian planet in about the same place as that derived by Lowell (*Harvard Annals*, vol. lxxxii, no. 3, 1919). Pluto was discovered on Feb. 18, 1930, by Clyde William Tombaugh at the Lowell observatory on photographs he had taken on Jan. 23 and 29, 1930 (Scientific *Monthly*, vol. xxxiv, Jan. 1932). He recognized the new planet by its motion, which was much slower than that of the numerous asteroids also recorded on the photographs. In spite of the fact that Pluto was near the position predicted by the computations, its small mass indicates that its discovery was due to the thoroughness of the search rather than to the theoretical calculations. Both Lowell and Pickering predicted that the unknown planet would be much larger and brighter than Pluto is. (S. B. N.)

PLUTO MONKEY, a guenon (*q.v.*), *Cercopithecus mitis*, which takes its name from the black fur of the underparts, passing into blackish gray on the head and back. The violet-coloured face is fringed by large bushy whiskers and surmounted by a white band above the brows. The typical form extends from the Congo to Nyasaland and Angola.

PLUTONIUM. The element plutonium has the chemical symbol Pu and the atomic number 94. It was given its name after the planet Pluto, following the convention used in naming uranium and neptunium. Since all of the isotopes are produced synthetically. the atomic weight depends on the particular isotopic composition of any given sample, which in turn depends on the source of the sample. Plutonium occupies a position in the periodic system of the elements as the fifth member of a transition series, the actinide series. which includes the heaviest known elements and in which an inner electronic shell (the 5f shell) is being filled. For an account of its discovery, see the article TRANSURANIUM ELEMENTS.

The isotope of plutonium which is of greatest importance is the one with mass number 239. This isotope, which decays by the emission of alpha particles with a half life of about 24.000 years. has the property of being fissionable with slow neutrons, a property which makes it useful as a nuclear fuel and a source of atomic or nuclear energy. The first pure chemical compound of plutonium. free from carrier material and all other foreign matter, was isolated by Burris B. Cunningham and Louis B. Werner at the Metallurgical laboratory (now the Argonne National laboratory) of The University of Chicago during Aug. 1942. This isolation marked the first sight of a synthetic element and the first isolation of a weighable amount of an artificially produced isotope of any element. This isotope, Pu^{239}, was the one used for the study of plutonium in weighable amounts.

Occurrence.— Plutonium occurs in nature in uranium-containing ores in a very small concentration. Such plutonium was first discovered in Canadian pitchblende by Glenn T. Seaborg and Morris L. Perlman in 1942. The isotope involved is Pu^{239} which is formed continuously as a result of the absorption of neutrons by U^{238}. The neutrons are those emitted during the spontaneous fission of uranium and those resulting from the action of alpha particles on the nearby light elements. The concentration of Pu^{239} is determined by the equilibrium balance between its rate of formation and its rate of radioactive decay.

TABLE I.—Concentvations of Plutonium in Common Ores

Ore	Pu^{239}/ore*
Pitchblendes:	
Canada (13.5% U)	9.1×10^{-13}
Belgian Congo (38% U)	4.8×10^{-12}
Colorado (50% U)	3.8×10^{-12}
Monazites:	
Brazil (0.24% U)	2.1×10^{-14}
North Carolina (1.64% U)	5.9×10^{-14}

*Fraction by weight of Pu^{239} in ore.

Production.— By far the most important source of plutonium has been its manufacture in nuclear reactors or chain-reacting piles. An example is a nuclear reactor consisting of natural uranium and some neutron-slowing material or moderator such as carbon (graphite) or heavy water (deuterium oxide). In such a reactor a self-sustaining nuclear chain reaction results from the fission of the uranium isotope U^{235} with neutrons. and a large proportion of the excess neutrons are absorbed by U^{238} to form U^{239} which decays by two successive beta-particle emissions to Pu^{239}. In such production methods some of the Pu^{239} captures neutrons to form heavier isotopes such as Pu^{240}, Pu^{241}, etc. Since the isotopic composition of any given sample of plutonium depends on its source, the concept of atomic weight has no meaning in the ordinary sense. The plutonium is separated by chemical means from the highly radioactive fission products and the uranium and other foreign material. The chemical plants for this purpose are massive structures engineered to solve the grave problems inherent in handling extremely high levels of radioactivity due to the fission products. Operations in these plants are carried out entirely by remote control through heavy walls of shielding material.

The earliest industrial process for the isolation of plutonium, used at the Hanford Engineer Works in the state of Washington during World War II, is based on bismuth phosphate and lanthanum fluoride as carrier precipitation agents. This process was conceived by Stanley G. Thompson. Seaborg and their collaborators at the Metallurgical laboratory of The University of Chicago. Neutron-irradiated uranium is dissolved in nitric acid and after the addition of sulfuric acid. plutonium IV is coprecipitated with bismuth phosphate. The precipitate is dissolved in nitric acid. the plutonium IV is oxidized to plutonium VI and a by-product precipitate of bismuth phosphate is formed and removed. the plutonium VI remaining in solution. After the reduction of plutonium VI to plutonium IV, the latter is again coprecipitated with bismuth phosphate and the whole "decontamination cycle" is repeated. At this point the carrier is changed to lanthanum fluoride, and a similar "oxidation-reduction cycle" is carried out using this carrier, which achieves further decontamination and concentration. The plutonium at this point is sufficiently concentrated so that final purification can be carried out without the use of carrier compounds.

Many of the commercial processes for the separation and decontamination of plutonium in use later were based upon extraction into organic solvents. The solvent extraction is performed in packed columns or pulsed columns, or in a series of mixing-settling chambers in which the aqueous phase and solvent phase pass in countercurrent flow in a multistage process. These processes are very similar in principle as used throughout the world and can be illustrated by two of the U.S. processes. In the industrial "Redox" process, uranium and plutonium are separated from fission products and from each other by extraction with methyl n-butyl ketone (hexone). The uranium nitrate dissolver solution is oxidized and contacted with hexone to extract uranium VI and plutonium VI. The hexone is then contacted with an aluminum nitrate solution containing a reducing agent which does not affect the uranium but reduces the plutonium to plutonium III and strips it into the aqueous phase. The plutonium product from this cycle is oxidized to prepare it for re-extraction, and the entire sequence — extraction as oxidized plutonium, followed by reduction and stripping as tripositive plutonium — is repeated once or twice more. In the industrial "Purex" process, tributyl phosphate diluted with a kerosene-type solvent is used. The uranium slugs are dissolved in nitric acid, plutonium is fixed as plutonium IV and the acid strength is adjusted so that plutonium IV and uranium VI are extracted away from the fission products. In a second part of the process, the solvent is contacted with a nitric acid solution containing a reducing agent. Uranium VI is left in the tributyl phosphate phase while plutonium III is removed. Both uranium and plutonium are put through additional purification before complete purification is achieved.

Uses. — The main use for plutonium, dependent on the isotope Pu^{239}, lies in its application for nuclear (or atomic) energy. Nuclear reactors may be built to use the isotope Pu^{239} as fuel, and these reactors can also be operated in conjunction with the abundant isotope of uranium, U^{238}. The reactors can generate energy by "burning" the Pu^{239}, while at the same time they produce more Pu^{239} as a result of the absorption of neutrons in U^{238}. Such a system is known as a "breeder." This process, in theory, should make it possible eventually to convert all the nonfissionable U^{238} into fissionable Pu^{239}. Hence the rate of nuclear power production could be increased steadily. It is possible to use Th^{232} instead of U^{238} in these breeder reactors. In this case the following reaction would occur:

$$Th^{232} \xrightarrow{\eta,\gamma} Th^{233} \xrightarrow{\beta^-} Pa^{233} \xrightarrow{\beta^-} U^{233}$$

The product U^{233} is a long-lived, fissionable isotope similar to Pu^{239} and U^{235}. A fissionable isotope such as Pu^{239} gives rise to an amount of heat energy equivalent to about 10,000,000 kw.hr. per pound when it undergoes the fission reaction completely. In industrial uses the energy may be used in this heat form or, in most cases. converted into the more convenient electrical form by more or less standard turbine equipment. The efficiency with which heat energy can be turned into electrical power in an industrial nuclear reactor depends on the details of the particular machine, but it seemed likely that efficiencies of some 20% to 30% might be realized.

The isotope Pu^{239} can also be used as an explosive ingredient for nuclear (atomic) weapons. An important use of the by-product radioactive tracers, which may be formed by neutron absorption in various chemical elements inserted into a chain reacting unit, is for fundamental and applied investigation in basic science, agriculture and industry, and for fundamental investigations and therapeutic uses in biology and medicine.

Metallic Plutonium. — Plutonium metal has very unusual properties. It exists in six allotropic forms below its melting point

Table 11.—Phase Transitions in Plutonium Metal

Phase Change	Temperature of Transition on Heating (° C.)	
	Dilatometer	Thermal Analysis
a—6	122±2	122
β—γ	206f 3	203
γ—δ	319±5	317
δ—δ'	451±4	453
δ'—ϵ	476f 5	477
ϵ—liquid		639 5±2

(639° C.) at atmospheric pressure, a behaviour unique to this metal The temperatures at which the phase changes occur have been determined by a dilatometric method and by thermal analysis.

The density of a-plutonium (monoclinic) is quite high, 19.737; however. the densities of the other phases are lower, *i.e.*, 17.65 for β-plutonium (body-centred monoclinic), 17.19 for y-plutonium (face-centred orthorhombic), 15.92 for 6-plutonium (face-centred cubic), 15.99 for 6'-plutonium (face-centred tetragonal) and 16.48 for ϵ-plutonium (body-centred cubic).

Marked changes in electrical resistivity and thermal expansion accompany the phase changes. The electrical resistivity of a-plutonium is higher than that of any other metallic element at room temperature, being 145 micro-ohm centimetres. Plutonium metal is highly electropositive.

The metal also forms intermetallic compounds with aluminum, beryllium, cobalt, iron, manganese, nickel and silver. These compounds include $PuAl_2$, $PuAl_3$, $PuAl_4$, $PuBe_{13}$, $PuCo_2$, $PuFe_2$, $PuMn_2$, $PuNi_2$, $PuNi_5$ and Pu_2Ni_{17}.

Table 111.—Isotopes of Plutonium

Isotope*	Half life	Type† and energy of radiation (Mev)
Pu^{232}	36 min.	EC (<98%) α(>2%) 6.58
Pu^{233}	20 min.	EC α (0.1%) 6.30
Pu^{234}	9.0 hr.	EC (95%) α (5%) 6.19
Pu^{235}	26 min.	EC α (3×10^{-3}%) 5.85
Pu^{236}	2.85 yr.	α 5.75
Pu^{237}	45.6 days	EC; α (3×10^{-3}%) 5.65, 5.36
Pu^{237m}	0.18 sec.	IT
Pu^{238}	86.4 yr.	α 5.49 (72%) 5.45 (28%)
Pu^{239}	24.4×10^3 yr.	α 5.150 (69%) 5.137 (20%) 5.099 (11%)
Pu^{240}	6,600 yr.	α 5.16 (76%) 5.12 (24%)
Pu^{241}	13 yr.	β^- ~0.02 α (4×10^{-3}%) 4.893, 4.848
Pu^{242}	3.73×10^5	α 4.898
Pu^{243}	4.98 hr.	β^-0.579 (62%) 0.490 (38%)
Pu^{244}	7.6×10^7 yr.	α
Pu^{245}	10.1 hr.	β^-
Pu^{246}	10.85 days	β^-0.33, 0.15

*The symbol m placed after the mass number refers to an isomeric form of isotope.
†EC = electron capture; α = alpha particle; β^- = negative beta particle; IT = isomeric transition.

Chemical Properties in Aqueous Solution. — The chemistry of plutonium is markedly similar to that of uranium and neptunium, the elements immediately preceding it in the periodic table. The differences in the chemical properties of these elements are due primarily to a progressive increase in the energy required to form their positive ions.

Plutonium exhibits four oxidation states in aqueous solution: 3+, 4+, 5+ and 6+. The ionic species corresponding to these oxidation states vary with the acidity of the solution. In moderately strong (one molar) acid the species are Pu^{3+}, Pu^{4+}, PuO_2^+ and PuO_2^{2+}. The potential scheme of the ions in one-molar perchloric acid is the following:

$$Pu^0 \xrightarrow{+2.03\ v.} Pu^{3+} \xrightarrow{-0.982\ v.} Pu^{4+} \xrightarrow{-1.172\ v.} PuO_2^+ \xrightarrow{-0.9133\ v.} PuO_2^{2+}$$

$$Pu^{4+} \xrightarrow{-1.043\ v.} PuO_2^{2+} \qquad Pu^{3+} \xrightarrow{-1.0224\ v.} PuO_2^{2+}$$

The potentials are in volts relative to the hydrogen-hydrogen ion couple as zero.

The potentials of the various couples are so nearly the same that the intermediate oxidation states are unstable with respect to self-oxidation and reduction:

$$3Pu^{4+} + 2H_2O = 2Pu^{3+} + PuO_2^{2+} + 4H^+$$

and

$$2PuO_2^+ + 4H^+ = Pu^{4+} + PuO_2^{2+} + 2H_2O$$

These net changes do not indicate the mechanisms of the reactions, which are more complex. The disproportionation of PuO_2^+ is accompanied by a simultaneous oxidation of PuO_2^+ by Pu^{4+} (with the products PuO_2^{2+} and Pu^{3+} formed).

The oxidation-reduction relationships of the plutonium ions in acid solution are among the most intricate to be found in the field of inorganic chemistry.

The values given for the potential scheme in one-molar acid may be altered extensively by a change in hydrogen-ion concentration or as a result of the addition of substances capable of forming complex ions with the plutonium species. Among such substances are sulfate, phosphate, fluoride and oxalate ions, and various organic compounds, especially those known as chelating agents. The tetrapositive and hexapositive ions are complexed appreciably even by nitrate and chloride ions. The stability of the complex formed with a specified anion increases in this order: PuO_2^+, Pu^{3+}, PuO_2^{2+}, Pu^{4+}.

The hydrolysis of the ions follows a similar order: Pu^{4+} begins to hydrolyze even in tenth-molar acid and in hundredth-molar acid forms partly the hydroxide $Pu(OH)_4$ and partly a colloidal polymer of variable but approximate composition $Pu(OH)_{3.85}X_{0\ 15}$, where X is an anion present in the solution. Further reduction of the acidity results in the hydrolysis of PuO_2^{2+} near pH 5, of Pu^{3+} at about pH 7, and of PuO_2^+ at about pH 9.

The potentials of the couples involving either of the two lower states with either of the two upper states have an approximately fourth-power hydrogen-ion concentration dependence in moderately acid solution. This dependence, together with the hydrolytic effects just mentioned. causes rapid alteration of the potential values with change in acidity.

The plutonium ions in aqueous solution possess characteristic colours: blue-lavender for Pu^{3+}, yellow-brown for Pu^{4+} and pink-orange for PuO_2^{2+}. Pure solutions of PuO_2^+ have not been prepared, and since the ion shows but little absorption of visible light, its appearance in solution is not definitely known. The colours of the plutonium ions are altered by hydrolysis or complex ion formation. The absorption spectra of plutonium solutions are found to consist of a number of relatively narrow bands. Each oxidation state exhibits a characteristic spectrum that may be used for the quantitative as well as the qualitative analysis for that oxidation state in solution. Absorption bands as sharp as those found in plutonium solutions are observed only in solutions of other actinide elements or of the rare earths. It is inferred that in plutonium. as in the rare earths, the bands originate from transitions occurring in protected inner f electron orbitals.

The aqueous ions of plutonium are strongly paramagnetic, and measurements of the magnetism are in agreement with the assignment of five, four, three and two f electrons, respectively, for the oxidation states from 3+ through 6+.

Pure solutions of the upper and lower oxidation states may be obtained without difficulty. the former by oxidation with oxidizing agents such as bromate, dichromate or ozone, and the latter by treatment with reducing agents such as sulfur dioxide, hydroxylamine or hydrogen in the presence of platinum black. Because of the disproportionation reactions mentioned previously. the intermediate oxidation states are not stable. However, fairly pure solutions of Pu^{4+} may be obtained by dissolving the hydroxide in warm. concentrated perchloric acid, allowing several days at room temperature for reproportionation. and diluting the resulting solution. The disproportionation reaction is rather slow and the concentrations of Pu^{3+} and PuO_2^{2+} remain small for some hours.

The pentapositive state is quite unstable in strongly acid solution, but becomes increasingly stable as the hydrogen-ion concentration is decreased, down to about ten-thousandth molar. Dilute solutions containing a major proportion of plutonium as PuO_2^+ are stable at this acidity.

The precipitation properties of Pu^{3+} are similar to those of the tripositive rare-earth ions, of Pu^{4+} to Ce^{4+}. and of PuO_2^{2+} to the corresponding ions of uranium and neptunium.

Tri- and tetrapositive plutonium ions form salts of low solubility with fluoride, oxalate. ferricyanide and hydroxide ions. The tetrapositive ion is precipitated also by iodate and arsenate, even in strongly acid solution.

Pentapositive plutonium may be precipitated as a potassium salt from strong carbonate solutions, but no other solid compounds of this oxidation state are known.

The plutonyl ion, PuO_2^{2+}, separates as the beautifully crystalline pink salt $NaPuO_2(CH_3COO)_3$, sodium plutonyl acetate, from solutions containing a high concentration of sodium ions and acetate ions. This salt is analogous to sodium uranyl acetate and sodium neptunyl acetate. Under special conditions fluorescence is observed in crystalline tripositive compounds of plutonium.

Nonaqueous Chemistry. — Many of the most important compounds of plutonium are formed by reactions between solid phases or solid and gas phases, rather than in aqueous media. The most interesting and important of these compounds are the oxides, the halides and oxyhalides, and the binary compounds with carbon, nitrogen, silicon or sulfur.

Oxides. — The plutonium oxygen system does not present the degree of complexity exhibited by the uranium oxygen system (see URANIUM) largely because of the stability of the dioxide. Analogous behaviour is shown in the variable composition of the so-called sesquioxide ($PuO_{1.5-1.75}$), a typical mixed oxidation state oxide, similar to those formed by uranium, praseodymium, terbium: titanium and many other metals. Its composition shows continuous variation with changes in temperature and pressure of oxygen above the oxide. The limits of composition given above are only approximate. Near the lower limit of the oxygen range the structure is hexagonal. A higher proportion of oxygen causes the oxide to assume the cubic C type modification of the rare-earth sesquioxides. Plutonium sesquioxide may be formed by the thermal decomposition of the dioxide at about 1,500" C. in high vacuum.

Plutonium dioxide is the most important oxide of the element. Almost all compounds of plutonium are converted to the dioxide upon ignition in air at about 1,000° C. The ignited oxide is chemically inert at ordinary temperatures and has a well-defined composition; for these reasons it is a satisfactory compound for weighing in the gravimetric determination of plutonium.

The dioxide is frequently used as the starting material in the synthesis of other compounds of plutonium. In these cases prolonged high-temperature ignition of the oxide is avoided, since this leads to progressive chemical inertness.

TABLE IV.—*Important Halides and Oxyhalides of Plutonium*

Compound	Colour	Crystal Structure	Density (g./cc.)	M.P. (° C.)	B.P. (° C.)
PuFa	violet	hexagonal, tysonite type	9.32	1,425	2,190*
PuF_4	light brown	monoclinic	7.0	1,037	—
PuFa	deep brown gas, red or reddish-brown solid	orthorhombic	—	50.75	—
$PuCl_3$	emerald green	hexagonal, UCl_3 type	5.70	760	1,770*
$PuBr_3$	green	orthorhombic	6.69	681	1,510*
PuI_3	bright green	orthorhombic, $PuBr_3$ type	6.9	777	1,380*
PuOF	metallic	tetragonal	9.76	above 1,635	
PuOCl	blue green	tetragonal, PbFCl type	8.81	—	—
PuOBr	deep green	tetragoual, PbFCl type	9.07	—	—
PuOI	green	tetragonal, PbFCl type	8.46	—	—

*Estimated value.

Plutonium dioxide was the first compound of the element to be isolated and weighed in pure form and it was in fact the first compound of any synthetic element to be separated in pure form in weighable amounts. It was also the first compound of a synthetic element to be identified by X-ray diffraction methods.

Halides and *Oxyhalides*.—All of the halides except the tri-iodide, the hexafluoride and the oxyfluoride may be prepared by the hydrohalogenation of the dioxide or of the oxalate of plutonium III at a temperature of about 700° C. With hydrogen fluoride the reaction product is PuF_4, unless hydrogen is added to the gas stream, in which case the trifluoride is produced. With hydrogen iodide the reaction product is PuOI, and the other oxyhalides may be formed by the addition of appropriate quantities of water vapour to the hydrogen halide gas. Plutonium tri-iodide is produced by the reaction of the metal with hydrogen iodide at about 400" C.

Plutonium hexafluoride, the volatile plutonium analogue of uranium hexafluoride, can be prepared by the reaction of pure gaseous fluorine with plutonium tetrafluoride at 700" C. It is unstable with respect to dissociation into fluorine and plutonium tetrafluoride and is a powerful fluorinating agent. The rate of decomposition when stored as a vapour is, however, only about 0.1% per day. When it is stored principally as a solid. the radiation decomposition induced by the intense alpha activity destroys about 1.5% of the hexafluoride per day.

Plutonium oxyfluoride has been prepared by heating PuF_3 to 1,635° C. in an atmosphere of argon and oxygen.

The trihalides are appreciably. volatile at moderately elevated temperatures and all except the trifluoride may be purified by sublimation in quartz tubes in high vacuum at around 800° to 1,000° C.

Except for the trifluoride, the halides are so hygroscopic that they must be handled in an anhydrous atmosphere. The trifluoride shows so little tendency to hydration that the anhydrous salt is obtained directly upon precipitation from aqueous solution.

The crystal chemistry of the halides and oxyhalides of plutonium is closely similar to that of the analogous compounds of the rare earths—a consequence of the fact that these compounds are predominantly ionic and that the cations have nearly the same ionic radii. Sharp absorption bands and, under certain conditions, fluorescence similar to that in the analogous rare-earth compounds also are observed.

Carbides, Nitrides, Silicides and Sulfides.--Plutonium forms several binary compounds which are of interest because of their refractory character and stability at high temperatures. These compounds include the carbide, nitride, silicide and sulfide of the element. The monocarbide is formed by the reaction of the dioxide in intimate mixture with carbon at about 1.600" C., and the mononitride may be obtained by heating the trichloride in a stream of anhydrous ammonia at 900° C.; it is prepared more easily, however. by the reaction of finely divided metal with ammonia at 650° C. Although the lower temperatures are favourable to the production of higher nitrides, none is obtained, in contrast with the uranium-nitrogen system in which compositions up to UN, $_{75}$ are easily realized.

The disilicide is formed when a slight stoichiometric excess of calcium disilicide is heated with plutonium dioxide in vacuum at about 1,550° C. The disilicide is only moderately stable in air and burns slowly to the dioxide when heated to about 700° C.

Plutonium "sesquisulfide" may be prepared by prolonged treatment of the dioxide in a graphite crucible with anhydrous hydrogen sulfide at 1,340°–1,400° C., or by reaction of the trichloride with hydrogen sulfide at 900° C.

Only the most important compounds of plutonium have been mentioned in this article. The number of known compounds is very large. See also references under "Plutonium" in the Index volume.

(G. T. Sg.)

PLUTUS, properly, the abundant increase of the earth; child of Demeter (*q.v.*) and Iasion; in art, usually shown as a child. alone or in company with Tyche, Eirene, Athena or some other goddess. In popular thought, allegories and comedy, he was represented as Wealth. He was said to be blind.

PLYMOUTH, a city, county and parliamentary borough, naval base and seaport of Devon. Eng.. 42 mi. S.W. of Exeter by road. Pop. (1961) 204,279. Area 20.5 sq.mi.

It lies at the head of Plymouth Sound. stretching westward from the Plym river toward the mouth of the Tamar, from which it is separated by the totvnship of East Stonehouse and the borough of Devonport. both of which were included in Plymouth in 1914. The water frontage of the "Three Tonns" consists of Plymouth Sound, with its inlets, two of which, the Cattewater (east) and Harnoaze (west), are flanked by high ground on which are forts. On the northern side of the entrance to Cattewater is the Citadel, founded in the reign of Henry VIII and rebuilt by Charles II to the plan of an irregular bastioned pentagon. The adjacent Hoe extends along the northern edge of the Sound in which lies Drake's (formerly St. Nicholas) Island. Devonport dockyard fronts the Hamoaze. Stonehouse lies between. The city suffered air raids during World War II, and more than 80,000 houses and buildings were damaged or destroyed. Among churches, St. Andrew's, a Perpendicular building of 1480–1520 restored in 1874, was destroyed, only the walls and clock tower remaining. The beginning of the reconstruction of the city on a new plan was marked by a foundation stone laid by King George VI near the ruined guildhall.

Plymouth is the seat of a Roman Catholic bishopric founded in 1851, the cathedral being completed in 1858. The building is in the Early English style, and adjoining are the bishop's house and the convent of Notre Dame. Plymouth, the Sutton of Domesday, was divided into the town of Sutton Prior, the hamlet of Sutton Valletort and the tithing of Sutton Ralph. The market, established about 1253, became town property in 1311. In 1292 the town first returned members to parliament. In the 14th century it was often used for the transshipment of armies to and from France and it suffered from French attacks. In 1412 the inhabitants petitioned for a charter, which was granted on Nov. 12, 1439, the town being the first in England to be incorporated by act of parliament.

In the discovery of the new world Plymouth played an important part. Sir John Hawkins was a native of Plymouth, and it was from there that in 1577 Sir Francis Drake set out on his voyage round the world and in 1583 Sir Humphrey Gilbert sailed on his second colonizing expedition to America. In 1581 Drake became mayor of Plymouth and represented the borough in parliament during 1592–93. Plymouth supplied seven ships against the Armada and it was in the Sound that the English fleet awaited the Spaniards. A stone on a quay at the Barbican records the fact that this was the last port touched by the Pilgrim Fathers on their voyage to America. During the Civil War the town withstood all efforts by the Royalists to take it, and it early declared for William of Orange. Plymouth was created a city under royal letters patent in 1929 and the title of lord mayor was granted in 1935. Four years later its area was extended by almost 4.000 ac.

The port of Plymouth in 1311 embraced Plympton, Modbury and Newton Ferrers, and received a customs grant from Richard II. In 1435, 65 cargoes were imported, and in the reign of Elizabeth I it rose to be the foremost port in England. The 18th century saw a great development of trade with Virginia and the West Indies, and this resulted in the establishment of a sugar-refining industry that was maintained into the 20th century.

In 1749.the "town's water" was carried to the Barbican to supply shipping. The port of Plymouth as at present constituted embraces the waters of the Plymouth Sound and the Hamoaze. The chief water area within the limits of the port is the Sound with its inlets, the Cattewater, Sutton pool, Millbay, Stonehouse pool and the Hamoaze. The Sound itself covers an area of 4,500 ac. and is sheltered from the southwest gales by a breakwater (built in 1841) a mile long with a lighthouse at its western end. Cattewater, Sutton pool and Millbay constitute the three mercantile harbours of Cattewater harbour, Sutton harbour and the Great Western docks, while Hamoaze was set aside for the royal navy. The royal naval dockyard at Devonport covers 240 ac. Cattewater harbour has an area of 260 ac. and 8,000 ft. of quayage space. Sutton harbour entered from Cattewater has a quayage space of 4,500 ft. Great Western docks at Millbay has an outer basin of 35 ac., an inner one of 13. The port has productive fisheries. It has also a considerable export and import trade. As a naval station it is second only to Portsmouth. The industries of Plymouth include soapmaking, the manufacture of clothing, chemicals and artificial manure, paper staining and electrical engineering. The marine biological laboratory is situated on Citadel hill.

Plymouth returned three members to parliament, from the Drake, Devonport and Sutton divisions, from 1918 to 1950, after which the number was reduced to two, for Devonport and Sutton. Lady Astor, the first woman elected to the house of commons, represented the Sutton division from 1919 to 1945.

PLYMOUTH, the seat of Plymouth county, Mass., U.S.. and site of the first permanent settlement by Europeans in New England, is 37 mi. S.E. of Boston on Plymouth bay. Thousands of visitors are drawn annually by the historic interest of the town and its attractions as a summer resort. The modern town has a large cordage works, supplied by its own ships. Other important industries are cranberry growing and processing. commercial fishing, and varied manufactures such as sheeting for photoengraving and curtains. Seafaring was the heart of the older business life of the community and active wharves and boat yards remain.

Plymouth was founded by Pilgrims (*see* PILGRIM FATHERS)—Separatists from the Church of England who, in their search for religious toleration, had emigrated first to the Netherlands and then to North America. Sailing in the "Mayflower" (*q.v.*), the settlers reached the coast of New England in Dec. 1620, and an exploring party arrived in the Plymouth area on Dec. 21, now celebrated as Forefathers' day. The "Mayflower" anchored in the harbour five days later. (For a more detailed account of the colony's beginnings, and for its subsequent history, *see* MASSACHUSETTS: *History.)* The storied Plymouth Rock, first identified in 1741, became a symbol of freedom in 1774 when it was split by dragging it to Liberty Pole square in pre-revolutionary agitation. It rests today on its original water front site under a protecting portico of granite. Rising behind the rock is Cole's hill. where during their first terrible winter the Pilgrims buried half their number, levelling the ground and sowing it to grain in the spring "lest the Indians know how many were the graves" The first fort and watchtower were on Burial hill, which contains the graves of William Bradford (*q.v.*) and others of the original Pilgrims, although the oldest stone is dated 1681. "Plimoth Plantation," a nonprofit educational foundation, in 1957 began reconstructing an accurate replica of First Street in 1627 and other buildings of the early village. "Mayflower II," a good-will ship sent as a gift from England in 1957, is on display. Several mid-17th century houses still stand in the town. Pilgrim Hall. built in 1824, contains relics of the Pilgrims and early colonial times. Many surviving original records of the colony are in the Registry building. The National Monument to the Forefathers was dedicated in 1889. For comparative population figures *see* table in MASSACHUSETTS: *Population.* (CA M. C.)

PLYMOUTH BRETHREN, a community of Christians who received the name in 1830 when Rev. J. N. Darby (1800–1882) induced many of the inhabitants of Plymouth. Eng., to associate themselves with him for the promulgation of his opinions.

Although small Christian communities existed in Ireland and elsewhere calling themselves Brethren, and holding similar views, the accession to their ranks of Darby so increased their numbers and influence that he is usually called the founder of Plymouthism. Darby had been a curate in Wicklow 1825–27, when he felt himself constrained to leave the Anglican communion; going to Dublin, he became associated with several devout people who called themselves Brethren. Among these were A. N. Groves and J. G. Bellett, who rank among the founders of the movement. In 1830 Darby at Plymouth won over many people to his way of thinking, among them the well-known biblical scholar Samuel Prideaux Tregelles. During the next eight years progress mas rapid, and communities were founded in many towns of England

In 1838 Darby went to reside in French Switzerland and made many disciples. French Switzerland remained the stronghold of Plymouthism on the continent, and for his followers there Darby wrote two tracts, *Le Ministère considéré dans sa nature* and De *la Présence et de l'action du S. Esprit dans l'église.* The revolution in the canton Vaud brought persecution to the brethren in the canton and in other parts of French Switzerland.

He returned to England. and his reappearance was followed by divisions among the Brethren at home. These divisions began at Plymouth. Benjamin Wills Newton, head of the community there, who had been a fellow of Exeter college, Oxford, was accused of departing from the testimony of the Brethren by reintroducing the spirit of clericalism. Unable to detach the congregation from the teacher, Darby began a rival assembly. The majority of the Brethren out of Plymouth supported Darby, but a minority remained with Newton. The separation became wider in 184; on the discovery of supposed heretical teaching by Newton. In 1848 another division took place. The Bethesda congregation at Bristol, where George Müller was the most influential member, received into communion several of Newton's followers and justified their action. Out of this came the separation into Neutral Brethren, led by Miiller, and Exclusive Brethren. or Darbyites, who refused to hold communion with the followers of Newton or Miiller.

The Exclusives, who were the more numerous, suffered further divisions. An Irish clergyman named Samuel O'Malley Cluff had adopted views similar to those of Pearsall Smith, who preached a doctrine of sanctification called "Death to Nature" as an antidote to the supposed prevalent Laodiceanism, and when these were repudiated seceded with his followers. The most important division among the Exclusives came to a crisis in 1881, when William Kelly and Darby became the recognized leaders of two sections who separated on a point of discipline. This was followed (1885) by the disruption of the strict Darbyite section, two communions being formed out of it upon points of doctrine.

The theological views of the Brethren differ considerably from those held by evangelical Protestants. They make the baptism of infants an open question and celebrate the Lord's Supper weekly. Their distinctive doctrines are ecclesiastical. They hold that all official ministry, whether on Episcopalian. Presbyterian or Congregationalist theories, is a denial of the spiritual priesthood of all believers, and sets aside the Holy Spirit's guidance.

Sue W. B. Neatby, *A History* of *the Plymouth Brethren,* 2nd ed. *(1902).*

PLYNLIMON (**PEN** PLYNLIMMON, PUMPLUMON, PLINLIMMON: *pen,* "head"; *pump,* "five"; *lumon,* "chimney." "flag" or "beacon"), a ridge in Cardiganshire, central Wales. about 14 mi. inland from Aberystwyth and 10 mi. W. of Llanidloes. It is the culminating area of a wide moorland plateau stretching about 5 mi. from northeast to southwest, including six summits over 2.000 ft., the highest, Plynlimon, reaching 2,468 ft. The region was heavily glaciated and left with a thin coating of stiff boulder clay over the impervious Ordovician grits of which it is composed. Once forest (see Leland's *Itineraries,* 1500), it is largely covered with rough grass and bracken providing only poor pasture for sheep and summer grazing for young beef cattle. and much of the surface is boggy. Heavy rainfall and deep winter snows feed the many streams that radiate from the ridge—the Severn. Wye and Clywedog flowing southeastward to the Bristol channel and the Rheidol and Llyfnant westward to Cardigan bay. Rlining (for lead and copper) and quarrying are no longer carried on. The region is famous as a nursery of native Welsh tradition. There is a large proportion of short. dark, long-headed people, possibly a relic of ancient races. and ancient customs, songs and tales are preserved in the remote homesteads. (T. HER.)

PLYWOOD, a composite wood panel made of three or more layers glued together with the grain of adjoining plies at right angles to each other. For thin panels veneer is used exclusively, but for thicker panels sawed lumber often is used as the centre ply, or core, in which case it is known as lumber-core plywood.

The veneer may be rotary cut (*i.e.*, peeled from the log), sliced or, less commonly. sawed in thin sheets from a flitch or bolt. Rotary-cut veneer always presents a flat-grain or tangential surface, whereas sliced and sawed vcnecrs may be cut in a radial or any other plane through the log. Veneer used for plywood usually varies in thickness from $\frac{1}{28}$ to $\frac{1}{8}$ in.! but both thinner and thicker veneers often are used. Thin veneers have an advantage, especially for the outer or face plies, in that they set up less severe transverse stresses with changes in moisture content. thereby reducing warping arid surface checking of panels. The use of thin veneer also makes valuable wood go farther. In lumber-core panels the plies next to the faces, or the crossbands. usually are thicker than the face plies and largely control the stability of the panel. Plywood is almost always composed of an odd number of plies so that the grain of corresponding plies from the outside in runs in the same direction, thereby balancing and stabilizing the construction.

Plywood has a number of advantages over solid wood: it can be manufactured into large sheets with limited defects; it is stronger across the grain of the face plies than are boards of the same thickness; because the plies cross each other. shrinking and swelling are almost eliminated; splitting in handling and nailing are greatly reduced; and wood of the lower grades can be used for the interior plies. Since veneer can be dried in a matter of minutes. dry plywood can be produced from green logs in a day.

Two types of plywood are made: interior plywood, for use only in dry locations, and exterior plywood, for which water-resistant glues are used.

Since successively cut layers of thin veneers are similar in appearance, identical areas from adjacent sheets can be matched so as to make highly ornamental symmetrical patterns.

In sandwich construction thin facings are bonded on a thick core. The facings are made of strong material, such as thin, dense plywood, and the core of a lightweight material, such as balsa wood, cellular cellulose acetate or paper honeycomb. The core serves primarily to separate and stabilize the thin faces, which are the principal load-carrying portions. The complete assembly is exceedingly strong and stiff for its weight.

PLYWOOD CONSTRUCTION

(A) Three-ply, all veneer; (B) three-ply, lumber core; (C) five-ply, all veneer. Edge views

Utilization.—Plywood is used whenever a material is required to cover large areas with a light but strong and rigid sheeting; *e.g.*, in cabinetmaking (for chests, dressers, wardrobes, tables. etc.), housebuilding (for walls, ceilings, floors, doors, cupboards, cement forms, etc.), coachbuilding (for railway carriage roofs and walls, trucks, vans, trailers, etc.), shipbuilding (for small boat hulls. decks! cabins, etc.), boxmaking (for shipping and storage chests and cases, etc.) and aircraft construction (for fuselages, wings. floors, hydroplane hulls. etc.).

Perry, *Modern Plywood,* 2nd ed. (1948); Forest Products Laboratory, U.S. Department of Agriculture, *Wood Handbook* (1955). (AR. K.)

PNEUMATIC CONVEYING is the utilization of the conveying power of air in motion. It will be realized that conveyance of material through a pipeline, either by suction or blast, is ideal; since there are no mechanical parts in the path of the material there cannot be any contamination by lubrication. Another advantage is the greater flexibility of pneumatic plant; every part of the hold of a vessel, for instance, can be reached by flexible tubes for the purpose of unloading a grain cargo, whereas a more complex mechanical plant is rigidly fettered to straight lines. The *modus operandi* of a pneumatic plant is extremely simple and is as follows: Into a grain cargo in a vessel, for instance. a hosepipe is lowered, the nozzle at the end of which admits a mixture of air and grain. The other end of the pipeline enters tangentially into the upper part of a cylindrical receiver from which the air is exhausted, while the grain is withdrawn from the cone-shaped lower end by an air trap, without, however, admitting air into the receiver. When comparing pneumatic with mechanical handling devices the former have but one drawback; viz., the greater consumption of driving power for handling a given quantity. This. however, is more than compensated for by the greater flexibility and the hygienic value of the system. The first grain-handling installation on the Duckham system was known as "Mark Lane No. 1" and was built, under the personal supervision of the inventor, by the East Ferry Road Engineering Co. during the closing years of the 19th century. This was one of the most epoch-making revelations of all systems of handling. The plant is mounted on a pontoon and sucks the grain through a nozzle and pipeline from the ship's hold to an elevated receiver. whence it runs by gravity to a given point, via an air trap; an exhauster furnishes a partial vacuum by pipes connected with the receiver.

As has been shown, the material in a pneumatic plant floats. so to speak, in a current of air, from which it is separated by its specific gravity when the air expands in the receiver. The heavier the material to be handled, the greater must be the speed of travel of the air in the conveying pipes in order to ensure the floating of the material in and with the air. If the air speed is too slow the tendency will be for the material to separate from the air and thus block the pipes, especially such portions as are horizontally disposed, or nearly so. Therefore, installations for such heavy materials as coal and ash require more powerful pumps. Similar installations in which draught is induced by steam jets are successfully used for handling ash from boilers.

Because of the advantages accruing from the use of pneumatic handling plants, new avenues for their employment are being constantly opened. Such varied materials as grain, small coal, chemicals, ashes, potatoes, and even red-hot rivets and artillery shells are now successfully handled by pneumatic means. An offshoot of this system is the pneumatic tube, which is largely employed in postal and telegraph offices, as well as in great variety in business offices and stores. (G. F. Z.)

PNEUMATIC DISPATCH, a system of transporting written dispatches through long tubes of small diameter by means of compressed or rarefied air. It was introduced in 1853 by J. Latimer Clark between the Central and Stock Exchange stations of the Electric and International Telegraph company in London, the stations being connected by a tube $1\frac{1}{2}$in. in diameter and 220yd. long, the messages, enclosed in a tight fitting carrier, being drawn through it by the production of a partial vacuum at one end. The system was improved in 1858 by C. F. Varley, who used compressed air to return the carriers in the other direction. By this means it was possible to develop two-way working on single tubes between a central station, equipped with air-compressing plant, and outlying offices.

Pneumatic dispatch tubes are also used for internal communication in offices, hotels and stores. (J. McG.)

PNEUMATIC TOOLS can be divided into two main classes: (1) air-operated portable tools; and (2) air-operated rock drills and associated tools. The first class includes abrasive tools, drills, screw drivers, hammers, riveters and hoists; the second class, hand-held rock drills and paving breakers, mobile earth-boring machines, etc.

The pneumatic tool may be driven by a rotor or a reciprocating piston. In the first case, a rotor with vanes is surrounded by a housing; air enters the housing, pushes on the vanes and thus rotates a central shaft or spindle. A drill, grinder or some other part may be fastened to the spindle. In the second case, compressed air enters a cylinder, expands and pushes a piston back and forth. The reciprocating piston may be connected to or may strike some part such as a riveting hammer or a chisel. Pneumatic tools are usually supplied with compressed air at about 90 lb. per square inch above atmospheric pressure. A compressed-air system with a compressor, piping and an air motor is analogous to an electric system with an electric generator, electric wires and an electric motor.

With compressed air as the power source, it is possible to use tools which are relatively light in weight, compact, portable and easy to operate. Air motors introduce no spark hazard in explosive atmospheres, and they also are employed in wet conditions because they present no danger of electric shock. In underwater service, the compressed air prevents water from entering the motor.

Portable Tools.—Air-driven portable tools include such devices as grinders, buffers, sanders, drills and reamers, screw drivers and nut setters, all of which are powered by rotary-vane motors; trench diggers, riveters and various types of hammers, powered by pistons; and such specialty tools as concrete vibrators, cranking motors and railway roadbed tampers.

Air-driven grinders, drills, screw drivers, etc., are of conventional design except that an air motor is substituted for the more familiar electric motor; operating speeds usually can be varied by throttling the air to the motor.

In the pneumatic chipping or scaling hammer there is an air-operated piston that delivers successive blows to a chisel or forming tool at the end of the hammer. In the valve type of tool there is a separate mechanism to control the flow of air to the piston, thus allowing the operator to govern the speed and force of the blows; in the valveless type, the piston itself performs the valving action and the operator can exercise only an on-off control of the tool. The former type is used for chipping and riveting, for which control of the blows is important; the latter is used for such work as removing scale.

Riveting hammers are of two designs: in a compression riveter the compression or squeezing action on the rivet is obtained from an air piston and cylinder connected to a cam, wedge or toggle; a yoke riveter has an air-operated clamp or vise that holds the work in place; the yoke absorbs the hammering action and thus reduces operator fatigue.

Hoists operated by compressed air are used in operations which require accurate and definite control of lifting and lowering speeds. Air hoists are used outdoors and under conditions where corrosive fumes, explosive gases and inflammable fluids are present. Safety devices prevent sudden dropping of the load when the air pressure falls or the brakes fail.

There are various portable pneumatic tools which are usually classed as specialty tools, such as concrete vibrators, countersinking tools, spike drivers, paint mixers, air cranking motors, railway roadbed tampers, valve grinders, reciprocating filing machines, shank grinders and saws.

Rock Drills. — For mining and general rock excavation the usual air-operated tool is the hammer drill or percussion hammer, composed of a piston and a drill made of high-carbon steel. The shank of the drill is not attached directly to the piston but is held loosely in a chuck at the end of the cylinder and is struck by rapid blows from the freely moving piston.

For downward-sloping holes, some means must be provided to remove drill cuttings, dust and sludge; thus, a hollow bit is used, and water or air is passed through it to remove the cuttings and cool the drill bit. In addition, the bit must be rotated to produce a round, uniform hole, and this may be done either manually by the operator, with a wrench attached to the drill. or automatically by a ratchet-and-pawl mechanism that turns the bit slightly after each blow from the piston.

Hand-Held Rock Drills. — The hand-held rock drill, with a self-rotating hammer, is sometimes called a sinker or a jackhammer. Rock drills are frequently classified on the basis of weight—a drill of less than 25 lb. may be used for drilling shallow holes in brick or concrete; a 55-lb. drill may be used for road construction.

Drifter, Stoper and *Wagon* Drills. — The drifter drill is generally used for horizontal holes in mining operations and tunnel driving. The usual air-cylinder bore diameters are 3 in., 33 in. and 4 in. The drill is mounted on some type of rig or frame. The usual drifter is mechanically fed into the work. Stoper drills are used primarily on up-hole or overhead drilling. The usual stoper is a hammer drill with a self-rotating drill and an automatic feed by means of an air piston.

Large air-operated earth drills, mounted on motor trucks or trailers, are used for putting down water wells and blast holes for quarry operations. A high-capacity compressor provides air not only to power the drilling tool but also to raise and lower the tools in the hole and remove drill cuttings from the hole. Such machines are used to advantage in areas where surface water supplies are insufficient to provide the drilling fluid needed for standard rotary and cable-tool well drilling machines.

Paving Breakers. — Hand-operated pneumatic paving breakers generally use solid drill steels and are not equipped with automatic rotation. One type of tool is valve actuated; the other is valveless. Heavy machines, weighing about 80 lb., are used to break concrete pavement, foundations and boulders. Medium breakers, weighing 50 to 70 lb., are used to break light concrete floors,'macadam and frozen ground. The light tools, weighing less than 50 lb., are used for breaking floors, paving and masonry walls. Heavy- and medium-weight breakers can be adapted for use in driving spikes. (R. C. BR.; X.)

PNEUMATISM. The theory of pneumatism in medicine, based on the premise that life is associated with a subtle vapour called the pneuma, was expounded by the Alexandrian anatomist and physiologist Erasistratus (*q.v.*), who flourished about 300 B.C. The concept of pneumatism had been previously suggested by other commentators.

Unlike Herophilus, who accepted the old theory of humoral pathology, Erasistratus held that health and disease and, in fact, the nature of life were intimately connected with the pneuma, which had affinities with the air man breathes.

Erasistratus drew a distinction between two kinds of pneuma: one was a "vital spirit" formed in the heart from air; the second type was formed in the brain from the first kind. The former was transported by arteries to the parts of the body and the latter, styled the "animal spirit," by the nerves, being the prime cause of movement.

Although Erasistratus held that hindrance of the action of the pneuma, or an excess of blood, was the essential cause of certain diseases, he did not follow the contemporary practice of bloodletting, preferring to attempt to control the blood supply by diet and other less violent measures.

PNEUMATOLYSIS, in petrology, the discharge of vapours from igneous magmas and the effects produced by these vapours on rock masses. See VOLCANISM.

PNEUMONIA, an inflammation of the lung. Pneumonia was recognized as a disease by the ancients. but no progress was made in the knowledge of it until the time of Leopold Auenbrugger (1761) and René Laennec (1819). when order was brought into its classification. From then until the bacteriologic era opened, classification depended on the anatomic or clinical features, and adjectives such as lobar, lobular, broncho-, interstitial, pleural, double, central, croupous and catarrhal were used. Other pneumonias were called aspiration, contusion, hypostatic or terminal pneumonia, depending upon the cause. Although after 1880 various bacteria and viruses were known to cause pneumonia, the modern etiologic classification did not become popular until about 1930. Precise knowledge of the bacterial or other cause permits the use of specific therapeutic or preventive measures and other rational management in the control of the disease. More than 50 different infectious, physical or chemical causes of pneumonia were known by the second half of the 20th century, but of these, relatively few were of common occurrence. Pneumonias may be grouped as follows: (1) primary, *i.e.*, those caused by pathogenic cocci, bacilli, viruses and fungi that attack the lung primarily; (2) pneumonias that occur in more or less specific forms as part of systemic infections such as tularemia, psittacosis, tuberculosis, rheumatic fever, rickettsial and protozoal diseases, lupus erythematosus and others; (3) pneumonias caused by mixed infection induced by physical or mechanical injury of the lung such as shock. debility, passive congestion, aspiration of foreign bodies of fluid, obstruction to airway, atelectasis, trauma and others; and (4) pneumonias caused by the aspiration of oil, chemicals or dusts, by exposure to roentgen rays, by allergic reaction and other causes.

Pneumococcal Pneumonia. — The modern era of this disease began with the discovery of the pneumococcus in 1880 by G. M. Sternberg and its association with pneumonia by A. Fraenke! and A Weichselbaum in 1884. F. Neufeld first pointed out serologic differences among strains of pneumococci in 1910, and shortly afterward F. S. Lister and A. R. Dochez independently classified them into types. Much fundamental work on the bacteriology, etiology, pathogenesis. clinical aspects and treatment of pneumococcal pneumonia was done after 1911 at the Hospital of the Rockefeller Institute under the leadership of Rufus Cole and Oswald Avery. Extensive bacteriologic. clinical and epidemiologic contributions on the subject were also made. notably by Russell Cecil, O. H. Robertson and Maxwell Finland in the United States and by H Loeschke and Max Gundel in Germany. Specific immune serum for treatment reached its greatest effectiveness and popularity as the refined, concentrated form, only to be displaced by the sulfonamide compounds after 1935 and by penicillin in 1942.

Etiology. — There are about 75 types and subtypes of pneumococci of which only a few are of clinical importance. Types 1, 2. 3, 4. 5, 7, 8 and 14 account for about 80% of all pneumococcal lobar pneumonias. The rest are caused by pneumococci of other types that, in contrast with those mentioned, often are present in the throats of healthy persons.

Pneumococci rarely are primary invaders of the lung. In almost all instances there is evidence of some preceding condition that injures the lung and favours invasion, especially minor infections of the respiratory tract commonly called colds; chilling of the body, and debilitation. The pneumococci that become invasive are acquired by inhalation from outside sources or are already present in the pharynx; the first circumstance indicates that pneumonia may be a contagious disease contracted from other patients or carriers of pneumococci, and the second that it may arise as an autogenous infection. Under certain conditions when the general resistance is lowered by serious conditions, and in old age, the pneumonia is apt to be atypical or lobular (bronchopneumonia); in other words, it does not behave like the lobar form. The onset is gradual, pulmonic solidification may not occur and the course is irregular. The pneumococci causing this form are usually of the higher numbered types, indicating that they are part of the normal flora of the respiratory tract and have become invasive.

Pathology.—Pneumococci reach the lung by way of the air passages, settle in an area where they find circumstances suitable for growth and give rise to an area of inflammation conditioned by complex factors. among which partial immunity, allergy and nervous influences seem to play an important role. The inflammation spreads rapidly and soon involves part or most of a lobe, first as congestion and then with an outpouring of fibrin and polymorphonuclear leukocytes into the alveolar spaces. The exudate becomes rather solid and grayish over a period of several days, and finally. when recovery occurs, it softens and is resorbed. Pneumococci often enter the blood stream and may localize on the valves of the heart, the meninges or elsewhere. The pleura may be invaded, resulting in empyema.

Epidemiology.—Pneumococcal pneumonia is contagious at times, but susceptibility to infection is largely controlled by the resistance of the host. The prevalence of pneumonia usually parallels the incidence of minor respiratory tract infections. Both are most common in cold months but may occur at any season. Household and institutional epidemics have been recorded. Pneumonia varies in incidence from year to year and to some extent in its clinical manifestations, depending on the type of pneumococci predominant at the time. It is most prevalent in the temperate climates but may occur anywhere. All races are susceptible. Men are affected more often than women because of greater exposure. It is commonest in early adult life. Pneumococcal pneumonia declined in incidence after 1900. Yet in 1960 pneumonias were the sixth most important cause of death in the United States.

Clinical Features.—Lobar pneumonia is a strikingly clear-cut disease. It often develops in a person who has a cold and begins suddenly with a chill, pain in the chest. high fever, cough and thick rusty sputum. These are present in variable combinations and constitute the chief features. Other symptoms and signs are headache. vomiting, rapid respiration, cyanosis, dyspnea, tachycardia and herpes. The course in untreated patients may last a week or more, during which severe illness occurs. Characteristic signs in the chest in the early stage are those of congestion changing to those of consolidation of a lobe or lobes with dullness, bronchial breathing. bronchophony, egophony, pectoriloquy and occasionally friction sounds. Roentgenography is of great aid in observing the location and course of the pulmonary lesion. In patients who develop pleural effusion or empyema, signs of fluid appear. The leukocyte count and sedimentation rate of red cells usually are increased and the blood culture often becomes positive. In certain patients the onset is gradual and the course is not so characteristic, giving an atypical clinical response.

In those who recover, improvement often begins abruptly as a crisis with rapid fall of temperature and general improvement unless other involvement occurs. Death is caused by toxemia, overwhelming infection, circulatory collapse or extrapulmonary localization the chief of which are empyema. meningitis, endocarditis and arthritis. In patients treated with penicillin or sulfadiazine the course usually is terminated within 24 to 48 hours.

The mortality rate is 30% in untreated patients and about 5% in those treated with antibiotics. Five per cent is probably a minimum rate, since there are instances in which therapy is unsuccessful or for various reasons may be delayed or is not available. The disease is more often fatal in infants, debilitated or senile patients or in those with other chronic disease such as diabetes, hypertension or nephritis, or when treatment is postponed. Overwhelming infection that does not respond to any treatment may occur.

One attack of pneumonia does not necessarily predispose a person to another. There are certain persons who. for unknown reasons, have repeated attacks of pneumonia caused by the same type or by different types of pneumococci, or by other bacteria. There is some evidence of a hereditary tendency to the disease.

Diagnosis should be established by clinical. roentgenologic and bacteriologic methods. Material for tests must be obtained before treatment is begun.

Treatment.—Penicillin should be given promptly by injection or by mouth daily until the temperature becomes normal and for several days afterward. Tetracycline, erythromycin, chloramphenicol or sulfadiazine may be used if penicillin is unavailable or if the patient is sensitive to it. Appropriate symptomatic treatment must be given.

Prevention—The fundamental measures of prophylaxis are the prevention of minor respiratory tract infections and other conditions that predispose to pneumonia and the control of carriers of pneumococci. The maintenance of general health by adequate food, exercise and rest is important. Specific vaccines consisting of pneumococcal polysaccharides are of practical advantage only among well-controlled groups.

Hemolytic Streptococcal Pneumonia.—This form of pneumonia is less common than the pneumococcal forms and occurs often as a complication of influenza, as it did in the pandemic of 1918. It is caused by any of the 27 or more types of group A beta hemolytic streptococci. It may occur in sporadic or in epidemic form, the latter depending on the prevalence of a predisposing viral infection. The bronchi and trachea are involved more often and more severely than in pneumococcal pneumonia. There is lymphangitis and involvement of interstitial tissues. The exudate is thin and hemorrhagic, and streptococci are numerous. The pleura is usually inflamed.

The symptoms are not characteristic. The disease begins as an aggravation of the mild primary disease. There are fever, cough, pain in the chest, chills or chilly sensations and prostration in widely varying degrees of severity. The sputum is thin. mucopurulent and bloody. Bacteremia is uncommon. The leukocytes may be normal or increased in number. Massive pleural effusion with serosanguineous fluid or empyema are common. The patient may be mildly sick or extremely so with ashy pallor, cyanosis and evidence of circulatory collapse. The pulmonary signs are chiefly those of atypical pneumonia with patchy areas of congestion and areas of undeveloped consolidation.

The mortality rate in untreated patients varies from 10% to 60%; not enough patients have been treated with penicillin or sulfadiazine to judge their beneficial effects.

The diagnosis is made chiefly by the epidemiologic characteristics of the disease and by the predominance of hemolytic streptococci of group A in the sputum, blood or exudate. Retrospective diagnosis may be made by the demonstration of specific precipitins, antistreptolysin and antifibrinolysin in the blood. Roentgenography is useful in determining the nature and extent of the pulmonary lesions. Penicillin is indicated and must be given in large dosage. Sulfadiazine is said to be of some value. The symptomatic treatment is the same as for other pneumonias. Pleural effusion should be aspirated repeatedly and, if empyema is present, penicillin may be injected into the cavity.

Staphylococcal Pneumonia.—The staphylococcus, like the hemolytic streptococcus, invades the lung particularly during minor viral infections of the respiratory tract. Staphylococcal pneumonia occurs sporadically or in epidemic form during epidemics of viral diseases of the respiratory tract. Many cases occurred in the influenza pandemics of 1918 and 1957. In recent years. it has increased in incidence due to the overuse of antibiotics. Corticosteroids and radiation therapy given for other diseases lower resistance and favour the invasion of staphylococci. The causative staphylococci usually are those present normally in the patient but they may be acquired from outside sources. Their invasion gives rise to patchy areas of inflammation in the lungs. In the course of several days, multiple small abscesses form and tend to coalesce

The symptoms usually begin gradually. They vary greatly in intensity from mild to severe with high remittent fever, chills or chilliness, sweating, cough, cyanosis, prostration and purulent sputum. The leukocyte count is variable and bacteremia seldom occurs. When abscesses form and discharge through the bronchi, the sputum increases in amount and the signs change from those of patchy pneumonia to those of cavitation. The mortality rate is variable; in some cases studied, most patients recovered and in others 70% died.

Diagnosis is based on the epidemiologic aspects of the disease; the presence of great numbers of staphylococci in the sputum, exudates or the blood stream; and the signs and roentgenographic evidence of the development of multiple cavities.

Penicillin is the agent of choice, but it must be given in large amounts parenterally. Synthetic penicillins, novobiocin and vancomycin are specific for staphylococci.

Klebsiellar (Friedländer's Bacillus) Pneumonia.—This infection occurs chiefly in debilitated or senile persons. The onset often is like that of pneumococcal pneumonia. The disease is characterized by a severe course, irregular fever, occasional abscess formation but less evidence of firm consolidation of the lung than in pneumococcal pneumonia. The sputum is bloody, mucinous or mucopurulent and its bacteriological content consists predominantly of capsulated gram-negative coccobacilli. A chronic form with cavitation resembling tuberculosis may ensue. Because the infection occurs chiefly in weakened persons, the mortality rate is high (about 50% to 70%). The treatment is not so effective as for other forms of pneumonia. Antibiotics must be selected according to the sensitivity of the bacilli; they are used in large dosage singly or in combination.

The Viral **Pneumonias.**—While much attention had been given to the serious bacterial pneumonias, little was paid prior to about 1920 to those of viral origin, chiefly because they seldom caused death and the technique of identifying viruses was undeveloped. It had been known since 1861 that viral diseases such as measles are characterized by pulmonary involvement, but the nature of the pneumonia was obscured by the activity of secondarily invading bacteria. Because of this, the pneumonias that occur during severe colds also were regarded as complications caused by bacteria, although they rarely are. However, the experimental production of pneumonia in animals with the viruses of influenza and vaccinia, and the absence of bacteria in the pneumonic lungs of patients who died during the pandemic of influenza in 1918, left little doubt that viruses do cause pneumonia. Between 1920 and 1938 European and U.S. roentgenologists demonstrated unsuspected pneumonias in many patients with mild, acute respiratory tract infection.

In 1938 Hobart A. Reimann established viral pneumonias as entities and demonstrated their occurrence as the severest forms in 5% to 10% of epidemic viral minor respiratory tract infections. Specific nosography became possible later after the discovery of a number of causative viruses in addition to influenza viruses, namely, adenoviruses, Coxsackie, ECHO (enteric cytopathogenic human orphan). reo-, respiratory syncytial and myxoviruses. Each of these causes epidemics of mild disease with occasional pneumonias. Other agents that are not true viruses, such as the Bedsonias (psittacosis, ornithosis) and mycoplasma (Eaton agent), cause similar disease. Viral pneumonias, in general, outnumber those caused by bacteria. Their incidence varies from year to year depending upon the epidemic prevalence of the respective viral infections, of which they are the severe forms.

The symptoms are similar for each entity. As the mild infection worsens, headache, dry paroxysmal cough, slight sore throat, sweating, chilliness and irregular fever develop although there are few or no abnormal physical signs in the lungs. Roentgenography, however, may reveal extensive infiltration. Later, dullness to percussion. suppressed breath sounds and *râles* appear. The leukocytes may increase slightly in number. The pneumonia often is so mild as to be unsuspected but may be severe with dyspnea, cyanosis and prostration. It may last a week or more. Complications are rare The mortality rate is less than 1%. Death usually is caused by circulatory failure, especially in patients debilitated by other conditions. Pathologically, parts of or all of the respiratory mucous membrane is inflamed with but little exudate. The interstitial tissues of the lungs are inflamed and invaded by monocytic cells. The lesions disappear slowly.

Diagnosis is made by the epidemiologic aspects, the clinical behaviour, the low leukocyte count and the absence of pathogenic bacteria in the sputum. Etiologic proof depends upon the isolation and identification of the causative viruses and seriologic evidence of their activity. It is of importance to diagnose pneumonias caused by the Eaton agent (mycoplasma) and of psittacosis and ornithosis (Bedsonia) that respond to antibiotic therapy. The same is true for the pneumonias of tuberculosis, Q fever and others that resemble viral pneumonias.

Antibiotics now available have no therapeutic value for viral pneumonias. The treatment is symptomatic for the relief of headache, aching and cough.

Miscellaneous Primary Agents.—Rarer forms of pneumonia are caused by *Hemophilus influenzae, H. pertussis, Bacillus anthracis, Pasteurella pestis, P. tularensis, Gaffkya tetragena, Histoplasma capsulatum, Coccidioides immitis, Coxiella burnetii, Toxoplasma, Mycoplasma, Pneumocystis carinii, Bedsoniae* and others.

Pneumonias of Systemic Diseases.—Pneumonia may occur as an integral part of many systemic diseases. It may dominate the clinical picture, or it may be a minor factor or not occur at all in tuberculosis, tularemia, plague, undulant fever, glanders, syphilis, rheumatic fever, ascariasis, polyvasculitis, sarcoidosis and many others. The pneumonia usually is not characteristic clinically and often is obscured by symptoms of the systemic disease. Pathologically it may assume features characteristic of the respective disease. The treatment is that of the primary disease.

Pneumonias of Mixed Infections.—The pneumonias brought about by injury to the lungs or interference with their self-cleansing process usually are caused by a mixture of various kinds of bacteria that reside habitually in the air passages and are enabled to become invasive by the presence of injured tissue. The injury or interference of the cleaning action may be caused by obstruction of the airways by foreign bodies or tumours, failing circulation, submersion in or aspiration of fluids, trauma, atelectasis after surgical operation, shock and many other causes. Pneumococci, influenza bacilli, hemolytic streptococci and staphylococci are most frequently implicated. The iatrogenic reduction of bodily resistance by corticosteroids, radiation and other agents has increased the incidence of pneumonias caused by gram-negative bacilli and fungi. The treatment is directed primarily to the control or removal of the underlying cause. Antibiotic agents are given according to the sensitivity of the invading bacteria or fungi to the respective drugs, and appropriate supportive measures are applied.

Pneumonias Caused by **Noninfective** Agents.—The aspiration of oil over long periods or in large amounts often causes a chronic reaction commonly called lipoid pneumonia. Long exposure to roentgen rays may give rise to a pulmonary reaction called irradiation pneumonitis that leads to fibrosis. The inhalation of irritating chemicals (silo filler's disease), dusts (farmer's lung. byssinosis, bagassosis, berylliosis) and toxic gases used in warfare or industry. or fumes from certain molten metals may cause forms of pneumonia. Allergic pneumonitis or Loffler's syndrome represents the hyperergic inflammatory reaction of sensitized pulmonary tissue to repeated exposure to a specific antigen. The prevention and treatment of each of these conditions is the removal of the offending agent.

See RESPIRATORY SYSTEM, DISEASES OF; DANGEROUS OCCUPATIONS; and references under "Pneumonia" in the Index volume.

PNEUMONOCONIOSIS, also called pneumoconiosis, a term denoting a variety of industrial diseases of the lung, embracing lung response to any type of respirable hazard. Precise definition of the term is a matter of legal consequence, because occupational chest diseases are among the most litigious of medicolegal issues. In several countries many of these conditions are obligatorily compensable. To more than 3,000 naturally occurring minerals presenting respiratory hazard are added yearly an ever-increasing number of synthetic chemical agents. The biological action of less than 1% of these substances is known, yet about 10% of working persons handle such agents. While pneumonoconiosis is a generic term, silicosis has for many years been its chief specific manifestation. Because of the increasing range of dangerous respirable agents, however, emphasis is shifting from silicosis to other forms of pneumonoconioses. The majority of the significant reactions represent insidiously progressive chronic responses, frequently with a distinct latent period during which the workman is symptom-free. Fulminating cases also occur when exposure has been unduly severe or adjuvant factors play a part. A simplified etiological classification of the main varieties of pneumonoconioses is given in the table.

Pneumonoconioses

Siliceous	Nonsiliceous
Free silica (SiO_2)	Carbonaceous
Crystalline	Anthracosis* } ......coal miners
Silicosis proper	Emphysema* }
Mining*	Graphitosis ....graphite
Ceramics*	Smog lung ....carbon and chemicals
Glass industry*	
Abrasives*	Metallogenic
Sandblasting*	Siderosis ....iron
Foundry*	Baritosis ....barium
Etc.	Stannosis............tin
Aberrant silicosis	Cobaltosis...........cobalt
Tridimytosis*	Argyrosis .... silver
Cristobalitosis*	Aluminosis† ....aluminum
Amorphous	Berylliosis*..........beryllium
Natural	Cadmiosis*. ....cadmium
Diatomatosis {raw	Manganosis ....manganese
calcined*	Vanadiosis ....vanadium
Synthetic	Thioconiosis ....sulfur
Submicron, 20Å–4,000 Å	Plumboconiosis ......lead
	Welder's lung†.......iron + ozone or nitrogen dioxide
Silicates (SiO_4)	Brass foundry lung ..copper + zinc
Mineral	
Asbestosis*	Organic
Talcosis*	Byssinosis* ....cotton
Micatosis	Bagassosis*..........sugar cane
Kaolinosis	Ptilosis ....feather
Fuller's earth†	Tabacosis ....tobacco
Artificial	Papricosis ....pepper
Cementosis	Suberosis............cork
Glass wool†	Hemp lung..........hemp
	Flax lung ....flax
Mixed forms	Wood lung? ....wood
Disease in Bauxite extractors*	Rubber lung†........rubber
Granite polishers*	Plastics lung?........plastics
Slate workers*	Farmer's lung*.......fungi
Boiler scalers*	Silo filler's lung*. .....nitrogen dioxide
Kiln liners*	Wheat handler's lung†..............?
Basic slag workers	
Hematite miners*	Miscellaneous
Magnetite miners*	Oleogranuloma ......oil mists
Kolar gold miners	Fume injury*........nitric acid, etc.
Insulation workers*	Gas injury*..........hydrogen fluoride, etc.
Transite pipe workers*	Chemical pneumonitis* ......inorganic, organic

*Disabling and lethal. †Disputed entities.

History.—Man-made lung diseases have been known for the past 2,000 years and were discussed by, among others, Hippocrates and Pliny. "Potters' rot" of ceramic workers, "grinders' rot" of steel implement sharpeners, and "coal miners' asthma" evolved as by-products of the Industrial Revolution. But this group of disorders first assumed major importance when, at the turn of the 20th century, thousands of gold miners in South Africa began to die from "miners' phthisis." Since that time, research and the introduction of rigorous environmental hygiene measures have brought about control over these diseases.

In modern industries, dust hazards have been virtually eliminated by advance engineering planning. Employees in well-controlled plants can anticipate trouble-free working periods of 30 to 40 years in spite of processing highly dangerous substances. Pneumonoconiosis arises in such industries in exceptional cases only. The explanation usually is either extreme individual susceptibility, predisposing disease such as tuberculosis, accidental excessive exposures, hazardous technical innovations or the potentiating effects of exposure to several different substances. The pneumonoconioses have in a few instances affected nonworking persons. Police officers, housewives and school children have contracted berylliosis from the inhalation of smokestack effluvia, dust from soiled working clothes or fluorescent lamp phosphors. The lung injury caused by city smog results from the action of chemical agents adsorbed onto carbon particles emanating in industrial operations. The catastrophic deaths at Donora, Pa. (1946), the Meuse valley in Belgium (1949) and in London (1952) illustrate the disastrous potential of industrial waste products immoderately disseminated into the air of cities.

Causes.—Theories of the causation of pneumonoconiosis include tissue injury by mechanical trauma, protoplasmic poisoning, metabolic changes in cells through a disturbance of pH, protein denaturing through piezoelectric and surface molecular forces, immune and antibody reactions, polymerization and the nonspecific action of submicron particles. No single explanation is universally acceptable. The pathogenic propensity of a number of specific agents has been proved by experimental reproduction of pathognomonic lesions in animals.

Symptoms.—Pneumonoconioses range from innocuous through variably disabling to lethal syndromes. Symptoms are determined by the focus of major lung injury, combinations of lesions, severity and rate of exposure, and infective or other complications. Dominant states include bronchitis, bronchiolitis, bronchiectasis, emphysema, pulmonary fibrosis and pulmonary hypertension. The main complications, which also determine the mode of lethal outcome in most instances, are cor pulmonale with congestive cardiac failure, tuberculosis, pneumonia, pulmonary insufficiency, hemorrhage, lung gangrene and erosion of a blood vessel, a bronchus or the esophagus. Remote lesions may also occur; *e.g.,* portal artery obstruction, metastatic tuberculosis and liver, kidney or suprarenal failure. Respiratory tract cancer is closely associated with exposures to monochromates, asbestos! beryllium, nickel. arsenic and radioactive particles.

Diagnosis and Treatment.—Precise diagnosis depends largely on radiography, but so eclectic and diversified are the manifestations of the pneumonoconioses that interpretation of the X-rays requires great skill and experience. Advanced physiological studies have contributed greatly to understanding of the associated disability. Final diagnosis, however, often must await histopathological and petrographic confirmation.

Once established, the majority of the severe pneumonoconioses are irreversible. Some syndromes may become arrested on cessation of exposure but others, such as silicosis and asbestosis, progress inexorably. Therapy is directed at the alleviation of symptoms such as pain or bronchospasm, support of the failing heart and treatment of complicating infection. Apart from dust suppression, adequate ventilation and the use of exhaust equipment, the only effective prophylactic agent against silicosis is inhaled aluminum administered in the form of aerosols of aluminum oxide, hydroxide or hydroxychloride. Good results have been achieved in cases of berylliosis by means of the chelating agent aurin tricarboxylic acid or by cortisone. No specific therapy is available for other pneumonoconioses. See also DANGEROUS OCCUPATIONS; DUST; INDUSTRIAL MEDICINE. (G. W. H. S.)

PNEUMOTHORAX, the presence of free air in the pleural space (*i.e.,* between the chest walls and lungs), which normally contains no air. Air may be introduced into the pleural space as the result of trauma, by spontaneous rupture of the visceral pleura or by means of a needle inserted through the chest wall.

The chest is divided into two airtight compartments by the mediastinum. A thin membrane called the pleura covers each lung and is reflected at the root of the lung to form the lining of the inner surface of the chest wall. Normally the visceral pleura (covering the lung) is in contact with the parietal pleura (covering the inner surface of the thorax) and the potential space between them is Spoken of as the pleural space. A pneumothorax exists if the two layers of pleura are separated by air and the lung collapses away from the chest wall. Usually, the pleural rent heals spontaneously and re-expansion of the lung follows as the air is absorbed. In some cases, the air must be removed by needle or rubber catheter to aid breathing or speed recovery. In special cases. surgery is necessary.

Traumatic **Pneumothorax.**—Since the lung is an elastic organ and tends to be pulled toward the lung root. the pressure in the pleural space is less than atmospheric, averaging minus five centimetres of water. This means that air under atmospheric pressure will be sucked into the pleural space if the visceral pleura is torn (*e.g.*, by a fractured rib) or if an open wound in the chest wall penetrates the parietal pleura. If a "sucking wound" of the chest wall exists. more air may be pulled into the pleural cavity via the wound than is pulled into the lung via the larynx, with the result that the collapsed lung and mediastinum are pushed toward the healthy side on inspiration and away from it on expiration. This paradoxical motion of the lung and mediastinum causes progressive asphyxia unless the wound is closed.

Spontaneous **Pneumothorax.**—The sudden collapse of the lung without previous trauma. termed spontaneous pneumothorax. is usually accompanied by severe chest pain and difficulty in breathing. Most cases occur in apparently healthy persons. Because spontaneous pneumothorax may occur as a complication of pulmonary tuberculosis. it was assumed for years that almost all cases were due to tuberculosis. This is not true. In 1932 H. Kiaergaard suggested the emphysematous blebs in the pleural surface of the lung were the common cause of spontaneous pneumothorax. and this concept was later confirmed. Superficial blebs on the pleural surface are weakened areas of pleura: they may blow o'ut as a result of suddenly raising the intrapleural pressure by lifting, coughing or laughing. When spontaneous pneumothorax tends to recur it can usually be successfully treated surgically.

Artificial **Pneumothorax.**—In 1882 Carlo Forlanini first reported the successful use of artificial pneumothorax in the treatment of pulmonary tuberculosis and until recently the procedure was used extensively in the treatment of that disease. However. after both the introduction of several highly effective antituberculous drugs in the 1940s and the perfection of thoracic surgery for the resection of the diseased portions of the lung. its therapeutic use was drastically reduced. It has no value in the treatment of other pulmonary diseases.

See M. Pinner, *Pulmonary Tuberculosis in the Adult, p. 395* (1945); E. H. Rubin. *Diseases of the Chest, p.* 564 *(1947).*

(R. H. E,; D. K.-W.)

PO (anc. *Padus*), a river of northern Italy, and the dominating factor in its geography. It is the longest river in Italy (310 mi. direct, 405 mi. including its many windings), and the area of its basin, which includes portions of Switzerland, is estimated at 27.062 sq.mi. For its course and principal tributaries, *see* ITALY.

The lower valley of the Po was at an early period occupied by people of the Palaeolithic and Neolithic stages of civilization, who built houses on piles along the swampy borders of the streams. The river regulation works originated in pre-Roman times. The reclaiming and protecting of the riparian lands went on rapidly under the Romans. and in several places the rectangular divisions of the ground are still remarkably distinct. *(See* ESTE.) During the barbarian invasions much of the protective system decayed but the later middle ages saw the works resumed, so that the present arrangement existed in the main by the close of the 15th century.

The Ligurian name of the Po was Bodincus or Bodencus; *i.e.,* the bottomless. The name Padus was taken from the Celts or the Veneti. Thus Bodincomagus is found as a town name (Industria) on the upper course, and Padua as a name of one of the mouths of the river. The name Eridanus of Greek poetry was identified with it at a comparatively late period.

POBÊDONOSTSEV, KONSTANTIN PETROVICH (1827–1907), Russian jurist and state official. Born in Moscow in 1827, he studied at the School of Law in St. Petersburg, and entered the public service as an official in one of the Moscow departments of the senate.

In the early years of the reign of Alexander II (1855–1881), Pobêdonostsev maintained that occidental institutions were radically bad in themselves and totally inapplicable to Russia. Parliamentary methods of administration, modern judicial organization and procedure, trial by jury, freedom of the press, secular education—these were among the principal objects of his aversion. He therefore persecuted the dissenters, Stundists, Doukhobors and others, and insisted on severe measures of repression in education and in the press.

He exercised considerable influence by inspiring and encouraging the Russification policy of Alexander III (1881–1894). Pobêdonostsev died on March 23, 1907.

POCAHONTAS (1595–1617), daughter of the Indian chief Powhatan is the heroine of one of the best-known traditions connected with the beginnings of American history.

The story is that Capt. John Smith, who was head of a band of soldiers in search of food and exploring the Chickahominy river, was waylaid by Indians and taken prisoner by their chief, Powhatan. Smith had been forced to kneel down while his head was laid on a stone preparatory to having his brains crushed out with heavy clubs, when Pocahontas, a young daughter of the chief, sprang forward, seized Smith's head in her arms, and saved his life. She is supposed to have come again to his aid a year later by revealing a plot made against Smith by her father.

The first story concerning Pocahodtas appears in the *Generall Historie*, first published in 1624, after she had been made much of in England as the attractive daughter of an emperor and the first convert of her tribe to Christianity, and it is to be feared that the temptation to bring her on the stage as heroine in a new character in connection with Smith, ever the hero of his own chronicles, was more than he or the publishers of the *Generall Historie* could withstand.

Many prominent Virginia families trace their ancestry to the son of Pocahontas and her husband, John Rolfe.

POCATELLO, a city of southeastern Idaho, U.S.. the seat of Bannock county, occupies a mountain valley (elevation 4,460 ft.) at the mouth of Portneuf canyon about 15 mi. from the Snake river. Settled in 1882 during railway construction and named for an Indian leader friendly to the whites, Pocatello grew slowly at first because of its location on the Fort Hall Indian reservation. But its strategic position as a major railway junction brought important Union Pacific shops there in 1887; with the opening of the Fort Hall reservation to settlement in 1902, Pocatello grew rapidly and became the most prominent railway centre on the Union Pacific between Omaha and Portland. The Academy of Idaho was established in Pocatello in 1901 and began instruction at college level in 1927; the name mas changed to Idaho State college in 1917. Expansion of nearby irrigation helped the city to become a wholesale distributing centre with a variety of manufacturing and agricultural processing plants. An army air base reverted to a municipal airport after World War II, but the community expanded industrially with the acquisition of a large naval ordnance plant in 1912 and of important phosphate reduction works in 1946. The city has a council-manager form of government, in effect since 1951.

For comparative population figures *see* table in IDAHO: *Population.* (M. D. B.)

POCHARD, a diving duck (*q.v.*), *Nyroca ferina;* the female is sometimes called the dunbird. In the male in full plumage the head is coppery-red, the breast black, and the back and flanks a dull white, closely barred with fine undulating black lines. The tail coverts and quill feathers are black and the lower surface dull white. The female is duller. The pochard breeds throughout the northern hemisphere, migrating to the coast in winter and retiring southward. The American subspecies is larger. A second American species is the much bigger canvasback duck (*q.v.*). Both species are excellent table birds when they frequent fresh water, the canvasback being pre-eminent.

Allied to the pochards are the scaup duck (*N. marila*), the tufted duck and the eiders.

POCKET GOPHER, the name of a group of (chiefly North) American ratlike rodents, characterized by large cheek pouches, the openings of which are external to the mouth, while their inner surface is lined with fur. The second, and third front claws are greatly enlarged, and the fingers are furnished along their sides with bristles. The eyes are small, and the external ears rudimentary. Pocket gophers, which typify a family, the Geomyidae, spend practically all their time underground, their powerful claws being adapted for digging, while the bristles on the toes prevent the earth from passing between them. The upper incisor teeth are employed to loosen the ground, like a fork; and the little rodents are able to move both backward and forward in their runs. The cheek pouches are employed in carrying food, which consists of roots. The common pocket gopher, Geomys bursarius, of the Mississippi valley is about 8 in. long, plus a tail of 3 to 4 in.; colour, rufous brown and grayish beneath. Another is the northwestern plains pocket gopher *Thomomys* talpoides, which is considerably smaller. See RODENTIA.

POCKET MOUSE, the name of a number of small, mouse-like, western North American rodents belonging to the subfamily Perognathinae of the family Heteromyidae and including several genera, all with fur-lined external cheek pouches. The typical pocket mice (*Perognathus*) are small, with rather long tails and hind feet. They live in deserts and on the Great Plains, feeding on seeds. The kangaroo rat (*q.v.;* Dipodomys), subfamily Dipodomyinae, is closely related to the pocket mouse but has a very broad head. Heteromys and *Liomys,* the spiny pocket mice (subfamily Heteromyinae), have bristles mixed in the coat. They are dark gray or blackish in colour. Most species of these two genera are Central American, extending to northern South America. See also POCKET GOPHER; RODENTIA. (J. E. HL.; X.)

POCOCKE, EDWARD (1604–1691), English orientalist and Biblical scholar, the son of a Berkshire clergyman, was born at Oxford and baptized Nov. 8, 1604. He was educated at Corpus Christi college, Oxford. He served as English chaplain at Aleppo (1630–35) and on his return to England was appointed first professor of Arabic at Oxford, succeeding to the chair of Hebrew in 1648. Pococke discovered in a manuscript at the Bodleian library at Oxford the missing Syriac versions of the four New Testament epistles (II Peter, II and III John and Jude) which were not in the old Syriac canon; his edition of these was published at Leyden in 1630. In 1649 he published Specimen *historiae arabum,* a short account of the origin and manners of the Arabs, followed in 1655 by Porta *Mosis,* extracts from the Arabic commentary of Maimonides on the Mishnah, with translation and notes. His *magnum* opus—a complete edition of the Arabic history of Bar-Hebraeus, with a Latin translation, was dedicated to the king in 1663. Pococke died on Sept. 10, 1691.

See L. Twells (ed.), *Theological Works of* ***the Learned*** Dr. *Pocock,* 2 vol. (1740), which contains a biography.

PODEBRAD, GEORGE OF (1420–1471), king of Bohemia, was the son of Victoria of Kunstat and Poděbrad, a Bohemian nobleman, who was one of the leaders of the "Orphans" or modem Taborites during the Hussite wars. George became prominent early as leader of the National, or Calixtine party in Bohemia, becoming its chief at the death of Ptacek of Pirkstein. In 1448, during the minority of Ladislas Posthumus, having raised a force of 9,000 men in northeast Bohemia, where the National cause was strongest and where his own ancestral castle was situated, he marched on Prague and took it, afterward defeating the Romanist or Austrian party led by Ulrich von Rosenberg. In 1451 the emperor Frederick III, Ladislas' guardian, entrusted Poděbrad with the administration of Bohemia. In the same year a diet assembled at Prague also conferred on Poděbrad the regency. The struggle of the Bohemians against Rome continued uninterruptedly, and Poděbrad's position became very difficult when Ladislas, who was crowned in 1453, expressed his sympathies for the Roman Church, though recognizing the compacts and ancient privileges of Bohemia. In 1457 King Ladislas died suddenly. Public opinion from an early period accused Poděbrad of having poisoned him; but the suggestion is undoubtedly a calumny. On Feb. 27, 1458, the estates of Bohemia unanimously chose Poděbrad as king, even the adherents of the Austrian party voting for him. A year later, Pius II became pope, and his hostility proved a serious obstacle to Poděbrad's rule.

Though refusing to let the compacts be abolished, as Pius demanded, PodEbrad placated him by punishing the most advanced enemies of the papacy, including the newly-founded community of the Bohemian brethren; but his endeavours to establish peace with Rome proved ineffectual, although the death of Pius II prevented him from carrying out his planned crusade against Bohemia. Despite the prosperity enjoyed by Bohemia under Poděbrad's rule, the malcontent nobles of the Romanist party, meeting on Nov. 28, 1465, at Zelena Hora, formed a confederacy against him which was supported by the Roman see. On Dec. 23, 1466, Paul II, the successor of Pius II, excommunicated PodEbrad and pronounced his deposition as king of Bohemia, forbidding all Romanists to continue in his allegiance. The emperor Frederick III, and King Matthias of Hungary, Poděbrad's former ally, joined the insurgents. Matthias conquered a large part of Moravia and was crow-ned king of Bohemia at Brünn on May 3, 1469. On March 22, 1471, Poděbrad's death ended the war. He was the only native king of Bohemia, and the only one not a Catholic.

PODGORICA (TITOGRAD), the commercial capital of Montenegro, Yugos. Pop. (1953) 16,324. The town lies in a fertile plain on the Moracha, there spanned by a Turkish bridge. A tributary separates the Turkish town lying within the ruined ramparts, and inhabited by Albanians, from the Montenegrin quarter built in 1878.

PODIATRY (CHIROPODY) is the healing art concerned with the human foot. The Ebers medical papyrus (c. 1500 B.C.) records foot remedies from earlier centuries. Other references are found in the literature of all succeeding cultures. The word chiropody derives from a 1774 treatise, Chiropodologia, by D. Low, of London, where a Dr. Lyons in 1785 applied for a licence limited to practice on the feet. The term podiatry was coined in 1917 by M. J. Lewi of New York.

The first practice act was enacted in New York state in 1895, and by 1938 all the states of the United States, Canada, the United Kingdom, Australia and New Zealand had licensure provisions. In the United States the National Association of Chiropodists was organized in 1912 and adopted the name American Podiatry association in 1958. In Great Britain chiropodists function under the national health service. The first college of podiatry was organized in 1912.

Podiatrists diagnose and treat by medical, surgical and other means diseases and deformities of the human foot; they utilize mechanical devices, special shoes, physiotherapy, pharmaceuticals and surgery. (A. Ru.)

PODIUM, in architecture, a continuous pedestal, a low mall supporting columns, or the lowest portion of the wall of a building when given a separate architectural treatment. Sometimes the basement story of a classic building may be treated as a podium. The podium is usually designed with a molded base and plinth at the bottom, a central plane surface known as a die, or dado, and a projecting cornice or cap. The majority of Etruscan and Roman temples were raised on podiums, and the entrance steps ascended between wing walls, which were the continuations of the podium at the sides. By extension the term has been applied to other raised platforms, particularly those used by orchestra conductors.

PODOCARPACEAE. A family of conifers consisting of large trees and shrubs, found predominantly in the southern hemisphere. Many are important as timber trees and as a source of tanbark. The seven genera commonly admitted are Pherosphaera, *Microcachrys,* Saxegothaea, *Dacrydium, Acmopyle,* Podocarpus and *Phyllocladus.* All occur in the Australasian region except *Saxegothaea,* which is South American; *Podocarpus* and *Dacrydium* also extend their range to that continent. The Podocarpaceae are usually dioecious (having separate male and female plants) and have leaves variously awl-shaped, needlelike or broad, with many parallel veins. In the genus *Phyllocladus,* the foliar leaves are replaced by flattened branchlets (phylloclads) resembling leaves. The staminate, or pollen-bearing, cones are borne in a terminal or axillary position on leafy twigs, each scale bearing two pollen sacs. The ovulate, or seed-bearing, cones may have numerous scales but usually are reduced t~ one or a few scales with a single ovule and several sterile scales below. At maturity the latter become fleshy and sometimes brightly coloured and surmount the fleshy cone axis. Both cleavage and simple polyembryony occur. There are two cotyledons (seed leaves) in the mature embryo.

See also CONIFERS. (R. W. H.)

PODOLSK, a town of the Russian Soviet Federated Socialist Republic, U.S.S.R., 55° 27' N., 37° 28' E., 26 mi. S. of Moscow, on the railway and on the Pakhra river, crossed by a suspension and a railway bridge. Pop. (1956 est.) 113,000. It manufactures cement, lime, silicates and silk goods and has a railway repair shop. Until 1781 it was a dependency of the Danilov monastery of Moscow. Near it is an unkept park on the banks of the Pakhra, on the former estate of Count Tolstoi.

PODOPHYLLIN, a drug obtained from the rhizome of the American mandrake or May apple (*q.v.*). As met with in commerce, the rhizome occurs in cylindrical pieces two or three inches long and about a quarter of an inch in diameter, of a chocolate or purplish-brown colour, smooth, and slightly enlarged where the juncture of the leafy stem is indicated by a circular scar on the upper and a few broken rootlets on the under side. The odour is heavy and disagreeable, and the taste acrid and bitter.

Podophyllin was known to the American Indians, who realized its cathartic and caustic properties. It is no longer included in the *U.S. Pharmacopoeia*. The *British Pharmacopoeia* recognizes preparations from an Indian species, *P. emodi*. Podophyllin is used chiefly for its cathartic properties in patent medicines, often combined with aloes or calomel. It should be used cautiously, since its intense action may lead to inflammation of the bowel and death. It finds some use applied locally to certain types of warts.

The drug is a resinous powder obtained by precipitating an alcoholic tincture of the rhizome by means of water acidulated with hydrochloric acid. The powder is soluble in alcohol and strong solutions of alkalis. There are at least two resins in the powder (which is known officially as *Podophylli resina*), one being soluble and the other insoluble in ether. Each contains an active substance, which can be obtained in crystalline form and is known as podophyllotoxin. It is soluble in alcohol, ether, chloroform and boiling water. The properties of podophyllin resin vary with the reaction of the tissue with which it is in contact; where this is acid the drug is inert, picropodophyllin being precipitated.

PODOSTEMONACEAE, a remarkable family of dicotyledonous plants, living only on rocks in rushing streams. The seeds are shed on the rocks during the dry season, germinating when the rocks become submerged in the rainy season. The vegetative parts consist mainly of a flattened green thallus, usually derived from adventitious roots. There are 40 genera and about 175 species, nearly all tropical, a single representative, *Podostemon ceratophyllum* (river weed), occurring in North America, found in shallow streams from Maine to Minnesota and southward to Georgia and Alabama.

For a treatment of the genera, *see* A. Engler, "Podostemonaceae" in A. Engler and K. Prantl, *Natürlichen Pflanzenfamilien,* 2nd ed., 18a: 3–68, fig. 1–61 (1930).

POE, EDGAR ALLAN (1809–1849), U.S. poet, critic and short-story writer, who cultivated the literature of mystery and the macabre, was born Jan. 19, 1809, in Boston, Mass. He was the son of the English-born actress Elizabeth Arnold Poe and David Poe, Jr., an actor from Baltimore. After both parents died in Richmond, Va., in 1811, the boy was taken into the home of his godfather, the wealthy Richmond merchant John Allan, and his childless wife. He was taken to Scotland and England (1815–20), where he was given a classical education that was continued in Richmond. For a few months in 1826 he attended the University of Virginia, where he studied Greek, Latin, French, Spanish and Italian; but his gambling losses at the university incensed his guardian, Allan, who refused to let him continue, and Poe returned to Richmond to find his sweetheart, Elmira Royster, married. Poe went to Boston where he published a pamphlet of youthful Byronic poems, *Tamerlane* (1827), many of which concern Elmira. Poverty forced him to join the army under the name of Edgar A. Perry. The death of his foster mother caused Allan to purchase his release from the army, and to help in getting him an appointment to West Point. Before going, Poe published a new volume at Baltimore, *Al Aaraaf* (1829), showing the influence of the local poet E. C. Pinkney and an awakened interest in Milton and Thomas Moore. He successfully sought expulsion from the academy, where he was absent from all drills and classes for a week. He proceeded to New York and brought out a volume of *Poems* (1831), containing several masterpieces, some showing the influence of Keats, Shelley and Coleridge. He then returned to Baltimore, where he began to write stories. The rumour that he was again in the army under another name in 1832 seems credible. In 1833 his tale "A MS Found in a Bottle" won $50 from a Baltimore weekly, and by 1835 he was in Richmond as editor of the *Southern Literary Messenger*. There he made a name as a critical reviewer and married his young cousin Virginia Clemm, who was less than 14. Poe seems to have been an affectionate husband and son-in-law and wrote the tribute "Sonnet to My Mother" to his aunt, Mrs. Clemm.

Poe was dismissed from his job in Richmond, apparently for drinking, and went to New York. His drinking was the bane of his life. To talk well in a large company he needed a slight stimulant, but a glass of sherry might start him on a spree; and although he rarely succumbed, he was often seen in public when he did. Poe probably did not use drugs but did experience occasional psychotic episodes.

While in New York he published a long prose narrative, *The Narrative of Arthur Gordon Pym* (1838), combining (as so often in his tales) much factual material with the wildest fancies. It is considered one inspiration of Melville's *Moby Dick*. In 1839 he began editing *Burton's Magazine* in Philadelphia. There a contract for a monthly feature stimulated him to write "William Wilson" and "The Fall of the House of Usher"—stories of supernatural horror. The latter contains a study of a neurotic now known to have been an acquaintance of Poe, not Poe himself.

Later in 1839 his *Tales of the Grotesque and Arabesque* appeared (dated 1840). He resigned from *Burton's* about June 1840 but returned in 1841 to edit its successor, *Graham's Magazine,* in which he printed the first detective story, *"The Murders in the Rue Morgue."* In 1843 his "Gold Bug" won a prize of $100 from the *Philadelphia Dollar Newspaper,* which gave him great publicity. In 1844 he came to New York, wrote the "Balloon Hoax" for the *Sun* and became subeditor of the *Evening Mirror* under N. P. Willis, thereafter another lifelong friend. In the *Evening Mirror* of Jan. 29, 1845, appeared, from advance sheets of the *American Review,* his most famous poem, "The Raven," which gave him national fame at once. Poe then became editor of the *Broadway Journal,* a short-lived weekly in which he republished most of his short stories, in 1845. During this year the poet Frances Sargent Osgood pursued Poe. Virginia did not object, but "Fanny's" indiscreet writings about her literary love caused great scandal.

His *The Raven and Other Poems* and a selection of his *Tales* came out in 1845, and in 1846 Poe moved to a cottage at Fordham (now part of New York), where he wrote for *Godey's Lady's Book* (May–Oct. 1846) on the "Literati of New York"—gossipy sketches on personalities of the day that led to a libel suit.

His wife Virginia, who had burst a blood vessel several years before, died in Jan. 1847. In 1848 Poe went to Providence, R.I., to woo the poet Helen Whitman. There was a brief engagement. Poe had intimate but platonic entanglements with Annie Richmond and with Sarah Anna Lewis, who helped him financially. He composed poetic tributes to all of them.

In 1848 also he published the lecture *Eureka,* a transcendental "explanation" of the universe, which has been hailed as a masterpiece by some critics and as nonsense by others. In 1849 he went south, had a wild spree in Philadelphia but got safely to Richmond, where he again became engaged to Elmira Royster, by then the widowed Mrs. Shelton, and spent a happy summer with only one or two relapses. He enjoyed the companionship of childhood friends and an unromantic friendship with a young poet, Susan Archer Talley.

Poe had some forebodings of death when he left Richmond for Baltimore late in September. There he toasted a lady at her birthday party and began to drink heavily. The indulgence proved fatal, for Poe had a weak heart. He died on Oct. 7, 1849, and was buried in Westminster churchyard in Baltimore.

Poe's work owes much to the drift of romanticism, of which he was a late heir, toward the occult and satanic. It owes much also to his own feverish dreams, to which he applied a rare faculty of shaping plausible fabrics out of impalpable materials. With an air of objectivity and spontaneity, his productions are closely dependent on his own idiosyncrasy and an elaborate technique. His keen and sound judgment as appraiser of contemporary literature, his idealism and musical gift as a poet, his weirdness and dramatic power as a storyteller, considerably appreciated in his lifetime, secured him a prominent place among universally known men of letters.

The outstanding fact in Poe's character is a strange duality. The wide divergence of contemporary judgments on the man seems to point to the coexistence in him of two persons. With those he loved he was gentle and devoted. Others. who were the butt of his sharp criticism. found him irritable and self-centred and went so far as to accuse him of lack of principle. Was it, in the latter case, a double of the man rising from harrowing nightmares, or from the haggard inner vision of dark crimes, or from appalling graveyard fantasies that loomed in Poe's unstable being?

Much of Poe's best work is concerned with terror and sadness, but in ordinary circumstances the poet was a pleasant companion. He talked brilliantly, chiefly of literature, and read his own poetry and that of others in a voice of surpassing beauty. He admired Shakespeare and Alexander Pope. He had a sense of humour, apologizing to a visitor for not keeping a pet raven.

If the mind of Poe is considered, the duality is still more striking. On one side he was an idealist and a visionary. His yearning for the ideal was both of the heart and of the imagination. His sensitiveness to the beauty and sweetness of women inspired his most touching lyrics ("To Helen," "The Sleeper," "Eulalie," "To One in Paradise") and the full-toned prose hymns to beauty and love in "Ligeia" and "Eleonora." In "Israfel" his imagination carried him away from the material world into a dreamland. This Pythian mood was especially characteristic of the later years of his life.

More generally, in such verses as "Valley of Unrest," "Lenore," "The Raven," "For Annie" and "Ulalume" and in his prose tales, his familiar mode of evasion from the universe of common experience was through eerie thoughts, impulses or fears. From these materials he drew the startling effects of his tales of death ("House of Usher," "Red Death," "Valdemar," "Premature Burial," "Oval Portrait." "Shadow"), his tales of uickedness and crime ("Berenice," "Black Cat," "William Wilson," "Imp of the Perverse," "Cask of Amontillado," "Tell-Tale Heart"), his tales of survival after dissolution ("Ligeia," "Morella," "Metzengerstein") and his tales of fatality ("Assignation," "Man of the Crowd"). Even when he does not hurl his characters into the clutch of mysterious forces or onto the untrodden paths of the beyond, he uses the anguish of imminent death as the means of causing the nerves to quiver ("Pit and the Pendulum"), and his grotesque inventions deal with corpses and decay in an uncanny play uith the aftermath of death.

On the other side. Poe is conspicuous for a close observation of minute details, as in the long narratives and in many of the descriptions that introduce the tales or constitute their settings. Closely connected with this is his power of ratiocination. He prided himself on his logic and carefully handled this real accomplishment so as to impress the public with his possessing still more of it than he had; hence the would-be feats of thought reading, problem unraveling and cryptography which he attributed to his Legrand and Dupin. This suggested to him the analytical tales, which introduced into literature the detective story, and his tales of pseudo science.

The same duality is evinced in his art. He was capable of writing angelic or weird poetry. with a supreme sense of rhythm and word appeal, or prose of sumptuaus beauty and suggestiveness, with the apparent abandon of compelling inspiration; yet he would write down a problem of morbid psychology or the outlines of an unrelenting plot in a hard and dry style. In Poe's masterpieces the double contents of his temper, of his mind and of his art are fused into a oneness of tone, structure and movement, the more effective. perhaps. as it is compounded of various elements that give depth and intensity to the total sheen or dismal glow.

Poe's genius was recognized abroad. No one did more to persuade the world and, in the long run, America, of Poe's greatness than Baudelaire and Mallarmé.

The first collected edition of Poe's works is that of R. W. Griswold, 4 vol. (1850–56). That of J. A. Harrison, 17 vol. (1903), includes biography and correspondence; the Ostrom edition of the *Letters* (1948) includes only Poe's side of the correspondence. The standard edition of the *Poems* is by Killis Campbell (1917).

BIBLIOGRAPHY.—Poe's early biographer, R. W. Griswold (1850), blackened his character. Hervey Allen, *Israfel: the Life and Times of E. A. Poe,* 2 vol. (1926), is partly fictional; J. H. Ingram, *Edgar Allen Poe,* 2 vol. (1880), and A. H. Quinn, *Edgar Allan Poe, a Critical Biography* (1941), were written for the defense. G. E. Woodberry, *The Life of E. A. Poe, Personal and Literary,* 2 vol. (1909), is the most perceptive of the biographies. S. A. Weiss, *The Home Life of Poe* (1907), presents a picture from a friend; Mary E. Phillips, *Edgar Allan Poe, the Man,* 2 vol. (1926), uncritically collects much information. *See* also N. B. Fagin, *The Histrionic Mr. Poe* (1949); Arthur Ransome, *Edgar Allan Poe* (1910).

(C. C.; T. O. M.)

POELZIG, HANS (1869–1936), German architect, was born in Berlin on April 30, 1869. He studied architecture at the Berlin Technische Hochschule and was subsequently director of the Breslau Academy of Arts (1903–16). He mas city architect of Dresden from 1916 to 1920 and also an honorary professor at the Technische Hochschule there. In 1920 he started an advanced atelier for applied arts at the Berlin Academy of Arts. From 1924 to 1935 he was also professor of the architectural faculty of the Berlin Technische Hochschule. With the architect Peter Behrens (1868–1938), Poelzig was a pioneer of the German industrial-art movement: he was president of the Deutscher Werkbund. an association of progressive architects, designers and industrialists, founded in 1907. Poelzig, like Behrens, was much concerned with freeing buildings from all superficial mannerisms: thus his sulfur factory (1912) at Lauban (Luban), Pol., was a group of purely functional block shapes, and the façade of the Berlin radio building (Funkhaus) of the late 1920s was virtually a great expanse of smooth wall pierced by well-balanced ranges of simple windows. However, he was also responsible for the remarkably decorated Grosses Schauspielhaus. Berlin, which he converted for Max Reinhardt from the old Schumann circus building. Poelzig died on June 14. 1936.

POERIO, ALESSANDRO (1802–1848), Italian poet and patriot, was descended from an old Calabrian family, his father, Baron Giuseppe Poerio. being a distinguished Neapolitan lawyer. In 1815 he and his brother Carlo accompanied their father, who had been identified with Murat's cause, into exile, and settled at Florence. In 1818 they were allowed to return to Naples. Alessandro fought as a volunteer, under Guglielmo Pepe (*q.v.*), against the Austrians in 1821, but when the latter reoccupied Naples and the king abolished the constitution, the family was again exiled and settled at Gratz. Alessandro studied in Germany, and at Weimar he became the friend of Goethe. In 1835 the Poerios returned to Naples. In 1848 Alessandro accompanied Pepe as a volunteer to fight the Austrians in northern Italy, and on the recall of the Neapolitan contingent he followed Pepe to Venice. He mas severely wounded in the fighting round Mestre, and died on Nov. 3, 1848. His poetry "reveals the idealism of a tender and delicate mind"; but he could also sound the clarion note of patriotism, as in his stirring poem *Il Risorgimento.*

His brother CARLO (1803–67), after returning to Naples, practised as an advocate, and from 1837 to 1848 was frequently arrested and imprisoned. Under the short lived constitution of 1848 he was minister of education. He resigned office in April and took his seat in parliament, where he led the constitutional opposition. After the Austrian victory Poerio was arrested (July 19, 1849) tried, and condemned to 19 years in irons. Chained in pairs, he and other political prisoners were confined in one small room in the bagno of Nisida, near the lazaretto. The exposure (1851) of the horrors of the Neapolitan dungeons by Gladstone, who emphasized especially the case of Poerio, awakened the indignation of Europe. but he was not released till 1858. He and other exiles were then placed on board a ship bound for the United States, but the son of Settembrini, another of the exiles, who was on board in disguise, compelled the crew to land them at Cork, whence Poerio made his way to London. In the following year he returned to Italy, and in 1860 he was elected deputy to the parliament of Turin, of which he was chosen vice-president in 1861. He died at Florence on April 28, 1867.

See Baldachini, *Della Vita e de' tempi di Carlo Poerio* (1867); W. E. Gladstone, *Two Letters to the Earl of Aberdeen* (1851); *Carlo Poerio and the Neapolitan Police* (1858); Vannucci, *I Martiri della libertà italiana*, vol. iii. (Milan, 1880); Imbriani, *Alessandro Poerio a Venezia* (Naples, 1884); Del Giudice, *I Fratelli Poerio* (Turin, 1899); Countess Martinengo Cesaresco, *Italian Characters* (1901).

POET LAUREATE. The laurel (Lat. *laurea*) was sacred to Apollo, and as such was used to form a crown or wreath of honour for poets and heroes. The word "laureate" or "laureated" thus came in English to signify eminent, or associated with glory, literary or military. "Laureate letters" in old times meant the despatches announcing a victory; and the epithet was given, even officially (*e.g.*, to John Skelton) by universities, to distinguished poets. The term "poet laureate" was ultimately restricted to the office of the poet attached to the royal household, first held by Ben Jonson, for whom the position was, in its essentials, created by James I. in 1617. (Jonson's appointment does not seem to have been formally made as poet-laureate, but his position was equivalent to that). The office was really a development of the practice of earlier times, when minstrels and versifiers were part of the retinue of the king; it is recorded that Richard Coeur de Lion had a *versificator regis* (Gulielmus Peregrinus), and Henry III. had a versificator (Master Henry); in the 15th century John Kay, also a "versifier," described himself as Edward IV.'s "humble poet laureate." Moreover, the Crown had shown its patronage in various ways; Chaucer had been given a pension and a perquisite of wine by Edward III., and Spenser a pension by Queen Elizabeth. Sir William Davenant succeeded Jonson in 1638, and the title of poet laureate was conferred by letters patent on Dryden in 1670, two years after Davenant's death, coupled with a pension of £300 and a butt of Canary wine. This was the beginning of the official laureateship. The successors of Dryden were T. Shadwell (who originated annual birthday and new year odes), Nahum Tate, Nicholas Rowe, Laurence Eusden, Colley Cibber, William Whitehead, Thomas Warton, H. J. Pye, Southey, Wordsworth, Tennyson, Alfred Austin, Robert Bridges (appointed 1913) and John Masefield (appointed 1930).

The poet laureate, being a court official, was considered responsible for producing formal and appropriate verses on birthdays and state occasions. Wordsworth stipulated before accepting the honour, that no formal effusions from him should be considered a necessity; but Tennyson was generally happy in his numerous poems of this class. The emoluments of the post have varied. To Pye an allowance of £27 was made instead of the Canary wine. Tennyson drew £72 a year, and £27 in lieu of the "butt of sack."

See Walter Hamilton, *Poets Laureate of England* (1879), and E. K. Broadus, *The Laureateship* (1921).

POETRY. The term poetry is generally applied to imaginative literature involving language especially heightened by verse, imagery (*qq.v.*), figures of speech or similar devices to affect the imagination and emotions. Perhaps no other term has been so frequently defined in the history of literary criticism; but its various definitions have been less significant as statements of the nature of poetry than as clues to the tastes and interests of the critic or philosopher who produced the definition. Indeed, the term poetry and its synonyms have referred, in various ages and cultures, to works which have nothing in common beyond the use of language as a medium. For example, in certain uses, the term has been applied to any composition in verse, while in others it has been applied to compositions of a certain character, regardless of the presence or absence of verse. It is far less profitable to attempt one more definition than to consider the history of the compositions which have been called poetry, and so offer some notion of the meanings of the term.

Any art has its origin in the nature of man; *i.e.*, in elementary instinctive activities. In its first form it is apparently an activity simply enjoyable in itself, and practised by anyone. Thus children at play practise any art for which they have the means—music, sculpture, painting, dancing and so on—and the fact that children do so in play indicates that these activities are naturally pleasant. In a second stage, art develops in connection with some practical activity which it facilitates or renders more effective; thus work songs grow out of various labours, and hymns and dirges grow out of the charms and prayers of religious or magical ceremonials. In this stage the practitioner of art is naturally the practitioner of the occupation to which art is subordinate. In a third stage, however, art develops in itself, beginning with the development of special skills in its practitioners and resulting in the creation of works which, independently of any practical end, are valuable in themselves. This is not to say that works of art produced in the earlier stages are without artistic value, but that their possession of such value is incidental to some other end.

An art form does not arise immediately, even so. Its materials must first be provided; from some incidental combination of these there must result some effect which is recognized as valuable in its own right, and the materials must be reworked and reorganized specifically to produce that effect. This is the fashion in which drama, for instance, in antiquity and in the middle ages, grew out of liturgical practices. Once established, a given art tends either to move toward its own perfection or to generate other arts, or to perfect these, as in its own development it brings about the conditions requisite for their existence or perfection.

The history of an art is not merely a matter, however, of the genesis, perfection and dissolution of forms; it is also a history of the changing associations of certain materials, techniques and devices with certain forms, and—since art is created by men and addressed to men—of the changing human contexts in which art is pursued. The following account will deal in these terms with the development of European poetry generally from antiquity to the Renaissance, and with the subsequent development of poetry in English.

For accounts of European poetry not in English after the Renaissance *see* FRENCH LITERATURE; PROVENÇAL LITERATURE; SPANISH LITERATURE; ITALIAN LITERATURE; and GERMAN LITERATURE. 7. Romantic and Victorian Poets
8. American Poetry

V. English and American Poetry of the 20th Century

I. GREEK POETRY

1. Epic.—While Greek poetry begins with the two great epics of Homer. the *Iliad* and the *Odyssey,* there. is no doubt that the poetic arts of the Greeks had already progressed greatly by Homer's time. *(See* EPIC POETRY; GREEK LITERATURE; HOMER.) The Homeric epics themselves tell us a good deal about the earlier poetry. Thus we know that such forms as the marriage hymn. the funeral dirge, the hymn to a god, the victory song, the song in praise of a hero and other kinds of lyric already existed, and that narrative poetry also existed, in the form of the heroic lay, out of mhich the epic itself probably grew. We know, too, that these forms, originally religious and ritualistic, had evolved in certain instances into purely secular forms; that the poetic arts existed in combination with the arts of music and dancing and mere practised by experts—minstrels distinguished for their inspiration and skill—who were at once poets and musicians, accompanying their own songs and stories on the lyre. and perhaps leading the dance as well. There had developed. too, many of the metres which were to be adapted to epic. dramatic and lyric uses *(see* DRAMA: *Greek Drama: Origins;* LYRICAL POETRY) ; and there existed also certain devices which were to lay the foundation for arts as yet unknown. Notable among these was the division between a speaker and a responding group *(Iliad,* xxiv, 718 ff.) mhich led to the division of choragus (chorus leader) and chorus and so gave rise to dialogue, first in the dithyramb and later in drama *(see* DITHYRAMBIC POETRY). Moreover, the direct impersonation of different characters, without which drama is impossible, is everywhere present in the Homeric epics, and had probably originated in the heroic lay. The heroic lay itself seems to have grown out of the narrative portion of the earlier hymns.

The names of a number of poets have come down to us from the half-legendary time before Homer. Orpheus, Musaeus, Eumolpus and Thamyras were all given the title "Thracian." which means that they mere associated with the worship of the Muses, goddesses of poetry. Olen. Chrysothemis and Philammon are said to have made the first hymns to Apollo; Olympus and Hyagnis, the first hymns to Cybele. This earliest sacred poetry must have been composed soon after the migration of the Greeks from Asia. Panegyric or encomiastic poetry seems to have originated as a secular form of the hymn. In general the Greeks show an early tendency to divest poetry of its liturgical character and make it a popular rather than a ritualistic art.

However great the development of poetry before Homer, there is no doubt of his pre-eminence in the art. Aristotle calls him the poet of poets in the serious style, and credits him with many innovations or improvements—for example, with the construction of a single unified action, uhereas other poets had simply related all that befell their heroes, without regard to the connection of events; with the reduction of the poet's speeches in his own person to a minimum, and with the dramatic impersonation, instead, of character after character. "each with his distinctive characteristics"; with the ingenious concealment of improbabilities in his plots, where these could not be avoided; with the use of the "graphic," or especially vivid, metaphor; and even with the foundation of comedy, though this last rests upon the doubtful attribution to Homer of the *Margites*.

The Homeric epics are long narrative poems, in dactylic hexameter verse, the plots of which are serious single actions comprising many episodes. In their grandeur of conception and skill of execution they set a standard which the Greek epic poets who followed could not equal. Between the 8th and the 6th centuries B.C. epic poets of the Ionian school disregarded the principle of unity of action and sought instead to complete the account of the adventures of their heroes. According to the grammarian Proclus (flourished A.D. 140), Stasinus dealt, in *The Cyprian Lays,* with the events leading up to those of the *Iliad;* Arctinus of Miletus, in the *Lay of Aethiopia,* continued the *Iliad* to the death of Achilles, and composed a further continuation in *Tke Sack of Troy;* Lesches of Mytilene, in *The Little Iliad,* composed a similar sequel; Agias of Troezen, in *The Homeward Voyages,* filled in the gap between the *Iliad* and the *Odyssey;* and Eugammon of Cyrene, in *The Lay of Telegonus,* recounted the adventures of the son of Odysseus and Circe. These are poets of the Trojan cycle; others dealt with the Theban War, and still others with the exploits of Hercules. Important as the work of these cyclic poets may have been for Greek drama and art, their work represents a decline from the near perfection of the Homeric epic.

It is probable that until Aristotle there existed no very clear-cut conception of epic as a special art form. Even Plato offers only a crude formulation of the Homeric epic; in common practice, any poet who employed hexameter verses was called an epic poet, and if the name meant anything further, it implied that the verses were recited rather than sung, and that the composition as a whole followed certain conventions. Thus the name of "epic poet" was given to Hesiod, who lived in the 10th or 9th century B.C., and whose *Works and Days* and *Theogony* are not narratives of heroic actions, as were Homer's. but didactic pieces. Hesiod deals, not with noble fictions, but with the truths of daily life, with rules for farming and husbandry, with precepts for moral behaviour and religious beliefs. His poems founded a school of bucolic poetry which the Roman poet Virgil and others were later to bring to exquisite art, but Hesiod is simply concerned with instruction.

2. Elegiac and Iambic.—About 690 B.C. elegiac and iambic verses emerge (*see* ELEGY; IAMBIC). Elegiac verse grew out of the hexameter; the elegiac couplet is simply a specific form of hexameter couplet, though it is often inaccurately described as a hexameter followed by a pentameter. The elegy is a kind of lyric, personal in character, but reflective rather than passionate; originally it was sung to the flute. Callinus and Tyrtaeus, who flourished early in the 7th century are among the early elegists. Archilochus, slightly later, also wrote elegies but is chiefly famous for his iambic verses, and is regarded as the father of satire (*q.v.*). Simonides of Amorgos (flourished about 655 B.C.) wrote iambic satire, including a famous one on women. Other elegists of the 7th and 6th centuries include Minermus of Smyrna, Solon the lawmaker, Theognis of Megara and Phocylides of Miletus. Indeed, the elegy was to retain its popularity for a long time.

3. Lyric.—Greek lyric, or more properly melic (Greek *melikos* from *melos,* "song"), poetry was inseparable from music. Hence traditionally it is said to owe its origin to Terpander's enlargement of the lyre from four strings to seven, so that the instrument encompassed all of the seven modes of Greek music. Alcman and Stesichorus of Himera in the 7th century and Ibycus in the 6th wrote choral lyrics; Alcaeus and his contemporary Sappho, late in the 7th century, were the most famous lyrists of the Lesbian school. Anacreon of Teos in the 6th century, according to tradition, composed many graceful and gay songs which have found imitators through the ages. Arion late in the 7th century brought the dithyramb, a choral hymn to Dionysus, to its most finished form. Simonides of Ceos in the 6th and 5th centuries composed odes, hymns, dirges and other kinds of lyric, and his nephew Bacchylides composed choral lyrics. The literary remains of Pindar include almost every kind of lyric—hymns, choral dithyrambs, processionals, paeans. hyporchemes or choral dance songs, encomia or eulogies, scolia or drinking songs, choral songs for maidens, and dirges. These we possess as fragments, but we have 44 complete epinicia or victory odes celebrating the victors of the Olympian, Pythian, Nemean and Isthmian games.

4. Dramatic.—Greek drama began with the Dionysian festi-

vals. Tragedy takes its name from the "goat song," a hymn sung at these festivals. The dithyramb developed from this hymn; and in the performance of the dithyramb. the impersonation of the god by the choragus led to dialogue betneen nhat were by then distinct dramatic entities. Thespis in the 6th century is said to have detached another member from the chorus to serve as "answerer" (*hypokrites*), introducing an innovation which increased the importance of dialogue; Phrynichus divided the chorus into separate bands, making them in effect different dramatic groups. Even so, these are but the rude beginnings of drama, for such devices permitted the enactment of only a few incidents. It was only with the introduction of a second actor by Aeschylus that dialogue became really independent of the chorus; moreover, the number of actors was now sufficient to permit. by their exits and entrances. the dramatic representation of an extensive succession of episodes. Dialogue now became more important than the choral song to which it had hitherto been subordinate, and itself became subordinate to character, which in turn became subordinate to action or plot.

Thus with Aeschylus the new form of tragedy comes into being, its birth signalized by a revolution in the ordering of parts developed out of earlier forms. The tragic action is a serious one which involves characters of more than ordinary moral stature; consequently the language of tragedy grew dignified in both style and rhythm. Later poets made other improvements. Sophocles introduced both a third actor and painted scenery, thereby permitting greater extension of the action and greater spectacular effect; and Euripides made women important characters in his tragedies, thus extending the subject matter of the art.

Comedy. like tragedy, had its origin in the Dionysian festivals, but grew out of the rustic revelry of the satyrs attending the god, developing from banter, invective and practical jokes into its proper form (see DRAMA: Greek Drama: Origins). Doubtless its technical development closely paralleled that of tragedy. Susarion in the 6th century and Epicharmus in the 5th century, both Megarians, produced brief farces. doubtless extremely crude in their humour; Attic comedy, more refined in character, begins with Rlagnes in the 5th century, and in the same century is carried further by Cratinus, and reaches its culmination in the works of the great Aristophanes.

5. The Decline. — In the Alexandrian period (336–146 B.C.) the great creative spirit of Greek poetry declined. Except for pastoral poetry, no new kind emerged; the poets were frequently learned imitators of their predecessors. Callimachus composed hymns and elegies as aell as epigrams. Apollonius of Rhodes imitated the Homeric epic in his *Argonautica*. Lycophron left a highly artificial Alexandra. The epic became didactic otherwise: Aratus of Soli wrote a versified astronomy. and Nicander composed two versified treatises on medicine, as well as some works. now lost, which influenced the Roman poets Virgil and Ovid. Theocritus, Moschus and Bion wrote exquisite pastorals or idyls. Satire and parody flourished; their most famous exponent was Timon of Phlius. Subsequently Greek poetry became silent until nhat may have been two poets of the same name, Oppian, in the 2nd and 3rd centuries A.D., wrote didactic epics on fishing and hunting; Babrius in the 3rd century versified the Fables of Aesop; and Quintus Smyrnaeus of the 4th century and Nonnus of the 5th revived the mimetic epic. the former offering one more sequel to the Iliad, the latter recounting the adventures of Dionysus. (See also ANTHOLOGY: *The* "Greek Anthology.")

II. ROMAN POETRY

1. Early Period. — Though, like the Greeks, the Romans possessed the germ of drama in their festivals and the germ of epic in their heroic lays, there is no evidence that they cultivated these. Such early poetry as they had was evidently of a rude order. Roman poetry does not evolve naturally and gradually. as does that of the Greeks; it is rather transported bodily, like the other arts, like, indeed. even Roman religion and mythology. from the matured and perfected culture of Greece. The Romans neither originated nor significantly improved any poetic art. but they produced many illustrious poets who kept alive, if only in reflection, the genius of Greek literature, and whose own influence was to extend even to the 20th century. The Romans borrowed the very name for a poet. for neither poeta nor vates is of Latin origin. They seem to have held minstrels in contempt. and the only native Italian rhythm is the so-called Saturnian metre, a crude form of trochaic hexameter. It would seem, thus, that the Romans neglected both poets and poetry until, as the Roman poet Horace says, they came into contact with Greek culture in the interval between the First and Second Punic Wars in the 3rd century B.C.

2. Greek Influence. — Once brought into that contact, however, they were affected as perhaps no other nation has been by a foreign culture; "subdued Greece subdued her savage subduer and brought her arts into rude Latium." Livius Andronicus. an emancipated Greek slave of the 3rd century B.C. who translated at least ten Greek tragedies, and nho even turned the Odyssey into the rough Saturnian measure, achieved fame despite the poor quality of his work. Gnaeus Naevius translated from the Greek and produced tragedies and comedies. as well as praetextae, or historical dramas. He is credited nith the introduction of subplots or underplots. Quintus Ennius composed comedies, tragedies, an epic on Roman history and other pieces. He was the first to replace the Saturnian measure with the epic (dactylic) hexameter. In the and century B.C. Caecilius Statius wrote comedies, and Marcus Pacuvius, tragedies. Lucius Accius was the first to employ Roman subjects for his tragedies. Plautus and Terence made free adaptations from Greek drama. Gaius Lucilius wrote satires which remained unequaled until Horace. Of all these poets, Plautus and Terence alone are still venerated.

3. The Golden Age. — The great age of Roman poetry was still to come. Lucretius in the 1st century B.C. produced his splendid didactic epic in defense of the Epicurean philosophy — De *Rerum Natura*—when the republican spirit in Rome was dying. To the same time belongs G. Valerius Catullus, an extremely gifted poet who composed more than a hundred poems on various subjects and in various metres, of which the most important are the *Atys* and The Marriage *of Peleus* and Thetis. In the new age of imperialism which succeeded, the other arts declined. but Roman poetry came to its highest flower before it, too, took the downward course. P. Vergilius Maro (70–19 B.c.) wrote the Georgics, the Eclogues and the greatest of Latin epics, the Aeneid (see VIRGIL). Q. Horatius Flaccus (6j–8 B *c.)* composed odes, epodes, epistles and satires (see HORACE). P. Ovidius Naso (43 B.C.–A.D. 17) wrote the *Metamorphoses,* the *Art* of Love, the Fasti and elegiacs, as well as a tragedy, *Medea,* which has been lost (see OVID). Albius Tibullus and Sextus Propertius (*qq.v.*) wrote elegies.

4. The Silver Age. — The Augustan age was the golden age of Roman poetry, but the silver age which followed in the 1st century AD. also had its distinguished poets: the satirists Persius and Juvenal and the epigrammatist Martial brought their respective forms to the highest finish these mere to have in Roman letters (see EPIGRAM). On the other hand, the epic poets Lucan, Silius Italicus. Valerius Flaccus and Statius represent at best a marked decline in that form. In the 4th century with Claudian (see CLAUDIANUS, CLAUDIUS) the epic turns into a form of encomium celebrating contemporary heroes — unless we wish to say that that had happened earlier with the Pharsalia of Lucan or the *Punica* of Silius Italicus, or even with the Aeneid. Indeed, the fundamental Roman genius was always for rhetoric. and in Latin nearly all the Greek poetic forms eventually approach forms of rhetoric. Thus tragedy, with Seneca (see SENECA, LUCIUS ANNAEUS), becomes declamatory rather than dramatic; and satire, always a rhetoric of dissuasion, quickly succeeds pure comedy.

5. Conclusion. — Even at its best Roman poetry was derivative, and even its greatest poets followed Greek models closely. To observe this is not to decry Roman poetry, for an art is preserved if not advanced by the Imitation of great models; and in the middle ages, nhen the poetry of the Greeks nas forgotten or but dimly remembered, it was the fortune of the Roman poets to remain as monuments of the greatness of antiquity. After all, the great conductor of Dante in his *Divine* Comedy was Virgil, who was to conduct many another poet from darkness to light. (See also LATIN LITERATURE.)

III. MEDIEVAL POETRY

The history of poetry during the medieval period can be represented here only in the crudest outline, because of its extraordinary complexity. When the poetic arts follow a natural evolution, as in Greece. or are imported totally, as in Rome, their development is continuous and orderly, and the task of the historian is relatively simple. When, on the other hand, tradition is disrupted, and the arts themselves are in a process of disintegration and reintegration, no easy description is possible.

1. Poetry **and** the Church. — During the early middle ages, causes existed which affected every aspect of the poetic arts. The decline of Roman power made access to certain parts of the empire difficult. or even impossible. This fact, together with the incursions of the barbarians, brought about a gradual "corruption" of the Latin language as it used to be called; more accurately, difficulty of access multiplied the differentiation of dialects. These linguistic changes were bound to affect both style and versification. Even more importantly, the rise of the Christian religion and the Christian ethic affected the subject matter of poetry, for both repudiated most of the moral attitudes on which pagan poetry had depended for its emotional power. Indeed, the general hostility which the church fathers felt toward all the arts, on the grounds of their immorality, falsity or idolatry, involved a special hostility toward drama and poetry. Tertullian calls literature "folly in the sight of God"; Jerome calls poetry the "food of devils"; Augustine and Gregory attack poetry as destructive of both religion and morality. Yet too much can be made of this hostility; no branch of literature — with the exception of drama— was completely rejected. Moreover, if pagan poetry, when read literally, offended, it might be read allegorically and found to contain meanings perfectly compatible with, perhaps even confirming, Christian doctrine and morality.

2. The Hymn. — Even so, the process of making poetry a servant of the church w-as no easy one. The Christian hymn itself, against considerable opposition, was introduced into western ecclesiastical use only in the 4th century, through the labours of St. Hilarius of Poitiers and St. Ambrose of Milan *(see* HYMNS). Once definitely established, however, the hymn remained one of the important poetic forms of the medieval period. Ambrose, Hilary, Pope Damasus and the great poet Prudentius wrote hymns in the 4th century; Sedulius. Elpis, Pope Gelasius. Ennodius, Gregory the Great *(see* GREGORY) and Fortunatus *(see* FORTUNATUS, VENANTIUS) composed hymns in the 5th and 6th centuries; and in succeeding centuries Bede. Paulus Diaconus, Hrabanus Maurus, Bernard of Clairvaux *(see* BERNARD, SAINT). Xbelard, Adam of St. Victor, St. Thomas Aquinas and many others produced notable or even great works of this kind. The anonymous "Te Deum," the "Dies Irae" of Thomas de Celano and the "Stabat Mater" of Jacopone da Todi — the first of the 4th century, the other two of the 13th — have been translated repeatedly, and set to music by the greatest composers. *(See* RHYME.)

3. Secular Poetry. — It must not be supposed, however, that medieval Latin poetry was confined to hymnography. We have already noted the epic poet Claudian, and there were many similar secular poets. In the 3rd century Reposianus wrote on the intrigue of Mars and Venus, Modestinus on Cupid asleep, Pentadius on the changes of fortune. on the arrival of spring and on Narcissus. In the 4th century there are such poets as Ausonius and Tiberian, who are primarily secular. Philosophers such as Boethius (5th–6th century) and Bernardus Sylvestris (13th century) wrote verses and veiled their doctrines in poetic allegory. **A** host of student songs, like those of the *Carmina Buruna,* dealt with wine, women and song. Satire, too. flourished, especially satire against the clergy. Wet the greatest medieval Latin literature. so far as intellect, imagination and even technical skill are concerned, is to be found in prose; and the greatest medieval poetry is not in Latin but in the Romance languages which gradually formed from the various dialects, and in the Teutonic languages. *(See* also LATIN LITERATURE : *Mediaeval.)*

4. French Poetry. — The earliest French poetry dates from the 10th century. a poem on St. Eulalia, a *Passion of Christ* and a *Life of St. Leger (see* also FRENCH LITERATURE). The three succeeding centuries saw the unfolding of the four great epic cycles of the *chansons de geste* (*q.v.*). The most venerable as well as most remarkable work is the *Chanson de Roland* (11th century; *see* ROLAND, LEGEND OF), which belongs. with the *Pilgrimage of Charlemagne* and *Huon de Bordeaux,* to the *Geste du roi,* or the cycle of King Charlemagne (*see* CHARLEMAGNE LEGENDS). The three other cycles are the *Geste de Garin de Monglane,* the *Geste de Doon de Mayence* and the *Geste féodale.* There were also romances of the Round Table, of Celtic origin, and brought into France in the 12th century. Among these we may note the Arthurian legends translated by Robert Wace, a Norman, in his *Roman de Brut* (1155); the legends of the Holy Grail; the *Tristan et Yseult* of Béroul (1150?) *(see* TRISTAN); and the *Erkc, Cligēs, Lancelot, Yvain* and *Percivale* of Chrétien de Troyes, composed 1160–80 *(see* ARTHURIAN LEGEND). There were also the *romans antiques,* such as the *Alixandre* and the *Enéas,* as well as the *romans d'aventure,* such as *Aucassin et Nicolette* and *Floire et Blanchefleur,* both from the 13th century *(see* ROMANCE). The lays of Marie de France (12th century) are related to the romances as the short story is to the novel, and are tender and melancholy rather than spirited as are earlier lays. Allegory, satire and lyric also flourished. The great allegory is the *Roman de la rose,* begun about 1230 by Guillaume de Lorris and finished about 1270 by Jean de Meun. Its satiric counterpart is the *Roman de Renart* (13th century), which employs the animal fable as allegory. Fabliaux *(see* FABLIAU), or short jocular tales in verse, were written by such poets as Rutebeuf. Lyric poetry reached exquisite refinement in the work of the troubadours of Provence *(see* PROVENÇAL LITERATURE; SESTINA; TROUBADOURS), of whom the most celebrated were William IX. count of Poitiers, Eble II, viscount of Ventadour, Bertran de Born, Arnault Daniel, Giraut de Bornelh and Sordello. These poets took as their theme a high conception of courtly love; both their subject matter and their elaborate techniques were to start innumerable echoes in western Europe *(see* SESTINA). The trouvères (*q.v.*) of northern France, less subjective, tend toward a kind of lyric narrative resembling the ballad.

French lyric poetry of the 14th and 15th centuries shows a tendency to ard fixed forms of great prosodic intricacy. This tendency is reflected in the work of Guillaume de Machaut, Eustache Deschamps, Christine de Pisan, Alain Chartier, Charles d'Orléans, and especially the *grands rhétoriqueurs*—Georges Chastellain, Jean Molinet, Guillaume Crétin (d. 1525) and Jean le Maire de Belges. These last developed the most intricate technique, so far as the mechanics of verse are concerned, that the world has ever seen *(see* BALLADE; CHANT ROYAL; RONDEAU; RONDEL). Even François Villon, the greatest French poet of the middle ages, uses elaborate verse forms in his *Little Testament* and *Great Testament.* These satirical wills are a powerful counterblast to the singers of kingly majesty and courtly love; they voice the bitter, cynical, often passionate response of the poor and the socially outcast. (For French poetry after the middle ages, *see* FRENCH LITERATURE.)

5. Spanish Poetry. — Of the Spanish epics, or *cantares de gesta,* there remain only three specimens, the *Cantar de mio Cid* (about 1140), the *Crdnica Rimada* (early 15th century) and the *Roncesvalles,* a 100-line fragment of a Spanish version of the *Chanson de Roland.* Beyond these, Spanish poetry of the middle ages falls into two main modes, the *mester de juglaria,* or mode of the minstrels, and the *mester de clerecia,* or mode of the clergy. The former is lyric or narrative; the latter is devotional or didactic, and is largely derived from French or Latin sources. The first known poet of Spain is Gonzalo de Berceo, who in the 13th century produced saints' lives and devotional pieces, the most important of which is the *Miracles of Our Lady. On the Wretchedness of Man,* discovered in the 20th century, is probably of Berceo's school; the attribution to him of a long poem on Alexander is doubtful. Other early Spanish poems include several in the convention of the debate or dispute — one between soul and body, one between two lovers, followed by a debate between water and wine; a long poem on Apollonius of Tyre, drawn from the old Milesian tale; and poems on the adoration of the Magi, on the life of St. Mary of Egypt and on Joseph and his brethren. There survive also a long

poem on the victories of Alphonso XI over the Moors, the versified moral proverbs of a Spanish rabbi, Sem Tob, and, in typical medieval fashion, a "Dance of Death." The first great Spanish poet of original and varied genius, however, is Juan Ruiz. whose *Book of Virtuous Love* is a fantastic medley of tales, fables and devotional poems unified by a history of his love affairs. His poems, together with the equally miscellaneous *Rimado de palacio* of Pedro López de Ayala, offer a fairly full view of medieval life in Spain.

Five hundred and eighty-three poems of the late 14th and early 15th centuries have been preserved in a collection made in 1445, the *Cancionero de Baena*. These are significant chiefly as showing the attempts of poets to master their medium. Better poets follow: the marqués de Santillana (1398–1458) and Jorge Manrique. (For Spanish poetry after the middle ages *see* SPANISH LITERATURE.)

6. Italian Poetry.—The Italian language was extremely slow in developing, and consequently Italian poetry gained no real impetus until about the middle of the 13th century. *(See* ITALIAN LANGUAGE, MODERN: *The Literary Language;* ITALIAN LITERATURE.) In northern Italy, at that time, Giacomino of Verona and Bonvesin of Riva composed religious narratives; in the south, love songs prevailed. A poem often accepted as the first Italian poem is the *contrasto* of Cielo Dalcamo, a debate between lover and lady in which the lover finally gains his suit. It would seem to be a relic of Sicilian popular poetry, as opposed to the literary poetry produced, in close imitation of the troubadours, at the Sicilian court of the emperor Frederick II. This courtly school, headed by Frederick himself, included among others his natural son Enzio, king of Sardinia, Pier della Vigna and Odo and Guido delle Colonne. The school has frequently been derided as imitative of an already decadent literature, but such judgment is hardly sound. The Provençal was the first Latin tongue to develop a cultivated vernacular literature, and though the language lived only three centuries, its poets have found imitators, such as Ezra Pound, even in the 20th century. As for the merits of Frederick's school: we may remember that Guido, at least, was praised by Dante; next to greatness is the praise of the great.

Italian poetry also progressed along other lines. A strong religious movement, strengthened by the rise of the Dominican and Franciscan orders, produced much devotional poetry. Some of this has been attributed—dubiously; however—to St. Francis of Assisi; but the most powerful figure of this Umbrian school is the half-mad mystic and hermit Jacopone da Todi. Tuscany fostered a comic and satiric poetry which was indebted to the Sicilian popular poets. As one might expect, its writers are antichivalric and anti-mystical. Principal among them are Folgore de San Gimignano, Rustico di Filippo, Cecco Angiolieri and Dante of Majano. The last two did not spare the great Dante Alighieri himself; Cecco called himself the goad and Dante the bull, and Dante of Majano interpreted Dante Alighieri's dream sonnet as meaning that the poet needed a purge. Guido Guinicelli led the development of a philosophic poetry of love in which the old chivalry was sublimated to the new mysticism. Allegory also .developed; the *Tesoretto* of Brunetto Latini, brief as it is, prefigures the *Divine Comedy*.

It was the Tuscan lyric school of Cino da Pistoia, Guido Cavalcanti and Dante Alighieri, however, which was to bring Italian poetry of the middle ages to high art; and even that was to be dwarfed—as indeed almost all poetry has been—by Dante's *Divine Comedy*. So much has been written about this great work that perhaps its essential character has been obscured. It is usually styled an epic; but it has little relation to Homer, nor do the principles of Aristotle's *Poetics* apply to it. It is, as Dante's letter to Can Grande della Scala makes clear, a didactic work; indeed, a scholastic treatise. Its thesis is that men must live virtuously, and this thesis is argued by showing that divine justice is everywhere omnipotent: in hell, in purgatory and in paradise. The manner of argument is inductive, from the particular to the general, and Dante continually avails himself of the *exemplum* form so popular in the medieval period—that is. the argument from a concrete instance. In such argument, everything depends upon the power with which the concrete instance is presented, and a great part of Dante's power lies in the vividness with which he conceives incidents of great emotional power, in the swiftness and surety with which he presents them and in the fourfold significance with which he invests them. Critics with a predilection for the "Inferno" have often suggested that the work might have stopped with that part, but this view reflects a basic misunderstanding of its whole design. To cease with the "Inferno" would be to reveal Divine Justice only as punitive, and to show humanity only as vicious, as well as to set aside the Christian doctrines of redemption and salvation, and thus to deny the efficacy of the Passion of Christ; in short. to deny everything to which Dante was dedicated. Too much has been said. also, of Dante's originality. What is more important is that just as the *Comedy* utilizes the vision, the *exemplum*, allegory and every other device of 'medieval literature, so it subsumes the history and mythology. the theology and philosophy, of the medieval period, and so much of antiquity as the middle ages could transmit. It means so much because what went into it had meant so much; the ages prepared it, and it remains for the ages.

The *Divine Comedy* found imitators in Fazio degli Uberti (d. 1367), who wrote a long geographical-historical poem, the *Dittamondo,* and Federigo Frezzi (d. 1416), who wrote the *Quadriregio,* a moral poem of the four kingdoms of Love, Satan, Vice and Virtue. In the former the geographer Solinus takes the place of Dante's guide Virgil, as does Pallas Athena in the latter.

The 14th century witnessed the lyric genius of Petrarch and Boccaccio, as well as much humorous and historical poetry. A number of other poets may be mentioned: Senuccio del Bene, the friend of Petrarch; Domenico Burchiello (1404–49), Giusto de' Conti (d. 1449), Franco Sacchetti and Giovanni Fiorentino. (For Italian poetry after the middle ages *see* ITALIAN LITERATURE.)

7. German **Poetry.**—Of the battle songs and epic lays of the Goths, no trace remains. In the 5th and 6th centuries, however, there gradually arose a body of legends centring around Dietrich of Berne (Theodoric), the Burgundians and Attila the Hun. Some of these materials, gathered into the *Nibelungensaga,* spread through the Teutonic nations and formed part of the Scandinavian *Edda* (*q.v.*). The lays of the *Edda* originate during the period 850–1050; but the German *Nibelungenlied* (*q.v.*) itself is of the 12th century. Charlemagne ordered the collection of popular poetry, but of this. too, there is no vestige. Beyond the fragmentary *Song of Hildebrand* (about 800), in alliterative verse: and the *Waldere,* a fragment of a translation from the Old High German into Anglo-Saxon, the national epic of the Carolingian age is irrecoverably lost.

Two biblical epics date from the 9th century. *Der Heliand* ("The Savior"), together with fragments of a translation of Genesis, may be remnants of an Old Saxon translation of the Bible commanded by Louis the Pious. The *Evangelienbuch* ("Gospel Book") of the monk Otfrid (flourished 840) is the earliest German poem in rhymed verse. The former is interesting as transforming Christ and his disciples into a king and his vassals, after the heroic Saxon mold. The *Muspilli,* a fragment of 106 lines, powerfully depicts the destruction of the world.

The 10th and 11th centuries produced little of importance in German poetry beyond certain ascetic religious pieces, such as the verse sermon *Memento mori* (about 1070) or biblical poems such as the *Ezzolied, Judith* and *The Three Youths in the Fiery Furnace,* all of about 1060. Secular poetry seems not to have flourished, except for the collection of lays known as the *Lombard Cycle*. The 12th and 13th centuries, however, are a splendid epoch in German literature. This is the age of the minnesingers (*q.v.*), chief among whom is Walther von der Vogelweide; of chivalric romances such as the *Parzival* of Wolfram von Eschenbach and the *Tristan* of Gottfried von Strassburg; of the *Heldenbuch* (*q.v.*) ("Book of Heroes"); and of the *Nibelungenlied,* besides a vast body of popular poetry.

With the end of the Swabian dynasty in the 13th century, German chivalry and chivalric poetry declined. The 14th and 15th centuries are chiefly remarkable for the establishment of a guild of poets, the Meistersingers *(see* MEISTERSINGER), which was to last until 1878, for satires such as *The Ship of Fools* and *Friar*

Amis and for beast fables such as *Reynard the Fox* (*q.v.*).

8. Old English Poetry. — The most considerable specimen of Old English poetry, and the oldest of the Teutonic epics, is *Beowulf* (*q.v.;* probably 7th-8th centuries). A fusion of history and legend, of pagan and Christian elements, it is almost certainly an art epic derived from a cycle of heroic lays, rather than a primitive folk epic. Besides *Beowulf* there survive brief epic fragments. such as *Finnsburg* and *Waldere*. A number of lyric poems survive: *Deor's Lament, Wulf and Eadwacer, The Husband's Message, The Ruin, The Seafarer, The Wanderer* and *The Wife's Complaint*. Of Anglo-Saxon Christian poets, Caedmon, who flourished about 670, is the first known and Cynewulf, in the late 8th or early 9th century, is the best. The nine lines of a hymn constitute the only authentic specimen of Caedmon's work, although *Christ and Satan, Daniel, Exodus, Genesis, Judith* and other biblical paraphrases were formerly attributed to him. Certain of Cynewulf's poems, *The Ascension, Elene, Juliana* and *The Fates of the Apostles,* are thought genuinely his because they are signed with runic characters composing his name. Other poems of less certain attribution are *Andreas, the Dream of the Rood, Guthlac* and the *Phoenix*. Besides these forms, there survive certain Anglo-Saxon riddles, charms and gnomic verses. (*See* also ENGLISH LITERATURE: *Earliest Times to Chaucer*.)

9. Middle English and Scottish **Poetry.**—The Anglo-Norman period (1066–1340) offers poetry of somewhat more diversity. There are the usual religious and allegorical works, such as the *Ormulum* (about 1200), a mixture of biblical paraphrase and verse homilies, chiefly remarkable for its adaptation of the Latin *septenarius* (seven-foot line) and for its departure from alliteration (*q.v.*) as a verse principle; *Cursor Mundi* (about 1300), another scriptural poem; and *The Pricke of Conscience* by Richard Rolle de Hampole. There are also poems in the debate form so popular in medieval Europe, such as the *Debate Between Body and Soul* and *The Owl and the Nightingale*. There are also remarkable lyrics, such as "Alysoun," "The Cuckoo-Song" and "The Lenten (Spring) Song," and political and social satires such as *The Fox and the Wolf* and *The Land of Cockaygne*. *Brut,* adapted by Layamon from the *Roman de Brut* of Robert Wace, is a notable landmark in the history of the metrical romance. A copious literature of ballads has survived from the 13th and 14th centuries.

The age of Chaucer (1340–1400) produces nothing so rich as that poet's greatest work, *The Canterbury Tales* (*see* CHAUCER, GEOFFREY), yet it contains other notable poets: John Barbour, the first Scottish poet of merit; William Langland, whose *Piers Plowman* is thought the greatest social satire of the period; John Gower; and the authors of *Pearl* (*q.v.*) and of *Sir Gawayne and the Grene Knight* (*see* GAWAIN). The 15th century saw the rise of many imitators of Chaucer: Thomas Occleve (about 1368–1450), John Lydgate and Stephen Hawes in England; King James I of Scotland, Robert Henryson, William Dunbar, Gavin Douglas and Sir David Lyndsay in Scotland. Perhaps the most original poet of the period is John Skelton. (*See* also SCOTTISH LITERATURE.)

10. Poetic Drama. — Medieval European poetic drama is so complex a topic that little can be said of it here, except that it followed much the same pattern of development as had the drama of ancient Greece (*see* DRAMA: *Medieval Drama*). Liturgical in origin, it arose out of antiphonal uses of dialogue in the Christmas and Easter services. The earliest specimen of this is the *Quem quaeritis* trope. probably of the 9th century. Dialogue presently became dominant, and longer actions were represented; subsequently drama became differentiated into distinct forms, such as the mystery, the morality, the miracle play and various folk forms. It was not until the middle of the 16th century, however, that England produced its first true comedy, *Ralph Roister Doister* (performed about 1554), by Nicholas Udall, and its first true tragedy, *Gorboduc* (performed 1562, new style), by Thomas Sackville and Thomas Norton. Early English tragedy is modeled upon the tragedies of Seneca, which had been popular in the middle ages, though they had not been performed, and which were translated into English 1559–81.

ENGLISH AND AMERICAN POETRY FROM THE RENAISSANCE TO 1900

1. 16th Century. — The situation of English poets in the 16th century had its difficulties as well as its advantages. On the favourable side, poets were supplied—by antiquity, by the middle ages and even by certain oriental literature—with a vast variety of subjects, the rich possibilities of which have not even been exhausted by the 20th century. Poets had, moreover, an almost equally rich variety of models for imitation, as well as a body of critical and poetic theory greatly augmented and broadened by the recent recovery of important works such as the more humanistic rhetorical treatises of Cicero. the *Institutes* of Quintilian and the *Rhetoric* and *Poetics* of Aristotle (*see* RHETORIC; CRITICISM). On the other hand: they were faced, like the poets of continental Europe, with problems arising from the attempt to use the vernacular language as a medium of literature. They had to determine whether the vernacular was suitable for serious literary effort, what style of language was appropriate to a given literary form, whether accent or quantity was the proper basis for English verse, whether rhyme was admissible, what was and what mas not correct usage or even pronunciation. But the problem of "Englishing" the subjects supplied them went beyond questions of mere language; the problem involved also the translation of what had been significant for very different cultures into things significant in terms of the customs and manners, the emotions and beliefs of England.

Although these problems remained the centre of critical dispute for some time, they were resolved by poetic practice rather than by theory, and chiefly by the selection of certain models. Thus Thomas Sackville's *Induction* (1563) to *A Mirror for Magistrates* followed Boccaccio; Sir Thomas Wyat and Henry Howard, earl of Surrey (*see* SURREY, HENRY HOWARD, EARL OF), based upon the love sonnets of Petrarch, thereby establishing a perennial convention of English poetry; George Gascoigne imitated a great number of foreign models, principally Ariosto. A landmark in English poetry is Tottel's *Miscellany* (1557), which set the vogue for a great many similar collections. Translation flourished; by 1600 many of the great poetic works of antiquity, and many even of the contemporary literatures: had been cast into English verse. The sonnet (*q.v.*), the song (*see* SONG: *Early Song* and *English Song*), the pastoral (*q.v.*), the heroic poem, the romantic epic and the verse drama were all brought to high art in Elizabeth's reign.

The last decade of the 16th century alone produced the notable sonnet sequences *Astrophel and Stella* (1591; 1598) by Sir Philip Sidney; *Diana* (1592) by Henry Constable; *Delia* (1592) by Samuel Daniel; *Idea's Mirror* (1594) by Michael Drayton; the sonnets of Shakespeare (written about 1592–98, published 1609); and the *Amoretti* of Edmund Spenser (1595.) More than 20 songbooks were completed from 1585 to 1605, including the exquisite *Book of Airs* (1601) by Thomas Campion. The pastoral was represented by *The Shepherd's Calendar* (1579) of Edmund Spenser, the eclogues in Sidney's *Arcadia* (1590) and the pastoral sonnets of Drayton. Heroic poems on classical themes included *Hero and Leander,* begun by Christopher Marlowe before 1593 and finished by George Chapman in 1598, and Shakespeare's *Venus and Adonis* (1593) and *The Rape of Lucrece* (1594). Narrative poems on historical and national themes included *Albion's England* (1586) by William Warner; the *Complaint of Rosamund* (1592) and the *Civil Wars of York and Lancaster* (1595–1609) by Daniel; *The Barons' Wars* (1603), *England's Heroical Epistles* (1597) and *The Poly-Olbion* (1612–22) by Drayton. The romantic epic reached its height in the didactic moral allegory of *The Faerie Queene* of Spenser (1590–1609).

2. Elizabethan and Jacobean Verse Drama. — Greatest of all achievements, however, was the verse drama, brought to rapid development by John Lyly, Thomas Kyd, Robert Greene. George Peele and Christopher Marlowe and culminating in the tremendous works of William Shakespeare. In a few years the drama progressed from bombastic declamation, melodramatic or crudely comic plots and faltering or monotonous versification to works of incredible power and perfection. Cntil the closing of the English theatres by the puritans (1642), nearly every form was exploited by Shakespeare and his contemporaries or successors: Ben Jonson, George Chapman. Thomas Dekker, Thomas Middleton, Thomas Heywood, Francis Beaumont. John Fletcher (*see* BEAUMONT AND FLETCHER). Philip Massinger, John Webster. John Marston, John Ford; Cyril Tourneur and James Shirley. The comedies of Jonson and the tragedies of Webster almost bear comparison with those of Shakespeare himself.

3. 17th Century. — The 17th century also had its poets of talent or genius. Some, like the so-called Spenserians, followed the model of an English poet; thus the school of Spenser includes Giles Fletcher, whose *Christ's Victory and Triumph* (1610) anticipates John Milton's *Paradise Lost;* his brother Phineas, William Browne, George Wither and William Drummond of Hawthornden. Others, like John Donne and John Milton, based chiefly upon foreign models. The "metaphysical school," of which Donne is usually designated as the founder, includes such men as George Herbert. Richard Crashaw, Henry Vaughan, Thomas Traherne, William Habington and Francis Quarles. There were also the poets of gallantry, "Cavalier poets": Thomas Carew, Sir John Suckling, Richard Lovelace and Robert Herrick.

Brilliant and profound as had been the best poetry of the Elizabethan and Jacobean periods, it seemed "incorrect" to some who followed as compared with the works of antiquity or even of contemporary France, and a "classical reaction" set in. Aimed chiefly in the beginning at producing a more coherent, precise and restrained diction and a more regular and polished versification; it gradually affected every aspect of the poetic arts. The heroic couplets of Edmund Waller and of John Denham evoked extraordinary admiration at their finish and smoothness; on similar grounds, Abraham Cowley was considered the equal of Chaucer and Spenser and the superior of Milton. These judgments are likely to seem absurd unless their historical context is considered. They had at least this foundation, that an age had passed, and with it. the emotional attitudes out of which Elizabethan poetry had sprung; that the language itself was altering, and the old formulas would serve no longer; and that the changing temper of men was to require a style at once more moderate and more easy for its expression. Though this "classical" tendency was to find its justification as well as its culmination in the genius of Alexander Pope in the 18th century, two of the greatest poets of the latter 17th century, John Milton and Andrea Marvell, remained free of it. Marvell followed his own course; Milton forged for himself the mighty style of *Paradise Lost* and *Samson Agonistes.* But another great poet, John Dryden, perhaps the equal of Milton himself, took the newer road of Edward Fairfax and Waller.

4. The Restoration. — The Restoration period in many respects foreshadows the 18th century. The serious lyric declined! as the sonnet had long before; Spanish and French influences, rather than Italian, dominated tragedy, which slowly weakened into the bombastic heroic play or the pathetic tragedy; comedy, satire and didactic poetry flourished; and much that was thought and felt called for prose expression rather than poetic. Yet no one can justly complain that poetic force and skill is wanting in such satirists as Dryden and Samuel Butler or such dramatist-poets (they were accounted such, even though some happened to write in prosej as Dryden, Thomas Otway, Nathaniel Lee, Nicholas Rowe, Sir George Etherege, William Wycherley, William Congreve, Sir John Vanbrugh and Sir George Farquhar. Brilliant as Restoration drama was, its moral laxity brought about attempts to reform it. Most notably, the *Cato* of Joseph Addison was an effort to bring English tragedy into conformance with the standards of ancient tragedy, as the comedies of Sir Richard Steele were efforts to effect the moral reform of comedy.

5. 18th Century. — The poetry of the 18th century is still viewed in the 20th century with contempt or indifference by those who conceive of poetry in terms of the 19th-century romantic poets Shelley and Keats; yet this low estimate results, not from the faulty art of Pope and his followers, but from the historical accident that they were succeeded by brilliant exponents of a poetry almost totally opposite to theirs. Eighteenth-century poetry is essentially didactic rather than imitative, and chiefly moralistic or satiric in its didacticism. It is not unemotional, but it is less interested in the direct expression of emotion than in the rational interpretation of emotion. It is not indifferent to the beauty of nature — what poets, indeed. have talked more continually of nature? — but it sets an intellectual response to nature above an emotional one, and in consequence it is a poetry of ideas rather than images. It is not impersonal. but it is urbane, and its urbanity demands the observance of decorum. It is concerned with certain aspects of human nature and condition, the romantics with others. We can see the achievement of Pope and his disciples, not by comparing them with poets of an entirely different order, but by measuring them against their own kind.

The great poet of the first half of the century is beyond question Alexander Pope, whose *The Rape of the Lock* and *Dunciad* remain unmatched as examples of mock-epic satire, and whose *Moral Essays* and *Essay on Man* are monuments of didactic poetry, not because of what they say, but because they say it so well. It is perhaps worthwhile to observe that next to Shakespeare the most frequently quoted of English poets is Pope. Matthew Prior, John Gay and Thomas Parnell are only less polished than Pope, and their work contains accents of gaiety or gravity not to be found in their master. In the second half of the century. Samuel Johnson and Oliver Goldsmith continued the "classic" tradition with distinction.

It must not be thought, however, that 18th-century poetry is wholly uniform with the school of Dryden and Pope. Milton and Spenser were the models of many poets who, though they are contemporary with Pope or Johnson, are of so different a vein that they have usually been classified as precursors of the romantics. Thus Allan Ramsay anticipates Robert Burns; John Dyer anticipates William Wordsworth; Milton was imitated by Parnell, Edward Young and Robert Blair; Spenser, by William Shenstone, Mark Akenside (*qq.v.*), Joseph Warton and James Beattie; James Thomson imitated Milton in his *Seasons,* Spenser in his *Castle of Indolence.* James Macpherson offered his poems as a translation of Ossian, a supposed Gaelic epicist, and Thomas Chatterton offered his as the work of a monk named Rowley. William Cowper and George Crabbe resemble Wordsworth in their feelings toward men and nature. William Collins, Thomas Gray, Robert Burns and William Blake are often considered outright romantics, figures of the 19th century rather than the 18th. The *Lyrical Ballads* (1798) of Wordsworth and Coleridge were themselves productions of the 18th century; Coleridge wrote "Kubla Khan," the first part of "Christabel" and "The Ancient Mariner" in 1797–98, and the great period of Wordsworth's production was over shortly after 1800.

6. **"Classic"** and "Romantic." — The distinction between "classic" and "romantic" is of such long establishment that it can scarcely be abandoned, but it has come to mean almost anything and everything. The history which lies behind this historical classification is much clearer.

Poetry, like all arts, takes its character from the models and traditions to which it attaches. Dryden, Pope and their followers modeled upon French poets who seemed to them to have best realized the classic tradition of antiquity — Roman antiquity primarily; the precursors of the romantics continued to base upon English models; the romantics themselves either continued the English tradition or modeled, like Coleridge and Scott, upon German poets who themselves imitated the English ballads collected by Thomas Percy in his *Reliques* (1765). One thing more must be said: the middle ages, long held in contempt, were gradually being returned to esteem, and their poetry and legend revealed values that made them at least a quarry for subject matter, and even possibly models for emulation. In England the romantic movement was primarily the return, after a brief and brilliant excursion in foreign realms, to native English traditions.

7. Romantic and Victorian Poets. — Though eminent romantics like Byron still followed the example of Pope when the occasion demanded, the poetry of the 19th century is on the whole different from that of the 18th, and its differences consist chiefly in that it involves an enlargement of the subject matter, of techniques and devices and of forms. It depicts processes of the imagination and of the emotions as well as those of discursive reasoning; it presents images as well as ideas. It addresses itself to the sensibilities as well as to the reason of the reader. It cultivates imitative as well as didactic forms. It finds new uses for old devices or old verse patterns — ballad conventions, for instance, are employed with great diversity, and the sonnet finds uses, lyric and even narrative, undreamed of by the few 18th-century sonneteers. Verse itself became extremely various; rapid narrative and certain kinds of lyric required a rhythmic lightness and speed beyond the possibilities of the heroic couplet, and in consequence, anapest, dactyl and amphibrach flourished in abundance *(see* VERSE). The classic distich itself relaxed its strictness and, in more plastic form, served as the medium for such narratives as *Endymion.*

Nearly every major poet of the century either made technical advances or gave a new significance and vitality to what had been supposed outworn. Thus William Wordsworth and Samuel Taylor Coleridge brought the ode (*q.v.*), the reflective lyric and the ballad to new heights, evoking tones from them that had not been heard before; Robert Southey revived the epic; Sir Walter Scott renovated the ballad and the heroic lay; George Gordon Byron, Lord Byron, carried the lay still further and enriched it with oriental themes, and, in *Don Juan,* created a new kind of romantic epic. Percy Bysshe Shelley produced a new order of philosophical lyric drama in *Prometheus Unbound,* and John Keats gave the narrative romance, in "The Eve of St. Agnes," unprecedented richness and subtlety. Alfred Tennyson brought nearly every species of poetry to technical perfection, and his *The Idylls of the King* remains the most notable achievement in epic in modern times. Robert Browning produced "dramatic lyrics" which had the sharp specificity, in character and circumstances, of drama itself; and his *The Ring and the Book* introduced a device which was to have profound influence upon later prose fiction — the device of viewing characters and incidents from many different points of view. Matthew Arnold and Gerard Manley Hopkins made extraordinary innovations in versification.

These are the great poets of the century; but the era abounds in minor poets of extreme distinction. such as Walter Savage Landor, Thomas Moore, George Darley. Thomas Lovell Beddoes, Elizabeth Barrett Browning, Dante Gabriel Rossetti, Christina Rossetti, William Morris and Algernon Charles Swinburne. Almost half of these would in nearly any other century be accounted great; and the last, Swinburne, is generally considered the most brilliant metrical virtuoso of the English language. George Meredith and Thomas Hardy, though famous primarily as novelists, are also poets of extraordinary merit.

The poets of the 1890s, whatever their virtues, are far inferior in invention and force. Principal among these were Oscar Wilde, Ernest Dowson, Lionel Johnson, Francis Thompson and Stephen Phillips. Phillips briefly enjoyed a reputation as a poet of the first magnitude. worthy of comparison with the great Elizabethans, but is now almost forgotten. Indeed, with the exception of Wilde, whose prose dramas are still popular, these poets are now remembered only for one or two pieces.

After the decline of poetic drama in the 18th century, the 19th century saw a resurgence. Nearly all the major poets composed tragedies; but these, even at their best, are eminently unsuited for the stage; and remain closet dramas merely. It is quite possible that the failure of these works, and the conspicuous success of prose plays, produced the general prejudice against verse in the modern popular theatre.

8. American Poetry. — American poetry, from colonial times to the end of the 19th century, offers little that will bear comparison with English Anne Bradstreet (1612–72), Edward Taylor (1644–1729) and Philip Freneau are the most important of the early poets. William Cullen Bryant. Ralph Waldo Emerson, Henry Wadsworth Longfellow, John Greenleaf Whittier. Oliver Wendell Holmes, Edgar Allan Poe, James Russell Lowell, Walt Whitman, Emily Dickinson and Sidney Lanier are the most famous American poets of the 19th century. Of these, perhaps only Emerson, Poe, Whitman and Dickinson are of remarkable merit Trumbull Stickney (1874–1904), William Vaughan Moody and Richard Hovey came to some fame, but had little effect on most readers by mid-20th century. Poe, Whitman and Dickinson alone anticipate the brilliant outbreak of poetic genius in the 20th century.

V. ENGLISH AND AMERICAN POETRY OF THE 20TH CENTURY

William Butler Yeats affirmed that England produced more good poets in the 20th century than in any period of the same length since the 17th century; Conrad Aiken made a similar claim for America. 4s one might expect, many distinguished poets remained within the English romantic tradition; on the whole, however, perhaps the most interesting and influential work was produced by poets who found their models in other traditions, or who experimented to produce a poetry as new as possible. Indeed, an insistence on the distinctively modern can be found in all the arts of this period. The frequent manifestoes and programs issued by artists reflect the belief that science and technology had produced a civilization which was unique, and that new forms of art must arise to express it.

Twentieth-century poetry must, like any other, await the verdict of other times than its own. Certain things, however, are clear already, as matters of fact rather than of judgment. It was a poetry innovative to an unprecedented degree, and its innovations affected every aspect, from subject matter to style and versification. No other poetry exhibits so wide a variety of techniques; no other shows such rapid interplay between poetry and the other arts. The discovery of a new device in one art led almost instantly to its adoption, where this was possible, in all others.

The causes underlying all this innovation, however. lie far deeper than matters of poetic method. They lie in the fact that the 20th century was, and is, historically self-conscious, peculiarly aware of itself as a historical epoch and as an epoch distinct from any that has gone before. Doubtless this sense of modernity was due in part to mechanical and industrial progress, but man himself had changed more than his machines. The complex structure of emotions, beliefs and moral attitudes on which the arts depend for their effects, and on which, indeed, human conduct at a given time is predicated, had changed significantly since mid-Victorian times. The conception of man, human society and the universe itself had altered; the rupture with artistic tradition was a token of a rupture with a far deeper and older tradition of human nature and conduct.

The new psychology, in particular the Freudian, presented man as far more irrational than rational, and in questioning the principles of motivation and moral responsibility, reinterpreted human action in such fashion as to challenge the very foundations of morality. Comparative anthropology cast doubt on the uniqueness of the Christian religion by emphasizing its similarity with primitive pagan cults; and the comparative study of customs and mores exhibited contradictions so marked as to suggest that standards of right and wrong were themselves only conventional. The natural sciences widened the breach between religion and science which had already been widening in the 19th century. In short, a system of values was conceived either as threatened, or as already in hopeless disrepair. Much of the best modern literature stems from a search for a new system of values; and the spiritual malaise which it expresses has its primary cause in the feeling that 20th-century man was pretty much on his own, unhelped by the past, and confronted with problems peculiar to his age. The true and the false, the beautiful and the ugly, the good and the bad, had to be distinguished anew.

The poetry which was created in these circumstances was bound to be analytic, experimental and various. It is a poetry which permits of no simple description and which exhibits no very clear patterns, and it ranges from the extreme of the objective to the extreme of the subjective. Schools, movements and poetic programs abound; but with few exceptions — suth as the Imagist group of the second decade and the Marxist groups in the fourth and fifth — the dominant influences are exerted by particular poets, such as Ezra Pound, T. S. Eliot, W. B. Yeats and W. H. Auden. These poets affected strongly both the theory and the practice of poetry, but their influence, so far as their better followers were concerned, resulted in variety rather than uniformity.

The modern period began, overtly at least, in a general reaction against conventional poetic diction, versification, technique and subject matter, and shortly thereafter advanced to a general decision to rediscover the principies, or to find new principles, on which a valid modern poetry might be written. Even in the first decade Harold Monro and others in England, Ezra Pound and others in America, protested against the prolixity, vagueness, rhetoricism and vapidity of conventional verse. A number of nearly simultaneous events lent great impetus to the pressure for a new poetry: the publication of the first anthology of "Georgian poets." in 1911. by Monro, followed by his founding, a year later, of the Poetry Bookshop; the rise of the Imagist group, and in the same year. the founding of Poetry: a *Magazine* of *Verse,* in Chicago, by Harriet Monroe. In retrospect, the last seems most important. From the first, it sought to discover new talent and to encourage progressive writing, and by mid-century it had published nearly every English and American poet of distinction, "discovered" many of these and broadened the reputation of many more.

The Georgian poets were not a school. The group included such sharply different poets as W. H. Davies. Walter de la Mare. Lascelles Abercrombie, Ralph Hodgson (1871–) and Rupert Brooke. The last later fell into some disfavour, after a period of extraordinary popularity; nevertheless, he must be reckoned among the early moderns because of his efforts to extend poetic subjects to include the ugly, and because of his deliberate deflation. in certain of his poems, of stock romantic attitudes.

The Imagists had something of a common program in their insistence on certain poetic reforms and on accurate images of the external world. The group included Amy Lowell, Ezra Pound, "H. D." (Hilda Doolittle; 1886–1961), F. S. Flint, John Gould Fletcher and others. Their use of free verse emphasized the importance in poetry of organic rhythms of speech as opposed to mere metre and rhyme; the extreme concision and brevity of some of their poems—especially those in which Chinese or Japanese influence is apparent—greatly affected the conception of poetic style. The restriction of poetry to imagistic techniques proved too severe, however, and Pound, among others. quickly forsook imagism for methods that permitted a greater variety of effect.

The second and third decades saw the rise of a host of new or newly famous poets. Besides those already mentioned—and besides those already well known, such as Robert Bridges, A. E. Housman, John Masefield and Rudyard Kipling, England produced James Elroy Flecker. D. H. Lawrence. Robert Graves, Edward Thomas (1878–1917), Isaac Rosenberg (1890–1918), Wilfred Owen (1893–1918), Wilfrid Wilson Gibson (1878–1962). Edmund Blunden (1896– j, W. J. Turner (1889–1946), Richard Aldington (1892–), Edith Sitwell (1887–), Sir Osbert Sitwell (1892–) and Sacheverell Sitwell (1897–). (*See* also ENGLISH LITERATURE: Twentieth *Century.*) The United States produced E. A. Robinson. Edgar Lee Plasters. Vachel Lindsay, Robert Frost. Carl Sandburg, Edna St. Vincent Millay, Elinor Wylie, Sara Teasdale, Conrad Aiken (1889–), E. E. Cummings (1894–1962). William Carlos Williams (1883–). Robinson Jeffers (1887–1962), T. S. Eliot, Wallace Stevens (1879–1955), Marianne Moore (1857–), Archibald MacLeish (1892–), John Crowe Ransom (1888–), Hart Crane, Allen Tate (1899–), Léonie Adams (1899–), Louise Bogan (1897–) and many others. (See AMERICAN LITERATURE: *The* **New** Poetry.)

Ireland as well had undergone a literary revival after the stimulation of Standish O'Grady's History of *Ireland* (1878–80), and provided many poets, principal among them "Æ" (George William Russell). Katherine Tynan Hinkson (1861–1931), James Stephens. Francis Ledwidge (1891–191j) and, above all, the great William Butler Yeats.

World War I had marked effects upon poetry as upon all else; perhaps the most noticeable are a bitter realism, if not cynicism, a growing introspectiveness, an extreme dislike of obvious thought or "easy emotion" and a preoccupation with disillusion and despair. Whatever optimism had accompanied scientific and technological progress rapidly faded. A sense of chaos, a sense that civilization was disintegrating, underlies much of the reflective poetry of the time. T. S. Eliot's The *Waste* Land (1922) and "The Hollow Men" (1925), violent as were the outbursts against them, were interpreted as epitomizing the feeling of the generation. Other influences affected the directions which poetry was to take. The publication by Robert Bridges, in 1918, of the Poems of Gerard Manley Hopkins made known a poet of the highest eloquence, whose experiments in style and versification gave a new turn to innovations already in progress. The Freudian and Jungian systems of psychology extended the conception of human experience to the subconscious and unconscious mind. The former contributed a symbology. the latter a mythology, which gave modern literature both a method of interpreting and a method of expressing aspects of psychological experience hitherto inaccessible. A resuscitation of interest in Elizabethan and "metaphysical" poets brought about a return to these as models. Most important, however, was the growing influence of the 19th-century French symbolists (see SYMBOLISTS, THE) and their later disciples, such as Guillaume Xpollinaire and Paul Valéry.

It is a matter of some curiosity that while Pound and Eliot had repugned the American poetic tradition, and had in fact become expatriates in the apparent conviction that American culture had little if anything to offer, certain French poets, beginning with Baudelaire, had been greatly impressed with American poets, with Poe in particular. Nearly all the important symbolists read Poe or Whitman with excitement, and many translated and imitated them. Both Pound and Eliot now fell under the spell of an American tradition in a French version. The French version, however, contained elements that the American original did not. It was suggestive rather than explicit; it was concerned with the emotional aura surrounding objects rather than with objects themselves; it was predicated upon the existence of mysteries inaccessible to science and intellect, and its techniques were techniques for the revelation of those mysteries. It seldom presented a literal surface meaning; it depended upon suggestion. implication and allusion; it began where allegory. conventional metaphor and conventional symbol left off. As practised by Yeats, Pound and Eliot. it exerted enormous influence upon English poetry; influence of uhich we have not yet seen the end.

If symbolist poetry, with certain exceptions, had elements of otherworldliness. there were other kinds of poetry that did not. Particularly as a result of the great depression, many poets made themselves the voices of economic, social and political dissatisfaction. In the 1930s Kenneth Fearing (1902–1961), Muriel Rukeyser (1913–) and others in the United States, W. H. Auden (1907–), Stephen Spender (1909–), Cecil Day Lewis (1904–), Louis MacNeice (1907–) and others in England composed poems which in style. versification and theme had nothing to do with the poetry of which Yeats and Eliot had become the chief exemplars. In most instances they based upon poets like John Davidson, Thomas Hardy or Wilfred Owen; the problems which they confronted were practical problems, and they sought practical solutions to them. They were critics of uhat they took to be a sick society, and they were not averse to making poetry openly didactic, or, in the case of such as were Marxists, propagandistic.

World War II wrought changes in belief and feeling which produced a reaction against this poetry as well. A host of new schools arose; different as these were in character, they had in common a greater concern with individual feelings and ideas. German models —in particular, Johann Holderlin and Rainer Marie Rilke—now supplanted the French.

The 1940s brought to wide attention Karl Shapiro (1913–), Elizabeth Bishop (1911–). Richard Eberhart (1904–), Delmore Schwartz (1913–), John Berryman (1914–), Randall Jarrell (1914–), Robert Lowell (1917–), Richard Wilbur (1921–) and Anthony Hecht (1923–) in the United States; in England. Vernon Watkins (1906–), George Barker (1913–), W. R. Rodgers (1911–), Alex Comfort (1920–), Lawrence Durrell (1912–), Roy Fuller (1912–), F. T. Prince (1912–) and. above all, Dylan Thomas (1914–53). The latter produced a mysterious, violent and eloquent poetry which led many to consider him the greatest lyric poet of the age. Many considerable poetic talents began to appear in the 1950s; perhaps Philip Larkin in England and Isabella Gardner in America were the most promising. A number had not, in the 1950s, received the acclaim they deserved; we may mention Jean Garrigue, Stanley J. Kunitz. Reuel Denney and Kenneth Rexroth, all U.S.; Kathleen Raine, Keidrych Rhys, Ruthven Todd, Hugh MacDiarmid and others in Great Britain.

Seen as a whole. 20th-century poetry exhibits certain striking characteristics, It began in antiromanticism; yet, despite T. E. Hulme's prediction in 1913 that a classical age was at hand. the poetry of the period remained essentially romantic; it simply passed from overt to covert romanticism, from romantic exuberance to romantic asceticism. It extended enormously the conception of human 'experience. and with it the subject matter of poems; but certain kinds of subject matter dropped out—most notably the heroic and tragic—and certain poetic forms disappeared almost altogether. There is nothing that can strictly be called epic; indeed, with the exception of Bridges' *The Testament of Beauty,* Stephen Vincent Benét's *John Brown's Body,* Pound's *Cantos,* MacLeish's *Conquistador,* Spender's *Vienna* and a few other pieces, there was a general dearth of long poems. Despite notable plays in verse by Yeats, Eliot, MacLeish, Jeffers. Christopher Fry and others, there was no real restoration of verse drama to the stage; there were simply individual successes. Moreover, many of the verse plays were either too brief or too stylized to find production outside of the "art theatre." The finest poets of the period were highly specialized. even esoteric. Yeats. Frost. Eliot, Stevens, Moore, Auden and Thomas are of almost unquestionable greatness, but whatever their genius. they are poets of very limited range as compared with Chaucer, Shakespeare and Browning, and some of them are so difficult that. once their vogue is past, they may quite possibly appeal to a very restricted audience only.

The period began with protests against poetic "artificiality" and with demands for a more "natural" language; but the greater part of its productions were highly stylized and artificial, and far removed from common speech. It began with the highly experimental, but it gave signs of a return to extreme formalism. It began with a clamour for nationalism, even regionalism; it turned to cosmopolitanism and internationalism. Save for differences of language, the U.S. or British poet of the mid-20th century difiered very little from poets writing almost anywhere else on the face of the earth. Indeed, it could plausibly be maintained that the unity of culture and tradition—the disruption of which so much troubled the poets of the earlier decades—had simply been replaced by the unity of a cosmopolitan. an international culture; that the chaos and disorder were merely part of a reintegration toward a new order, in which poets would draw, not merely from the traditions of their own society and nation, but also from international sources.

POEY Y ALOY, FELIPE (1799–1891), Cuban naturalist, author of a ten-volume *Catálogo razonado de los peces cubanos,* was born in Havana on May 26, 1799. He received his degree in law at the University of Madrid (1820) but abandoned practice to devote himself to natural history. He returned to Cuba and formed a collection which he carried back to Paris. There he remained until 1833, publishing many articles and his *Centurie de Lepidopteres de l'ile de Cuba* (1832).

Poey became professor of zoology and comparative anatomy in the University of Havana in 1842 and in 1863 was appointed to the chair of botany, mineralogy and geology. From 1873 until his death at Havana on Jan. 28, 1891, he was professor of philosophy and belles-lettres.

Poey's masterpiece is the *Catálogo,* an atlas describing 800 tropical fish, about half of which he first made known to science.

POGGIO (1380–14jg). Gian Francesco Poggio Bracciolini, Italian scholar of the Renaissance, was born in 1380 at Terranuova, a village. in the territory of Florence. He studied Latin under John of Ravenna and Greek under Manuel Chrysoloras. His distinguished abilities and his dexterity as a copyist of manuscripts brought him into early notice with the chief scholars of Florence. Coluccio Salutati and Niccolo de' Niccoli befriended him, and in the year 1402 or 1403 he was received into the service of the Roman curia. His functions were those of a secretary; and, though he profited by benefices conferred on him in lieu of salary, he remained a layman to the end of his life. It is noticeable that, while he held his office in the curia through that momentous period of 50 years which witnessed the councils of Constance and of Basle and the final restoration of the papacy under Nicholas V. his sympathies were never attracted to ecclesiastical affairs. Nothing marks the secular attitude of the Italians at an epoch which decided the future course of both Renaissance and Reformation more strongly than the mundane proclivities of this apostolic secretary, heart and soul devoted to the resuscitation of classical studies amid conflicts of popes and antipopes, cardinals and councils, in all of which he bore an official part. Thus, when his duties called him to Constance in 1414, he employed his leisure in exploring the libraries of Swiss and Swabian convents. The treasures he brought to light at Reichenau, Weingarten and, above all, St. Gall restored many lost masterpieces of Latin literature. and supplied students with the texts of authors whose works had hitherto been accessible only in mutilated copies. In one of his epistles he describes how he recovered Quintilian, part of Valerius Flaccus and the commentaries of Asconius Pedianus at St. Gall.

Manuscripts of Lucretius, Columella, Silius Italicus, Manilius and Vitruvius were unearthed, copied by his hand and communicated to the learned. Wherever Poggio went he carried on the same industry of research. At Langres he discovered Cicero's *Oration for Caecina,* at Monte Cassino a manuscript of Frontinus. He also could boast of having recovered Ammianus Marcellinus, Nonius Marcellus, Probus, Flavius Caper and Eutyches. If a codex could not be obtained by fair means, he was ready to use fraud. as when he bribed a monk to abstract a Livy and an Ammianus from the convent library of Hersfield.

Poggio embraced the whole sphere of contemporary studies, and distinguished himself as an orator, a writer of rhetorical treatises. a panegyrist of the dead, a violent impugner of the living, a translator from the Greek. an epistolographer and grave historian and a facetious compiler of fabliaux in Latin. Of his moral essays it may suffice to notice the dissertations *On Nobility, On Vicissitudes* of *Fortune, On the Misery of Human Life, On the Infelicity of Princes* and *On Marriage in Old Age.* These compositions belonged to a species which, since Petrarch set the fashion, were very popular among Italian scholars. They have lost their value, except for the few matters of fact which are embedded in a mass of commonplace meditation, and for occasional brilliant illustrations.

Poggio's *History of Florence,* written in avowed imitation of Livy's manner, requires separate mention, since it exemplifies by its defects the weakness of that merely stylistic treatment which deprived so much of Bruni's. Carlo Aretino's and Bembo's work of historical weight. A somewhat different criticism must be passed on the *Facetiae,* a collection of humorous and indecent tales expressed in such Latinity as Poggio could command. This book is chiefly remarkable for its unsparing satires on the monastic orders and the secular clergy.

Among his contemporaries Poggio passed for one of the most formidable polemical or gladiatorial rhetoricians; and a considerable section of his extant works are invectives. One of these, the *Dialogue Against Hypocrites,* was aimed in a spirit of vindictive hatred at the vices of ecclesiastics; another, written at the request of Nicholas V. covered the antipope Felix with scurrilous abuse. But his most famous compositions in this kind are the personal invectives which he discharged against Filelfo and Valla. All the resources of a copious and unclean Latin vocabulary were employed to degrade the objects of his satire; and every crime of which humanity is capable was ascribed to them without discrimination. In Filelfo and Valla, Poggio found his match; and Italy was amused for years with the spectacle of their indecent combats.

About the year 1452 Poggio finally retired to Florence, where he was admitted to the burghership, and on the death of Carlo

Aretino in 1453 was appointed chancellor and historiographer to the republic. His declining days were spent in the discharge of his honourable Florentine office and in the composition of his history. He died in 1459.

Poggio's works were printed at Basle in 1538, "ex aedibus Henrici Petri." Shepherd, *Life of Poggio Bracciolini* (1802), is a good authority on his biography. For his position in the history of the revival, *see* Voigt, *Wiederbelebung des classischen Alterthums*, 3rd ed. (1893); Symonds, *Renaissance in Italy* (1875–86). (J. A. S; X.)

POGROM is a Russian word that became naturalized in other languages about 1903–05. Originally the word for "storm," pogrom came in the course of time to mean any devastation or desolation; then specifically the planned rapine and murder of helpless Jews by their government-led or government-approved Russian neighbours; later, devastation of Jews by their neighbours in other countries (conspicuously Rumania, Poland and Nazi Germany); and finally such devastation anywhere of any helpless, undefended people. Examples include U.S. Negroes as victimized by lynch mobs in the south or in such cities as Chicago, Ill., and Detroit, Mich.; strikers attacked, with the active approval or passive sympathy of police power, by gunmen hired for the purpose; multitudes gathered to protest some grievance shot and ridden down as in the case of the St. Petersburg crowd before the Winter palace in 1905; and the massacre of Hindus at Amritsar, India, in 1919. Massacre is sometimes used as a synonym for pogrom, but pogrom includes looting and destruction of property as well as slaughter of innocents. Looting and destruction without slaughter is called dry pogrom.

The occasion which established pogrom in the world's languages as a contribution of tsarist culture was the devastation of the Jews of Kishinev, in the Ukraine, in April 1903. Widely discussed and condemned throughout the civilized world, it was one pogrom in a series implementing an anti-Jewish program devised by Constantine Pobedonostsev, procurator of the Holy synod under the reactionary tsar Alexander III, and executed by successive ministers of state, of whom Viatscheslaf Plehve was outstanding. Faced by popular discontent and intellectual agitation, the bureaucracy found in the Jews a convenient scapegoat for the government's failures. The Kishinev pogrom was followed by that at Gomel, Russia, in Aug. 1903. The conscription for the unpopular war with Japan brought continuous "mobilization pogroms"; Russia's defeat and the abortive revolution of 1905 brought the "patriotic pogroms" led by the Black Hundreds with the slogan: "The enemies of Christ are the only enemies of the Tsar."

POINCARÉ, (JULES) HENRI (1854–1912), French mathematician and philosopher of science, who at the turn of the century was generally acknowledged to be the outstanding mathematician of his age, was born at Nancy on April 29, 1854. He was a first cousin of Raymond Poincaré, president of the French republic during World War I. After attending the École Polytechnique, Henri Poincaré entered the École des Mines. In 1879 he was appointed to a mathematical post at Caen university. In 1881 he moved to Paris university, where he lectured in turn on almost all branches of pure and applied mathematics. He was a prolific writer, producing more than 30 books and 500 original memoirs.

Poincaré's first great achievement was in pure mathematics. He generalized the idea of functional periodicity in his theory of automorphic functions which are invariant under a denumerably infinite group of linear fractional transformations. He showed how these functions can be used to integrate linear differential equations with rational algebraic coefficients and also to uniformize algebraic curves; *i.e.,* to express the co-ordinates of any point of an algebraic curve as uniform functions of a single parameter. The class of automorphic functions which he called Fuchsian, after the German mathematician I. L. Fuchs (1833–1902), he found to be associated with transformations arising in non-Euclidean geometry.

In celestial mechanics he made important contributions to the theory of orbits, particularly in connection with the classical three-body problem. In the course of this work he developed powerful new mathematical techniques, including the theories of asymptotic expansions and integral invariants, and he made fundamental discoveries on the behaviour of the integral curves of differential equations near singularities. His researches on new mathematical methods in astronomy were summed up in his great three-volume treatise *Les Me'thodes nouvelles de la Mécanique céleste* (1892, 1893 and 1899). In his theory of periodic orbits he founded the subject of topological dynamics. His memoirs on *analysis situs,* as it was then called, mark the beginning of modern topology.

Poincaré made important contributions to the theory of the figures of equilibrium of rotating fluid masses, and in particular discovered the pear-shaped figures which played so prominent a part in the researches of G. H. Darwin. J. H. Jeans and A. M. Liapunov. But his greatest contribution to mathematical physics was his famous paper on the dynamics of the electron published in 1906. In this paper he obtained, independently of Einstein, many of the results of the special theory of relativity. The principal difference was that Einstein developed the theory from elementary considerations concerning light signaling, whereas Poincaré's treatment was based on the full theory of electromagnetism and so was essentially restricted to phenomena associated with the latter.

Poincaré's writings on the philosophy of science, gathered together in his books *La Science et l'hypothèse* (1903; Eng. trans., 1905), *La Valeur* de *la Science* (1904) and *Science et Me'thode* (1908; Eng. trans., 1914), were no less important than his contributions to mathematics. He was a forerunner of the modern intuitionist school founded by L. E. J. Brouwer and believed that some mathemetical ideas precede logic. In one of the most famous of his essays he made an original analysis of the psychology of mathematical discovery and invention. But the greatest of his contributions to philosophy was his emphasis on the role played by convention in scientific method.

In his writings on philosophical topics Poincaré revealed himself as a master of French prose and was read by thousands in all walks of life. He was elected to the Académie Française in 1908 to fill the vacancy caused by the death of the poet R. F. A. P. Sully Prudhomme. Poincaré died in Paris on July 17, 1912.

See J. S. Hadamard, *The Early Scientific Work of Henri Poincaré* (1922), *The Later Scientific Work of Henri Poincaré* (1933). (G. J. Ww.)

POINCARÉ, RAYMOND (1860–1934), French statesman, was born at Bar-le-duc on Aug. 20, 1860, the son of Nicolas Poincaré, a distinguished civil servant and meteorologist. Educated at the University of Paris, Raymond was called to the Paris bar, and was for some time law editor of the *Voltaire*. He had served for over a year in the department of agriculture when in 1887 he was elected deputy for the Meuse. He made a great reputation in the chamber as an economist, and sat on the budget commissions of 1890–91 and 1892. He was minister of education, fine arts and religion in the first cabinet (April–Nov. 1893) of Charles Dupuy, and minister of finance in the second and third (May 1894–Jan. 1895). In the succeeding Ribot cabinet Poincaré became minister of public instruction. Although he was excluded from the Radical cabinet which followed, the revised scheme of death duties proposed by the new ministry was based upon his proposals of the previous year. He became vice-president of the chamber in the autumn of 1895, and in spite of the bitter hostility of the Radicals retained his position in 1896–97.

In March 1906 Poincaré became minister of finance in the Sarrien government, but he gave up his portfolio to Caillaux in October of the same year, when Sarrien was succeeded by Clemenceau as prime minister. During the next five years, though he still continued to exercise a powerful influence in the senate, Poincaré devoted himself mainly to his legal career. In 1909 he was elected a member of the French Academy. In Jan. 1912, Caillaux, who had been prime minister from the beginning of the previous year, resigned, whereupon Poincaré formed a government in which he himself held the portfolio of foreign affairs.

Poincaré's cabinet constituted an *entente netionale,* and his first aim was to pursue a more definite foreign policy. In home affairs the problem which presented the greatest difficulties was that of electoral reform. Poincaré induced the chamber to pass a proportional representation bill. But above all diplomatic affairs claimed his constant attention; for during the negotiations with Germany which took place in consequence of the dispatch of a gunboat by that country to Agadir, certain incidents had occurred during the Caillaux administration which had produced a feeling of disquietude in regard to foreign policy. Poincaré therefore sought to re-establish a continuity of policy; and though he maintained courteous relations with Germany his main endeavour was to prove that France would remain faithful to both friends and allies. The ratification by the senate of the Franco-German treaty of Nov. 4, 1911, was followed by France's definite establishment in hlorocco.

Almost immediately after the establishment of the Poincaré government, the Italians, who at that moment were at war with the Turks, seized two French mail steamers. Poincaré, by his calmness and resolution. succeeded in re-establishing amicable relations between the two countries. By the end of October Italian sovereignty in Libya was recognized, and by a mutual declaration of the two governments, full liberty of action was granted to France in Morocco and to Italy in Libya. When in the autumn of 1912 the Balkan War broke out, Poincaré made every effort possible to prevent the conflagration from spreading. On Jan. 17, 1913, Poincaré was elected president of the republic in place of Fallières. In power, he endeavoured to cement the friendships and strengthen the alliances of France. (*See* FRANCE: History.) He claimed that he did his utmost to avert war, holding that the way to prevent the conflict was for those poners against nhom the menace was directed to present a powerful and united front, thus making it imprudent to attempt any act of aggression.

In July 1914 Poincaré went to Russia on a visit which had been planned for some time past. He was on his way home when the news of the Austrian ultimatum to Serbia reached him. After a short stay in Stockholm he returned hastily to Paris; and in a letter to King George V he pleaded for a clear declaration that the entente cordiale. if necessary, would prove its strength on the battlefield, pointing out that such a statement would have a restraining effect on the policy of Vienna and Berlin. In Nov. 1917 he gave proof of his vision and disregard of self by placing in power Clemenceau, who, though undoubtedly the man of the moment, was one with whom he had little sympathy. During the critical months of 1918. Poincaré revealed an inflexible resolution and a supreme confidence in the ultimate victory.

During the peace negotiations divergence of views again became apparent between Poincaré and Clemenceau. On more than one occasion the president found it necessary to write to the prime minister pointing out the errors which. from his point of view, were being committed. His counsels. however, were not followed, and at the beginning of 1920, after having completed seven years as president, he left the Elysée and was shortly after re-elected senator for the department of the Meuse. In Jan. 1922, the Briand cabinet having resigned, Poincaré once more became prime minister and minister for foreign affairs. He made it his chief aim to insist on the fulfillment by Germany of its obligations in regard to reparations. During the first year of his new government he failed to arrive at any agreement on this subject with the British cabinet, whose views differed so widely from his own. The Inter-Allied conference in London in Aug. and Dec. 1922 produced no result. A further conference took place in Paris on Jan. 2 and 5, 1923. But Poincaré rejected the proposals drawn up by Bonar Law.

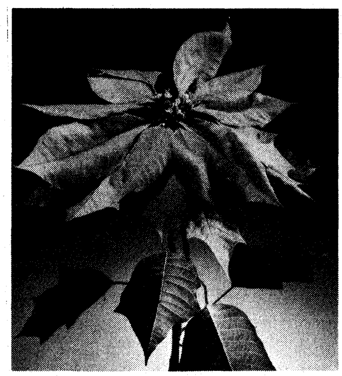
At this moment, the Reparations commission, with Britain dissenting, having declared that Germany had failed to fulfill its obligations in regard to the delivery of coal and coke, Poincaré, in agreement with Belgium, undertook the occupation of the Ruhr (*q.v.*). At first this measure involved merely a method of control, but gradually, because of the passive resistance of the Germans, it became necessary to exploit the railways and to some extent also the mines by means of Franco-British supervision. But by autumn the passive resistance had ceased. and Poincaré awaited the German proposals which never came. He then accepted the U.S. suggestion that a group of experts should be given the task of finding the solution of the reparation problem; this resulted in the adoption of the Dawes plan. But Poincaré had made up his mind not to withdraw from the Ruhr until he was satisfied that this plan was being carried out.

During the first three months of 1924 Poincaré had to face a financial crisis because of the state of the exchange. Not without difficulty he induced parliament to vote new taxes and succeeded in saving the situation. But from now onward he had to withstand strenuous opposition from the parties of the left consisting of the Radicals and Socialists. The policy of these groups met with a marked success at the general elections of May 11, 1924, and resulted in a majority for the left which now formed a coalition under the name of the Cartel des Gauches. Immediately the results were announced, Poincaré stated that he would retire on the day when the new chamber was to assemble, which took place on June 1, 1924.

Thenceforward he took his place in the senate, intervening only rarely in political debates. But he was to come into power once more. When, in the middle of the summer of 1926, the financial crisis, which successive cabinets since 1924 had been unable to check, became more and more serious, public opinion saw in him the only man capable of meeting the situation. After the fall of the Briand-Caillaux cabinet, which only lasted a few weeks, and of the Herriot cabinet. which only existed a few hours, Poincaré, in the last days of July, formed a ministry which included both moderate Republicans and Radical-Socialists, and had as its object the stabilization of French finances by means of a policy of national union. Public opinion was immediately reassured. At the beginning of August the ministry caused the national assembly, meeting at Versailles, to pass, as articles embodied in the constitution, and therefore not at the mercy of political changes, regulations for the establishment of an automatic sinking fund, to which would be attributed funds which could not be touched (death duties, revenues from the tobacco monopoly, etc.).

In three months he succeeded in raising the value of the franc from 264 fr. to the pound sterling, to 124. This rate mas achieved in Dec. 1926, and thenceforward the value of the franc did not fluctuate. For a year and a half Poincaré, who had restored a strict financial equilibrium, maintained this stabilization of the currency *de facto*. The general election of April 1928 having returned a majority which approved of his policy, a law was voted in June by the new assembly, and by the senate, establishing the stabilization *de jure*. It was one of the most successful operations of this nature in history. Withdrawal of the Radical-Socialist support from his government, engineered by Caillaux, caused his resignation on Nov. 7, 1928, but he formed a new ministry on Nov. 12. He resigned because of illness, on July 27, 1929. Poincaré undertook the publication of an important work in 10 volumes, entitled *Au service de la France; neuf années de souvenirs,* the plan of which is to describe the sequence of events from 1911 to 1920 and the role he played in them. Four of these volumes appeared in 1926, 1927 and 1928 under the titles of *Le Lendemain d'Agadir, Les Balkans en feu, L'Europe sous les armes,* and *L'Union sacrée*. He died Oct. 15, 1934. (P. B.)

POINSETTIA, a showy tropical shrub of the Euphorbiaceae (*q.v.*) family, native to Mexico and Central America. It is the traditional flower of the Christmas season, known scientifically as *Euphorbia pulcherrima,* meaning most beautiful. The poinsettia was named after Joel R. Poinsett of Charleston, S.C., who introduced the plant to the Cnited States in 1828 when he was minister to Mexico. The true flowers of the poinsettia are inconspicuous, forming a yellow cluster in the centre of the red, white or pink bracts. In the rarer double poinsettia most of the flowers have been trans-



ROCHE

COMMON POINSETTIA (EUPHORBIA PULCHERRIMA) formed into bracts giving a more showy effect.

The poinsettia is abundantly used as a yuletide gift plant in the north, while in Florida and other tropical lands it is a popular flowering shrub.

When used as a gift plant it should be placed in a room with constant temperature as it cannot tolerate drafts or fluctuating temperatures. It needs plenty of water while blooming. Although it is possible to carry a plant over from one year to the next, it is not advisable unless greenhouse facilities are available. Poinsettias are propagated by cuttings in March. (R. T. V. T.)

POINT FOUR PLAN, a program advocated by Pres. Harry S. Truman as the fourth point of proposed U.S. policy in his inaugural address of Jan. 20, 1949. Point Four called for "a bold new program for making the benefits of our scientific advances and industrial progress available for the improvement and grouth of underdeveloped areas." Emphasizing a type of international, intergovernmental educational program that came to be known as technical assistance and that long had been carried out privately by missionaries and overseas branches of industrial corporations. Point Four, with massive economic aid as exemplified by the European recovery program, refugee and disaster assistance and military assistance. later formed one of the principal foreign aid activities of U.S. mutual security programs. Its principal focus has been on health, education and agriculture. *See* FOREIGN AID PROGRAMS; and for similar international activity, UNITED NATIONS.

POINT SETS. The study of the properties of point sets constitutes that branch of mathematics known as point sets, or the theory of sets of points, or the theory of aggregates. A point set is a collection of points selected from a given space. Generally speaking, the properties of a point set may be classified under two heads, (1) topological and (2) metric. For a description of the former *see* TOPOLOGY, GENERAL. *A* brief introduction to the metric properties of point sets is given below.

The Problem of Measure.—In order to approach the subject with as simple an example as possible, let us confine ourselves to the case where the given space is an ordinary straight line, L. If P and Q are distinct points of L. then the point set consisting of P and Q together with all points between them is called an interval and is denoted by [P,Q]. Let us imagine that we have a common foot rule which can be applied to L in order to measure lengths. Then given an interval [P,Q] we can measure its length and say that it is a certain number of feet Of a single point we would say, in accordance with the ordinary geometry notion. that its length is zero. If we are given two intervals which have no point in common, it is not natural to speak of the length of the set of points which they represent, the word length being usually applied only to connected pieces. In this case we shall use the word measure, and say that the measure of this point set is the sum of the lengths of the two intervals.

However, when we speak of a point set on L, this does not necessarily imply that we are thinking of an interval. a single point or a set of intervals; we sometimes mean to indicate a set of points which contains no connected portion; *i.e.,* which contains no interval. One might be tempted to say that since a point has length zero, the measure of such a set would be the sum of the lengths of its individual points; *i e.,* the sum of a set of zeros. and hence zero. Such a hasty decision would not lead to very fruitful results, however. for the following reason. If we determine upon a measure for two point sets, A and B. which have no points in common, the sum of their measures should naturally be the measure of the point set which is made up of A & B taken together. Thus. above, we have stated that the measure of a set consisting of two intervals with no common point is the sum of the lengths of those intervals. Now any interval [P,Q] can easily be shown to be the sum of two sets A and B each of which fails to contain any interval. and if we arbitrarily call the measure of both A and B zero, the sum of their measures would be zero, which is not the length of [P,Q], no matter how small the length of [P,Q]. In other words, we want a measure of a set of points which will correspond to the ordinary idea of length.

We have now introduced what is known, in the theory of sets of points, as the problem of measure. There have been several methods devised for finding a measure of an arbitrary set of points. We shall describe, briefly, the theory of Lebesgue measure. which is the foundation of the theory of integration formulated by H. L. Lebesgue in 1902.

Lebesgue Measure.—Any set, A, is said to be covered by a collection, G, of intervals, when every point of A is in some interval of G. If the set of intervals G is denumerable, then we shall say that it is a covering of A. (The set is called denumerable if its elements can be "tagged" with positive integers in such a way that no two elements of the set are "tagged" with the same integer.) If the sum of the lengths of the intervals of G exists, let us call this the sum-length of the covering. Now of all possible coverings of A consider the corresponding sum-lengths, and let N be the largest number which is not greater than any of these sum-lengths. Then N is called the exterior measure of A and is denoted by m_eA. Suppose, now, that [P,Q] is some interval, whose length we shall denote by d, such that all points of A are within [P,Q]. Let B be the set of all points of [P,Q] that do not belong to A, and let m_eB denote the exterior measure of B, found just as m_eA was found. If it happens that $m_eA + m_eB = d$, then m_eA is accepted as the measure of A, and is what is known as the Lebesgue measure of A. Of course we know at the same time that m_eB is the Lebesgue measure of B, and in accordance with our ideas of length we have required that the sum of the two measures give the length of [P,Q]. To be sure, the Lebesgue measure of a set of points may not exist, but it does exist for all ordinary point sets. Indeed it is not at all easy to give an example of a set of points which has no Lebesgue measure, and all those examples which have been given make use of certain methods which are held to be unacceptable by many mathematicians.

For the measure of a set of points in a plane, areas are employed. Thus, the measure of the set of all points in a square is the area of the square. And to get the measure of a general plane point set M, a covering of M is made by means of squares. In three dimensions cubes are employed, and we deal with sum-volumes.

The introduction of the notion of measure has led to an enriching of the content of general analysis that hardly could have been realized otherwise. The effect has been felt not only in mathematics itself, but in the closely allied fields of mechanics and dynamics. *See* also SET THEORY (THEORY OF AGGREGATES); FOURIER SERIES; FUNCTION: *History;* MATHEMATICS, HISTORY OF: *Modern Period.*

See E. W. Hobson, *The Theory of Functions of a Real Variable and the Theory of Fourier's Series (1921)';* Edward Kasner and James Newman, *Mathematics and the Imagination,* pp. *201–207 (1940).* (R. L. WI.)

POISON is a substance that, when taken into the mauth or stomach, or when absorbed into the blood, is capable of affecting health seriously or of destroying life by its action on the tissues with which it comes into contact immediately or after absorption. Toxicology is the science that embodies the knowledge of the sources, characters and properties of poisons, the symptom they produce, the nature of their fatal effects and the remedial measures that should be employed to combat their actions or effects.

Sale of Poison.—In the United States, the Caustic Poison act, 1927, safeguards the distribution and sale of certain dangerous caustic or corrosive acids, alkalies or other substances in interstate and foreign commerce. This act names 12 materials which are classified as dangerous, caustic or corrosive substances: hydrochloric acid, sulfuric acid, nitric acid, carbolic acid, oxalic acid, salt of oxalic acid, acetic acid, hypochlorous acid, sodium hydroxide, potassium hydroxide, ammonium hydroxide and silver nitrate. The Federal Food. Drug and Cosmetic act, 1938, successor of the Food and Drugs act, 1906, prohibits the movement in interstate commerce of adulterated and misbranded food, drugs, devices and cosmetics. Both the Caustic Poison act and the Federal Food, Drug and Cosmetic act are enforced by the Food and Drug administration. The U.S. public health service administers the Virus, Serum and Toxin act, 1902, which provides for the maintenance of potency and purity of biological products. The Harrison Narcotic act, 1914, and the Marihuana Tax act, 1937, are administered by the bureau of narcotics of the U.S. treasury department. These acts regulate the importation, sale or giving away of preparations of opium or coca leaves and of marijuana, respectively.

The following are the statutes governing the sale of poisons in Great Britain: Pharmacy and Poisons act. 1933; Poisons rules. 1935; Poisons (Colouring) rules. 1936; statutory rules and orders made in connection with the Pharmacy and Poisons act, 1933; Dangerous Drugs act, 1951; and statutory regulations and orders made in connection with them; Therapeutic Substances act, 1925; and Therapeutic Substances regulations. 1931–44.

The objects of these acts, put broadly, are to control the sale of poisons to the public and to reduce the danger to human life from indiscriminate sale by unqualified persons. The Dangerous Drugs acts regulate the use of drugs of addiction such as opium, morphine and cocaine. With certain exceptions, only duly qualified and registered pharmacists and registered medical practitioners are permitted to sell poisons.

Poisoning. — Poisoning may be accidental, suicidal or homicidal. By far the commonest type is poisoning from accidental causes. In spite of the precautions taken by the state in the sale of poisons, far too little care is taken by the public in the safeguarding of poisons in their possession. As a result, these are frequently taken by mistake instead of other substances of a harmless nature, or often an overdose is taken from pure carelessness. Thus, oxalic acid crystals when purchased in a paper packet may be transferred to an unlabeled bottle or jar and then taken by mistake for Epsom salts, which they closely resemble. Similarly. tablets of corrosive sublimate have been taken by mistake. It is the duty of every person possessing a substance of poisonous nature to take the utmost care that this is correctly labeled and kept safely guarded under lock and key.

Two poisons very commonly responsible for poisoning are Lysol and carbon monoxide. Both are usually present in the average home. Carbon monoxide is responsible for many deaths yearly as a result of accident or suicide. It is a constituent of illuminant gas; for example, town gas, when prepared in the vertical retort, may contain as much as 22% of carbon monoxide. Defective gas heaters. especially in bathrooms, and fractured gas pipes and mains may provide a source of poisoning. Exhaust gases from internal-combustion engines also cause poisoning. It has been estimated that such gases contain from 1% to 7% depending on the richness of the mixture. Self-administration of barbiturates is a dangerous practice, since the patient having already become confused by an initial dose of a barbituric compound may continue. on the same occasion, to take further and possibly fatal quantities of the drug without realizing the danger. This is the possible explanation of some of the acute and even fatal cases of barbiturate poisoning which might otherwise appear inexplicable.

ACTION OF POISONS

Poisons may have a local action or a general systemic action after absorption into the circulatory system. or they may act in both ways. Almost all poisons have a general systemic action. Some poisons such as corrosives destroy the mucous membrane or tissues with which they come in contact and cause serious or dangerous injury thereby. Irritant poisons set up a local inflammatory reaction in the mucous membrane of the alimentary tract.

Apart from these local effects, the common result of absorption of a poison is the harmful effect produced on the important organs of the body: for example, the liver, kidneys, heart and nervous system are almost certain to be adversely affected. A poison after absorption attacks all the organs of the body in varying degrees, and it is a mistake to regard poisons as being exclusively selective in their action though some poisons appear to direct the brunt of their attack on a particular system.

Among the conditions affecting the action of a poison may be mentioned the following:

Amount Taken. — From the point of view of dosage, potent drugs can be divided. in an arbitrary manner, into two groups: those in which the lethal dose lies far in excess of the active dose, and those in which it lies close to the active dose. There is a definite distinction between the terms "toxic dose" and "fatal dose," since the former merely causes symptoms of poisoning while the latter induces poisoning to such a degree that death results. The term "fatal dose" when applied to a poison means the smallest dose which is known to have caused death in an adult. Usually the quantity of a poison taken bears a relation to the effects produced. Exceptions to this rule are substances in the case of nhich, as a result of the quantity taken, vomiting occurs so that most of the poison is expelled; oxalic acid and tartar emetic are examples. Frequently larger doses may be taken without death resulting, but much depends on other factors than quantity, and also on whether adequate treatment has been adopted.

Habit. — A tolerance to some poisons occurs after their repeated use, and in some cases doses far greater than a normal fatal dose may be tolerated without serious symptoms developing. Examples of such drugs are arsenic, morphine, opium, cocaine and alcohol. In the case of some of these poisons their repeated use leads to addiction, with all its pernicious symptoms and effects.

Idiosyncrasy. — Some persons are exceedingly intolerant of certain drugs which in moderate doses may thus cause in them dangerous or even fatal symptoms. Examples are morphine, cocaine, quinine, iodine. bromine, salicylates and acetylsalicylic acid (aspirin), which in some persons have a severe cardiac depressant action.

Age. — Usually children are much more susceptible to the effects of a poison than adults. The dosage of drugs in the case of children has been fixed by a pharmacological rule, but exceptions to this are morphine, opium and its preparations which are much more toxic than the rule would indicate; on the other hand, children tolerate belladonna preparations better than adults. Aged persons withstand poisons badly.

State of Health. — A relatively small dose, from which a stronger person would probably recover, may kill a weakly person. In disease, drugs are usually much more toxic, and this is especially so where the excretory organs are affected. For example, in nephritis. medicinal doses of such drugs as morphine, salvarsan, hyoscine, etc., often cause dangerous symptoms; likewise in cirrhosis of the liver there is a greatly increased susceptibility to such drugs. In conditions of gastritis or enteritis, drugs like arsenic are especially toxic. On the other hand, in some conditions associated with delirium or pain, large doses of sedative drugs produce little effect provided that the excretory organs are healthy.

Condition and Mode of Administration. — If a poison is taken in solution, by the mouth, it acts much more powerfully than if taken in an insoluble form. For example, an insoluble preparation of arsenic may produce little poisonous effect even in large doses; similarly strychnine given in hard pills has a much-delayed action.

The presence of food in the stomach has a marked influence on the effect of a poison. If the stomach is empty the effect will be rapid. particularly so when the poison is in a soluble form; on the other hand, if the stomach is full, considerable delay may occur in the action of the poison as is well shown in acute arsenical poisoning.

A poison acts most rapidly when inhaled in a gaseous or vaporous form or when injected intravenously; next in order of rapidity, when injected subcutaneously; and least rapidly when ingested. Poisons may be absorbed by the skin or mucous membrane of the vagina or rectum, with fatal result.

Chemical Combination. — Some substances when in certain combinations are very poisonous, but when in others are comparatively innocuous. While the component parts of a mixture may have a poisonous action when administered singly, the compound may be comparatively inert.

Cumulative Action. — Certain poisons tend to accumulate within the body as the result of slow excretion (for example. strychnine, lead, mercury, digitalis and carbon monoxide) and therefore the continued administration of relatively small doses may occasion symptoms of poisoning.

DIAGNOSIS AND TREATMENT OF POISONING

Evidence of Poisoning.—It must be remembered that the symptoms of poisoning may be closely simulated by the symptoms of natural disease, and the greatest care must be taken before a diagnosis of poisoning is arrived at. Thus, the symptoms of acute arsenical poisoning closely resemble those of cholera or of acute bacterial food poisoning. The only certain differentiation is the finding of arsenic in the vomit. feces or urine, or of the bacteriological evidence of a cholera or food poisoning infection.

Various factors may provide evidence of poisoning: (1) The symptoms are usually sudden in their onset and they occur after the taking of food or drink, or after exposure to poisonous gases or vapours. (2) If several persons are similarly exposed all are affected more or less with similar symptoms. An exception may occur in the case of bacterial food poisoning, where certain persons may be relatively immune and some may be specially susceptible. (3) The analysis which should always be carried out in suspected cases may reveal the presence of the poison in the vomit. urine and feces, and possibly also in some articles of food or medicine.

Post-mortem Evidence.—If death occurs, a post-mortem examination should be made only following instructions from the appropriate official. The post-mortem signs found should be consistent with those occurring from poisoning by the suspected poison. The analysis of the viscera should yield results consistent with that of poisoning by the suspected poison. taking into account the circumstances of administration and death.

Treatment.—The mode of treatment to be adopted varies according to the nature of the poison.

The poison should be removed from the stomach without delay, antidotes should be administered, the poison should be eliminated from the body by natural channels, symptomatic treatment should be undertaken and stimulation of the respiratory and circulatory systems should be resorted to immediately indications present themselves. Emetics are a poor substitute for the emptying and washing out of the stomach by means of the funnel and stomach tube, but they may be employed if the more effective treatment is impossible. Safe emetics are mustard and water, salt and water, ammonium carbonate or apomorphine. The emptying and washing out of the stomach by means of the stomach tube and funnel is, however, contraindicated when poisoning occurs from the corrosive mineral acids or alkalies. In such cases there is a danger of perforation. After the stomach has been emptied and washed out, suitable antidotes should be given, such as chalk and lime water to neutralize oxalic acid and the mineral acids, lime water for carbolic acid. Atropine may be given hypodermically in the case of morphine poisoning. Where morphia and cocaine are taken. the stomach should be washed out with diluted permanganate of potash solution.

Elimination by the bowel is facilitated by colon washes with warm normal saline solution and by free bowel evacuations. The symptoms of poisoning are subdued by the administration of appropriate remedies; thus, pain may be relieved by hypodermic injection of morphine, and the convulsions from strychnine by chloroform inhalation.

CHARACTERISTICS OF DIFFERENT POISONS

Poisons may be classified in many different ways; *e.g.*, according to their chemical composition, to their action on the body, to their physical characters, etc.

The following is a convenient and simple classification.

1. Corrosive poisons are those which destroy by direct action the tissues with which they come in contact. To this category belong the mineral acids, such as sulfuric. hydrochloric, nitric, etc.; the caustic alkalies. such as caustic soda, caustic potash. ammonia. carbolic acid; metallic poisons. such as corrosive sublimate, zinc chloride, silver nitrate. The last mentioned will also be considered under irritant poisons. It should be remembered that corrosive poisons in diluted condition lose their corrosive effect and become irritants.

2. Irritant poisons, by their direct action on the mucous membrane, set up inflammation. Examples are: oxalic acid and its soluble salts; arsenic compounds and antimony compounds; most of the metallic poisons in solution; phosphorus; bromine; iodine; boracic acid, etc.

3. Systemic poisons which act on the nervous system or other important organs such as the heart, liver, lungs or kidneys without having any special irritant or corrosive effect. This group includes the majority of poisonous substances such as the vegetable poisons or their alkaloids, hydrocyanic acid and its salts, chloral, chloroform, alcohol, ether, hypnotic drugs such as veronal, sulfonal, etc. Certain poisons affect the liver and produce toxic jaundice (for example, tetrachlorethane, trinitrotoluene, picric acid, etc.), while others. such as cantharides and turpentine, involve the kidneys.

4. Gaseous poisons such as chlorine, carbon monoxide and coal gas, carbon dioxide, etc.

5. Poisonous foods such as mushrooms, shellfish and food contaminated with dangerous pathogenic bacteria.

Corrosive Poisons

Symptoms.—Corrosive poisons produce severe symptoms immediately they are taken—a burning pain in the mouth, throat and esophagus and pain referred from the stomach and intestines. Vomiting occurs quickly and the vomit contains blood which may be altered in colour by the action of the poison; often also shreds of destroyed mucosa are present. Collapse occurs early; and perforation is common when, should the patient survive, signs of general peritonitis develop.

An examination of the patient will show signs of the corrosive action of the poison on the mouth and throat, and marked tenderness will be present on palpation over the stomach and intestine. Corrosive poisons if swallowed in poisonous quantity are usually fatal within 24 hours unless immediate treatment with a suitable antidote is adopted.

Should the patient survive the immediate effects of the poison, serious aftereffects result from damage to the alimentary tract, and in the case of volatile corrosives serious pulmonary complications often ensue. Post-mortem examination shows evidence of the destructive action of the poison on the mucous membrane of the mouth, throat, esophagus and stomach, there being often extensive hemorrhage in the underlying tissues.

Among examples of corrosive poisons may be named:

Corrosive Mineral Acids.—These include *sulfuric acid,* commonly known as oil of vitriol; this is used in various industries and in all chemical laboratories. It is a most powerful corrosive in the concentrated form, whether taken internally or applied externally as in cases of "vitriol throwing." One dram has caused death in an adult, and half that quantity in a child.

Hydrochloric acid is known also as muriatic acid or spirits of salts. It is used largely for industrial and chemical purposes and is a common article of domestic use. It is readily obtainable and is very commonly used for suicidal purposes. It is a most dangerous corrosive and one dram has caused death in an adult.

Nitric acid, known as aqua fortis and red spirit of nitre, is used for industrial and chemical purposes. It is a most dangerous corrosive and produces characteristic yellow staining of the tissues with uhich the strong acid comes in contact. The vapour of the acid, if inhaled into the lungs, often produces an acute fatal form of pneumonia which is a common cause of death in nitric acid poisoning.

Other mineral acids such as *hydrofluoric, phosphoric* and *sulfurous* acids in concentrated form produce similar effects.

The treatment of poisoning by corrosive mineral acids consists in giving as soon as possible harmless alkaline remedies such as magnesia powder, milk of magnesia, lime water or chalk. These should be administered freely, and plenty of egg albumen (white of egg) should also be given, since this tends to neutralize the acid by forming a protein combination, and also it has a soothing effect on the damaged mucosa.

The stomach should not be washed out for fear of perforation. Pain is relieved by the free use of morphine hypodermically, and after the swallowed acid has been neutralized food should be withheld by the mouth and normal saline given as freely as can be retained per rectum. In urgent cases of circulatory shock, caused by fluid loss and blood concentration, continuous intravenous infusion of normal saline, or saline with glucose, should be carried out.

Caustic Alkalies.—Among these may be named the following: *caustic potash* or potassium hydrate or potash lye is a powerful corrosive, and *potassium carbonate,* known as salt of tartar, has a similar but less powerful effect. Both are used industrially. Forty grains of caustic potash have caused death.

Caustic soda or sodium hydrate or soda lye is a powerful corrosive and quite as dangerous as caustic potash. It is commonly used industrially.

Ammonia, liquid ammonia or spirits of hartshorn is used largely for domestic and industrial purposes. It is also used in the form of smelling salts when mixed with carbonate of ammonia. It is a powerful corrosive poison and in addition the vapour has a very injurious effect on the lungs, giving rise to bronchopneumonia which may assume a septic type.

As regards treatment following ingestion, harmless acid drinks such as diluted vinegar, lemon juice, citric or tartaric acid should be given freely. Olive oil or egg albumen may be usefully employed. Pain should be relieved by the free use of morphine hypodermically and nourishment should not be given by the mouth, but rectal feeding adopted.

Corrosive Organic Acids.—*Carbolic acid,* or phenol, is commonly used as a disinfectant for domestic and surgical purposes. Allied preparations such as creosote or cresol have a similar poisonous effect. Lysol is a combination of cresol with soap and is similar in action to phenol.

Carbolic acid and the allied substances have a powerful corrosive action causing necrosis of the tissues with which they come in contact, the superficial part of which becomes of whitish appearance, the deeper parts becoming dark red as a result of hemorrhage into them. Carbolic acid is one of the poisons most frequently used by suicides, and because of its common use for domestic purposes is also a frequent cause of accidental poisoning.

The symptoms caused by carbolic acid are those of corrosive poisoning, but because of its local anesthetic action vomiting may be absent and pain may be less marked. If death does not result from shock, the profound effect of the poison on the nervous system causes paralysis of the respiratory and cardiac centres, with rapid feeble pulse and stertorous breathing; coma develops in severe cases and is usually followed by death. Death has also resulted from absorption by the skin, and from rectal injections in solution. Usually death occurs within three to four hours following ingestion of a large dose.

The aim of treatment is to limit the absorption of the poison, to sustain the patient and to aid the elimination of the poison from the system. The stomach should be washed out by means of a soft stomach tube with diluted saccharated lime water or fresh lime water; by this means the phenol is converted into calcium phenate which is not poisonous. Alternatively, thorough gastric lavage, using a 10% solution of glycerin, or plain water, should be carried out without delay until the washings no longer emit an odour, and a quantity of medicinal paraffin should be left in the stomach. Egg albumen, since it precipitates phenol, will delay absorption. When necessary, rectal feeding should be adopted for several days.

Irritant Poisons

The more important irritant poisons will be considered under this heading *(see* list, above), but it must be remembered that many of the general poisons (*e.g.,* savin, cantharides, etc.) have an irritant action on the stomach and intestines in addition to their special action on important organs and nerve centres.

Oxalic acid occurs in colourless crystals resembling Epsom salts; it is very soluble in water. *Salts of sorrel* or *salts of lemon* is the quadrioxalate of potash; it is a white powder very soluble in water. Both of these substances are commonly used for domestic purposes; *e.g.,* for cleaning straw hats, removing ink stains, cleaning brasses, etc. They are frequently the cause of accidental and of suicidal poisoning.

When swallowed in solution the typical symptoms of irritant poisoning are set up. but in addition the poison when absorbed into the system has a profound depressant action on the heart and nervous system. Thus an acrid burning taste is experienced and pain occurs which is referred from the throat, esophagus and stomach and later possibly from the intestines. Vomiting is common, the vomit being very acid, and giving positive results to the tests for oxalic acid. It often contains blood. Unless immediate treatment is adopted collapse speedily occurs. the patient becoming cold, pale and faint with a rapid feeble pulse; at this stage death from syncope may occur. In some cases nervous symptoms such as tinglings and numbness, muscular spasms, convulsions, delirium and coma occur, but these symptoms are uncommon. Because of the rapid absorption of the poison death is likely to occur rapidly (*e.g.,* within an hour), but it may be delayed.

For treatment, fresh lime water or, preferably, saccharated lime water which is 15 times as strong, should be given in large quantities and it should be mixed with calcium carbonate in the form of chalk or whiting. Since oxalic acid has only slight corrosive action the stomach should be washed out immediately if no antidote is at hand. It is best to give the antidote freely if immediately available and after a few minutes to wash out the stomach thoroughly with a soft stomach tube and funnel, and then finally introduce a pint of lime water made into a thin cream with an ounce of chalk, leaving this mixture in the stomach. Intravenous injections of calcium chloride or gluconate (calcium Sandoz) are recommended.

Arsenic is the most important of the irritant poisons and because of the tasteless property of many of its compounds and preparations it is the commonest poison used for homicidal purposes.

The most notable and commonest compound is arsenious acid, arsenious oxide or white arsenic. It exists in the form of a white powder or in lumps of a white porcelainlike appearance. The powdered form resembles powdered sugar or flour and when mixed with food is almost tasteless. It is sparingly soluble in cold water, which will dissolve only 0.03 to 0.06 g. in 30 ml. About 4 g. in 30 ml., however, will be held in boiling water. When mixed with alkaline substances, white arsenic becomes freely soluble.

Commercial preparations containing white arsenic mixed with alkalies such as sodium hydrate or carbonate are weed killers, sheep-dip and wood preservatives which may contain from 20% to 40% of white arsenic. Copper arsenite (Scheele's green), lead arsenate and other arsenical preparations are used as insecticides for the spraying of fruit trees. Rat poisons may contain arsenic as the active ingredient. Wallpapers which formerly often contained green pigment (Scheele's green) or the yellow sulfides of arsenic are now coloured with arsenic-free pigments, arsenic being prohibited from use. White arsenic, if sold for other than medicinal purposes, must be mixed with a dye of distinctive colour which is water soluble.

Accidental contamination of food with arsenic has occurred in the past. Thus in 1900 a beer poisoning epidemic occurred as the result of the use of commercial glucose which contained arsenic in the preparation of beer. Prosecutions have been brought for the presence on apples of prohibitive amounts of arsenic alleged to have been caused by spraying of trees.

When arsenic is taken by the mouth in poisonous quantities, symptoms of acute gastrointestinal irritation such as vomiting, diarrhea and abdominal pain usually occur within a few hours. Death may ensue within a period varying from several hours to several days. A dose of 0.12 g. of arsenic has caused death, though larger quantities have been taken without fatal result. In acute arsenical poisoning the heart, kidneys and other organs are seriously affected so that the poison has a systemic action in addition to its irritant properties to the stomach and intestines.

Chronic arsenical poisoning occurs when small quantities of arsenic are absorbed over long periods. The gastrointestinal symptoms may be slight, but other symptoms, such as gradual loss of weight, alopecia, skin rashes and pigmentation and conjunctivitis. become manifest.

In suspected acute arsenical poisoning the diagnosis can be made certain by analysis of the vomit, urine and feces. In chronic cases additional information may be obtained by analysis of the hair and nails.

Antimony is an irritant poison like arsenic. Tartar emetic or potassium antimony tartrate is one of the most commonly used compounds. It has on several occasions been used for homicidal purposes because of the possibility of its being administered without detection by taste or smell.

Metallic poisons if taken by the mouth give rise to irritant poisoning. Examples are:

In large doses, the common salts of lead will cause gastrointestinal irritation. Acute poisoning by lead is rare. Chronic lead poisoning is caused by continued absorption of small quantities of lead and is a dangerous condition as it causes disease of the kidneys, blood vessels, heart and nervous system. Lead tetraethyl is a very poisonous organic compound of lead. It is used commercially as a constituent of ethyl gasoline, and is claimed to counteract "knocking" or "pinking" in motor engines. On inhalation in sufficient quantity it is extremely toxic. The sulfate of copper (blue vitriol) and other copper compounds are irritant poisons. The use of copper salts as a colouring matter of foodstuffs such as preserved green vegetables is reprehensible, and has often led to legal action. The Public Health (Preservatives, etc. in Food) regulations of England, 1925–40, prohibited all save scheduled colours and limited the preservatives to benzoic and sulfurous acids and sodium or potassium nitrate, and these only in specified amounts in certain foods.

Zinc salts are irritant poisons. The sulfate of zinc (white vitriol) occurs in crystals like Epsom salts for which it has been taken in mistake. Zinc chloride has a corrosive as well as an irritant action.

Barium salts, except for the quite insoluble sulfate, are irritant poisons and may also act on the cardiovascular or nervous system.

Chromates especially potassium bichromate are powerful irritant poisons.

The yellow variety of phosphorus is intensely poisonous and formerly was widely used in the manufacture of matches. Yellow phosphorus is used as a constituent of some vermin exterminators. The substance, in addition to being a gastrointestinal irritant, is a deadly poison to the liver and kidneys.

Acute mercurial poisoning usually arises from the taking of mercuric chloride (corrosive sublimate) or from the biniodide of mercury, both of which are extensively used as disinfectants for medical purposes. The immediate symptoms are those of acute gastrointestinal irritation (vomiting, abdominal pain and diarrhea) but they are generally followed by suppression of urine and symptoms of acute ulcerative colitis which latter symptoms are commonly fatal. Chronic mercurial poisoning is characterized by inflammation of the mouth and gums.

Systemic Poisons

The systemic poisons include the following:

Prussic or Hydrocyanic Acid.—Hydrocyanic acid is one of the best known poisons and a very deadly one. In the pure state it is said to kill with lightninglike rapidity. It is met with in commerce only in a dilute state. In Great Britain two kinds of acid are commonly sold—the pharmacopoeial acid, containing 2% of anhydrous prussic acid, and Scheele's acid. containing 4% to 5%. About four millilitres of the 2% acid may cause death.

Hydrocyanic acid and the cyanides must be regarded as true protoplasmic poisons since they arrest the activity of all forms of living matter by inhibiting tissue oxidation and suspending vital functions. Such poisons not only inhibit the enzymic activities, but also act upon the central nervous system.

Given in fatal doses, the symptoms of prussic acid poisoning set in with great rapidity; and. in consequence of the readiness with which the poison is absorbed from the stomach and diffused through the circulation, the onset of symptoms is reckoned by seconds rather than by minutes. Occasionally the victim may be able to perform a few voluntary actions before loss of consciousness. There is first a very brief stage of difficult breathing and slow action of the heart, with a tendency for the organ to stop in the state of dilatation. With widely dilated pupils of the eye, the patient is then seized with violent irregular convulsive movements. The rhythm of the respiratory movements is disturbed, and the countenance assumes a bluish colour. The patient collapses with complete loss of muscular power; and the third or asphyxial stage is reached, in which there are slow gasping respirations, loss of pulse and paralysis of motion. Death is frequently preceded by spasms. The lightninglike character of the illness and the speedy death of the patient, coupled with the peculiar odour of the acid in the breath and atmosphere around the body, seldom leave any doubt as to the nature of the case.

Other soluble cyanides, more especially cyanide of potassium a salt largely used in photography and in the arts, are highly poisonous but are slightly less rapid in action than hydrocyanic acid.

When the poison has been swallowed, the stomach should be washed out immediately and free lavage established. A suitable medium for the purpose is water at body temperature containing a 5% to 10% solution of sodium thiosulfate, or a mixture of the sulfates (ferrous and ferric) of iron followed by a solution of potassium carbonate to form prussian blue which is inert. Sodium thiosulfate (10 to 50 ml. of 20% solution) or methylene blue (50 ml. of 1% solution) may be administered intravenously, provided there is time for either of these preparations to act. Ammonia inhalations, artificial respiration and oxygen, with or without carbon dioxide (7%). should be used to stimulate respiration. In desperate cases, a slow venous injection of five millilitres of a 25% solution of nikethamide has been recommended. Stimulation of the cardiac and respiratory centres may be effected by injections of lobeline and pentylenetetrazol (metrazol, cardiazol).

Strychnine and Strychnine-Yielding Plants.—The alkaloids strychnine and brucine, as well as the plants in which they are found, all act in the same manner, being highly poisonous and causing death after spasms of a severe character. Many vermin killers contain strychnine as their active ingredient.

Strychnine and all substances containing that alkaloid usually produce their effects within 10 or 15 minutes. The patient complains of stiffness about the neck, and his aspect exhibits terror. There is an impression of impending calamity or death. Very speedily the head is jerked back, the limbs extended. the back arched (opisthotonos) so that the body may rest on the head and heels only. In a few moments these symptoms pass off, and there is complete relaxation of the spasm. The spasmodic condition speedily returns. and is brought about by the slightest touch or movement of the patient. Accessions and remissions of the tetanic state ensue rapidly till the patient succumbs, usually within half an hour of the administration of the poison.

The best treatment is to put the patient under the influence of chloroform and wash out the stomach with a solution of potassium permanganate in water, four grams in two gallons. To follow, medicinal charcoal in water is recommended, and this should be freely given and removed from time to time. Sodium amytal or phenobarbital sodium should be given intravenously. Only a sufficient quantity to put the patient to sleep should be given, or, if convulsions are present. only enough to stop them.

Nicotine.—The alkaloid nicotine is obtained from the plant *Nicotiana* tabacum, the common tobacco of commerce, and has a pungent, acrid taste. Its content in tobacco leaves varies from 0.6% to 6%. Poisoning may be caused by absorption through the skin, by inhalation or by ingestion. Industrial poisoning caused by commercial preparations, such as fertilizers and fumigants, has occurred.

Cases of acute poisoning are comparatively rare, but subacute and chronic symptoms may result from the immoderate use of tobacco. When nicotine is absorbed in poisonous dose, the outstanding symptoms are those of successive central and peripheral stimulation, nausea, sickness, tachycardia, cardiac oppression and irregularity and severe prostration and cardiovascular collapse may become manifest. Treatment consists of gastric lavage when the poison has been ingested. Strong coffee or a hypodermic injection of nikethamide should be given.

Opium.—In consequence of the extent to which opium. its preparations and its active alkaloid morphia are used for the relief of pain, poisoning by opium is of frequent occurrence. It is largely used by suicides, and children, being very susceptible to its influence, frequently die from misadventure after administration of an overdose of the drug. The ordinary preparations of the drug itself, which is the dried juice of the capsules of the poppy (*Papaver somniferum*) known in commerce as Turkish, Persian, Indian or European opium, and the tincture, commonly known as laudanum. The British Pharmacopoeia requires opium in its moist state, as imported, to contain not less than 9.5% of anhydrous morphine.

The treatment of opium poisoning is governed by the condition of each case in relation to the time of intake. It consists of free gastric lavage with warm water and then with two grams of potassium permanganate in two gallons of warm water. The use of medicinal charcoal is beneficial. In coma, the airway should be kept clear, the patient catheterized and artificial respiration and inhalations of oxygen, or of oxygen with 7% carbon dioxide, should be employed if thought necessary.

Heroin is an artificial derivative of morphine (diacetyl morphine hydrochloride) and is more toxic than morphine. It has been largely used medicinally. It is a dangerous drug of addiction.

Belladonna.—The belladonna, or deadly nightshade, Atropa belladonna, contains an alkaloid, atropine, which is largely used by oculists to procure dilatation of the pupils of the eye. The brown or black berries of the plant have been eaten by children, who are attracted by their appearance. Besides dilatation of the pupils, belladonna produces rapid pulse, hot, dry, flushed skin with an eruption not unlike that of scarlatina, soreness of the throat with difficulty in swallowing, and intense thirst and delirium.

The treatment consists of gastric lavage with a solution of 1 in 5,000 of potassium permanganate. Excitement should be controlled by sedatives or mild hypnotics. Lumbar puncture may prove beneficial in certain cases.

Stramonium, hyoscyamus (henbane), hyoscyamine, hyoscine and scopolamine all produce symptoms similar to atropine poisoning, the narcotic effects being more marked.

Aconite.—The ordinary aconite, wolfsbane or monkshood (Aconitum napellus), and an alkaloid extracted from it, aconitine, are perhaps the most deadly of known poisons. A dose of 0.004 g. of aconitine has proved fatal to man. The root of aconite has been eaten in mistake for that of horse-radish. All the preparations of aconite produce a peculiar burning, tingling and numbness of the parts to which they are applied. When given in large doses they produce violent vomiting, as a rule, more or less paralysis of motion and sensation and great depression of the heart, usually ending in death from syncope. Intelligence remains unaffected till almost the last.

The treatment consists of free gastric lavage with a solution composed of 12 g. of tannic acid in two gallons of warm water. Tannic acid (1.2 g. in 180 ml. of tepid water) should be given and followed by animal charcoal suspended in water. Cardiac and respiratory stimulants should be administered in accordance with clinical indications. Artificial respiration and oxygen inhalations may prove necessary.

Cocaine.—Cocaine is the active alkaloid of coca leaves—*Erythroxylum* coca—and is chemically methyl benzoylecgonine. The hydrochloric salt is the commonly used preparation. It is a powerful deliriant narcotic poison. If taken by the mouth, given hypodermically or otherwise absorbed, it may cause delirium and coma. Sometimes convulsions and sudden death occur. It acts on the heart and may cause fatal syncope. Cocaine is a dangerous drug of addiction.

Organic Compounds Used as Hypnotics.—These if taken in excessive doses act as poisons, and the symptom which attracts attention is the deep coma produced. Examples are: chloral, barbital and its derivatives, etc. Any hypnotic drug taken in excessive quantity will act as a coma-producing poison. (See BARBITURATES; SULFONAL GROUP.)

Gaseous Poisons and War Gases

Carbon Monoxide.—Poisoning by carbon monoxide may occur from coal gas, water gas or from exposure to the suffocating fumes of fires, smoky grates and stoves; also from the fumes of gas heaters and internal-combustion engines.

The diagnosis may be made at once from the clinical symptoms of drowsiness, collapse and coma, and the cherry-red colour of the face, body and mucous membranes. Examination of the blood will make the diagnosis certain, since the presence of carboxyhemoglobin may be readily detected by the spectroscope.

The treatment consists in giving oxygen with 7% carbon dioxide freely, and employing artificial respiration if necessary. The use of carbon dioxide is important since it stimulates breathing and breaks down the carbon monoxide-hemoglobin molecule. The body warmth must be maintained. This is important since carbon monoxide disturbs the heat-regulating centre with reduction in the processes of oxidation. Stimulants administered hypodermically will also prove beneficial.

Carbon Dioxide or Carbonic Acid.—This occurs in coal mines from chokedamp or afterdamp. Cellars of houses, wells, brewers' vats, lime kilns, etc., frequently contain large quantities of carbonic acid gas.

The treatment consists in fresh air, rest, oxygen, artificial respiration if necessary, and employment of warmth and stimulants.

Sulfureted Hydrogen.—This occurs from contamination of the air with sewer gas, and from the gases evolved when iron slag becomes moistened with water. The gas is frequently produced in various chemical processes.

The treatment consists in giving the patient plenty of fresh air. Oxygen and stimulant treatment must be used.

War Gases.—Despite the fact that a mixture of gases may be employed, it is customary to classify war gases into four groups: (1) gases producing irritation of the lungs (choking gases); (2) gases producing irritation of the nose (nasal irritants); (3) gases producing irritation of the eyes (lachrymators); and (4) gases producing irritation of the skin (vesicants).

Group 1 includes phosgene, diphosgene, chlorine and chloropicrin. All these gases when inhaled produce rapid bronchial and pulmonary irritation which may lead to death within a day or two from cardiac failure brought about by inflammatory edema. A later fatal complication results from bronchopneumonia.

Group 2 includes smokes which are liberated from the highly toxic arsenical compounds diphenylamine chlorarsine or DM, diphenyl chlorarsine or DA, and diphenyl cyanarsine or DC. These are capable of causing profound sensory disturbance which in warfare diminishes physical capacity and undermines morale.

Group 3 includes ethyl iodoacetate or KSK, bromobenzyl cyanide or BBC, and chloroacetophenone or CAP. The vapours of these substances produce transient irritating effects on the eyes, which water copiously. If the liquids from which these vapours arise are brought into contact with the eyes severe and permanent damage may result.

Group 4 includes bis β-chlorethylsulfide or mustard gas, and β-chlorvinyldichlorarsine or lewisite. These liquids give off toxic vapours which affect the lung, eye and skin on account of their irritant action. In their liquid form such fluids cause severe burning with destruction of the tissue with which they are brought into contact. Their power of penetration of the skin is very considerable since they are capable of producing lipoid solubility. Mustard gas has a delayed action and on this account serious delay in treatment may occur. Lewisite acts much more rapidly. The arsenic content of lewisite when absorbed by the skin may produce tissue damage in the secretory and urinary systems. (See CHEMICAL WARFARE.) (W. H. WI.; JO. GR.)

Poisonous Foods

The term food poisoning is generally applied to a group of illnesses occurring after the ingestion of food containing a variety of agents such as chemical, plant and animal poisons as well as certain microbes or their poisons. Ptomaine poisoning is a misnomer since it does not represent a defined chemical entity capable of causing food poisoning.

Toxic chemicals mav find their way into food bv malicious intent. Chemicals such-as insecticides: rodenticides-and herbicides may cause poisoning if allowed to remain in toxic doses on food when eaten. Chemicals that are added to foods to improve quality may be toxic under certain circumstances and not recognized immediately. For example, flour bleached with gaseous nitrogen trichloride (agene) caused convulsions when fed to dogs. As a result. use of agene as a bleaching agent for flour was prohibited.

Plants such as poisonous mushrooms, snakeroot, water hemlock, rhubarb leaves. rye infected with the ergot fungus, seeds of the unripe ackee and tung nuts are poisonous when eaten.

Shellfish, eaten raw or cooked, may be poisonous after ingesting certain toxic plankton. Several tropical fish have been shown to be toxic. Organs such as the liver and ovaries of globe fish and certain sharks may be toxic. The flesh of the Moray eel is also poisonous when eaten.

Microbial food poisoning is of two types: (1) that in which the poison (or toxin) is produced in a food by the growth of microorganisms, and the poison (not the microorganism) gives rise to illness, and (2) that in which living organisms are present in a food in numbers large enough to cause illness. The mechanism of illness caused by living organisms is not understood.

Botulism, caused by a toxin produced by *Clostridium botulinum,* is the most serious type of food poisoning, fatal in approximately 65% of the cases in the United States. It leads to muscle paralysis, and death is due to respiratory failure. The microorganism causing botulism grows in the soil and produces heat-resistant spores that grow in the absence of air in low-acid, underprocessed home-canned foods. Boiling destroys botulinum toxin.

The poison produced by the growth of staphylococci in foods causes severe gastrointestinal disturbances usually within 2½ to 3 hours after ingestion of the food. These bacteria are commonly found in the throat and on the skin of man. where they may cause pimples and abscesses. Staphylococci grow in many foods with a high salt and sugar content. and control of staphylococcic food poisoning depends on adequate refrigeration of perishable foods. The food poisoning toxin of staphylococci is resistant to boiling.

Living microorganisms that cause food poisoning include *Salmonella,* which produce infection with gastrointestinal disturbances usually from seven hours to one day or more following the ingestion of a meal containing them. *Salmonella* grow in the intestines of man and animals and are sometimes found in raw meat and poultry products and food subject to fecal contamination. These microorganisms are readily destroyed at pasteurization temperatures.

Other living microorganisms causing illness are certain types of cocci and bacilli, which produce mild illness characterized principally by vomiting and diarrhea 6 to 1j hours after ingestion of food containing large numbers of them (alpha-type streptococcus. *Clostrzdium perfringens* and *Bacillus cereus).*

POISON FISH *(Synanceja verrucosa),* an ugly, rather shapeless, tropical, marine-bottom fish, of the family Scorpaenidae, reaching a length of about one foot, inconspicuous as it lies partly buried in the sand or in some hollow of a rock or coral bottom, which it commonly does.

Though veiled in skin, the spines of the dorsal fin of the poison fish have large poison glands at their bases and can inflict a severe wound. Like the related lion fish (*q.v.*) this species is found in the Indian ocean. East Indies and eastward into Polynesia. *See* also SCORPION FISHES. (J. T. N.)

POISON GAS: *see* CHEMICAL WARFARE.

POISON HEMLOCK is a common name (derived from the Anglo-Saxon *hem,* "meadow" or "border"; and *lok* or *lich,* "death") for the Eurasian species *Conium maculatum* of the parsley family Umbelliferae. It is a branching biennial herb from 3 to 10 ft. tall with parsleylike, malodorous leaves, small white flowers in compound umbels and conspicuously purple-blotched stems and leaf stalks It has become widely naturalized in moist areas in North and South America and is not uncommon in gardens, where it has even been grown as an herbaceous hedge under the name of California fern. In the Pacific coast states poison hemlock may form dense thickets in net roadside ditches, the plants reaching 10 ft. or more in height. The leaves are reported to cause dermatitis. All parts of the plant contain the toxic principles coniine, conhydrine, methyconiine and coniceine and are poisonous to eat. The leaves, sometimes mistaken for parsley, are most toxic when the plant is in flower; the roots are least toxic in the spring. Chickens have been killed from eating the seeds. Death occurs in man and animals from respiratory paralysis and differs from water hemlock (*q.v.*) poisoning in that no convulsions occur and the mind reportedly remains clear until the end. Poison hemlock is one of the historically famous plant poisons, presumably the one administered by the Greeks to Socrates and other state prisoners. From Plato's description of the effect of the poison drink on Socrates *(Phaedo)* there is little question of its identity. *See* also ALKALOIDS; POISONOUS PLANTS. (MD. E. M.)

POISON IVY, the name commonly applied to several. mostly white-fruited, trifoliate species of woody vines or shrubs of the genus *Toxicodencron* of the cashew or sumac family (Anacardiaceae), native to North America. The forms with bushy habit and lobed leaflets are often called poison oak, especially in the western United States. The common poison ivy *(Toxicodendron radicans),* the most widespread species, abundant in eastern North America and less common westward, is a variable species with a bushy or climbing habit and leaves with three leaflets which may be smooth and glossy or hairy, entire, toothed or lobed. Many of these not too constant variations have been designated as separate species or varieties. The commoner of these forms with their ranges are: *T. quercifolium,* with deeply lobed leaflets, Maryland to Texas; *T. radicans rydbergi,* with thicker leaves, Great Plains to Rocky mountains; and *T. diversilobum,* with leaflets mostly scalloped on the margin. Pacific coast. The poison sumac *(T. vernix),* native in swamps from Quebec to Minnesota and south to Texas and Florida, is a tall bush or small tree with pinnately compound leaves with 7 to 13 entire leaflets and drooping, axillary clusters of persisting white fruits. (The common nonpoisonous sumacs of the genus *Rhus [see* SUMAC] have distinctive reddish fruit.)

All species of *Toxicodendron* are poisonous to touch, producing in many persons a severe inflammation of the skin, or dermatitis *(see* below). The toxic principle, urushiol, is produced in the resinous juice of the resin ducts of the leaves, flowers, fruits and bark of stems and roots but not in the pollen grains. Being almost nonvolatile, the urushiol may be carried from the plant on clothing, shoes, tools, soil, by animals, by smoke from burning plants, to persons who never go near the poison ivy plants. Poisoning may occur if clothing is worn a year after contact with poison ivy. (W. C. M.)

Poison **Ivy Dermatitis.**—The juice of all portions of the poisonous plants discussed above is not irritating or poisonous on first exposure; but after one or more contacts, most persons become sensitized or allergic and will react to the juice with a rash. The sap must get on the skin for the dermatitis to develop. The hands and clothing may transfer sap to other portions of the body not directly exposed. The rash may develop as early as 6 to 12 hours or as late as a week or more after exposure; most commonly it appears within 24 to 48 hours. No one is born with sensitivity; it is generally acquired during childhood and tends to be highest at this time, but over the years it declines despite exposure to the plants. Once sensitivity is lost, a solid immunity remains and the person cannot easily be made sensitive again. The plants are so common and the juices such highly potent sensitizers that over three-fourths of the American population acquires poison ivy dermatitis at some time.

The severity of the rash varies directly with the quantity of sap deposited on the skin and with the person's inherent degree of sensitivity. Sensitivity may be so great that the sap diluted 50,000,000 times will still induce a rash. Even a mildly sensitive person can develop an intense eruption following a high degree of exposure, but the rash heals in a week or less as contrasted with two or three weeks for the highly sensitized.

A moderate degree of immunity can be established, plant extracts given orally (very small doses at first. increased daily over the next few months) being effective. Although complete desensitization is impossible, and skin rash may occur as a side effect, this prophylactic treatment is justified for the highly sensitive because it lessens the intensity and duration of the rash.

Anointing the skin before exposure with "barrier" or detoxifying creams is generally useless, and washing the skin with solvents, soaps or detoxicants is ineffective unless performed within a few minutes after contact. ACTH and cortisonelike drugs, by mouth or injection. promptly control the rash; this is the only known treatment that has a clear-cut beneficial effect. The great majority of popular and folk remedies for local application are without benefit and many are harmful. Bland compresses and soothing lotions do not restrain the rash, but provide comfort and maintain hygiene until the skin recovers spontaneously. *See* also POISONOUS PLANTS. (A. M. K.)

POISONOUS PLANTS are plants that produce adverse physical effects, and sometimes death, when eaten or touched by man or animals. Most plant species are harmless; a few are poisonous under ordinary conditions. others are poisonous under special conditions. Toxic materials are often very strictly localized in the plant. Opium and its related drugs come from the milky latex of the opium poppy (*Papaver* somniferum) but are absent from the seeds, which may be eaten for food. In the water hemlock (*Cicuta* maculata) the root and fruit are poisonous, whereas in corn cockle (Agrostemma) the poisonous glycoside is confined to the seeds. The leaf blades of rhubarb (Rheum *rhaponticum*) are highly poisonous but the leaf stalks are nonpoisonous. Some plants are harmless when eaten green and fresh but poisonous when wilted or dried. Others are poisonous when raw but nonpoisonous when cooked. While it is not possible to classify poisonous plants by the toxic ingredient, knowledge of the type of toxic substance is helpful in diagnosing symptoms and treatment.

Types of Toxic Substance.—In general the poisonous character of a plant is due to the presence of one of four groups of organic compounds: an alkaloid, a glycoside, a resin or an organic acid.

Alkaloids.—An alkaloid is a nitrogen-containing organic base; it is colourless, odourless, nearly insoluble in water and very bitter. Except for the fungus ergot (Claviceps *purpurea*), a parasite on rye, and poisonous mushrooms, the sources of all alkaloids are flowering plants. Notable among alkaloids are the opiates and codeines of the opium poppy, the atropine-nicotine groups in the Solanaceae (the nightshade family) and the curines (curare poisons) in tropical members of several families. (See ALKALOIDS.)

Glycosides.—A glycoside (glucoside, in part) is a complex carbohydrate which on hydrolysis and in the presence of amino acids or enzymes produces one or more simple sugars and a nonsugar end product called aglycon. These carbohydrates are water-soluble, bitter, often odour producing and may be coloured or colourless. Three primary groups of plant glycosides yielding toxic products on hydrolysis are: (1) cyanogenetic glycosides, in which the poisonous by-product is hydrocyanic acid or prussic acid and found in species of Sorghum, *Prunus* (wild cherries. almonds) and Linum (flax); (2) saponin glycosides, produced in species of Agrostemma (cockle), Digitalis (foxglove), Actinea (rubberweed); and (3) solanine glycosides, produced in members

JOHN H. GERARD

POISON IVY (TOXICODENDRON [RHUS] RADICANS)

of the nightshade family, especially berries of *Solanum.* (See also GLYCOSIDES. NATURAL.)

Resins.—The toxic resins or resinoids occur in poisonous members of the heath family (Ericaceae), water hemlock (Cicuta) of the carrot family, and in the milkweeds (Asclepiadaceae). For the most part they are an insoluble gummy material of complex organic structure, localized in resin- or latex-containing ducts.

Types of Physiological Action.—Poisonous plants may be grouped according to the physiological actions they produce. These groups and some plant examples include: (1) blood poisons: species of *Prunus,* seeds of castor bean (*Ricinus*) and rosary pea (Abrus); (2) nerve poisons: poisonous mushrooms. Jimson weed (Datura) and henbane (*Hyoscyamus*); (3) neuromuscular poisons: ergot. foxglove and arrow poisons (curare); (4) muscular poisons: false hellebore (Veratrum); and (5) skin irritants or dermatitis-producing plants: poison ivy (Toxicodendron [Rhus]), parsnip (*Pastinaca*), mustard (Brassica), poisonwood (*Metopium*) and snow-on-the-mountain (Euphorbia marginata).

Plants Poisonous on Contact.—Skin poisoning, or dermatitis, is the typical plant contact poisoning. This type of reaction varies from a minor or temporary irritation to an itching rash or a painful inflammation with watery blisters that may last for days or weeks. In most plants that produce this reaction the toxic ingredient is concentrated in a resinous or milky juice. The severity of the symptoms varies with the susceptibility of the individual and with the amount of contact with the toxic agent. Some persons may be immune to poisoning by one species but susceptible to that by another; immunity may be complete or only partial; it may be lost or acquired over the years.

Plants noted for dermatitis-producing qualities include:

Cashew Family (Anacardiaceae).—Poison ivy and poison oak (Toxicodendron species), poison sumac and poison dogwood (Toxicodendron *vernix*) and Japanese lacauer tree (Toxicodendron *verniciflua*) are native to temperate regions and may be distinguished from nonpoisonous sumacs by the white (not red) fruits. In poison ivy and its relatives the leaves are of three leaflets (never five), are usually coarsely toothed, and are glossy on the upper surface when young. Poison sumac leaves have 7 to 15 leaflets, whose margins are never toothed, and the hairless leaf stalk is usually reddish. The poisonwood of southeastern United States and the West Indies (Metopium toxiferum) resembles the more northern poison sumac.

Spurge Family (Euphorbiaceae).—The milky sap of the following plants produces varying degrees of dermatitis in susceptible individuals: many species of spurge (*Euphorbia*), including the cultivated ornamental snow-on-the-mountain (*E.* marginata). an annual whose leaves are margined white; and the manchineel tree (*Hippomane mancinella*) of the American tropics.

Nettles.—Some plants produce a nonpoisonous but very irritating stinging rash of short duration, termed an urtication. These plants bear sharp, brittle. glandular hairs that are hollow and filled with an irritating watery material which enters the skin when punctured by the hair. Included among these are the common nettle (*Urtica* gracilis, *U. urens*), the stinging nettle (*U.* dioica) and the wood nettle (Laportea *canadensis*).

Others.—Miscellaneous kinds of dermatitis-producing plants include the wild parsnip (*Pastinaca sativa*), which has coarse. celerylike foliage and bright yellow flowers; certain primroses (especially *Primula* obconica, P. malacoides and P. *sinensis*); several kinds of ladyslipper orchids (*Cypripedium* acaule, C. *calceolus*, C. reginae and C. *parviflorum*); several species of milkweed (Asclepias) and osage orange (*Maclura pomifera*). Foods made of buckwheat flower (Fagopyrum *esculentum*) produce dermatitis in some individuals.

Plants Poisonous on **Ingestion.**—Most plants that are poisonous when eaten are not tasty or likely to be eaten. except by children. Unfortunately, the quantity of poison fatal for a child is only a fraction of that fatal for, an adult. These plants may be conveniently grouped according to the plant part that carries the toxic substance.

Roots.—Roots of the following may cause serious or fatal poisoning when eaten: (1) Jack-in-the-pulpit (*Arisaema*); the tuberous rhizome is rich in calcium oxylate crystals and produces inflammation of the membranes of the mouth and the throat when eaten raw; boiling the tubers in water dissolves the crystals and makes them edible. (2) Death camass (Zigadenus); the bulbs are rich in the highly toxic alkaloid zygadenine, and sometimes are eaten by children. (3) Star-of-Bethlehem (*Ornithogalum*); all parts of the plant are poisonous, and the bulbs especially should not be kept where children have access to them. (4) Amaryllis and relatives (*Hippeastrum, Zephyranthes, Crinum* and *Hymenocallis*) produce bulbs containing poisonous alkaloids; they also should not be kept where children may obtain them. (5) Water hemlock (Cicuta) and poison hemlock (Conium *maculatum*) contain a highly toxic yellowish resin in the roots: fatal poisoning may result from eating them. These plants belong to the carrot family. produce flat-topped clusters of white flowers and grow in wet open swales or along streams. (6) Potato (*Solanum tuberosum*) is poisonous when the tuber grows at the surface of the soil and becomes green through exposure to the sun; "greened" potato tubers should never be eaten.

Shoots and Foliage.—Shoots and foliage of the following may cause poisoning: (1) Pokeweed (Phytolacca *americana*); young shoots cooked as a potherb are edible, but the water should be poured off and replaced with fresh to remove the water-soluble toxic material. (2) Poison hemlock (Conium *maculatum*); children have been fatally poisoned by eating small quantities of foliage or stalk. (3) Fool's-parsley (Aethusa *cynapium*), an annual with parsleylike leaves, is sometimes eaten in error for garden parsley with fatal results; the leaves are never mosslike or curly. (4) Tansy (Tanacetum vulgare); a tea made from the foliage is poisonous, and overdoses have been fatal.

Flowers.—Flowers of poisonous plants are rarely eaten deliberately. However, children eating flowers or buds of tiger lily (Lilium tigrinum) have been poisoned with near-fatal results. The anthers contain an alkaloid not known in other lily species.

Fruits and Seeds.—Fruits and seeds of poisonous plants are occasionally eaten with fatal or near-fatal results! especially by children. The following, while by no means complete, is a listing of common poisonous fruits to be avoided: (1) Baneberry (Actaea, a woodland perennial herb bearing bright red or white berries about half an inch long; the berries are not tasty and are moderately toxic. (2) Belladonna (Atropa belladonna), a perennial producing bell-shaped dull-purplish flowers and black berries with violet juice; the toxic alkaloid hyoscyamine is present in all parts of the plant. (3) Bittersweet (Celastrus), a woody vine producing orange-red berrylike fruits in autumn, prized for decorative uses; the outer scarlet pulp contains a moderately toxic, sweetish but disagreeable-tasting alkaloid. celastrin. (4) Black nightshade. or garden huckleberry (*Solanum nigrum*), an annual herb with drooping clusters of black. globose berries about three-quarters of an inch in diameter; the unripe berries are poisonous, but the ripe fruit is edible, and cooking or boiling destroys remnants of the poisonous material. (5) Blue cohosh (Caulophyllum *thalictroides*), a low. perennial herb of moist. rich, woodland areas. produces stiffly erect stalks of pea-sized dark-blue "berries" above the foliage; the very bitter berries contain a poisonous alkaloid. (6) Chinaberry (*Melia* azedarach) is a tree of warm temperate regions producing panicles of fragrant purple flowers followed by pale yellow, berrylike drupes about half an inch across; the fleshy pulp of the fruit contains a paralyzing nerve poison. Coyotillo (Karwinskia humboldtitma), a rangeland shrub with oval, brownish-black berries about half an inch long; the pulp is believed to be nonpoisonous. but the seeds are highly toxic. (7) Daphne (Daphne), a low shrub producing fragrant, showy flowers in spring, followed by orange or red berrylike drupes about one-fourth inch long; a small number of the berries may cause fatal poisoning in children. (8) English ivy (Hedera helix), an evergreen vine, produces umbels of black or orange poisonous berries sometimes eaten by children. (9) Euonymus. burning bush, wahoo (Euonymus *atropurpureus*), a shrub with reddish capsules whose few seeds are each covered by a bright, orange-red, fleshy aril; the fruits and seeds are moderately poisonous when eaten. (10) European bittersweet, or blue nightshade (*Solanum* dulcamara), is a clambering vine, herbaceous becoming woody. with clusters of small white flowers followed by attractive bright red berries about one-third inch across; both leaves and bark have a strong, disagreeable odour, and the berries, moderately poisonous if eaten in quantity. contain the alkaloidal glucoside solanine. (11) Henbane (*Hyoscyamus niger*), a much-branched, clammy-hairy herb with a fetid odour when crushed. produces yellowish, funnel-shaped flowers with purple veins. followed by a seed pod enclosed in a persistent calyx: children eating seed pods or seeds have been poisoned by the alkaloid hyoscyamine. (12) Holly (*Ilex*) produces attractive red yellow or black berries that are someuhat (but not highly) poisonous and should not be eaten. (13) Jerusalem cherry (Solanum pseudo-capsicum) is grown as an ornamental pot plant and prized for its showy globose orange berries nearly an inch across; the fruits contain toxic quantities of several poisonous materials and should never be eaten. (14) Jimson weed (Datura *stramonium*), an annual weed with showy white or purplish funnel-form flowers, three to six inches long, followed by globose prickly pods about one inch across; the soft, unripe seed pods are poisonous when eaten, and the seeds are increasingly toxic. (15) Manchineel tree (Hippomane *mancinella*), a small subtropical tree of the Euphorbiaceae, produces milky sap, spikes of small greenish flowers. followed by berrylike drupes about $1\frac{1}{4}$ in. across; persons eating the fruits in the belief that they were edible have been fatally poisoned. (16) Matrimony vine (Lycium halimifolium), a woody clambering vine of the Solanaceae, somewhat thorny, produces small white funnelform flowers in leaf axils, followed by bright orange-red berries about one-third inch across; the berries are moderately toxic and contain a hyoscyaminelike alkaloid. (17) May apple (Podophyllum) is a perennial herb of rich, open woodlands or pastures. producing large, umbrella-shaped leaves, beneath which appear one or two nodding white flowers an inch across, followed by a yellow or reddish berry about $1\frac{1}{2}$ in. long; when fully ripe the berries are edible, but when hard, green and immature, they contain highly toxic quantities of a purgative resin, podophyllin. (18) Mistletoe (Phoradendron, Viscum *album*), an evergreen parasitic plant growing on trees, produces decorative whitish berries that are reported to have been fatally poisonous when eaten by children. (19) Pokeweed (Phytolacca americana). a coarse tall perennial herb with reddish-purple stems and glossy green leaves, produces dense terminal racemes of small white flowers followed by crimson-juiced. glossy black berries; the berry pulp is believed to be nonpoisonous. but the black glossy seeds contain toxic quantities of saponins and alkaloids. (20) Privet *(Ligustrum),* a common shrub often grown for hedges, has small racemes of white flowers

JOHN H. GERARD

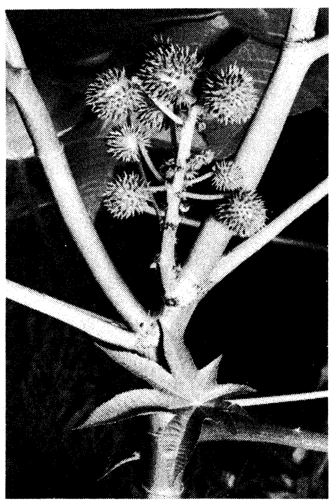
POKEWEED (PHYTOLACCA)

followed by bluish-black berries about one-fourth inch across; the berries are reported to be fatally toxic to children.

Mushrooms.—Mushroom poisoning commonly is fatal to man. Many mushrooms contain toxic alkaloids (muscarine. agaricine, phalline) and identification of poisonous types from the non-poisonous should be made only by an expert. The edible mushroom of commerce is *Agaricus campestris,* but some species of the genus are poisonous. The designation of poisonous types as toadstools and the nonpoisonous as mushrooms is common but meaningless. *(See* also MUSHROOM.)

Stock-Poisoning Plants. — These are of many kinds and vary with the different countries and regions. Refer to the work by W. C. Muenscher. cited in the bibliography.

Arrow Poisons. — These. concocted from the juices and resins of a variety of plants. are of importance to aborigines of many areas. particularly of the tropics. for shooting of animals and fish and in warfare. In the 20th century the active ingredients have proved to be important in medicine. All South American Indian arrow poisons are grouped under the name curare and may be classified as neuromuscular toxins. From them the alkaloid curine has been isolated. Derivatives of this arrow poison have proved useful in anesthetics to induce muscle relaxation. The material as used by the Indians is a black gummy mass. Small quantities carried on the tip of an arrow to the flesh of man or animal induce paralysis of the voluntary muscles followed by stupor and death due to failure of respiratory muscles.



JOHN H. GERARD

CASTOR BEAN (RICINUS COMMUNIS)

Crude arron-poisoning material was first introduced to modern civilization in 1595, when Sir Walter Raleigh brought a tiny vial of it to England. From that time onward reports of its preparation, use and efficacy became a mixture of folklore and fact. The aboriginal use of the potion was accurately observed in 1800 and reported in 1807 by Humboldt. Later the German botanist R. H. Schomburgk witnessed its preparation by Indians in British Guiana and reported it in detail in 1844. Preparation of the poison was a closely guarded secret and ritual. handed down from father to son, and today, through the influence of firearms, it is rapidly becoming a lost art in much of South America.

Detailed information on the plants used and procedures for making the poison were learned from the Tecuna Indians of Brazil by B. A. Krukoff,who reported on them in 1937. Bundles of stems of the plants *Strychnos castelnaei* and *Clzondodendron polyanthum* were gathered and brought from the forest. The outer bark was peeled or scraped from the stems, packed into a bundle, wrapped in palm leaves and allowed to set over night. It was then suspended over an empty clay pot and opened at the top. About two quarts of cold water was poured very slowly over the bark and collected in the pot. This extract was transferred to a larger pot and brought to boil over a steady fire. Several collections of the cold-water extract were similarly prepared and added to the concoction, which was kept boiling for at least eight hours, when it was reduced to about one-eighth its original volume. On the third day the extract was triple-strained through a palm spathe and again boiled gently for several more hours. To this a decoction of macerated roots of other plants *(e.g.,* species of *Piper)* were added, boiled and strained. During the process an extract of stems and leaves of *Dieffenbachia insignis* and of tubers of *Aristolochia* were added and the whole boiled down to a thick, gluelike sirup of dark chocolate colour. When cool its potency was tested on some bird or animal. The material was stored in covered pots. gourds or bamboo tubes and kept as dry and cool as possible.

The identity of all the plants used in the preparation of curare remains incomplete, but leaves and stems of the following plants are known to be used: *Chondodendron tomentosum* (Menispermaceae). *Strophanthus* (Apocynaceae), *Strychnos* (Loganiaceae) and *Cocculus* (Menispermaceae).

POISSON, SIMÉON DENIS (1781–1830), French mathematician. known for his work on definite integrals, electromagnetic theory and probability. was born at Pithiviers in the *département* of Loiret on June 21, 1781. He studied medicine but gave it up in favour of mathematics. In 1798 he entered the Ecole Polytechnique at Paris, where he attracted the notice of Lagrange and Laplace. Until his death on April 25, 1840, he was almost entirely occupied in mathematical research and in teaching. He was made deputy professor at the École Polytechnique in 1802, and full professor in succession to Fourier in 1806. In 1808 he became astronomer to the Bureau des Longitudes: and when the Faculté des Sciences was instituted in 1809 he was appointed professor of pure mechanics. His most important work was on the application of mathematics to physics. and in particular to electrostatics and magnetism. In the field of pure mathematics, his most important works were his series of memoirs on definite integrals, and his discussion of Fourier's series, which paved the way for the classical researches of Dirichlet and Riemann on the same subject. His studies on probability and the Poisson distribution law are of great importance.

Resides his many memoirs. Poisson published a number of treatises: *Traité de mdcanique,* 2 vol.. (1811 and 1833), which was long a standard work; *Théorie nouvelle de l'action capillaire* (1831); *The'orie mathe'matique de la chaleur* (183j); *Supplément* to the same (1837); *Recherches sur la probabilité des jugements,* etc. (1837). (O. OE.)

POITIERS, a town of western France, formerly capital of Poitou *(q.v.)* and now the chief town of the *département* of Vienne, 61 mi. S.S.W. of Tours on the railway to Bordeaux. Pop. (1954) 45,805. Called Limonum at the time of the Roman conquest, Poitiers afterward took the name of its Gallic founders, the Pictones or Pictavi. Christianity was introduced in the 3rd century, and the first bishop of Poitiers, from 350 to 367, mas St. Hilarius. Fifty years later the city had fallen into the hands of the Arian Visigoths and became one of the principal residences of their kings. Alaric II nas defeated by Clovis at Vouillé. not far from Poitiers, in 507, and the town became a part of the Frankish dominion. This was the first occasion on which the peoples of northern and southern Gaul met in conflict near the town which was to see them so often join battle. By his victory in 732 over the Mohammedans at Moussais-la-Bataille in this region, Charles Martel proved the saviour of Christendom. Eleanor of Guienne frequently resided in the city and in 1199 entrusted it with communal rights. After the battle of Poitiers in 1356 (*see* below), Poitou was recognized as an English possession by the treaty of Brétigny (1360) ; but by 1373 it was recovered by Bertrand du Guesclin.

Between the northwest of the plateau central and the Gâtine, both heights of old rock, lies the relatively low land called the Seuil du Poitou, giving a historic connection between the Paris basin and the basin of the Garonne. In this lowland streams have dissected valleys in the Jurassic rocks, and Poitiers stands on a promontory above the junction of the Boivre and the Clain. Till 1857 Poitiers contained the ruins of a Roman amphitheatre; remains of Roman baths were laid bare in 1877; and in 1879 the tombs of Christian martyrs were discovered to the southeast.

The Cathedral of St. Peter was begun in 1162 by Henry II of England and Eleanor of Guienne on the ruins of a Roman basilica. It was completed by 1379. The Church of St. Jean, most ancient Christian monument in France, was built as a baptistery in the first half of the 4th century, and enlarged in the 7th century.

The Church of St. Radegonde, a great resort of pilgrims, commemorates the consort of Clotaire (d. 587), preserving in its crypt the tomb of Radegonde, who founded at Poitiers the abbey of the Holy Cross: and two others reputed to be those of St. Agnes and St. Disciola. Notre-Dame la Grande (late 11th century) represents a much older collegiate church and has a richly sculptured Romanesque façade. The Church of Montierneuf (hfonasterium Novum) was begun in 1077 by William VI, duke of Aquitaine and count of Poitiers.

Poitiers has a university with various faculties. Trade is in farm produce, wine, wool: honey, and leather. The industries include the preparation of goose and swan skins, printing and the manufacture of hosiery, brushes, oil and paint.

Counts of Poitiem — In the time of Charlemagne the countship of Poitiers, then part of the kingdom of Aquitaine, was represented by a certain Abbon. Renoul (Ranulph), created count of Poitiers by Louis the Pious in 839, was the ancestor of a family distinguished in the 9th and 10th centuries for its attachment to the Carolingian dynasty. One of his successors, Ebles the Bastard (d. 935), took the title of duke of Aquitaine, and his descendants retained the hereditary name of William. In accordance mith the dying wishes of William X his daughter Eleanor was married in 1137 to Louis, the son of Louis VI of France. Sole heiress, she brought her husband Poitou, Saintonge, Aunis, a part of Touraine and Berry, Marche, Angoumois, Périgord, Auvergne, Limousin, Bordelais, Agénois and Gascony. After a divorce in 1152. Eleanor married the count of Anjou, Henry Plantagenet, who became king of England as Henry II. The west of France thus passed into the hands of England. Philip Augustus reconquered Poitou in 1204. When Charles VII ascended the throne he united the countship of Poitiers to the crown.

Battle of **Poitiers.**—The battle of Poitiers, which was fought on Sept. 19, 1356, between the armies of King John of France and of Edward the "Black Prince," was the second of the three great English victories of the Hundred Years' War. From Bordeaux the Black Prince had led an army into central France and had amassed an enormous booty. King John, in Normandy, hurried south to intercept the raiding army and to bar its homeward road. After an unexpected encounter with the French rear, the Black Prince, by forced marching, was able to slip past the French, but reaching Maupertuis, 7 mi. S.E. of Poitiers, with the king's army in chase, he found himself compelled to choose between fighting and abandoning his spoil. He chose the former course, in spite of the enemy's great superiority in numbers (perhaps 16,000 to 6,500), and in order to give his trains time to draw off took up a defensive position on Sept. 18 mith a slight hollow in iront and a wood behind, between the Poitiers-Boideaux main road and the Maussion river. John, instead of maneuvering to outflank the English, alloned the cardinal Hélie de Talleyrand-Périgord to attempt to negotiate a peace. This proving vain, the French army attacked without any attempt at maneuver or reconnaissance, and on a iront so narrow that the advantage of superior numbers was iorieited. Moreover, King John ordrred all but the leading line to attack on ioot and thus condemned the best part of his army to a iatiguing advance on foot across difficult country in iull armour.

The French crossbowmen, who might have crushed the relatively few English archers present, mere mingled with the mounted men in first line, but, as the latter charged, their advance masked the fire of the crossbowmen in the first few seconds, besides leaving the others, dismounted, lines far in rear. Thus the first attack on the Black Prince's line, which was greatly strengthened by trees and hedges in iront of it, was promptly brought to a standstill by the arrows of the archers lining a hedge which overlooked the hollow in front; and the earl of Oxiord, hastily drawing out a body of archers beyond the defenders' left, into the marshy valley of the Maussion, completed their rout by firing up the hollow into their flank. But it mas not so easy to deal with the second line of dismounted men-at-arms, led by the dauphin, which was the next to arrive on the French side. The hedge indeed was held, and the assailants, unable to advance beyond the hollow, gave way, but to achieve this the prince had to use all but 400 of his men. Had the third body of the French advanced with equal spirit the battle mould probably have ended. but the duke of Orleans. who commanded it, led his force off the field without attacking.

Thereupon the king himself advanced furiously with the fourth and last line, and as it came on, the situation of the English seemed so desperate that the prince mas advised to retreat. But his determined courage was unshaken; seeing that this was the last attack he put his reserve into line. He dispatched 60 men-at-arms and 100 archers under the Captal de Buch to ride round the flank oi the enemy and to appear in their rear at the crisis of the fight. When both lines were fighting hand-to-hand, the 60 horsemen of the Captal de Buch appeared in the rear of the French. The iront ranks fought on, but the rearmost Frenchmen melted away rapidly. and at last only a group oi the bravest, with King John and his son Philip, a bop oi 14, in their midst. was left This band continued their hopeless resistance ior a time, but in the end they mere killed or captured to a man The rest of the French army, totally dispersed, was pursued until nightfall Two thousand five hundred oi the French were killed The prisoners included the king and his son Philip The Black Prince then resumed his march to Bordeaux, making no effort to exploit his military ascendancy, ior he had now in his hands a political key which could yield him all the possible profits of victorv, without military cost. ***See*** also FRANCE: *History.*

POITOU, a former province of France, roughly corresponding to the modern *départements* of Vienne, Deux-Sèvres and Vendée. The Seuil du Poitou is a low-lying zone of sedimentary rocks, about 60 mi. wide, separating two higher countries of older rocks (Limousin in the east, the southern part of the Massif Armoricain in the west) and forming the easiest natural passage between northern and southwestern France.

Poitou, incorporated by the Romans into Aquitania, mas for centuries the northern part of Aquitaine (*q.v.*) and, as such. a border country and a battlefield (Vouillé, 507; Poitiers, 732 and 1356: Moncontour. 1569) as well as the meeting place of northern and southern cultures Its golden age (11th–12th centuries) is represented by a great school of Romanesque architecture, sculpture and painting (Saint-Savin). Philip Augustus occupied it in 1204; and the treaty of Paris (1259) recognized the French conquest, after which Poitou was subject to the royal authority (except for a few years after the treaty of Brétigny). From 1417 it was a stronghold of the dauphin Charles. who made Poitiers his capital much more than Bourges. Poitou suffered much in the Wars of Religion; its later history was quieter, apart from the insurrection of the Vendée against the Revolutionary government.

BIBLIOGRAPHY.—G Chagnolleau et al., *Visages du Poitou,* 2nd ed (1946) ; R Crozet, *Histoire du Poitou* (1949), and *L'Art roman en Poitou (1948)* (F. CT)

PQKEBERRY or POKEWEED. the popular name (from the American Indian *pocan,* applied to any plant yielding a red or yellow dye) of *Phytolacca americana,* a strong-smelling perennial herb. a native of North America, with ovate-lanceolate sharp-pointed leaves. racemes of small greenish-white flowers and flattish berries nearly † in in diameter, nhich contain a crimson juice. The young asparaguslike shoots are sometimes used as a potherb, but the roots are poisonous. The plant is often cultivated in Europe, and has become naturalized in the Mediterranean region

POKER, a card game played in various forms throughout the world Its popularity is greatest in the English-speaking countries and after the 1850s it was called "the national card game of the United States." Because Queen Victoria found the principle of the game interesting, poker had a brief vogue in British court circles in the 1870s. but its acceptance in Great Britain and on the continent came chiefly in the decade 1911–20 and was undoubtedly much influenced by the American Expeditionary Forces in World War I. For nearly 100 years in the United States poker nas considered a gambling game for men, unsuited to polite or mixed gatherings, but after the 1920s its popularity extended to both sexes and all levels of society. Surveys made in 1956 shoned poker to be the favourite U.S. game of men and the third-most-favoured (after rummy and bridge) with women; and in Great Britain it ranked next after contract bridge with both sexes.

In one respect poker is rather a family of games than a single game (see History, below). It is played in countless variants and at least 150 are named and described in the literature of the game. All forms of poker, however, share certain essential features: A poker hand comprises five cards. The value of the hand is in inverse proportion to its mathematical frequency; that is, the more unusual the combination of cards, the higher the hand ranks. Each player may bet that he has the best hand, and other players must either "call" or meet his bet or concede. Therefore a player may "bluff" by betting he has the best hand when in fact he does not, and he may win by bluffing if players holding superior hands will not call his bet. See also CARDS. PLAYING.

GENERAL PRINCIPLES OF POKER

The following principles apply to nearly all forms of poker:

Players. — There are forms of poker suitable to any number of players from 2 to 14. but in most forms the ideal number is 6, 7 or 8 players.

Cards. — Poker is almost always played with the standard 52-card deck, the cards in each of the four suits (♠, ♥, ♦, ♣) ranking A (high). K, Q. J, 10, 9. 8, 7, 6, 5. 4, 3, 2, A (low only in the straight or straight flush 5–4–3–2–A and in certain variants described below).

Wild Cards or **"Freaks."**—A wild card stands for any other card its holder wishes to name. There are many methods of introducing wild cards into the game. The most popular are: (1) Joker; a 53-card pack is used, including the joker as a wild card. (2) Bug; the same 53-card pack including the joker is used. but the joker (here called the bug) counts only as a fifth ace or to fill a flush, straight or special hand (described below). (3) Deuces wild or freak pots; all four deuces are wild cards. (4) One-eyes; in the usual British or U.S. pack, the ♦ K. ♠ J and ♥ J are the only cards shown in profile. They are often designated as wild cards.

Rank of Poker Hands. — The traditional, universally accepted ranking of poker hands, from highest to lowest, is:

1. Straight flush: five cards of the same suit and in sequence. The highest straight flush is A-K-Q-J-10 of the same suit, called a royal flush; the lowest straight flush is 5-4-3-2-.4 of the same suit.
2. Four of a kind, as all four 6s, with any fifth card.
3. Full house or full hand: three of one kind and two of another, as 10-10-10-3-3.
4. Flush: five cards of the same suit.
5. Straight: five cards in sequence, in two or more suits. The highest straight is A-K-Q-J-10, the lowest 5-4-3-2-A.
6. Three of a kind or triplets, with any two other cards, not a pair.
7. Two pairs, as A-A-9-9 and any fiith card.
8. One pair, with three unmatched cards.
9. No pair, each such hand being rated by its highest card or cards, as ace high or ace-king high.

When there is any wild card in the game the highest possible hand is five of a kind, which beats any straight flush.

As between two hands having combinations in the same category, the winner is determined as follows:

Straight flushes, flushes, straights or no pair: the one containing the highest card wins; if these cards are identical in rank. the next-highest decides and so on. Four of a kind or three of a kind (or five of a kind): the one composed of the higher-ranking cards. Full house: the higher three of a kind. Two pairs: the highest pair: if these are identical, the higher of the second pairs; if these are identical. the higher of the unmatched cards. One pair: the higher pair; if the pairs are identical, the highest of the unmatched cards and so on. When there are several wild cards there may be identical fours of a kind or threes of a kind, in which case ties are broken by the highest unmatched cards or secondary pairs (in a full house).

Two or more identical hands tie and divide any winning equally. The suits have no relative rank in poker.

In some games value is accorded to one or more (but seldom all) of the following special hands or to other combinations arbitrarily adopted by the players.

1. Big tiger or big cat: king high, 8 low, no pair, as K-J-10-9-8.
2. Little tiger or little cat: 8 high, 3 low, no pair, as 8-7-6-5-3.
3. Big dog: ace high, 9 low, no pair, as A-Q-J-10-9.
4. Little dog: 7 high, 2 low, no pair, as 7-5-4-3-2.

(Tigers and dogs rank in the order listed. Any tiger or dog beats a straight but loses to a flush.)

5. Skeet: five cards, 9 high, including 9,5,2, no pair, as 9-7-5-3-2; beats a straight, loses to a flush.
6. Skip straight or Dutch straight, as 2-4-6-8-10: or round-the-corner straight, as 3-2-.4-K-Q; beats three of a kind, loses to a straight. (The name pelter or kilter is sometimes applied to the skeet or skip straight.)
7. Blaze: five face cards, as K-Q-Q-J-J; beats any two pair, loses to three of a kind.
8. Four-flush: four cards of the same suit; beats one pair, loses to two pairs.

As between two special hands in the same category, ties are broken as between regular poker hands.

Object of the Game. — The object is to win the "pot," which is the aggregate of all bets made by all players in any one deal. The pot may be won either by having the highest-ranking poker hand or by making a bet that no other player calls.

Preliminaries and Rotation. — At the start of the game any player takes a pack of cards and deals them in rotation to his left. one at a time face up. until a knave (jack) appears; the player receiving that card becomes the first dealer. The turn to deal and the turn to bet always pass from player to player to the left. For each deal, any player may shuffle the cards, the dealer having last right. The dealer must offer the shuffled pack to his right-hand opponent for a cut. If that player declines to cut, any other player may cut.

Betting Procedure. — In each deal there are one or more betting intervals. In each betting interval one player, as designated by the rules of the variant being played, has the privilege or obligation of making the first bet. This player and each player in turn after him must place in the pot a number of chips (representing money. for which poker is almost invariably played) to make his total contribution to the pot at least equal the total contribution of any player before him. When a player does this he is said to be in the pot or an active player. If a player declines to do this, he discards his hand and is said to drop or pass and he may no longer compete for the pot.

Before the deal, each player may be required to make a contribution to the pot, called an ante. In each betting interval, the first player to make a bet is said to bet; a player who exactly meets the last previous bet is said to call or stay (in); and a player who bets more than the last previous bettor is said to raise. In some variants a player is permitted to check, which is to stay in without betting, provided no other player has made a bet in that betting interval.

At the end of each betting interval except the last, dealing is resumed; at the end of the last betting interval there is the "showdown," in which each active player shows his full hand and the highest-ranking hand wins the pot. In practice, especially in informal games, players usually announce the values of their hands and show their hands as confirmation only, but on demand of any player the full hand must be shown and any mistaken announcement is not valid: "The cards speak for themselves."

Betting Limits. — In poker legends there were "no-limit" or "sky's-the-limit" games, but in practice some limit is placed on what one may bet in any game. There are three popular methods.

Fixed Limit.—No one may bet or raise by more than the established limit. In draw poker the limit is usually twice as much after the draw as before; for example, two chips before the draw. four chips after. In stud poker the limit is usually twice as much in the final betting interval as in previous betting intervals. (The higher limit applies also when any player's exposed cards include a pair.) These respective forms of the game are described below. In a fixed limit game a limit is often placed on the number of raises that may be made in any betting interval.

Pot *Limit*.—A player may bet or raise by no more than the amount in the pot at the time the bet or raise is made. When raising, he may first put in the pot the number of chips required to call the previous bet and then raise by the number of chips in the pot. When pot limit is played, it is customary also to place a maximum limit on any bet or raise, regardless of the size of the pot or to play table stakes.

Table Stakes.—This method most closely approximates the legendary no-limit game. Each player's limit is the number of chips he has on the table at the beginning of the deal. He may not bet more, but for this amount he may call any higher bet and compete for the pot in the showdown. Other players having more chips may continue to bet, but their further bets go into one or more side pots in which the winner is decided as among the players who contributed fully to the side pot. When a player drops out of any side pot he has dropped out of the original pot as well, in effect surrendering his rights in the original pot to the player whose later bet he did not call.

PRINCIPAL FORMS OF POKER

Poker has two main branches: closed (straight or draw) poker, in which each player's full hand remains concealed until the showdown; and open (stud) poker, in which some but not all of a player's cards are dealt or turned face up. Within each of these branches, but especially in closed poker, there are "pass-and-out" games, in which a player must bet or drop in each turn, and "pass-and-back-in" games, in which in certain circumstances a player is permitted to check.

Straight Poker.—Each player is dealt five cards, face down. There is one betting interval, beginning with the player nearest dealer's left. then a showdown. This was the original form of poker and has almost passed out of existence except, paradoxically, in the highest-stake games among professional gamblers.

Draw Poker.—This game has two main branches: (1) blind opening, played almost to the exclusion of other variants in England, Europe and the British Commonwealth except Canada, and favoured in men's clubs in the U.S. and Latin America; and (2) jackpots, the draw poker variant most played in the U.S. and Canada. In dram poker, each player is dealt five cards, face down. There is a better interval. Then each active player, in turn beginning at dealer's left, may discard one or more of his original cards and receive replacements for them, dealt from the undealt portion of the pack. (A player who declines to draw cards is said to stand pat.) After this process, called the draw, there is a final betting interval, followed by the showdown.

Blind Opening.—There are three contributions to the pot before the deal. The dealers (or in some games, every player) puts in an ante, which does not rank as a bet. The player at dealer's left, formerly called the "age" or "edge," now called the opener. makes an opening bet of one chip or unit, called the blind. The player at his left puts in two or three units, constituting a call of the blind opening bet and a raise of one or two units; this is called the straddle or blind raise. Each player in turn thereafter may call (for the amount bet by the preceding player), raise (by one unit) or drop. The limit before the draw is usually the one unit of the ante. The limit after the dram is twice this amount or more; in some games it is the amount bet by each player before the draw. After the draw the betting begins with the active player nearest the dealer's left, and checking is permitted.

Jackpots.—Before the deal, each player antes one chip of lowest value. The game is pass-and-back-in both before and after the draw. In the first betting interval each player in turn, beginning with the one at dealer's left. may check (called also pass) or open (make the first bet); in most games a player may not open unless he has jacks or better (a pair of jacks or any higher-ranking hand). but the requirements for openers may be set higher or lower. If any player opens, each player in turn after him may call or raise until the betting interval is ended. There follow the draw, a second betting interval beginning with the opener (or if he has dropped, with the active player nearest his left) and a showdown. There are penalties for opening without openers (see Laws, below). In a similar game, called passout, no openers are required and the game is played pass-and-out (see above) before the draw.

Stud Poker.—Each player receives one card face down. called his hole card, then one card face up. The deal is then interrupted for a betting interval. There follow three rounds of dealing, each consisting of one face-up card to each active player, with a betting interval after each. There is a showdown in which the hole cards are shown after the fourth and last betting interval. In each betting interval the first bettor is the player with the highest-ranking poker combination in his face-up cards; if two or more players have the same combinations, the "first" one (nearest the dealer's left) bets first. In the first betting interval the high player must bet at least an established minimum; in any later betting interval he may check. Few games have lost popularity so fast as regular five-card stud. In the 1920s and into the 1930s it mas played in two-thirds of the high-stake and professional games in the United States; in the 1950s it was not played in one-tenth of them.

Seven-Card Stud.—Each player is dealt two hole cards, then a face-up card, followed by a betting interval; then three more face-up cards and one final face-down card, each followed by a betting interval. For the showdown each player selects any five of his seven cards to be his poker hand. There are six-card and eight-card variants of this game, in each of which a player ultimately selects five of his cards.

High-LOW Poker.—The highest-ranking poker hand and the lowest-ranking poker hand divide the pot equally. If there is an odd chip, the high hand gets it. If two or more hands tie for high or low, they divide their half of the pot equally. Nearly any form of poker may be played high-low. In most games the lowest possible hand is 7–5–4–3–2 in two or more suits, but in some games the ace may optionally be treated as the lowest card and 6–4–3–2–A becomes the lowest hand, while a pair of aces is the lowest pair.

High-Low Seven-Card Stud.—The high and low hands divide the pot, but each player may select any five of his cards as his candidate for high hand and any five as his candidate for low hand and so win the entire pot. In some games declarations are required: before the showdown each player must announce whether he is trying for high. for low or for both, and he cannot win unless his entire announcement is fulfilled.

Low Poker or Lowball.—This is draw poker played similarly to jackpots except that a player may open on any hand and the lowest-ranking hand wins the pot. In California, where the game is most popular. straights and flushes never count and the ace is always the lowest-ranking card, so the lowest possible hand is 5–4–3–2–A regardless of suits, called a bicycle or wheel.

Dealer's Choice or Dealer's Option.—In informal poker games, each successive dealer is usually permitted to dictate the variant of poker that will be played. This privilege is most often expressed by the dealer's selecting one of the forms of poker described above and designating certain cards to be wild. Ordinarily the dealer can select or invent any variant he wishes. subject to only two restrictions: the dealer cannot require any player to ante more than any other player; if the game requires a minimum to open (as jackpots) and is passed out, the same dealer deals again.

LAWS OF POKER

No code of poker laws has been universally adopted as the laws of bridge have been. Nearly every club or serious game has certain house rules that may differ in some respects (usually minor) from those of other clubs and groups. The usual practice is to adopt a published code and add the house rules to it. A code prepared by O. Jacoby in 1940 and another (nearly identical in substance) appearing in The *Official Rules* of *Card* Games since 1945, are the ones most often adopted in the United States. Poker laws, unlike those of other card games, provide only rectification and no penalties for irregularities.

Certain departures from regular procedure are necessarily treated differently in draw poker and stud poker. The following summary follows the Jacoby code.

Laws Applying to All Forms of Poker.—Misdeal—The same dealer deals again with the same pack if: a card is exposed in the cut; two or more cards are exposed in the deal; the pack is found to be imperfect (but after the next deal begins, all previous deals stand); a player is dealing out of turn and attention is drawn to that fact by a player who has not looked at any of his cards. If one card is exposed during the deal the player must take it.

Betting.—Money (chips) put in the pot may not be removed for any reason; except that in a jackpots game when a player has opened illegally each other player may remove his chips bet after the pot was opened and before the disclosure of the false openers. A player has no redress if he misunderstood a previous bet or announcement. In table stakes a player may never bet more than his entire stack.

Action Out of *Turn*—An announcement out of turn of intention to drop or bet is binding, but is temporarily canceled pending action by any player rightfully in turn. When the offender's turn comes, he may forfeit the announced amount and drop, if that amount was insufficient to call; he may if necessary add enough to call but not to raise; he is deemed to have raised by any excess of the announced amount over the amount necessary to call. (In some games action out of turn is simply void.)

Incorrect *Number* of Cards.—A player who has only four valid cards may play on but may not make a flush, straight or any special hand based on five cards. (In many games a four-card hand is dead and cannot win the pot.)

Laws Applying to Draw Poker.—Incorrect Hand.—If one player is dealt four cards, another six, and if neither has looked at his hand, the former draws a card from the latter; if either has looked at his hand, the hand is foul (cannot win the pot). If a player has not looked at his hand and has four cards, the dealer gives him another from the top of the pack; if he has six cards, the dealer draws one card and places it on the bottom of the pack.

Card Exposed During *the Draw*.—If the card was faced in the pack, it is discarded and the draw continues. If the card was exposed in dealing, it is discarded and the player is given a replacement after all other players have drawn.

Wrong Number of Cards *Drawn*.—A player must take the number of cards he asked for, unless he corrects himself before he looks at any card drann and before the next player has drawn. If he has discarded, he may discard more to make room for additional cards or he may if necessary play on nith four (but no fewer) cards; he may not reclaim any discard. Ii he has been given too many cards and looks at any of them, his hand is foul. He has no redress whether an error was his or the dealer's.

Insufficient Cards in Pack.—The bottom card of the pack may not be dealt. If there are too few cards remaining to complete the draw, the dealer gathers together all discards of players who have dropped or have already drawn, shuffles them, has them cut and continues the draw. The opener's discards, if identifiable, are exempted.

Laws Applying to Stud Poker.—Incorrect Hand.—If a player, for any reason, has an incorrect number of cards his hand is foul.

Exposed Card.—If a hole card is exposed accidentally in the deal, the dealer gives the player his next card face down. A player may not intentionally expose a hole card and receive a subsequent card face down; he may play on with that card exposed. If a card to be dealt is exposed before a betting interval is ended, then that card and one card for each other active player are buried before the deal is resumed.

Insufficient Cards in Pack.—The bottom card of the pack may not be dealt. If there are not enough cards to complete every active player's hand, the dealer flashes (exposes) a card instead of dealing the last round, and the exposed card is considered the last card of every active player's hand.

SKILLFUL PLAY

Poker better rewards skillful play than any other card game. Though it is not so complex a game as bridge and numerous other games, the player has greater control over the result (largely because he is permitted to drop bad hands); consequently a good player is less likely to lose in a game with inferior players.

Since poker has a mathematical basis (the less probable a particular holding, the higher its rank), the science of the game begins with the relative expectancies of the several hands, though this is only background knowledge that seldom has practical application in play.

There are possible 2,598,960 different five-card hands that may be dealt from a 52-card pack, as follows:

Possible Poker Hands In 52-Card Pack

Hand	*No. possible*	*Chance of being dealt*
Straight flush	40	64,974
Four of a kind	624	4,165
Full house	3,744	694
Flush	5,108	509
Straight	10,200	256
Three of a kind	54,912	48
Two paps	123,552	21
One pair	1,098,240	2.5
No pair	1,302,540	2

A person beginning the study of poker on purely theoretical grounds would find such a table indispensable. It would tell him, for example, that if he is dealt a flush there are only a few thousand possible hands that might beat him while there are more than 2.500.000 he can beat, whereupon he would be justified in making or calling a maximal bet.

From a practical standpoint, the player needs chiefly to know what constitutes a good hand, a fair hand and a poor hand in a given form of poker. Experience as well as mathematics indicates the following as the average winning hands in the forms of poker most frequently played.

Game	*Average winning hand*
Draw poker, nothing wild	Jacks up
Five-card stud	Aces or kings
Seven-card stud	3 eights
Dram poker, joker wild	3 eights
Draw poker, with bug	Aces up
Draw poker, deuces wild	3 aces
Draw poker, high-low	Jacks up high; 10 or 9 low
Lowball	9-6-x-x-x

The fundamental principle of skillful play is that a person should stay in the pot only if: (1) he probably has the best hand or (2) the odds against his drawing the best hand are less than the odds offered by the pot. To illustrate the latter: There are four chips in the pot and the player must put in one chip to stay; thereiore the pot offers 4–to–1 odds. The player has a four-flush or "bobtail" straight (open at both ends as 8–7–6–5), to either of which he can draw one card. The odds against filling either of these hands ranges $4\frac{1}{4}$–5 to 1. The pot offers less than the odds against filling, so the player should drop.

The approximate odds against improving the original hand in draw poker are as follows:

Hand	*Odds against improving*
One pair	$2\frac{1}{2}$ to 1
Two pairs	11 to 1
Three of a kind	$8\frac{1}{2}$ to 1
Straight, open	5 to 1 (39 to 8)
Straight, inside (as 8–7–5–4)	11 to 1
Straight flush, open	2 to 1
Straight flush, inside	3 to 1

In five-card stud poker it is wise to stay in only if one has a pair. a hole card higher than any card showing or a card at least as high as any card showing plus another high card. It is never wise to stay in when another player has showing a pair higher than one's own pair (or if one has no pair). In seven-card stud, it is usually best to stay in only if one has a pair. three cards of the same suit or three cards in sequence. In seven-card high-low stud. the guiding principle is to play for low.

The only hand with which to play for high is three of a kind in the first three cards.

Bluffing and psychological play, though they are of essential importance, depend more on experience and moral ascendancy than on rules of play or maxims.

HISTORY

The principle of poker is very ancient. One of its ancestral games (Sp. primero, It. primiera, Fr. la prime) appears in literature at least as early as 1526. In this game each player had three cards and the counting combinations were three of a kind. a pair and a flux (flush). three cards of the same suit. In later developments certain cards had special value, equivalent to wild cards in modern poker. By about 1700 the betting and bluffing aspects had produced the games brag in England (one of four card games about which Edmond Hoyle wrote) and pochen (Ger. "to bluff") in Germany. From the latter the French developed a similar game called *poque,* played in French America in 1803. when the Louisiana purchase made New Orleans and its environs territories of the United States. During the next 20 years English-speaking settlers in the Louisiana territory adopted the game, anglicized its name to poker and established the essential features of the modern game.

The earliest-known reference to poker in American literature occurs (1829) in the memoirs of Joe Cowell, a touring English actor. From his description it is clear that the original American game was played with a pack of cards that included five cards for each player: all the cards were dealt and the players bet on which had the best five-card combination.

So played. poker is virtually indistinguishable from an older Persian game called *As nas,* a four-hand game played with a 20-card pack. five cards dealt to each player. This coincidence has led some students of games to call poker a derivative of As *nas,* but there is no record of any connection between the two.

By 1834. the date of the second known reference to poker, the game had been adapted to the 52-card deck. No description of poker is given in any book of the rules of games before 1858. but in such books published in the 1860s it is not characterized as a new game. The history of the game since then consists entirely of new features introduced to encourage freer betting: the straight, introduced as an additional valuable hand; the draw, so that players might stay in even when they were not originally dealt good hands; stud poker, to increase the number of opportunities for betting; jackpots, originally only applying to a pot to which each player antes, creating an unusually large pot at the start. Most of these innovations came in the decade 1861–70 and probably were engendered in the great amount of poker played by soldiers on both sides in the Civil War.

The spread of poker to other countries probably began in 1871 when Col. Jacob Schenck, the U.S. minister to Great Britain, explained the game to a group of gentlemen including members of the British court. Queen Victoria heard about the game and expressed interest, whereupon Schenck wrote and had privately printed (1872) a set of rules to send to her. This is the earliest-known work devoted exclusively to poker, although the game had previously (1858. 1864, etc.) been treated in compendiums. Poker was already sufficiently identified with the United States so that Schenck described it as "our national game." However this may have been only because all other card games played in the U.S. were undeniably of European origin.

Whether rapidly or gradually, between 1870 and the end of the 19th century, poker became a matter of general knowledge in the United States, and early in the 20th century it spread to other parts of the world.

See *Oswald Jacoby on Poker* (1947) for the game as played in the U.S.; Maurice Ellinger, *Poker* (1950) for the game as played in England. (O. JY.; A. H. MD.)

POKOMAM, a group of Indians speaking a Maya dialect who live in southern Guatemala. Their territory runs from the upper part of the Motaqua river to the border of Salvador. They inhabit the departments of Chimaltenango (in part). Guatemala. Amatitlán and Jalapa in Guatemala, and at the time of the conquest they extended to Chalchuapa in Salvador. The principal towns where this tongue is spoken are San Martin Jilotepeque, Mixco, Petapa. Jalapa, Jilotepeque and Asunción Mita. They number about 50,000, of whom more than half speak their native tongue.

The ancient capital of the Pokomam was the fortress of Mixco situated on a steep hill in the valley of Xilotepeque.

POLABS (Po = on, *Laba* = Elbe), the Slavs (*q.v.*) who dwelt upon the Elbe and eastward to the Oder. Except the Lithuanians they were the last Europeans to be Christianized; their chief sanctuary was at Arcona on the Isle of Rügen. They were converted and conquered in the 12th century and germanized. By the 17th century Slavonic survived only in a tiny patch in the east of Hanover about Lüchow: its scanty remains are corrupt.

POLAND (POLSKA), a country of eastern Europe lying between the Baltic sea to the north and the Sudeten and the Carpathian mountains to the south and bounded, from 1945, on the east by the U.S.S.R., on the south by Czechoslovakia and on the west by Germany. (For population, see below.)

PHYSICAL GEOGRAPHY

The main morphological features have been moulded by two great influences: the northward thrust of the alpine fold mountains against the Hercynian plateaus (represented there by the Bohemian massif and the submerged Polish platform which reaches the surface in the Lysagora) and the southward sweep of the Scandinavian ice-sheet. Conditioned by these influences the natural regions tend to form zones running broadly east and west across the country.

In the extreme south, the mountain frontier zone is divided into two sections. The first, composed of the older, much peneplained rocks of the Sudeten mountains, reaches its highest point in Mt. Sniezka (5.259 ft.): the second. formed by the young fold mountains of the Carpathians, assumes a truly alpine appearance in the High Tatras, the highest point of which, Gerlachovka (8,737 ft.), lies across the frontier in Slovakia. The submontane zone of southern Poland, consisting of upland-rimmed river basins interconnected by narrow gateways, is again capable of subdivision. Thus Silesia, drained northwestward by the Oder, forms a unity centring upon Wroclaw (Breslau); bounded on the north by the Trzebnica hills, this basin represents an extension of the great carboniferous deposits of northwestern Europe. The sub-Carpathian basins. on the other hand, occupy a tectonic hollow running from the Moravian gate through the small Oswiecim basin and the Cracow gate to the wider Sandomierz basin drained by the Vistula and San, with the Przemysl gate separating the latter from the headwaters of the Dniester, within the Soviet frontier. The Little Polish tableland which separates the Silesian and sub-Carpathian basins, consists of the Cracow-Czestochowa limestone plateau (1,653 ft.), opening southeastward to the Tertiary deposits of the Nida basin, and the Holy Cross (Swietokrzyskie) mountains (Lysagora. 1.946 ft.). The southeastern edge of the latter, the level Sandomierz tableland, is noted for its fertile loess deposits. Finally, east of the Vistula the upland rim is represented by the Lublin tableland, with its rich soils derived from chalk marl, and the Roztocze ridge.

The remainder of Poland is dominated by glacial features. The characteristic east-west sectors of the great rivers and their tributaries (*e.g.,* the lines formed by the Bug-Vistula-Notec-Warta and the Warta-Obra-Oder) mark stages in the successive northward retreat of the ice sheet, when drainage was forced toward the west. Central Poland, an undulating country crossed by the great valleys, is subdivided into the Great Polish and Kujavian lowlands around Poznan and the Mazovian Podlasian lowlands around the capital city, Warsaw. The soils are based on fluvioglacial and fluvial deposits. Further north, breached by the Oder and Vistula in their lower courses, lies the Baltic lake zone, Pomorze (Pomerania) to the west and Mazuria to the east of the Vistula. It is a region of classic morainic topography: the boulder clay, sands and gravels form hummocky ridges, reaching often more than 650 ft. in height and interspersed with numerous lake-filled, peaty hollows. The morainic hills descend to a low sandy plain along the Baltic coast. The half-formed deltas of the Oder and Vistula are classic examples of the lagoon-and-bar coastal formation, where the sea currents and prevailing winds drag the river deposits and coastal sands eastward along shore. Modern methods of port maintenance and navigation enabled the old ports to continue their ocean-going trade.

Flora and Fauna.—The natural forests of Poland are transitional between the mainly coniferous stands of northern Europe, closely associated with the podsols, and the deciduous woodlands of central and western Europe growing on the more fertile brown soils. The fauna is that associated nith the temperate forests which once covered most of the country apart from the alpine zone of the high mountains. The reindeer, sable and mild horse, however, survive only in tradition; the bear is restricted to the Carpathians, the elk was found in the former northeastern provinces and the beaver in the Polesian marshes, which became Soviet territory.

About 70% of Poland's forests are coniferous, with the pine dominant, followed by spruce. There are few firs, while larches and yews appear only sporadically. The deciduous trees, more characteristic of the southern provinces, are mainly birch, beech, wych-elm, aspen, ash, oak and alder. One of the best-known forests is that of Bialowieza, famed for its ancient trees and, up to 1918, its herd of aurochs or European bison (later crossbred with animals of Canadian origin). The main timber products are deal boards. building timber, pit props and fuel. Losses incurred in World War II made it necessary to import certain types of timber, whereas before that war the export of timber accounted for one-fifth of the active foreign trade balance.

Climate.—Climatically, Poland belongs to the major zone which includes eastern Germany, most of Finland and western U.S.S.R. It is open to the influence of the prevailing, variable westerly winds. except when these are replaced during winter by the heavy masses of cold air cushioning the interior of the continent. The summers are warm or very warm, according to distance from the sea and latitude, although the latter is offset by the increasing height of the land toward the south. The winters are cold and are particularly unpleasant when pressure conditions are right for the influx of strong winds from the Russian plains. Temperatures are everywhere below freezing point for at least two winter months in the west and three months in the east. The Oder, for example, is frozen for an average of 80 days, the Vistula 80–100 days; and the Baltic harbours, especially where distant from the open sea, are icebound for a considerable period every year —Swinoujscie for 20 days on the average, Szczecin for 61 days. The open Baltic itself is frequently impeded by drift ice, but navigation usually continues along the sea lanes connecting the favourably placed docks of Gdynia-Gdansk (Danzig). The following figures for the mean January and July temperatures, in degrees Fahrenheit, are typical: Szczecin, 30.4 and 64.9; Warsaw, 26.8 and 65.5; Tomaszow Lubelski, 23.9 and 64. Sniezka, with a range between 19.2 and 46.9 and below freezing point for six months, is typical of conditions in the highest mountain regions; even in the Tatras, however, there are no permanent snows.

Precipitation, in winter mostly in the form of snow, is moderate, 20–27.5 in., except along the southern highland fringe. More falls in the summer half-year, because of the development of thundery conditions in early summer and of the passage of depressions in autumn. The skies are on the whole cloudy, mean cloudiness averaging somewhat less than seven out of ten points; the summers are brighter and less humid, although more rainy, than the winters. Wroclaw is representative, with a mean annual rainfall of 23.3 in, and cloudiness of 6.8 points; precipitation is distributed seasonally, in percentages of the total, beginning with winter, as follows: 16, 24, 38 and 22. Sniezka has a mean annual precipitation of 45.6 in.. typical of the narrow mountain fringe.

HISTORY

Polish history begins in the year 963 when a German border knight came into contact with Mieczyslaw or Mieszko I, who was prince of Poland till 992. The unity of the Polish state, surrounded as it was by other pagan and mostly Slavonic tribes, had been achieved under the descendants of Piast (said to have been either of peasant origin or an official at the court of an older dynasty), who founded the dynasty which gave his people strong and valiant rulers down to 1370. Mieszko's predecessors had succeeded not only in uniting a number of tribes but in establishing a highly developed political community which had neither enjoyed the benefits nor suffered the disadvantages of contact with the high civilizations of western and southern Europe. To meet the dangers that arose when the Germans began to penetrate the barrier formed by the western Slavonic tribes. Mieszko conceived that policy of deliberately adopting western civilization which was the chief object of the rulers of Poland for several centuries. He secured his state from the aggression of his new neighbours by acknowledging himself a tributary of the western emperor Otto I, and removed all danger of a hostile crusade by accepting Christianity for himself and for his people in 966 with the help of the Czech princess Dubravka or Dabrowka, whom he had married a year before. Finally he placed all his lands in the hands of the pope, thus inaugurating a close relationship that gave Poland the special protection of the Holy See. He seems to have been successful in gaining Pomorze (Pomerania; *i.e.*, the seaboard), but lost part of his eastern territory to Vladimir the Saint.

THE PIAST KINGDOM

Mieszko's son Boleslaw I the Brave (see BOLESLAW I) (992–1025) was one of the great soldiers and statesmen of his time. From the congress of Gniezno (Gnesen) (1000) with his friend the emperor Otto III, where he secured for Poland an independent church, organized in a number of bishoprics under a metropolitan at Gniezno. to his coronation as king (1024), he achieved the transformation of his father's principality into a powerful and independent kingdom. His wars of defense and expansion against Germany and Bohemia ended successfully in 1018; then he turned east and occupied the Russian capital. Kiev, thus recovering the territory lost in the preceding reign. His younger son Ilieszko II (1025–34) succeeded him as king, but the power of the kingdom waned in spite of its partial revival under Mieszko II's son Casimir (Kazimierz) I the Restorer (1038–58) and the strong rule of Casimir's son Boleslaw II the Bold (*see* BOLESLAW II) (1058–79). But under Boleslaw III Wrymouth (*see* BOLESLAW III) (1102–38), a nephew of Boleslaw II, Poland made great advances. Boleslaw maintained the independence of his country when the emperor Henry V invaded Silesia in 1109 by a victory at Glogow. His reign saw a considerable cultural advance, and an anonymous chronicler recorded the earlier history of Poland. He collaborated with Otto, bishop of Bamberg, in converting the Pomeranians to Christianity and occupied the greater part of that province.

The Period of Division, 1138–1314.—Boleslaw III divided Poland among his sons, so that Poland, like its neighbours Germany and Kievan Russia: ceased to be a united state for two centuries. The capital was established at Cracow, the ruler of which held the central provinces of Poland together with Pomorze and had "seniority" over his brothers, who ruled over Silesia, Mazovia, Great (or western) Poland and Sandomierz. In each of these principalities there grew up round the Piast prince a powerful upper class consisting of the officials and the clergy headed by the local bishop, a process which modified the *jus* ducale of the monarchical system. This period of divided loyalties laid the country open to many dangers; while the empire remained strong, a ruler like Frederick I Barbarossa in 1157 could assert his claim to Polish allegiance, and a major disaster like the Mongol invasion in 1241 found the chivalry of Little (or southern) Poland unsupported and the heroic efforts of Prince Henry of Silesia made in vain. Worst of all were the incessant raids of the barbarian neighbours, notably the Lithuanians and Prussians. To avert these, Prince Conrad of Mazovia called in the Teutonic Order, a purely German crusading organization that had lost a sphere for its activities in Palestine. Well established on the northern border, the order was helped by the Poles to occupy not only the borderland but the whole of Prussia, which was speedily colonized mainly by German immigrants. By a brilliant piece of diplomacy the grand master Hermann von Salza persuaded the emperor Frederick II to accept his homage as ruler of the newly acquired lands (1226). The divided Polish states found themselves face to face with a powerful German state on their northern border.

In spite of the political weakness of Poland, of the great Mongol disaster and of the menace from Germany, this age was one of great importance to the development of Poland. In the process of decentralization, each province was able to assert its own individuality, helping its prince and bishop to enlarge its capital city and to intensify their efforts to develop the resources of its small territory. The petty princes were able to imitate western Europe by encouraging the immigration of German peasants, townsmen and artisans, who helped them to raise the level of economic life. The ideal of the 13th-century Polish prince, especially in Silesia, was *melioratio terrae,* to achieve which he was prepared to sacrifice both part of his own sovereign power and vague national ideals. This lack of a Polish patriotism resulted in the loss to Poland of some areas: Lower Silesia and western Pomorze were gradually colonized by Germans. But the economic and cultural advance of the country as a whole was worth the sacrifice. The community thus strengthened was able to maintain its ethnical frontier in spite of political disaster for six centuries. In most of Poland the Germans were ultimately absorbed. The princes further reduced their sovereign power by the granting of charters to different groups and individuals. The Jews, whom crusading zeal had expelled from nearly every country, were granted the right to settle in Poland, to maintain their own schools and to practise their religion. For the Poles they were skilled middlemen who made an important contribution to the economic life of the country but who were never absorbed as the Germans were and hampered the formation of a Polish middle class. The achievements of this period of division, in spite of its difficulties and weaknesses, can be appreciated through a comparison of the low social and economic situation in the 12th century with the resources available to the revived monarchy after 1305, whereby the rulers were able to reunite the divided principalities and to preside over the rapid development of a state that had no need to copy the social and economic life of its neighbours.

Wladyslaw I, 1314–33.—The idea of reuniting the Polish principalities in one state first appears in the experiments of the princes of Silesia, especially in those of Henry I the Bearded. These princes failed partly because they gradually succumbed to the attraction of German civilization and joined the empire under Czech auspices. Przemyslaw II of Great Poland actually assumed the royal title in 1295; but the real task of reunion was undertaken, at a time when Poland had come under the rule of Czech kings, by the hard-fighting Wladyslaw Lokietek (Ladislas the Short) (see WLADISLAUS) of Kujavia. The idea was strongly supported by the ecclesiastical leaders. These men had represented for a long time the links that bound Poles together and led the enlightened magnates who realized that a divided Poland would suffer extinction at the hands of such powerful neighbours as Bohemia, Brandenburg, Hungary and the Teutonic Order. Wladyslaw cleverly availed himself of the support of Hungary and of the traditional protection of the Holy See. After occupying Little Poland in 1305 and Great Poland in 1314, he was crowned king of Poland in 1320 as Wladyslaw I (1314–33). He had many disappointments: the Teutonic Order seized Pomorze in 1308; his country long continued to suffer from the raids of the pagan Lithuanians; and he never reigned over Silesia or Mazovia, which preferred to do homage to John of Bohemia. But he held his own against the order in the battle of Plowce (1331), strengthened his position by his diplomatic friendship with Hungary (which was sealed in 1320 by his daughter Elizabeth's marriage to the new Angevin king Charles I) and ended for a time the Lithuanian raids by marrying his son Casimir to Anne (Aldona), daughter of the grand duke Gedymin, in 1325.

Casimir III the Great, 1333–70.—Unlike his father, Casimir was born in the purple and was a man of peace. A realist and a shrewd diplomatist with a zest for the Latin culture that he learned at the court of his sister in Hungary, he was ready to make great sacrifices to secure the independence, unity and prosperity of his kingdom. Happily for Poland the decline of the empire, the disunity of Germany, the weakness of Russia and the death of the last great khan of the Tatars lessened the dangers on the western and eastern frontiers. Poland had to face in the south the powerful kingdom of Bohemia, whose king in 1355 was crowned emperor as Charles IV, and in the north the great military strength of the Teutonic Knights. Basing his foreign policy on a close alliance with Hungary, he was content to allow Charles IV, another lover of peace, to hold Silesia, and to give up his claim to Pomorze and the border districts held by the order. As compensation for this loss of Polish territory, he found himself able by inheritance and diplomacy to annex Halicz and to begin that policy of conciliation with the Lithuanian princes which was to bring such important results later on. His own prestige grew abroad, and he made Poland a full member of the European community. By thus gaining for Poland a long period of peace and security, he was able to make great changes in the internal relations of the country. He codified the laws of Great and Little Poland and succeeded in persuading these two rival states to cooperate, while the local officials of Little Poland became national ministers. The princes of Mazovia were persuaded to acknowledge Casimir as their king. He acquired great wealth, reformed the currency and introduced western methods in town and country. He befriended the Jews, improved the position of the peasants and encouraged the immigration of Germans and Armenians, so that the cities grew in size and prosperity. especially Cracow and Lwow. He was a great builder and was said to have "found a country of wood and left a country of stone." The administration was made more efficient, and it was mainly to train young men in law that Casimir founded the University of Cracow in 1364. He encouraged learning and was able, through the Italian influences at the court of Hungary and the French connections of Prague, to raise the level of learning among the Poles to western European standards. By his foresight, his patience and genius for creation and adaptation, this great statesman made possible the strong and prosperous position of the Polish kingdom during his lifetime and its great development in the next two centuries.

Louis I of Hungary, 1370–82.—Having no sons, Casimir III bequeathed his kingdom to his sister Elizabeth's son Louis I of Hungary (1370–82), already one of the leading rulers of central Europe, who continued the co-operation of his two realms in the spirit of his predecessor. Like Casimir, he left no sons, and the future of central Europe depended to some extent on the fate of his two daughters. After an interregnum of two years the Poles accepted his younger daughter Jadwiga as their queen (1384–98) and consummated the efforts of Casimir III to conciliate the pagan rulers of Lithuania by arranging the marriage of Jadwiga to Jagiello. grand duke of Lithuania, who became king of Poland as Wladyslaw II (1386–1434).

Social and Constitutional Development, 1138–1384.—The social structure of the Polish state at the time of the dynastic union with Lithuania was very different from what it had been under the early kings. In the period of division there had grown up round each prince a class of ecclesiastical and lay magnates whose function was at first to advise and later to share with the prince the government of his principality. In addition to this privileged class, the general mass of the gentry, organized in their clans, each with its coat of arms and slogan, was becoming conscious of its own importance as a social and political element in the country. As the prince gradually lost his monopoly of political and legal power by the grant of charters to various groups, this body, which came to be called the *szlachta,* began to share political privileges with the magnates. The extinction of the Piast dynasty gave them the opportunity by the pact of Koszyce (Kosice) in 1374 to obtain from Louis a number of privileges, the magna *carta* of Poland. The chief of these was the right to pay no taxes beyond a certain sum, unless they had expressly consented to them. During the period of division the church, which had established its position at the synod of Leczyca in 1180, played a leading part, not only in the social and moral life of the community but also as the sole factor of unity between the numerous principalities. The inhabitants of the towns had received charters mainly under Magdeburg law to encourage the settlement of Germans. Besides Wroclaw (Breslau) and Poznan, the two great cities Cracow and Lwow grew to prosperity on the great eastern trade route. These towns, though at first largely foreign in race, became integral members of the community, able to aid and to advise the prince and to attain political importance. The peasants. with the rise of the gentry, lost in social standing but gained economically by the rights granted under Magdeburg law in the reign of Casimir 111—a situation that only slowly worsened as serfdom grew up a century later. From the small body of educated men who made the court of Boleslaw III superior to that of the early kings (with the famous Otto, later bishop of Bamberg, and the anonymous scholar who wrote the first history of Poland), through the spread of western social and moral ideas (at first chiefly by the Cistercians) to the writing of a real historical work by Wincenty Kadlubek (d. 1223), the great progress of learning in the Polish community can be followed, only temporarily interrupted by the Mongol invasions. The great problem of the Poles was to seek and assimilate western institutions and ideas while retaining and cherishing their own native civilization. They were forced to learn mainly from the Germans. But the political exploitation of this position by the latter led to the rise of strong anti-German feeling and to the practice of seeking models in Italy, France or the Low Countries in preference to Germany. The union of Poland and Lithuania was a mortal blow to the position of the Teutonic Order, the greatest German power on the Polish border.

THE JAGIELLON DYNASTY

***Jadwiga and Wladyslaw* II Jagiello.**—The magnates of Cracow, Casimir III's pupils and successors, were able to instruct the girl queen and the pagan king in the arts of government. One of the first acts of the new king was to receive Christianity for himself and his people. The Lithuanians, unlike the Ruthenian members of their grand duchy who were Orthodox, joined the western Catholic Church. So the Poles gained by peaceful agreement what the German Knights had sought by violence during a century and failed to win: the conversion of the last great body of pagans in Europe. The very reason for the existence of the order had gone, and it would have to struggle to preserve its territories which included Pomorze with Danzig (Gdansk) and the whole of Prussia. But the settlement was delayed for some time, partly because of Jadwiga's religious scruples against fighting a crusading body, and partly because Wladyslaw Jagiello had to solve the difficult problem of Lithuania, where he had a rival in his cousin Vytautas (Witold). The order exploited this situation so adroitly that the king was forced to recognize Vytautas as grand duke of Lithuania. This arrangement was successful for a time, and in 1409 the aggression of the order provoked the two cousins to join their forces against their common enemy. Advancing into Prussia they completely defeated the Knights in the great battle of Grunwald (Tannenberg) in 1410. Unfortunately, though the victory was followed by the union of Horodlo (1413), which established in Lithuania institutions based on those of Poland, the two cousins did not always agree; and Poland was exposed in the south to the hostility of Sigismund of Bohemia, who had succeeded to the possessions of Louis of Hungary in 1387 and to the German kingdom in 1410. Jagiello lost his wife Jadwiga in 1398 and remained without male issue by his next two wives; but his fourth, whom he married in 1422, the Lithuanian princess Sophia Holszanska, gave him what Poland needed: two sons. Throughout his long reign he continued to collaborate amicably with the Polish leaders or, occasionally, to oppose them, knowing well that the union with Lithuania depended on his own person. He suffered great anxiety from the ambitions of Vytautas, who was a great warrior and statesman and planned to conquer the Tatars and to annex Moscow. Beloved by the Lithuanian people, Vytautas died in 1430. Wladyslaw Jagiello died in 1434, after a reign of 48 years, at a great age. He was, like most of his family, a prudent, tolerant and tenacious ruler, and he founded a dynasty that was to be one of the greatest in Europe.

***Wladyslaw* III, 1434–44.**—Jagiello was succeeded by his ten-year-old son Wladyslaw III, the chief position in the realm being held by the most eminent of the Cracow magnates, Zbigniew Olesnicki, bishop of Cracow and one of the previous king's chief advisers, who became a cardinal. Olesnicki had to deal with a number of urgent problems: the spread of Hussitism among the gentry; the threat to European civilization from the Turks on the Danube; the possibility of the recovery of Silesia from the Czechs and of Pomorze from the Teutonic Order; and the dangerous rise of rebellion in Lithuania among the Orthodox Ruthenians. A highly cultured scholar, a great orator and diplomatist, he played a leading part in the council of Basel. The Lithuanian rebels, though supported by the master of Livonia (the Knights of the Sword had been amalgamated with the Teutonic Order in 1237), were decisively defeated in 1435 near Wilkomierz (Vilkomir, Ukmerge). A churchman. Olesnicki was, like Queen Jadwiga, prepared to conciliate the Teutonic Order and to concentrate the national forces against the heretical Czechs (so as to recover Silesia) and against the Turk in the south. He failed in the first project, and his great crusade, which involved securing the throne of Hungary for Wladyslaw III (who thus became Ulaszlo I of Hungary), was brought to a disastrous end by the defeat at Varna (1444), where Wladyslaw was killed and his supporter John Hunyadi routed. Until his death was certain, Poland remained without a ruler for three years (1444–47), when Wladyslaw II Jagiello's second son, Casimir, who had made himself popular in Lithuania, ascended the Polish throne. (A. B. Bo.)

Casimir IV, 1447–92.—The difficulties which confronted Casimir were great. He recognized not only the vital necessity of the maintenance of the union between the two states but also the fact that the chief source of danger to the union lay in Lithuania. For political reasons, during the earlier years of his reign, Casimir was obliged to reside for the most part in Lithuania, and his interest in the grand duchy was always resented in Poland, where, to the very end of his reign, he was regarded with suspicion. In particular, he could never rely on adequate Polish support in the struggle, which he inherited from his predecessors, with the Teutonic Order.

The struggle assumed a new form in 1454, when Casimir accepted the suzerainty offered to him by the Prussian league, which had repudiated the authority of the order and needed a protector. The acquisition of the Prussian lands was vital to the existence of Poland. It meant the command of the principal rivers of Poland, the Vistula and the Niemen, and the acquisition of a seaboard with its corollaries of sea power and commerce. Yet, except in the border province of Great Poland, which was interested commercially, the king received little support, military or financial, and it was only with his victory at Puck (Sept. 17, 1462) that he obtained any decisive success against the order. The war was ended in 1466 by the second treaty of Torun (Oct. 14), by which Poland recovered the provinces of Pomorze, Chelmno and Michalow, with the bishopric of Warmia (Ermeland), numerous cities and fortresses, including Marienburg, Elbing, Danzig and Torun. The territory of the Knights was now reduced to Prussia proper, embracing, roughly speaking, the district between the Baltic, the lower Vistula and the lower Niemen, with Konigsberg as its capital. For this territory each grand master within nine months of his election was in future to render homage to the Polish king, who undertook not to make war or to engage in any important enterprise without Prussian consent. Prussia had now become a Polish province, and Poland had acquired a seaboard.

The whole foreign policy of Casimir IV was influenced by the

Prussian question. At the beginning of the war both the empire and the papacy were against him. He therefore allied himself with George of Podebrad, whom the Hussites had placed on the throne of Bohemia. On the death of George (1471), Casimir's eldest son, Vladislav (*i.e.,* in Polish, Wladyslaw), was elected king of Bohemia by the Utraquist party, despite the determined opposition of Matthias Corvinus (Matthias I Hunyadi), the king of Hungary, who thenceforward deliberately set about traversing all the plans of Casimir. He encouraged the Teutonic Order to rebel against Poland; he entertained at his court anti-Polish embassies from Moscow; he encouraged the Tatars to ravage Lithuania; he thwarted Casimir's policy in Moldavia. His death in 1490 came, therefore, as a distinct relief to Poland, and all danger from the side of Hungary was removed when Vladislav, already king of Bohemia, was elected king of Hungary also.

It was in the reign of Casimir IV that Poland first came into direct collision with the Turks. The Jagiellons, as a rule, prudently avoided committing themselves to any political system which might irritate the still distant but much-dreaded Turk, but when their dominions extended so far southward as to embrace Moldavia the observance of a strict neutrality became exceedingly difficult. Poland had established a sort of suzerainty over Moldavia as early as the end of the 14th century, but at best it was a loose and vague overlordship which the hospodars repudiated whenever they were strong enough to do so. The Turks themselves were too much occupied elsewhere to pay much attention to the Danubian principalities till the middle of the 15th century, and it was not till 1484 that they became inconvenient neighbours to Poland. In that year a Turkish fleet captured the strongholds of Kilia and Akkerman, commanding, respectively, the mouths of the Danube and Dniester. This aggression seriously threatened the trade of Poland, and induced Casimir IV to accede to a general league against the Porte. In 1485, after driving the Turks out of Moldavia, the Polish king, at the head of 20,000 men, proceeded to Kolomyja on the Pruth, where Bayezid II, then embarrassed by an Egyptian war, offered peace; but as no agreement concerning the captured fortresses could be arrived at, hostilities were suspended by a truce. During the remainder of Casimir's reign the Turks gave no trouble.

John Albert and Alexander.—The death of Casimir was followed by the temporary separation of Poland and Lithuania and by a strong aristocratic reaction in Poland itself. Casimir's third son, John Albert, was elected king of Poland, and his fourth son, Alexander, became grand duke of Lithuania. On the death of John Albert in 1501, Alexander succeeded him as king, and the union of Poland and Lithuania assumed a more definite character, the senate of each country agreeing that in future the king of Poland should always be grand duke of Lithuania. The acquiescence of Lithuania was essentially the result of a new danger which had arisen in the east. Till the accession of Ivan III in 1462 Moscow had been a negligible factor in Polish politics. During the earlier part of the 15th century the Lithuanian princes had successfully contested Muscovite influence even in Pskov and Great Novgorod. Many Russian historians even maintain that, but for the fact that he had simultaneously to cope with the Teutonic Order and the Tatars, Vytautas would have extinguished struggling Moscow altogether. But since the death of Vytautas (1430) the military efficiency of Lithuania had sensibly declined, and the natural attraction of the Orthodox Greek element in Lithuania toward Moscow threatened the integrity of the grand duchy. During the reign of Alexander, who was too poor to maintain any adequate standing army in Lithuania, the Muscovites and Tatars ravaged the whole country at will and were prevented from conquering it altogether only by their inability to capture the chief fortresses. In Poland, meanwhile, Alexander had practically surrendered his authority to an incapable aristocracy, while the dependent states of Prussia in the north and Moldavia in the south made strenuous efforts to break away.

Sigismund I, 1506–48.—Fortunately for the integrity of the Polish state, the premature death of Alexander in 1506 brought upon the throne his capable brother Sigismund, the fifth son of Casimir IV. Eminently practical, Sigismund I recognized that the first need of Poland was a standing army, that Poland, in order to hold its own, must in future follow the example of the west and wage its warfare with trained mercenaries. The great financial and military liberties of the Polish gentry for long prevented both the organization of an adequate national army and the development of a modern fiscal system. Much of the internal history of Sigismund's reign turns on the various proposals made toward these ends, most of which were defeated or mutilated by the aristocratic opposition in the *sejm.* The long, open frontiers of the Polish kingdom invited invasion, and the misfortunes which fell on Poland at a later time largely resulted from the failure of the defensive measures proposed by Sigismund and his advisers. Throughout his reign, the king was hampered by lack of resources. In 1525 he was compelled to grant autonomy to the province of Prussia instead of annexing it; he was unable to succour his unfortunate nephew, Louis II of Hungary, against the Turkish peril, or to prevent the occupation of one Lithuanian province after the other by the Muscovites.

To this period belong the first attempts to provide for the defense of the dzikie *pola,* or "savage steppe," as the vast plain was called which extended from Kiev to the Black sea. In the reign of Alexander, the fugitive serfs who had escaped into this wilderness (they were subsequently known as Kazaks, or Cossacks, a Tatar word meaning "freebooters") had been formed into companies (c. 1504) and placed at the disposal of the frontier *starostas*, or lord marchers, of Kaniow, Kamieniec Podolski (Kamenets-Podolsk), Cherkask on the Don and other places. But these measures proved inadequate, and in 1533 the lord marcher Ostafi Daszkiewicz, the hero of Kaniow, which he had successfully defended against a countless host of Turks and Tatars, was consulted by the diet as to the best way of defending the Ukraine permanently against such inroads. The veteran expert advised the populating and fortifying of the islands of the Dnieper. But nothing was done officially. The selfish prudence of Bona Sforza, Sigismund's second wife, did more for the national defense than the Polish state could do. To defend her immense possessions in Volhynia and Podolia, she converted the castles of Bar and Krzemieniec into first-class fortresses and placed the former in the hands of her Silesian steward, who acquitted himself so manfully of his charge that "the Tatars fell away from the frontier all the days of Pan Pretficz," and a large population settled securely beneath the walls of Bar, henceforth known as "the bastion of Podolia."

The most important political event in eastern Europe during the reign of Sigismund was the collapse of the ancient Hungarian monarchy at Mohacs in 1526. After the death of King Louis in the battle, the emperor Ferdinand and John Zapolya, voivode of Transylvania, competed for the vacant crown, and both were elected almost simultaneously. In Poland Zapolya's was the popular cause, and he also found powerful support in the influential and highly gifted Laski family, represented by the Polish chancellor and his nephews Jan and Hieronymus. Sigismund, on the other hand, favoured Ferdinand of Austria. He argued that the best way to keep the Turk from Poland was for Austria to incorporate Hungary, in which case the Austrian dominion would be a strong and permanent barrier against a Moslem invasion of Europe. History more than justified him, and the long duel which ensued between Ferdinand and Zapolya (see HUNGARY: History) enabled the Polish monarch to maintain to the end a cautious but observant neutrality. More than once, indeed, Sigismund was seriously compromised by the diplomatic vagaries of Hieronymus Laski, who entered the service of Zapolya (since 1529 the protégé of the sultan) and greatly alarmed both the emperor and the pope by his disturbing philo-Turk proclivities. As a result of Laski's intrigues, the new hospodar of Moldavia, Petrylo, after doing homage to the Porte, intervened in the struggle as the foe of both Ferdinand and Sigismund, and besieged the grand hetman of the crown, Jan Tarnowski, in Obertyn, where, however, the Moldavians (Aug. 22, 1531) sustained a crushing defeat, and Petrylo was slain. Nevertheless, so anxious was Sigismund to avoid a collision with the Turks that he forbade Tarnowski to cross the Moldavian frontier and sent a letter of explanation to Constantinople. On the death of John Zapolya, the Austro-Polish alliance was still further cemented by the marriage of Sigismund's son and heir, Sigismund Augustus, with the archduchess Elizabeth. In the reign of Sigismund was effected the incorporation of the duchy of Mazovia with the Polish crown, after an independent existence of 500 years. In 1526 the male line of the ancient dynasty became extinct, and on Aug. 26 Sigismund received the homage of the Mazovians at Warsaw, the capital of the duchy and before long of the whole kingdom.

(R. N. B.; F. M. S.; X.)

Sigismund II Augustus, 1548–72.—Already in the 15th century the University of Cracow had brought forth humanist scholars of European repute and begun to attract distinguished lecturers and numerous students from abroad. Thanks to Sigismund I's marriage to a Sforza of Milan, the royal court at Cracow became the home of the highest Renaissance art of Italy, and the royal castle on Wawel hill at Cracow, rebuilt by Italian architects and their Polish disciples, became one of the finest monuments of Renaissance style north of the Alps. Under Sigismund II the third great spiritual factor of the age, next to humanist scholarship and Renaissance art—the doctrine of the Reformation—entered potently into Poland's intellectual life, uniting with Italian culture on the common ground of literature and helping to produce the first great age of Polish poetry and prose. There followed the clash between the New Learning and the strong tradition of Poland's chivalrous Catholicism; the difficulties with the Scandinavian powers and the rising empire of the Moscow tsars; the dilemma produced between the evolution of the Polish parliamentary system and the Renaissance tendency toward the strengthening of central government authority. Even a king of genius could be only partially successful in coping with all these tasks, and the reign of Sigismund II, in many respects one of the most brilliant in Polish annals, left the seeds of decay and failure behind it.

Reformation and Counter Reformation.—The new king having shown his temper by marrying a lady of the noble house of Radziwill without asking for the opinion of the senate, the reign began in a storm of demands for constitutional guarantees to secure the parliamentary "gentry democracy" against the powers of the crown and the nobility. The king resolutely allied himself with Austria abroad and with the bishops and the nobles at home, against a threatened revolt of the gentry. In doing so, he had to take the bishops' side in the issue between the Reformation and Catholic orthodoxy, and he affirmed this by an edict against heresy in 1550. But this act only opened up the long-maturing dispute about the creation of a national church after the recent example of Henry VIII of England. The king, a man of enlightened mind, the first Polish monarch who habitually used the vernacular language instead of Latin at public functions, showed in many ways a sympathetic understanding for the tendencies of the new era. The influence of the Bohemian Hussite movement of 100 years before combined with nascent modern nationalism to inspire definite programs for a Reformed Polish state church with Polish ritual, independent of Rome, and with a priesthood subject to government authority. The large Greek Orthodox element among the citizens of the eastern provinces of the monarchy furnished an additional stimulus, which gave strength to such demands as that for the abolition of clerical celibacy in the Lutheran fashion. The bishops resorting to highhanded measures of repression, the *sejm* of Piotrkow in 1552 voted, at the king's own suggestion, the suspension of clerical courts for a twelvemonth. This was extended afterward and solemnly renewed by another *sejm* in 1555, during which masses were actually said in Polish and the communion was administered in two kinds. A religious interim of about ten years followed, during which Protestantism in Poland flourished exceedingly. Presently reformers of every shade of opinion, even those who were tolerated nowhere else, poured into Poland, which speedily became the battleground of all the sects of Europe. Soon the Protestants became numerous enough to form ecclesiastical districts of their own. The first Calvinist synod in Poland was held at Pinczow in 1550. The Bohemian Brethren, expelled from their own country, ultimately coalesced with the Calvinists at the synod of Kozminek (Aug. 1555). In the sejm itself the Protestants were absolutely supreme and invariably elected a Calvinist to be their marshal. The king, however, perceiving a danger to the constitution in the violence of the gentry, not only supported the bishops but quashed reiterated demands for a national synod. The *sejm* of 1558–59 indicates the high-water mark of Polish Protestantism. From this time forward it began to subside, gradually but unmistakably, chiefly because of the division among the reformers themselves. From the chaos of creeds resulted a chaos of ideas on all imaginable subjects, politics included. The anti-Trinitarian heresy proved to be the chief dissolvent, and from 1560 onward the relations between the Lutherans and the Calvinists were fratricidal rather than fraternal; Jan Laski (*q.v.*) vainly strove to unite all Polish Protestants round the Helvetian standard, and a federation of all Poles of the Reformed faith—the "concord of Sandomierz," 1570, predominantly Calvinist in character—met resolute Lutheran opposition and led to nothing.

While the strong individualism of the Polish national character thus thwarted all endeavours at Protestant consolidation, the wars against Orthodox Moscow effectively united Poles round their old Catholic banners, and the vigorous Protestant propaganda conducted from Konigsberg by Poland's vassal Albert, duke of East Prussia, appeared to the bulk of the nation under the guise of a German menace. These political factors told in favour of Catholicism; so did presently the wiser policy of Rome. Pope Pius IV, unlike his predecessor, adopted a conciliatory attitude toward the Polish crown in the matter of disputed appointments of bishops. The new bishops were holy and learned men, very unlike the creations of Queen Bona Sforza, and capable papal nuncios reorganized the scattered and faint-hearted Catholic forces in the land. From one of the ablest of them, Giovanni Commendone, the king, at the *sejm* of 1564, accepted the book of the decrees of the Council of Trent; immediately afterward he issued decrees banishing the more extreme heretics from the country. In 1565 the Jesuits, the vanguard of the Catholic Counter Reformation, appeared in Poland.

At their best, the various forms of Protestantism had never won more than a scanty noble and intellectual elite of the nation; they had never taken root among the peasantry or the petty bourgeoisie. While the gradual effacement of Reformed creeds removed a powerfully creative intellectual and literary factor from Poland's life, the re-establishment of Catholicism restored to the country that spiritual unity which was to be the chief source of national strength in the coming struggle against the aggression both of Orthodox Russia and of Lutheran Germany.

The Incorporation of Livonia.—Access to the Baltic had been a vital question since the dawn of the Polish state in the 10th and 11th centuries. Poland's expansion eastward, which began definitely in the 14th century through the acquisition of Halicz by Casimir the Great and was continued in the 15th through the dynastic union with Lithuania, made an extension of its foothold on the Baltic shore imperative. At the same time, the knights of the Teutonic Order (*q.v.*) had threatened to cut Poland off from access to the sea altogether. They had been beaten down by the earlier Jagiellons, and access to the sea was secured by way of Danzig. But in the 16th century the foe began to regain strength in the secular and Protestant duchy of East Prussia, formally owning allegiance to Poland. Sigismund II was naturally attracted by an opportunity to outflank this foe and to gain a separate outlet to the sea.

In the middle of the 16th century the Order of the Knights of the Sword (the Livonian Order), whose territory embraced Estonia, Livonia, Courland, Semigalliia and the islands of Dago and Oesel, was tottering. All the Baltic powers were more or less interested in the apportionment of this vast tract of land, whose geographical position made it not only the chief commercial link be. tween east and west but also the emporium whence the English, Dutch, Swedes, Danes and Germans obtained their grain, timber and most of the raw products of Lithuania and Moscow. Poland and Moscow as the nearest neighbours of this moribund state, which had so long excluded them from the sea, were vitally concerned in its fate. After an anarchic period of suspense, lasting from 1546 to 1561, during which Sweden secured Estonia while

Ivan the Terrible fearfully ravaged Livonia, Sigismund II, to whom both the master of Livonia and the archbishop of Riga had appealed more than once for protection, at length intervened decisively. At his camp before Riga in 1561 the last master, who had long been at the head of the Polish party in Livonia and had embraced Protestantism, and the archbishop of Riga gladly placed themselves beneath Sigismund's protection, and by a subsequent convention signed at Wilno (Nov. 28, 1561) Livonia was incorporated with Lithuania in much the same way as Prussia had been incorporated with Poland 36 years previously; that is to say, as a new Protestant duchy and as a fief of the Polish crown, with local autonomy and freedom of worship.

Union with Lithuania, 1569.—The danger to Lithuania, revealed in the Baltic wars with Ivan the Terrible, as well as the apathy shown in these matters by the Polish sejm, must have convinced so statesmanlike a prince as Sigismund II of the necessity of preventing any possibility of cleavage in the future between the two halves of his dominions. A personal union under one monarch had proved inadequate. A further step must be taken—the two independent countries must be transformed into a single state. The principal obstacle was the opposition of the Lithuanian magnates, who feared to lose their dominance in the grand duchy if they were merged in the szlachta (gentry) of the kingdom. When things came to a deadlock in 1564, the king tactfully intervened and voluntarily relinquished his hereditary title to Lithuania, thus placing the two countries on a constitutional equality and preparing the way for fresh negotiations. The death in 1565 of Nicholas Radziwill the Black, the chief opponent of the union, still further weakened the Lithuanians, but the negotiations, reopened at the sejm of Lublin in 1569, at first also led only to rupture. Then Sigismund executed his master stroke. Knowing the sensitiveness of the Lithuanians regarding Volhynia and Podolia, he suddenly, of his own authority, formally incorporated both these provinces with the kingdom of Poland, whereupon, amid great enthusiasm, the Volhynian and Podolian deputies took their places on the same benches as their Polish brethren. The hands of the Lithuanians were forced. Even a complete union on equal terms was better than mutilated independence. Accordingly they returned to the sejm and the union was unanimously adopted on July 1, 1569. Henceforth the kingdom of Poland and the grand duchy of Lithuania were to be one inseparable and indivisible body politic; all dependencies and colonies, including Prussia and Livonia, were to belong to Poland and Lithuania in common. The retention of the old duality of dignities was the one reminiscence of the original separation; it was not abolished till 1791, four years before the final partition of Poland.

The union definitely shifted Poland's political centre of gravity eastward; it created a common interest in the Russian menace to the long and naturally defenseless eastern frontier and in the millions of Greek Orthodox people living in the eastern borderlands. Warsaw was appointed one of the meeting places of the joint sejm, thus preparing the transfer of the capital from Cracow to Warsaw. The union was the last great historical act of the Jagiellon dynasty; it put the coping stone to the structure of a monarchy which, with growing consolidation, seemed to bear in it the promise of empire.

Political Development.—Simultaneously with the transformation into a great power of the petty principalities which composed ancient Poland, another and equally momentous political transformation was proceeding within the country itself.

The origin of the Polish constitution is to be sought in the *wiece* or councils of the Polish princes during the period of division. The privileges conferred upon the magnates of whom these councils were composed, especially upon the magnates of Little Poland (who brought the Jagiellons to the throne, directed their policy and grew rich upon their liberality), angered the less favoured szlachta, who, toward the end of the 14th century, combined for mutual defense in their *sejmiki* or local diets.

The first sejm to legislate for all Poland was that of Piotrkow (1493), summoned by John Albert to grant him subsidies; but the mandates of its deputies were limited to 12 months, and its decrees were to have force for only three years. John Albert's second sejm (1496), after granting subsidies the burden of which fell entirely on the towns and peasantry, passed a series of statutes benefiting the nobility at the expense of the other classes. These were followed by others of the same kind under his successor, Alexander, which, by facilitating import and crippling export trade in the interests of the gentry, enfeebled and degraded the middle class and thereby seriously disturbed the social equilibrium of the state. Nevertheless, so long as the Jagiellon dynasty lasted, the political rights of the cities were jealously protected by the crown against the usurpations of the nobility. The burgesses of Cracow, the most enlightened economists in the kingdom, supplied Sigismund I with his most capable counsellors during the first 20 years of his reign (1506–26). Sigismund's predecessor, Alexander, had been compelled to accept the statute *Nihil novi* (1505), which gave the sejm and the senate an equal voice with the crown in all executive matters. Under Sigismund I some of the royal prerogatives were recovered, but in his later years the influence of the gentry returned and the sejm succeeded in controlling all the great offices of state, The Polish parliamentary system, vesting supreme powers in the two houses of the sejm, was an established fact. Sigismund II knew that only a strengthening of the central authority could save the state. But his endeavours to manoeuvre his way between the two rival powers of the magnates and the lesser gentry were, on the whole, unsuccessful. A patriotic party of gentry democrats arose, veiling its program of democratic reforms under the conservative watchword of the "execution of the laws" and dealing further legislative blows at the trade of the towns and the social status of the middle class. The king, who at first sided with the great nobles against the "executionists," afterward allied himself with the latter to curtail the power of the magnates by a repeal of former royal grants of land and by the imposition of a tax on all tenants of crown lands for the maintenance of the army (1562–63). Beneficial as this was, it was obtained only at the price of further dependence of the crown on the szlachta.

THE ELECTIVE KINGS

The childless Sigismund II Augustus died suddenly in 1572. Fortunately for Poland, the political horizon was unclouded. Domestic affairs, however, were in an almost anarchical condition. The union of Lublin. barely three years old, was anything but consolidated, and in Lithuania it continued to be extremely unpopular. Worst of all, there was no recognized authority in the land to curb its jarring centrifugal political elements. Civil war was happily averted at the last moment, and a national convention assembled at Warsaw in April 1573 for the purpose of electing a new king. Five candidates for the throne were already in the field. Lithuania favoured Ivan IV. In Poland the bishops and most of the Catholic magnates were for an Austrian archduke, while the strongly anti-German szlachta were inclined to accept almost any candidate but a German. It was easy, therefore, for the adroit and energetic French ambassador to procure the election of the French candidate, Henry of Valois, duke of Anjou. Well provided with funds, he speedily bought over many of the leading magnates. Having been one of the instigators of the St. Bartholomew massacre. he was looked at askance by the Protestants; the religious difficulty in Poland, however, had meanwhile been adjusted to the satisfaction of all parties by the compact of Warsaw (Jan. 28, 1573), which granted absolute religious liberty to all non-Catholic denominations without exception—a far more liberal measure than the Germans had made in the religious peace of Augsburg 18 years before. Finally, early in April 1573 the election sejm assembled at Warsaw, and Henry was elected king of Poland.

Henry of Valois, **1573–74.**—The election had been preceded by a correctura *iurum*, or reform of the constitution. which resulted in the famous "Henrician articles" which converted Poland from a limited monarchy into a republic with an elective chief magistrate. The king was to have no voice in the choice of his successor. He was to marry a wife selected for him by the senate. He was to be neutral in all religious matters. He was not to lead the militia across the border without the consent of the szlachta, and then only for three months at a time. Should the king fail to observe any one of these articles, the nation was *ipso facto* absolved from its allegiance. Whatever its intrinsic demerits, the disastrous fruits of this reform were largely caused by the precarious geographical position of Poland, and it must be remembered to Poland's credit that it alone with England preserved the tradition of parliamentary government in the increasingly absolutist Europe of the time.

The reign of Henry of Valois lasted 13 months. The tidings of the death of his brother Charles IX determined him to exchange a thorny for what he hoped would be a flowery throne, and at midnight on June 14, 1574, he literally fled from Poland to become Henry III of France. In Nov. 1575 the senate elected the emperor Maximilian II to the throne; but the gentry democracy, at the suggestion of its new leader Jan Zamoyski (*q.v.*), chose a prince of Transylvania, Stephen Bathory, assigning him for husband to the last surviving princess of the Jagiellon dynasty, and enforced this election by arms.

Stephen Bathory, 1575–86.—The king elected by the "patriotic" party proved one of Poland's greatest kings. The glorious 11 years of his reign, too brief to be permanently effective, yet represent the high-water mark of Poland's international power, and the achievements of his genius both in foreign and domestic policy remain unsurpassed in Polish annals. (See STEPHEN [ISTVÁN] BÁTHORY.)

With the insight of a born statesman he focused his energy on two vital objectives: the maintenance of Poland's access to the sea by way of Danzig, and the defense of its newly gained further seaboard in the northeast against the rising power of Moscow. Danzig, on Bathory's election, began to intrigue against him with the emperor Maximilian (until his death in Oct. 1576) and with Russia and Denmark. In spite of a deplorable lack of understanding on the part of the Polish gentry for the issue at stake, Bathory, who had throughout the able and strenuous support of his chancellor Zamoyski, conducted a campaign against Danzig both by land and sea and finally enforced its complete submission to his rule.

Before peace was made with Danzig, Ivan the Terrible had raided Livonia once more. Bathory, for the first time in the history of Polish warfare using infantry rather than cavalry and calling peasants and burghers to arms together with the gentry, achieved in the operations against Russia the greatest military triumphs of his reign. In three successive expeditions he pushed his way northeastward as far as Pskov, and the tsar was fain to obtain the pope's intervention by a promise of making Russia Catholic. As a result of Bathory's victories, Poland pushed Russia entirely away from the Baltic for a long time and regained sway over nearly the whole of Livonia.

Brilliant as these foreign successes were, the greatness of Bathory's statesmanship was even more manifest at home. He conciliated, by concessions and privileges, two of the most important minority groups, the Ukrainian Cossacks and the Jews. The Cossacks were largely runaway serfs, who had organized themselves into a sort of military republic on the vast and scantily inhabited plains of the Ukraine or "borderland," stretching from the southeast of the monarchy toward the Black sea along the river Dnieper. The Cossack community had been drawn into the Polish military system under Bathory's predecessors by registration and pay and had already been granted exemption from taxation, as well as their own jurisdiction. Bathory, who needed them for his Russian wars, confirmed and enlarged these privileges. His successors used the Cossacks against the Russians, Turks and Tatars; but soon the Cossacks themselves were to grow into a factor of trouble for Poland, not without serious errors of policy on the Polish side.

The privileges which the Jews had obtained from former kings were augmented; from Bathory's day until 1764 the Polish Jews had a parliament of their own, meeting twice a year, with powers of taxation. It was also chiefly in the interest of the Jews that Bathory restricted, by special edict, the trading rights of Scottish pedlars, of whom as many as 30,000 were abroad in Poland in his time. Among other domestic measures, Bathory reformed the Polish judicial system by the creation of a supreme court of appeal for civil cases, and he founded, in 1579, the University of Wilno as a bulwark of western European culture in the east.

The growing imperial ambitions of the house of Habsburg had developed into a menace to Poland's international position; they now threatened to outflank and encircle Poland on the southern side. Bathory proposed to counteract them by the project of a union with Russia and a joint crusade against Turkey under the auspices of the pope. This grandiose plan would have given Poland again a firm footing on the shore of its "second sea"—the Black sea—which it had reached once before in the time of the Jagiellons. But the idea was carried with Bathory to his grave on his sudden death in 1586.

Sigismund III, 1587–1632.—The Vasa period of Polish history, which began with the election of Sigismund, son of John III of Sweden and of Sigismund I's daughter Catherine, was one of last and lost chances. The collapse of the Muscovite tsardom and the submersion of Germany by the Thirty Years' War presented Poland with an unprecedented opportunity of consolidating, once for all, its hard-won position as the dominating power between central and eastern Europe; it might even have wrested the best part of the Baltic littoral from the Scandinavian powers and pushed Russia back beyond the Volga. That this was not achieved was partly caused by the class spirit and blind selfishness of the Polish gentry. Apathetic toward vital problems of foreign policy and unwilling to make material sacrifices to the cause of national defense, they persisted in a doctrinaire defense of "republican liberty" at the very time when the need of a strong central executive was more urgent than ever.

But other grave causes of failure were not wanting. One of them consists in the very personality of the new foreign-bred king: the tenacity with which he clung to his hereditary rights to the Swedish crown involved Poland in unnecessary wars with Sweden at most inopportune times; and his bigoted devotion to the cause of Catholicism introduced a new spirit of religious fanaticism and persecution into the atmosphere of a country hitherto distinguished for toleration, while the same bigotry served Poland's interests very ill abroad. Poland's greatest statesman of the time, Jan Zamoyski, discovered in the earliest years of the reign that the king, who had married Anne, daughter of the Habsburg Charles of Styria, was willing to surrender the crown of Poland to an Austrian archduke and to return to his native Sweden in order to bring it back to the Catholic fold. Zamoyski, who had himself placed Sigismund on the throne by conquering a rival Austrian candidate. was naturally indignant. and the whole disgraceful affair of the king's secret negotiations with Austria culminated in his having to answer the charges of a special "court of inquisition" (1592)—the first time that the prestige of the crown in Poland was exposed to such an ordeal.

The Uniate Church.—It was only where the expansion of Catholicism served the interests of the Polish state that Zamoyski saw eye to eye with the king's Catholic zeal. Thus, he became instrumental in creating, at the synod of Brzesc in 1596, the Uniate Church as a halfway house for those of the republic's Greek Orthodox citizens who were willing to recognize the supremacy of Rome but desired to preserve their accustomed Eastern ritual and Slavonic liturgy. The Uniate Church served the purpose of drawing a large section of the population of the eastern border provinces out of the orbit of Moscow and into that of Polish influences; but by the antagonisms which soon began between Uniates and non-Uniates, it became in itself a source of new troubles for Poland. Besides this, the pride of Poland's Roman Catholic prelates, who looked down on the Uniate hierarchy, forced the Uniate Church into the position of a "peasant religion" and contributed to making it the social nucleus of anti-Polish Ukrainian nationalism which it henceforth remained. Even in Sigismund's time, Austria, competing with Poland for influence in the eastern Balkans, began to seduce the Ukrainian element (represented in organized form by the military community of the Cossacks) against Poland—a policy which the same Austria was to resume later in changed form and under different conditions when mistress of eastern Galicia.

Swedish, Muscovite and Turkish Wars.—The dispute over Sigismund's rights to the Swedish crown began, from the earliest years of the reign, to drag its weary course of alternate victories and defeats. At first the areas that later became Estonia and Latvia were both the scene and the principal object of the strife; in the later stages, Gustavus Adolphus transferred the ground nearer to the heart of Poland by espousing the cause of the Calvinist elector of Brandenburg. who had come into possession of East Prussia and thus laid the foundation of a large Protestant power on the Baltic. The danger to Danzig and Poland's grain exports roused even the gentry from their apathy; but in spite of some brilliant victories by sea and land. an armistice toward the end of the reign was highly unfavourable to Poland.

Sigismund's persistent Swedish ambitions, his equally persistent Austrian sympathies. but, more than all. his absolutist leanings and cherished plans for a drastic and arbitrary constitutional reform on foreign models and on antiparliamentary lines occasioned in 1606 an armed revolt of the Polish gentry against their king — the *rokosz* (or insurrection) of Mikolaj Zebrzydowski, who was supported by the discontented Protestants. The *rokosz* was at last suppressed in 1607, but it left as its legacy such ruinous precedents as an enforced recognition of the doctrine of the subjects' right to depose their king (de non *praestanda* obedientia) and, being undertaken in justified defense of the native parliamentary tradition against wholesale foreign innovations, had the harmful effect of blocking the way toward any and every reform of the parliamentary system.

Soon after the constitutional cataclysm of the *rokosz,* Poland became embroiled in prolonged wars with Moscow. The motive was partly a vague conception of a Polish-Russian union as opposed to the king's Austrian propensities, but partly also the very real desire of some border magnates for more and more land east of the Dnieper. An occasion was furnished by the extinction of the dynasty of Rurik in Russia and the subsequent struggle for the throne, particularly the emergence of one candidate — the ill-fated Pseudo-Demetrius (see DIMITRI. FALSE)—whom certain Polish nobles and finally also the king supported. The appearance of a second Pseudo-Demetrius after the fall of the first prolonged the strife. Throughout the campaigns against Moscow the king found himself at variance with some leading Polish statesmen and soldiers of the time, such as Zamoyski and, later, Stanislaw Zolkiewski; he thought of the problem only in terms of conquest, of the establishment of Catholicism in Russia and of strong monarchical rule over the united kingdoms, while Zolkiewski, even at the height of military successes against Russia, had a union like that of Poland with Lithuania in his mind and advocated tolerance of Russia's creed and social order. The Poles once actually held the Kremlin of Moscow for a time (1610) and once again laid siege to it (1617); Sigismund's son Wladyslaw was elected tsar, and his opponent did homage to Sigismund as a prisoner. But a national insurrection in Russia and the establishment of the Romanoff dynasty checked the Polish advance, and only certain territorial gains (including Smolensk), as well as a good deal of influence of Polish customs and institutions on the Russian nobility. were definite results of the struggle in Sigismund's time. It was to be continued under his successors.

The wars with hloscow temporarily ended in an armistice at the very moment (1618) when the Thirty Years' War broke out in central Europe. In this Poland remained officially neutral, but Sigismund's favourable attitude toward the Habsburgs entangled Poland in renewed and long wars with Turkey, which the later Jagiellons and their first successors had managed to avoid. A definite success was attained against the Turks at Hotin (1621), a year after Zolkiewski's heroic death at Cecora. But the Swedish trouble began anew in the same year, and Sigismund's long and unlucky reign ended 11 years later amid turmoil abroad and at home, setbacks to Polish power on all sides without and seriously increased constitutional disorder within.

Wladyslaw IV, 1632–48. — Sigismund's son, born in Poland and brought up as a Pole. enjoyed a popularity which had never been his father's lot. As crown prince. he had been successful in military operations against Moscow and Turkey; on his ascension to the throne he ingratiated himself with the gentry by some new concessions, including even exemption from income tax. The "wisest of the Polish Vasas," as he has been called, intended to create a basis of public favour and confidence for the constitutional reforms which he planned.

But the international difficulties inherited from his father diverted his energies largely into channels of foreign policy. The very first years of his reign are marked by new victories over Russia and the Turk and also by a new and much more advantageous truce with Sweden He was less fortunate in a ne conflict with Danzig, and with its supporter Denmark, over the tolls he intended to impose on the trade of the Baltic ports; no interest in these matters was to be anakened in the gentry. and the most powerful magnates — those of the eastern border — thought more of expansion into the fertile Ukrainian regions than of sea power. Accordingly, the Polish navy, which had begun to develop in a promising manner under Sigismund III, was allowed to fall into permanent decay, and Wladyslaw's plans for foreign action on a large scale were unrealized. He wavered in his diplomacy between Austrian and French influences, represented by his two successive queens; his tolerant and friendly attitude toward the Orthodox east caused serious trouble with the Vatican; and his project of a great crusade against the Turks, although encouraged by the Venetian republic and acclaimed by the south Slav nations, in the end came to nothing.

The Cossack Revolt. — The chief obstacle which prevented Wladyslaw's Turkish plans from maturing was the impossibility of winning the help of the decisive factor, the Ukrainian Cossacks, who had become too numerous and powerful to be willing instruments of Polish policy. Catholic intolerance toward this Orthodox population, in the time of Sigismund III, had combined with the proud and highhanded behaviour of Polish landowners to produce in the Cossacks a spirit of religious, racial and social enmity against the Polish element; the Polish parliament had not kept the financial terms of its compacts with the Cossacks; repressions inspired by the border magnates had infuriated them. Already in the earlier years of Wladyslaw's reign terrible Cossack revolts had flared up and been unwisely punished by the abolition of ancient privileges. Now, instead of letting themselves be made the tools of Wladyslaw's anti-Turkish plans, the Cossacks made common cause with the Tatars of the Crimea, who were the most immediate objective of the king's crusading plans: and the reign ended amid a wave of Cossack insurrection, engineered by the sultan, assisted by Tatar hordes and led by Bohdan Chmielnicki (*q.v.*), a country gentleman personally wronged by a Polish official, now the rising hero of Ukrainianism. It was only the resistance of the Polish burghers of Lwow that stemmed the Cossack and Tatar tide from flooding the inner provinces of Poland; the same patriotic town was to arrest two other invasions — a Russian and a Transylvanian one—in the next few years. But the defense of Lwow meant only a respite, and on Wladyslaw's death his brother and successor, the last of the Polish Vasas. found himself faced by a powerful renewal of Chmielnicki's attack on central Poland.

John Casimir, 1648–68.—John Casimir, summoned to the throne from France, where he had lived as a priest and become a cardinal, was obliged to begin his reign by negotiating with his rebel subject Chmielnicki. But Chmielnicki's conditions of peace were so extravagant that the negotiations came to nothing. It was only after a second invasion of Poland, in 1639, by a host of Cossacks and Tatars, that the compact of Zborow was concluded, by which Chmielnicki was officially recognized as chief (hetman) of the Cossack community. A general amnesty was also granted, and it was agreed that all official dignities in the Orthodox palatinates of Lithuania should henceforth be held solely by the Orthodox gentry. For the next 18 months Chmielnicki ruled the Ukraine like a sovereign prince. He made Czehryn, his native place, the Cossack capital, subdivided the country into 16 provinces and entered into direct relations with foreign powers. The Orthodox patriarchs of Alexandria and Constantinople were his friends and protectors. His attempt to carve a principality for his son out of Moldavia led to the outbreak of a third war between suzerain and subject in Feb. 1651. But fortune. so long Bohdan's friend. now deserted him, and at Beresteczko (1651) the

Cossack chieftain was utterly routed by John Casimir. All hope of an independent Cossackdom was now at an end, yet it was not Poland but Moscow which reaped the fruits of this great victory.

Chmielnicki, by suddenly laying bare the nakedness of the Polish republic, had opened the eyes of Moscow to the fact that its ancient enemy was no longer formidable. Three years after his defeat at Beresteczko, Chmielnicki, abandoned by his Tatar allies and finding himself unable to cope with the Poles single-

handed, very reluctantly transferred his allegiance to the tsar Alexius Mikhailovich, whose armies in the same year invaded Poland. The war thus begun is known in Russian history as the Thirteen Years' War and far exceeded even the Thirty Years' War in grossness and brutality.

In the summer of 1655, while Poland was still reeling beneath the shock of the Muscovite invasion, Charles X of Sweden, on the flimsiest of pretexts, forced a war to gratify his greed of martial glory, and before the year was out his forces had occupied the capital, the coronation city and the best half of the land. King John Casimir, betrayed and abandoned by his own subjects, fled to Silesia. Profiting by the cataclysm which, for the moment, had swept the Polish state out of existence, the Muscovites quickly appropriated nearly everything which was not already occupied by the Swedes. At this crisis Poland owed its salvation to two events—the formation of a general league against Sweden, brought about by the apprehensive court of Vienna, and a popular outburst of religious enthusiasm on the part of the Polish people. The first of these events, to be dated from the alliance between the emperor Leopold I and John Casimir (1657), led to a truce with the tsar and the welcome diversion of all the Muscovite forces against Swedish Livonia. The second event, which began with the heroic and successful defense of the monastery of Czestochowa by Prior Augustyn Kordecki against the Swedes, resulted in the return of the king from exile, the formation of a national army and the recovery of almost all the lost provinces from the Swedes, who were driven back headlong to the sea, where with difficulty they held their own. On the sudden death of Charles X, Poland seized the opportunity of adjusting all its outstanding differences with Sweden. By the peace of Oliwa (Oliva) (1660), made under French mediation, John Casimir ceded Livonia and renounced all claim to the Swedish crown. The war with Moscow was then prosecuted with renewed energy and extraordinary success. In 1664 a peace congress was opened, and the prospects of Poland seemed most brilliant; but at the very moment when it needed all its armed strength to sustain its diplomacy, the rebellion of Prince Jerzy Lubomirski involved the country in a dangerous civil war, compelled it to reopen negotiations with the Muscovites and practically to accept the Muscovite terms. By the truce of Andruszowo (1667) Poland received back from Moscow Vitebsk, Polotsk and Polish Livonia, but ceded in perpetuity Smolensk, Severia, Chernigov and the whole of the eastern bank of the Dnieper. The Cossacks of the Dnieper were henceforth to be divided between the dominion of the tsar and the king of Poland. Kiev, the religious metropolis of southwestern Russia, was to remain in the hands of Moscow for two years.

The "truce" of Andruszowo proved to be one of the most permanent peaces in history, and Kiev, though pledged for only two years. was never again to be recovered. Henceforth the political influence of Russia over Poland was steadily to increase, without any struggle at all, although influences of Polish culture and manners, exercised chiefly through the academy of Kiev, still continued to permeate Russia until the advent of Peter the Great.

The "Liberum Veto" in the 17th Century.—Poland had, in fact, emerged from the cataclysm of 1648–67 a moribund state, though its not unskilful diplomacy had enabled it for a time to save appearances. Its territorial losses, though considerable, were, in the circumstances, not excessive, and it was still a power in the opinion of Europe. But a fatal change had come over the country during the age of the Vasas. The period synchronized with and was partly determined by the new European system of dynastic diplomatic competition and the unscrupulous employment of unlimited secret service funds. This system, which dates from Richelieu and culminated in the reign of Louis XIV, was based on the rivalry of the houses of Bourbon and Habsburg, and very soon nearly all the monarchs of the continent and their ministers were in the pay of one or other of the antagonists. Poland was no exception to the general rule. To do them justice, the *szlachta* at first not only were free from the taint of official corruption but endeavoured to fight against it. But they themselves unconsciously played into the hands of the enemies of their country by making the so-called *liberum veto* an integral part of the Polish constitution. The *liberum veto* was based on the assumption of the absolute political equality of every Polish gentleman, with the corollary that every measure introduced into the Polish *sejm* must be adopted unanimously. Consequently, if any single deputy believed that a measure already approved of by the rest of the house might be injurious to his constituency, he had the right to exclaim *"Nie pozwalam,"* "I disapprove," the measure in question falling at once to the ground. Subsequently this vicious principle was extended still further A deputy, by interposing his individual veto, could at any time dissolve the *sejm,* and all measures previously passed had to be resubmitted to the consideration of the following *sejm.* Before the end of the 17th century the *liberum veto* was used so recklessly that all business was frequently brought to a standstill. Later it became the chief instrument of foreign ambassadors for dissolving inconvenient sessions, as a deputy could always be bribed to exercise his veto.

Michael Wisniowiecki, 1669–74.—With the election of Michael Wisniowiecki in 1669 a new era began. A native Pole, he was freely elected by the unanimous vote of his countrymen; but he was chiefly chosen for the merit of his father, a great border magnate who had victoriously kept down the Cossacks, and he proved to be a passive tool in the hands of the Habsburgs. In view of this the French party rallied round John Sobieski, a military commander of rising fame. The dissensions between the two camps cost Poland a new defeat at the hands of the united Turks and Cossacks. Sealed by a shameful treaty of Buczacz (1672), this defeat was only wiped out by a brilliant victory of Sobieski's at Hotin, which also, after King Michael's early death, carried him to the throne against an Austrian candidate.

John **III** Sobieski, **1674–96.**—Connected with France by marriage and by political sympathies, Sobieski, although he had half a lifetime of constant wars against the Turks behind him, stood at first, in accordance with French policy, for peaceful relations with Turkey and directed his eyes toward the Baltic, attempting with French help to check the rising Hohenzollern power in that quarter. But his secret dealings with France turned his o n subjects against him. while continuous Turkish invasions forced him into war. until an attack of unprecedented magnitude, aimed at the very heart of Europe, called forth that unprecedented outburst of Polish heroism — the gallant rescue of Vienna in 1683. That great act was the last noble reflex of the great crusading impulse of the middle ages; it was a unique service, rendered in the old chivalrous spirit by one nation to another in an age of Machiavellian diplomacy and growing national selfishness. It won Poland offers of friendship from all the great powers. Rut its positive gains for Poland proved little; cessions of territory to Moscow did not buy any active support in further campaigns against Turkey, nor did the delivered Austria assist Poland in its endeavour to re-establish the Rumanian outpost against the Turk.

Augustus II, 1697–1733.---On the death of John III no fewer than 18 candidates for the vacant Polish throne presented themselves. The successful competitor was Frederick Augustus I, elector of Saxony, who cheerfully renounced Lutheranism for the coveted croan and won the day because he happened to arrive last of all, with fresh funds, when the agents of his rivals had spent all their money. He was crowned, as Augustus II, in 1697, and his first act was to expel from the country his French rival, François Louis de Bourbon, prince de Conti, whose defeat was also partly caused by the growing Russian influence, which, from the accession of Peter the Great (1700), became a permanent factor in Polish domestic politics.

Good luck attended the opening years of the new reign. In 1699 the long Turkish war, which had been going on since 1683, was concluded by the peace of Karlowitz, whereby Podolia. the Ukraine and the fortress of Kamieniec Podolski were retroceded to the republic by the Ottoman Porte. But the permanent weakening of Turkey brought little good, for the power of Russia soon became a greater menace to Poland than Turkey had ever been.

Shortly after the peace of Karlowitz, Augustus was persuaded by the plausible Livonian exile Johann Reinhold Patkul to form a nefarious league with Frederick of Denmark and Peter of Russia, for the purpose of despoiling the youthful king of Sweden, Charles XII *(see* SWEDEN: *History).* This he did as elector of Saxony, but it was the unfortunate Polish republic which paid for the hazardous speculation of its newly elected king. Throughout the Great Northern War, which wasted northern and central Europe for 20 years (1700–21), all the belligerents treated Poland as if it had no political existence. Swedes, Saxons and Russians not only lived upon the country, but plundered it systematically. The *sejm* was the humble servant of the conqueror of the moment, and the leading magnates chose their own sides without the slightest regard for the interests of their country, the Lithuanians for the most part supporting Charles XII, while the Poles divided their allegiance between Augustus and Stanislam Leszczynski *(see* STANISLAUS I), whom Charles maintained upon the throne from 1704 to 1jog. At the end of the war Poland was ruined materially as well as politically. Augustus offered Courland, Polish Prussia and even part of Great Poland to Frederick William I of Prussia provided that he were allowed a free hand in the disposal of the rest of his kingdom. When Prussia declined this tempting offer for fear of Russia, Augustus went a step further and actually suggested that "the four eagles" (viz.. the black ones of Austria, Prussia and Russia and the white eagle of Poland proper) should divide the other Polish territories between them. He died, however, before he could give effect to this shameless design.

Augustus III, 1733–63.—On the death of Augustus II, Stanislaw Leszczynski, who had, in the meantime, become the father-in-law of Louis XV, attempted to regain his throne with the aid of a small French army corps. Some of the best men in Poland, including the Czartoryski family, were also in his favour, and he was elected king for the second time. But there were many malcontents, principally among the Lithuanians, who solicited the intervention of Russia in favour of the elector Frederick Augustus II of Saxony, son of the late king. A Russian army appeared be'ore Warsaw and compelled a phantom *sejm* (it consisted of but 15 senators and 500 of the *szlachta*) to proclaim Augustus III. Stanislaw and his partisans were besieged by the Russians in Danzig, and with its surrender their cause was lost. He retired to become duke of Lorraine and Bar, keeping the title of king of Poland but leaving Augustus III in possession of the kingdom.

Augustus III left everything to his omnipotent minister, Heinrich, count von Bruhl, and Bruhl entrusted the government of Poland to the noble family of the Czartoryskis, who had close relations of long standing with the court of Dresden. "The Family," as their opponents sarcastically called them, were to dominate Polish politics for the next half-century, and they were honourably determined to save the republic by a radical constitutional reconstruction which was to include the abolition of the *liberum veto* and the formation of a standing army.

Unfortunately, the other great families of Poland were obstinately opposed to any reform or, as they called it. any "violation" of the existing constitution. The Potockis, in particular, whose possessions in southern Poland and the Ukraine covered thousands of square miles, hated the Czartoryskis and successfully obstructed all their efforts. During the reigns of the two Saxon kings, every *sejm* was dissolved by the hirelings of some great lord or, still worse, of some foreign potentate.

It was against this primitive state of things that the Czartoryskis struggled and struggled in vain. First they attempted to abolish the *liberum veto* with the assistance of the Saxon court, but fear of foreign complications and the opposition of the Potockis prevented anything from being done. Then they broke with their old friend Brühl and turned to Russia. Their chief intermediary was their nephew Stanislaw Poniatowski *(see* STANISLAUS II AUGUSTUS), whom they sent, as Saxon minister, to the Russian court in the suite of the English minister Sir Charles Hanbury Williams in 1755. The handsome and insinuating Poniatowski speedily won the susceptible heart of the grand duchess Catherine, but he won nothing else and returned to Poland in 1759 somewhat discredited. Nevertheless, the Czartoryskis looked to Russia again for support on the death of Augustus III. They rejected with scorn and derision the pacific overtures of their political opponents, Prince Fryderyk Michal Czartoryski openly declaring that he preferred the tyranny of the Muscovite to the tyranny of his equals. He had in fact already summoned a Russian army corps to assist him to reform his country, which sufficiently explains his own haughtiness and the unwonted compliance of the rival magnates.

Stanislaw II Poniatowski and the Partitions, 1764–95.— The simplicity of the Czartoryskis was even more mischievous than their haughtiness. Their naive expectations were very speedily disappointed. Catherine II and Frederick II had already determined (treaty of St. Petersburg, 1764) that the existing state of things in Poland must be maintained, and as early as 1763 Catherine had recommended the election of Stanislaw Poniatowski as "the individual most convenient for our common interests." The personal question did not interest Frederick; so long as Poland was kept in an anarchical condition he cared not who was called king. Moreover, the opponents of the Czartoryskis made no serious attempt to oppose the entry of the Russian troops.

Shortly afterward Stanislaw Poniatowski was elected king and crowned. But at the beginning of 1766 Prince Nikolai Repnin was sent as Russian minister to Warsaw with instructions which can only be described as a carefully elaborated plan for destroying the republic. The first weapon employed was the question of the dissidents. At that time the population of Poland was, in round numbers, 11,500 000, of whom about 1,000,000 were dissidents or dissenters. Half of these aere the Protestants of the towns of Polish Prussia and Great Poland, the other half was composed of the Orthodox population of Lithuania. The dissidents had no political rights, and their religious liberties had also been unjustly restricted; but two-thirds of them being agricultural labourers and most of the rest artisans or petty tradesmen, they had no desire to enter public life and were so ignorant and illiterate that their new protectors, on a closer acquaintance, became heartily ashamed of them. Yet it was for these persons that Repnin, in the name of the empress, now demanded absolute equality, political and religious, with the gentlemen of Poland. He was well aware that an aristocratic and Catholic assembly like the *sejm* would never concede so preposterous a demand.

Early in 1767 the malcontents, fortified by the adhesion of the leading political refugees, formed at Radom a confederation whose first act was to send a deputation to St. Petersburg, petitioning Catherine to guarantee the liberties of the republic. With a carte blanche in his pocket, Repnin proceeded to treat the *sejm* as if it were already the slave of the Russian empress. But despite threats, wholesale corruption and the presence of Russian troops outside and even inside the chamber of deputies, the patriots, headed by four bishops, offered a determined resistance to Repnin's demands. Only when brute force in its extremest form had been ruthlessly employed, only when two of the bishops and some other deputies had been arrested in full session by Russian grenadiers and sent as prisoners to Kaluga, did the opposition collapse. The liberum *veto* and all the other ancient abuses were now declared unalterable parts of the Polish constitution, which was placed under the guarantee of Russia. All the edicts against the dissidents were, at the same time, repealed.

Confederation of Bar.—This shameful surrender led to a Catholic patriotic uprising, known as the Confederation of Bar, which was formed in 1768 at Bar in the Ukraine, by a handful of small squires. It never had a chance of permanent success, though, feebly fed by French subsidies and French volunteers, it lingered on for four years, until finally suppressed in 1772. But, insignificant itself, it was the cause of great events. Some of the Bar confederates, scattered by the Russian regulars, fled over the Turkish border, pursued by their victors. The Turks, already alarmed at the progress of the Russians in Poland and stimulated by Charles Gravier, comte de Vergennes,'at that time French ambassador at Constantinople, at once declared war against Russia. Seriously disturbed at the prospect of Russian aggrandizement, the courts of Berlin and Vienna conceived the idea that the best mode of preserving the equilibrium of Europe was for all three powers to readjust their territories at the expense of Poland. Negotiations led to no definite result at first; then Austria took the first step by occupying, in 1769, the county of Spiz (Szepes, Zips), which had been hypothecated by Hungary to Poland in 1411 and never redeemed. This act decided the other powers; in June 1770 Frederick surrounded with a military cordon, ostensibly to keep out the cattle plague, those of the Polish provinces that he coveted. Catherine's consent had been previously obtained.

First Partition, 1772.—The first treaty of partition was signed at St. Petersburg between Prussia and Russia on Feb. 6–17, 1772; the second treaty, which admitted Austria also to a share of the spoil, was signed on Aug. 5–16 the same year. The consent of the *sejm* to this act of brigandage was extorted by bribery and 'force in 1773. Russia obtained the palatinates of Vitebsk, Polotsk, Mscislaw: 34,616 sq.mi. of territory, with a population of 550,000. Austria got Little Poland without Cracow and also Lwow, Tarnopol and Halicz and, by corrupting the name of the last, called the new province Galicia: 32,045 sq.mi., with a population of 816,000. Prussia received the palatinate of Pomorze minus Danzig, the palatinate of Chelmno minus Torun, the northern half of Great Poland and the palatinates of Marienburg and Warmia, calling the new acquisition West Prussia: 14,025 sq.mi., with a population of 378,000. The total area of Poland before 1772 was about 283,200 sq.mi., with an estimated population of 8,750,000.

The partitioning powers presented Poland with a new constitution. The elective monarchy and the *liberum veto* were of course retained. Poland was to be dependent on its despoilers, but they evidently meant to make it a serviceable dependent. The government was henceforth to be in the hands of a permanent council of 36 members, 18 senators and 18 deputies, elected biennially by the *sejm* in secret ballot, subdivided into the five departments of foreign affairs, police, war, justice and the exchequer, whose principal members and assistants, as well as all other public functionaries, were to have fixed salaries. The royal prerogative was still further reduced. The king was indeed the president of the permanent council, but he could not summon the *sejm* without its consent and in all cases of preferment was bound to select one out of three of the council's nominees. Still, the new organization made for order and economy and enabled Poland to develop and husband its resources and devote itself uninterruptedly to the now burning question of national education.

The shock of the first partition had a certain salutary effect on national mentality. Already in the darkest days of Saxon rule, important educational reforms had been carried out in the schools of the Piarist order by Stanislaw Konarski. Now, the dissolution of the Jesuit order in 1773, putting its rich possessions and the system of schools conducted by it into the hands of the state, gave Poland opportunity to secularize as well as modernize the whole educational fabric of the nation. This huge task was admirably performed by the Commission of National Education, the first ministry of education in Europe. It reorganized both the program of teaching and the structure of the schools—including the decayed universities of Cracow and Wilno—in a thoroughly modern and truly enlightened way. Less progress was made with the cause of constitutional reform: the chancellor Andrzej Zamoyski indeed drafted a new comprehensive code of laws, in which a beginning was made with the emancipation of the peasant serfs and of the town population, but this was rejected by the gentry in the *sejm* (1780).

In the meantime, important events in the international field seemed to give Poland another chance of reasserting its independence against its despoilers. The death of Frederick the Great in 1786 loosened the bonds of the alliance between Prussia and Russia. Russia, drawing nearer to Austria, undertook, jointly with Austria, a war against Turkey which proved unexpectedly hard; and Russia was at the same time attacked by Sweden. Prussia, having changed its policy and concluded an alliance against Russia with England and Holland, was now emboldened by Russia's difficulties to go further: it invited Poland also to forsake the Russian alliance and offered to place an army corps of 40,000 men at its disposal.

The Constitution of May 1791.—It was under these exceptional circumstances that the "four years' *sejm*" assembled (1788). Its leaders, Stanislaw Malachowski, Hugo Kollontaj and Ignacy Potocki, were men of character and capacity, and its measures were correspondingly vigorous. Within a few months of its assembling it had abolished the permanent council, enlarged the royal prerogative, raised the army to 65,000 men, established direct communications with the western powers, declared its own session permanent and finally settled down to the crucial task of reforming the constitution on modern lines. But the difficulties of the patriots were commensurate with their energies, and though the new constitution was drafted as early as Dec. 1789 it was not till May 1791 that it could safely be presented to the *sejm*. Meanwhile, Poland endeavoured to strengthen its position by an alliance with Prussia. Frederick William II stipulated at first that Poland should surrender Danzig and Torun; but the Poles proving obstinate and Austria simultaneously displaying a disquieting interest in the welfare of the republic, Prussia in 1791 concluded an alliance with Poland which engaged the two powers to guarantee each other's possessions and render mutual assistance in case either were attacked.

But external aid was useless so long as Poland was hampered by its anarchical constitution. The most indispensable reforms had been frantically opposed; the debate on the reorganization of the army alone had lasted six months. It was only by an audacious surprise that Kollontaj and his associates contrived to carry through the new constitution. Taking advantage of the Easter recess, when most of the malcontents were out of town, they suddenly, on May 3, brought the whole question before the *sejm* and demanded urgency for it. Before the opposition could remonstrate, the marshal of the *sejm* produced the latest foreign dispatches, which unanimously predicted another partition, whereupon, at the solemn adjuration of Ignacy Potocki, King Stanislaw exhorted the deputies to accept the new constitution as the last means of saving their country and himself set the example by swearing to defend it.

The constitution of May 3, 1791, converted Poland into a hereditary limited monarchy, with ministerial responsibility and biennial parliaments. The *liberum veto* and all the intricate and obstructive machinery of the anomalous old system were forever abolished. All invidious class distinctions were done away with. The towns, in a special bill confirmed by the new constitution, got full administrative and judicial autonomy, as well as a certain measure of parliamentary representation; the personal privileges of the gentry, such as possession of land and access to office in the state and in the church, were thrown open to the townsmen. The peasants were placed under the protection of the law, and their-serfdom was mitigated with a view to its entire abolition. Absolute religious toleration was established. Provision was made for further periodical reforms by subsequent parliaments.

The constitution of May 3 had scarcely been signed when Stanislaw Feliks Potocki, Seweryn Rzewuski and Ksawery Branicki, three of the chief dignitaries of Poland, hastened to St. Petersburg and there entered into a secret convention with the empress. whereby she undertook to restore the old constitution by force of arms but at the same time promised to respect the territorial integrity of the republic. Entering Polish territory with Russian troops, the conspirators formed a confederation at the little town of Targowica in the Ukraine. protesting against the new constitution as tyrannous and revolutionary; at the same time the new Russian minister at Warsaw presented a formal declaration of war to the king and the *sejm*. The *sejm* met the crisis with dignity and firmness. The army was at once dispatched to the frontier; the male population was called to arms, and Ignacy Potocki was sent to Berlin to claim the assistance stipulated by the treaty of March 19, 1791. The king of Prussia, in direct violation of all his oaths and promises, declined to defend a constitution which had never had his "concurrence." Thus Poland was left entirely to its own resources. The little Polish army of 46,000 men. under Prince Joseph Anthony Poniatowski, nephew of King Stanislaw II, and Tadeusz Kosciuszko, did all that was possible under the circumstances. For more than three months they kept back the invader, and, after winning three pitched battles, retired in perfect order on the capital (*see* KOSCIUSZKO, TADEUSZ ANDRZEJ BONAWENTURA; PONIATOWSKI, JOSEPH ANTHONY). But the king, and even Kollontaj, despairing of success, now acceded to the confederation; hostilities were suspended; the indignant officers threw up their commissions; the rank and file were distributed all over the country; the reformers fled abroad; and the constitution of May 3 was abolished by the Targowicians as a "dangerous novelty." The Russians then poured into eastern Poland; the Prussians, at the beginning of 1793, alarmed lest Catherine should appropriate the whole republic, occupied Great Poland; and a diminutive, debased and helpless *sejm* met at Grodno in order, in the midst of a Russian army corps, "to come to an amicable understanding" with the partitioning powers.

Second Partition, 1793.—After every conceivable means of intimidation had been unscrupulously applied, the second treaty of partition was signed at three o'clock on the morning of Sept. 23, 1793. By this *pactum subjectionis,* as the Polish patriots called it, Russia got all the eastern provinces of Poland. extending from Livonia to Moldavia, comprising a territory of 96.751 sq.mi., while Prussia got Dobrzyn, Kujavia, Great Poland, Torun and Danzig. Poland was now reduced to less than one-third of its original dimensions, with a population of about 3,500,000.

Kosciuszko and the Third Partition.—The focus of Polish nationality was now transferred from Warsaw, where the Targowicians and their Russian patrons reigned supreme, to Leipzig, whither the Polish patriots, Kosciuszko, Kollontaj and Ignacy Potocki among the number, assembled from all quarters. From the first they meditated a national rising, but their ignorance, enthusiasm and simplicity led them to commit blunder after blunder. The first of such blunders was Kosciuszko's mission to Paris in Jan. 1793. He was full of the idea of a league of republics against the league of sovereigns; but he was unaware that the Jacobins themselves were already considering the best mode of detaching Prussia, Poland's worst enemy, from the anti-French coalition. Kosciuszko received an evasive reply and returned to Leipzig empty-handed. In the meantime, certain officers in Poland had revolted against the reduction of the Polish army to 15,000, imposed upon the country by the partition treaty. Kosciuszko himself condemned their hastiness; but the march of events forced his hand, and in March 1794 he went to Cracow, proclaimed a national insurrection and assumed the powers of a dictator. He called the peasants to arms, and they responded nobly, in return for which he supplemented the provisions of the constitution of 1791 by a manifesto giving them complete freedom. At first, Kosciuszko's arms were almost universally successful. The Russians were defeated in more than one pitched battle; three-quarters of the

FIG. 2.— PARTITIONS IN THE 18TH CENTURY

ancient territory was recovered, and Warsaw and Wilno, the capitals of Poland and Lithuania, respectively, were liberated. The first serious reverse at Szczekociny, was more than made up for by the successful defense of Warsaw against the Russians (July 9–Sept. 6). But even during that heroic defense mob lawlessness in Warsaw and violent dissensions in the supreme council and in the army began to frustrate the superhuman efforts of the unfortunate but still undaunted dictator. The appearance of overwhelming masses of Russian troops, together with the open hostility of Austria as well as Prussia, did the rest, and Kosciuszko's insurrection received its deathblow on the battlefield of Maciejowice, where he himself was wounded and taken prisoner. Warsaw was taken amid a terrible massacre of the population in the suburb of Praga, and the remainder of the troops capitulated a few weeks later.

The greed of the victorious powers nearly led to a rupture between Austria and Prussia, but, after some dissensions, the third partition of Poland was effected by successive treaties in 1795 and 1796. Austria had to be content with Lublin, Siedlce, Radom and Kielce, while Prussia took Suwalki, Bialystok, Lomza and Warsaw. Russia annexed all the rest and was afterward to tear even parts of their booty from the two others. Thus the name of Poland was wiped from the map of Europe, to reappear only after more than a century. (R. N. B.; R. DY.; X.)

THE DUCHY AND FOREIGN RULE

After the third partition, the more high-spirited Poles, chiefly officers and soldiers of Kosciuszko's army, emigrated and formed, on Italian soil, the Polish legions, which, during the next ten years, fought the battles of the French republic and of Napoleon all over Europe and even outside it, from Egypt to the West Indies. They were commanded by Jan Henryk Dombrowski, one of Kosciuszko's ablest generals; but Kosciuszko himself stood aloof, distrusting Napoleon.

The Duchy of Warsaw.—In 1806 and 1807, when Napoleon defeated Prussia and engaged in a war with Russia, Polish soldiers once more appeared on Polish soil, and the hopes of the nation seemed near fulfilment. In fact, the peace of Tilsit resulted in the reconstruction of a Polish state out of the central provinces of Prussian Poland; but Napoleon's anxiety to conciliate Russia effectually prevented him from making his new creation large enough to be self-supporting. The duchy of Warsaw, as it was called, consisted in 1807 of territories taken by Prussia in the second and third partitions, to which territory seized by Austria in the third partition was added in 1809. The total area of the duchy was then about 64,000 sq.mi., with a population of about 4,350,000. The constitution was dictated by Napoleon; it was framed on the French model and on very advanced lines. Equality before the law (implying personal freedom of the peasant), absolute religious toleration and highly developed local autonomy were its salient features. The king of Saxony, Frederick Augustus I (previously elector as Frederick Augustus III; grandson of Augustus III of Poland), whom Napoleon made duke, took the initiative in all legislative matters, but the administration was practically controlled by the French. In spite of being subject to most burdensome financial and military exigencies for the purposes of Napoleon's continuous wars, the small duchy contrived, during the few years of its existence, to do much peaceful, productive, organizing work, especially in the educational and economic spheres.

Poland's hopes for greater things revived once more when Napoleon announced his war against Russia (1812), as his "second Polish war." The duchy, by an immense effort, put an army corps of nearly 98,000 men into the field. But the calamity that overtook Napoleon in Russia also sealed the fortunes of the duchy. The remainder of the Polish troops faithfully followed Napoleon in his campaign of 1813–14, during which the heroic leader of the Poles, Prince Joseph Anthony Poniatowski, perished in covering the emperor's retreat from Leipzig. The duchy was occupied by the Russians.

The Congress Kingdom and Russian Rule.—Tsar Alexander I had been united by youthful friendship to the most eminent Polish noble of his time, Prince Adam Czartoryski, and had even made him, on his accession, foreign minister of the Russian empire. On Napoleon's downfall the Poles, to whom Alexander did not spare promises and flatteries, entertained the highest hopes.

It was not Alexander's fault, indeed, if the congress of Vienna, because of jealousy among the great powers and the entanglement of the Polish question with that of Saxony and other territories, did not lead to a reunion of Poland, even under the Russian sceptre, but confirmed the division of the country among the three partitioning powers. Cracow only, with a small surrounding territory, was erected into a free city republic. Great Poland, with Poznan for its centre and a population of 850,000, was left to Prussia. Austria remained in possession of Galicia with 1,500,000 inhabitants. The eastern borderlands, from Lithuania and White Russia to Volhynia and the Ukraine, continued to be incorporated in Russia. The remnant of central Poland only—about three-fourths of the territory of Napoleon's duchy of Warsaw—was constituted as the so-called Congress kingdom under the emperor of Russia as king of Poland. Guarantees of home rule in all parts of the divided country and of free communication between them were given by all powers concerned, only to prove soon more or less futile.

Alexander, who had a sentimental regard for freedom, so long as it meant obedience to himself, had promised the Poles a constitution. That constitution was soon duly drafted and signed. It contained 165 articles divided under seven heads. The kingdom of Poland was declared to be united to Russia in the person of the tsar, as a separate political entity. Lithuania and the Ruthenian palatinates continued to be incorporated with Russia as the Western Provinces and were divided from the Congress kingdom by a customs barrier till the reign of Nicholas I. The kingdom of Poland thus defined was to have at its head a lieutenant of the emperor (namiestnik), who must be a member of the imperial house or a Pole. The first holder of the office, Gen. Jozef Zajonczek (1752–1826), was a veteran who had served Napoleon. Roman Catholicism was recognized as the religion of the state, but other religions were tolerated. Liberty of the press was promised, subject to the passing of a law to restrain its abuses. Individual liberty, the use of the Polish language in the law courts and the executive employment of Poles in the civil government were secured by the constitution. The machinery of government included a council of state (at which the imperial government was represented by a commissioner plenipotentiary) and a *sejm* divided into a senate, composed of the princes of the blood, the palatines and councillors named for life, and a house of deputies elected for seven years. Poland retained its flag and a national army based on that which had been raised by and had fought for Napoleon. The command of the army was given to the emperor's brother Constantine, a man of somewhat erratic character, who did much to offend the Poles by violence (*see* CONSTANTINE PAVLOVICH).

The sejm met three times during the reign of Alexander, in 1818, in 1820 and in 1825, and was on all three occasions opened by the tsar. But the tsar and the *sejm* soon quarrelled. The third session of the *sejm* (May 13 to June 13, 1825) was a mere formality. All publicity was suppressed, and one whole district was disfranchised because it persisted in electing candidates who were disapproved of at court. All Europe at the time was seething with secret societies organized to combat the reactionary governments of the Holy Alliance. In Poland the National Freemasonry, or National Patriotic society as it was afterward called, had a large membership, especially among the students and the younger officers. Outside Congress Poland, a similar student movement arose in the University of Wilno. Severe measures—imprisonment, deportation and exile—were taken against students and graduates of Wilno (including the poet Adam Mickiewicz), and they added to the excitement in Warsaw.

No open breach occurred during the reign of Alexander I, nor for five years after his death in 1825. On the death of the unpopular Zajonczek in 1826, the grand duke Constantine became imperial lieutenant. His brother, the new tsar Nicholas I, soon became entangled in a war with Turkey. Austria, as usual, desirous of profiting by Russia's difficulties, began to court the favour of the Poles. Nicholas was crowned king of Poland in Warsaw in 1829 and personally opened the *sejm* in 1830. But the *sejm* already in 1828 had refused to sentence to death a group of Polish conspirators accused of dealings with the Russian "Decembrists" who had plotted Nicholas' overthrow, and in 1829 there was even an abortive Polish plot to murder him at his coronation in Warsaw. Fresh excitement was created in Poland by the outbreak of the Revolution in France in July 1830 and the revolt of Belgium; a rumour was current—not without justification—that Nicholas, acting in concert with the other autocrats of the Holy Alliance, intended to use the Polish army to coerce the French and Belgian revolutionaries.

The Rising of *1830*.—On Nov. 29, 1830, a military revolt broke out in Warsaw. It was started by the young hotheads of the officers' training school and began with the murder of several senior officers loyal to the government. Regiments of the army and masses of the civilian population began to join the rising; the weakness of Constantine allowed it to gather strength. He evacuated Warsaw and finally left the country. The war lasted from Jan. till Sept. 1831. The Poles began with some chances of success; they had a well-drilled and well-equipped army of about 30,000 men, which they increased by recruiting to about 80,000. Against this, the Russians, with considerable difficulty, succeeded in putting only about 114,000 men into the field. Their ultimate success resulted partly from the friendly attitude of Prussia, partly from the fact that the Polish *sejm*, having proclaimed the deposition of the tsar at an early stage of the conflict, received no response to its appeal for western European protection. But to a large extent the defeat of the insurrection was caused by certain faults on the Polish side: want of ability and decision on the part of the generals; a succession of rapid changes in the command of the army; fierce party strife within the civil government in the capital; a deplorable outbreak of mob violence in Warsaw at a critical moment of the war; and, finally, an irresolute attitude of the insurrectionary parliament toward the peasant claims.

After the suppression of the insurrection, certain remnants of a constitution were still granted to Russian Poland by the "organic statute" of 1832, but they were soon rendered illusory; the administration avowedly aimed at destroying the nationality and even the language of Poland. The universities of Warsaw and Wilno were suppressed, the Polish students compelled to go to St. Petersburg and Kiev. The recruits from Poland were distributed in Russian regiments, and the use of the Russian language was enforced as far as possible in the civil administration and in the law courts. The customs barrier between Lithuania and the former Congress Poland was removed, in the hope that Russian influence would spread more easily over Poland. A hostile policy was adopted against the Roman Catholic Church. But though these measures cowed the Poles, they failed to achieve their main purpose. Polish national sentiment was intensified. The Poles in Russia, whether at the universities or in the public service, formed an element which refused to assimilate with the Russians. In Poland itself the tsar left much of the current civil administration in the hands of the nobles, whose power over their peasants was hardly diminished and was misused as of old. The Polish exiles who filled Europe after 1830 maintained a constant agitation from abroad. The stern government of Nicholas was, however, so far effective that Poland remained quiescent during the Crimean War.

Alexander *II* and the Rising of 1863.—The reign of the new tsar Alexander II began with certain concessions to Poland in the political and educational field. Exiles were allowed to return, administrative pressure was lightened, the church was propitiated, an "agricultural society" was allowed to be formed and to discuss important affairs of the community, a medical faculty and, later on, a complete university were re-established in Warsaw. Finally, even a Polish council of state and a Polish administrative apparatus for the kingdom began to be organized. In their later stages these reforms were the work of Count Aleksander Wielopolski, who was installed in high office and stood for a national policy of loyal union with Russia. But his autocratic temper lost him the sympathies of the moderate elements of the gentry, while, on the ardent minds of the young, Wielopolski's methods acted like fuel heaped on fire. Religious ceremonies were used as the occasion for demonstrative political processions, there were collisions with the Russian troops and victims fell in the streets of Warsaw. Wielopolski had the unhappy idea of causing the revolutionary youth of the cities to be recruited en masse for the Russian army; the plan became known, numbers of the young people fled into the forests, and a revolutionary committee on Jan. 22, 1863, started an ill-prepared insurrection.

The struggle of the ill-equipped and ill-organized insurgent bands against the Russian garrisons dragged on in the form of guerrilla warfare throughout the country for nearly two years. A secret national government was set up in Warsaw, the movement spread successfully into Lithuania and the insurrection occupied the diplomatic attention of western Europe. But the assistance promised by Napoleon III never became effective; the rising was crushed; wholesale executions, confiscations and deportations followed its suppression; and Poland was now definitely turned into a Russian province.

Russification.—All self-government in Congress Poland was suppressed in 1863; all education was russified in 1869, justice in 1873. On the other hand, the abolition in 1851 of the customs frontier between Russia and Poland had laid the foundation for an extraordinary industrial expansion: Russian Poland, with its great textile factories at Lodz, became the chief industrial region for all Russia. Its vast market in agricultural Russia was protected against western competition by high tariffs; the Russian government took every possible measure (such as the introduction of specially favourable railway tariffs) to assist this expansion. The Poles, being excluded from state service in their own country, busied themselves with productive occupations, and the upper and middle classes achieved a well-being far superior to anything enjoyed by their cousins in Galicia. A second result of this expansion was the growth in Congress Poland of a large and radical proletariat which made common cause with the Russian Social Democratic movement. In the country districts, the agrarian policy of the Russian government was expressly calculated to stir up ill-feeling between the Polish peasants, whom the government demonstratively took under its protection, and the country gentry, whom it was determined to punish in every way for the leading part they had played in the insurrections. The peasant of Russian Poland officially got his freedom from the tsar in 1864. All peasants, whatever their tenure had been, and the mass of the landless proletariat became freeholders, on a far more generous basis than the Russian peasant in 1861. The landlords received compensation in the form of Russian treasury bonds, which stood far below par, and the peasants got the right to use the landlords' pastures and woods.

In the sphere of education, the most thoroughgoing system of russification set in after 1864. All the revived Polish schools of the Wielopolski period were made Russian again, including the University of Warsaw, and no effort was spared to produce in the minds of youth a distorted image of Poland's past. Secret patriotic education, however, counteracted this policy successfully both in town and country, and private Polish schools, struggling against great difficulties, kept the Polish cultural tradition alive.

The civil government of Russian Poland was reorganized strictly on the model of the rest of the Russian empire, the Poles being debarred, however, from certain liberal institutions which the Russians by that time possessed, such as municipal self-government and trial by jury. The Russian language was made compulsory in all official relations and at a later time even in the records of private institutions. A corrupt Russian bureaucracy filled all government offices, a severe censorship strangled every free utterance of the nation in the press and in literature, and a drastic police regime kept the prisons filled with political offenders.

After Russia's defeat in the Japanese war of 1904, the outbreak of a revolution in 1905 kindled all Polish hopes once more. A constitution was granted to the Russians, and 36 Polish deputies sat in the first Russian parliament (duma). A certain measure of freedom in the educational field was obtained and eagerly used for the foundation of new schools by a Warsaw society called the Mother of Schools (Macierz Szkolna). The peasants of Russian Poland spontaneously introduced the Polish language in their self-governing bodies. In the duma itself, the Liberals were not averse to granting Poland a large measure of autonomy within Russia. At the same time, persecution in Prussian Poland increased under Prince Bernhard von Bulow, while the Ukrainian national movement, developing in Austrian Poland especially since the grant of universal suffrage in 1907, was unwelcome both to Poles and Russians. Under these circumstances, Russian propaganda, reviving the pan-Slav ideals of 30 years ago, could count on some success even among the Poles. There were gestures of reconciliation at two Slav congresses, in 1908 and 1910, the Czechs willingly acting as mediators. The idea of uniting all Poles with autonomy within the Russian empire was widely preached; it became the program of the National Democratic, or all-Polish, party, led by Roman Dmowski, the head of the Polish representation in the duma.

Opposed to Dmowski and the followers whom he found even among Austrian Poles there stood the irreconcilable revolutionaries, led by Joseph Pilsudski. Both the insurrectionary movement started by Pilsudski in 1905 and the constitutional endeavour of Dmowski and his friends in the duma were soon stifled by the Russian reaction of the Peter Stolypin period. Pilsudski took refuge in Galicia and began to organize armed resistance to Russia from that base. In the duma, the Polish representation was lowered from 36 to 10 deputies. In the country, all the liberties gained after 1905 soon disappeared. The government's purchase of the railway line from Warsaw to the Austrian frontier resulted in the removal of all Polish railwaymen from the service and was a great blow to the Polish element. In 1912 the separation of the district of Chelm, in the southeast of Russian Poland, from the body of the province and its incorporation in Russia proper was received with indignant protests by Polish opinion as a new partition of Poland.

Prussian Poland. — The regime in Prussian Poland during the first 15 years after the congress of Vienna had been endurable. A Polish nobleman related by marriage to the Prussian dynasty—Prince Antoni Radziwill—was appointed lieutenant governor of the province; there was a provincial assembly and local representative bodies both urban and rural. The landowners were allowed to organize for economic purposes, and the peasants were fully enfranchised in 1823. After the insurrection of 1830, a period of more oppressive government by a German provincial president, E. Flottwell, set in; he revived Frederick the Great's method of German colonization of the Polish province, and he began to germanize the administration and the school system. A period of new concessions to the Poles under Frederick William IV was interrupted by the revolution of 1846–48. The constitution with which Prussia emerged from the revolution put an end to the self-government of Prussian Poland. Another interval of relaxation, in the first years of William I, was soon succeeded by the period of Bismarck's and Bülow's resolutely anti-Polish policy—characterized by the *Kulturkampf*, the "Colonizing committee," the Wrzesnia scandal, the schools' strike, the Expropriation bill and the like, for an account of which *see* POZNANIA. The result of the Prussian methods was to create a sturdy class of peasants and small *bourgeoisie*, disciplined and economically and culturally advanced; and a fellow feeling arose between the peasants and the landowning gentry such as was hardly known in other parts of Poland.

Austrian Poland.—After the insurrection of 1830–31, no remnant of Poland's independent political existence had been left except the minute city republic of Cracow, created by the congress of Vienna. For 30 years this miniature state led a flourishing existence. When the ferment of the approaching European revolution of 1848 was stirring most continental countries to their depths, thefe were active preparations for another rising both in Austrian and Prussian Poland. For Austria the menace was diverted by a peasant revolt in Galicia in Feb. 1846, which led to a massacre of about 2,000 landowners by the peasantry incited by the Austrian governor general Baron Krieg von Hochfelden. At the same time, Austria availed itself of the unrest among its Poles to obtain the consent of Russia and Prussia to the suppression of the city republic of Cracow. But it was not until 1848 that Cracow was finally occupied by Austria and incorporated into Galicia.

Austria under the old autocratic regime oppressed its Polish province politically and exploited it economically in the most ruthless fashion. The revolution of 1848 brought a change, but not until the defeat of Austria by Prussia in 1866 was it realized at Vienna that only a more liberal policy could hold the tottering, mixed monarchy together. The relation with Hungary having been placed on a federal footing, concessions had to be granted to the strong Polish element in Austria. The Poles began to be active in Austrian politics. The numerical strength of Polish deputies in the Vienna parliament was such that no Austrian government could be formed without it. Galicia (as Austrian Poland was officially called), containing a large Ukrainian element in its eastern half, was granted a special minister to represent its interests in the Vienna cabinet. It also got a provincial legislative assembly and a governor, who was invariably appointed from the ranks of the Polish aristocracy. With purely Polish administration, schools and courts of law, Galicia became indeed almost an independent Polish state within Austria and successfully defied the centralizing efforts of the Vienna bureaucracy. The Polish landowning class, which practically governed the country for the next few decades, managed its affairs in a one-sidedly agrarian spirit; the interests of the towns were not properly considered, hardly any attention was given to the development of industries, and Galicia remained economically backward. Even its oil fields were largely developed by foreign capital. On the other hand. political and cultural activities had more scope than in the two other parts of Poland; Galicia became the "Piedmont" of the Polish national movement, and Cracow, with its old university and new Academy of Sciences, an intellectual, artistic and literary centre for the whole nation. With the growth of a new educated class and the introduction of universal suffrage in Austria (1907) the social structure of the country began to change, its politics were strongly democratized, new economic tendencies got the upper hand, and Galicia was at last on the road of material advance when World War I began.

World War I.—World War I found the Poles estranged from one another and without a united national policy. "Brygadier" Pilsudski crossed the frontier from Galicia with a few hundred of his legion and engaged the Russian empire in battle as forerunner of the army of an independent and united Poland. But the Polish Supreme committee, formed in Cracow on Aug. 16, aimed at uniting Galicia and Congress Poland as a third party in the dual monarchy and required the Polish legion to take the oath to the emperor. In Warsaw the Polish National committee under Dmowski denied the right of the Cracow committee to speak in the name of the Polish nation, protested loyalty to the tsar and attempted to form a Polish legion on the side of Russia. Meanwhile the grand duke Nicholas issued a proclamation (Aug. 14) in which he promised to unite the three parts of Poland in an autonomous state with the Russian empire.

In the summer of 1915, however, the Central Powers conquered all Congress Poland. After the fall of Warsaw on Aug. 5, 1915, military governments were set up on behalf of Germany at Warsaw and of Austria-Hungary at Lublin. But fresh difficulties confronted the Austrian solution. The Polish Socialist party (P.P.S.) under Pilsudski declared that no recruiting should take place for Polish legions until an independent Polish government had been formed to conduct it. Meanwhile, Istvan Tisza, the Hungarian premier, had vetoed the Austrian trialist scheme, which was also opposed by Germany. Vienna again rejected the plans put forward b~ Germany of annexing Congress Poland to Germany or of forming an independent Polish buffer state in economic, military and political alliance with the Central Powers.

In Aug. 1916, however, after the defeat of the Austro-Hungarian troops at Luck, the German supreme command acquired complete control of policy on the eastern front. Erich Ludendorff believed it possible to gain a large Polish army if his ideas were adopted. Germany and Austria-Hungary issued a proclamation on Nov. 5, 1916, holding out a prospect of the restoration of an independent Congress Poland as a hereditary constitutional monarchy closely attached to the Central Powers. Francis Joseph promised Galicia increased autonomy within Austria-Hungary. The discussion of details was shelved; the military governments at Warsaw and Lublin continued to administer the country. On Nov. 26, 1916, a provisional council of state of 25 members was appointed; it was solemnly opened on Jan. 14, 1917. Pilsudski, who was one of the members of the council, began to work out the plans for a national Polish army. He refused, however, to raise it for German use, and the German plan of raising a Polish army failed completely.

In March 1917 the Russian dynasty fell. On March 30 the new Russian government recognized Poland's right to self-determination and promised the creation of a new Polish state. These events altered the attitude of the Allies toward Poland. particularly as they were now reinforced by the entry of the United States into the war. The answer of the Entente Powers to the peace proposals of the Central Powers issued on Jan. 10, 1917, had already declared their adhesion to the tsar's manifesto to his armies (Dec. 25, 1916) which had spoken of "the formation of a free Poland in all parts into which it is at present divided."

The danger still threatening Poland from Russia vanished with the breakdown of Alexander Kerensky's offensive (July 1917). The Central Powers were now the only enemy. In May 1917 the Polish members of the Austrian *reichsrat* unanimously demanded "an independent united Poland with an outlet to the sea," and declared that the Polish case was one for "international consideration." At the same time, the Polish council of state in Warsaw asked the occupants for a widening of its powers and split up over the German demand for a recruiting appeal and an oath of loyalty. Pilsudski resigned from the council with his adherents and set about turning his secret military organization against Germany.

On July 22 Polish discontent was increased by the arrest of Pilsudski. On Aug. 25 the council of state, now discredited with the people, resigned. On Sept. 12 Germany and Austria-Hungary introduced a new project of a regency of three, a cabinet and premier and'council of state, elected but enjoying limited powers, the German and Austrian military governments retaining the right of veto. The regency was appointed on Oct. 15; it consisted of the archbishop of Warsaw, Aleksander Kakowski, Prince Zdzislaw Lubomirski and Jozef Ostrowski, a large landowner. The first prime minister, Jan Rucharzewski, was appointed on Nov. 26 and formed his first ministry on Dec. 7.

While Polish affairs were taking this course under Austro-German occupation, Dmowski was making propaganda for the Polish cause in France and Great Britain and I. J. Paderewski was working tirelessly in the United States. In Nov. 1916 the so-called Polish National department in Chicago, Ill., had united all the organizations of the 4,000,000 Poles in the U.S.; and under Paderewski's influence, Pres. Woodrow Wilson, in his tentative peace message of Jan. 22, 1917, alluded to a "united, independent and autonomous Poland." In the course of 1917 a Polish corps was organized by Gen. Jozef Dowbor-Musnicki in Russia, and a Polish army began to be formed in France. The Polish National committee, founded by Dmowski and Paderewski at Lausanne in Aug. 1917 and later established in Paris, was gaining increasing influence in the councils of the Allies. Between Sept. 20 and Dec. 1, 1917, France, Great Britain, Italy and the United States had recognized it as the official representative of the Polish people. The 13th of President Wilson's Fourteen Points (Jan. 8, 1918) declared that a Polish state should be erected which should include the territories inhabited by indisputably Polish population "with an outlet to the sea and an international guarantee of its independence and integrity."

In the meantime, the utter collapse of the Russian army had led to peace negotiations between the Central Powers and the Bolsheviks. The Bolshevik delegates who arrived at Brest-Litovsk (*q.v.*) in Dec. 1917 recognized, in theory, the right of the Polish people to self-determination, but Polish delegates were not admitted to the deliberations. By the treaty as concluded on March 1, 1918, Soviet Russia renounced all claims over Poland; but the treaty (Feb. 9, 1918) between the Central Powers and the Ukraine allotted to the Ukraine the disputed province of Chelm, while Austria-Hungary further pledged itself in a secret clause to form East Galicia and Bukovina into a separate crownland. These clauses became known and Polish opinion was infuriated; the Polish club in the Austrian reichsrat went over to the opposition and the remnant of Pilsudski's legions still fighting for the Central Powers mutinied. Some were interned, some, under Gen. Jozef Haller, fought their way to the coast and joined the new Polish army in France. The council of state in Poland was opened in Warsaw on June 22. Little interest was taken in it, and general feeling in Poland tended to ignore this body in favour of the National committee in Paris. Even before the breakdown of the German offensive in July 1918, the prime ministers of Great Britain, France and Italy had declared in favour of an independent and united Poland at Versailles on June 3, 1918.

The Declaration of **Independence.**—On Oct. 6 the Polish regency council published a manifesto to the Polish nation declaring its intention of dissolving the council of state, forming a representative national government and summoning a *sejm* for a "free and united Poland." On Oct. 15 the Polish representatives in the Austrian reichsrat declared themselves to be "subjects and citizens of a free and re-united Polish State." On Nov. 10 Pilsudski, who had been released from imprisonment at Magdeburg on Oct. 7, arrived in Warsaw. The German troops of occupation were disarmed and expelled, and the Poles assumed the executive power in Warsaw on Nov. 11. The regency council declared on the same day that it appointed Pilsudski to the supreme command of all Polish troops and on Nov. 14 resigned in favour of Pilsudski.

On Nov. 14, too, the Polish members of the German reichstag and of the Prussian *landtag* met in Poznan and formed a supreme popular council. On Dec. 27 the Poznanian Poles rose against the Germans and turned them out of their province. Severe fighting broke out and went on till Feb. 16, 1919, when an armistice was concluded at Trier by Marshal Ferdinand Foch, acting on behalf of the Allies and Poland. Not until after the treaty of Versailles was signed did Poznan send deputies to the constituent assembly in Warsaw.

POLAND RESTORED

Of all the new or resurrected states of Europe, Poland was in many respects in the most difficult position. The territory of Congress Poland and Galicia had been devastated in the war. Most of the factories that had not been actually dismantled were closed for lack of raw material. The fields of the peasants had been laid waste, their livestock slaughtered, their farms burned. Many districts were actually famine stricken, others swept by epidemics. Communications were disorganized and rolling stock was in a deplorable state. Marks, roubles and crowns circulated freely, but their values were low and uncertain, and public and private finances were chaotic. Because of the past policy of Prussia and Russia, a Polish civil service existed only in Galicia. Thirty thousand German troops were still in the country.

Pilsudski, the old revolutionary, had begun by appointing a cabinet of the left, composed mainly of Galician Socialists and peasants' representatives, under the presidency of Jedrzej Moraczewski. But the propertied classes refused him their support, and his attempt to float an internal loan met with little response. In December Paderewski, the second man in Poland enjoying almost unlimited prestige, arrived in the country, composed his differences with Pilsudski and became premier on Jan. 17, 1919. Dmowski was appointed president of the Polish delegation to negotiate peace. It was possible to hold elections for a constituent assembly on Jan. 26, 1919. The constituent sejm met on Feb. 10. It passed a vote of confidence in Paderewski's cabinet and confirmed Pilsudski as head of the state. Paderewski proceeded to Paris to urge Poland's claims; Pilsudski raised an army to defend them. General Haller's 100,000 troops, returning in April from France overland across Germany, were a valuable addition to the 230,000 men then at Pilsudski's disposal. The unification of the army was celebrated on Oct. 19, 1919, the French system of instruction and organization was adopted and by the beginning of 1920 the Polish army grew to about 600,000 men in 21 divisions of infantry and 7 brigades of cavalry. (R. DY.)

The Treaty of **Versailles** and Frontier **Problems.**—On June 28, 1919, on behalf of Poland, Dmowski and Paderewski signed the treaty of Versailles, which, however, left the major part of the country's frontiers undefined. Poland regained Pomorze and Poznan, but in East Prussia and Upper Silesia the Polish-German frontier was to be decided by plebiscite. Danzig (*q.v.*) was to be a free city under the protection of the League of Nations but was to be included within the Polish customs frontier in order to provide Poland with a free and secure access to the sea; in addition, Poland was to have free, unrestricted use of the port and to undertake the conduct of the free city's foreign relations. There was a Polish-Czechoslovakian dispute over Teschen (Cieszyn or Tesin) and also over the territories of Orawa (Orava) and Spisz. Of the eastern frontiers of Poland article 87 of the treaty stated that they would be "subsequently determined by the principal Allied and Associated Powers."

East *Prussia.*—Two plebiscite zones were established, that of Marienwerder (Kwidzyn), an area of 1,036 sq.mi. with 174,000 inhabitants, and that of Allenstein (Olsztyn), about 4,800 sq.mi. with 565,000. All Prussian civil servants were left in the plebiscite areas and the presence of German security police precluded freedom of speech.

The vote was taken on July 11, 1920, when Soviet forces were at the gates of Warsaw. In the Allenstein zone 363,209 votes were cast for Germany and 7,980 for Poland. in the Marienwerder zone 96,923 for Germany and 8,018 for Poland. Making the utmost of a stipulation that not only residents but also persons born in the area had the right to vote. the Germans sent to the plebiscite zones 202,700 "emigrants," who constituted nearly half of the voters. while 40% of the qualified residents abstained from voting. Thus the plebiscite, lost by Poland, could scarcely be described as a fair expression of the popular will.

Upper *Silesia.*—The plebiscite area of Upper Silesia was 4,250 sq.mi. with 1,942,200 inhabitants. Out of 706.820 votes cast for Germany on March 20, 1921, emigrant voters were responsible for 182,288; Poland obtained 479,414 votes. In all, 682 communes voted for Poland and 792 for Germany, but the Poles secured preponderance in the southeastern plebiscite area, which economically was the most important. Disregarding the treaty provisions for the partition of the area according to the wishes of the inhabitants expressed by communes, Germany claimed the whole of Upper Silesia, while Wojciech Korfanty, the leader of the Silesian Poles, demanded that 59% of the area, in which 673 communes voted for Poland and 230 for Germany, be awarded to Poland.

The Inter-Allied commission failed to agree on a unanimous proposal to the Supreme council of the principal Allied Powers, the British and Italian commissioners favouring cession to Poland of only the two southern agricultural districts of Rybnik and Pszczyna (Pless) while the French commissioner proposed a frontier less favourable than the Korfanty line but leaving the industrial basin to Poland. Learning of this basic disagreement, the Polish military organization, of which Michal Grazynski was the chief organizer, thought that only an insurrection could save the Polish cause. Korfanty agreed and gave the order for a rising, .which broke out on May 3, 1921. In a few days almost all the area within the Korfanty line was occupied. Taken by surprise, the Germans were thrown back. After six weeks' fighting the Inter-Allied commission effected a cessation of hostilities on June 24, and both the belligerents withdrew their troops.

The Supreme council assembled in Paris on Aug. 8–12 failed to draw a new frontier across Upper Silesia because David Lloyd George was anxious to save for Germany as much of the industrial area as possible. The only way out of the deadlock was to submit the question to the council of the League of Nations, where Great Britain was represented by Arthur James Balfour. The council's verdict, given on Oct. 12, 1921, was endorsed by the Allied Powers eight days later. The new frontier divided the industrial area: Poland was awarded 1,241 sq.mi. with about 996,-000 inhabitants, 76% of the coal production, 22 out of 37 blast furnaces and 9 out of 14 steelworks. Thus a basis for economic independence was assured. (See also SILESIA.)

Teschen.—On Nov. 5, 1918, close upon the final dissolution of the Habsburg monarchy, the Polish and Czech National council of Teschen Silesia concluded an agreement dividing the four districts of the province into two ethnographic entities. On Jan. 23, 1919, however, on orders from Prague, the Czech forces fell unexpectedly upon insignificant Polish forces in the area and occupied the greater part of the province. The government of Prague argued that Teschen was historically a Czech land and, moreover, that the new Czechoslovakia needed its coal.

The fighting was stopped by the Supreme council on Feb. 3, 1919. After a vain attempt to reach agreement by direct negotiation, the Supreme council decided on Sept. 27 that the dispute should be settled by plebiscite. On July 10, 1920, Poland, whose existence was menaced by the Soviet offensive, agreed a.t Spa that the Conference of Ambassadors should draw a final frontier. On July 28 less than half of Teschen Silesia was awarded to Poland (387 sq.mi. out of 858, with a population of 142,000 out of 435,-000). Czechoslovakia secured all coal mines. No Czechs were left on the Polish side of the new frontier, hut on the opposite side were 140,000 Poles. The decision relating to Orawa and Spisz was likewise disadvantageous to Poland, which kept 27 villages; the 44 villages awarded to Czechoslovakia had a Polish population of 45,000.

Eastern *Galicia.*—Of 4,743,000 inhabitants of Eastern Galicia (18,245 sq.mi.), Ukrainians formed 52.7%, Poles 39.3% and Jews 7.2% ; there was, however, a considerable Polish majority at Lwow (64% of a population of 300,000) and in some other towns. Enabled by the Austrian authorities to assume control of the whole area, the Ukrainians on Nov. 1, 1918, proclaimed at Lwow (Lviv) an independent republic of the Western Ukraine. Thereupon the local Polish population organized military formations, which succeeded in freeing the city by Nov. 22. In May 1919, after the fighting had continued for six months, the Polish army occupied the whole of the disputed province.

In March 1919 the Commission on Polish Affairs at the Paris peace conference considered the following alternatives regarding the future of Eastern Galicia: (a) a Polish mandate over the whole territory for 25 years, after which its fate was to be settled by plebiscite; (b) partition between Poland and a Ukrainian state. There were alternative demarcation lines in connection with these schemes: line A (see fig. 3), to run east of Przemysl, if the whole territory were to be entrusted to Poland under a mandate; and line B, which would leave Lwow and the Drohobycz oil fields to Poland in the event of the creation of a Ukrainian state. On June 25 the Supreme council accepted line A and authorized Poland to occupy the whole area; on Nov. 21, it approved the draft of an autonomous statute for the area with a 25-year mandate; on Dec. 22, 1919, giving satisfaction to Polish demands, the Supreme council rescinded its previous decision and allowed Poland to incorporate the whole area (see also GALICIA).

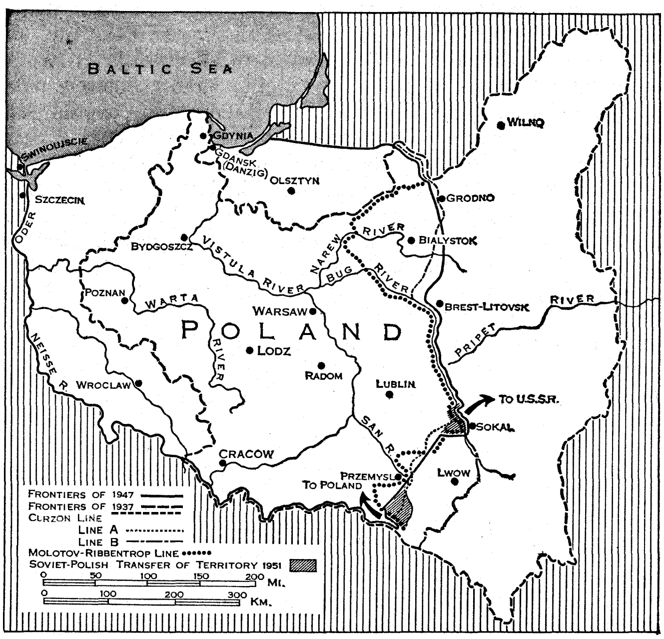

FIG. 3.—POLAND'S FRONTIERS, 1919-51 (SEE TEXT FOR EXPLANATION)

The Soviet Frontier.—Under the terms of the armistice of Nov. 11, 1918, the German armies had to evacuate western Russia and Poland. As the Germans withdrew, the Soviet army was advancing westward. In Nov. 1918 it was still on the Dnieper, but by Feb. 1919 had moved forward to the Bug. "Militant international Bolshevism urgently required contact with revolutionary Germany, and this could only be won over the body of Poland," says Sir Bernard Pares in his *History of Russia* (Alfred A. Knopf Inc. and Jonathan Cape Limited, publishers), thus succinctly indicating the origin of the Polish-Soviet war. The Soviet government hoped, of course, that the Polish workers and peasants would greet its armies as liberators, and was greatly dismayed when they did not. (*See* also RUSSO-POLISH CAMPAIGN.)

A counteroffensive launched by the Polish army under Pilsudski brought the Polish-Soviet front, by the end of 1919, along the river Berezina in Byelorussia, and in the Ukraine Novograd-Volynsk, Starokonstantinov and Bar were in Polish hands. Although in no haste to decide on Poland's eastern frontiers, the Supreme council, on Dec. 8, 1919, authorized Poland to organize a regular administration within a temporary line of demarcation "on the territories of the former Russian empire"; *i.e.,* not encroaching upon the formerly Austrian territory of Galicia. The declaration of Dec. 8 stated explicitly that the line fixed was a provisional minimum frontier, without 'prejudice to later terms which might be designed to fix the final eastern frontier of Poland.

On Jan. 28, 1920, Nicolai Lenin, Georghy Chicherin and Lev Trotsky handed a peace proposal to the Polish government suggesting the actual front as the armistice line. Pilsudski doubted the sincerity of this offer because he had information that the Soviet command was concentrating new divisions on the front and Trotsky himself, in a letter to three prominent French Communists, had written shortly before: "When we have finished with Denikin, we are going to attack the Poles" (Internationale *Com-*

muniste, Dec. 15, 1919). When, however, on March 27, 1920, the Polish government decided to open negotiations the Soviet government's rejection of Borisov, near the front, as a suggested meeting place confirmed Pilsudski's suspicion of a threatened Soviet offensive. On April 22, 1920, he accordingly signed a treaty of alliance with Simeon Petlyura, head of a Ukrainian government at Kamieniec Podolski (Kamenets-Podolsk), and three days later a Polish offensive started in the Ukraine. On May 7 the Poles occupied Kiev, but on June 8 the Soviet cavalry under Simeon (later Marshal) Budenny broke through the Polish line southwest of Kiev, and on July 7 Mikhail (later Marshal) Tukhachevsky attacked north of Borisov. The military situation of Poland became critical. On July 10 Wladyslaw Grabski, the premier, went to Spa where the Supreme council was assembled to ask for immediate help in the shape of war supplies. With the assent of representatives of France and Italy, Lloyd George undertook to act as mediator. He suggested an armistice along the line of Dec. 8, 1919; in Eastern Galicia the armies were to stand on the line reached on the date of the armistice. Grabski agreed, and on July 11 Lord Curzon, the British foreign secretary, suggested an armistice to Moscow and the Polish army's withdrawal to the line of Dec. 8, 1919, and in Eastern Galicia to the line A (see above), an obvious discrepancy with the agreement reached the previous day. Thus was born the "Curzon line."

Meanwhile the situation on the front gradually changed. By mid-August Pilsudski's counteroffensive brought a decisive victory. Poland was saved, but not only Poland. "By attacking Poland," said Lenin in Moscow on Oct. 8, 1920, "we are attacking also the Allies. By destroying the Polish army we are destroying the Versailles settlement." A Soviet-sponsored government for "liberated" Poland, headed by Feliks Dzierzynski, Julian Marchlewski and Feliks Kon, which had already established itself at Bialystok, had to flee back to Moscow. A Polish-Soviet peace treaty, concluded on March 18, 1921, at Riga, added to Poland an area of 51,762 sq.mi. east of the line of Dec. 8, 1919.

The Wilno Dispute.—During the advance of their armies westward, the Soviet government "ceded" Wilno (Vilnius) to Lithuania by a peace treaty signed on July 12, 1920. The city was evacuated by the Russians during their general retreat following the Polish victory and on Aug. 26 was entered by Lithuanian troops. The Poles appealed to the League of Nations and a partial armistice was signed at Suwalki on Oct. 7. Pilsudski was strongly inclined toward a federal solution of the dispute, with Wilno and its region providing an independent link between Poland and Lithuania. Gen. Lucjan Zeligowski accordingly occupied Wilno on Oct. 9 and set up a local government. Pilsudski's scheme, however, was incompatible with the prevailing temper of the Poles and Lithuanians. On Feb. 20, 1922, therefore, the democratically elected regional assembly of 106 members voted the incorporation of the whole province in the Polish republic; 96 members voted for the incorporation, 6 abstained and 4 were absent. It remained only to obtain the approval of the principal Allied Powers. The Soviet government had declared in the Riga treaty its disinterestedness in the Polish-Lithuanian dispute. The council of the League of Nations was no longer interested and on Feb. 3, 1923, adopted a final resolution fixing the Polish-Lithuanian line of demarcation. On March 15, 1923, the Conference of Ambassadors, requested by both the Polish and Lithuanian governments to use their right to fix the frontier, recognized the demarcation line of Feb. 3 as the final frontier between the two states. (See also VILNIUS.)

By the same decision the Conference of Ambassadors recognized as final the Polish-Soviet frontier fixed by the treaty of Riga. On April 5, 1923, both Polish-Soviet and Polish-Lithuanian frontiers were recognized by the government of the United States. The long series of territorial disputes which handicapped Poland's foreign policy and its internal reconstruction was definitely settled, both legally and in fact. The new Poland had a total area of 150,052 sq.mi. with an approximate population of 27,200,000. (K. SM.)

Constitution and Internal Affairs, to 1925.—Under the constitution of March 17, 1921, Poland was a republic. The legislative power was vested in a sejm and a senate, which were summoned, adjourned and dissolved, but not without their own consent, by the president. The sejm was composed of paid members elected for five years, upon a system of proportional representation. Suffrage was universal, all who enjoyed full civic rights and who were over 21 being qualified to vote; soldiers on active service were excluded. Citizens over 25 were eligible for election to the sejm; members of the civil service could not be elected for the district in which they held office. The minimum age for voting in senatorial elections was 30, while no one under 40 was eligible for election. Bills went to the senate after being passed by the sejm, and if no objection was raised within 30 days the bill became law. Taxes and customs duties could be established only by law and a supreme board of control superintended the management of state finance. The executive power was exercised by the president and a council of ministers who were responsible for his official actions. He was elected for seven years by the national assembly; that is, the sejm and senate acting together.

For purposes of administration Poland was divided into 16 palatinates, which again were subdivided into districts and urban and rural communes. The palatine or the wojewoda represented the executive government in the palatinate, the starosta in the district. Local legislation was to be exercised by *sejmiki* in the palatinates and by district councils in the districts. Economic autonomy was established by means of chambers of agriculture, commerce, industry, etc.; judicial control over the whole administration was vested in a supreme administrative tribunal.

Poland was reconstructed out of provinces of three empires in which widely different systems of law were operative. A codifying commission began to work out a body of uniform codes of law for the whole republic; in the meantime, Russian, German and Austrian codes remained in force in the different parts of the country. Gradually many domains of legal relations were covered by parliamentary legislation and, after 1926, by presidential decrees. A supreme court of justice in Warsaw was established at an early date, but it was not until 1928 that the country found itself in possession of a unified judicial organization and a uniform code of judicial procedure. Judges were nominated by the president and irremovable except by judicial decision. Justices of the peace were locally elected by the people. Over property in land, forests and mineral wealth, however, a certain amount of state control was extended by special provisions of the constitution. State protection was given to labour, and insurance against unemployment, illness and accident was guaranteed. The exercise of religion was free, as far as it was in accordance with the law. The Roman Catholic religion, the predominant denomination of the country, was placed by the constitution in a privileged position.

The constituent sejm had 13 political parties, as well as two independent members, and it was difficult to ensure a stable government. The resignation of Paderewski (Nov. 1919) was followed by a succession of quickly changing cabinets, always based on unstable coalitions—chiefly between the Peasant centre and either the Nationalist right or the mainly Socialist left. A coalition government of national defense under the peasant leader Wincenty Witos, with Ignacy Daszynski, the Socialist leader, as deputy premier, succeeded at a critical moment in rousing the country to resist the Bolshevik invasion.

Toward the end of 1922 the prolonged legislative period of the constituent assembly came to an end. An electoral law was passed on July 28, and in November elections for the upper and lower house of the first regular sejm were held. They ended by distributing power in the chamber between the Nationalists (161), the Peasant groups (124) and the Party of Labour (18); the Socialists obtained only 41 seats, but the national minorities, by organizing a bloc for electioneering purposes. got 81 (of whom 35 were Jews) and accordingly, in spite of the large abstention of the Ukrainian element from the elections, became an important and occasionally a decisive factor in the parliamentary system.

The first business of the two houses of the new parliament was jointly to elect a president of the republic. Marshal Pilsudski refused to stand. The parties of the left, supported by the national minorities and the Witos Peasant party, secured the election of Gabriel Narutowicz, a friend of Pilsudski, who had acted as minister of foreign affairs in several cabinets. Polish nationalism was infuriated by the election of a president through the votes of the national minorities, and on Dec. 16 a fanatic assassinated Narutowicz. The new president was Stanislaw Wojciechowski, a former Socialist and father of the Polish co-operative movement. Gen. Wladyslaw Sikorski became premier.

Poland's position in the early part of 1923 was still very unsettled. The Polish mark, a provisional currency, was affected by the collapse of the German mark. A government formed in the spring by Witos, on the basis of an alliance between the Peasant party and the National party, had to struggle against the resolute opposition of the left and the national minorities; the government proved unable to cope with the continued, disastrous fall of the mark and there was serious unrest in the country, culminating in riots at Cracow on Nov. 6; the government was obliged to resign on Dec. 11. It was followed by a nonparty one under Wladyslaw Grabski, who, as prime minister and minister of finance, made financial reform his principal task. The political parties now at last agreed to subordinate all other problems to those of financial reconstruction. On Jan. 3, 1924, Grabski's government was granted emergency powers for the purpose. Fulfilling partly the recommendations of a British financial adviser, Edward Hilton Young (later Lord Kennet), Grabski strenuously reorganized the financial system of the country. A Bank of Poland was once more created on a basis of private subscription. The budget was balanced by Draconian reductions in expenditure, the printing of paper money stopped, the currency became stabilized at the rate of exchange which it had reached (1,800,000 marks to the gold franc), and finally a new currency unit, the zloty, was introduced and declared equal to the gold franc. The drastic manner in which this financial reform was accomplished inevitably brought about its revenge. The too-high level at which the value of the new currency had been fixed caused a period of heavy economic depression.

On Feb. 10. 1925, a concordat with the Holy See was signed. The Catholic Church was granted absolute freedom of execution of its authority and jurisdiction in Poland, the assistance and support of the state being assured it in this respect. The state's interests in connection with nominations for the higher ecclesiastical posts were adequately protected. In religious education, the competencies of church and state were exactly defined. The division of Poland into ecclesiastical provinces was carried out in such a way that no portion of Polish territory remained subject to the jurisdiction of a bishop residing outside the borders of the state. An autocephalous Orthodox Church also established in Poland received the blessing of the synod and of the ecumenical patriarchate in Constantinople on Nov. 11, 1924. The Protestant Church in Poland was likewise placed beyond reach of political influences from abroad.

Alliances and Security.—In the first years of Polish independence, France's support was Poland's greatest asset. At the end of 1920 the French premier, Alexandre Millerand, invited Pilsudski to visit Paris in his capacity of head of state. As a result of discussions during this visit a political agreement was signed in Paris on Feb. 19, 1921, by Aristide Briand and Prince Eustachy Sapieha, ministers of foreign affairs. It provided that the two governments should take concerted measures for the defense of their territory and the protection of their legitimate interests if either or both of the contracting states. in spite of sincere peaceful intentions, should be attacked without provocation. On March 3, 1921, a treaty of alliance with Rumania was signed at Bucharest by Sapieha and Take Jonescu. On March 26, 1926, the Polish-Rumanian alliance was renewed. It stipulated that the two countries should pledge themselves to defend their territorial integrity and political independence against any outside aggression.

A definite alliance between Poland and the Baltic states was attempted on March 17, 1922, when a political treaty was signed in Warsaw by the foreign ministers of Poland, Finland, Estonia and Latvia. It stipulated that in the event of aggression against one of the contracting parties all four governments should cooperate on measures to be taken. On May 12, however, the Finnish parliament refused to ratify the treaty.

By the end of 1921 Polish-Czechoslovakian relations became cordial enough. and Konstanty Skirmunt, the foreign minister, paid an official visit to Prague. On Nov. 6 he signed with Eduard Benes a political convention by which the two governments agreed to act in concert for the application of the treaties which they had signed in common. There was some talk at that time of closer collaboration between Poland and the Little Entente, but the latter's aim, directed against Hungarian revisionism, was from the Polish point of view too limited. In June 1923 Marian Seyda, the Polish foreign minister, suggested the transformation of the Little Entente into a quadruple alliance, providing all the members with a collective guarantee of security, but this idea met with a cool reception in Prague. Count Alexander Skrzynski, Seyda's successor at the foreign office, was less ambitious. Benes paid a visit to Warsaw in April 1925 and a Polish-Czechoslovakian treaty of conciliation and arbitration was concluded.

Great Britain's rejection of the so-called Geneva protocol and of the principle of collective security alarmed Poland, as did the German proposals to France, which treated separately the problems of Germany's western and eastern frontiers. The Polish thesis was that European security was indivisible. A not too satisfactory compromise formula was found. The treaties initialled at Locarno (*q.v.*) on Oct. 16, 1925, and signed in London on Dec. 1 included two agreements concerning Poland: a Polish-German arbitration treaty and a Franco-Polish treaty of guarantee. The former provided for the peaceful settlement of disputes; in the latter France guaranteed the Polish frontier with Germany. Polish opinion was not easily reconciled to the idea of the Locarno treaties. They were accepted, but for the first time the Poles felt that they were abandoned by France.

The Second Coalition Government.—Soon after the breakdown of his financial policy Grabski resigned. He remained in power for 23 months, a record in Polish parliamentary history. On Nov. 20, 1925, Skrzynski formed a coalition cabinet, the second of this kind since the restoration of the state. This time the frontiers were secure, but the country was again in danger. The treasury was almost empty, the shortage of private capital was acute, unemployment was rife and the zloty continued to fall. Another storm centre of embittered dispute was the question of reinstating Marshal Pilsudski In the position of commander in chief of the army. He had resigned the office of chief of staff in May 1923 when a government of the Nationalist-Peasant coalition was formed.

In foreign affairs the Skrzynski administration was under the shadow of a growing feeling of international insecurity for Poland. When, a month after the ratification of the Locarno agreements, the League of Nations proceeded to elect Germany a permanent member of the council, Skrzynski claimed a permanent seat for Poland as well. It was not till after a good deal of dramatic friction in the League that a solution was found, Germany getting a permanent and Poland a so-called quasi-permanent seat in the council.

Pilsudski's Rule, **1926–35.**—Meanwhile internal dissensions intensified while the conclusion of a new Soviet-German treaty in Berlin (March 1926) increased the general nervousness. Pilsudski, in his retreat at Sulejowek, was looked up to by large masses of the people as the only man who could secure a better future for the country. His adherents and opponents formed two opposing camps in the army. In parliament, the right, since the days of his provisional presidency, had used every legislative device to limit his power and influence. Now, in the dispute over his commandership, the right desired to frame the Army Organization bill in such a way as to bring the army under the direct control of parliament, while Pilsudski insisted on complete independence of the commander in chief.

Matters came to a crisis when, because of the dissensions over the budget, the Socialist ministers left the cabinet, and Skrzynski himself resigned in consequence. After a prolonged period of negotiations Witos succeeded in forming a ministry. Rumours were current that he meant to rely exclusively upon the support of the right and to settle the question of the commandership in the sense demanded by the Nationalists. Thereupon, on May 12, Pilsudski suddenly entered Warsaw at the head of troops. The government proclaimed him a rebel. The concentration of government troops in Warsaw, however, was hampered by a strong strike movement in the country, chiefly among the railwaymen; and after two days of heavy fighting in the streets of Warsaw, Pilsudski was master of the capital. The government resigned and the president of the republic abdicated. Maciej Rataj, the speaker of the sejm, became acting head of the state, in accordance with the terms of the constitution. A provisional cabinet under Kazimierz Bartel was appointed, pending the election of a new president. When the two chambers met on May 31 for the presidential election, there resulted a majority of 292 to 193 in favour of Pilsudski. He, however, refused the office in favour of his nominee, Ignacy Moscicki, a scientist not formerly engaged in politics. who was duly elected on June 1 by 281 votes to 200. Pilsudski himself became minister of war and a few months later officially assumed premiership in the cabinet.

Pilsudski met with little opposition when on Aug. 2, 1926, he proceeded to reform the constitution in the sense of limiting the powers of parliament with respect to the budget: if within a period of five months the budget was not passed, the finance bill acquired the force of law. Another provision gave the president the right to dissolve the parliament on a unanimous proposal of the government, the new elections taking place within 90 days.

A year and a half after Marshal Pilsudski's coup d'état, a new parliamentary election became due in Poland. He had left the outward structure of the parliamentary system intact. The practical impotence, however, to which his rule reduced the sometime all-powerful parliamentary parties had a profound effect on them. The largest groups began to disintegrate, and when the elections approached as many as 3j different factions appeared in the field with lists of candidates of their own. This "pulverization of the party system" was the result of splits in the larger groups on the one issue that remained dominant under the circumstances; viz., the question: for Pilsudski or against him. In the midst of this reshuffling of all former groupings, the government created a nonparty bloc of its supporters of various shades of opinion. From the elections held on March 4 and 11, 1928, only the Socialists emerged with a substantial increase in the number of their seats (64 as against 41); the other parties which had once been strong factors—the Peasant, the Party of Labour, the Christian Democratic and the Nationalist—dwindled from 230 to 150 seats. The government bloc obtained 135 seats. (R. Dy.; X.)

The opposition, however, remained strong, and a normal cooperation of the parliament with Pilsudski proved impossible. In the autumn of 1930 the growing tension resulted in the arrest of some of the party leaders, who were imprisoned at Brzesc and treated there very badly. New elections held on Nov. 16 and 23 gave the government bloc an absolute majority of 247 seats in a sejm of 444, the National Democrats winning 63 seats, the Centre-Left coalition 92 and the national minorities 33.

The Constitution of 1935.—After his electoral success Pilsudski said that the principal task of the new parliament was the revision of the constitution. A draft was introduced to the sejm on Dec. 20, 1933; it was passed by it on Jan. 26. 1934, and by the senate on Jan. 18, 1935. On March 23, 1935, the new constitution was definitely adopted by the sejm by 260 votes to 139; it became law on April 23.

It was based on the following principles: the state being considered as the "common good" of all the citizens, the executive became considerably strengthened at the expense of the legislature; the president appointed and dismissed the prime minister and the commander of the army, could dissolve the sejm and was responsible to none; the six "organs of the state"—government, sejm, senate, army, courts of justice and court of supervision—were accordingly under the president's control; the powers of the legislature were strictly limited and the number of its members reduced to 208 in the lower and 96 in the upper house, one-third of the latter being nominated by the president.

Foreign Relations.--During the first six years of Pilsudski's regime, August Zaleski being minister of foreign affairs, Poland's policy was chiefly based upon the League of Nations and the close alliance with France. Poland, which had proposed to the League's assembly of 1927 a resolution outlawing wars of aggression, not only signed the Kellogg pact of the next year but even anticipated its realization by a special agreement with Soviet Russia in 1929. On July 25, 1932, that protocol was developed into a pact of nonaggression. At the disarmament conference of the same year the Polish delegation had played an active part, submitting an elaborate plan of "moral disarmament"; but it became obvious that the idea of collective security had failed, and Poland sought better guarantees in bilateral agreements with its neighbours.

After 1932 this method was developed by the new minister of foreign affairs, Col. Jozef Beck, formerly Pilsudski's chef de cabinet, and found its strongest expression in another ten-year nonaggression pact, concluded on Jan. 26, 1934, with Germany. There was of course a reservation that the new treaty was not to affect Poland's previous engagements, particularly its alliance with France. Nevertheless, it seemed to involve a change in Poland's general attitude. Seeing that nobody in Europe was prepared to fight the new Adolf Hitler regime, Pilsudski found it necessary to accept a direct understanding with Poland's western neighbour also, holding the balance between the Soviet Union and Germany.

Moscicki and **Smigly-Rydz.**—After Pilsudski's death on May 12, 1935, the form of government which he had established continued without much change. The voting regulations, as applied at the elections of Sept. 8 and 15, 1935, without having been defined in the new constitution itself, again raised much discontent; but attempts were started to come to some co-operation with various groups of the opposition. The government bloc was dissolved and replaced by a Camp of National Unity. Both President Moscicki, who had been re-elected in 1933 for another seven-year period, and Marshal Edward Smigly-Rydz, Pilsudski's successor as commander of the army (who was styled "the second person" in the republic), exercised their authority with moderation and in a conciliatory spirit. Such an appeal to internal unity was indeed indispensable in face of the increasing danger of the international situation.

That danger resulted from the policy adopted by Germany. After the annexation of Austria and the destruction of Czechoslovakia, it was clear that Hitler wanted to isolate the eastern European states so as to be able to attack them one by one. Soon after Munich, when Poland had seized the opportunity to claim the contested Teschen territory (see above), there began a new tension with Germany. Yet on Jan. 30, 1939, Hitler reaffirmed the importance of the German-Polish nonaggression pact as a contribution to the peace of Europe; but he had already decided to annex the Free City of Danzig, and on March 27 he officially requested the Polish government to accept that solution as well as the construction of an extraterritorial motor road through the Polish province of Pomorze. Touched in its vital interest and realizing that it was a first challenge against its independence, Poland refused, making counterproposals which were never taken into serious consideration. As soon as Poland had exchanged with Great Britain reciprocal guarantees of independence and integrity, Hitler took it as a pretext to denounce, in his speech of April 28, the nonaggression pact of 1934.

During the next four months he tried to provoke Poland by various incidents in Danzig and started a propaganda campaign against an alleged ill treatment of the German minorities in Poland. But it was not until Germany had concluded, on Aug. 23, a new partition treaty with the U.S.S.R. that he finally decided to attack Poland. Two days later a close alliance was signed between Poland and Great Britain which made it absolutely clear that Great Britain, as well as France, would support its ally in case of war; but in spite of a patient conciliatory effort made by British diplomacy and proposals of a peaceful settlement put forward by various powers and accepted by Poland, Germany invaded Poland on Sept. 1, 1939.

WORLD WAR II

Poland, which had postponed the general mobilization to the last moment, was unable to stand against the overwhelming German forces, the long open frontier stretching from East Prussia to Slovakia being already occupied by German troops; nevertheless, it made a courageous resistance in the centre of the country until Sept. 17, when the Soviet army invaded its territory from the east under the pretext that the Polish state was no more in existence. Even then in various regions desperate fighting was continued, and Warsaw, although severely bombed, like so many other open places, defended itself heroically until Sept. 27. The next day a second German-Russian treaty was signed in Moscow by Joachim von Ribbentrop and Vyacheslav Molotov redistributing the spoils; the eastern provinces, including purely Polish territories, were incorporated in the Soviet republics of Byelorussia and the Ukraine; the western part was left within the German sphere of influence.

Before leaving Polish territory, President Moscicki resigned and designated Wladyslaw Raczkiewicz as his successor. The new president appointed a new government, the former having been interned in Rumania. General Sikorski became prime minister, Zaleski minister of foreign affairs, and both president and government were established at Angers, Fr. The Polish army was also reconstituted in France to fight with the Allies, while some Polish warships, having escaped, joined the British navy.

Sikorski also became the commander in chief of the reorganized Polish army. This was possible because part of the army had passed into Hungary and Rumania and succeeded in assembling in France, where its ranks were swelled by mobilization among the prewar Polish emigrants in that country. The Polish army, numbering nearly 100,000, was ready by the spring of 1940. A Polish brigade fought in the Norwegian expedition of the Allies, especially in the battle of Narvik, and the Poles joined also in the defense of France.

The collapse of France was likewise a heavy blow for Poland. In spite of fresh losses and the capitulation of one of the Allies, the Polish army did not even then dream of ceasing to fight. About 15,000 who had heroically protected the retreat of one of the French armies had to cross into Switzerland, where they were interned. A part of the Polish army was transported to Great Britain, where, at the end of June 1940, the Polish government together with the president transferred itself. The Polish airmen began increasingly to distinguish themselves, acting with the royal air force, and simultaneously Polish divisions, dispersed through the world as of old in the Napoleonic wars, appeared in Palestine and on the Egyptian-Libyan battlefield. (See also **World War II**.) (O. Ha.; X.)

Germany divided the conquered Polish land into two zones. The provinces that had been ruled by Prussia from the Vienna settlement to 1918 and also part of central Poland with Lodz (renamed Litzmannstadt) and Plock were incorporated into the reich on Oct. 19, 1939. All the incorporated lands were destined for complete germanization. The remaining territory between the new German frontier and the Molotov-Ribbentrop line was organized as a General Gouvernement. It was divided into four districts: Warsaw, Lublin, Radom and Cracow. In Aug. 1941, shortly after the German attack on the Soviet Union, the province of Bialystok was incorporated into Germany, while Eastern Galicia, with Lwow, was added as the fifth district to the General *Gouvernement*. This territory was to be used mainly as a reserve pool of labour. All Polish elements were submerged, and it became for a time, as Hans Frank, the governor general, described it, "an intellectual desert."

Such a policy was countered by immediate reactions in the community. The professors of Cracow university, who were invited to co-operate in the administration of the General Gouvernement, preferred internment and death to assisting the Germans in any way. Polish property was confiscated, and continual deportations of workers into the reich enabled the Germans to solve their growing problem of manpower. Concentration camps were established, and Oswiecim (Auschwitz) became especially notorious for the deliberate and systematic torture and murder of its inmates. Unknown numbers of Poles perished there and it became the grave of a great part of the 3,000,000 Polish Jews. In opposition to this terror, the Poles organized a powerful underground movement which continued the cultural and social life of the people in secret schools, social services and an active press. A secret home army grew to considerable strength and carried out operations against German communications and institutions. The administration of the underground organization took its orders from the Polish government in London.

Far more complicated was the position of the Poles in the eastern areas occupied by the Soviet Union from Sept. 17, 1939, to late June 1941. There the problem was Ukrainian as well as Polish. All political leaders, Polish and Ukrainian, together with the bulk of the educated classes were deported, but less open violence and more subtlety were used than in the German zone and the annexation to the Soviet Union was effected only after a so-called plebiscite which was claimed to have justified the act. The growing terror under the Soviet police was checked by the German invasion, which made the position of Poles in the U.S.S.R. easier but offered a difficult problem to the Polish government in London. The great mass of the Poles abroad continued to regard the Italians, who had helped many of them to escape, as their friends, and to mistrust Soviet intentions toward their country. But political and military reasons led Sikorski to make an agreement with the U.S.S.R. The terms of this agreement, signed in London on July 30, 1941, ended the state of war between the two countries and raised hopes of an ultimate restoration of Poland in its former boundaries; but it was more immediately important in enabling Gen. Wladyslaw Anders to organize a Polish army in the Soviet Union. Sikorski visited Moscow and on Dec. 4 signed with Joseph Stalin a Polish-Soviet declaration of mutual assistance and collaboration. Stalin agreed that the Polish army in the U.S.S.R., originally projected as two divisions, should be increased to a strength of six divisions. About 75,000 of the men already recruited by Anders were allowed to leave for the middle east in March and Aug. 1942. Unfortunately, as the danger of defeat by the Germans was averted, the Soviet authorities began to adopt a more aggressive attitude to Polish claims.

It was possible to form a Polish army in the U.S.S.R. since there were more than 200,000 Polish prisoners of war taken by the Russians in Sept. 1939 and hundreds of thousands of Polish nationals deported. Securing a corps of officers for the new army offered a more serious problem. In Oct. 1939 about 14,300 Polish officers were segregated by the Soviet authorities into three prison camps at Ostashkov, Kozelsk and Starobelsk. The Polish authorities in the Soviet Union and the Polish underground in the homeland failed to find any trace of the missing officers after April 1940, although it was suggested by the Soviet government that they had been exchanged with their German allies in 1940. When in April 1943 mass graves were discovered in Katyn wood near Smolensk, containing the bodies of the men who had been imprisoned in the Kozelsk camp, the Germans accused the Russians of having murdered them. The Soviet government refused an investigation by an International Red Cross commission suggested by Sikorski and, on April 25, 1943, broke off diplomatic relations with the Polish government.

Sikorski was killed in an aeroplane accident at Gibraltar on July 4, 1943, and was succeeded as prime minister by Stanislaw Mikolajczyk, the leader of the Peasant party, and as commander in chief by Gen. Kazimierz Sosnkowski. As their military position improved and they began to reoccupy Polish territory, the Soviet authorities' new policy became more anti-Polish. They revived their claim to the eastern provinces and began to protect a group of Poles who were prepared to accept this claim. This group was joined by a number of Polish Communists including Boleslaw Bierut and came to be known as the "Lublin committee" and then to be a provisional Polish government. All attempts by the London government to co-operate with or oppose them came to nothing, and the Soviet authorities started a great campaign of propaganda to discredit the legal Polish government in London.

Another move was to smuggle Communists into German-occupied Poland ostensibly to help but really to displace the leaders of the underground movement. These leaders continued to carry on their heroic struggle in co-operation with the government in London. As at the end of July 1944 the Soviet army

reached the Vistula and neared Warsaw the underground was requested by broadcasts from Moscow to support it, and Gen. Tadeusz Bor-Komorowski, commander of the home army. under orders from the military headquarters in London, started an open struggle in Warsaw on Aug. 1, 1944. Despite the efforts of the western Allies to send arms and supplies by air, the sacrifice was made useless by the inactivity of the Soviet armies. which refused to send any support. The struggle continued for 63 days, after which further resistance was impossible.

Even before this tragic event the Soviet generals, as they advanced into Poland, had been disarming and deporting members of the home army which was helping them. Now that the main army of the underground had perished, the task of the Soviet political leaders was made easier. While the Polish forces in the west continued to fight the battle with their Allies on land, sea and in the air, especially in the great advance through Italy, and, after June 6, 1944, in northern France, Belgium and the Netherlands, the Russians did all they could to discredit the Poles fighting against the common enemy in Poland and the government in London to which they gave their allegiance.

The fate of Poland was now taken over by the Great Powers, which at the Yalta conference in Feb. 1945 tried to settle the difficult questions which had arisen. As a result, the Soviet Union was able to obtain recognition of the Lublin committee. Both the Polish government and the underground movement sank out of sight, and when World War II came to an end a Polish "people's republic" was established. (A. B. Bo.)

THE PEOPLE'S REPUBLIC

Pres. Franklin D. Roosevelt, Winston Churchill and Marshal Stalin decided at Yalta, on Feb. 11, 1945, that a "Polish provisional government of national unity" should be created; *i.e.,* that the Soviet-sponsored government formed at Lublin on Dec. 31, 1944, should be reorganized to include "other Polish democratic leaders from Poland and from abroad." The three powers jointly engaged that free and unfettered elections on the basis of universal suffrage and secret ballot should be held as soon as possible. After four months of diplomatic discussion among Moscow, London and Washington concerning the exact interpretation of the Yalta decision, a Polish round-table conference met in Moscow on June 17 to discuss the formation of a Polish government. Among leaders from within Poland and from abroad attending the conference was Mikolajczyk (until Nov. 24, 1944 premier of the Polish government in London). On June 28, 1945, the composition of the government was announced. It showed that the Soviet interpretation of the Yalta declaration had prevailed: of the 21 members of the cabinet only 5 were newcomers, the most important being Mikolajczyk, who became second deputy premier; 16 ministers were former members of the Lublin government, including Edward Osobka-Morawski, leader of a split Socialist group, who remained premier. Bierut, who from July 22, 1944, had been chairman of the presidium of the so-called Polish national home council, became provisional president of the republic. Without waiting for the formation of the provisional government of "national unity," Stalin and Osobka-Morawski on April 21, 1945, signed in Moscow a Soviet-Polish treaty of friendship, mutual assistance and postwar collaboration. On July 5 the British and the U.S. governments recognized the new Warsaw government and withdrew recognition from the London government composed of representatives of the National, Christian Democratic and Socialist parties and presided over by Tomasz Arciszewski (1877–1955), a senior Socialist leader who until July 1944 was the chairman of the underground Council of National Unity in Warsaw.

The New Frontiers. — On Aug. 16, 1945, Molotov and Osobka-Morawski signed in Moscow a treaty demarcating the Soviet-Polish frontier. This demarcation. more or less identical with the Curzon line, restored to Poland the province of Bialystok in the north and a smaller area in the south including Przemysl, which the Molotov-Ribbentrop line had assigned to the U.S.S.R. In a small exchange of territory on Feb. 15, 1951, the U.S.S.R. acquired a strip of land of 185 sq.mi. south of Hrubieszow, while a similar area south of Przemysl, including the town of Ustrzyki Dolne, was returned to Poland.

On Aug. 2, 1945, at Potsdam, Pres. Harry S. Truman, Clement Attlee and Marshal Stalin published a statement establishing a new de facto western frontier of Poland along the Oder and Neisse rivers. The former German territories east of this line, including the free city of Danzig but excluding the portion of East Prussia incorporated in the U.S.S.R., were placed under Polish administration. Poland was also authorized to undertake the transfer to Germany of the German populations east of the Oder-Neisse line. On July 6, 1950, an agreement recognizing the Oder-Neisse line as the permanent frontier was signed at Zgorzelec (Görlitz) by Otto Grotewohl and Cyrankiewicz, premiers of the German Democratic Republic and Poland. The Polish-Czechoslovakian frontier in its prewar half remained as fixed on July 28. 1920; *i.e.,* the disputed territories of Cieszyn or Tesin (349 sq.mi.) and of Orawa and Spisz (70 sq.mi.), which had been seized by Poland in Oct. 1938, were left to Czechoslovakia. As compared with its territory before World War II, Poland was shifted westward considerably. In the east it lost 69,290 sq.mi. and in the west it gained 39,597 sq.mi., its new area being 120,359 sq.mi.

Home Affairs.—Only on Nov. 13, 1946, under pressure of the British and U.S. governments, Bierut signed a decree fixing Jan. 19, 1947 as the date for the Polish elections. The official figures stated that 11,413,618 voted out of 12,701,056 qualified electors: 9,003,682 (89.8%) voted for the Communist-controlled Democratic bloc which secured 382 seats out of 444. It was officially stated in both the United States and Great Britain that the elections were neither free nor fair. The new *sejm* on Feb. 5 elected Bierut president, and two days later he appointed a new government headed by Jozef Cyrankiewicz, a Socialist.

A striking political development took place within the ranks of the Polish Workers' (Communist) party on Sept. 3, 1948, when it was announced that Wladyslaw Gomulka (1905–), its secretary-general and first deputy premier, had been accused of "rightist and nationalist deviation" and had been obliged to recant and to resign from both offices. Although the leadership of the split Polish Socialist party was already purged, there was still resistance against a proposed merger with the Communist party which, for the former, was equal to dissolution. Nevertheless, the merger congress assembled in Warsaw from Dec. 15 to Dec. 22, 1948. The new party was called the Polish United Workers' party (*Polska* Zjednoczona *Partia* Robotnicza or P.Z.P.R.), and Bierut became its chairman. Mikolajczyk, accused on Oct. 12, 1947, of being "an ally of foreign imperialists," escaped and arrived in London on Nov. 3, 1947. On Nov. 30, 1949, the rump of the Polish Peasant party and the two Communist-controlled peasant groups were iused under the name of United Peasant party. In July 1950 the (Christian Democratic) Party of Labour was absorbed into the Democratic party.

The new constitution passed unanimously by the sejm on July 22, 1952, was modelled on the Soviet constitution of 1936. (See below.) The 425 members of the new sejm were elected on Oct. 26, 1952, in Soviet fashion, *i.e.,* there was only one list of official candidates in each of 67 constituencies and 99.8% of valid votes were allegedly cast for them. On Nov. 20, 1952, as the sejm elected a new council of state and Aleksander Zawadzki as chairman, Bierut formed a new government.

The 2nd congress of the P.Z.P.R. was held in Warsaw in March 1954. The party membership at that time was 1,296,938, of whom 413,449 were new members accepted after April 1949, when the membership was 1,368,759, in four years, therefore, 485,270 members had either died or been expelled. The congress adopted a new party statute which defined the P.Z.P.R. as the "organized shock detachment of the Polish working class—the vanguard of the Polish nation." It elected a central committee of 77 members and 50 candidates which named a Politburo of 13 members and 2 candidates. Bierut, the leading member of the Politburo, was appointed first secretary. Following the example of "collective leadership" adopted in Moscow after Stalin's death, he resigned the premiership on March 19. 1954 and was succeeded by Cyrankiewicz.

Return of Gomulka.—Bierut died in Moscow on March 12, 1956, at the age of 64. His death left the party leadership deeply divided. On March 20 the party's plenary session of the central committee unanimously elected Edward Ochab as its first secretary. Though he was believed to be the candidate of N. S. Khrushchev, first secretary of the Communist Party of the Soviet Union, Ochab nevertheless began to prepare for the return of Gomulka to the party leadership. (Arrested in July 1951, Gomulka was released in Dec. 1954, but this became publicly known only after Bierut's death.) On May 6 it was announced that Jakub Berman, a member of the Politburo and deputy premier, had resigned from both posts. With Bierut dead and Berman dismissed, of the original Communist triumvirate only Hilary Minc remained in the Politburo, and the influence of Cyrankiewicz, the premier, was growing and his partnership with Ochab was becoming closer.

On June 28, 1956, an event of historic significance broke down the pretense of popular support for the Communist regime. Industrial workers of Poznan staged a general strike and a procession of 50,000 demanded bread, freedom, free elections and the departure of the Russians. Riots followed, a security police officer was lynched and order was restored the following day only by the army's use of tanks. According to official reports, 53 people were killed and zoo wounded.

The July plenary session of the central committee became a contest during which three trends were apparent. The Stalinists recommended strict censorship of the press and the curtailment of "democratization." They were opposed by the younger generation of Communist leaders who wanted democratization to continue. Between these two groups there were the Realists, led by Cyrankiewicz and Ochab. They, too. were supporters of change, but desired to achieve it more slowly. But the only man who could restore party unity and authority and count on wider support was Gomulka. All three groups desired his return to the Politburo although it was clear that the Stalinists wanted him only as a figurehead. On Aug. 5 Gomulka was officially rehabilitated and restored as a party member. On Oct. 9 it was announced that Minc had resigned from the Politburo and from his office of deputy premier. Agreement was reached among Gomulka, Ochab and Cyrankiewicz as to the composition of the new Politburo.

On Oct. 19 when the party's central committee had assembled to elect a new Politburo. quite unexpectedly Khrushchev, V. M. Molotov, L. M. Kaganovich and A. I. Mikoyan arrived in Warsaw. It was learned that Soviet divisions stationed in southnestern Poland mere moving toward Warsaw, while a Soviet naval squadron appeared before Danzig. The meeting of the central committee, after co-opting Gomulka as its new member, decided that the old Politburo including Gomulka would discuss Polish-Soviet relations with the Soviet guests and, on the night of Oct. 19–20, the Polish leaders succeeded in explaining to the Soviet visitors that the Polish people's democracy must be an equal, independent and sovereign state.

Meanwhile, Polish workers and university students, aroused by the Soviet intervention, demonstrated, through meetings and processions, their protest against foreign pressure and their support for Gomulka. Khrushchev and his colleagues understood that by supporting the Stalinists they were risking bloodshed. They accordingly retreated and on Oct. 20 returned to Moscow. When the Polish central committee reassembled, Gomulka presented his program and the next day his speech was broadcast to the nation. On Oct. 21 the plenary session elected the new nine-member Politburo. In a secret ballot. Gomulka obtained 74 votes. the maximum possible being 75, while Marshal Konstantin Rokossovsky secured only 23 votes. (Rokossovsky, a Russian of Polish origin, had been appointed on Nov. 7, 1949, Polish minister of defense and commander in chief; on May 8, 1950, he had been co-opted to the Politburo.) In quick succession a series of army changes was announced. The most important was the replacement on Nov. 13 of Marshal Rokossovsky as minister of defense by Gen. Marian Spychalski, a friend of Gomulka. Rokossovsky returned to Moscow and on Nov. 15 was appointed deputy minister of defense of the U.S.S.R. In the first week of November 32 Russian officers in the high command of the Polish armed forces were dismissed and replaced by Poles.

Struggle with the Church. — Early in 1950 relations between the regime and the Roman Catholic Church became openly strained when the state took control of church charitable funds. and Cardinal Adam Sapieha (1867–195 ~)archbishop of Cracow, and Mgr. Stefan Wyszynski (1901–), archbishop of Gniezno and Warsaw and primate of Poland, accused the government of bad faith in its dealings with the church. On April 14, however, the government and the hierarchy signed an agreement which made provision for considerable religious toleration and recognized the pope as head of the church; the church, in turn, agreed to support the government's foreign policy and to ask the Holy See to recognize Poland's sovereignty over the recovered territories east of the Oder-Neisse line by appointing diocesan bishops there in place of apostolic administrators. When the bishops were not at once appointed, the government suppressed religious tuition in schools. In Jan. 1951, when the five apostolic administrators had been relieved of their office and in their place the diocesan councils. under the government's pressure, appointed five vicars capitular, Mgr. Wyszynski saved the unity of the church by vesting canonical jurisdiction in them. He visited Rome in April and obtained from the Holy See the appointment of new residential bishops, but the government forbade the nominees to assume their posts and continued to accuse the Vatican and the hierarchy of refusing to recognize the new western frontier as final.

On Feb 9. 1953, the government made a law by which it claimed rights of appointment to ecclesiastical office. In a memorandum of May 8, 1953, the hierarchy protested to the government against this and other steps to create schism. The publication of this document was forbidden in Poland and a bishop was put on trial. On Sept. 24, Wyszynski (made cardinal on Nov. 29, 1952) protested. He nas arrested and secretly detained. On Dec. 17, 1953, the bishops, auxiliary bishops and vicars capitular from all the dioceses took an oath of loyalty to the Polish state.

For three years an uneasy truce existed between the church and the state, but in Oct. 1956, soon after his return to power, Gomulka decided to make peace On Oct. 28 Cardinal Wyszynski. released from internment, returned to Warsaw as head of the Polish hierarchy. Five other bishops and all priests who had been imprisoned were released from confinement. On Dec 8 an agreement between the state and the church was announced. The government promised to replace the law of Feb. 9, 1953, by another one which would respect church jurisdiction. Religious instruction was again to be given in schools as an extracurricular subject. The government agreed to the appointment of five residential bishops in the recovered territories to the sees of Wroclaw, Opole, Gorzow, Gdansk and Olsztyn.

Foreign Affairs. — Besides the bilateral Polish-Soviet treaty of alliance of 1945, Poland nas bound by similar treaties with Czechoslovakia (March 10, 1947), Hungary (June 19, 1948), Rumania (Jan. 26, 1949) and Bulgaria (May 29. 1948). A treaty of alliance with Yugoslavia, signed in Warsaw on March 16, 1946, was denounced in 1948 when Yugoslavia was expelled from the Communist bloc. The net of alliances was completed by a treaty signed in Warsaw on May 14, 1955, by which Albania, Bulgaria, Czechoslovakia, the German Democratic Republic, Hungary, Poland. Rumania and the U S S R. agreed that in the event of an armed attack in Europe on one or several signatory states each state that was a party to the treaty would render immediate assistance to the state or states so attacked. A joint command for their armed forces was established.

From Kov. 15 to 18, 1956. Gomulka, Cyrankiewicz and Zawadzki were in Moscow discussing the future of Polish-Soviet relations with Khrushchev, Bulganin, Mikoyan and others. Both sides agreed that the Soviet-Polish alliance was a reliable guarantee of their mutual security as well as of the inviolability of the Polish-German frontier on the Oder and the Neisse; and that the temporary presence of Soviet army units on the territory of Poland was still desirable but should in no way infringe the sovereignty of Poland or interfere in its domestic affairs. A special treaty concerning the legal status of Soviet troops stationed in Poland was signed in Warsaw on Dec. 17 by the foreign and defense ministers of the two countries.

POPULATION

At the beginning of the historical period the Poles lived between the Baltic sea and the Carpathian mountains and the Oder and Bug rivers. They were one of the western branch of the Slavonic group of peoples. The Polish nation originated from three main tribal groups, the Polanie. the Mazowszanie and the Pomorzanie. Because of their central position! the Polanie, or dwellers in the plains (pole, "field"), gave their name to the country, Polskn, and to the people, *Polacy* (singular *Polak*).

The Polanie themselves were originally composed of many tribes, the most important of them being the Slezanie (now Slazacy or Silesians) who settled on both sides of the middle and upper Oder; the Kujawiacy (Kujavians) who lived between Lake Goplo and the Vistula; and the Wislanie, later called Malopolanie, on both sides of the upper Vistula.

The Mazowszanie or Mazovians lived on both sides of the middle Vistula, and their Baltic neighbours to the northeast were the Lithuanians and the Prussians. The Mazurians of East Prussia were descendants of Mazovian settlers who settled there in the 15th century. The Pomorzanie or Pomeranians, as their name indicates, were living along the seacoast (po, "toward"; *morze*, "sea") between the lower Oder and lower Vistula. They formed an element of transition between the Polanie and the Polabians (*po Labě*, "along the Elbe"). The Polabians were germanized between the 10th and 18th centuries. as were also those Pomeranians who remained outside Poland after the treaty of Torun of 1466.

Linguistically, however, two local Pomeranian dialects remained until the 20th century, the Slovince (Slowinski) and the Cassubian (Kaszubski). Slovince was spoken until World War I along the Baltic coast line between Slupsk (Stolp) and Lebork (Lauenburg). At mid-20th century Cassubian was still spoken west of Danzig in the districts of Wejhercwo and Kartuzy.

The first census (1921) after the restoration of the Polish state revealed a total population of 27,176,717. The second (1931) recorded a total of 32,107,252, while an estimate for Sept. 1, 1939, assessed the population as at 35,339,000 (excluding the Teschen disputed territory). Poland between World Wars I and II was not a homogeneous national state, the Poles amounting, according to the 1931 census. to 68.9% of the population.

No part of Europe was more profoundly affected by the great displacements of population which occurred in World War II and for a few years afterward. Polish citizens were deported by both occupying powers during the German-Soviet partition and by the Germans over the whole of Poland after June 1941. Of Poland's

Zielona Gora	5,604	777,300	138.7
Total	120,359	29,731,000†	247.0

*Preliminary. †Included in the total only are 369,800 persons not included in the breakdown by *województwa*.

3.351.000 Jews (1939 est.) the great majority were exterminated by the Germans, and only about 90.000 remained in post-1945 Poland; by 1956 their number was estimated at 65.000.

The territories annexed by the Soviet Union had a population of 10.864.000 in 1939: by June 30. 1949, only 1.503.800 persons of Polish nationality had been transferred from Soviet territory to the new Poland. while 515.200 Ukrainians. Byelorussians and Lithuanians had been moved from Poland to their respective Soviet republics. According to the 1939 German census. the population of the then German lands east of the Oder-Neisse line incorporated into Poland amounted to 8.372.700. To this total must be added the German population of the free city of Danzig (392,000 in 1939) and the German minority in the pre-1939 frontiers of Poland but there must be subtracted the 1.011.700 Polish population of the recovered territories.

Theoretically. the total number of Germans living within the frontiers of 1945 Poland was 8.494.000. In fact. almost half of that number fled before the Soviet armies and in May 1945 only 4.400.000 remained. According to the census of Feb. 14. 1946. the population of Poland within its new frontiers was 23.929.757. including 2.288.300 Germans. By the end of 1948, a further 2,170,-866 Germans had been repatriated from Poland. while 2.266.000 Polish forced labourers, prisoners of war and demobilized soldiers returned to Poland from Germany and from western Europe. The Polish census of Dec. 3, 1950. revealed a total population of 24.976.926.

By mid-1956 the population of the recovered territories amounted to about 7.280.000. The natural increase in the years 1950–54 was 19.0 per thousand, the highest in Europe. The 1960 census revealed a total population of 29.731.000. with about 550.000 of national minorities (Germans. Jews, Byelorussians. Ukrainians. Lithuanians. Slovaks, Czechs and Gypsies'!. The density of population in 1960 was 247.0 per square mile (228.8 in 1950).

Towns.—In 1931 the urban population of Poland amounted to 27.5%; in 1950 this proportion rose to 40% and in 1960 to 47.5%.

Table II illustrates the main trends of urban population after 1880. It shows clearly the sudden development of Polish cities after 1920 with the restoration of Polish sovereignty, and especially the transformation of Gdynia from a fishing village to a port of international significance—a development which was one of the more remarkable feats of pre-I 939 Poland. The vast losses borne by Warsaw during World War II, the decline of the Silesian towns and the Baltic ports and the changes in other towns appear in the figures for 1946. Those for 1960 show to what extent the losses were reversed.

The population of Warsaw. reduced to 153.000 in Jan. 1945. had recovered by 1960 to 1,136.000 within wider administrative boundaries.

The rate of rehuilding devastated Warsaw was one of the controlling factors; another was the increasing attention given to the

development of heavy industry. particularly although not exclusively in Silesia and the recovered lands. An example of the last trend was the development of a new town at Nowa Huta, which at the beginning of 1955 had a population of 75,000, included in the Cracow urban district. In 1960 there were 22 towns with a population of more than 100.000.

In addition to the 16 mentioned in Table II. these included the towns of Sosnowiec (132,000), Ruda Slaska (131,000), Radom (130.000). Bialystok (121,000), Walbrzych (117.000) and Torun (105,000).

Poles Abroad.—Poles abroad are divided into two categories: the autochthonous Poles inhabiting alien territory contiguous with the political frontiers of Poland and the emigrants and refugees. Between 1922 and 1939, the largest groups of autochthonous Poles were in eastern Germany and in the U.S.S.R., where, according to the Soviet census of 1926, there were 792,471 Poles, including 476,435 in the Ukraine and 97,948 in Byelorussia. Poles were estimated in Lithuania at 200,000, in Latvia at 75,000 and in Rumania at 65,000 (including 50,000 in Bukovina). The three last-named territories all formed part of the U.S.S.R. by 1945. To these were added the Poles in the Polish territories incorporated by the Soviet Union in 1945. Finally, according to the Czechoslovakian census of 1930, there were 77,300 Poles living in the disputed Cieszyn area; which later again became part of Czechoslovakian territory; according to Polish official estimates these numbered 170,000.

The largest number of emigrants before 1939 settled in the Americas. By 1951 they included about 180,000 in Canada (mostly in Ontario and the prairie provinces), 300,000 in Brazil (mostly in Paraná), 70.000 in Argentina and 18,000 in Paraguay; but the greatest single group was in the United States, where there were probably 6,000,000 persons of Polish descent. The 1940 census revealed that there were 2,416,320 persons in the United States whose mother tongue was Polish, the largest non-English-speaking group after the German- and Italian-speakers. According to the 1950 census 861,186 of the U.S. population mere born in Poland. Chicago was the largest Polish centre, with about 500,000 Poles; Detroit had 200,000-Buffalo, Cleveland and Milwaukee each more than 100.000 and New York city, Pittsburgh and Philadelphia each 50,000. Poles engaged in agriculture (about one-fifth of the total) were spread across the states of Michigan, Wisconsin, Missouri, North and South Dakota and Texas. Steady assimilation ensued, of course, but these U.S. citizens maintained a strong interest in Polish culture and the homeland. They established innumerable social and cultural organizations, including the Polish National alliance, the Polish Roman Catholic union and the Polish-American congress—all with headquarters in Chicago. By the later 1950s there were about 800 Roman Catholic Polish parishes. The number of Polish-language schools and publications, although tending to decline, remained large; in 1955 there were 600 primary schools, with 300,000 pupils, and 20 higher schools. Out of a total of about 80 Polish periodicals appearing in the United States there were 8 daily, 24 meekly newspapers and 28 other periodicals.

The largest group of emigrants in Europe went to France, settling for the most part in the northern mining areas. After the onset of the economic depression they declined from 800,000 to about 622,000 in 1939. In 1950 they probably numbered about 500,000. There was a daily newspaper, many periodicals and an old established Polish library. In the Ruhr (Ger.), the "Westphalian" Poles formed another considerable group but were somewhat reduced in numbers by World War II and by postwar repatriation, numbering fewer than 100,000 in 1955.

The greatest change brought about by the war was the establishment of a Polish colony in Great Britain, where the Polish government had its seat. The great majority of the 140,000 Poles in Great Britain was constituted by former servicemen and their families who were assisted by the Polish Resettlement corps in finding civilian employment. Most of the political parties—the National, the Freedom-and-Independence, the Christian Democratic, the Socialist and a Peasant group—organized in 1954 in London a Polish Council of National Unity with a "committee of three" as a supreme body whose members were Gen. Wladyslaw Anders, the Socialist leader T. Arciszewski and Count Edward Raczynski, former ambassador to Great Britain. (Arciszewski died on Nov. 20, 1955, and was succeeded by Gen. Bor-Komorowski.) The Peasant leader Mikolajczyk and his followers mere excluded from the council. A Polish research centre, the Sikorski Historical institute and many cultural: social, professional and trade organizations were established. There were more than 20 Polish periodicals in Great Britain at mid-70th century, including an independent daily paper, the *Dziennik Polski.*

Zubrzycki, *Polish Immigrants in Britain: a Study of Adjustment* (The Hague, 1956).

GOVERNMENT, DEFENSE AND EDUCATION

The first constitution after the restoration of the Polish state, promulgated on March 17, 1921, was modelled on the French system. It was passed by a coalition of Conservatives, Nationalists, Christian Democrats, Middle Class deputies and moderate Peasants (Piast), with the idea of giving much power to the legislature at the expense of the executive. It reflected the prevalent fear of Marshal Pilsudski, then chief of state. Coupled with the electoral system

*Including the Communist-controlled Ukrainians and Byelorussians.
Note: The results of the elections of Sept. 1935 and Nov. 1938 are not recorded here because a complicated élite electoral law of July 8, 1935, besides reducing the number of deputies to 208, enabled the government to influence the voting. The opposition parties boycotted these elections.

of proportional representation it produced a *sejm*, or chamber of deputies, of 16 parliamentary groups, four of uhich represented national minorities. (See Table IV.) A parliamentary government could be based only on a coalition, and these did not last long. Another solution, successfully tried by W. Grabski (Dec. 1922 to Nov. 1924), was a nonparty government.

When the Pilsudski bloc won the 1930 election it prepared a new constitution which was promulgated on April 23, 1935. It made the president of the republic virtually a king without a crown, but it did not do auay nith the *sejm* which fixed the budget. imposed the charges upon the citizens and had the right to demand the resignation of the cabinet or of a minister. Under article 24, in time of war the president had the right to appoint his successor. It was by virtue of this provision that Moscicki (1867–

1946) appointed Raczkiewicz (1885–1947) his successor. (See above.) To make the post of president the symbol of true national unity, a constitutional compromise was reached in Paris on Nov. 30, 1939, between the political leaders by which thenceforward the president would exercise his prerogatives "in agreement with the prime minister." The political leaders in exile continued to cling to this "legal continuity" of the constitution of 1935 until it could be modified by a freely elected Polish sejm.

On Feb. 19, 1947, the Warsaw Communist government promulgated a temporary constitutional act which was democratic but never became effective. The new constitution was passed by the sejm on July 22, 1952, and was claimed in the debate to be "modelled on and inspired by the great Stalin constitution of 1936." The supreme organ of state authority was the council of state (rada *stanu,* similar to the Soviet presidium) composed of a chairman, four deputy chairmen, a secretary and nine members. The supreme organ of state administration was the council of ministers (rada *ministrow*) appointed by and responsible to the sejm, or to the council of state if the sejm were not in session.

The electoral law adopted by the sejm on Aug. 1, 1952, accorded the franchise to all citizens of 18 years, including members of the armed forces; citizens of 21 years were eligible for election. There was one deputy for every 60,000 inhabitants; in every constituency there could be only one list of candidates equal in number to the deputies fixed for the constituency. For the 1952 election the council of state divided the country into 67 constituencies electing 42j deputies. The candidates were formally nominated by the National front grouping the three existing political parties, the Communist, the United Peasant and the Democratic, also the Trade Unions federation, the Union of Polish Youth and other "mass social organizations of the working people."

Administration. — From June 1, 1950, the number of provinces (*wojewodztwa*) was increased to 17 by the creation of three new provinces in the western territories. In 1945 in these territories, all Pomorze or maritime land had been divided between the two provinces of Gdansk and Szczecin; in 1950 a new province of Koszalin (Koslin) was created between the two. The province of Poznan, which in 1945 had been extended westward to the Oder, was divided into two, Poznan and Zielona Gora (Griinberg). Recovered Silesia. previously divided into two provinces, was redistributed to form three: a ne province of Opole was created between those of Wroclaw and Katouice. The two largest cities, Warsaw and Lodz, formed separate administrative units. In Sept. 1955 the 17 provinces were divided into 371 districts (*powiaty*).

Defense. — Between the armed forces of pre-World War II Poland and those established after 1945 there was no continuity: personnel, organization, training and equipment were completely changed. The Polish army suffered catastrophically from the German and Soviet invasions, although certain naval, army and air force units escaped abroad and made an uninterrupted and important contribution to the Allied war effort from the Polish headquarters in Britain. The fate of the Polish units in the east, their imprisonment, release and recruitment into the Polish army under Gen. Wladyslaw Anders, their exodus from the U.S.S R. through the middle east and their subsequent battle engagements in the battle of Britain (during which the Polish airmen shot down 14% of the enemy aircraft destroyed), at Narvik in Norway, at Tobruk in Cyrenaica, at Monte Cassino in Italy and at Falaise in France provided one of the great epics of World War II. Out of 215,000 Poles fighting with the Allies in the west, 150,000 chose to remain in exile, and those who returned a-ere not allowed to form any part in the new defense organizations.

A Communist-dominated Polish army was organized in the Soviet Union in 1943 and 1944, eventually numbering ten infantry divisions, an armoured corps and an air force.

Between 1944 and 1947 the Communists were occupied with the liquidation of the Polish home army, the main fighting organization of the underground government. which was supported by the mass of people and directed by the Polish government in London until its derecognition in 1945. By 1947, aided by the presence in strength of the Soviet army and by the Communist militia, a new "people's army" had been established around the nucleus formed in Russia.

Including the forces of the interior (frontier guards and security troops), the Polish armed forces were estimated in Oct. 1956 at 370,000. There were three military areas (Warsaw, Bydgoszcz and Wroclaw) comprising 24 Soviet-type divisions, including 4 motorized and 4 armoured. The number of trained reservists was estimated at more than 2,000,000. The Polish air force was believed to amount to 12 air divisions (all jet) of 9 squadrons each, a fighter squadron comprising 11 aircraft. The Polish navy in 19jj consisted of two destroyers, three submarines and a number of minesweepers and auxiliary craft.

Military service was made universal and compulsory between the ages 20 and 50. In 1950 active service was two years in the army, three years in the air force and the navy, two years in the antiaircraft units and 27 months in the forces of the interior. Women were called up for six months' active service. Premilitary training was afforded by the youth clubs.

Education. — Restored Poland had an enormous task in the organizing of a national system of education. In the formerly Russian part of Poland there was a great need for school buildings and teachers, illiteracy being about 50%. In the German part there were school buildings but no teachers. Only in the Austrian part of Poland was there a system of Polish education, although illiteracy exceeded 20%. On Feb. 7, 1919, the first Polish government issued a decree of compulsory education for all between the ages of 8 and 1j years. Not until 1926 could this act be more or less effectively applied. In 1921 illiteracy in Poland amounted to 33.1%, by 1931 this proportion was reduced to 23.1% and by 1939 illiteracy was estimated at 12%.

Secondary education, which was selective, was provided in two stages, the grammar schools for those aged 12–16 years and the lyceums for those aged 16–18, the latter being maintained by the state, municipalities and private organizations. In addition, there was a great variety of trade and professional schools which afforded theoretical and practical professional training as well as general education. In the great release of Polish intellectual life which began in 1918, the needs of the various national minorities were not forgotten. In 1938 there were 3,525 primary Ukrainian schools with 532,200 pupils; 597 German with 72,800 pupils; 452 Jewish (Yiddish and Hebrew) with 64,900 pupils; 67 Lithuanian with 3,800 pupils; 22 Czech with 1,100 pupils; j Byelorussian with 800 pupils and 6 Russian with 1,200 pupils. There also was an adequate number of secondary schools.

The policy of the post-1945 Polish government was the gradual replacement of the old system by a Stalinist-Marxist system at every level. The state control and censorship of all organs of information rendered this policy more effective. The influence of the state and, therefore, of the Communist party became absolute; private and independent institutions (such as those organized by the Roman Catholic Church, the Lutheran Church, the religious orders and the scientific and historical societies) had by 1952 been closed or subjected to governmental interference. Besides the steady imposition of Marxist uniformity, the government was confronted with the need to supply trained citizens to man the ambitious program of industrial expansion, maintain and if possible improve technical standards and fill the ever-increasing state services. civil, security and military and the public utilities. At mid-20th century there was free, compulsory and universal education for the nursery, primary and intermediate stages, which covered the years from 4 to 6. from 7 to 15 and from 15 to 18 or 19.

From 1952 the ministry of education controlled the lower schools, nursery, primary and intermediate, both general and vocational; the technical and special schools and supplementary courses on the appropriate level; and the central office of vocational training. The ministry of higher schools and learning controlled the universities, colleges of engineering and the increasing number of institutions affording specialist training at the highest level. The organization of the medical, pharmaceutical, dental and nursing professions was the concern of the ministry of health. The medical faculties were detached from the universities, and 11 medical academies had been established by the early 1950s.

The senior learned societies of pre-1939 Poland were the Polish

Academy of Learning in Cracow, founded in 1872, which maintained stations in Paris and Rome, and the Warsaw Scientific society, reopened as a continuation of the Royal Society of the Friends of Science, dating from the 18th century. Both were seriously affected by the depredations of war and postwar political

EASTFOTO

conditions. At the first congress of Polish science, held in Warsaw in July 1951, a new Soviet-type Polish academy of sciences was initiated; this body, in collaboration with the various government departments and party committees, was created to ensure the conformity of all higher learning and research with Marxist theory.

The oldest Polish institution of higher education (one of the oldest and finest in Europe) is the University of Cracow; although called Jagiellonian it was in fact founded in 1364 by Casimir II the Great, the last king of the Piast dynasty. The loss of the eastern territories deprived Poland of the University of Wilno (Vilnius), founded by King Stephen Bathory in 1578, and of Lwow (Lviv), founded by King John Casimir in 1661. Besides the University of Cracow there were in pre-1939 Poland, state universities in Warsaw and at Poznan, and a Catholic university at Lublin. Four new state universities were founded after 1945, at

NOTE: In 1954 there were 133 German primary schools with 6,500 pupils, 1 secondary school with 76 pupils and 1 teachers' training college; 62 Byelorussian primary schools with 4,500 pupils and 3 secondary with 418 pupils; 5 Lithuanian primary and 1 secondary school; 7 Jewish primary schools and 2 secondary; 33 Slovak primary schools and 1 secondary; and 1 Czech primary school.

Wroclaw, Torun, Lodz and Lublin. Before 1939 there were two colleges of engineering, in Warsaw and Lwow. In 1955 there were eight colleges of engineering, in Warsaw and new ones at Wroclaw, Lodz, Gdansk, Gliwice, Poznan, Szczecin and Czestochowa. (See Table V.)

ECONOMIC CONDITIONS

There was a certain similarity between the problems facing the Polish government in 1918 and those in 1945. After World War I losses of national wealth had to be made good and the differing systems of the Austrian, German and Russian zones unified into one viable whole. World War II, it was estimated, destroyed 38% of the total national wealth, more than three times as much as World War I. In addition, Poland had acquired important new territories and lost 45% of its former area. Apart from the work of reconstruction, however, the new state embarked upon an ambitious program of industrial development and was forced to set about transforming the old economy into one based on Stalinist-Marxist theories.

Agriculture. — Between World Wars I and II Poland was a predominantly agricultural country. Out of a total area of 38,863,400 ha. there were 25,589,000 ha. (65.5%) of agricultural land. Arable land alone covered 18,557,000 ha. (47.5% of the total area). In July 1921 Poland had 19,454 estates of 50 ha. or more covering a total area of 10,498,100 ha. and 3,075,700 small holdings of under 50 ha. covering an area of 24,646,200 ha. While the first group included 4,256 large estates of 500 ha. and over, totalling 7,942,300 ha., among the small holdings there were 991,000 of from 2 ha. to 5 ha. and 931,300 of under 2 ha.

A Land Reform act was passed by the constituent sejm on July 15, 1920. It encouraged a redistribution, with compensation under state control. By the end of 1938 a total of 2,654,900 ha. belonging to large estates had been distributed, and in the same period small farms received 595,400 ha. as equivalent of abolished praedial servitudes. Consequently, the amount of land which passed from the large estates to the small farmers and landless peasants amounted to 3,250,295 ha., an area equal to that of all the arable land in England and Wales. The total number of persons who received land in this way in the interwar period was

TABLE VI.—Rural Holdings in Poland, 1931–49

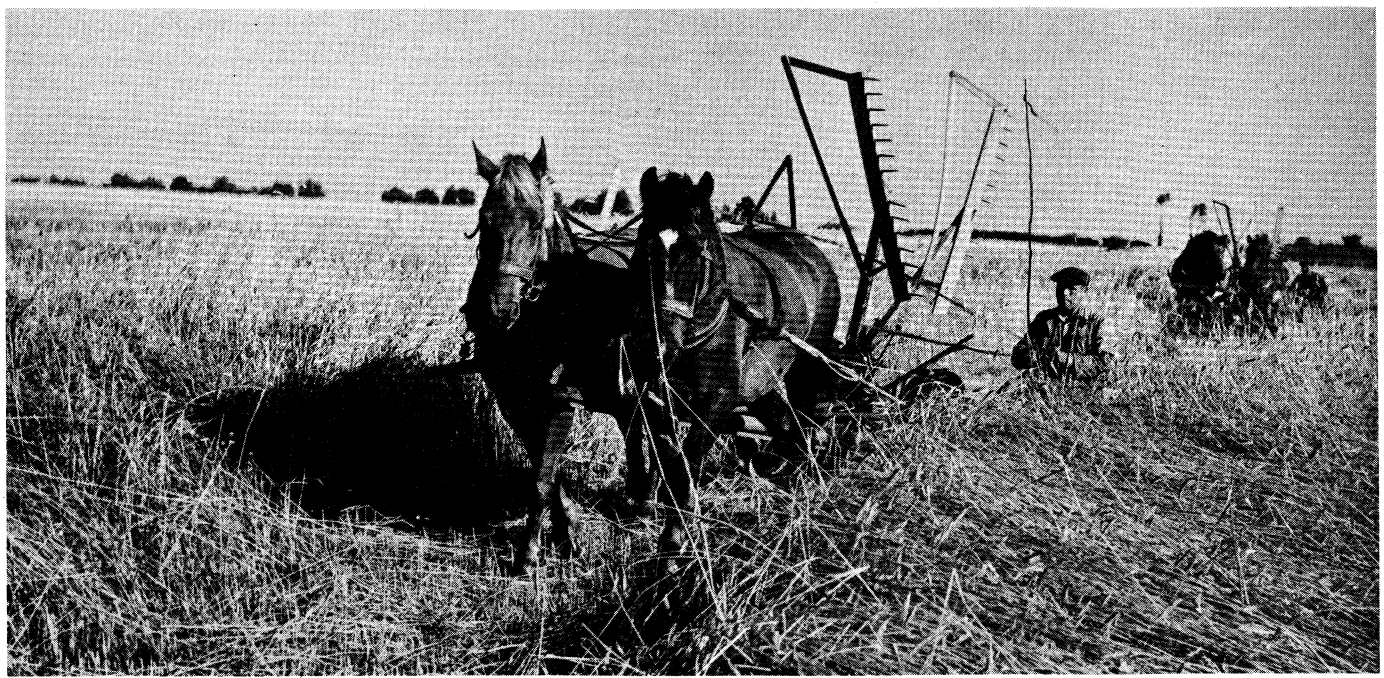
(Area of holdings in thousands of hectares)						
1949	1,048.8 5.9%	3,790.2 21.2%	6,848.6 38.3%	5,944.3 33.2%	259.4 1.4%	17,891.3 100%

*In 1931 there were also 260,300 small holdings of unknown area, two-thirds of them in the eastern provinces.

734,100. Nevertheless Poland continued to suffer from rural overpopulation.

Although Poland after 1945 was one-fifth smaller than before 1939, the area of arable land was not reduced in the same proportion, for meadows, pastures, forests and barren land occupied a higher percentage of land utilized for agriculture in the east than in the west. The area of agricultural land in post-1945 Poland was 20,864,200 ha. (67.3% of the total area), including 17,891,300 ha. (57.7%) of arable land. By its decree of Sept. 6, 1944, the Polish Committee of National Liberation (the Lublin committee, which later formed the nucleus of the Communist government) expropriated without compensation all private land over 50 ha., except church land, although that too was confiscated in the reform of March 20, 1950. In all, in Jan. 1949, in the territories which were part of Poland before 1939, 1,210,900 ha. of arable land were received by 407,500 peasants. In the recovered territories in the west 4,004,900 ha. were shared out and 483,307 new small holdings were created.

The results of the land reform are given in Table VI. Its effect was to increase both the number and proportion of very small farms of under 2 ha., which were economically unsound, and at the



TRIANGLE PHOTO SERVICE

WHEAT HARVESTING IN THE PROVINCE OF LODZ. SOUTHWEST OF WARSAW

same time to increase the number and proportion of larger holdings between 10 ha. and 50 ha. owned by the richer peasants. Collectivization was not pressed forward rapidly. There were 9,322 producers' co-operatives (*spoldzielnie produkcyjne,* as the Polish kolkhozy are called) by the end of 1954 with a total membership of 191,600 holdings and a combined area of 1,597,400 ha. Progress was slight, for the proportion of collectivized land was about 7.6% of the total agricultural area and socialized holdings were 5.8% of the total number of peasant farms. In addition there were 6.157 state agricultural farms (*panstwowe* gospodarstwa *rolne,* the Polish equivalent of *sovkhozy*), with a total area of 2,482,100 ha., or 11.4% of the agricultural land.

Climate and soil combine to give Poland a mixed type of farming. The main crops are grains (rye, oats, wheat and barley), potatoes, sugar beet and fodder crops. Rye and potatoes are more characteristic of the poorer sandy soils (podzols) of the glaciated regions, wheat and sugar beet of the more fertile brown soils (radzines) of southern Poland. Hops and tobacco are located on favourable soils in the centre and south. Temperate fruit, dairy, poultry and pig products are part of the general farming in most districts of the country. The production of grain and potatoes was more than sufficient for home consumption before World War II, and the surplus was exported.

The tendency in the mid-1950s was to concentrate on foodstuffs of value to the export market; such as sugar, poultry products, bacon and hams, the Soviet Union and the United Kingdom being the chief customers. Sugar production, for instance, was higher than the prewar 506,000 tons and in 1953 was 1,120,000 tons. The demands of the export drive and the victualling of the considerable armed forces, coupled with the direction of labour into heavy industry, imposed heavy burdens upon the ordinary civilian consumer. Changes in the agrarian system, lack of incentives for farmers and shortage of consumer goods also hindered agricultural

production. (See Table VII.) Internal food shortages became apparent in 1948 and increased after 1950. From 1953 Poland had to import annually about 1,000,000 tons of grain. Between 1946 and 1950 a striking restoration of livestock was achieved. (See Table VIII.) The shortage of foodstuffs was attributed to the necessary concentration of the economy on rapid industrialization

and rearmament and also to the fact that, whereas in 1931 the agricultural population had constituted 61.4%, in 1953 the proportion was only 47.1%, as a result of the transfer of workers to industry.

Industry. — After World War II a short-term plan for industry was encouraged, aiming at recovery and producing conditions better than before the war. The physical scars left by the war were far more severe than anything previously suffered by Poland and were to entail prodigious efforts of rehabilitation and reconstruction.

The three-year plan of 1947–49 prepared by the Central Planning board, presided over by Hilary Minc, envisaged a total capital expenditure of $1,950,000,000, of which 39% was to be invested in industry, 24% in transport, 13% in agriculture, 9% in housing and 15% elsewhere. Rapid industrialization, however. was impossible without outside help. The Soviet Union was unable to supply capital goods, engaged as it was in the restoration of its own industry. Only the industrialized countries of the west remained as possible sources of supply, and Minc counted on getting a $600,000,000 loan from the United States. This hope did not materialize, and the only help Poland received from the west was: (1) through the UN Relief and Rehabilitation administration (2,235,000 metric tons of supplies valued at $471,000,000); (2) when the U.S. government, in Dec. 1946, released Bank of Poland gold to the nominal value of $27,000,000 and $10,200,000 of Polish assets in U.S. banks; (3) ontheratificationon June 19, 1947, of a Polish-British agreement for the settlement of outstanding financial questions (signed on June 24, 1946): out of £10,000,000 Polish gold reserves deposited with the Bank of England £7,000,000 were handed back and surplus British military stocks of

£6,000,000 were made available to Poland; and (4) when, on Jan. 14, 1949, a five-year trade agreement was signed with Great Britain for an exchange of goods worth £130,000,000.

When Poland, on orders of the U.S.S.R., rejected the European Recovery program, a Soviet-Polish agreement was concluded in Jan. 1948 for an exchange of goods to the total value of $1,000,000,000 in five years and for a $450,000,000 investment credit. But, as the Soviet machinery and heavy equipment could not be delivered immediately, the three-year plan was not a complete success, and the six-year plan, discussed between Warsaw and Moscow during 1948, had to be revised to make lower demands. The six-year plan 1950–55 was adopted in Dec. 1948 by the first congress of the P.Z.P.R. On Jan. 25,1949, the Council of Mutual Economic Aid was created in Moscow. This central planning authority for the whole Soviet bloc considered the Polish six-year plan too modest, and the plan was therefore speeded up by a substantial increase of capital investment and an augmented output of heavy industry.

On June 29,1950, the Soviet government accorded Poland an additional credit of $100,000,000. The total credit of $550,000,000 was, however, reduced from 2,915,000,000 rb. to 2,200,000,000 rb. by the revaluation of the rouble which took place on March 1, 1950, when a new exchange rate of $1 = 4.00 rb. was introduced instead of $1 = 5.30 rb. This increased by 25% the prices of Soviet supplies and reduced by the same amount the prices of Poland's deliveries to the U.S.S.R. On July 21, 1950, the law on the six-year plan was promulgated. The total capital investment was increased from 120,000,000,000 zl. to 185,000,000,000 zl.; the total industrial output was to increase by 158% between 1949 and 1955 and not by 95% as originally planned.

The progress of industrialization is illustrated by Table IX. The territorial shift to the west considerably increased the country's industrial capacity, except crude petroleum, of which three-quarters of the production was lost, and potassium salts, the production of which amounted in 1938 to 567,000 tons. The progress of industrialization can also be seen in the proportion of persons engaged in nonagricultural occupations: this was 2,730,000 in 1938 and it rose to 5,860,000 in 1955.

Finance. — From 1950 Poland had a comprehensive Soviet-type budget including not only all state revenue and expenditure but also those of the whole nationalized economy. The percentage of budget expenditure on national economy after 1952 was over 50% of the total. (See Table X.) As already mentioned, Soviet help amounted to 2,200,000,000 rb., which Poland was to receive between 1950 and 1958 in raw materials, machinery and equipment, to supplement the 185,000,000,000 zl. to be raised from the Polish people themselves to finance the six-year plan.

*From 1951 in new zlotys. On Oct. 28,1950, the zloty was revalued and brought at par with the Soviet rouble. The new exchange rates were (old in parentheses); £1 = 11.20 (280) zlotys, $1 = 4.00 (100) zlotys. †Part of budget expenditure, extracted from figure.

German reparations were also expected to assist the industrialization of Poland. On Aug. 2, 1945, at Potsdam, Stalin undertook to settle reparations to Poland from the Soviet share. On Aug. 16, 1945, a reparations agreement with the Soviet Union was signed in Moscow, according to which Poland was to receive 15% of all reparations obtained by the U.S.S.R. from Germany. In May 1950 the Soviet government, in agreement with the Polish government, announced the reduction of German reparations. They estimated that by the end of 1950 the German Democratic Republic would have paid an estimated $3,658,000,000 (western calculations estimated a much higher figure) on account of total demands of $10,000,000,000. The sum of reparations still to be paid was reduced by 50%, namely to $3,171,000,000. By the end of 1953 the U.S.S.R. and Poland renounced any further payment of reparations. The amount of the Polish share was not published.

During the visit of Gomulka to Moscow, in Nov. 1956 (see above), the Soviet government agreed to consider as settled as from Nov. 1, 1956, Poland's indebtedness for the credits granted to it by the U.S.S.R., which, on that date, amounted to 2,300,000,000 rb. ($575,000,000). By agreeing to this cancellation the Soviet government indirectly recognized the Polish claim that by delivering to the Soviet Union during 1946–53 about 50,000,000 tons of coal at a nominal price of $1.25 per ton Poland actually lost about $737,500,000. In addition the Soviet government agreed to grant Polanda new long-term credit of 700,000,000 rb.

Foreign **Trade.**—The transition from a mixed to a Communist economy was paralleled by important changes in the economic relations of Poland. The six-year plan was largely dependent upon a vast program of capital investment and the production of capital goods, requiring loans and equipment from abroad as well as an unprecedented internal effort. Poland was to pay principally with coal and goods to be manufactured by the industries developed, particularly iron and steel, shipbuilding and textiles. Relations continued to develop with the U.S.S.R. and other people's democracies.

The Soviet Union was not the only source of assistance in the three-year and six-year plans. The United Kingdom was supplying Poland with a variety of goods, including machinery, machine tools, ships, etc., in return for food and other products. The Scandinavian countries, Switzerland, Austria, the Netherlands, Belgium, France and Italy, anxious to obtain Polish coal (which had little to fear from the competition of the pre-war British and German exporters), all made important contributions to Poland's planning. By the early 1950s, however, increasing political differences induced the countries of the North Atlantic Treaty organization to curtail the export to Poland of goods classified as strategic.

In 1948 the Soviet share in Polish foreign trade amounted to 22.1%, that of people's democracies 19.2%; in 1954 these propor-

tions rose respectively to 37.3% and 31.6%. At the same time Polish trade with western Europe and the overseas countries decreased from 58.7% to 31.1% of the total turnover. (See Table XI.)

In April 1956 it was revealed in the debates of the Polish parliament that in the previous year 51.7% of Polish imports consisted of raw materials, and crude petroleum and products; 30.9% of machinery and industrial equipment; 13.1% of foodstuffs and 4.370 of other consumer goods. Exports comprised coal and coke (46.6%), raw materials (17.8%), machinery and transport equipment (13.1%), foodstuffs (15.3%) and other consumer goods (7.3%).

In 1955 the U.S.S.R. took 33.7% of Polish exports of coal, 19.7% of coke, 21% of rolled steel, 59.8% of zinc (55,000 tons out of a total of 92,000 tons), 71% of caustic soda and soda ash (36,800 tons out of a total of 51,800 tons), 57.8% of sugar, 72.6% of wool fabrics, 95.6% of railway rolling stock and 84.5% of ships. The Soviet part in the Polish imports in 1955 were as follows: iron ore 68.1%, crude petroleum 74.3%, petroleum products 27.1%, cotton 73.870 and grain 34.7%. In 1955 Polandimported machines and industrial equipment for a total value of 1,152,000,coo zl.. including 486,000,000 zl. (42.2%) from the U.S.S.R. (See also Table XII.)

TABLE XII.—*Trade by Principal Commodities*
(In thousands of metric tons, if not otherwise stated)

Imports			Exports		
Commodity	1954	1955	Commodity	1954	1955
Iron ore	4,105	4,407	Coal	24,235	24,299
Crude petroleum	463.2	544.9	Coke	1,927	2,240
Petroleum products	716.2	885.7	Steel, rolled	194.6	247.3
Cotton	93.8	95.2	Timber*	964	915
Wool	14.3	16.3	Cement	548	674
Hides and skins'	24.7	30.1	Sugar	540	372.3
Rubber (incl. syn.)	23	25.7	Cotton fabrics†	78,826	57,500
Wheat and rye.	1,204	1,154	Woolfabricst	7,354	5,800
Tobacco (tons).	7,225	11,900	Locomotives‡	259	237
Tea (tons)	1,567	2,020	Railway coachesf	265	277
Rice (tons)	8,743	30,588	Railway box cars‡	2,701	2,136
Shoes ('000 pairs)	635	1,050	Shipping5	...	148

*In thousand cubic metres. †In thousand metres. ‡Units. §In million zlotys.

While relations reached a very low ebb with the United States and became strained with the other western powers, Poland developed trade contacts with the middle east, with Indonesia and with Communist China. With the establishment of new shipping lines, Polish ships became an important factor in the carrying trade of the orient. The two great Polish port authorities, Gdynia-Gdansk and Szczecin-Swinoujscie, achieved major importance, rivalling Hamburg and Trieste in the trade of central Europe.

Transport and Communications — Therestored Poland inherited in 1918 three differing systems of communications, of which the Prussian was most highly developed, the Russian least so. The damage resulting from World War I and the Polish-Soviet war was very great. Roads were singularly ill provided, a disadvantage from which the country was still to suffer despite continuous road building between 1921 and 1939. Cpper Silesia. the economic heart of Poland, remained divided; and, although Danzig formed a customs union with Poland, the Baltic was not freely accessible until after the opening of the new port of Gdynia.

The shiit of frontiers in 1945 enriched the system of communications by bringing in the industrial areas of German Silesia and their outlet through the Oder valley, a region well supplied nith railnays, canals, rivers and roads. War damage was, however, higher than after World War I, and the period 1945–50 was occupied mainly with the work of reconstruction and the improvement of existing facilities.

Railway traffic in 1955 was as follows: passengers, 40,536,700,000 pass.-km. (as compared with 7,493,000,000 pass.-km. in 1938 in prewar territory); ireight, 70,107,800,000 ton-km. (20,371,000,000 ton-km. in 1938). The rolling stock in 1947 comprised: locomotives, 6,874 (5,477 in 1937); passenger stock, 7.796 (10,688 in 1937); freight cars, 144,453 (167,596 in 1937). In 1955 there were 26,985 km. of railways, including 3,862 km. of narrow-gauge track.

Licensed motor vehicles in 1955 were estimated, excluding the military, at 30.000 passenger cars and 57,000 commercial vehicles. *In* 1955 there were 267,611 km. of highways, including 98,679 km. hard surfaced.

The inland waterways have always been oi considerableimportance to Poland. By far the greatest stretches of inland navigation are provided by the Vistula and Oder and their main tributaries. The low sandy banks, the fast-flowing streams and the tendency to flood after the spring thaw necessitated regulation and canalization. The interconnecting glacial valleys provided means of linking by short canals a whole series of east-west tributaries and so, eventually, the main river systems of Germany. Poland and the C.S.S.R. Thus the Oginski and Royal canals (built in the 18th century. north and west of Pinsk) and the Augustow canal (built in 1825) joined the Vistula and Bug with the Niemen, Pripet and Dnieper. They were used between 1921 and 1939 for drifting Polesian timber westward, but later became part of Soviet territory. The Bydgoszcz (Bromberg) canal, built in 1914–16, was used for barge traffic between Germany and East Prussia; it linked Königsberg (Kaliningrad), now in Soviet territory, with the Oder and central Germany by way of the sheltered lagoons of the Baltic coast, the canalized Nogat distributary of the Vistula and the rivers Brda and Notec. This canal was linked in 1949 through Lake Goplo with the canalized river Warta. The Cpper Silesian coalfields are served by a canal leading into the Oder. In 1955 the total length of inland waterways amounted to 6,908 km.

In 1950, the total of 12,453,000 metric tons of exports overseas handled by all Polish ports, Gdynia-Gdansk accounted for 7,894,000 tons; in 1937 Gdynia and Gdansk alone loaded 12,973,000 tons of goods. The imports from abroad through all Polish ports in 1950 amounted to 3,215,000 tons, including 2,234,000 through Gdynia and Gdansk, as compared with 3,234,000 tons in 1937 for the last-named ports alone. In 1955 the total turnover of goods in all Polish ports amounted to 17,066,000 tons. Ships entered in all ports in 1955 totalled 7,913,000 gross tons (as compared with 9,664,000 gross tons in 1937 for Gdynia and Gdansk alone). In 1955 the Polish merchant navy had 147 ships (of 100 tons or over) totalling 316,000 gross tons (121,600 in 1939).

The Polish state-owned air lines, Lot, form part of the interlocking system of services linking the main cities of the Soviet bloc countries. In 1956 Lot maintained services to Moscow, Paris, Brussels, Copenhagen, Amsterdam and Athens. In 1955 Lot's traffic was 4,020,000 km. flown and 65,900,000 pass.-km.; the figures ior 1938 were 1,999,000 km. and 9,447,000 pass.-km.

The number of telephones in use was estimated in 1956 at 453,600 (as compared with 272,300 in 1937). In April 1954 there were about 2,671,000 radio receiving sets.

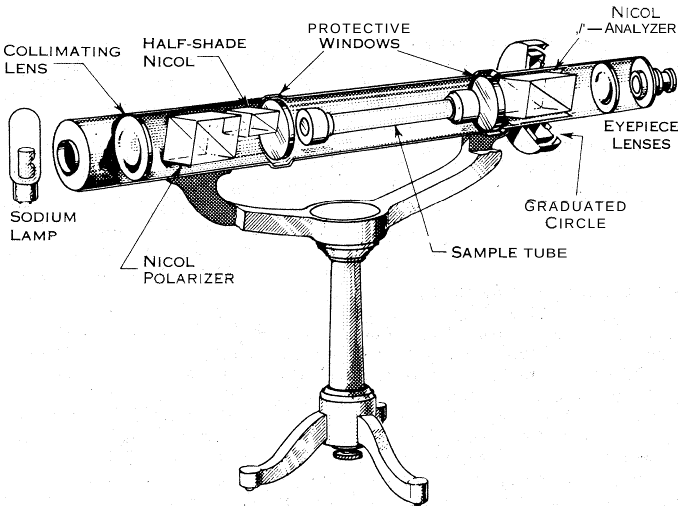
POLAR BEAR: see BEAR; CARNIVORA.

POLARIMETRY. Polarimetry is the science of measuring the angle of rotation of the plane of plane-polarized light (see LIGHT).

Polarimetry is primarily of interest to the chemist, because many compounds. either in the pure state or in solution. possess the power of rotating the plane of polarization of a beam of polarized light. The phenomenon is displayed by compounds, which lack a centre of symmetry in their molecular or crystalline structure, such that the compound and its mirror image are not superimposable. This situation most commonly results from the presence of a carbon atom which is covalently bound to four different atoms or groups of atoms. The angle through which the plane is rotated varies directly with the length of the light path through the sample, and in the case of solutions. with the concentration. For a given path length and concentration, the angle depends on the wave length of the light. the temperature, and the nature of the sample and its solvent, if any. Substances which are capable of producing this effect are said to be optically active. They are characterized by a constant known as the specific rotation, designated by the symbol $[\alpha]$ usually accompanied by a subscript letter to indicate the wave length and a superscript number for the temperature. Thus: $[\alpha]_D^{20}$ means that the value was determined at 20° C. with the D-line of sodium as light source. The specific rotation is defined by the relation,

$$[\alpha]=\frac{a}{dc},$$

where a is the observed angle of rotation in degrees, d is the length of light path through the sample in decimeters and c is the concentration in grams per milliliter.



FROM G. W. EWING, "INSTRUMENTAL METHODS OF CHEMICAL ANALYSIS": BY COURTESY OF MC GRAW-HILL BOOK CO., INC.

DIAGRAM OF A CONVENTIONAL POLARIMETER

The angle of rotation is measured with a polarimeter (see figure). Monochromatic radiation, polarized by a Nicol prism, is passed through the sample and a second Nicol (the analyzer), to the eyepiece for visual observation. Between the first Nicol and the sample a small, auxiliary Nicol is so placed as to cause a slight modification of the polarization angle of one-half of the light beam.

This permits visual balance of the two half-beams at an intermediate level of intensity between dark and light, as the eye is most sensitive under such conditions.

The chief application of polarimetric analysis is in the sugar industry, since sucrose has a much greater specific rotation than impurities likely to be present. Many other compounds, principally organic, are optically active; some are of biological and pharmacological significance.

Wheland, *Advanced Organic Chemistry,* p. 130 *ff,* 2nd ed. (New York, 1949); Galen W. Ewing, *Instrumental Methods of Chemical Analysis,* p. 241 *ff* (New York, 1954). (G. W. E.)

POLARITY, a term used for discriminating between the positive and negative poles of an electrolytic cell or battery, or referring to the positive and negative terminals of direct current generators or dynamos. In the older conventional sense the electric current flows in these devices from positive to negative. In electrolytic cells positive and negative ions move in opposite directions inside the cell; in metallic conductors negative electrons move to the positive from the negative pole in the external circuit. (H. B. LM.)

POLAROGRAPHY (POLAROGRAPHIC ANALYSIS, VOLTAMMETRY), an electrochemical method of analyzing solutions of reducible or oxidizable substances, invented by Jaroslav Heyrovský at Charles university, Prague, Czech., in 1922.

The aqueous solution to be analyzed is placed in a glass cell containing two electrodes.' One electrode consists of a glass capillary tube (internal diameter about 0.05 mm. or 0.002 in.) from which mercury slowly flows in drops (dropping mercury electrodej, and the other is a pool of mercury or other nonpolarizable electrode. The cell is connected in series with a galvanometer for measuring the flow of current, in an electrical circuit which contains a battery, or other source of direct current, and a rheostat by means of which the voltage applied to the electrodes can be varied from zero up to about two volts. Usually with the dropping mercury electrode connected to the negative side of the polarizing voltage, the voltage is increased by small increments and the corresponding current is observed on the galvanometer. The current is very small until the applied voltage is increased to a value large enough to cause the substance being determined to be reduced at the dropping mercury electrode. The current increases rapidly at first as the applied voltage is increased above this critical value, but gradually attains a limiting value and remains more or less constant as the voltage is increased further. The critical voltage required to cause the rapid increase in current is characteristic of, and serves to identify, the substance being reduced (qualitative analysis). Under proper conditions the constant limiting current is governed by the rate of diffusion of the reducible substance up to the surface of the mercury drops, and its magnitude is a measure of the concentration of the reducible substance (quantitative analysis). Limiting currents also result from the oxidation of certain oxidizable substances when the dropping electrode is the anode.

In 1925 J. Heyrovský and M. Shikata invented an instrument called the polarograph, which automatically applies an increasing voltage to the dropping electrode cell and photographically records the resulting current-voltage curve. Curves thus recorded are called polarograms.

When the solution contains several substances that are reduced or oxidized at different voltages, the polarogram shows a separate current increase (polarographic wave) and limiting current for each. The method is thus capable of detecting and determining several substances simultaneously, and is applicable to relatively small concentrations, *e.g.,* 10^{-5} up to about 0.01 moles per litre, or approximately 1 to 1,000 parts per 1,000,000.

The majority of the chemical elements can be determined by polarographic analysis, and the method is applicable to the analysis of alloys and to various inorganic compounds. Polarography is also used to determine many types of organic compounds, and to study chemical equilibria and rates of reactions in solutions. A kind of volumetric analysis called voltammetry uses the polarographic principle for end-point detection in titrations.

POLAR REGIONS: see ANTARCTICA; ARCTIC. THE.

POLDING, JOHN BEDE (1794–1877), English Benedictine, first Roman Catholic bishop in Australia, first archbishop of Sydney. and a man full of zeal for the spiritual welfare of the isolated settlers of the new continent and of the numerous convicts who were constantly being shipped from England; was born at Liverpool on Oct. 18, 1794. He became a Benedictine monk and quickly rose to positions of influence and trust in his order. Consecrated as the first Australian bishop, he arrived at Sydney in Sept. 1835. There were but four Roman Catholic clergymen to meet him. The new bishop vigorously set to work dividing up his territory into missionary districts and providing priests, churches and schools as rapidly and extensively as he could: Visits to Europe enabled him to procure help for his people in various ways. From one of these visits he returned in March 1843 as archbishop of Sydney (appointed April 10, 1842). Kevertheless his kindness and humility were more evident than his administrative gifts. He died on hlarch 16, 1877.

See P. F. Moran, *History of the Catholic Church in Australasia,* (1894); H. N. Birt, *Benedictine Pioneers in Australia,* 2 vol. (1911). (E. McD.)

POLE (FAMILY). The family of the Poles, earls and dukes of Suffolk, which. but for Richard III's defeat at Bosworth. might have given the next king to England, had its origin in a house of merchants at Kingston-upon-Hull. The Poles were among the first English peers whose fortunes had been founded upon riches gained in trade.

William atte Pole (d. *c.* 1329). a merchant of Ravensrode, settled in Hull. His sons. Sir Richard and Sir William atte Pole, were both famous for their nealth.

Sir Richard (d. 1345), the king's butler in 1327. moved to London. and is styled a London citizen in his will. The male line of this, the elder branch of the Poles, failed with a grandson, John Pole, whose daughter was Joan, lady of Cobham, the Kentish heiress. whose fourth husband was Sir John Oldcastle the Lollard.

Sir William atte Pole (d. 1366). the second son of William, joined his brother in advancing large sums to the government while keeping safely apart from politics. The first mayor of Hull, he sat for Hull in five parliaments, and was advanced to be knight banneret and a baron of the exchequer. He was counted "second to no merchant in England," but after his time his descendants left the countinghouse, his four sons all serving in the French wars. The eldest son, MICHAEL DE LA POLE, 1st earl of Suffolk, who had fought under the Black Prince and John of Gaunt, became (1383) chancellor of England. In 138j he was created earl of Suffolk, a grant from the crown giving him the castle and honour of Eye with other East Anglian lands formerly held by the Ufford earls. In 1386 the opposition, led by Gloucester, the king's 'uncle, pulled him down. He was dismissed from his chancellorship, impeached, and convicted. Richard was forced to send his minister into ward at Windsor until the parliament was dissolved, when Suffolk once more appeared as the leader of the king's party. But the opposition was insistent, and Suffolk fled over sea to Calais. He died an exile in Paris in 1389.

The exile's son Michael, 2nd earl, was restored in 1397, died of dysentery at Harfleur, and his son Michael was killed at Agincourt. Michael was succeeded as 4th earl by his brother William. *(See* SUFFOLK, WILLIAM DE LA POLE, DUKE OF.)

John Pole (1442–1492), the only son of the 4th earl, should have succeeded to the dukedom, his father having died unattainted. But the honours were apparently regarded as forfeited, and the dukedom was formally restored to the boy in 1455, the earldom of Pembroke being allowed to lapse. He married King Edward IV's sister Elizabeth. The marriage confirmed him a partisan of the White Rose. Before he mas of age he was steward of England at his brother-in-law's crowning, and at Queen Elizabeth I's crowning he bore her sceptre. Having held many offices under Edward IV he was ready to bear a sceptre at Richard's coronation, and, after Bosworth, to swear fealty to the Tudor dynasty and to bear another sceptre for another Queen Elizabeth. He died in 1491, having safely kept his lands, his dukedom, and his head through perilous years. *(See* SUFFOLK, EARLS AND DUKES OF and POLE, RICHARD DE LA.)

Another family of the name of Pole. having no kinship with the house of Suffolk, owed their advancement and their fall to a match with a princess of the royal house. Sir Richard Pole, a Buckinghamshire knight. was the son of Geoffrey Pole, a squire whose wife, Edith St. John, was sister of the half blood to the mother of Henry VII. About 1490 or 1491 he married the Lady Margaret, daughter of George, duke of Clarence. He died in 1505, and in 1513 King Henry VIII created the widow countess of Salisbury, as some amends for the judicial murder of her brother, the earl of Warwick. Four years later, the barony of Montague was revived for her eldest son Henry. Until the king's marriage with Anne Boleyn, the countess of Salisbury was governess of her godchild, the Lady Mary. When her son. the famous Cardinal Pole, published his *Pro ecclesiasticae unitatis defensione* the whole family fell under the displeasure of the king, who resolved to make an end of them. The Lord Montague was the first victim, beheaded in 1538 on a charge of treasonable conversations, on evidence of his brother, Sir Geoffrey Pole. In 1541 the aged countess, attainted with her son Montague, was also executed. Sir Geoffrey Pole fled the country, and joined the cardinal in exile. He returned with him at Mary's accession, both dying in 1558. His sons Arthur and Edmund, taken in 1562 as plotters against Queen Elizabeth, were committed to the Tower of London, where they died after eight years of imprisonment.

POLE, REGINALD (1500–1558), English cardinal and archbishop of Canterbury, born at Stourton castle. Staffordshire, in March 1500, was the third son of Sir Richard Pole and Margaret, countess of Salisbury, a niece of Edward IV. Intended for the church, he spent five years at the grammar school founded by John Colet at Sheen, where his kinsman Henry VIII contributed to the cost of his education. In his 13th year he went to Oxford. matriculating from Magdalen college. Thomas Linacre and William Latimer were among his tutors. He took his B.A. in 1515. In 1518 the king appointed him to the deanery of Wimborne and then to two prebends in Salisbury cathedral. In 1521 he went, with an annual grant of £100 from the king, to continue his studies at Padua, where during the next few years he corresponded with Desiderius Erasmus and formed friendships with Pietro Bembo, Christophe de Longolius, and other prominent humanists. He paid a brief visit to Rome for the 1525 jubilee.

Two years later he returned to England and was appointed dean of Exeter. He showed, however, little desire to desert his studies for a more active career; and it is possible that Thomas Cromwell, by recommending to him the precepts of Niccolo Machiavelli, helped to encourage this distaste for public life. When the question of Henry VIII's "divorce" from Catherine of Aragon arose, Pole at first sought to avoid taking part on either side. In 1529 he obtained the king's leave, and £100, to continue his studies at the University of Paris. The following year, however, by the king's order he helped to secure that university's pronouncement in favour of the divorce. On returning to England he was offered the archbishopric of York, vacant by Thomas Wolsey's death, but was required first to declare his opinion about the divorce, Henry not wishing to confer so great an honour upon an adversary. Pole suggested that he was ready to satisfy the king, but then apparently changed his mind, for in a stormy interview at York place he roundly denounced the royal policy. He later wrote to Henry. explaining his reasons against the divorce, and in,Jan. 1532 he received permission to go abroad again, without losing the revenues of his benefices. After a brief stay at Avignon, he settled once more at Padua and devoted himself to the serious study of theology. These studies soon led him to become a prominent member of the group of Catholic reformers, headed by Gasparo Cardinal Contarini, Giovanni Giberti and Giovanni Caraffa, who were eager to reform ecclesiastical abuses but regarded the maintenance of papal supremacy as necessary to preserve the unity of Catholic Christendom.

At this point in his development his relations with Henry VIII reached their crisis. In Feb. 1535, after the king's final break with Rome. Pole was called upon to make a formal statement of his opinion about the divorce and the royal supremacy. The executions of Bishop John Fisher and Sir Thomas More (June and July 1535) gave him grim warning of the fate which his answer might bring upon his family as well as upon himself; and the task of answering was not made easier by the genuine admiration which hitherto he had felt for Henry or by his reluctance to abandon all hope of reconciliation. Thus he took a year over writing his reply and by the time that it was dispatched to England (May 1536) it had grown into a full-sized book. Although later published, without Pole's consent, under the title *Pro ecclesiasticae unitatis defensione* (usually known as *De Unitate*). it was meant for the king's eye alone. It contained a severe attack on the royal policy and a strong defense of the pope's spiritual supremacy.

In July 1536, Paul III summoned Pole to Rome to serve with Contarini, Giberti, Caraffa and others on the commission to consider the reform of church discipline. After some hesitation, caused by letters from his mother and brother emphasizing the dangers that his conduct might lead them into. he eventually obeyed this papal call. In December he was made a cardinal and by Feb. 1537 the commission's report, *Consilium de emendanda ecclesia,* was completed. This most important document trenchantly summarized the outstanding abuses in the church and pointed to the remedies with plain-spoken directness. Pole's share in this notable work was hardly completed when a new task was thrust upon him. Paul III, who had already prepared a bull of deposition and excommunication against Henry VIII. now appointed Pole legate *a latere* for England and sent him to persuade the Catholic powers to take advantage of the difficulties created for Henry by the Pilgrimage of Grace. The mission was ill-timed and quite unsuccessful. The pilgrimage had been crushed almost before Pole left Rome (Feb. 1537); Francis I refused to let him stay in France; Charles V's representative would not admit him to the Netherlands; Henry would not negotiate with him in his capacity as papal legate; and in Aug. 1j37 the pope recalled him to Rome. A second mission in 1538–39 to persuade Charles and Francis to enforce the bull resulted in an equally humiliating failure and Pole. his life threatened by Henry's agents. sought refuge with his old friend Jacopo Sadoleto at Carpentras before returning to Rome at the end of 1539. Meanwhile the royal vengeance had fallen upon his family in England. His eldest brother, Lord Montague, and his cousin, the marquess of Exeter. were executed in 1538; his mother and he himself were attainted in 1j39; and his mother executed in 1541.

On Aug. 21. 1541, Pole was appointed legate of the *Patrimonium Petri*, the oldest of the papal states, and took up his residence at. Viterbo. There he gathered around him a group which included Marc-Antonio Flaminio and Vittoria Colonna. the poetess and friend of Michelangelo. With them he discussed many of the great theological questions raised by the German reformers and by the Spanish reiormer Juan de Valdes. Justification by faith, the burning question of the day. was a special subject of discussion. Pole's own attitude at this time may be best summed up in his advice to Vittoria Colonna, that she should believe as though she could be saved by faith alone and act as though she could be saved by works alone. His open-mindedness. the leniency of his rule at Viterbo, and his reluctance to abandon all hope of healing the divisions of Christendom were. however, by now beginning to separate him from Caraffa and those who felt that, after the failure of Contarini's negotiations with the Lutherans at Ratisbon (Regensburg) (1541), the time had come for sterner measures to defend and define the Catholic faith. Indeed, after the conversion to Protestantism in 1542 of Vittoria's friend Bernardino Ochino and of Peter Martyr, whom Contarini had defended. the newly established Roman Inquisition. headed by Caraffa, regarded the entire Viterbo circle as no better than heretics.

Nevertheless Pole was one of the three legates appointed in 1542 to open the Council of Trent and. when the council eventually met in Dec. 1545, he was one of the three who presided over its session. after journeying to Trent by a devious route for fear of assassins hired by Henry VIII. He urged the council very strongly to reform the abuses as well as to define the doctrines of the church and when the question of justification came up for discussion he entreated :he fathers to study the subject well before committing themselves to a final decision. Soon after this discussion began. however. his health broke down and he retired to Padua (June 1546). There is no reason to believe that this was a feigned illness. It is true that the council did not accept the compromise on justification that Contarini had put forward at Ratisbon and which Pole still favoured. Rut Pole kept in touch with its proceedings by letter; his view was well represented in the discussions by Seripando; and he accepted readily enough the decree that the council finally passed.

On the death of Paul III (Nov. 1549) Pole, thanks to Charles V's support, came near to election as pope. After hesitating to let himself he acknowledged by acclamation before all the French cardinals had arrived. he just failed to obtain the necessary two-thirds of the votes. In the end the French and imperialist factions compromised by electing Julius III. Under him reform made little headway. Pole lost his legacy at Viterbo (1550), was openly (though vainly) denounced by Caraffa for heretical leanings. and about 1553 retired to the monastery of Maguzzano on Lake of Garda.

However, on the accession of Mary Tudor (July 1553), the pope at once appointed Pole legate for England. Yet even now his course was not smooth. He had often been spoken of as a possible husband for Mary—he was still only in deacon's orders, so that a papal dispensation might have been obtained—and Charles V n-as therefore determined to keep him out of England until Mary's marriage to his own son Philip had been arranged. Moreover Pole himself thought this marriage a mistake! although he failed to convince the pope. Even when Philip and Mary were safely married (July 1554), other obstacles remained, notably the English parliament's insistence upon adequate guarantees that lay holders of confiscated church lands should not be disturbed. Thus it was not until Nov. 20 that he landed at Dover. Ten days later he formally absolved the realm and received it back into the Roman fold. On Dec. 24 he issued a decree guaranteeing holders of church property against all ecclesiastical censures, though he would not add that they might hold it with a clear conscience. On Philip's departure in Aug. 1j j5, Mary turned more and more to Pole for advice on all matters. He was not responsible for the religious persecution that disfigured the last four years of her reign, although he did nothing to stop it and occasionally himself issued commissions to repress heresy. First and foremost he was still the Catholic reformer. In Nov. 155j he assembled at Westminster a national synod of the two convocations. which quickly agreed to measures to enforce clerical residence, reduce pluralism, increase preaching, compel priests to set a good example to their flocks, and to provide a new book of homilies and a new translation of the New Testament. On Thomas Cranmer's deposition. Pole became archbishop of Canterbury (March 1556), after being ordained priest two days before, and sought to enforce these decrees by a metropolitical visitation. He also attempted to refound some of the monasteries and sent commissioners to carry out a visitation of the universities. All this work, however, went forward too slowly to take any firm root within the few short years of Mary's reign.

hloreover. Pole was thwarted by the papacy itself. In May 1555 Caraffa had become pope as Paul IV. He adopted a violent anti-Spanish policy which soon brought renewal of the war between France and the Habsburgs. Pole's efforts to prevent the conflict only infuriated Paul. In April 1557 he was deprived of his legatine authority and in June, after England's declaration of war on France. he was summoned to Rome. the aged William Peto being appointed legate in his place. At the same time the Pope inveighed against Pole as a heretic and handed his friend Cardinal Morone over to the Inquisition. Doubtless Pole would have shared this fate had Mary not prevented the delivery of the pope's summons. Instead, he remained in England until, broken as much by the unmerited blow of the papal disgrace as by ill-health, he died at Lambeth on Nov. 17, 1j58, 12 hours after Mary. He was buried at Canterbury, near the site of the shrine of St. Thomas à Becket.

BIBLIOGRAPHY.—G. Quirini's *Epistolarum* R. *Poli collectio,* 5 vol. (Brescia, 1744–57) also contains the liie written in Italian by Pole's secretary Beccatelli, which Andrew Dudith translated into Latin (*Vita Poli cardinalis*, Venice, 1563). *See* also A. Zimmermann, *Kardinal Pole, sein Leben und seine Schriften* (Repensburg, 1893); W. Schenk, *Reginald Pole, Cardinal of England* (London, New Eork, 1950). (R. B. WM.)

POLE, RICHARD DE LA (d. 152j). pretender to the English crown. was the fifth son of John de la Pole (1442–92), 2nd duke of Suffolk. and Elizabeth. second daughter of Richard. duke of York, and sister of Edward IV. His eldest brother John de la Pole, earl of Lincoln (c. 1462–87), was named heir to the throne by his uncle Richard III, who gave him a pension and the reversion of the estates of Lady Margaret Beaufort. On the accession of Henry VII Lincoln quickly submitted; but in 1487 he joined the rebellion of Lambert Simnel and was killed at the battle of Stoke. The second brother Edmund (c. 1472–1513) succeeded his father while still in his minority. His estates suffered under the attainder of his brother. and he was compelled to pay £5.000 to Henry VII for the recovery of part of the forfeited lands, and also to exchange his title of duke for that of earl. He fled abroad in 1499; returned in 1500; but fled again in 1501 and intrigued with the emperor Maximilian for an invasion of England. In 1502 Henry seized his brother William de la Pole, with four other Yorkist noblemen. Two of them, Sir James Tyrell and Sir John Wyndham, were executed. William de la Pole was imprisoned and Suffolk outlawed. Then in July 1502 Henry concluded a treaty with Maximilian by which the emperor bound himself not to countenance English rebels. Presently Suffolk, who had been attainted in 1504, fell into the hands of Philip, king of Castile. who imprisoned him at Namur, and in 1jo6 surrendered him to Henry VII on condition that his life was to be spared. He remained a prisoner until 1513, when he was beheaded at the time his brother Richard took up arms with the French king.

Richard de la Pole escaped overseas with Edmund in 1501, and remained at Xix as surety for his elder brother's debts. The creditors threatened to surrender him to Henry VII. but, more fortunate than his brother: he found a refuge with King Ladislaus VI of Hungary. He was attainted in 1504 and excepted from the general pardon proclaimed at the accession of Henry VIII. When England and France went to war in 1512 Louis XII recognized Pole's pretensions to the English crown and gave him a command in the French army. In 1513 after the execution of Edmund, he assumed the title of duke of Suffolk; he was also known as "White Rose." In 1514 he was given 12.000 German mercenaries ostensibly for the defense of Normandy, but really for an invasion of England. These he led to St. Malo, but the conclusion of peace with England prevented their embarkation. Pole was required to leave France and he established himself at Metz, in Lorraine, and built a palace at La Haute Pierre, near St. Simphorien. He had numerous interviews with Francis I and in 1523 he was permitted in concert with John Stewart; duke of Albany and the Scottish regent, to arrange an invasion of England which was never carried out. He was with Francis I at Pavia and was killed on the field on Feb. 24, 1525, so ending the male line.

POLE. For pole star *see* POLE STAR; for polar regions *see* ANTARCTICA; ARCTIC, THE; for magnetic poles *see* MAGNETISM. *See* also BATTERY; CRYSTALLOGRAPHY; GEODESY; GEOMETRY; POLE VAULTING; SPHERE.

POLE AND POLAR, in mathematics. If from a point P outside a circle the two tangents to the circle be drawn, the line joining the points of contact is called the *polar* of the point P, and P is called the *pole* of the secant line. If P is on the circle, the two tangents coincide and the polar of P is the single tangent at P. For Q, a point inside the circle, draw two secants to the circle through it. The line joining their poles is called the polar of Q. If the polar of P passes through Q, the polar of Q passes through P. In the figure shown, $\overline{AB}$ is the polar of P_1; $\overline{CD}$ is the polar of P_2; line *1* is the polar of A; P_1P_2 is the polar of Q. The same principle applies to any conic. In space there is a corresponding theory of points and polar planes as to a sphere or any fixed quadric surface. The idea is due to C. J. Brianchon, who first applied it in 1806, but it was developed by J. V. Poncelet, and presented in final form in 1829. Later the concept was extended to other curves and surfaces, and to other configurations.

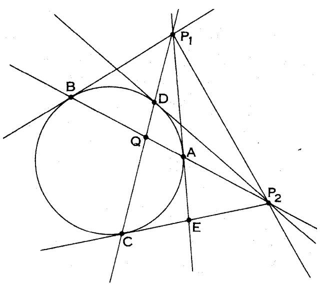

DIAGRAM ILLUSTRATING THE THEORY OF POLE AND POLAR PLANES (SEE TEXT)

POLECAT (FITCH), *Mustela putorius,* of the family Mustelidae. which also includes the weasel, mink, otter, etc. (*See* CARNIVORE.) Polecats are confined to the northern hemisphere, being found in the central and northern parts of the European continent, east to Siberia and Mongolia and south to the Himalayas. The polecat is well known in its domesticated, albino variety as the ferret. The wild polecat is dark brown above and black below, the face being variegated with white. The fur is long, coarse and of little commercial value. It is more powerful than the marten (*q.v.*) but less active and rarely climbs trees. Its food consists of small mammals and any birds it can catch, especially poultry. It also eats snakes. lizards, frogs, fish and eggs. It is extremely bloodthirsty and hunts at night. From three to eight young are produced in April or May, after a two months' gestation. It is tenacious of life and has a fetid smell.

POLECAT OR BLACK-FOOTED FERRET (MUSTELA NIGRIPES)

On the central plateau of the United States is found the black-footed ferret, *M. nigripes,* a related species with creamy-yellow fur, brown legs and black feet and tail. A related genus, *Vormela,* whose fur is white marbled with reddish spots above, extends from east Poland to Afghanistan. These animals resemble M. *putorius* in habits. *See* also FERRET; WEASEL.

POLEMONIACEAE, the phlox family, consisting of bland dicotyledonous herbs. rarely shrubs or small trees, with about 13 species native in Europe, Asia and America, chiefly North America. Leaves are alternate or opposite, simple or compound, the flowers bisexual, mostly regular and often showy, especially in the garden forms. Among the well-known genera are *Phlox, Polemonium, Cobaea* and *Gilia.*

See PHLOX. (*J. M.* BL.)

POLENTA, DA, the name of a castle in Romagna from which came the noble and ancient Italian family of Da Polenta. The founder of the house is said to have been Guido. surnamed l'Antico or the Elder. who wielded great authority in Ravenna in the 13th century. His grandson Guido Novello upheld the power of the house and was also *capitano del popolo* at Bologna; he was overthrown in 1322 and died in 1323. In 1321 he gave hospitality to the poet Dante who immortalized the tragic history of Guido's daughter Francesca, unhappily married to Malatesta, lord of Rimini, in an episode of the *Inferno.* Guido's kinsman Ostasio I was lord of Cervia and Ravenna from 1322 to 1329, and, after being recognized as a vassal of the Holy See, again became independent and went over to the house of Este whom he served faithfully in their struggles with the church until his death in 1346. His son Bernardino who succeeded him as lord of Ravenna in 1346 was deposed in 1347 by his brothers, Pandolfo and Lamberto II, but was reinstated a few months later and ruled until his death in 1359; he was famous for his profligacy and cruelty. His son Guido III ruled more mildly and died in 1390. Then followed Ostasio II (d. 1396), Obizzo (d. 1431). Pietro (d. 1404) and Aldobrandino (d. 1406), all sons of Guido III. Ostasio III (or V), son of Obizzo, was at first allied with the Venetians; later he went over to the Milanese, and, although he again joined the Venetians, the latter never forgave his intrigue with their enemies and in 1441 they deprived him of his dominions. He died in a monastery in 1447.

POLESIE (POLESYE), at one time the largest and most sparsely populated province of Poland. Area. 14,219 sq.mi. Polesie was taken by the U.S.S.R. in 1939 and by Germany in 1941. After World War II Polesie became part of the Byelorussian Soviet Socialist Republic, U.S.S.R.

Polesie forms an eastward extension of the central Polish plain sloping up to the northern highlands and the plateau of Podolia. It forms the basin of the Prypet, a tributary of the Dnieper. The falls of the lower Dnieper hinder the drainage of Polesie, and the deepening of the channel of the Dnieper tends to dry up the Pinsk marshes. In spring the whole country is flooded. In reality it consists partly of marshes and lakes, partly of damp meadows with islands of clay or sand, on which most of the villages are built. In such a dreary plain the main feature is the vegetation, which consists of wide pine forests on the sand or on the swamps, with invading firs from the north, of mixed forests and birch groves. and of damp meadows grown with grasses, reeds and stunted willotvs. It is the only remaining home of the beaver in Poland, and the elk is still found there.

Polesie originally formed the early Russian principality of Turov or Pinsk. Conquered by the Lithuanians in 1320, it became, after the union with Poland in 1569, the province of Brest Litovsk. The northwest portion formed part of the estates of the great Polish magnates, the Radziwills and Sapiehas. Wolczyn was the seat of the Czartoryski family. The chief towns are Brest, pop. (1959) 73,000, the capital; Pinsk, the seat of an ancient Orthodox bishopric; Kobryn and Kamenets.

POLE STAR (POLARIS), the (naked-eye) star nearest the north celestial pole, is the brightest star in the constellation Ursa Minor (*q.v.*), hence its Bayer designation, α Ursae Minoris. The closeness of the star to the pole (minimum distance 27′.6 in the year 2102) causes its apparent position to remain nearly constant all night and all year. The location and moderate brightness of Polaris make it a convenient object for navigators and surveyors to use in determining latitude and north-south direction in the northern hemisphere.

Polaris. a single star to the naked eye, is a system of three stars. A faint companion is visible in a small telescope; spectrographic observations indicate the presence of a third star very close to the brighter of the visual pair.

The bright star is a pulsating variable of the classical Cepheid type, undergoing changes in diameter and in brightness during a four-day period. (EH. R.)

POLE VAULTING, the art of jumping over an obstacle with the aid of a pole. Originally a means of clearing objects, such as ditches, brooks and fences, pole vaulting for height, clearing a bar supported by two uprights set not less than 12 ft. apart. became a competitive sport. In competition, each vaulter is given three chances to clear a specified height. The bar is raised progressively until a winner emerges. Requirements of the athlete include a high degree of co-ordination, timing, speed and gymnastic ability. The pole may be of any material (most vaulters use bamboo or metal) and of any length or diameter. A slideway is sunk into the ground, the back of which is placed directly below the crossbar. Into this slideway the pole is thrust. A soft pit, generally of sawdust, is provided for the vaulter's landing.

The modern pole vaulter approaches the take-oif with great speed, carrying the pole with his hands about $2\frac{1}{2}$ ft. apart. As the stride, next before the spring, is completed, he performs the shift, which consists of advancing the pole toward the slideway (which is known as the advance) and at the same time allowing the lower hand to slip up the pole until it reaches the upper hand, and raising both hands as high above his head as possible before leaving the ground. He is thus enabled to exert the full pulling power of both arms to raise his body and help the swing-up of his legs. There are two factors the pole vaulter bears in mind —one is height and the other is carry. Height gives him the elevation, and carry takes him across the bar. It is noteworthy that this trick, perfected by Raymond G. Clapp of Yale university. New Haven, Conn., raised the world's record in 1898 to 11 ft. $10\frac{1}{2}$ in.; whereas, not employing the manual shift, H. H. Baxter of the Sew York Athletic club, in 1863, vaulted to a record of 11 ft. $\frac{1}{2}$ in.

The modern pole vaulter generally uses the following techniques: A long run of approximately 100 ft. to 130 ft., great speed donn the runway and exact timing when the shift takes place, so that his hands are extended high above his head at the minute of the take-off. He then runs off the ground (he does not jump) leaving his body hanging by the hands as long as possible, not pulling too soon. He then lets his legs swing upward and to the side of the pole. The athlete's feet should reach a point well above the crossbar, in an attempt to actually make a handstand. At this stage the vaulter shoots his legs high above the crossbar by means of a strong arm pull on the pole. He next turns his body face downward and converts his pulling force into a pushing force. The bar lies in the concavity of the stomach, so that his feet are on one side and his head and shoulders are on the other side. The athlete finally carries his body across the crossbar, by what is known as the carry, which is the speed he has acquired from his run.

Introduction of the bamboo pole, used with the modern technique, added approximately a foot to the records.

Astounding improvements in performance are best illustrated as follows: (1) H. B. Baxter (New York Athletic club), in 1883, 11 ft. $\frac{1}{2}$ in. (using old style). the first man to vault over 11 ft.; (2) Norman E. Dole, 1904 world's record, 12 ft. $1\frac{32}{100}$ in., the first man to vault over 12 ft.; (3) Robert A. Gardner (Yale university), at the I.C.A.A.A.A. games in 1912. 13 ft. 1 in.. the first man to vault over 13 ft.; (4) Sabin W. Carr (Yale university), at the I.C.A.A.A.A. games in 1927, 14 ft.. the first man to vault 14 ft.; (5) Cornelius Warmerdam (Olympic club), at Berkeley, Calif.. in 1940. the first man to vault 15 ft.; (6) John Uelses (U.S. Marine corps), using a fibreglass pole. at Santa Barbara, Calif.. In 1962. the first man to vault 16 ft.

POLIANTHES, one of the florists' flowers, commonly called tuberose, probably derived from P. *tuberosa,* which is unknown as a wild plant. See TUBEROSE.

POLICE. In a broad sense, the term police connotes the maintenance of public order and the protection of persons and property from the hazards of public accidents and the commission of unlawful acts; specifically. it applies to the body of civil officers charged with maintaining the public order and safety and enforcement of the law. including the detection and suppression of crime. In its wider aspects, it included at one time such limited activities as street paving and lighting, or scavenging and sanitation, as well as applications broad enough to comprehend the entire range of the domestic policies of government. In modern usage, it comprises various inspectional, licensing and other regulatory activities.

Authoritarian states set up secret political police organizations that operate independently of the regular civil police establishments. Political police are always highly centralized agencies. The nazi gestapo and schutzstaffel, the tsarist ochrana, the soviet cheka, O.G.P.U. and N.K.V.D. and Mussolini's ovra all had common characteristics sharply distinguishing them from other civil police. Their governments, among others, came to be known as "police states." Democratic governments are also impelled to establish their security from subversive elements, but they do not hesitate to entrust it primarily to police forces charged with law enforcement in general. Popular governments permit much local autonomy in police administration while authoritarian states tend to centralize police control. but the intrusion of other factors also may produce centralized police control even under democratic patterns. England. Wales and Scotland have scores of local police forces, whereas the Republic of Ireland and the government of Sorthern Ireland each maintains but a single police establishment. Belgium has dual police systems for the national and local levels with municipal forces resting upon almost complete local autonomy, whereas in Denmark all police activities are administered by functionaries of the crown. For the most part, European countries followed the French pattern of a national police charged with the maintenance of public order, the investigation of all major crimes, and the full policing of the larger cities. together with locally recruited forces concerned with routine law enforcement duties, including local traffic control, in the smaller places. In some countries, such as France and Italy, a branch of the national police force also performs routine police duties in country districts. Japan, under a law of 1954, has centralized all police forces under the Sational Police agency; even so, a certain degree of autonomy as respects authority, administration and finance is left to the prefectural and larger municipal departments. In the United States and Canada, national and state (or provincial) police lie parallel to local police systems.

Police administration in the English-speaking countries has five major aspects: uniformed patrol, criminal investigation (detection of criminals), traffic regulation, special measures for controlling commercialized vice (liquor, narcotics! prostitution and gambling) and procedures and facilities for dealing with women offenders and juvenile delinquents.

United **States.**—Strictly speaking, the United States has no police system. It has about 40.000 police jurisdictions represented by the federal government, the states, the sheriffs and deputy sheriffs of 3,000 counties, a handful of county police forces independent of the sheriffs' offices. the police of 1,000 cities and occasional constables in more than 20,000 townships, magisterial districts or county districts. together with other minor forces in 15,000 villages. boroughs and incorporated towns. In addition, there are a number of special districts concerned with the patrol of parks, parkways, tunnels, bridges and aqueducts. In short, police administration follows the jurisdiction of the civil governments. whether federal. state or local. This produces serious internal strains since in a given area there may be as many as five or six levels of police administration, It also unduly complicates the task of co-ordinating investigations and other police activities. Central clearinghouses for crime records, criminal identification and police training and the vast interstate networks of police teletype and radio serve in part to overcome some of the more flagrant defects, however.

The total numerical strength of all full-time and part-time police in the service of these many jurisdictions was estimated at 295,000 in the latter 1950s. The well-defined trend is away from part-time police, particularly the township constables and deputy sheriffs; but when such as these are found to be inadequate, state and local governments still are prone to create new and additional police bodies without disposing of the outworn agencies.

Local police agencies range in size from only one or two part-time employees to a highly developed force of thousands in New York city. The ratios of police to population generally are highest in the largest cities and decline by graduated steps. Thus, in cities of more than 250,000 population the number of police per thousand of population was 2.4 in the latter 1950s; while in places of less than 10.000 population, the ratio was only 1.4.

Similar variations appear when geographic location is considered. New England led in police ratios for cities over 250,000 population, and the Pacific Coast for places under 25,000. Lowest ratios are most commonly found in the central states.

The general effect of such relationships to size and location is that police strength is not only disproportionately greater in those parts of the country having the larger urban centres. but it is in large degree actually concentrated in the big cities. Thus, of the total number of police employed in about 3,700 urban places more than half were concentrated in less than 50 cities with populations exceeding 250,000.

The inherent weakness of the smallest police establishments and the abdication of police authority by many rural functionaries combined to produce inadequate police defenses throughout most of the U.S. countryside. For many years this condition was ignored, but the advent of the motor age brought with it so many problems of crime control and traffic regulation that the ancient sheriff-constable system was quickly overwhelmed. A new type of police agency thereupon emerged—one destined to have a far-reaching influence upon the future development of police in the United States and upon the ultimate distribution of functions among local and state governments. The 19th century witnessed several limited and tentative experiments in state police administration—in Texas, Massachusetts and Connecticut—but it was not until 1905 that Pennsylvania established its state police force; and when New York and other large commonwealths followed at about the time of World War I, and shortly thereafter, success of the state police idea was assured. Because these agencies were in fact wholly new. they did not inherit the old United States police tradition, parts of which were thoroughly bad. Furthermore they were able to experiment with new devices for selection, training, promotion and discipline.

By the time of World War II every state had acquired a police agency of its own. Some of these were rudimentary in conception and limited in both authority and numbers. Some were charged merely with the patrol of state highways for the single purpose of traffic law enforcement. Others sprang into existence with broad enforcement powers exercised throughout great and populous states but especially in the rural areas where local policing was least adequate. Without exception, state police forces represented a break with the past and with the tradition of local autonomy in police management. But their numbers were nowhere great—and all told they did not total more than 25,000 in the service of the states. The establishment of state police was not accompanied by any large-scale abandonment of the outworn and outdated local police units.

The federal government also was drawn more and more into the police field, because it could not be expected indefinitely to entrust the enforcement of many federal statutes to local and state police bodies. The stresses of the Civil War brought several rudimentary investigative agencies into existence while an expanding field of federal regulation encouraged the development of others. In all but a mere handful of these, law enforcement was either auxiliary to other administrative activities or was performed within a narrowly restricted area or involved in the conduct of military or naval operations.

General police jurisdiction at the national level is exercised only by the Federal Bureau of Investigation, popularly known as the FBI. This select corps of criminal investigators has performed its various law-enforcement functions in such fashion as to encourage repeated additions to the scope of its responsibilities. Extensive crime laboratories and a uniform system of crime reporting for all jurisdictions in the United States and its possessions serve to round out the central services performed by the FBI for state and local law-enforcement agencies.

In a special category are the police patrols maintained by such federal agencies as the Tennessee Valley authority, while the police department of Washington, D.C.. is wholly unique on the United States scene. Commissioners appointed by the president administer the governmental affairs of this federal district and accordingly are responsible for law enforcement within its boundaries.

A prominent feature in a typical police force in the United States is the wealth of equipment, particularly for transportation and communication, Whatever the shortcomings of the various federal, state and local police systems, there can be no doubt that in the use of mechanical aids they lead the world by a wide margin. Also notable is the steady rise in police salary scales after 1910, the shortened work week and the increasing adoption of retirement systems. some established on a sound actuarial basis.

Great Britain. — Modern police administration in Great Britain stems from the establishment in 1829 of the metropolitan police in the sprawling urban and subdrban area surrounding the City of London. This extends in a wide circle of 700 sq.mi., most of it lying within a radius of 15 mi. from Charing Cross as a centre. The ancient City, however, is only 1 sq.mi. in area. is of limited resident population but of great wealth and importance and has never been a part of the metropolitan police district. With this exception. the metropolitan police district embraces all of London and Middlesex counties and parts of Surrey. Essex, Kent and Hertford, the whole including several score municipal and county boroughs.

Headquarters of the metropolitan force are at New Scotland Yard in the borough of Westminster on the Thames embankment—close by the offices of the national government and the seat of empire in Whitehall. The police commissioner of the metropolis is appointed by the crown, with the home office occupying the position of responsible police authority in all metropolitan police matters. The home secretary exercises direct control over this critically important agency for law enforcement in the nation's capital.

The commissioner of the City of London police is chosen by the mayor and aldermen, while in other cities and boroughs having their own police establishments, the watch committee of the city or borough council appoints the chief constable in each instance. Each county constabulary is under the control of a standing joint committee consisting of specially designated members of the county council and justices of the peace (quarter sessions). This committee selects the chief constable; but in counties, cities and boroughs alike, the choice of a chief constable must be ratified by the home office.

The early county constabularies were created around 1840, primarily for the protection of rural areas, but many now are also charged with responsibility for policing cities and boroughs, some of them of considerable size. This process of consolidation was going on for many years and was speeded up greatly by the exigencies of World War II. Further absorption of 45 of the 47 noncounty borough forces followed application of the terms of the Police Act of 1946. Another trend toward integration is marked by the device of placing a single chief constable in command of two or more neighbouring forces.

Authorized strength of the metropolitan police in the latter 1950s was nearly 20.000 with the separately protected City of London adding nearly 1,000 to the area's quota. In addition county constabularies with an authorized strength of about 30,000 and city or borough forces totalling about 22,000 were responsible for policing almost 500 cities: boroughs and counties in England and Wales. The Scottish establishment consisted of county constabularies with a total authorized strength of about 3,200 and borough forces aggregating nearly 4,500 men.

Ratios of police to population are highest in England, where in the latter 1950s there were 1.66 police per thousand of population as against Scotland's 1.49 and 1.39 in Wales. Some of this disparity is caused by the varying ratios of urban and rural population, some of it by special influences affecting the gravity of the local police problem.

Although the British police system is deeply imbedded in local political institutions. the national government nevertheless maintains a certain degree of surveillance over the administration of even the smallest borough forces and county constabularies and extends financial and technical aid in various important ways. This represents an effort to introduce some degree of unity and coherence into a system that in most respects is wholly decentralized. Hence, the home secretary (for England and Wales) and the secretary of stnte for Scotland may enforce standards of efficiency in all police establishments. They also control the conditions of police employment (appointment, promotion, discipline. compensation, etc.) through widely ranging regulations. Such controls are made effective by the grant-in-aid annually made to each police establishment, totalling one-half of the net cost of each force, including pensions. With the various forces thereby made dependent in large degree upon the national exchequer, it is provided that the grants shall be made only to those meeting the required standards. Annual visitations by her majesty's inspectors of constabulary (four for the home office,one for the Scottish office) operate to enforce compliance.

The national government provides various central facilities. It operates seven forensic science laboratories, district recruiting offices, regional networks for wireless communication and eight training centres serving a number of neighbouring forces. It also bears a special relationship to the metropolitan police that springs from the unique position and character of that force. For example, the metropolitan police force through its Special Branch is charged with certain imperial and national duties not readily performed by any other existing body. It is responsible for the protection of the royal family; the ministers of government and distinguished foreign visitors; the regulation of traffic and maintenance of order in the vicinity of the houses of parliament; the guarding of government buildings and special precautions taken at state functions; and protection against political agitators and sabotage. A special contribution of £100,000 a year is made from the exchequer for these purposes.

The metropolitan police force performs a widely heralded and generally misunderstood function in investigating certain crimes committed outside the metropolitan area. For the most part these excursions are confined to cases of murder; and since they are authorized only upon the request of the local authorities directly concerned, their number in any one year is small. A new branch was formed in 1954 to co-operate on country crimes committed by London criminals. The metropolitan police force also operates the Criminal Record office, a national registry of crimes and criminals, and publishes the daily *Police Gazette* which carries details of persons wanted for crime, and of stolen property and is distributed without charge to both British and other police forces.

(BR. S.; L. GU.)

POLICE COURTS, courts of summary jurisdiction held in London and certain large towns in England and Wales by specially appointed and salaried magistrates.

Police magistrates are appointed by the Crown. They must be practising barristers for seven years or stipendiary magistrates for some place in England or Wales. One police magistrate has the same powers as two justices.

In the Cnited States there are no so-called police courts in the Federal system of courts except in the District of Columbia. where the President appoints, subject to confirmation by the Senate. two judges of the police court. In the various States, police courts, the presiding official of which is either a judge or a magistrate. were created for many cities. They are elected by the voters, and try the violators of municipal ordinances.

POLICE POWER is a term used in U.S. constitutional law to describe the permissible scope of state legislation. In spite of its importance. police power is not mentioned in the U.S. constitution; the concept was created by the courts to reflect the conclusion that an approved law did not violate specific constitutional prohibitions —especially the 14th amendment's provision that no state may "deprive any person of life, liberty or property without due process of lam."

During the decades immediately preceding 1937, while the U.S. supreme court was forcefully using the due process clause to outlaw social and economic controls, such as minimum wage and maximum hour laws, an important step in the court's reasoning was a narron definition of the police power. The freedom of labour to bargain was thought of as a liberty protected under the due process clause; an invasion of this liberty could be justified only by a proper exercise of the police power. The critical point in the court's reasoning was the further assertion that the state's police power existed only for certain limited objectives which the court frequently described as the promotion of "health, safety and morals."

Under this formula much social and economic legislation could be outlawed. Limiting the hours of work might not directly affect health. except in unusual situations such as underground mines and smelters; through this approach the supreme court in 1905 invalidated New York's 60-hour maximum work week for bakers. The court similarly concluded that minimum wage legislation did not fit under any of the permitted headings of the police power. Thus in 1923, the court invalidated the establishment of minimum wages for women, observing: "It cannot be shown that well-paid women safeguard their morals more carefully than those who are poorly paid." Even in cases where the police power was said to extend to "health, safety, morals and welfare," the court's early decisions indicated that it was physical, rather than economic or social, welfare which fell within the permissible scope for legislation.

In 1937, notably first in a decision upholding a Washington state minimum wage law (R'est *Coast Hotel Co.* v. *Parrish,* 300 U.S. 379). the supreme court sharply altered its approach to allow wide latitude for social and economic legislation; in the course of this development the court virtually abandoned the police power concept as a means of limiting legislative power. For example, in the 1952 *Day-Brite* case upholding a state law which required that workers be paid for time spent going to the polls on election day, the court's opinion declared that the police power "is not confined to a narrow category" but "extends to all the great public needs." Although the validity of aesthetics as a goal of regulation was once in doubt, the court in 1954 sustained a program of urban development, declaring that the state may legislate to make the community "beautiful as uell as healthy"; the goals of legislation may be "spiritual as well as physical, aesthetic as well as monetary." While police power as a concept for limiting governmental objectives thus was virtually abandoned by the supreme court, state supreme courts in construing their own state constitutional provisions in many cases continued the earlier approach which requires that legislation be justified under distinct and traditional headings.

Police power has occasionally been invoked to sustain rather than to invalidate legislation. This has been true in dealing with laws which impair the value of property, *e.g.,* by shutting down a still on the advent of prohibition or by restricting the use of property through zoning; the court has sustained such legislation on the ground that effective exercise of the police power justified the restriction. But this reference to police power is only another way of saying that constitutional provisions for the protection of property, such as those of the 5th and 14th amendments, cannot have been intended to block the necessary processes of government even though some financial loss may result In similar manner, the police power has been invoked in deciding whether laws, such as those suspending mortgage obligations in times of economic depression, violate the constitutional prohibition against impairing the obligation of contracts. In all these cases, resolving the question whether public or private interest must yield has called for balancing delicate and elusive considerations applicable to each individual case; the general concept of police power, although often invoked, has not in reality supplied the specific materials for decisions.

POLIDORO CALDARA DA CARAVAGGIO: see CARAVAGGIO, POLIDORO DA.

POLIGNAC, an ancient French family, which had its seat in the Cevennes near Puy-en-Velay (Haute Loire). It can be traced to the 9th century, but in 1421 the male line became extinct. The heiress married Guillaume, sire de Chalanqon (not to be confused with the barons of Chalanqon in Vivarais), who assumed the name and arms of Polignac.

The first historically important member was Cardinal MELCHIOR DE POLIGNAC (1661–1742), a younger son of Armand XVI, marquis de Polignac, who became a distinguished diplomatist. In 1695 he was sent as ambassador to Poland, where he brought about the election of the prince of Conti as successor to John Sobieski (1697). In 1712 he was sent as the plenipotentiary of Louis XIV to the Congress of Utrecht. During the regency he became involved in the Cellamare plot, and was sent to Flanders for three years. From 1725 to li32 he acted for France at the Vatican. In 1726 he received the archbishopric of Auch, and he died at Paris in 1742.

Prince JULES DE POLIGNAC (1780–1847), son of Count Jules (d. 1817). played a conspicuous part in the clerical and ultraroyalist reaction after the Revolution. Cnder the empire he was implicated in the conspiracy of Cadoudal and Pichegru (1804). and was imprisoned till 1813. After the restoration of the Bourbons he held various offices, received from the pope his title of "prince" in 1820, and in 1823 was made ambassador to the English court. On Aug. 8, 1823, he was called by Charles X to the ministry of foreign affairs. and in November became president of the council. His appointment was taken as symbolical of the king's intention to overthrow the constitution, and, with the other ministers, he nas held responsible for the policy which culminated in the issue of the Four Ordinances uhich were the immediate cause of the revolution of July 1830. On the outbreak of this he fled for his life, but was arrested at Granville and condemned to perpetual imprisonment. The sentence was commuted to one of exile by the amnesty of 1836. During his captivity he nrote *Considérations politiques* (1832). He spent some years in England. but was permitted to re-enter France on condition that he did not live in Paris. He died at St. Germain on March 29. 1847.

POLISH LANGUAGE, Polish, the mother tongue of probably 30.000.000 speakers, belongs to the western group of the Slavonic languages (*q.v.*). Its first written records consist of proper names in Latin documents of the 12th century, and extant manuscripts containing any considerable amount of connected Polish text go back no earlier than the 14th century. The modern literary language may be dated from the 16th century. when the ferment of Reformation, Renaissance and Counter-Reformation produced the first outstanding Polish writers, such as Mikołaj Rej, Jan Kochanowski. Piotr Skarga and others associated with the Golden Age of Polish literature. Under their cultivation, Polish developed with astonishing rapidity into the refined instrument of literary expression that it has since remained.

Foreign influences on Polish have been numerous, but (except for the macaronic aberrations of the late lith and early 18th centuries) have been easily absorbed without harm to the integrity of the language. The introduction of Christianity brought not only Latin, but also Czech, the language of the first missionaries, into living contact with Polish. As an already developed literary language. Czech continued to enjoy high prestige among the Poles as late as the 14th and 15th centuries. and there are still Polish words whose form betrays their Czech origin, such as *hańba* "disgrace," *brama* "gate," *władać* "to rule." The large medieval German immigration and settlement in Polish cities is reflected in an extensive layer of the vocabulary. such as *ratusz* "town hall," *burmistrz* "mayor," *malarz* "painter." *handel* "trade," *rachunek* "account." *gmach* "building," *szlachta* "nobility" and many others (compare German *Rathaus,* Biiugermeister, *Maler, Handel, Rechnung, Gemach, Geschlecht*). Italian (at the time of the Renaissance), French (in the 17th and 18th centuries) and English have supplemented the Polish vocabulary. In addition; special mention should be made of White Russian and Ukranian influences, particularly as they penetrated into Polish through the works of writers from the eastern borderlands.

Polish shares with other West Slavonic languages a number of notable phonological characteristics, such as: (1) fixed stress accent—in Polish, on the penultimate syllable of the word; (2) nonpalatalization of Common Slavonic (CS) velars in forms like kwiat, *gwiazda*—compare Czech *květ, hvězda* and contrast Russian *cvet, zvezdá;* (3) the development of CS *tj,* dj to hissing, sounds, as in *świeca, miedza* (<CS **světja, *medja*)—compare Low Sorbian *swěca, mjaza* and contrast Russian *svečá, mežá;* (4) š (spelled *sz*) resulting from the second palatalization of CS *x,* as in *wszystek,* wszak—contrast the hissing sibilant in Russian ves', *vsjákij;* (5) preservation of dental stops before *l,* as in *wiódł, mydło*—compare Czech *vedl, mýdlo* and contrast Russian vel, *mylo.*

More or less peculiar to Polish, particularly in contrast to Czech and Slovak, are such phenomena as: (1) nasal vowels (spelled *ę, ą*), indirectly continuing the nasal vowels of CS. as in *mięso, trząść*—contrast Czech *maso, třásti;* (2) dispalatalization of CS *e, ě, ŕ* to o, a, *ar* before nonpalatalized t, d, n, *s, z, r* and *ł* as in zona, *wiara, twardy*—contrast Czech *žena, víra, tvrdý;* (3) palatalization of consonants (indicated in the spelling by i following the consonant letter) before e from CS front *jer*—contrast, for example, Polish pies, *dzień* and Czech pes, den.

The dialects, whose difference cause no practical difficulties in understanding. are customarily grouped into a few major types, notably Great Polish and Pomeranian, Silesian, Little Polish and Mazovian. In addition, Cassubian has come to assume the role of a Polish dialect although, historically speaking, it is not. The dialect base of the literary language, which displays some features associated with Great Polish and others associated with Little Polish, is still a matter of dispute.

POLISH LITERATURE. Although Poland's historical presence in Christian Europe dates from the 10th century. Polish literature was late in emerging. This was because of Poland's geographical remoteness from cultural centres and the difficulties that assailed the young state. frequently attacked from without by plundering invaders and weakened from within by division into small principalities; an additional factor was the foreign clergy.

THE MIDDLE AGES

Latin Remains. — Just as in other European countries, Latin was at the beginning the only literary language in Poland Early writings were confined to lives of saints such as the life of St. Wojciech or Voytech (Xdalbert), the first Polish martyr (d. 997), probably written by his brother, a Czech (a 12th-century version was undoubtedly already Polish). The 13th century brings two tales of the life of Stanisław of Szczepanów, uhose story bears a great similarity to that of Thomas à Becket. Ecclesiastics are also the authors (in Latin again) of the beginnings of historical writing which took the form of annals and chronicles. An anonymous author called Gallus, a Frenchman most probably, wrote a biography of King Bolesław III Wrymouth in the *chanson de geste* style brought up to 1113. Wincenty Kadłubek (1160–1223), an ecclesiastic who studied in Paris. wrote a chronicle with all the characteristics of an allegorical, devotional romance in a very artificial and florid style. The so-called *Chronicle of Great Poland* relates events up to 1271. The masterpiece among chronicles is the *Historia Polonica* written by Jan Dlugosz (*q.v.;* 1415–80). It is the first and. for centuries, the only attempt at a systematic and scholarly history of mediaeval Poland.

The 15th century produced a lay writer and the first man openly to criticize the church in the person of Jan Ostroróg (1436–1501), author of *Monumentum . . . pro Reipublicae ordinatione.* The first Polish lay poet, Stanislaw Ciolek (1382?–1437), wrote court poetry on a European pattern.

Polish Remains. — The vernacular was at first only admitted by the church in circumstances where Latin could not meet particular needs. It was used in prayers, sermons and songs The oldest Polish literary text is a song in honour of the Virgin Mary, the *Bogurodzica;* its archaic language is used with high artistic craftsmanship. Although it belongs to the category of church hymns, it may be presumed to be an original work, no Latin prototype ever having been found. The first copy dates from the 14th century but it was probably written much earlier.

The practice of preaching became established toward the end of the 13th century when the Polonization of the clergy made itself felt. The *Sermons of the Holy Cross,* the oldest specimen of Polish prose, odd scraps of six sermons, dates from the end of the 13th or the beginning of the 14th century.

The first translation of a psalter which has been preserved (the so-called *Psalter of Queen Jadwzga)* dates from the end of the 14th century and the text is in three languages Latin. German and Polish (the latter probably a copy of an earlier manuscript). Jędrzej of Jaszowice the chaplain of Queen Sofia. widow of King Władysław II Jagiello, made a thorough translation of the Bible in 1455, but only parts have been preserved. This again was based on an earlier, now lost, translation.

The natural supplement to those works were the Polish lives of saints, legends and apocrypha. *The Meditation on the Ltfe* of *Our Lord Jesus* appeared in manuscript form at the end of the 1 jth century. *Raj duszny* ("The Soul's Paradise," 1513), a prayer book by Biernat of Lublin. is the first book printed entirely in Polish

Toward the end of the 15th century devotional literature is supplemented by secular works. Song literature is represented by a song directed against "the Roman Antichrists" written by Jędrzej Gałka, a follower of Wycliffe and Huss. The highest literary standard was achieved in a work of morality poetry, the *Dialogue Between Master and Death,* satirical and grotesque.

Mediaeval literature was slow in disappearing in Poland and some of its characteristics lived on well into the 16th century. Marcin Bielski (1495–1575), although a Proteslant in creed, was one of the representatives of late mediaevalism. He was :he author of the *Kronika uszystkiego Swiata* ("Chronicle of the World," 1551), the first book on general history in Polish.

This period shows no original characteristics: its literature is but a peripheral part of the western European Christian literature. It produced no outstanding work of universal appeal and it lacked certain genres (*i e.,* chivalrous poetry). After a very slow and difficult start, there was a sudden leap forward at the time of Casimir III the Great. a catching-up with the rest of Europe. It was rnarked less by literary works than by the appearance of a greater number of thinkers and men of learning such as Paweł Włodkowic (d. 1435).

RENAISSANCE

The Renaissance reached Poland comparatively late, lasted for a shorter period than in other countries but flourished abundantly; hence the name "golden age" given to it. This blossoming was caused by several factors such as external security, constitutional consolidation and the disturbance caused by the Reformation. All this occurred because of close contact with the west, above all with Italy whence came the inspiration of two generations of poets, the first continuing to write in Latin, the second using both Latin and Polish.

The First Generation of Humanists. — The humanists made their appearance at a time when the lingering echoes of mediaevalism still resounded. Among them were Andrzej Krzycki (1482–1537), chancellor, bishop and primate, author of witty, satirical, sometimes frivolous epigrams and courtly panegyrics as well as of touchingly sincere religious poems and of political verse; and Jan Flachsbinder, known as Joannes Dantiscus (1485–1548), a courtier, diplomat, author of incidental verse, love and panegyrical poetry, who gained laurels in Vienna for his political and moral epistles. The dominating figure of this group was Klemens of Januszkowo (Janicius, 1516–43), the son of a peasant. student at the university of Padua, poet laureate and the first true poet in Poland. His tender elegies, in the manner of Tibullus and Ovid, bear the mark of his personality, full of deep emotion and melancholy.

On the Border Line of Two Epochs: **Rej.**—Between the two generations of Renaissance humanists looms the massive personality of Mikołaj Rej of Nagłowice (1505–68). A self-educated man of extreme vitality and of the greatest literary force, he reflected the clash of two ethical ideals, the mediaeval and the Renaissance. He is the first truly original writer in Polish and the first widely read writer of his time; hence his right to the title of "the father of Polish literature." He wrote numerous works in verse and a large collection of satirical epigrams called *Figliki* ("Trifles," 1574). But Rej is above all a prose writer with an extremely rich, vivid, expressive and individual style, his most representative works being his *Postilla* (1557), a collection of sermons written from the Calvinist point of view, and the *Żywot człowieka poczciwego* ("Life of an Honest Man." 1568). This narrative of an average nobleman's life contains an account of customs and conditions in 16th-century Poland, unique of its kind.

Kochanowski and the Second Generation of Poets. — Jan Kochanowski (1530–84) is the leading personality of this generation and of the whole period. The son of a country squire, he studied in Padua. He met Ronsard in Paris and became acquainted with his works written in French. Kochanowski wrote in Latin to the end of his life, but his importance lies in his numerous works in Polish. He was the first in Poland to attempt heroic-satirical poetry; he wrote the first Polish classical drama on a subject taken from the *Iliad, Odprawa posłów greckich* ("The Dismissal of the Greek Envoys," 1578). Best of all, however, were his lyrical works. His translation of the *Psalterz Dawidów* (1578) shows a happy blend of sensitivity and mastery of poetic form as well as the painstaking care of an accomplished philologist. The *Fraszki* ("Trifles"). of which he wrote about 300, are his most typically Renaissance works. displaying a vigorous joy of life with epigrammatic brevity and dramatic precision. The posthumous *Pieśni* ("Songs," 1 j86) in their great variety include love songs, patriotic songs and festive and meditative songs. The crowning work of Kochanowski, the first Polish masterpiece which can be put alongside the great European works, are the *Treny* ("Laments," 1580), the outcome of a crisis through which he passed after the death of his infant daughter and of his recovery of spiritual harmony. Kochanowski ranked as a classic already during his lifetime; he exercised an influence unrivaled until Mickiewicz.

Among poets in Kochanowski's circle Szymon Szymonowic (1558–1629) should be mentioned. A burgher of Lwów, educated in Cracow and abroad, he published a collection of *Sielanki* ("Pastorals," 1614), introducing to Poland a new kind of poetry inspired by the classics but instilled with original life and colour.

Renaissance Prose.—The 16th century's prose ranks with the poetry of the age and sometimes even surpasses it in vitality and range. The first place among prose writers writing exclusively in Latin belongs to Andrzej Frycz Modrzewski (1503–72). In his *De Republica emendanda* (1551–54) he evolved a bold concept of a social and political system which reached out far beyond the accepted ideas of his own time; it was based on the Christian principle of the equality of men before God and before the law. Polish prose of the period is represented by three outstanding men: Stanisław Orzechowski (1513–66), Łukasz Górnicki (1527–1603) and Piotr Skarga (1536–1612). Orzechowski was a controversialist who commanded a keen and artistically sure range of vocabulary and imagery, hitherto unknown in Poland. Górnicki, in his free and original version of Baldassare Castiglione's *Il Cortegiano,* which he transplanted on Polish soil and adapted to Polish conditions (1566). created, in aristocratic prose, the ideal of the Renaissance man. Skarga. a militant Jesuit, the first representative of the Polish Counter Reformation, wrote *Żywoty Świętych* ("Life of Saints," 1579), the most popular among the didactic works of old Poland Skarga's masterpiece, unsurpassed by anything in Polish Renaissance prose. was the *Kazania sejmowe* ("Parliamentary Sermons." 1597). This treatise was written by a royalist who saw his country's salvation in the strengthening of royal authority, the curtailing of the rights of parliament and the rejection of the Reformation. His prose has an extraordinary fervour.

The 16th century left a great wealth of historical writings, though none of them may be compared with Dlugosz' work. It also witnessed the beginnings of polemical writing, a characteristic of Polish literature which flourished until the collapse of the old Polish state. The most outstanding representatives of this type of literature are Cardinal Stanislaw Hose (Stanislaus Hosius, *q.v.;* 1504–79), author of *Confessio fidei,* translated into almost every European language, and, among the anti-Catholics, Szymon Budny (c. 1535–*c.* 1596), a member of the Polish Brethren, who wrote in language of great beauty. There appeared many translations of the Bible published by Protestants and Catholics alike. The Catholic translation (1593) by Fr. Jakub Wujek (1540–97) is the Polish counterpart of the authorized (King James) version and an outstanding literary work.

Polish literature in this period reflected Poland's position as a great poner, the evolution of the nobility as a ruling class and the economic prosperity of the country. It became a national literature expressing a fully awakened collective awareness and the ethos of a people, its love of rural life, sense of stability and a moderate optimism. It radiated strongly to countries east of the Polish border and above all to Moscow. Rej's *Postilla* appeared both in Russian and in Lithuanian. The Moldavian poet Miron Costîn wrote in Polish. In the west the culture of the Polish Renaissance was represented by men of high repute such as Nicolaus Copernicus *(q v.).*

BAROQUE

In contrast with the Renaissance, the baroque appeared in Poland very early, almost at the same time as in Italy. In 1564 Poland accepted the resolutions of the Council of Trent and invited the Jesuits to settle in the country. The baroque style and the attitude of mind that accompanied it were congenial to the Polish spirit. The baroque period engendered very considerable literary output, in spite of almost incessant wars.

Baroque **Poetry.**—An early representative, a forerunner even, of the poetry of this period is Mikołaj Sęp-Szarzyński (1550–81), a contemporary of Kochanowski. He died in his prime and left only one volume, *Rytmy* (1601), erotics, epigrams, religious and chivalrous poetry akin to the English "metaphysical poets."

Polish baroque had a special preference for two literary forms, the bucolic and the satire. The first is represented by Samuel Twardowski (1600–61) and his mythological pastoral *Daphnis* (1638), written in flowing octaves. In the same group Szymon Zimorowic (1608–29), with *Roksolanki,* graceful, tuneful and subtly intricate in form, represented a fresh development of the love lyric. Foremost among the satirists is Krzysztof Opalinski (1610–56), a haughty Polish magnate. His satires in blank verse are violently Juvenalian, keenly satirical and pessimistic.

A remarkable development of lyrical poetry produced two contrasting literary tenors. The first was a sort of rustic poetry of the gentry, praising country life and showing a markedly religious, though not very profound, attitude toward life; the second produced a poetry of extravagant conceits in the *seicento* manner. The first is represented by Wespazjan Kochowski (1633–1700), soldier and country squire; his *Psalmodia Polska* (1695) was written under the impact of John Sobieski's victory over the Turks at Vienna. In rhythmical, poetic and biblical prose, it is an outstanding work. The other contrasting line of baroque lyrics is represented at its best by Jan Andrzej Morsztyn (1613–93), a court dignitary and an able diplomat deeply read in Italian and French poetry. His *Psyche* is a free paraphrase of Giambattista Marino's work; he translated Corneille's *Cid* (1661) for the royal theatre. His court lyrics, mostly love poems of refined style and intricate form. achieved the peak of literary artistry in the baroque lyric. The palm for other forms of baroque poetry goes to Maciej Kazimierz Sarbiewski (1595–1640), a Jesuit and a poet laureate, for his Latin writings. His *Lyricorum libri* (1625) went through 36 editions in the 17th century and as many in later times. It was internationally known, particularly in England.

Heroic epics mere the ambition of the age. Torquato Tasso's *Gerusalemme liberata,* the classical example in this field. was brilliantly translated by Piotr Kochanowski (1566–1620) and inspired attempts at historic epic writing. Wacław Potocki (1625–96), a versatile and prolific writer. produced *Wojna chocimska* ("The War of Chocim"), a verse chronicle of great poetic vigour. Potocki practised all literary genres. including the short story and the novel in verse form.

Baroque Prose.—The prose of the period does not rise to the level of Renaissance prose or to that of the poetry of its own time. Memoirs are among the best writings of the age. This rich domain is best represented by two works: the first by Stanislaw Zółkiewski (1547–1620), *Początek i progres wojny moskiewskiej* ("The Beginning and the Progress of the Muscovite War," 1612). Żółkiewski's style is impressive in its monumental simplicity. Altogether different are the *Pamiętniki* ("Memoirs") of Jan Chryzostom Pasek *(c.* 1630–1701), a country squire whose writing displays spontaneity, liveliness and humour. Andrzej Maksymilian Fredro (1620–79) in his *Przysłowia* ("Proverbs." 1658), a collection of aphorisms. displayed keen understanding of human nature and reactionary political views. Stanisław Herakliusz Lubomirski (1636–1702), one of the most enlightened men of the time, in his *De vanitate consiliorum,* draws nihilistic conclusions from meditations on political systems.

Decadence and Indications of Change.—The age of baroque stretched into the middle of the 18th century. Its last stage, called after the two kings the "Saxon period." shows signs of decadence. also of the emergence of a nem classical style. The period was dominated by the personality of Stanisław Konarski (1700–73) whose writings forecast the coming changes. Konarski was a member of the Patres Scholarum Piarum, an advocate of 17th-century French classical poetry, a reformer of schools. of literary style *(De emendandis eloquentiae vitiis,* 1741) and of the decadent political system It li-as not until mid-20th century that this period nas fully appreciated. With the many contradictions it bore. it had produced an abundance of works and was an original contribution to the European baroque.

ENLIGHTENMENT

Close contact with western Europe, especially with France and to a lesser extent with England, for the first time in Polish history, characterizes the period of the Enlightenment. Certain ideas and tendencies of the second half of the 18th century coincided with the peculiar situation of Poland. The country, exhausted by the wars of the preceding century. burdened with a corrupt political system, was menaced by aggressive neighbours. Literature at this period is imbued with a desire to improve and reform, to strengthen the state against collapse and, at the least, to save Poland's national culture.

Drama. — The earliest significant event was the inauguration in 1765, on the king's initiative, of the first public theatre. Foremost among a line of playwrights inspired by Molière was Franciszek Zablocki (1750–1821), from 1779 the chief provider of stage plays. He practised the art of Polonizing foreign comedy plots successfully. instilling them with a Polish atmosphere and often a perfect poetical rendering. He wrote about 60 plays. Some, like *Fircyk* w *zalotach* ("The Dandy's Courtship." 1781), still delight modern audiences.

The comedies of Aleksander Fredro (1793–1876) are the crowning achievement in drama. Written toward the end of the period. their appearance coincided with the birth of romanticism in Poland. In them the influence of Molière and the more recent one of Carlo Goldoni were apparent.

Prose. — The writing of the age of Enlightenment was mainly didactic. Periodicals were important, above all the Monitor (first issue 1763). The most representative writers are Stanisław Staszic (1755–1826) and Hugo Kołłataj (Kollontaj) (1750–1812). Staszic, in his Przestrogi dla *Polski* ("Warning to Poland," 1790), voiced the need of moderate political and social reforms. Kołłataj placed his talent at the service of the Reform party both as a politician and as a writer. He advocated the "mild revolution" and was one of the authors of the constitution of May 3, 1791. His works attain the high standard of French 18th-century prose.

Two Principal Trends in Poetry. — Earliest of the poets of this period was Bishop Adam Naruszewicz (1733–96). His works are representative of the transition from baroque to classicism. He also won a place among the prose writers of the epoch with his important *Historia* narodu polskiego ("History of the Polish Nation." 7 vol., 1780–86). After Długosz, this was the second scholarly treatment of the subject. The central figure of the period was Ignacy Krasicki (1735–1801), prince-bishop of Warmia, truly European and modern in his writings. The latter include two comic-heroic poems, Satyry (1779) and Bajki i przy*powieści* ("Fables and Moral Tales," 1779). His Fables, epigrammatic in style, gems of conciseness and precision, are Krasicki's masterpiece outstanding among the poems of the age. Krasicki worked also as a novelist. His most important novel is *Doświadczyńskiego przypadki* ("The Adventures of Mr. Dośtviadczynski," 1776), the first Polish novel in the modern sense. Stanislaw Trembecki (1735–1812) equals Krasicki in clarity and is his superior in expressiveness of language. He wrote fables in the manner of La Fontaine, Anacreontics in the French manner as well as solemn odes and epistles.

The second trend in poetry is represented by a group of lyric writers whose rationalism is balanced or even outweighed by their sentimentality. The principal and most popular figure among them was Franciszek Karpinski (1741–182j). His love songs and pastorals, together with his religious songs, are still sung.

These two opposing trends were to outlast the partitions of Poland (1772–95). Classicism still lingered on. with its centre in Warsaw, gradually becoming formal and spiritless. The other trend was toward an expression of feeling. Its most, representative personality was Jan Paweł Woronicz (17j7–1829). His *Hymn* do Boga ("Hymn to God") strikes a note of religious and political prophecy which was later to become the creed of Polish Nessianism; this and others of his works brought the first indications of a tendency to idealize the past of the lost independent state.

From the spirit of Enlightenment sprouted a new and widespread cultural movement whose most imposing work was the *Słownik języka* polskiego ("Dictionary of the Polish Language," 6 vol., 1807–14) by Bogumił Linde (1771–1847). The personality which bridges the gap between the two eras. before and after the partitions, is that of Julian Ursyn (Ursin) Niemcewicz (*q.v.;* 1757–1841), the first Polish writer thoroughly acquainted with English literature. He was the first to write original *dumy* (ballads) under the influence of James Macpherson's *Ossian* and Thomas Percy; his *Śpiewy* historyczne ("Historical Songs," 1816) are a collection of historical ballads of a commonplace style but of great popular appeal. His Jan *z Tęczyna* (1825) is the first Polish romance in Sir Walter Scott's style.

The literature of the period of Enlightenment re-established a close contact with the west and, at the same time, became the mouthpiece of national awareness. Although mainly didactic in character, it reached high artistic standards and introduced hitherto unknown genres; Krasicki's Fables remains a work of lasting appeal. Although it was a literature of a community undergoing a severe crisis, it exercised an unmistakable influence on neighbouring countries (Krasicki on Russian, Czech and even Rumanian writers).

ROMANTICISM

The romantic movement began in Poland a quarter of a century later than in England and Germany, but it lasted longer than in any other European country. It coincided with a tragic moment in Poland's history, the loss of independence and the instinctive search for new sources of strength. Romanticism was to become one of them. It developed eventually into a distinct phenomenon, the most remarkable in Polish literature.

Romantic Poetry. — The publication in 1822–23 of two volumes of Poezje ("Poems") by Adam Mickiewicz (*q.v.;* 1798–1855) became a literary event of major importance. Mickiewicz was to become the leader of the romantic movement. The only author whose works do not show the influence of Mickiewicz was Antoni Malczeski (1793–1826), author of Maria, the first romantic tale in Byronic vein. The collapse of the national insurrection in 1831 drove the cultural élite of Poland into exile to France. This was the beginning of an experiment unique of its kind; the entire literature was born and shaped far from the mother country. The four greatest poets of the era, Mickiewicz, Słowacki, Krasinski and Norwid, were all refugees and all wrote in exile.

Juliusz Słowacki (1809–49), a romantic in the truest sense of the term, soon became Mickiewicz' rival. However. full recognition of his genius came long after his death. He began by writing poetical novels in the manner of Byron as well as excellent lyrical poems. As a counterpart to Mickiewicz' Dziady ("Forefathers") he published *Kordian* (1834), a drama of conspiracy and romantic spirit. The same applies to Anhelli (1838), again a counterpart to Mickietvicz' Ksipgi *pielgrzymstwa* ("Books of Pilgrimage"). Słowacki knew how to instill traditional forms with a new aesthetic content. *W* Szwajcarii ("In Switzerland." 1839) is a transformed pastoral. exalted to an unprecedented degree of subtlety; Ojciec *zadżumionych* ("The Father of the Plague-Stricken") discovered entirely new possibilities for the romantic poetical narrative. Much of his work comprises dramas written without experience of the stage and without the slightest hope of seeing them produced in a theatre. Nevertheless, these made Słowacki one of the greatest Polish dramatists. These plays show in turn his connection with the French romantic drama (Maria *Stuart, Mazepa*); with Shakespeare, whose work provided an experience intensely felt by Słowacki (*Balladyna,* a ballad in dramatic form with the charm of a fairy tale, and *Horsztyński,* which may be called the Polish *Hamlet*); with the antique tragedies (Lilla *Weneda,* the drama of a dying nation); and with Pedro Calderon (*Książę niezłomny,* a creative paraphrase of El *Principe* constante). The crowning effort of his dramatic ambition was the unfinished *Samuel Zborowski,* a bold transposition of historical and earthly events onto the cosmic plane. The last years of Słowacki's life were devoted to a poem of great length which he left unfinished — Krdl Duch ("The Spirit King," 1849). It is a lyrical and symbolic epic about the fate of a people! presented as the experience of a series of incarnations of the spirit of the nation.

Zygmunt Krasinski (1812–59) when 23 years of age published anonymously (as he did all his other works) *Nie-boska komedia* ("The Undivine Comedy," 1835). This play, making use of short, concentrated scenes (foreshadowing expressionism), presented, for the first time in Europe, the struggle of two social classes, two opposing outlooks and two civilizations. *Irydion* (1836), his second play, is a parable of Poland's fate, presented in the guise of a conflict between the Greeks and the Romans. The notion of Poland as the "Christ among the nations," a concept shared by most romantic writers and called Polish Messianism, is the subject of *Przedświt* ("The Dawn," 1843), a visionary poem.

The three poets—Mickiewicz, Slowacki and Krasihski — were very soon calied *wieszcz,* a term corresponding to the Latin *vates* ("national bard"). The genius of Cyprian Norwid (1821–83) was recognized only half a century later. He belonged to the second generation of Polish romantic poets, joined the writers in exile only in 1846 and became one of the most tragic figures among the refugees. During his lifetime he was completely misjudged and obscure. This lack of recognition resulted from the duality of his attitude. He accepted some of the romantic ideas while sharply criticizing others. He was an antirevolutionary and he opposed the Messianic delusion. Few of his works were published during his lifetime. Most of them appeared only in the 20th century, and an important collection of his lyrics, the *Vade mecum,* was published as late as 1953 in London. His life, his personality, his use of poetical language and the intellectual saturation of his poems are reminiscent of Gerard Manley Hopkins. His aesthetic ideas would place him among the Pre-Raphaelites; he foreshadowed symbolism in literature by inventing "free verse."

The lesser romantic *émigrés* formed the so-called Ukrainian school (the Ukraine played in Polish romanticism a role similar to that of Scotland in English literature). Bohdan Zaleski (1802–86) belonged to this group; his tuneful, playful poems, full of movement and light, owed a great deal to folk songs. Seweryn Goszczyhski (1801–76), a radical, conspirator and revolutionary and a romanticist of horror, wrote *Zamek Kaniowski* ("Kaniów Castle," 1828), a tale in verse with a distinct social bias.

Romantic Prose. — Prose writers in exile were outnumbered by poets. Among the novelists mention should be made of Zygmunt Milkowski (pen name T. T. Jez; 1824–1915), a writer with a very wide range of subjects which included folklore and the history of Balkan countries. The novel of the time is outshone by intellectual prose writing. Here the first place is taken by Joachim Lelewel (*q.v.;* 1786–1861), the most representative of the romantic historians.

Literary criticism is represented by Maurycy Mochnacki (1804–34), the first to outline the significance of the new romantic poetry and its national importance.

Writers in Poland. — Apart from Wincenty Pol (1807–72), representing the older generation, popular and superficial in his prolific writing of patriotic verses, a new generation of romantic poets emerged. Their activity was limited to closed, provincial circles which came into being because of the partitions. In Warsaw a large group of young, exuberant poets called the Warsaw Boheme was formed, but its activities were restricted by political pressure. The only noteworthy and more freely developed talent in this group was Teofil Lenartowicz (1822–93), who sang the praise of the countryside and the peasants of central Poland. In Poznań, under Prussian domination, in a traditionally unpoetical region, Ryszard Berwinski (1819–79) put in a meteoric appearance as a poet; he represented an extreme social radicalism. Kornel Ujejski (1823–97) lived in Lwów and is the author of *Skargi Jeremiego* ("The Lamentations of Jeremiah," 1847), a collection of elegies written under the impact of the tragic bloodshed during the peasant riots against the Galician landowners.

The situation of prose writers at home was the reverse of those in exile. Henryk Rzewuski (1791–1866), a genuine artist, belonged spiritually to the previous century; he wrote *Pamiątki Seweryna Soplicy* ("The Memoirs of Seweryn Soplica," 1839), a series of narratives on 18th-century themes evoking the atmosphere of the Polish baroque. Toward the end of the romantic period the first signs of a realistic tendency may be discerned. It is represented by the abundant output of Józef Korzeniowski (1797–1863). More important than his dramas, his folklore play *Karpaccy Gdrale* ("The Carpathian Highlanders," 1843) and his social comedies are his novels *Spekulant* (1846) and *Kollokacja* (1847), portraying the world of impoverished gentry in a remote countryside.

The dominating figure among the prose writers of the period is Józef Ignacy Kraszewski (*q.v.;* 1812–87), a giant of literary prolificacy (he published about 500 volumes of fiction, history, criticism, etc.). His most daring enterprise was a series of historical novels, covering the whole of Polish history from prehistoric times.

Romanticism made a deep mark, particularly as it appeared in a period in which literature played an exceptional role, not found in any other country or at any other time. It was not only the voice of the nation's awakened consciousness but its greatest asset, "a dominion over men's minds" which replaced government in the normal sense of the term. Polish romanticism, though oppressed by the realization of its special mission, produced works of the highest value and so far unsurpassed. They reached the homeland where they were prohibited and their possession and reading punished. Abroad they often provoked lively reactions. It may suffice to mention Mickiewicz' influence on Félicité de Lamennais and on the Slavonic literatures and George Sand's opinion when she compared Mickiewicz with Goethe and Byron. This exalted artistic estimation stood the test of time, though the practical implications of Polish romantic literature led to the disastrous insurrection of 1863.

POSITIVISM

This name was given to literature of the period which followed the year 1863. Polish positivism was a mood of practical thinking and action, a trend which expressed the rationalist reaction against romanticism and the domination of literature over life. "Work from the foundations" was the new realistic slogan. This meant the renunciation of armed resistance and the concentration of all energies on the preservation of the ideological and cultural assets of the nation.

Prose Works. — The natural consequence of this new outlook was the predominance of journalistic prose over poetry. Aleksander Swigtochowski (1849–1938) was a typical positivist commentator. He had a lucid and critical mind and he did not hesitate to draw radical conclusions from his beliefs. Together with the rest of the positivist Warsaw school of which he was the leader, he voiced democratic, anticlerical and antiaristocratic views.

Even historical prose of the time often had a polemical character. This was especially striking in Cracow, the second centre of Polish positivism. There a more conservative variety of the movement was represented by the so-called Cracow historical school. Michal Bobrzynski (1849–1935), its leading personality, was the author of the *Dzieje Polski* ("History of Poland," 1879) expounding the thesis that Poland's downfall was caused by its own shortcomings, by the absence of strong royal authority and by resulting anarchy.

Bolesław Prus (real name Aleksander Glowacki; 1847–1912) was both an essayist and a novelist. He represented positivism in its most noble and humanitarian form. He worked all his life as a journalist, ranks high among Polish short-story writers and is one of the most brilliant Polish novelists. *Lalka* ("The Doll," 1890) is the most outstanding novel of the time. It is an accomplished and vivid picture of Warsaw of Prus's time, with an intricate plot, presenting a large collection of characters drawn from every stratum of the community. The *Faraon* (1897) is an ambitious evocation of ancient Egypt. Eliza Orzeszkowa (*q.v.;* 1842–1910) was a woman writer of journalistic temperament who wrote on topics ranging from women's suffrage and the problems of general education to the Jewish question. The books of Henryk Sienkiewicz (*q.v.;* 1846–1916), the winner of the 1905 Nobel prize, were positivist in their aim of "lifting up the hearts" but in their subject matter they went back to the golden age and the baroque.

Toward the end of the period the somewhat tendentious didactic realism of Orzeszkowa and the idealizing realism of Sienkiewicz were supplanted by a more objective naturalism. Its principal promoter was Antoni Sygietynski (1850–1923), a shrewd and knowledgeable critic. Adolf Dygasinski (1839–1902) applied naturalist theories to his novels about animals and to his portrayals of peasant life. The most outstanding personality of this trend was Gabriela Zapolska (1860–1921), who with her many novels and plays belongs partly to the subsequent period. She ranks among the best of European playwrights of her period.

Poetry. — During this period there were only two poets of importance. Adam Asnyk (1838–97), a reflective lyricist of limited power and imagination, and Maria Konopnicka (1842–1910), a lyrical and emotional poetess who expressed her sympathy with the poor.

The period of positivism lasted barely a quarter of a century. In spite of its mainly utilitarian and defensive character it produced, particularly in the novel, works of great artistic value that thanks to Sienkiewicz became known throughout the world.

YOUNG POLAND

This movement is similar to those in western European countries. It denotes a large number of phenomena held together only by a general opposition to positivism. The dominating tone of this epoch was the return to the expression of feelings and to imaginative writing, hence its other name of neoromanticism. It aimed at freeing the arts from utilitarianism, hence a certain affinity with French naturalism and symbolism. Among the pioneers of the movement were Antoni Lange (1861–1929) and Zenon Przesmycki (1861–1944). Following in the steps of Sygietyhski they established again a close contact between Polish and foreign literature, particularly poetry. Both made translations from various languages; both furthered their aim by publishing critical essays. Przesmycki's greatest achievement was the spiritual "exhumation" of Norwid.

Poets. — The great lyricist of the time was Kazimierz Tetmajer (1865–1940). The first two series of his *Poems* (1891, 1894) met with a success as widespread as those of Mickiewicz' in the previous century. The main characteristics of Tetmajer's lyrics are his passionate yet very tender erotism, his nostalgia, disillusionment and pessimism put into an expressive, purposeful and concise form. But he also harboured a deep admiration for greatness and heroism which he expressed in a series of short stories entitled *Na skalnym Podhalu* ("Tales of the Tatras," 5 vol., 1903–10). A man who made his appearance earlier than Tetmajer but became known rather later was Jan Kasprowicz (1860–1926). He forsook didactic, naturalistic, revolutionary and antireligious poetry for lyrical writing of great inspiration in which he contemplated problems of life and death. The crowning work of his lyrical plays and collected poems was the volume *Ginącemu światu* ("To the Dying World," 1902). His *Księga ubogich* ("Book of the Poor," 1916) testifies to his inner harmony and his reconciliation with God and is remarkable for its moving simplicity. Close to Kasprowicz the entirely different talent of Leopold Staff (1878–1957) emerged. In this neoromantic period he is a representative of the classical trend. The dominant trait of his work is his capacity for compressing diverse and profound problems into precise and expressive poetic formulas. Beginning in 1901 with his volume of poems *Sny o potgdze* ("Dreams of Power"), Staff is a poet of extraordinarily long-lived creative force.

Novelists. — The most forceful personality among the prose writers was Stanislaw Przybyszewski (1868–1927). His early works were written in German. After his arrival in Cracow in 1898 he took charge of the periodical *Życie* ("Life"). There he revealed himself as a radical advocate of "art for art's sake" and an inspired prophet of modernism. By mid-20th century his works were outmoded. Of far more lasting value were the books of other prose writers of this age. The foremost personality according to the general opinion was Stefan (Stephen) Zeromski (*q.v.;* 1864–1925). As a result of his passionate interest in social and national problems his role was that of the "nation's conscience." His prose, both in short stories and in novels, displays certain affinities with naturalism, but his deep, sometimes overflowing lyricism, his impressionability and the archaic style of some of his works make him undoubtedly a representative of the neoromantic school. Wladyslaw Reymont (*q.v.;* 1868–1925) wrote novels and short stories dealing with everyday life, oscillating between naturalism and impressionism. His monumental epic, *Chłopi* ("The Peasants." 4 vol., 1904–09), was translated into every European language and he was awarded the Nobel prize in 1924. Just as *Chłopi* satisfied the craving for primitive, instinctive strength, so the novels and short stories of Wacław Sieroszewski (1860–1945) were an answer to the desire to escape mentally into exotic lands. Aesthetic escapism was represented by Wacław Berent (1873–1940).

Drama: **Wyspiański.**—Stanisław Wyspiahski (1869–1907) is supreme in the whole Young Poland movement. Painter, draftsman and designer of stained glass and typographer, he is next to Slowacki the greatest Polish dramatist. He created experimental scenic visions such as only a dramatist endowed with a great gift for the plastic arts and a vivid musical imagination could produce. He foreshadowed many of the revolutionary ideas of Edward Gordon Craig and was the true "artist of the theatre" *avant la lettre.* In his choice of subjects Wyspiahski turned to the problems of the romantic period, to Poland's past and present. He also took themes from Greek history. In two of his plays, *Wesele* ('(The Wedding," 1901) and *Wyzwolenie* ("The Deliverance," 1903), Wyspiański reached the peak of his inventiveness of artistic form and found the loftiest expression of his ideas. In the first, on the foundations of the primitive folk theatre, he created a visionary drama which he used as a vehicle for scathing criticism of the problems of his age. In the second he condemned romanticism and demanded a Poland of political reality, not one of poetical dreams. Thus Wyspiahski became the poet of the Poland that was to be reborn ten years after his death.

Close contact with western European literatures is characteristic of this period. The new generation of writers turned back to the Polish romantics, especially to Slowacki and the newly discovered Norwid, hence its Promethean tone not encountered in other literatures of the time.

RESTORED INDEPENDENCE

Normal conditions of existence, for which poets and prose writers had been fighting for more than a century, decisively affected the literary output and brought a change in its character.

Poetry. — For nearly the whole of the first decade, poetry predominated. A periodical called *Zdrój* appeared in Poznah which displayed certain connections with German expressionism. During the first stage of his career Józef Wittlin (1896–) was a member of this group. He is author of the stirring *Hymns* (1920), depicting the horrors of war, and of *Sdl ziemi* ("The Salt of the Earth." 1935), a novel portraying war experiences through the eyes of a humble man.

In Warsaw several young poets of different leanings formed a group called Skamander. This group had no general program, but was held together rather by the enthusiasm of its members arising out of the new situation. It introduced, however, new thematic, atmospheric and formal elements. The group was headed by Julian Tuwim (1894–1954), a lyricist of unusual emotional power as well as of extreme linguistic sensitivity. Kazimierz Wierzynski (1894–) gave the most striking expression to the intoxicating joy of the new life. His *Laur olimpijski* ("Olympic Laurels") sang the praise of sport, health and physical beauty. The poetry of Jan Lechon (1899–) treats of intellectual and national literary subjects rendered in a balanced classicist form. Antoni Slonimski (1899–) is yet another poet of that group, of a discursive and rhetorical temperament. Jarosław Iwaszkiewicz (1894–) showed himself to be an excellent prose writer. Among the sympathizers of the Skamander were Maria Pawlikowska-Jasnorzewska (1895–1945), the greatest poetess Poland had so far produced, with an exceptional gift for concentration, precision, control and objectivity in her emotional dispositions; Kazimiera Iłłakowiczówna (1892–), another poetess with a note of fantasy and mysteriousness in her poems; Stanisław Balinski (1898–), who strikes the romantic note of egotism and exoticism; and Władysław Broniewski (1898–1962), the poet of social revolution.

There were two other groups, equal in brilliance to the Skamander. Czartak, with an antiurban bent and a strong inclination toward country life and folklore, was headed by Emil Zegadlowicz (1888–1941), a poet, playwright and prose writer of great versatility but with a deplorable facility of writing. The Vanguard followed the steps of modern revolutionary trends in poetry which sprang up in France, Italy and Spain. This group contributed few really accomplished works, but it had a widespread influence upon the regeneration of poetical technique. Julian Przyboś (1901–), an exponent of this group, ranks among the best poets after World War II.

Prose. — Prose writing reached ascendancy in the second decade of independence. The works of Zofia Nalkowska (1885–1955) in their first period belonged to the Young Poland age and were a revelation of the feminine psyche. After World War I she turned to other themes, striving for objectivity in her narration and simplicity in literary technique. Ferdynand Goetel (1890–) came into the limelight after World War I, writing on his experiences in Russia during the Revolution (*Kar-Chat*), which he took up again in his novel *Z dnia na dzień* ("From Day to Day"). Zofia Kossak-Szczucka (1890–) began with the story of her experiences on the eastern border of Poland (*Poioga* ["The Blaze"], 1922) but later turned to historical novels. After World War II she lived in exile. Maria Kuncewiczowa (1897–) also continued writing in exile. She is the author of *Cudzoziemka* ("The Foreigner," 1935). The foremost personality among the prose writers of this period was Juliusz Kaden-Bandrowski (1885–1944). In his maturity he evolved a specific style of his own, a sort of realistic expressionism marked by a certain brutality. In this style he wrote the novel *Czarne skrzydła* ("Black Wings," 1921), set in the coal-mining areas, and the political satire *Mateusz Bigda* (1933).

The second decade brought several *romans-fleuves*. The most remarkable were written by women. The first was *Noce i dnie* ("Nights and Days") by Maria Dąbrowska (1892–). followed by *Krauzowie i inni* ("The Krauzes and Others") by Herminia Naglerowa (1892–). Both paint a vivid panorama of the life in central and eastern Poland in the second half of the 19th century.

Drama. — This literary genre was the weakest during this period. Włodzimierz Perzynski (1878–1930), a novelist who contributed realistic comedies, and Karol Hubert Rostworowski (1877–1938) with his poetical dramas both belong to the previous epoch. Toward the end of his career Rostworowski began writing plays in prose on social and moral problems in modern settings which at times attained the monumental grandeur of antique tragedies. Jerzy Szaniawski (1887–) was the third dramatist; he tried to give new meaning to the symbolist-lyrical drama.

The years of restored independence were a period of a rich and versatile literature which fully reflected the life of a free nation. It maintained a lively contact with western literature. Many translations from foreign languages, including English, were a proof of this interest.

COMMUNIST DOMINATION

Poland's subjugation to the U.S.S.R. inevitably produced a Polish literature in exile in addition to the one at home.

At Home. — During the first five years after World War II works were published in Poland that had been written secretly during the war. In general they represent the final stages of trends that developed during the country's political independence. The most striking are novels: *Mury Jerycha* ("The Walls of Jericho") by Tadeusz Breza (1905–); *Popidt i diament* ("Ashes and Diamonds") by Jerzy Andrzejewski (1909–); a novel of epic character, *Bolestaw Chrobry*, by Antoni Golubiew (1907–); and plays written by the adherent of Christian Personalism Jerzy Zawieyski (1906–).

The five years which followed bear the mark of the so-called social realism. This vague theory signifies in fact the subordination of literature to political directives and to Communist party control. No genuinely valuable work appeared during this time. The following may be considered above average: *Między wojnami* ("Between the Wars"), a trilogy by Kazimierz Brandys (1916–); and *Pamiqtka z Celulozy* ("A Souvenir of Cellulose") by Igor Newerly. The prevailing official doctrine exerted an even more disastrous effect on poetry. A partial deviation from the general rule may be noted in the works of Mieczysław Jastrun (1905–) and the prematurely deceased Konstanty Gałczyński (1905–45), whose poem *Niobe* is the only work of value to be born of the compromise between the doctrine of social realism and free poetical invention.

In Exile. — Literature in exile struggled against great odds. It was a literature of a political community dispersed all over the world. Among writers in exile were lyricists from the old Skamander group—Wierzyński, Lechon and Balinski, whose thematic and formal range had widened. From the circle close to the prewar avant-garde group there were three poets—Józef Lobodowski (1909–), whose work has been creatively enriched by Spanish and Spanish-Arabic lyric forms, Marian Czuchnowski (1909–) and Czeslaw Milosz (1911–). The two last are prose writers as well (Milosz won the Prix Littéraire Européen in 1953 for his novel *The Conquest of Power).*

Prose works were to a large extent dedicated to memoirs of the years spent in Soviet prisons and forced labour camps. Foremost among these from the literary point of view are *Between the Hammer and the Sickle* by Waclaw Grubinski (1883–) and *A World Apart* (1951) by Gustaw Herling-Grudzinski (1919–). Herminia Naglerowa's novel *The Case of Jdzej Most* is an artistic, strictly objective projection of the author's personal experiences in a Soviet prison. Novelettes by Czesław Straszewicz (1904–) and short stories in a picaresque style by Janusz Kowalewski (1910–) are an original contribution to postwar prose. They mark a reaction by the younger generation of writers against romantic pathos and the same may be said of *Transatlantyk* by Witold Gombrowicz (1904–), a satirical half novel, half memoir. Jerzy Pietrkiewicz (1916–), author of the *Knotted Cord* (1953), a novel written in English, is also a poet, playwright and historian of literature.

The essay occupies an important place and is represented by a number of writers such as Jerzy Stempowski (1894–), Tymon Terlecki (1905–). Wiktor Weintraub (1908–) and Stefania Zahorska (1896–). Mention should be made of the brilliant and passionate Zygmunt Nowakowski (1891–), columnist, novelist and playwright.

BIBLIOGRAPHY.—In Polish: G. Korbut, *Literatura polska* (1929–31), a general bibliographic compendium; addenda, contributed since 1951 by Maria Danilemicz in *The Year's Works in Modern Language Studies* (Cambridge); A. Brueckner, *Dzieje literatury polskiej w zarysie*, 2 vol., 3rd ed. (1921); K. Czachowski, *Obraz współczesnej literatury polskiej, 1884–1933*, 3 vol. (1934–36); M. Kridl, *Literatura polska na tle rozwoju kultury* (1945); J. Krzyianowski, *Historia literatury polskiej od średniowiecza do XIX w.* (1953).

POLISH SUCCESSION WAR (1733–35), the name given to a war which arose out of the competition for the throne of Poland between the elector August of Saxony, son of August II (the Strong), and Stanislaus Leszcynski. the king of Poland installed 30 years before by Charles XII of Sweden and displaced by August the Strong when Charles's projects collapsed. The claims of Stanislaus were supported by France, Spain and Sardinia. those of the Saxon prince by Russia and the empire, the local quarrel being made the pretext for the settlement of minor outstanding claims of the great powers among themselves. The war was therefore a typical 18th-century "war with a limited object," in which no one but the cabinets and the professional armies were concerned. It was fought on two theatres, the Rhine and Italy. The Rhine campaigns were entirely unimportant, and are remembered only for the last appearance in the field of Prince Eugène and Marshal Berwick — the latter was killed at the siege of Philippsburg — and the baptism of fire of the young crown prince of Russia, afterward Frederick the Great. In Italy, however, there were three hard-fought — though indecisive — battles, Parma (June 29, 1734), Luzzara (Sept. 19, 1734) and Bitonto (May 25, 1735), the first and last won by the Austrians. the second by the French and their allies. In Poland itself Stanislaus, elected king in Sept. 1733, was soon expelled by a Russian army and was afterward besieged in Danzig by the Russians and Saxons (Oct. 1734–June 1735).

POLITIAN (1454–1494). Angelo Ambrogini, known in literary annals as Angelo Poliziano or Politianus from his birthplace, was born at Montepulciano in Tuscany on July 14, 1454. His father, Benedetto, a jurist of good family and distinguished ability, was murdered by political antagonists for adopting the cause of Piero de' Medici in Montepulciano; this circumstance gave his eldest son, Angelo, a claim on the family of Medici. At the age of ten the boy came to study at Florence, where he learned Latin under Cristoforo Landino and Greek under Xrgyropulos and Andronicos Kallistos. From Marsilio Ficino he imbibed the rudiments of philosophy. His genius for scholarship and poetry was early manifested. At 13 years of age he began to circulate Latin letters; at 17 he sent forth essays in Greek versification; at 18 he published an edition of Catullus. In 1470 he won for himself the title of *Homericus juvenis* by translating four books of the *Iliad* into Latin hexameters. Lorenzo de' Medici, who was then the autocrat of Florence and the chief patron of learning in Italy, took Poliziano into his household. made him the tutor of his children and secured him a distinguished post in the University of Florence. Before he reached the age of 30. Poliziano expounded the humanities with almost unexampled lustre even for that epoch of brilliant professors. Among his pupils could be numbered the chief students of Europe, the men who were destined to carry to their homes the *spolia opima* of Italian culture. Not to mention Italians. it will suffice to record the names of the German Reuchlin, the English Grocyn and Linacre, and the Portuguese Tessiras.

Poliziano published the notes of his courses on Ovid, Statius, the younger Pliny. Quintilian and the writers of Augustan histories. He also undertook a recension of the text of the *Pandects* of Justinian, which formed the subject of one of his courses; and this recension, though it does not rank high in the scale of juristic erudition. gave an impulse to the scholarly criticism of the Roman code. His versions of Epictetus. Herodian. Hippocrates, Galen, Plutarch's *Eroticus* and Plato's *Charmides* delighted contemporaries by a certain limpid fluency of Latin style and grace of manner which distinguished him also as an original writer. Of these learned labours the most universally acceptable to the public of that time were a series of discursive essays on philology and criticism, first published in 1489 under the title of *Miscellanea.* They had an immediate. a lasting and a wide renown, encouraging the scholars of the next century and a half to throw their occasional discoveries in the field of scholarship into a form at once so attractive and so instructive. Poliziano was not, however. contented with these simply professorial and scholastic compositions. Nature had endowed him with literary and poetic gifts of the highest order. These he devoted to the composition of Latin and Greek verses. which count among the best of those produced by men of modern times in rivalry with ancient authors. The *Manto,* in which he pronounced a panegyric of Virgil; the *Ambra,* which contains a beautiful idyllic sketch of Tuscan landscape. and a studied eulogy of Homer; the *Rusticus,* which celebrated the pleasures of country life in no frigid or scholastic spirit; and the *Nutricia,* which was intended to serve as a general ,introduction to the study of ancient and modern poetry — these are the masterpieces of Poliziano in Latin verse, displaying an authenticity of inspiration, a sincerity of feeling and a command of metrical resources which mark them out as original productions of poetic genius rather than as merely professorial lucubrations. Exception may be taken to their style: when compared with the best work of the Augustan or even of the silver age. But what renders them note orthy to the student of modern humanistic literature is that they are in no sense imitative or conventional. but that they convey the genuine thoughts and emotions of a born poet in Latin diction and in metre moulded to suit the characteristics of the singer's temperament.

Poliziano's principal Italian works are the stanzas called *La Giostra,* written upon Giuliano de' Medici's victory in a tournament; the *Orfeo,* a lyrical drama performed at Mantua with musical accompaniment; and a collection of fugitive pieces, reproducing various forms of Tuscan popular poetry. *La Giostra* had no plan, and remained imperfect; but it demonstrated the capacities of the octave stanza for rich, harmonious and sonorous metrical effect. The *Orfeo* is a slight piece of work, thrown off at a heat, yet abounding in unpremeditated lyrical beauties. and containing in itself the germ both of the pastoral play and of the opera. The Tuscan songs are distinguished by a "roseate fluency." an exquisite charm of half romantic, half humorous abandonment to fancy, which mark them out as improvisations of genius. It may be added that in all these departments of Italian composition Poliziano showed how the taste and learning of a classical scholar could be engrafted on the stock of the vernacular, and how the highest perfection of artistic form might be attained in Italian without a sacrifice of native spontaneity .and natural flow of language.

Beyond the sphere of pure scholarship and pure literature Poliziano did not venture. He was present, indeed, at the attack made by the Pazzi conspirators on the persons of Lorenzo and Giuliano de' Medici, and wrote an interesting account of its partial success. He also contributed a curious document on the death of Lorenzo de' Medici. Otherwise, his uneventful life was passed as a house friend of the Medici, as the idol of the learned world and as a simple man of letters to whom (with truly Tuscan devotion to the Saturnian country) rural pleasures were always acceptable. He was never married; and his morals incurred suspicion, to which his own Greek verses lend a plausible colouring.

Poliziano died, half brokenhearted by the loss of his friend and patron Lorenzo de' Medici. on Sept. 24. 1494.

POLITICAL PHILOSOPHY. The traditional problems of political philosophy have been the nature and the justification of political obligation and authority. There are here two essentially different sets of questions. First, there are the questions how men came together under governments and what were the motives which originally influenced them to do this and which still prevail to keep them obedient to government orders. These are questions of fact and they are properly studied by social historians, sociologists and psychologists; but before sociology and psychology were established as independent sciences: many political philosophers included speculations on these historical and psychological topics in their works. The second question is that of the ethical justification of obedience to government; or, if we look at it from the point of view of the rulers, that of the moral basis of their authority. This question is the proper concern of political philosophy. In this article some representative answers to it are considered.

Force. — One answer is that there is no ethical justification for government. Rulers govern because they have the power and consequently they govern in their own interest., Subjects obey because they cannot help it: they are the tools of the rulers. Greek sophists, of whom Thrasymachus in Plato's *Republic* is an example, first gave this answer, but it is still alive, for it was the view of the 19th-century anarchists and is still the official Marxist doctrine. "The State is nothing more than a committee for the administration of the affairs of the ruling class" (*Communist* Manifesto); and "With the disappearance of classes the State too will disappear" (Friedrich Engels). How far this is a complete answer will depend on the merits of the alternative answers which follow.

The Organic Theory.—The state has been likened to an organism, the citizens to its organs: "We are members one of another." As an eye is good when it best serves the organism as a whole, so the good citizen is he whose whole life is dominated by the ideal of state service. If he fails to perform his civil functions he should be liquidated ("If thine eye offend thee, cut it out . . ."). The government is the brain of the state, the organ whose function is the control of the other organs in the interest of the whole body.

The difficulties in this theory are these. First, it tends to assume that actual states are ideal, that their governments do control the citizens in the interest of the whole. Secondly, it assumes that there is something correctly described as "the interest of the whole state," to which individual interests can be sacrificed. But there is no such thing: the interests of some can be sacrificed to the interests of others: but the good of the state must be analyzed without remainder into the goods of individual men (as must public health or social welfare). Thirdly. this theory assumes that the state is the only form of association, as was the Greek city-state in the time of Plato and Aristotle when the theory first appeared. But the scriptural quotations cited above stressed the unity and organic character not of the state but of the church. Nowadays, with the vast multiplication of associations, it is impossible for one type of association, the political, to claim the complete self-sufficiency, the overriding authority and the undivided loyalty which the organic theory of the state requires.

The General Will.--On this view it was argued that a moral rule, to be moral, must be self-imposed, and the problem of political authority thus became that of self-government. At first sight this leads straight to democracy as the only legitimate form of government. We have an obligation to obey laws only if we ourselves have made them. But in Jean Jacques Rousseau, who originated this theory, the argument took a different direction, in which it was further developed by Hegel and his followers (*e.g.*, Bernard Bosanquet, The Philosophical Theory of the State). My real good must be distinguished from what at the moment I actually want. My permanent aim, if I am reasonable, is my real good, though my passing desires may thwart and impede it. This distinction between ends or aims is then carried over as a distinction between two selves within me, my rational, true. permanent, higher self and my lower, fluctuating, impulsive, desiring self. When a law compels me to abstain from murder or blackmail it expresses my higher against my lower self. Thus when I obey the law, I am obeying my own real will, the law is self-imposed, and I am "forced to be free" (Rousseau). Since "the good" is the same for all rational men, the real selves of all will be identical. and the state can be said to have (or be) a single will. the general will. There is thus attributed to the state a unity of a type higher even than that of an organism. the unity of a self. In Hegel and his successors this led to a kind of deification of the state as "the march of God upon earth" (Hegel) and as the sole source of moral right and the sole centre of human devotion.

Parallel objections to those against the organic theory are valid here. U'hat is called "the will of the state" is in fact the will of the government, and governments are just as capable as individuals of making irrational decisions based on desire or short-term interest. A state decision is in any sense my responsibility only if I have had some actual share in bringing it about. Much of morality and much of human value is no concern of the state at all. Finally it may be objected that, even if all this theory were literally defensible, what is said of the state could be said of any other association: trade unions, colleges, churches and athletic clubs would have (or be) general wills too.

Pluralism.——From this last criticism there emerged a theory called pluralism in contrast with the "monistic" theory of Rousseau and the Hegelians with their single supreme association. The pluralists varied in their attitude to the state. Some of them found no rational function for the state to perform (except making wars). There they joined hands with the Marxists, who were pluralists so far as they substituted for the state a complex of voluntary associations. Others held that there were certain functions which the state should perform, but these gave it no supremacy over other associations, no monopoly of loyalty, no right to stand as the sole source of morality and no claim to obedience beyond the affairs which were its special charge.

The Liberal View.—These theories have now few defenders; the living issues in politics are to be sought elsewhere. They are here considered under labels which are not used with any suggestion that they correspond to the lines between political parties. The views here considered are distinguished by the divergence between their basic principles and between the elements in politics on which they lay most stress. We have seen how the pluralists asked what was the function of government, what purposes the state in particular among all other associations was alone or best fitted to achieve. This question is the way in which the problem has been seen by the English tradition from Hobbes through Locke and J. S. Mill; and it is on the whole characteristic of British and American thought to look at government in this practical and utilitarian light.

First, government is needed to provide security of life, as Hobbes insisted. No individual is strong enough to guarantee his own security unaided. No voluntary association is sufficiently inclusive or wields the sort of weapons needed to keep violence at bay. But security of life is not all that men need. Security of other interests (especially property. said Locke) and security from all kinds of damage by blackmail, arson, rape, assault, etc. (this was Mill's view) require government action. This is the field of criminal law. The Communist says that the state will wither away at the establishment of a classless society; but Marx and Engels nowhere explain what is to be done about crimes of violence. Lenin does face this problem in one place; he says:

> We are not utopians, and do not in the least deny the possibility and inevitability of excesses on the part of individual persons, or the need to suppress such excesses. But, in the first place, no special machine, no special apparatus of suppression is needed ior this; this will be done by the armed people itself, as simply and as readily as any crowd of civilized people, even in modern society, interferes to put a stop to a scuffle or to prevent a woman from being assaulted (V. I. Lenin, The State and Revolution, ch. 5, sec. 2. in Lenin, Selected *Works*, vol. ii, pt. i, pp. 293–294, Lawrence and Wishart, London, 1951).

But crowds do not part combatants and men do not violate women when there is a crowd standing by. Lenin's recipe is lynch law, and lynch law is notoriously incapable of dealing with most crimes or of dealing justly with those which it does assail. Here then is a clear case for government action.

Secondly, government is required to settle disputes which are not amenable to direct compromise or agreed settlement. This is the province of civil law. If government were to wither away, the victory in every dispute would go to the stronger or to the possessor. Things would be little better if a voluntary society undertook to adjudicate. for some disputants would not fall under its authority, nor could it enforce its awards.

These two functions of protection and of settlement of disputes exhausted the functions of the state as seen by the classic English tradition. Here the work of government is essentially negative: its force is applied only against bad men or against the side in a dispute which has the weaker case; and its only duty to the good and peaceable citizen is to leave him alone, except to the extent that it must tax him and perhaps enlist his services as juryman or soldier to enable it to perform its protective and arbitral functions.

The Socialist View.—English and American governments up to the middle of the 19th century restricted themselves to those minimal negative protective functions. But they performed two jobs which were the seeds of a more positive doctrine of state action. The state protected men's rights from invasion by other men. But there was one right for which it did more than that. On the Hobbes-Locke view. the state's concern with the right to life was to prevent other men at home or abroad from endangering my life. But what if my life is endangered by starvation (not because an ogre has shut me in a dungeon but because I cannot work or cannot find work to do)?

On the strict liberal or protective view, governments should agree with Arthur Hugh Clough:

> Thou shalt not kill, but need'st not strive
> Officiously to keep alive.

But in fact government did so strive, through poor relief and casual wards. Over no other right did government assume this paternal care, but this is obviously the thin end of a very thick wedge. The "right to work" was originally taken to mean the right to do whatever work I can find (and to stop doing it) without interference; and this was how the right was interpreted and protected by English law. But what of the unemployed? Unemployment pay ensured their right to life, not their right to work. It is only since the state undertook the provision of schemes of work and adopted a full-employment policy that the supply of work has been accepted as a government responsibility.

The first seed in fact grew into the welfare state. Kot only life, but education, health and pensions have become government responsibilities. It might be thought that there can be no limit to this extension, and the phrase welfare state encourages this idea. But even its strongest supporters would not propose state-guaranteed supplies of tobacco, cosmetics, television sets or theatre seats. "To each according to his needs"—not his wants—is the socialist slogan: the state should ensure the supply of those things from which. it is thought, no human being should be debarred by accident of birth or wealth or dwelling place. The welfare state really appeals to a principle of justice. not of welfare—to the view that is is unfair that some men should be deprived of things without which life is not worth living (health, education, work) because they cannot afford them.

Though the welfare state is not usually extended to supply luxuries there is sometimes invoked another principle, in addition to that of justice. which would work in that direction. It is the principle of equality—not merely equality of opportunity (which. the principle of justice achieves) but an equality more fundamental still. It is thought wrong that some people should have automobiles. television sets or vacations which others cannot have. On this principle the aim of state education is not merely to provide educational opportunities for those who cannot afford them but to equalize education for all. The aim of taxation is not merely to raise money for necessary and justifiable services but to redistribute and to equalize incomes. It is held to give a child an unfair advantage not only if other children have no education but also if he has parents who can afford to send him to a better school or if he has the ability to pass examinations earlier than other children.

The second seed of a theory much wider than the negative liberal one to be found in 19th-century government was the postal service. For here was the idea that a certain service was required which could not be effectively supplied to all who needed it unless it was supplied by government. This seed has grown into the program of nationalization. This program too has tended to operate on a distinction between needs and wants. There are some services which every citizen in a civilized community has a right to enjoy: roads; drainage; and a clean water supply. All of these used to be supplied by individual enterprise or by private persons or companies working for profit. But this meant that many poor people or people living in remote areas could not have these services or had to pay a prohibitive price for them. But the list has grown to include railways. gas and electricity, where it is more doubtful whether these are needs to which all men have an equal right and which must therefore be state-supplied. We noticed above how the principle of justice was supplemented and in places supplanted by the principle of equality. Here too another basic principle has come in to promote the development of state services: the principle that no man's labour should be exploited for the profit of another man, or. put the other way round, that no man should enjoy income unearned by his own efforts. On this principle there are no limits to nationalization as an ideal. since whenever any industry is nationalized the employment of labour for profit is correspondingly diminished; it ceases to matter whether services nationalized are necessary for civilized existence or whether the nationalization benefits the workers or the public.

The Conservative View.—In opposition to the liberal and socialist principles. it has been objected that they overemphasize human reason. No citizen regards his state in this cool, calculating way as an association existing to do certain jobs for him. "The state ought not to be considered as a partnership agreement in a trade . . . to be taken up for a little temporary interest or to be dissolved on the fancy of the parties" (Edmund Burke). To regard the moral claims of one's country in this light is like doing one's best for one's friends or one's children solely from a lively expectation of favours to come. Around these centres—country, family, friends—gather a loyalty and a devotion, traditions of fellowship and service which mere utility can never explain or exhaust.

Nor is reason an adequate guide for the rulers either: no human individual or committee can be trusted to change a society or to plan its future. The garnered uisdom of centuries expressed in custom, tradition, laws and constitutions, the slow process of unconscious change, adapted perhaps empirically here and there to some immediate problem—these form a better guide than the blue books and blueprints of the planners. The conservative tradition respects the individual. not the abstract identical individuals of liberal theory, the bearers of universal rights, but the individual in his rich variety It would rather have things done in an illogical. confused and piecemeal way, provided that this allowed individual variety and individual enterprise. than in an efficient. streamlined way through uniform leveling and dragooning. It sees state provision and state management in human terms. State or "free" education means education at the taxpayer's expense. It will not deny occasional justice to the Robin Hood ethic of robbing rich Peter to pay poor Paul, but it will require strong justification for it in each case. It sees state control as control by politicians and civil servants. Such control, the conservative would say, may on occasion be justified but there is no such inherent merit in it as to justify rejoicing in its every advance, as the nationalizers do.

Politics and Morals.—The aim of the preceding sections has been to show how political ideals rest on certain moral principles or judgments of value. To work out these connections is the task of political philosophy. But it may be doubted whether it is the task of political philosophy to decide between these principles or the systems erected upon them. Here political thinking is driven back on a fundamental issue in ethics. Some would hold that moral values are subjective: each man must make his own decision between them; none of them can be rationally defended against its rivals. If so, political philosophy cannot claim to do as it once did. to lay down the best kind of state or the best laws.

Analysis.—Developments since the middle of the 19th century have thus tended to diminish the function of political philosophy. Factual questions have been removed from it and handed over to sociology and to psychology. Its noniactual arguments have been driven back into ethics, and ethical principles in their turn have been removed from the field of rational discussion. By the middle of the 20th century, however, philosophical movements were showing a great positive interest in linguistic analysis. and here, it would seem, there was another remaining field for political philosophy. The analysis of language about politics, of such terms as government. sovereignty, law, rights and punishment. remained to be achieved.

POLITIS, NIKOLAOS SOKRATES (1872–1942), Greek jurist and diplomat, a brilliant champion of the peaceful settlement of disputes and of disarmament, was born at Corfu on Feb. 7, 1872. After holding professorships in the faculty of law at Aix-en-Provence, at Poitiers and at Paris, he was in 1914 summoned by Eleutherios Venizelos to reorganize the Greek ministry of foreign affairs, of which he became director-general. Appointed minister of foreign affairs in 1916, he went to the peace conference of 1919 as the delegate of Greece. In the League of Nations, where he was also the Greek delegate, he wrote the report on the Geneva protocol (1924). As vice-president of the Disarmament conference, he drew up the definition of the aggressor there propounded. His lucid, powerful and eloquent speeches put him in the first rank of the delegates to the League.

Politis published a number of books of jurisprudence, including *La Justice internationale* (1924) and *Les Nouvelles Tendances du droit international* (1927; Eng. trans., *New Aspects of International Law*, 1928). These showed him to be at once a thinker of far-reaching interests and a passionate believer in the future of international law. The foundation of the Academy of International Law at The Hague was largely the result of his efforts. In 1937 he was made president of the Institute of International Law. He died at Cannes, France, on March 4, 1942. (CH. D. V.)

POLK, JAMES KNOX (1795–1849), 11th president of the United States, was born in Mecklenburg county, N.C., on Nov. 2, 1795. At the age of 11 he accompanied his family to Tennessee, settling in a-hat is now Maury county. In his childhood formal schooling was impossible because of ill health, but at the age of 20 he successfully passed the entrance requirements for the second-year class of the University of North Carolina. As an undergraduate his record was "correct, punctual, and industrious." As a graduating senior in 1818 he was the Latin salutatorian of his class—the pre-eminent scholar in both the classics and mathematics.

With this academic background he began to read law, in the office of Felix Grundy in Nashville, Tenn., to associate with leading public figures in the state and to make political speeches. In 1820 he was admitted to the bar. Since he was a confirmed Democrat and an unfailing supporter of Andrew Jackson, and since his style of political oratory became so popular that he was characterized as the "Napoleon of the stump," his political career was assured. With him in his rapid rise to political power was his wife, Sarah Childress Polk (1803–1891), whom he married Jan. 1, 1824, during his service in the state house of representatives (1823–25). Mrs. Polk's home was Murfreesboro, Tenn., the temporary state capital. The social prominence of her family and her personal charm a-ere distinct assets for a politically ambitious lawyer. As an official hostess she won the admiration and esteem of the leading figures of the day. For 25 years she was her husband's close companion in state and national politics. In the long period of her childless widowhood she maintained Polk Place in Nashville as a shrine.

James K. Polk was by nature a student of government, by experience a legislator and by force of circumstance an administrator. He was not an easy man to know or to like. Boon companions did not relish his austerity. Associates tolerated but did not approve his inflexible living standards. He had many acquaintances, but very few friends. One friend was Andrew Jackson, who encouraged and advanced Polk and whose influence carried him from the Tennessee house of representatives to the U.S. house of representatives, where he served from 1825 to 1839. From 1835 to 1839 he was speaker of the house. In that service in Washington Polk acquired a reputation as a constant, undeviating supporter of Jacksonian principles. In 1839 he left the house to become governor of Tennessee. Two defeats for a second term (1841, 1843) by small majorities convinced him that to strengthen his party he should return to Washington in some capacity.

Polk's nomination for president on the Democratic ticket in 1844 was unsought by him, for the party had more prominent sons in Martin Van Buren, Lewis Cass and James Buchanan. However, they could not reconcile their differences and a compromise candidate had to be found; since the campaign was to be run on issues and not on personalities, it was decided Polk would do, and the wheel horse of the party as a vice-presidential candidate became the dark horse of the national convention at Baltimore. He was young and he was a party man from the west, and his experience as a legislator, it was thought, would make possible the realization of legislative and executive co-operation and understanding in the functioning of the national government. As a legislator he had taken a number of personal positions of significance in his later career. In his maiden speech in the house of representatives he had advocated a constitutional amendment for the popular election of the president. Later he opposed an appropriation for the Panamá mission because it might lead to war with Spain. In a committee report he stressed the constitutional requirement that public revenue should be reduced to the requirements of the public services. As a member of the ways and means committee he opposed the bank of the United States. While speaker of the house he decided many procedural questions and was usually sustained on appeal by majorities composed of the leaders of both parties. He was a party man and his party feeling was intense, but his integrity was unquestioned. He knew the rights and privileges of the house and he also knew its responsibilities.

Polk was nominated on the ninth ballot of the convention on May 27, 1844, won a 65-vote plurality of the electoral college on Nov. 12, 1844, and was inaugurated president, March 4, 1845. Campaigner Polk surprised the country by taking a positive stand on two burning issues of the day. While other candidates hedged on Texas, he demanded annexation. While other candidates evaded the Oregon problem he openly advocated a drastic change in policy in the boundary dispute with Great Britain. His election was close, but it was decisive—a popular plurality of 38,175 and 170 electoral votes against 105 for Henry Clay.

President Polk not yet 50 years of age was the youngest successful candidate up to that time. He entered the presidency a comparatively young man, full of vigour, and with an expressed zeal to serve his country to the best of his ability. He left the presidency four years later exhausted and enfeebled by the efforts he had made. In office he demonstrated not only skill in the selection of his official advisers but also in the control of these able and competent men. He mas the responsible head of an administration composed of James Buchanan of Pennsylvania, secretary of state; Robert J. Walker of Mississippi, secretary of the treasury; William L. Marcy of New York, secretary of war; George Bancroft of Massachusetts and later John Y. Mason of Virginia, secretary of the navy; John Y. Mason, then Nathan Clifford of Maine and later Isaac Toucey of Connecticut, attorney general; and Cave Johnson of Tennessee, postmaster general. In his formal relations with congress his legislative experience served him well. When his party was united, he yielded to the wishes of congress. When he disagreed with congressional policy and made an issue of it. he fortified his position with recognized precedent and established practice. His formal disapprovals (two message vetoes and one pocket veto) were questioned, but the two returned measures after formal reconsideration failed to command the necessary two-thirds majority for repassage. The house bill on appropriations for rivers and harbours after two days of debate failed repassage, Aug. 4, 1846, by a vote of 96 to 91. The senate bill on the French spoliation claims after a short debate, failed to proper repassage, Aug. 10, 1846, by a vote of 27 to 15. This was during a decade of strong partisanship in congress wherein Polk's predecessor, John Tyler, suffered a repassage of one of his six vetoed measures and Franklin Pierce in his short administration saw five of his nine vetoed measures repassed.

The administration of James K. Polk was marked by territorial gains. The annexation of Texas as a state of the union was concluded—resulting in a two-year war with Mexico. As a consequence of that war the southwest and far west (California), by conquest and by purchase, became part of the U.S. domain. During this period the northwest boundary became fixed by treaty, and the continental United States emerged a recognized reality. Additional achievements included a treaty with New Granada (Colombia) clearing up the problem of right of way for U.S. citizens across the Isthmus of Panama; establishment of a warehouse system which provided for the temporary retention of undistributed imports; and the passage of the Tariffact of 1846. As these helped foreign trade, so the re-enactment of the independent treasury system helped in the solution of domestic financial problems. The expansion of the country westward caused the creation of a new agency, the department of the interior.

The Polk administration should also be credited with the establishment of the U.S. naval academy and the authorization of the Smithsonian institution.

Polk's influence over his congresses may be gauged from the results of the recommendations of four annual messages and ten significant special messages to one or both houses. His control of legislative policy in bitterly partisan congresses must be judged in terms of results, not oratory or parliamentary delay. He recommended with a high degree of success: settlement of a trade dispute with Great Britain; an increase in C.S. armed forces; war with Mexico; peace mith Great Britain over Oregon, making available finances to expedite peace conclusions; collection and usage of Mexican revenues; organization of the Oregon Territory: peace with Mexico providing for limited conquest; removal of tariff restrictions; and a revised treasury system. As an executive he refused information desired by Congress, incompatible mith the public interest. recognized a new French revolutionary government and proclaimed the validity of the Monroe doctrine. These pronouncements were recognized by succeeding presidents.

The diary kept by Polk during his term of office stressed the presidential burden. Day after day, week after week, he recounted in his diary his experiences with the hosts of office seekers who infested Washington and who occupied so much of his public time. Again and again there was evident a note of despair in his writings. He knew from personal experience what an evil an unlimited executive patronage can become. Nevertheless, he felt powerless to change its obligations and too conscientious to avoid its duties. At the close of his term. March 4, 1849, Polk retired to his home in Nashville. where he died on June 15, 1849.

The office of chief executive under Polk was well filled. He maintained it with dignity, with integrity and with a sense of extraordinary duty. His great influence over congress was due to the justness of his policies and the persistence of his efforts in having the members see the questions not as interests of district or section but as matters of national welfare. It was his sturdy character and unblemished reputation that gave weight to his counsels and strengthened his pleas. History may not rate James K. Polk as one of the greatest of U.S. presidents, but for the accomplishments of his short time in office he cannot be rated among the least influential.

Polk, 1845–1849* (1910), an almost complete printing of the manuscript material and a revelation of the mind of a president; E. I. McCormac, *James K. Polk: a Political Biography* (1922); C. G. Sellers, *James K. Polk, Jacksonian, 1795–1843* (1957). (G. C. Ro.)

POLK, LEONIDAS (1806–1864), U.S. general. was born at Raleigh. N.C.. on April 10. 1806. He was educated at West Point, but resigned his army commission six months after graduation to enter the Virginia Theological seminary. In 1831 he took orders in the Protestant Episcopal Church. In 1838 he became missionary bishop of the southwest. and in 1841 he was consecrated bishop of Louisiana. At the outbreak of the American Civil War in 1861, he accepted a commission in the Confederate army and no longer exercised his episcopal authority. His rank in the hierarchy and the universal respect in which he was held in the south, rather than his early military education, caused him to be appointed to the important rank of major general. He fortified the post of Columbus. Ky., the foremost line of defense on the Mississippi, against which Brig. Gen. U. S. Grant directed the offensive reconnaissance of Belmont in the autumn. In the following spring, Polk commanded a corps at Shiloh. In Oct. 1862 he was promoted to lieutenant general. and commanded one of the three corps of the army of Tennessee under Bragg and afterward was in charge of the department of Alabama, Mississippi and East Louisiana. He was killed near Pine Mountain! Ga., on June 14, 1864.

POLKA, a lively dance in 2/4 time of Bohemian origin, characterized by three quick steps and a hop. Introduced in Paris about 1843. it became an extraordinary craze in the ballroom and on the stage, sweeping rapidly across Europe and the United States. Frequently introduced in ballets; such as F. Ashton's *Façade,* it has also retained considerable popularity as a social dance.

(LN. ME.)

POLLACK (Pollachius *virens*), a fish distinguished from others of the cod genus by the long pointed snout, and the prominent lower jaw without a barbel; the colour is greenish, with yellow markings. It ranges from Norway to the Mediterranean, but is most abundant southward; it prefers rocky ground, and is piscivorous. It attains a weight of over 20 lb.

POLLAIUOLO, the name of two Florentine brothers, Antonio, who was a sculptor, painter, engraver and goldsmith, and Piero, who was a painter and sculptor.

ANTONIO POLLAIUOLO (*c.* 1430–1498) was trained by his father as a goldsmith, and his most outstanding work in this field is the base for the silver reliquary of St. Giovanni (1457–59, now in the Opera del Duomo, Florence). Yet his chief claim to fame rests on his works in bronze, such as a lively small group of "Hercules and Antaeus" (Bargello, Florence), which once belonged to the Medici. Called to Rome in 1484, he executed aith the assistance of his brother the lavish bronze tombs of Pope Sixtus IV (now in the SS. Grotte of St. Peter's) and of Innocent VIII (St. Peter's). The latter, with the enthroned figure of the pope giving his blessing. had a considerable influence on later papal tombs. It seems that Antonio learned the technique of painting from his brother and completed a number of pictures in collaboration with him, among them the altarpiece in the chapel of the cardinal of Portugal in S. Miniato, Florence, and the "Rfartyrdom of St. Sebastian" (National gallery, London). Antonio's chief interest was the human figure in motion; he is supposed to have been one of the first artists to concern himself aith dissection and anatomical studies. Hence his engraving "Battle of the Nudes" as well as his drawings took for his and later generations the place of pattern books. He died in Rome on Feb 4, 1498.

PIERO POLLAIUOLO (1443–1496), born in Florence in 1443, was probably a pupil of Alessio Baldovinetti. He painted six of the "Virtues" for the Mercanzia of Florence (1469–70, Uffizi, Florence). His principal work, "Coronation of the Virgin," was painted for S. Agostino, S. Gimignano (now in the cathedral). He died in Rome in 1496.

POLLARD, ALBERT FREDERICK (1869–1948), English historian and editor, was born at Ryde on Dec. 16, 1869, and educated at Jesus college, Oxford. He was elected a fellow of All Souls college, Oxford, in 1898. From 1893 to 1901 he was assistant editor of the Dictionary *of National* Biography. From 1903 to 1931 he held professorial chairs of English history and constitutional history in the University of London. He was founder and first chairman of the Institute of Historical Research. He died Aug. 3, 1948, at Milford-on-Sea, Hampshire.

His publications include Thomas Cranmer and the English Reformation (1898; new ed., 1926); Henry VIII (1902); Factors in Modern *History* (1907; new ed., 1926); Evolution of Parliament (1920); Factors in American History (1925).

POLLEN ANALYSIS (PALYNOLOGY) is the science of the investigation of materials by their content of pollen grains (*q.v.*) or spores. In its widest sense it embraces investigations of honey, of allergies caused by wind-borne pollen and of the natural classification of the higher plants. Nonetheless it mainly concerns the reconstruction of former vegetation by systematic analysis of the pollen and spore content of geological deposits. Pollen is shed in vast amounts from the vegetation (tens of thousands of grains per square centimetre each year), and if it falls into accumulating deposits, such as those of lakes or peat bogs, the grains are incorporated in vast numbers. Their walls resist decay, and the grains can be recovered by suitable mechanical and chemical treatments from the muds, clays or peats containing them. Since pollen grains exhibit a very wide range of size, shape and wall pattern, and have distinctive numbers and disposition of pores and furrows, it is possible to recognize under high magnifications of the microscope the family, the genus or, in some instances, the species of plant to which a given grain belongs.

The proportions of different grains in any sample reflect the composition of the vegetation when the sample was deposited; thus. the quantitative changes in the pollen types in a series of samples through a deposit reveal the vegetational changes of the region throughout the formation of the deposit. In northwestern Europe, where the method has been most fully developed, pollen analyses have revealed a remarkably consistent picture of vegetational history for the period since the ice sheets began their final retreat. Open park tundra was replaced by birch woodland and then by pine forest and hazel scrub; these gave way to a phase of mixed oak forest, and finally beech. hornbeam and spruce expanded their range considerably. These changes in floristic composition were climatically controlled, and parallel developments were reflected widely in a system of pollen zones which can be employed as an approximate climatic and time scale. Pollen analysis of deposits containing archaeological objects (or even of adhering mud) allows an approximate dating to be made, and the method is applied similarly to geological features such as solifluction deposits. raised beaches and submerged forests.

Pollen analysis has been applied with great success to the study of interglacial and even older deposits and to the characterization of the stages of disforestation of Europe by Neolithic and succeeding groups of agriculturalists.

POLLEN GRAINS. In the biology of the plant, pollen grains are the structures that produce the male sex cell (sperm), which in turn effects bisexual reproduction by union with the female sex cell (egg). In the evolution of higher plants pollen grains are derived from asexual reproductive structures called spores, and in certain groups of plants, both living and fossil, the distinction between pollen and spore is arbitrary since they both perform a similar function in reproduction. The term pollen is usually restricted, however, to the male reproductive structure of seed-bearing plants, including the gymnosperms—conifers! cycads, ginkgo. etc.—and the angiosperms—all the flowering plants. Genetically the pollen grain is a minute plant. the cells of which bear one-half the chromosome number (the haploid number) found in the parent plant (which has diploid cells). Botanically the pollen grain is the male counterpart of the haploid female embryo sac in the ovule, the potential seed.

Transfer of pollen is carried out by wind, water, insects and other agents. After a pollen grain has made contact with the female reproductive structure—the moist stigma of the pistil—it sends out a pollen tube, which travels down through the pistil and into the ovary, where the ovules are. The pollen tube works into the ovule and fertilizes the egg cell within the embryo sac. After fertilization the ovule begins to develop into a seed. For further details on pollination see POLLINATION.

The role of pollen grains in the reproduction of plants mas known empirically to several ancient cultures. The earliest is perhaps that of the Assyrians, who employed hand pollination to ensure full yields of date palm fruits. Since pollen grains are minute in size—although produced in prodigious numbers in some plants and therefore visible as a dust—knowledge of their structure and details of their biologic function awaited the discovery of the microscope. The early microscopists Nehemiah Grew and Marcello Malpighi studied and drew pollen grains.

Because of their remarkably symmetrical structure and surface patterns pollen grains are readily recognizable in the microscope. The structure of the wall of a pollen grain is oftentimes so characteristic that in some cases species may be identified by pollen grains alone. On the other hand there are cases in which pollen grains of very like structure occur in quite unrelated plant families.

Because of their high resistance to decay. their widespread dispersal by wind and water and their abundant production by plants. pollen grains are very common constituents of geologic sediments. both recent and ancient. In view of these features pollen grains have provided much information on the origin and geologic history of terrestrial plant life (see POLLEN ANALYSIS).

Pollen is produced in such quantities that it comprises a significant component of the air-borne constituents of the earth's atmosphere, especially in areas over continents. The proteinaceous substance in many pollen grains (viz., ragweed and many grasses) induces an allergic reaction commonly known as hay fever (*q.v.*).

POLLENTIA, an ancient town of Liguria, It., 10 mi. N. of Augusta Bagiennorum, on the left bank of the Tanarus. Its position on the road from Augusta Taurinorum to the coast at Vada Sabatia, at the point of divergence of a road to Hasta (Asti) gave it military importance. Decimus Brutus managed to occupy it an hour before Mark Antony in 43 B.C.; and it was there that Stilicho on March 29, 403, fought the battle with Alaric which, though undecided, led the Goths to evacuate Italy. Considerable remains of ancient buildings survived.

POLLINATION, a botanical term for the transference of pollen, the dustlike powder produced by the stamen of seed plants, to the stigma (the receptive surface) of the ovary of the flower. (See also FLOWER; POLLEN GRAINS.) Pollination brings about the fertilization of the ovules in the ovary and their subsequent development into seeds. As the pollen-bearing parts of the stamens are rarely in contact with the stigma at the time when both of these are ripe, usually wind or insects, though sometimes other agencies such as water or birds, bring the pollen to the stigma. The great variety in the form, colour and scent of flowers was developed in relation to the particular agency of insects. Apart from the mechanism of pollination we can distinguish two types—self-pollination (autogamy) in which pollen is transferred from the stamen to the stigma of the same flower; and cross-pollination (allogamy) in which pollen is transferred to the stigma of another flower on the same plant (geitonogamy) or to the flower of another plant of the same species (xenogamy). Occasionally hybridization is possible, the pollen of one plant bringing about fertilization of the ovary of the flower of another species.

Cross-Pollination.—Cross-pollination is the only possible method in the case of unisexual flowers because these flowers have only stamens or pistils, not both. In hermaphrodites. *i.e.,* in flowers bearing both stamens and pistils: either self-pollination or cross-pollination can occur. It is interesting to note, however, that many flowers have special arrangements to ensure that the pollinating mechanism, whatever it may be, causes cross-pollination and not self-pollination. One of the commonest methods to achieve this is a separation in time of the sexes—the stamens burst and shed their pollen either before or after the stigma is receptive. This separation in time—and it may apply to the separate male and female flowers on the same plant—is known as dichogamy. When the stamens ripen first it is known as protandry, the more common case; while when the stigma is ready first. it is known as protogyny. Protandry is very common in insect-pollinated (entomophilous) flowers; as in nearly all members of the Compositae (*q.v.*) and Umbelliferae, many Labiatae (such as dead nettle [*Lamium*] and *Salvia*), the Caryophyllaceae, the large willow herb (*Epilobium* angustifolium), etc. Protogyny is found in the horse chestnut (Aesculus), the autumn crocus (*Colchicum*), many Araceae, and in wind-pollinated anemophilous flowers such as plantain (Plantago), meadow rue (Thalictrum) and many grasses. though here separation in time is very short and many are self-pollinated, such as wheat, barley and oats.

Another structural feature which is a bar to self-pollination is heterostyly. It is seen at its simplest and clearest in the primrose. About half the population of this plant has flowers with long styles which bring the stigmas to the mouth of the corollas as little "pinheads." The stamens lie halfway down the tubes. In the other half the style is short and the stamens form a "thrumhead" at the mouth of the corolla. Visiting bees transfer pollen from one type of flower to the other. An equal balance of the population is maintained by a special genetic system. Species of *Linum, Oxalis* and *Lythrum salicaria* (loosestrife) are other examples.

The most complete bar to self-fertilization is self-sterility, which is known to be widespread. This condition is brought about by failure of the pollen tube to grow properly on styles of the same plant, though it can do so on styles of most other plants of the species.

Cross-pollination gives two distinct results, one short-term and the other long-term. It tends to give more and better seed and more vigorous progeny—a result well known in the production of outbred maize. The long-term effect is on the process of evolution. Crossing maintains and replenishes the pool of mutations, patent and latent, on which natural selection acts. Crossing also brings about new combinations of mutations. It has a major effect on the rate at which species can evolve.

INSECT POLLINATION (ENTOMOPHILY)

The special characteristics of entomophilous flowers are the attractive colour of the floral envelope, the presence of scent and of nectar, and of pollen which is not powdery but sticky and is present in comparatively small quantities. The entomophilous is the most common type of pollination in flowering plants, and special floral conformations and irregularities adapted to insect visitors are characteristic of the higher families of flowering plants, as will be seen below. The evolution of flowers and of insects must have gone hand in hand; such groups as Lepidoptera (butterflies and moths) and Hymenoptera (bees, wasps, etc.) could not have existed without the more elaborate and honey-bearing flowers. The plants with such elaborate flowers are cross-pollinated only by insects with highly specialized organs for sucking nectar and gathering pollen.

Types of Insects.—Five classes of insects visit flowers. The Hemiptera (bugs) are unimportant. The Coleoptera (beetles) are frequent visitors, eating pollen and licking nectar with short tongues. The Diptera (flies) are important and varied visitors; many have only short tongues but some, *e.g.,* the hoverflies, are moderately long-tongued and suck concealed nectar. The Hymenoptera (bees, wasps, etc.) include the most important flower visitors. Many bees have long tongues and can manipulate complex floral mechanisms. The Lepidoptera (butterflies and moths) are also important visitors. They include the longest-tongued insects which alone can reach the most deeply concealed nectar.

Classes of Flowers.—The entomophilous flowers were divided by H. Müller into nine classes based on the structure of the flower and its relation to particular insects.

1. Class A, flowers with exposed nectar: in this class come most Cmbelliferae. many Saxifragaceae, the bedstraws (*Galium*), ivy (Hedera), and such trees as maple. elder and lime. The flowers are wide open and usually small and the visitors are mostly short-tongued.

2. Class XB, flowers with partially concealed nectar: in this class fall the buttercups (*Ranunculus*), the Cruciferae, the strawberry (*Fragaria*) and the willows (Salix). The nectar is protected and concealed by the position of the stamens, by the development of hairs or scales, or by the flower being partially tubular.

3. Class B, flowers with fully concealed nectar: in this class are the flowers of many Carophyllaceae (such as *Gypsophila*), Geranium, Polemonium, blackberry (*Rubus*), eyebright (*Euphrasin*), mint (Mentha), heather (*Calluna*). In these the nectar may be concealed by the stamens, by the calyx, by the receptacle becoming hollowed or by the petals being united to form a sympetalous corolla. The insect visitors are the smaller bees and a few of the longer-tongued flies.

4. Class B' is an extension of Class B and includes the flowers of the Compositae, most Dipsaceae and some Campanulaceae, in which the flowers have the same length of tube, etc., as Class B, but are aggregated into. an inflorescence.

5. Class F, lepidoptera flowers: this includes those flowers in which the floral tube is so deepened that in many cases only Lepidoptera can reach the nectar. The alpine moss campion (Silene *acaulis*), for example, is adapted to butterflies, while the bladder campion (Silene *inflata*) is adapted to moths and emits a scent at night.

6. Class H, bee flowers, are those which are visited mostly by long-tongued bees, the depth of the tube being 6 mm. to 15 mm. The flowers are also often markedly zygomorphic, providing a landing place for the bee.

7. and 8. The D and K classes of flowers include those adapted to small insects; they are pollinated by flies, beetles and small bees.

Lastly, there is (9) Class Po, pollen flowers. These provide no nectar. but abundant pollen for which the flower is visited, mainly by bees; examples: Clematis, meadowsweet (Spiraea), rockrose (Helianthemum), dog rose (Rose *canina*), poppy (Papaver).

Food, Colour and Scent.—The insect visits the flower for nectar or pollen. Nectar is produced by special glands, the nectaries, which may occur on any of the floral organs. In many flowers it collects at the bottom of the corolla tube or in a special spur. It is a solution of the sugars glucose, fructose and sucrose at a concentration of 8% to 70%. Pollen is rich in proteins and oil.

It seems obvious that scent and brightness must be the guides for the visiting insect. Whether the insect perceives colour as such or only brightness was long in doubt, as were the details of its reactions. Exact knowledge dates from the work of K. von Frisch begun in 1914. He studied the special senses of the honeybee, a domestic animal that lends itself to controlled experiment. The bees of a hive can be trained to visit a piece of blue paper with a watch glass of sugar water on it. They continue to visit the paper for a time after the sugar is removed. This fixation is the basis of the bee's habit of mass visits to one type of flower in nature. Moreover, the bee can pick out the blue paper from a series of graded grays, some of which must have the same brightness. It perceives blue colour as such. It also perceives white and yellow; but it cannot distinguish red from green, dark gray or black. It is significant that, where insect pollination is predominant. flowers show white, yellow, purple and blue colours, but very rarely red.

By other similar experiments, Frisch showed that bees can distinguish between scents in very much the same way as man can. The sense of scent is used by scout bees to inform their fellows in the hive of the kind of flower available for mass visiting. This extraordinary proceeding and the subject of the bee "language" lies in the domain of insect physiology.

F. Knoll carried out similar studies on other insects in the field as well as in the laboratory. He came to the conclusion that colour is the important "distant" signal for the bee and that scent is a "near" signal which aids in the final selection of a flower. He studied the behaviour of one of the long-tongued flies, the bee fly (*Bombylius fuliginosus*), as it visited the flowers of the grape hyacinth (*Muscari* racemosum) in Dalmatia. It flew from one spike to another, fixed to this one flower. It would dip to a piece of blue paper placed between the plants, and could pick out blue from surrounding grays. It also visited yellow flowers. If a spike of flowers was covered by a clear inverted test tube the fly would approach and circle the tube but would not try the opening from which the strong scent welled out. Its sense of smell seems to be deficient.

In another group the hummingbird hawk moth (Macroglossum stellatarum) also visits the grape hyacinth, perceiving its blue colour. At close quarters it is able to find the mouth of the corolla by perceiving the pattern of white petal tips on the blue ground. Here is a distant reaction to blue and a near reaction to white circle on blue ground. The same insect flies from a distance to the yellow flowers of the toadflax, perceives at close quarters a pattern of orange blotch on yellow and is enabled to probe the narrow entrance to the deep spur with great speed and accuracy, and while in flight. Such colour patterns are frequent in flowers; *e.g.,* the dark streaks on pansy petals and the orange eye on blue ground of the forget-me-not. They are called honey guides. Their recognition is responsible for the accuracy with which insects probe sources of concealed nectar. The hawk moth has a deficient sense of smell, but it is certain the night-flying moths perceive odours. J. H. Fabre showed that they can react to flower scents at a distance of more than 100 yd. Some flies and beetles react to stinks like that of rotten meat. Such odours are given off by the clubs of many aroids and the flowers of some asclepiads. The colour of these is often a dull red, In the case of the South European Arum *nigrum* (a close relation of Arum maculatum, the lords-and-ladies) Knoll showed that the insects reacted to the smell and not to the lurid colour. In this curious plant the small flies and beetles slide down the slippery hood and are trapped among the ripe female flowers for a day. On the following morning they are able to crawl out through the male flowers then shedding their pollen.

The Form of the Flower and Floral Mechanisms.—The form and size of the flower and the degree of concealment of nectar determine the kind of insect visitor. With long-tongued, clever insects, the structure of the flower often imposes a particular course of visit which favours cross-pollination. There is very great variety of detail and the variety of structure gives the elegant range of floral form.

In the flowers of Class A the visits of small insects are haphazard. The small flowers of the hedge parsley (*Anthriscus sylvestris*) are showy in the massed umbel. The nectar is freely exposed on lobed nectarial disks in the centre of the corolla. Small flies and beetles lick the nectar and transfer pollen at random. But the stamens are withered before the stigmas are ripe and cross-pollination is favoured.

The buttercup (*Ranunculus* acris) is an example of the more advanced flowers of Class AB. There is a nectary at the base of each petal and it is covered by a little scale. There is no definite manner of visit, but larger flies and small bees tend to settle on the centre of the flower where they touch the stigmas first. Willows (Salix spp.) are the earliest mass source of nectar in the spring and are much visited by bees. The flowers are small and simple but are so close-set in their catkins that small insects cannot reach the nectar. They are dioecious; *i.e.*, with staminate and pistillate flowers on different plants.

In Classes B, B', F and K are found the most elaborate examples of floral structure and the closest relation of this to insect visit. Some idea of the range is given in the following examples.

Sage.—Such a plant as the sage (*Salvia* pratensis) has a typical bumblebee flower. The bee alights on the platform formed by the lower lip of the sympetalous corolla and pushes its head down the tube to reach the nectar at the bottom. Each of the two stamens is of special shape; the connective is very large and two-armed, and is hinged to the short filament. The longer arm bears a half anther while the short arm is sterile. the whole stamen having a lever mechanism. The bee. in probing for the honey, comes in contact with the short arm of the lever and in pressing this down brings the half anther at the end of the longer arm down upon its back where the pollen becomes deposited. The flower is protandrous and in a later stage the style elongates and is brought into the same position as occupied by the back of the bee when in contact with the anther.

Papilionaceous Types.—The Leguminosae show a very interesting series of pollination mechanisms. In this familiar type of flower, to which the pea and gorse belong, the essential parts of the flower are enclosed in the keel. The nectar is secreted by the inner sides of the lower part of the staminal tube; one of the ten stamens is usually free and at its base are two openings leading to the nectar. The nectar is thus not only carefully concealed but is also at a considerable depth. Cleverness and length of proboscis are thus required so that, as might be expected, these flowers are bee flowers. An insect visiting the flower alights on the wings, thus depresses them and, as they are joined to the keel, this is depressed also. The stigma and stamens are thus forced out, the stigma usually first so that it has the chance of brushing off pollen from the underside of the bee and thus being cross-pollinated.

There are four different types. (1) Flowers in which the stamens and stigma return within the keel so that repeated visits are possible; examples are the clovers. melilot and laburnum. (2) Flowers that are explosive, since the style and stamens are confined under tension in the keel and when it is depressed they are released with suddenness, thus scattering pollen on the undersurface of the bee. Only one insect visit is thus effective. Examples are broom (Genista), gorse (Ulex), lucerne (Medicago). (3) Flowers which display a piston mechanism—the pollen is shed early and the heads of the five outer stamens act as a piston so that the weight of the bee on the keel squeezes a narrow ribbon of pollen through the pore at the apex of the keel. A further pressure causes a protrusion of the stigma which is thus brought in contact with the bee. Examples are lupin (Lupinus), restharrow (*Ononis*) and bird's-foot trefoil (Lotus *corniculatus*). (4) Flowers which show a brush mechanism, for the pollen is again shed early and the style, which is provided with a brush of hairs, sweeps the pollen in small portions out of the tip of the keel. An example is the bean (Vicia faba).

Orchids—The orchids show many and complicated adaptations to pollination by insects. A great impetus to their study was given by the publication in 1862 of Charles Darwin's monograph on the various pollination mechanisms exhibited by this group. As is well known, in this flower there is generally only one stamen, which is two-lobed, and the pollen is in the form of two-stalked masses, the pollinia, which the insect carries away stuck to its head. As the insect flies away, the pollinia, if not already properly oriented, execute such a movement as brings them into position to touch the sticky stigma of the next flower that is visited. There are, honever. a great many variations in the details of this process. Nectar is not usually secreted by the orchid flower, hut to obtain a sweet juice the insect has to pierce a special tissue, usually that of the labellum (the posterior petal), which is often spurlike.

Honeysuckle.—The honeysuckle (Lonicera *periclymenum*) is a moth flower. It is pale in colour and becomes highly scented in the evening. Probably the scent is here the distant guide and the pale colour, showing up in half light, acts at close quarters. The tube is so long that it can be plumbed only by moths, which suck in flight. Stamens and style project from the mouth of the corolla. On the first evening of opening the style is folded down on the lower lip and only the stamens are touched. On the second evening the stamens are withered and empty and the style stands out, exposing the stigma.

BIRD POLLINATION (ORNITHOPHILY)

Pollination by insects is the basic type in flowering plants but there has gradually accumulated a great deal of evidence that pollination by birds is widespread throughout the tropics and in some warm temperate regions, such as western Australia and parts of South America. In Brazil one-third of the families investigated were found to include ornithophilous species. The birds concerned are mostly hummingbirds and honey birds, creatures that may be no larger than a bumblebee. They suck nectar through a closed bill with the tongue as a piston. They usually suck in flight and are rough visitors, not exact and clever like the bees. They require large quantities of liquid. They have little sense of smell. Their colour sense differs from that of the bee in that they distinguish reds, yellows and greens but not blues. Corresponding to these characters of the bird are distinctive characters in the flowers frequented.

The most notable is the frequency of brilliant reds. Of 160 South American species known to be bird pollinated. 134 or 84% were red. Garish colour contrasts are frequent. The bird-of-paradise flower (Strelitzia *reginae*) is blue and yellow. appearing to the eye of the bird as a pattern of black and yellow. The flowers of Billbergia are pink and green. The stamens and styles stand clear of the corolla and resist rough treatment by their stiffness. The flowers have no landing platform, spurs or such features. When birds perch they usually do so on bracts or other strong structures near the flower. In the Chilean *Puja* the tip of the inflorescence forms a rigid, flowerless perch. The flowers have no scent. but nectar is very abundant, even welling from the mouth of the corolla.

These features may be seen in some plants commonly grown in European greenhouses and gardens. Strelitzia is prized as a greenhouse plant for its brilliant colour display. The garden fuchsia

(*Fuchsia magellanica*) has flowers of crimson and blue. Style and stamens are stiff and project far out of the corolla. The nectar is so abundant that it can be shaken from the flower in drops. Even more interesting is *Salviu splendens*, the scarlet sage, extensively used as a bedding plant. It may be contrasted with the culinary sage described above. Apart from the colour it can be seen that the hooded petal and the broad landing stage are absent and that stamens and style are no longer enclosed but protrude from the corolla. It is a fine example of the way a flower fitted for bird pollination has evolved from the insect-pollinated type. There can be no doubt that ornithophily is a later development than entomophily and that the bird flower has evolved from insect-pollinated ancestors.

POLLINATION BY OTHER ANIMALS

Among the bats a group of vampires in the new world and a group of flying dogs in the old world have evolved suctorial tongues and feed on nectar. They act as pollinators. The bat is night flying. clings to the flowers with its claws and is a rough visitor. Bat-pollinated flowers tend to stand away from the stems or to hang in free bunches: they are a dirty white in colour and have a peculiar smell. Details of visits by quick-flying nocturnal animals are naturally hard to come by. But that the activity of bats is considerable is shown by the fact that. in Java alone, 31 species of plants have been identified as bat pollinated.

In Australia about a dozen species of small marsupials—the honey mice—are nectar feeders and pollinate the flowers of species of *Eucalyptus, Protea* and other trees.

Various other animals: including snails: have been observed transferring pollen.

POLLINATION BY WIND (ANEMOPHILY)

The conifers. more primitive than the flowering plants, are all wind pollinated. The pollen is not transferred to a stigma, for these are naked-seeded plants. The ovule is exposed and the pollen is caught in a drop of liquid exuded from the micropylar opening of the integument. There is an enormous wastage of pollen drifting in air currents, and very great quantities are produced. A male yew shaken in February fills the air with "yew smoke." Lakes in the vicinity of pine woods may have their surface covered with a yellow film. The pollen is very light. and powdery. in contrast to the sticky pollen of insect flowers. In the conifers male and female organs are always in separate cones and sometimes on separate trees.

There are many wind-pollinated flowering plants. They, too, produce light. powdery pollen in large quantities—as any sufferer from hay fever knows. The corolla is either little developed and green. or absent. There is neither scent nor nectar. Attractive characters are wanting. The lack of corolla is a positive advantage as it allows the free exposure of stamens and stigmas. The flowers stand well above surrounding foliage in the grasses, and appear before the leaves in such trees as the hazel and elm. The stigmas are often large and feathery, or covered with hairs acting as pollen traps. The individual stamen in the plantain and grasses, and the whole inflorescence in the hazel, is easily shaken, so that the pollen is readily dispersed when the air is in motion. Protogyny occurs, as in the plantain, and protandry, as in the grasses. Stamens and carpels occur in separate catkins in hazel, oak and beech.

The salad burnet (*Poterium sanguisorba*) in the Rosaceae and the meadow rues (*Thalictrum* spp.) in the Ranunculaceae are examples of wind-pollinated flowers in families normally insect-pollinated. There is no doubt that these and others like them do not show a primitive condition but were evolved from insect-pollinated ancestors. The great group of wind-pollinated plants which includes the grasses, sedges and rushes may also exhibit a derived condition. There is evidence to suggest that the most specialized family. the grasses! evolved through sedgelike and rushlike ancestors from showy-flowered plants of the lily type. The other great group of wind-pollinated plants. which comprises many forest trees such as the oak. birch. hazel and alder. offers a more diffcult problem. It Is possible that they are primitive types which have retained a primitive pollinating mechanism.

Pollination by the agency of water currents is very rare: an example is the grass wrack (*Zostera marina*).

SELF-POLLINATION (AUTOGAMY)

Self-pollination frequently takes place at the end of the life of a flower, ensuring fertilization if cross-pollination failed. It is often brought about by movements of the stamens or style. It is well seen in the Compositae where the branches of the style curl back and bring the stigmas into contact with their own pollen. There is great variety of detail in other flowers.

Some flowers never open and are said to be cleistogamous. They are small and budlike and petals are reduced or absent. The wood sorrel (*Oxalis acetosella*) and the sweet violet (*Viola odorata*) are examples.

APPLICATIONS

The fig is pollinated by a small wasp which passes from male to female inflorescences. The two are borne on separate trees and the male fig, which bears no fruit, is called a goat fig or caprifig. It was known in Greece in the time of Aristotle that goat figs must be planted near the fruiting trees, or branches placed in their crowns: the practice is known as caprification and still goes on. When the Smyrna fig was introduced into California at the end of the 19th century the goat fig and its wasps had to be brought in as well. The date is another Mediterranean fruit tree which was artificially pollinated from time immemorial by hanging male inflorescences among the female. The peach, when grown in the greenhouse, is usually pollinated by hand, using a brush or hare's foot; so is the melon. In the orchard it is often an advantage to make sure of adequate pollination by having beehives among the trees. Red clover can be pollinated only by bumblebees with their heavy bodies and very long tongues. The crop was a failure when first introduced into New Zealand, but succeeded when the bee was successfully established.

Artificial pollination is essential in all breeding work. When crosses are made it is usual to remove the stamens before they are ripe and to enclose the flower or inflorescence in a paper bag to avoid chance pollination. The most suitable technique must be worked out for each plant and an intimate knowledge of the development of the flower is required. When growing crops for seed production it is necessary to make sure that crossing with other varieties, and consequent impurity in the seed stock, does not occur. The cereals give little trouble in this respect, for they are almost entirely self-pollinated. With other crops—such as brassicas and beets—this is not so. Plots must be isolated by distance, by hedges or otherwise. Exact knowledge of pollination agencies is the basis of such precautions, and may even show precautions to be unnecessary.

BIBLIOGRAPHY.—The standard work is P. Knuth, *Handbook of Flower Pollination,* trans. by J. R. Ainsworth Davis, 3 vol. (1906–09), which includes an account of the work of such pioneers as C. K. Sprengel, C. Darwin and H. Müller. General accounts are in A. Kerner von Marilaun and F. W. Oliver, *The Natural History of Plants* (1894, 1895); M. Skene, *Biology of Flowering Plants,* 4th imp. rev. (1947), with reference to newer work. Accounts are given in most textbooks of botany. On the sense reactions of insects the main works are K. von Frisch, *Der Farbensinn und Formensinn der Biene* (1914), *Über den Geruchsinn der Biene* (1919); F. Knoll, "Insekten und Blumen," *Abh. zool.-bot. Ges.,* vol. xii (1921–26). A short account in English is K. von Frisch, *Bees, Their Vision, Chemical Senses and Language* (1950). Ornithophilous flowers are described by O. Sargent, "Fragments of the Flower Biology of Westralian Plants," *Ann. Bot.,* vol. xxxii (1918). For self-sterility consult D. Lewis, "Incompatibility in Flowering Plants," *Biol. Rev.,* vol. xxiv (1949). (V. H. B.; M. SE.)

POLLIO, GAIUS ASINIUS (76 B.C.–A.D. 4 or 5). Roman orator, poet and historian whose contemporary history, although lost. provided much of the material for Appian and Plutarch. Born into a leading Marrucine family—his grandfather had been an Italian general in the Social War—Pollio moved in the literary circle of Catullus and entered public life in 56 by supporting the policy of Lentulus Spinther (*q.v.*). In 54 he impeached unsuccessfully the tribune C. Cato, incurring Pompey's displeasure. In the Civil War he joined Caesar at the Rubicon and campaigned in Africa with Curio and (49–45) in Greece, Africa and Spain with Caesar, for whom he held a praetorian command in Spain against Sextus Pompey (44). On Caesar's death he followed Antony, for whom he governed Transpadane Gaul. There he was friendly with Virgil and in distributing land to veterans saved the poet's property from confiscation. He stood aloof from Fulvia, Antony's wife, and L. Antonius in the Perusine War, but held his army firmly in Antony's interests, and shared in the negotiations leading to the pact of Brundisium between Antony and Octavian in 40. In that year he was consul, and Virgil addressed his Fourth Eclogue to him. In 39 Pollio subdued the Parthini, an Illyrian people, and celebrated a triumph (Oct. 25). From the booty he built the first public library in Rome, in the Atrium Libertatis, which he restored. With full honours he then retired from public life. Unwilling to join Antony in the east, hoping for nothing from Octavian, he took no part in the Actium campaign (31) and subsequently maintained a position of republican dignity and independence. He gave hospitality to the rhetorician Timagenes, when the latter was in disgrace with Augustus. This was the main period of his activity as an advocate, and he devoted himself to the support of literature, organizing public recitations. He died in his villa at Tusculum.

Pollio was a distinguished orator, combining, according to Tacitus and Seneca, careful composition and dry Atticist elegance in strict presentation of his argument. His style displeased Ciceronian critics such as Quintilian and his speeches are lost. As a poet he was accepted by Catullus, Helvius Cinna and Virgil and wrote tragedies, which Virgil and Horace praised, but he ceased to write serious verse when he turned to history shortly after 35. His *Historiae* covered the period from 60 probably to 42 (hardly as late as 35 or 31), that is, from the First Triumvirate to Philippi —the period in which the Roman republic fell. To this contemporary work ("a work full of perilous hazard"), Pollio brought personal experience, independent judgment and a sober style that aided historical analysis. Pollio may be ranked with Sallust and Tacitus. A stern critic of men and style, he corrected Caesar, attacked Cicero, praised Brutus, and reprimanded Sallust for archaism and Livy for *Patavinitas* (probably "provincialism"). Above all, he defended Roman *libertas* under the *principatus* of Augustus. His three letters to Cicero (Ad *Cam.* x, 31–33) bring him closer to the reader than any other work.

POLLOCK, the name of a great English legal family. The best-known members are:

SIR JONATHAN FREDERICK POLLOCK (1783–1870), chief baron of the exchequer. was born on Sept. 23, 1783, in London, the son of David Pollock, saddler, of Charing Cross. He was educated at St. Paul's and Trinity college, Cambridge, and was called to the bar in 1807. He took silk in 1827, and in 1831 became member of parliament for Huntingdon. In 1834 he became attorney general and was knighted. His party lost office in 1835, but he was again attorney general from 1841 until in 1844 he succeeded Lord Abinger as chief baron of the exchequer. In 1866 he retired with a baronetcy, and on Aug. 22, 1870, he died at Hatton, Middlesex.

See Lord Hanworth (grandson of the chief baron), *Lord Chief Baron Pollock* (1929); Sir F. Pollock, 2nd Bart., *Personal Remembrances* (1887).

SIR FREDERICK POLLOCK (1845–1937), 3rd Bart., a grandson of the chief baron, and a notable author, was born in London on Dec. 10, 1845. He was educated at Eton and Trinity college, Cambridge, where he became a fellow in 1868. He was called to the bar by Lincoln's Inn in 1871 and for several years he practised, though with little success. After holding various teaching posts, from 1883 to 1903 he was Corpus professor of jurisprudence at Oxford. In 1885 he played a leading part in founding the *Law Quarterly Review,* the distinguished learned legal periodical of the common-law world, which he edited for the first 34 years. He also edited the *Law Reports* from 1895 to 1935. In 1911 he was made a privy councilor and in 1914 judge of the admiralty court of the Cinque Ports, an office with only nominal duties. In 1920 he became one of the first of the few academic lawyers to be made a king's counsel. He died in London on Jan. 18, 1937.

Sir Frederick Pollock's *Principles of Contract* was in many ways the first of the modern textbooks with a critical, analytical and learned approach, concentrating on principles rather than details. For over half a century his writings, especially in the *Law Qziarterly Review,* exerted an influence on the development of English law that was unprecedented for an academic lawyer. Yet Pollock was no mere lawyer; he was a true scholar who was widely read in many tongues, both in lam and other subjects, especially philosophy. Although somewhat reserved in his manner, he could be an effective speaker; and he was kindness itself to the serious student. Much of his remarkable personal and intellectual friendship of over 60 years with Justice Oliver Wendell Holmes, Jr., is revealed by their correspondence, published in 1941 and edited by M. de W. Howe.

Sir Frederick Pollock's works include *Principles of Contract* (1876; 13th ed., 1950); *Digest of the Law of Partnership* (1877; 15th ed., 1952); *The Law of Torts* (1887; 15th ed., 1951); *Possession in the Common Law,* with R. S. Wright (1888); *The History of English Law Before the Time of Edward I,* 2 vol., with F. W. Maitland (1895; 2nd. ed., 1898); *Spinoza, His Life and Philosophy* (1880; 2nd. ed. reissued with additions, 1912).

See Law Quarterly Review, vol. 53, pp. 151–206 (1937). (R. E. MY.)

POLLOCK, JACKSON (1912–1956), U.S. abstract painter, one of the founders of a loose movement called Abstract Expressionism or Action painting in the U.S. and *tachisrne* in France, was born at Cody, Wyo., on Jan. 28, 1912. After a period of realism after the style of Thomas Hart Benton, Pollock's first paintings in the new style, in 1943, mingled energetic linear invention and a subconscious imagery derived from Surrealism. His later work was entirely abstract, characterized by an intense activism of surface and by the interweaving of whipped lines. After 1947, Pollock employed aluminum paint and commercial enamels, dripping and spattering them over the canvas surface. This radical technical innovation brought him unfavourable publicity, but also helped identify him in the minds of many young American artists as the most revolutionary artist of an older generation of innovators. Pollock died at East Hampton, L.I., N.Y., on Aug. 11, 1956. Abstract Expressionism became one of the dominating international tendencies after the close of World War II. Its aesthetic principle is based upon free and expressive handling and unarranged, chance pictorial effects, which seem to arise spontaneously under the brush stroke. (S. HU.)

POLLS, PUBLIC OPINION: *see* PUBLIC OPINION.

POLL TAX. A tax of a uniform amount levied on each individual; a tax of so much per head (middle English *polle,* "a head"). By mid-20th century this tax had long been abandoned by most countries and nas not an important revenue raiser in any tax system in the world.

The most famous poll tax in English history is the one levied in 1380. which led to the revolt of the peasants under Wat Tyler in 1381, but the first instance was in 1377, when a tax of a groat a head was voted by both clergy and laity. In 1379 the tax was again levied, but on a graduated scale. John of Gaunt, duke of Lancaster, paid ten marks, and the scale descended from him to the peasants. nho paid one groat each, every person over 16 years of age being liable. In 1380 the tax was also graduated, but less steeply. For years after the rising of 1381 money was raised in this way only from aliens, but in 1513 a general poll tax was imposed. This produced only about £50,000, instead of £160.000 as was expected, but a poll tax levied in 1641 resulted in a revenue of about 1400,600. During the reign of Charles II, money was obtained in this way on several occasions. For years after 1688 poll taxes were a favourite means of raising money for the prosecution of the war with France.

Although a few U.S. states at mid-20th century still levied the tax for revenue purposes only. most discussion of the tax centred around its use as a voting prerequisite in the southern states. Ten southern states made the poll tax a voting prerequisite between 1889 and 1902; an 11th, Georgia, had enacted the requirement many years earlier. In its origins the tax is associated with the agrarian unrest of the 1880s and 1890s, which culminated in the rise of the Populist party in the west and the south. The Populists, a low-income farmers' party, gave the Democrats the only serious competition they had experienced since the end of Reconstruction. The intensity of competition led both parties to bring the Negro back into politics and to compete for his vote. Once the Populists were defeated the Democrats amended their state constitutions or drafted new ones to include various disfranchising devices. The poll tax was one of these. Its purpose was to disfranchise Negroes and possibly also to weaken politically the poor whites who had made up the backbone of the Populist party.

After 1920 the poll tax was abolished by state action in North Carolina, Louisiana, Florida, Georgia, South Carolina and Tennessee. Constitutional amendments to wipe out the tax were submitted to the voters in Arkansas, Virginia and Texas, but failed to pass. The tax still prevailed in these states as well as in Alabama and Mississippi at mid-century; the rate ranged from $1 to $2 per year. In Texas and Arkansas, failure to pay merely disfranchised a person for that year only and did not create an obligation which must be paid in subsequent years if he wished to vote. In Virginia and Mississippi the tax was in some degree cumulative, and in Alabama it was possible to run up a bill of as much as $36 in delinquent poll taxes which would have to be paid in order to vote. (D. S. S.; X.)

POLLUCITE, a rare mineral consisting of hydrated cesium aluminum silicate, is the richest source of cesium, the oxide being present to the extent of 30% to 36%. Cesium, together with rubidium, is important in the manufacture of photoelectric cells, scintillation counters and optical instruments and devices. Pollucite occurs sparingly, associated with the mineral petalite (*q.v.*) in cavities in the granite of Elba. and with beryl in pegmatite dikes at Andover and Hebron, Me.. and in the pegmatite mines of the Black hills, S.D. It also is found in Brazil, South-West Africa and the Union of South Africa.

The composition of pollucite is $CsAlSi_2O_6.H_2O$. It is closely related to the mineral leucite, $KAlSi_2O_6$. It crystallizes in the cubic system. is colourless and transparent and has a vitreous lustre. There is no distinct cleavage and the fracture is conchoidal, so that the mineral closely resembles quartz. The hardness is 6.5 and the specific gravity 2 90. See also CESIUM.

(L. S. RL.; X.)

POLLUX, JULIUS (2nd century A.D.) Greek scholar and rhetorician of Naucratis in Egypt, was the author of an *Onomasticon*, a Greek thesaurus of terms. The emperor Commodus appointed him to a chair of rhetoric in Athens. The *Onomasticon,* his only surviving work, is in ten books. It is incomplete, having undergone abridgment and interpolation in antiquity. The work contains rhetorical material (*e.g.,* collections of synonyms and compounds) and technical terms pertaining to a wide variety of subjects, as well as citations from literature. The material on music and the theatre is of special interest. Editions include that by W. Dindorf (1824) and by E. Bethe in the Teubner *Lexicographi* Graeci, 3 vol. (1900–37). (G. DO.)

POLLUX, in astronomy, the brightest star of the zodiacal constellation Gemini (*q.v.*). This reddish first magnitude star and the slightly less bright blue star Castor mark the heads of the celestial Twins, whose feet are in the Milky Way across from Orion. Pollux is distant 35 light-years and is intrinsically 33 times as luminous as the sun. The Twin stars are not far from overhead in the early evenings of early spring for observers in middle northern latitudes. (R. H. BR.)

POLO, MARCO (c. 1254–1324), Venetian traveller, was grandson of Andrea Polo of San Felice, and son of Nicolo Polo. The three Polos were presumably "noble," for Marco the traveller is officially so styled (*nobilis vir*). The three sons of Andrea Polo were engaged in commerce; the eldest suggests, by his will, a long business partnership with Nicolo and Maffeo.

About 1260, Nicolo with his wife and Maffeo were at Constantinople. The two brothers were led in their trading operations to the Crimea, and eventually to Bukhara. where they joined some envoys returning from a mission from Kublai Khan, with whom they journeyed to Cathay. It was the first time that the khan had met Europeans and he was delighted with the Venetian brothers. whom he sent back to the pope, with letters requesting the despatch of a body of educated men to instruct his people in Christianity and the liberal arts. On arriving at Acre in April 1269, they learned that no new pope had been appointed after Clement IV's death in 1268, and they returned to Venice.

The brothers resolved after two years to start again for the east. taking with them Nicolo's son Marco. They had letters authenticating their delay; but. hearing of the papal election soon after their start, they returned to execute Kublai's mission. The new pope. however, could supply but two Dominicans, who soon turned back.

Leaving Acre about Nov. 1271, Polo's book indicates that the party proceeded to Hormuz (Hurmuz) at the mouth of the Persian gulf, with the purpose of going on to China by sea; but that, abandoning their plans, they returned northward through Persia. Traversing Kerman and Khurasan, they went on to Balkh and Badakshan and ascended the upper Oxus through Wakhan to the plateau of Pamir (a name first heard in Marco's book). Crossing the Pamir, the travellers descended upon Kashgar, Yarkand and Khotan (Khutan). These are regions which remained almost absolutely closed to western knowledge till after 1860. From Khotan they passed on to the vicinity of Lop-Nor. Thence the desert of Gobi was crossed to Tangut, the region at the extreme northwest of China, within and without the Wall. In his account of the Gobi, or desert of Lop, as he calls it, Polo describes the waste, strikingly reproducing the description of the superstitious terrors of Suan T'sang, who crossed the desert 600 years earlier.

Early in 1275 the Venetians were cordially received by the Great Khan at Shangtu, and Marco made rapid progress. The "young bachelor" studied the languages of the Khan's subjects and soon entered the public service. On his public missions he travelled through Shansi, Shensi, and Szechuen provinces, and the wild country on the borders of Tibet, to the province of Yunnan, called by the Mongols Karajang, and northern Burma (Mien), Marco, during his stay at court, had observed the khan's interest in strange countries, and his disgust at the stupidity of envoys and commissioners who could tell of nothing but their official business. He made notes on facts likely to interest Kublai, which, on his return, he related He encountered many semi-civilized and barbarous tribes, many of which interested Kublai greatly.

Marco rose rapidly in favour and was often employed on distant missions as well as in domestic administration; he held for three years the government of Tangchow; on another occasion he visited Kangchow, the capital of Tangut, just within the Great Wall, and perhaps Karakorum on the north of the Gobi, the former residence of the Great Khans: also Ciampa, or southern Cochin-China; and perhaps, once more, on a separate mission to the southern states of India. We are not informed whether his father and uncle shared in such employments, though they rendered great service to the khan, in forwarding the capture of Siang-yang (on the Han river) during the war against southern China, by the construction of powerful artillery engines—a story, however, perplexed by chronological difficulties.

The Polos had become rich, and after their exile they began to dread what might follow Kublai's death. The khan, however, was deaf to suggestions of departure and the opportunity only came by chance. Arghun, khan of Persia, a grand-nephew of Kublai, lost in 1286 his favourite wife. Her dying injunction was that her place should be filled only by a lady of her own Mongol tribe. Ambassadors were despatched to the court of Peking to obtain one. The lady Cocacin (Kukachin), a maiden of seventeen, was chosen. The overland road from Peking to Tabriz was then imperilled by war, and Arghun's envoys proposed to return by sea Having met the Venetians, and bring eager to profit by their experience. they begged the khan to send the Franks in their company. He fitted out the party nobly for the voyage, sending friendly messages to the potentates of Christendom, including the pope, and the kings of France, Spain and England. They sailed from *Zaiton* or Amoy harbour in Fukien (probably the modern Changchow), then one of the chief Chinese havens for foreign trade, in 1292. The voyage involved long detention on the coast of Sumatra, and in south India, and two years or more passed before they arrived in Persia. Two of the three envoys and most of their suite died by the way; but the three Venetians survived all perils, and so did the young lady, who had come to look on them with filial regard. Arghun Khan had died before they left China; his brother reigned in his stead; and his son Ghazan married the lady. The Polos went on by Tabriz, Trebizond, Constantinople and Negropont to Venice, arriving about the end of 1295.

The first biographer of Marco Polo was John Baptist Ramusio, who wrote more than two centuries after the traveller's death. We need not hesitate to accept as a genuine tradition the substance of his story of the Polos' arrival at their family mansion in St. John Chrysostom parish in worn and outlandish garb, of the scornful denial of their identity, and the stratagem by which they secured acknowledgment from Venetian society.

We next hear of Marco Polo in a militant capacity. Jealousies had been growing between Venice and Genoa throughout the 13th century. In 1298 the Genoese prepared to strike at their rivals on their own ground, and a powerful fleet under Lamba Doria made for the Adriatic. Venice equipped a larger fleet under Andrea Dandolo. The crew of a Venetian galley at this time amounted to 250 men, under a *comito* or master. On one of the galleys of Dandolo's fleet Marco Polo served as *sopracomito* or gentleman commander. The hostile fleets met before Curzola Island on Sept. 6, and engaged next morning. The battle ended in victory for Genoa, and Marco Polo was taken there as a prisoner. The captivity lasted less than a year, and Marco returned to Venice in July or August 1299.

His captivity was the immediate cause of his *Book.* Up to this time he had related his experiences among his friends; and from these stories he had acquired the nickname of *Marco Millioni.* Yet he had written nothing. The narratives not only of Marco Polo but of other famous mediaeval travellers seem to have been extorted from them by pressure, and written down by other hands. In the prison of Genoa Marco Polo met Rusticiano or Rustichello of Pisa, also a captive of the Genoese, who was a respectable literary hack; he wrote down Marco's experiences at his dictation.

We learn little of Marco Polo's history after this captivity; at his death he left a wife, Donata, and three daughters, Fantina, Bellela and Moreta. One last glimpse of the traveller is gathered from his will. On Jan. g, 1324, he sent for a priest and notary to make his testament, and died the same day. He was buried, according to his wish, in the Church of St. Lorenzo. The archives of Venice have yielded a few traces of our traveller. Besides his own will just alluded to, there are the wills of his uncles, Marco and Maffeo; a few legal documents connected with the house property in St. John Chrysostom, and two or three entries in the record of the Maggior Consiglio. We have mentioned the sobriquet of Marco Millioni. Ramusio tells us that he had himself noted the use of this name in the public books of the commonwealth, and this statement has been verified in an entry in the books of the great council (dated April 10, 1305), which records as one of the securities in a certain case the "Nobilis vir Marchus Paulo Milion." It is alleged that long after the traveller's death there was always in the Venetian masques one individual who assumed the character of Marco Millioni, and told Munchausen-like stories to divert the vulgar. There is also a record (March 9. 1311) of the judgment of the court of requests *(Curia Petitionum)* upon a suit brought by the "Nobilis vir hlarcus Polo" against Paulo Girardo, who had been an agent of his. Another document is a catalogue of curiosities and valuables in the house of Marino Faliero, which mentions several objects that Marco Polo had given to one of the Faliero family. The most tangible record of Polo's memory in Venice is a portion of the Ca' Polo—the mansion where the three travellers, after their long absence, were denied entrance. The court in which it stands was known in Ramusio's time as the *Corte del millioni,* and now is called Corte Sabbionera. That which remains of the ancient edifice is a passage with a decorated 13th century archway.

No genuine portrait of Marco Polo exists. There is a medallion portrait dated 1761 on the wall of the Sala dello Scudo in the ducal palace. The oldest professed portrait is one in the gallery of Monsignor Badia at Rome, which is inscribed *Marcus Polus venetus totius orbis et Indie peregrator primus.* It is a good picture, but of the 16th century. The Europeans at Canton have absurdly attached the name of Marco Polo to a figure in a Buddhist temple there containing a gallery of "Arhans" or Buddhist saints, and popularly known as the "temple of the five hundred gods." The Venetian municipality obtained a copy of this on the occasion of the geographical congress at Venice in 1881.

Polo was the first traveller to trace a route across the whole longitude of Asia, describing kingdoms which he had seen; the first to speak of the court at Peking; the first to reveal China in its wealth and vastness, and to tell of the nations on its borders; the first to tell more of Tibet than its name, to speak of Burma, Laos, Siam, Cochin-China, Japan, Java, Sumatra; the Nicobar and Andaman Islands, Ceylon, India, but as a country seen and partially explored; the first in mediaeval times to give any distinct account of the empire of Abyssinia, and of the island of Sokotra, and to mention Zanzibar and Madagascar; while he carries us also to the remotely opposite region of Siberia and the Arctic shores, to speak of dog sledges, white bears and reindeer-riding Tunguses.

Within the traveller's own lifetime, we find the earliest examples of the practical and truly scientific coast charts (*Portolani*), based upon the experience of pilots, mariners. merchants, etc. In two of the most famous of the 14th century Portolani, we trace Marco Polo's influence—in the *Laurentian* or *Medicean Portolano* of 1351 (at Florence), and in the *Catalan Atlas* of 1375 (now at Paris). Both represent a very advanced stage of mediaeval knowledge, a careful attempt to represent the known world on the basis of collected fact, and a disregard for theological or pseudo-scientific theory; in the *Catalan Atlas,* as regards central and further Asia, and partially as regards India. Marco Polo's book is the basis of the map. His names are often much perverted, and it is not always easy to understand the view that the compiler took of his itineraries. Still we have Cathay placed in the true position of China, as a great empire filling the south-east of Asia. The trans-Gangetic peninsula is absent, but India proper is for the first time represented with a fair approximation to correct form and position. The map of Fra Mauro (1459) gives a much less accurate idea of Asia than the *Carta catalana.* Columbus possessed a copy of the Latin version of Polo's book made by Pipino, and on many pages of this there are manuscript notes in the admiral's handwriting, testifying to the influence of the work of the Venetian merchant upon the discoverer of the new world.

When. in the 16th century, attempts were made to combine new and old knowledge, the results were unhappy. The earliest of such combinations tried to realize Columbus' ideas regarding the identity of his discoveries with the great khan's dominions; but even after America had vindicated its independent existence, and the new knowledge of the Portuguese had named China where the Catalan map had spoken of Cathay, the latter country, with the whole of Polo's nomenclature, was shunted to the north, forming a separate system. Henceforward the influence of Polo's work on maps was simply injurious; and when to his names was added a sprinkling of Ptolemy's, as was usual throughout the 16th century, the result was a hotchpotch conveying no approximation to facts.

As to the alleged introduction of important inventions into Europe by Polo—although the striking resemblance of early European block books to those of China seem clearly to indicate the derivation of the art from that country, there is no reason for connecting this introduction (any more than that of gunpowder or the mariner's compass) with the name of Marco. In the 14th century not only were missions of the Roman church established in eastern China, but a regular overland trade was carried on between Italy and China. Many a traveller other than Marco Polo might have brought home the block books, and some might have witnessed the process of making them. This is the less to be ascribed to Polo, because he so curiously omits to speak of the process of printing, when, in describing the block-printed paper money of China, his subject seems absolutely to challenge a description of the art.

The book indited by Rusticiano is in two parts. The first, or prologue, as it is termed, is unfortunately the only part which consists of actual personal narrative. It relates the circumstances which led the two elder Polos to the khan's court, together with those of their second journey (when accompanied by Marco), and of the return to the west by the Indian seas and Persia. The second part consists of a series of chapters of unequal length and unsystematic structure, descriptive of the different states and provinces of Asia (certain African islands and regions included), with occasional notices of their sights and products, of curious manners and remarkable events, and especially regarding the Emperor Kublai, his court, wars and administration. A series of chapters near the close treats of sundry wars that took place between various branches of the house of Jenghiz in the latter half of the 13th century. There is now no doubt that the original was written in French. A manuscript in rude and peculiar French, belonging to the National Library of Paris (Fonds, Fr., 1116), which was printed by the Société de géographie in 1824, is evidently either the original or a close transcript. It shows characteristics of the unrevised product of dictation which would necessarily have disappeared in a translation or revised copy. Eighty-five mss. of the book are known, and their texts exhibit considerable differences. For a discussion of these see the authorities quoted in the bibliography.

We know from Gilles Mallet's catalogue of the books collected in the Louvre by Charles V, dating *c.* 1370–75, that five copies of Marco Polo's work were then in the collection; but on the other hand. the 202 known mss. and the numerous early printed editions of "Mandeville," with his lying wonders, indicate a much greater popularity. Dante, who lived 23 years after the book was dictated, never alludes to Polo; nor can any trace of Polo be discovered in the book of his contemporary, Marino Sanudo the Elder, though he is well acquainted with the work of Hayton the Armenian. Mandeville himself, who plundered right and left, hardly ever plunders Polo. The only literary works we know of the 14th century which show acquaintance with Polo's book or achievements are Pipino's *Chronicle,* Villani's *Florentine History,* Pietro d'Abano's *Conciliator,* the *Chronicle* of John of Ypres, and the poetical romance of *Baudouin de Sebouro.*

BIBLIOGRAPHY.—Sir Henry Yule's edition, which in its final shape, as revised and augmented by Henri Cordier (. . . *Marco Polo* . . . London, 1903), is the most complete storehouse of Polo learning in existence, embodying the labours of all the best students of the subject, and giving the essence of such works as those of Major P. Molesworth Sykes *(Ten Thousand Miles in Persia,* etc.) so far as these touch Marco Polo; the Archimandrite Palladius Katharov's "Elucidations of Marco Polo" from vol. x of the *Journal* of the North China branch of the Royal Asiatic society (1876), pp. 1–54; F. von Richthofen, *Letters to Shanghai Chamber of Commerce;* E. C. Baber, *Travels . . . in Western China;* G. Phillips, *Identity of . . . Zaitun with Changchau in T'oung Pao* (Oct. 1890), and other studies in *T'oung Pao* (Dec. 1895 and July 1896). There are in all 10 French editions of Polo as well as 4 Latin editions, 27 Italian, 9 German, 4 Spanish, 1 Portuguese, 12 English, 2 Russian, 1 Dutch, 1 Bohemian (Czech), 1 Danish and 1 Swedish. *See* also E. Bretschneider, *Mediaeval Researches from Eastern Asiatic Sources,* i, 239, 167; ii, 8, 71, 81–84, 184; Léon Cahun, *Introduction à l'histoire de l'Asie,* 339, 386; C. Raymond Beazley, *Dawn of Modern Geography,* iii, 15–160, 545–547, 554, 556–563; R. Allulli, *Marco Polo* (1923). *(H. Y.;* X.)

POLO, the most ancient game with stick and ball, takes its name from the Tibetan *pulu,* "a ball." The earliest records of polo are Persian; there is evidence that it was played in the time of King Darius. From Persia it spread to Constantinople, and eastward through Turkistan to Tibet, China and Japan, and from Tibet to Gilgit and Chitral. It was imported to Manipur from China. Polo also flourished in India throughout the Mogul dynasty. Then for 200 years its records in India proper cease, though the game continued to be played in Chitral, Gilgit, Little Tibet and Manipur.

In 1859 the first Europeans' polo club was formed and the first rules of the game drawn up at Silchar in Cachar near Manipur. The Calcutta Polo club was formed in the early 1860s. In 1869 the 10th Hussars started to play polo in England after reading an account of the game in India.

In 1871 the first recorded match took place on Hounslow heath between the 9th Lancers and the 10th Hussars, with eight players a side; in 1873 the numbers were reduced to five and in 1882 to four. The Hurlingham Polo club was founded in 1874 and the first code of rules was drawn up. Two other famous London clubs, Ranelagh and Roehampton, were started in 1896 and 1902 respectively.

The Game.—Polo is played with four players on each side, on exactly the same principles as hockey or association football. The ball is light, made of willow or bamboo root, not more than $3\frac{1}{4}$ in. in diameter and weighing between $4\frac{1}{4}$ and $4\frac{3}{4}$ oz. The stick is made of cane, with a narrow wooden head set on it at a slight angle, and is from 48 to 52 in. long.

A full-sized polo ground should not exceed 300 yd. in length by 200 yd. in width, if unboarded; and 300 yd. in length by 160 yd. in width, if boarded. The goals are not less than 250 yd. apart, and each goal is 8 yd. wide. A match lasts about an hour, divided into periods of play known as chukkers; intervals between periods, when ponies are changed, are of three minutes with five minutes at half time. Ends are changed every time a goal is scored.

Two umpires are required in a first-class match and in an important tournament a referee at the side of the ground decides disputes if the umpires disagree.

Tournaments are organized according to a system of handicapping which is world-wide. Handicapping committees rate all players during a season between ten and no goals and teams of specified totals (*e.g.,* 12 or 20 goals) are made up.

Development of Modern Polo.—Before 1881, when John Watson laid the foundation of modern polo, the method of play was for one man on each side to be the goalkeeper, and for the others to play forward and to hit the ball when and how they could. Watson introduced the backhand stroke, and placed his men at forward (no. 1 and 2) halfback (no. 3) and back (no. 4). He also taught them to combine and hit to each other. But he taught the game on rather rigid lines.

Then the brothers J., A. E. and A. Peat demonstrated how to play the game more scientifically, with such success that they won the Champion cup at Hurlingham eight times. Then came the era of the Freebooters', Rugby, Old Cantab and Roehampton teams, and of the various good regimental teams.

English polo suffered a shock in 1909 when the U.S. team known as "the big four" beat England easily for the Westchester cup. The U.S. had never adopted the English offside rule; they consequently developed a much faster and more elastic game. They met the ball on all possible occasions and hit under their ponies' necks instead of hitting backhanders from the side of the ground. They had developed the science of the attack, galloped faster and were much more accurate goal hitters. Their handicap system, dating from 1891, brought on young players quickly.

In 1910 the Hurlingham club, profiting by the lessons learned from the U.S. in 1909, made two important alterations in their rules. Offside was abolished and handicapping was introduced.

World War I gave a serious setback to English polo. The cost of the game increased enormously. Pony wastage in the war had been heavy, and speeding up the game meant that better ponies were needed; the big thoroughbred trained pony was in great demand, and its price rose considerably. It was contended by some that the quality of polo deteriorated because the size of the ponies made accurate hitting more difficult and the training less thorough. In spite of this polo flourished up to World War II. Programs were organized so that there were tournaments for all classes of players every week. The number of periods played in a match was reduced from eight to six throughout the British empire after World War I.

In India polo playing began gradually to decline. India finally

TECHNIQUE AND PLAYS IN POLO

1. A thong attached to the haft of the mallet is wound tightly around the player's wrist to insure against loss of the mallet during play. The ball is hit with the side, not the head, of the mallet

2. Proper arrangement of the bridle reins on a polo pony. A martingale passed between the pony's forelegs and fastened to the girth under the belly gives the rider added control over his mount

3. Player making a backhand save. The ball is at the far right

4. Strobo-flash photograph of beginning of the swing in a backhand save

5. The player at the left is racing forward to receive a pass from his teammate (right) who is being pressed from behind by an opponent

6. Making a goal

ceased to be the training ground for British polo players in 1947.

The U.S. was at the height of its power between World Wars I and II, and all four members of its team in the Westchester cup of 1939 held handicaps of 10 goals. Argentina, with a unique pony power, were in the same class and in 1936 won the polo match at the Olympic games. Polo in the British empire was stronger than ever.

After World War II it looked as if polo in England was finished. In London, Ranelagh was derelict. The celebrated international ground at Hurlingham and the no. 2 ground were forcibly acquired by the London County council. Roehampton maintained one ground which was only available for a fortnight in the summer. In any case the cost of keeping ponies in London made a revival impossible. But the remnants of the prewar players were determined to carry on. The small Ham club was the first to start. Then Viscount Cowdray began a great revival with the Cowdray Park Polo club. Other old clubs revived and new ones started. A coronation tournament was organized in 1953; the U.S., Argentina, Spain and Chile brought teams. A feature of postwar polo was the large crowd of spectators that attended weekend polo at some clubs.

In 1949 the County Polo association was amalgamated with the Hurlingham Polo association, to which the associations of the following countries were affiliated and had representatives on the council — Ireland, India, Pakistan, South Africa, Egypt, New Zealand. Australia, Kenya, Nigeria, Malaya, Malta and Jamaica. In South Africa polo developed enormously after World War II. Argentina had become the leading polo-playing country. High-class polo had also developed rapidly in Mexico and in Chile, Colombia, and in other parts of South America.

Breeding of Polo Ponies. — The breeding of polo ponies is supervised in England by the National Pony society which maintains a stud book for all kinds of riding ponies and holds an annual show when prizes and medals are given for polo pony classes. Before World War I English- and Irish-bred ponies predominated, though there was a steady influx of Argentine ponies beginning in the '90s.

In India the small country-bred and Arab ponies held sway till the height increase to 14.1 and 14.2 brought in the Australian ponies in large numbers, and New Zealand produced some of high-class quality.

Polo Championships. — The two most important trophies for polo are the Hurlingham Champion cup, inaugurated in 1876, and the Westchester cup, an international contest between Great Britain and the United States. The first Westchester meeting took place in 1886.

Other important events in the London polo season before World War II were the matches for the Ranelagh open cup, started in 1897, the Coronation cup, 1911, and the Roehampton open cup, 1914.

Important events in India were the Indian Cavalry tournament (founded 1883), the Indian Infantry tournament (1884), the Indian Interregimental tournament (1877), the Indian Polo associations championship cup (1900) and the Prince of Wales cup (1921). The first Interregimental tournament at Hurlingham was held in 1878. (J. R. C. G.)

United States. — Attack has always been stressed in play in the U.S. In 1888 what came to be regarded as perhaps the most important legislative contribution to the sport was introduced with the first handicapping of players. Until that time, the game had been virtually monopolized by the better players and H. L. Herbert conceived the idea of the handicap to make possible a wider spread of play. The handicap, low at the start of a player's career, increases with his ability. Thus the beginners are able to play with the more experienced players on a far more even footing. Only the international matches and the open tournaments are played without handicap.

In a game the handicaps of all four players are totalled and the team handicaps compared. One team (unless the totals are even) receives the difference in total handicap. The handicapping system almost immediately resulted in new tournaments and new clubs.

Ten goals was the highest rating ever given to a player as of the mid-1950s. This was held in the U.S. game at varying times by Foxhall P. Keene, John E. Cowdin, Thomas Hitchcock, R. L. Agassiz. J. M. Waterbury, Jr., Lawrence Waterbury, Harry P. Whitney, Louis E. Stoddard, J. Watson Webb, Malcolm Stevenson, Devereux Milburn, Thomas Hitchcock, Jr., Cecil Smith. Elmer Boeseke, Stewart Iglehart, Michael Phipps and Robert Skene.

After the U.S. won its first victory in the Westchester cup international series with England in 1909, the rules were assimilated. The U.S. adopted the English rule permitting the hooking of mallets, and the English abandoned the outside rules and adopted the handicap system. At the close of World War I in 1918, all efforts at limiting the size of ponies were abandoned.

At first the U.S. teams played with native horses, mainly found in the southwest and descended, in part, from the Spanish barb left by those who penetrated that part of the United States in its early history. Later, though Texas and Wyoming produced many polo horses, the thoroughbred was much in demand, with English and Irish blood prominent in a certain line of mounts. The ponies of Argentina later became most popular, but thereafter, Texan mounts regained their popularity.

Although the number of international contests declined, there were more polo players in the United States in the 1950s than ever before. The reduction in the cost of playing was considered the reason for the increase. A new section of the sport, arena polo, a combination of outdoor and indoor polo, proved popular with both players and fans. (R. F. K.; G. E. Cn.)

POLOCK, MOSES (1817–1903), U.S. publisher and bibliophile, is chiefly remembered as the first rare-book dealer to devote himself solely to Americana. Born in Philadelphia, Pa., on May 14, 1817, he was apprenticed to the firm of McCarty and Davis, an old Philadelphia house of bookdealers and publishers. Polock succeeded to the ownership of the firm in 1851 and from 1853 the business was conducted under his name. The store was frequented by well-known literary figures of the time.

Notable among his publications was the first collected edition of the works of Charles Brockden Brown (*q.v.*), earliest U.S. novelist, which appeared in 1857. He was also responsible for the first U.S. collection of children's literature; he specialized in books on Benjamin Franklin and George Washington. He became an authority on the early history of Philadelphia and Pennsylvania. Polock died on Aug. 16, 1903.

See W. Brotherhead, *Forty Years Among the Old Booksellers of Philadelphia (1891)*; A. S. W. Rosenbach, *Books and Bidders (1927)*.

POLONAISE, a dignified ceremonial dance, in $\frac{3}{4}$ time. It frequently served, from the 17th to 19th centuries, to open court balls and other royal functions. Originally a folk dance or warriors' triumphal march, it was adopted by the Polish nobility as a formal march as early as 1573. In its aristocratic form the dancers, in couples, walked around the ballroom in stately procession, with slightly accented steps.

As a musical form, the polonaise was occasionally employed by Luduig van Beethoven, Wolfgang Mozart and George Frederick Handel, and was highly developed by Frédéric Chopin. The polonaise has been introduced in opera (Modest Mussorgsky's Boris *Godounoff*) and ballet (Peter Tschaikovsky's *The* Sleeping Beauty). (Ln. Me.)

POLONIUM (see also Radioactivity, Natural). A radioactive element; symbol Po; atomic number 84.

Historical. — This element was discovered in 1898 by Pierre and Marie Curie. Having found that the radioactivity of uranium and thorium minerals was much greater than could be predicted by the content of uranium and thorium. they undertook to extract the substance responsible for this anomaly from a uranium mineral. Joachimsthal pitchblende. Since the only known property of this hypothetical substance was its radioactivity. Pierre and Marie Curie developed a new experimental method which has remained the basis of all radioactive chemistry. They carried out separations of the various substances in the mineral and measured the radioactivity of each portion. They quickly found that the activity became concentrated, partly with the alkaline earths and partly with the sulphides precipitated from acid solution. They were soon able to confirm the existence of two new radioelements: one a higher homologue of barium — radium; the other a homologue of tellurium. to which they gave the name polonium in honour of Marie Curie's birthplace. Poland.

Polonium was the first element to be discovered by the radiochemical method.

Since then the term polonium has been used in a more general sense and fills the 84th place in Dmitri Mendeléyev's table. allotted to the numerous isotopes listed below. Some of these isotopes are members of the natural radioactive families. (Their individual symbols are given in parenthesis). The others are artificial radioelements.

Isotope	*Period*	*Manner of Disintegration*
Po^{206}	9 days	K (90%), α (10%)
Po^{207}	5.7 hr.	K (about 100%), a (0.01%)
Po^{208}	about 3 yr.	α
Po^{209}	very long (?)	–
Po^{210} (RaF)	140 days	α
Po^{211} (AcC′)	5×10^{-3} sec.	α
Po^{212} (ThC′)	3×10^{-7} sec.	α
Po^{213}	4.4×10^{-6} sec.	α
Po^{214} (RaC′)	1.5×10^{-4} sec.	a
Po^{215} (AcA)	1.8×10^{-3} sec.	β (about 5.10^{-4}%), α (about 100%)
Po^{216} (Th.4)	0.158 sec.	β (about 0.014%), a (about 100%)
Po^{217} (not discovered)		
Po^{218} (RaA)	3.05 min.	β (0.04%), α (about 100%)

The radioelement discovered by Pierre and Marie Curie is the principal isotope: Po^{210}.

Natural Occurrence and Preparation. — Polonium is found in much smaller amounts than radium in minerals containing uranium. About 2,900 kg. of uranium element are in radioactive equilibrium with 1 g. of radium and 0.224 mg. of polonium (1 curie). It can therefore be estimated that the polonium content of a Joachimsthal pitchblende containing **65%** of uranium is about 0.05 mg. in 1,000 kg. of the mineral.

The half life of polonium is long enough to enable it to be extracted directly from uranium minerals. This process has been used but is of little practical value. It is usually extracted either from radio-lead, which is a by-product of the extraction of radium from uranium minerals, or from radium D, obtained by washing old radium tubes which contain the long-lived active deposit: radium D+E+F (I. Curie), or it can be extracted from old preparations of radium salts (E. Rona).

The extraction of polonium from solutions of radium D, as well as the preparation of strong sources (up to about one to two millicuries/cm.^{2}) of this radioelement is usually carried out by electrochemical deposition on Ag or Ni from a weak solution of acetic, nitric or hydrochloric acid. On Ag, Po is deposited free from RaE and RaD; on Ni, from hot solution, Po and RaE are deposited almost free from RaD (W. Marckwald, I. Curie, O. Erbacher and K. Philipp).

Strong sources can be obtained by volatilizing polonium at red heat in a quartz tube in a current of nitrogen or argon and collecting it on a cooled metallic surface (E. Rona and E. Schmidt, I. Curie and F. Joliot).

Finally, element number **84** can be produced artificially by transmutation of atoms of lead or bismuth (J. J. Livingood; D. G. Hurst, R. Latham and W. B. Lewis; D. H. Templeton, J. J. Howland and I. Perlman).

In certain nuclear reactions it is formed directly:

Pb^{204}	(α,2n)	Po^{206}
Pb^{206}	(α,3n)	Po^{207}
Pb^{207}	(α,3n)	Po^{208}
Pb^{208}	(α,2n)	Po^{210}
Bi^{209}	(p,2n)	Po^{208}
Bi^{209}	(d,an)	Po^{208}
Bi^{209}	(d,n)	Po^{210}

In others, Bi^{210}(RaE) is formed intermediately:

Bi^{209}	(n,γ)	Bi^{210}
Bi^{209}	(d,p)	Bi^{210}
Pb^{208}	(α,pn)	Bi^{210}

and $Bi^{210}\xrightarrow{\beta}Po^{210}$.

Properties and Radioactivity. — In 1910 Marie Curie and A. Debierne, using about 0.1 mg. of Po mixed with a few milligrams of other metals. studied the spark spectrum of this material and observed several lines attributable to polonium. the most intense of which was at 4,170.5 A.U. In 1930 A. Czapek pointed out the existence of a line at 2,450.0 Å.U. B. Karlik and H Petterson confirmed this and have drawn attention to a line at **2,558**12 **Å.U.**

The coefficient of diffusion of polonium at ordinary temperature in Al, Fe, Ni, Cu, Ag, Au and Pb is low, about 10^{-14} cm.^{2}/day according to E. Rona and E. Schmidt. In gold and platinum at 470° it is about 10^{-9} cm.^{2}/day (L. Wertenstein and H. Dobrowolska).

According to P. Bonet-Maury, the rate of volatilization in *vacuo* of Po deposited on Ni is measurable at 108° C. and, on heating for 5 min. at 350° C., 90% of the polonium atoms are liberated. From Pt, volatilization does not begin until about 350°. According to Rona it begins from Au at a slightly lower temperature and from Pd only at about 500°–560° C. The vaporization temperature of Po increases with the age of the product. It also varies with the method of preparation of the sources and the gaseous atmosphere into which volatilization is carried out.

Since polonium belongs to the radioactive family uranium-radium and is formed by the disintegration of radium E, an isotope of bismuth, it is sometimes called radium F (RaF).

It disintegrates in its turn with the emission of a-rays to give radium G, an inactive isotope of lead (Pb^{206}). The disintegration period (half life) of polonium is **140** days.

$$\mathrm{Ra}\xrightarrow[\alpha]{}\mathrm{Rn}\xrightarrow[\alpha]{}\mathrm{RaA}\xrightarrow[\alpha]{}\mathrm{RaB}\xrightarrow[\beta]{}\mathrm{RaC}\begin{cases}\xrightarrow{\alpha}\underset{1.32\ \mathrm{min.}}{\mathrm{RaC''}}\xrightarrow{\beta}\\ \xrightarrow{\beta}\mathrm{RaC'}\xrightarrow{\alpha}\end{cases}\mathrm{RaD}\xrightarrow[\beta]{}\mathrm{RaE}\xrightarrow[\beta]{}\mathrm{Po(RaF)}\xrightarrow[\alpha]{}\mathrm{RaG\,(Pb)}$$

Period =	1,590 years	3.82 days	3.05 min.	26.8 min.	19.7 min.	1.5×10^{-4} sec.	22 years	5 days	140 days	stable

The range of the a-rays from polonium has been determined with great accuracy by Irène Joliot-Curie and is **3.87** cm. in air at 15° C. and 760 mm. of Hg. In the gelatin of usual photographic plates it is about 27μ and in aluminum, 22μ. During its passage through air each of the a-particles emitted gives rise to 152,000 pairs of ions. It is calculated that the amount of polonium corresponding to a saturation current of 1 E.S.U. in an ionization chamber utilizing all the ions produced in a solid angle of 2π is equal to 1.67×10^{-10} g. A current of 1,350 E.S.U. represents 1 millicurie of polonium. This a-radiation. which does not seem to be of uniform (kinetic) energy, is accompanied by γ-radiation of weak intensity (about one quantum of 0.773 Mev for 10^5 α-particles) and a secondary β-radiation. According to A. Sanielevici the hourly heat output of 1 E.S U. of polonium, equivalent to the kinetic energy of the a-rays and the recoil RaG atoms is equal to 20.24×10^{-6} cal.

M. Curie and A. Debierne have been able to make a direct determination of the Avogadro number by measuring the volume of helium corresponding to a known number of a-particles emitted by a source of polonium.

The radiation from polonium can bring about the decomposition of water, the ozonization of air, the marking of photographic plates and the coloration of glass or quartz. It exerts a toxic effect on living organisms. A rabbit injected with 500 E S U. of Po wasted considerably and died a few days afterward (A. Lacassagne, J. Lattès and J. Lavedan).

Polonium is often used in radioactivity as a source of a-radiation free from penetrating rays. I. Curie and F. Joliot discovered artificial radioactivity in 1934 by bombarding aluminum, boron and magnesium with a-rays from polonium. A deposit of polonium on beryllium forms a natural source of neutrons which are produced by the nuclear reaction:

$${}^{9}_{4}\mathrm{Be}+{}^{4}_{2}\alpha={}^{12}_{6}\mathrm{C}+{}^{1}_{0}\mathrm{n}$$

and $$^{9}_{4}\text{Be}+^{4}_{2}\alpha=3\,^{4}_{2}\alpha+^{1}_{0}\text{n}.$$

The chemical and electrochemical properties of polonium were determined by radiochemical methods using very small amounts of the order of 10^{-11} to 10^{-6} g. of Po^{210}(RaF).

Polonium in 0.1–0.5 normal solutions of nitric, hydrochloric or acetic acid is deposited spontaneously on Ag, Te, Bi, Ni and on the less noble metals (Marckwald and others).

By the action of an electric current it can be collected from acid solution on the cathode, probably in the metallic state, and on the anode as the peroxide (F. Paneth and G. Hevesy). Similarly, deposits on the cathode and the anode can be obtained from sufficiently alkaline soda solution (M. Haissinsky).

The critical deposition potential of Po in acid solution, for concentrations in the region of 10^{-8} to 10^{-10} normal, has been determined by the decomposition potential method devised by Hevesy and Paneth and considerably improved by F. Joliot. Assuming that Nernst's electrochemical law is applicable when extrapolating to normal potential, as shown by the experiments carried out by Haissinsky with solutions of Bi and its isotopes RaE and ThC, it is found for the electrode Po/Po^{++++} with respect to the hydrogen electrode that:

$$E_h^o\ (Po/Po^{++++}) = +0.77 \text{ v. at } 18° \text{ C.}$$

Polonium is situated, then, between Ag and Te in the normal potential series.

F. Joliot has shown that the cathode deposition potential is lowered if electrolysis is carried out in acid solution in the presence of different reducing agents.

Chemical Properties.—Chemically, polonium being the higher homologue of tellurium and next to bismuth in the periodic table is allied to both these elements.

The following properties of polonium are in common with those of tellurium and bismuth: hydrolysis of its compounds in aqueous solution near the neutral point with the formation of an insoluble hydroxide; precipitation of a sulphide insoluble in dilute acid (P. and M. Curie), reduction to the metallic state by hypophosphorus and hydrosulphurous acid, $TiCl_3$ in hydrochloric acid solution and by hydrazine and formaldehyde in soda solution (M. Guillot and Haissinsky).

Polonium resembles tellurium in its amphoteric character. It can, in effect, act as a cation in acid solution but also gives a volatile hydride PoH_2 (Paneth) and a sodium polonide $PoNa_2$ (V. Khlopin and A. Samartseva). Polonium hydroxide $(O{=}Po{=}[OH]_2)$ is equally amphoteric and dissolves in concentrated sodium hydroxide to give a polonite Na_2PoO_3, analogous to the tellurites (J. Escher-Desrivières). As with tellurium, polonium is precipitated in the metallic state from hydrochloric acid solution by $SnCl_2$ (Marckwald). Finally, according to M. Guillot, it forms polonium hexachlorides isomorphous with similar salts of Te, Pb, Sn, Pt $([M^{IV}Cl_6][NH_4]_2)$ and is then, in that case, quadrivalent and hexa-co-ordinated.

On the other hand, contrary to tellurium, polonium is not precipitated from acid solution by hydrazine and SO_2. It resembles bismuth in the insolubility of its sulphide in ammonium sulphide in alkaline solution (M. Curie) and the insolubility of its pyrogallate in weakly acid solution (Haissinsky). Furthermore, M. Guillot has obtained mixed crystals of dithiocarbamates of polonium and the trivalent metals Bi^{+++} and Co^{+++}. This worker explains the analogies between Po and Bi by supposing that certain reducing agents convert polonium to the trivalent state, which is in agreement with the existence of two cathode deposition potentials. The co-ordination index of the ion Po^{+++} in the complex should be the same as Po^{++++} and equal to 6. Under certain conditions it forms an oxychloride soluble in anhydrous ethyl alcohol, acetone and dioxane (G. Bouissières).

An acetylacetonate of polonium is known (M. Servigne), also a polonium methyl (V. Khlopin and A. Samartseva) and a polonium carbonyl (I. Curie and M. Lecoin).

Summarizing, chemical and electrochemical work has led to polonium's being attributed positive valencies 6, 4, 3 and negative valency 2.

Dosage.—A thin layer of polonium is prepared when measuring the ionization produced by its α-radiation. If it is mixed with other salts, it must be extracted by electrochemical deposition on silver or nickel foil (1 E.S.U. equals 1.67×10^{-10} g. of Po). The magnitude of the activity of a source can be readily judged by the luminosity produced in the dark on a screen of zinc sulphide placed in front of it.

Glossary of Technical Symbols Used in This Article

Ra	Radium	Te	Tellurium
Ac	Actinium	Bi	Bismuth
Th	Thorium	Pb	Lead
&	Silver	Sn	Tin
Ni	Nickel	Co	Cobalt
Pt	Platinum	$TiCl_3$	Titanous chloride
Al	Aluminum	$SnCl_2$	Stannous chloride
Fe	Iron	SO_2	Sulphur dioxide
Cu	Copper	μ	Micron ($=10^{-3}$ mm.)
Pd	Palladium	E.S.U.	Electrostatic unit
Hg	Mercury	Mev	Million electron volts

POLONNARUWA, a ruined city and ancient capital of Ceylon. It first became a royal residence in A.D. 368, when the lake of Topawewa was formed, and succeeded Anuradhapura as the capital in the middle of the 8th century. The principal ruins date chiefly from the time of Prakrama Bahu (A.D. 1153–86). The most imposing pile remaining is the Jetawanarama temple, a building 170 ft. in length, with walls about 80 ft. high and 12 ft. thick. The city is now entirely deserted, and, as in the case of Anuradhapura, its ruins have only recently been rescued from the jungle.

POLOTSK, a town of the Belorussian S.S.R., U.S.S.R., at the confluence of the Polota and Dvina, in 55° 29' N., 28° 49' E. Pop. (1956 est.) 38,100. It is on a railway junction and has saw-milling and timber industries and a flour mill. Its position between central Russia and the west made it a storm centre, and little of the ancient town remains; both the upper castle, which had seven towers, and the lower one are in ruins and its 12th-century cathedral fell in ruins in the 18th century.

Polotesk or Poltesk is mentioned in 862 as one of the towns given by the Scandinavian Rurik to his men. In 980 it had a prince of its own, Ragvald (Rogvolod or Rognvald), whose daughter is the subject of many legends. It remained an independent principality until the 12th century, resisting the repeated attacks of the princes of Kiev; those of Pskov, Lithuania, and the Livonian knights, however, proved more effective; and Polotsk fell under Lithuanian rule in 1320. About 1385 its independence was destroyed by the Lithuanian prince Vitovt. It was five times besieged by Moscow in 1500–18 and was taken by Ivan the Terrible in 1563. Recaptured by Stephen Bathory, king of Poland, 16 years later, it became Polish by the treaty of 1582. It was then a large and populous city and carried on an active commerce. Pestilences and conflagrations were its ruin; the plague of 1566 wrought great havoc among its inhabitants, and that of 1600 destroyed 15,000. The castles, the town and its walls were burned in 1607 and 1642. The Russians continued their attacks, burning and plundering the town, and twice, in 1633 and 1705, taking possession of it for a few years. It was not definitely annexed to Russia until 1772, after the first dismemberment of Poland. In 1812 its inhabitants resisted the French invasion, and the town was partially destroyed.

POLTAVA, a town in the Ukrainian S.S.R., Union of Soviet Socialist Republics, on the right bank of the Vorskla river, in 49° 36' N., 34° 35' E. Pop. (1959) 141,000.

It is the centre of an agricultural district in which grains, sugar beets, tobacco, vines and orchard fruits are grown. Leather is the chief manufacture, and there is an annual fair for the sale of skins, leather and leather goods. Other industries include smelting, stocking manufacture, distilling and brewing. The town is on the railway and is a grain-collecting centre. The Russian annals mention Poltava in 1174 under the name of Ltava. In 1430 it was given, together with Glinsk, to the Tatar prince Leksada by Gedimin, prince of Lithuania. Under the Cossack chief, Bogdan Chmielnicki, it was the chief town of the Poltava "regiment."

Peter the Great defeated Charles XII of Sweden in the neighbourhood of Poltava in 1709.

POLTROT, JEAN DE (*c.* 1537–1563), sieur de Méré or Mérey, a nobleman of Angoumois, who murdered Francis, duke of Guise. He had lived some time in Spain, and his knowledge of Spanish, together with his swarthy complexion, which earned him the nickname of the "Espagnolet," procured him employment as a spy in the wars against Spain. Becoming a fanatical Huguenot, he determined to kill the duke of Guise and gained admission as a deserter to the camp of the Catholics who were besieging Orléans. On Feb. 18, 1563, he hid by the side of a road along which he knew the duke would pass, fired a pistol at him and fled. He was captured the next day, tried, tortured and sentenced to be drawn and quartered. On March 18, 1563, he underwent a frightful punishment. The horses not being able to drag off his limbs, he was hacked to pieces with cutlasses. He had made several contradictory declarations regarding the complicity of Admiral Gaspard de Coligny, but his accusations seem to have had no foundation.

POLYAENUS (2nd century A.D.), a Macedonian living in Rome as a rhetorician and pleader, was the author of a work entitled Strategica (or Strategemata) which he dedicated to the emperors Marcus Aurelius and Lucius Verus on the outbreak of the Parthian War (162–165). This work, still extant, is a historical collection of stratagems and maxims of strategy written in Greek and strung together in the form of anecdotes; it includes also examples of wisdom, courage and cunning from civil and political life. Comprising eight books (parts of the sixth and seventh are lost) it originally contained 900 anecdotes, of which 833 are extant. Despite its many errors of judgment and fact, its contents have some historical value. Evidently highly esteemed by the Roman emperors, it was handed down by them as a sort of heirloom, and passed to Constantinople, being diligently studied by Leo VI who himself wrote a work on tactics. It was also used by Stobaeus and in the Suda lexicon.

POLYANDRY, the system under which a woman is married to several men at the same time (Gr. *polys*, "many" and *aner*, andros "man"). Polyandrous institutions include: (1) cases where children recognize more than one man as having the status of true father; (2) cases in which a woman bears legitimate children to several different fathers in succession; (3) cases where a legitimately married woman regularly cohabits with several men, none of whom rate as father to her children; and (4) cases where a single legitimate husband allows other men to have sexual access to his wife. It is debatable how far any of these varieties may properly be described as polyandrous marriage.

Type 1 occurs in Ceylon, parts of India and Tibet; the fathers in question are usually, but not always, full brothers (in the latter case called adelphic or fraternal polyandry). An unusual version was reported from the Lele of the Belgian Congo, where certain women are regarded as the common wife of all the men in the village. The child of such a woman is a "child of the village" and has a special exalted status. Type 2 is strictly polyandrous only if the successive fathers simultaneously have the status of husband, as seems to be the case among the Todas (south India) and among certain peoples of Northern Nigeria. Such cases may be hard to distinguish from those where each child is born of a different marriage separated from the last by a divorce. The classic example of type 3 is that of the Nayar of south India. Formerly every Nayar (Kair) girl, before attaining puberty, went through a form of marriage with a single husband designated by astrology. After three days the marriage was dissolved and the husband returned to his home. The wife then took lovers who had a recognized status but were not regarded as the legal fathers of her children. If she had several such lovers at one time they cohabited with her but did not reside with her. In this matrilineal society the initial marriage ceremony serves to make a woman's children legitimate, but these children belong to the matrilineage (taravad) of the mother; the social status of father is repudiated altogether. (See NAYAR.)

Polyandry of type 4 includes "wife lending," which may be simply an expression of hospitality and which serves a purpose among families liable to be separated over long periods, as among the Australian aborigines and the Eskimo. Type 4 also includes cicisbeism (male concubinage): the woman has only one legal husband and her children have only one legal father, but her lovers have a recognized and respectable status. Institutions of this kind have occurred sporadically throughout history: Caesar is a witness for the ancient Britons; Herman Melville for the Marquesas islanders; about 1716 it was fashionable at the court of Vienna. The distinction between cicisbeism, slavery and prostitution is not always easy to draw.

Why some societies should approve of polyandry and others not has not been satisfactorily explained. Some polyandrous peoples are said to have more men than women and their polyandry has sometimes been directly attributed to this fact, but the evidence on this point is unconvincing. Tibetan polyandry is alleged to check the increase of population in regions from which emigration is difficult,but since most adult Tibetan women bear children this can hardly be the case. The view that polyandry is designed to prevent the dispersal of family property has greater plausibility for some cases. Personal relations within polyandrous families are often markedly free from jealousy. The polyandry of the Nayar is linked historically not only with their matrilineal ideology but also with their military organization, which prevented the men from living the ordinary life of a husband and father of a family. Polyandry may coexist with monogamy and polygyny (*q.v.*).

POLYANTHUS, a common name applied to several flowers. Although its spelling suggests a true genus, there is no genus by this name. The name (as well as polyantha) is often used as a specific name for plants that produce flowers in clusters. The polyanthus primrose is a hybrid of Primula elatior, P. veris and P. *vulgaris*. Polyanthus narcissus is one of many forms of *Narcissus* tazetta. The old polyanthus or polyanthus lily of Victorian days is the tuberose — Polianthes *tuberosa*. (R. M. C.)

POLYBIUS (*c.* 200–after 118 B.C.), the Greek historian of 3rd- and 2nd-century Rome, was born at Megalopolis in Arcadia; his father Lycortas was a distinguished Achaean statesman. The dates of his birth and death have to be inferred. His reference to measurements along the Via Domitia in Narbonese Gaul (iii, 39, 8) suggests that he was still alive in 118, when this road was constructed; if he died from a fall from his horse at the age of 82, as stated in the pseudo-Lucian's Macrobii, he was probably born about 200 B.C. This would fit Plutarch's description of him (in his Philopoemen) as a boy when he carried Philopoemen's ashes to burial in 182, and also the fact that when appointed ambassador to Egypt in 180 he was under the legal age, which was probably 30 (xxiv, 6, 5; xxix, 24, 6).

Polybius received the upbringing appropriate for a son of rich landowners. His youthful biography of Philopoemen reflected his admiration for the great Achaean leader; and an interest in military matters found expression in his lost book on Tactics (ix, 20, 4). He enjoyed riding and hunting, but his knowledge of literature was rather specialized (apart from the historians) and his acquaintance with philosophy superficial. Between 180, when the Egyptian embassy was canceled because of Ptolemy V's sudden death, and 170/169, when he was hipparch in the Achaean confederation, nothing is known of his career. But he then became involved in critical events. Encumbered by their war with Perseus of Macedonia, the Romans were watching for disloyalty in the Greek states. Although Polybius declared for open support of Rome and was sent with the cavalry to the consul Q. Marcius, Achaean help was rejected (xxviii, 12–13). After Perseus' defeat at Pydna (168 B.C.) Polybius was one of 1,000 eminent Achaeans who were deported to Rome at the instigation of the pro-Roman Callicrates, and detained in Italy without trial.

At Rome Polybius had the good fortune to attract the friendship of L. Aemilius Paulus' two sons Q. Fabius Maximus Aemilianus and P. Cornelius Scipio Aemilianus; he became the latter's mentor and through his family's influence was allowed to remain in Rome when the other detainees were distributed into custody throughout Italy (xxxi, 23, 5). It is probable that Polybius accompanied Scipio to Spain in 151, went with him to Africa (where he saw the Numidian king Masinissa) and crossed the Alps in Hannibal's footsteps on his way back to Italy (iii, 48, 12). In 150, through Scipio's influence and Cato's acquiescence, the 300 surviving internees were allowed to return home (xxxv, 6). Shortly afterward Polybius joined Scipio at Carthage and was present at its siege and destruction in 146; and it is likely that he then undertook a voyage of exploration in the Atlantic as related in Pliny's *Naturalis historia*. Meanwhile hostilities had broken out between Achaea and Rome, and Polybius was in Corinth shortly after its destruction (146). He devoted himself to securing as favourable a settlement as possible for his countrymen, and to re-establishing order (xxxix, 5); and as the geographer Pausanias states, Achaean gratitude found expression in the erection of statues in his honour at Tegea, Pallantiurn, Mantineia, Lycosura—where the inscription declared that "Greece would never have come to grief, had she obeyed Polybius in all things, and having come to grief, she found succour through him alone"—and Megalopolis, where it was recorded that "he had roamed over all the earth and sea, had been the ally of the Romans, and had quenched their wrath against Greece." The inscribed base of a statue erected to him by Elis was discovered at Olympia in 1877; and in 1880 a relief shoning Polybius himself in idealized form was found at Clitor (reproduced in F. W. Walbank, Commentary, frontispiece; see bibliography) and above it a couplet recording that the city raised this most beautiful statue to Polybius, son of Lycortas, in recognition of his noble deeds. Of Polybius' life after 146 little is known. At some date he visited Alexandria and Sardis (xxi. 38, 7). He is known to have discussed political problems with Scipio and Panaetius of Rhodes. He wrote a history of the Numantine War, evidently after 133 B.C., and also a treatise on the habitability of the equatorial region; but when he composed the latter is unknown.

Scope of the History.—The history on ahich his reputation rests consisted of 40 books, the last being indices. Books i–v are extant. For the rest there are excerpts in the collection of passages from Greek historians assembled for Constantine Porphyrogenitus in the 10th century, rediscovered and published by various editors from the 16th to the 19th centuries; excerpts from books i–xvi and xviii, first published at Basel in 1549; and citations and extracts in numerous authors writing between the 1st and 6th centuries A.D., and from the Suda lexicon and that of Stephanus of Byzantium.

Polybius' original purpose was to narrate the history of the 53 years (220–168 B.C.)—from Hannibal's Spanish campaign to the battle of Pydna—during which Rome had made itself master of the world. Books i–ii form an introduction covering Roman history from the crossing into Sicily against the Carthaginians in 264 and including events in various other parts of the world (especially Achaea) between 264 and 220. In book iii, 4, Polybius sketches a modified plan, proposing to add an account of how the Romans exercised their supremacy down to the destruction of Carthage in 146. These events of 168–146 were related in books xxx–xxxix. Probably Polybius conceived his revision after 146, having by this date completed his narrative down to the end of the Second Punic War. At least books i–vi seem to have been published by about 150; there is no information as to when the rest of the work, including the revised plan in book iii, appeared.

Conception of History.—"All historians," according to Polybius (i, 1, 2), "have insisted that the soundest education and training for political activity is the study of history, and that the surest and indeed the only way to learn how to bear bravely the vicissitudes of fortune is to recall the disasters of others." Practical experience and fortitude in facing calamity are the rewards of studying history, and are stressed repeatedly throughout the aork History is essentially didactic. Pleasure is not to be nholly excluded; but the scale comes donn sharply on the side of profit. To be really profitable history must deal with political and military matters; and this is *pragmatike* Izistoria, in contrast to other sorts of history (ix, 1–2)—genealogies and mythical stories, appealing to the casual reader, and accounts of colonies, foundations of cities and ties of kindred, nhich attract the man with antiquarian interests. Its nature is austere, though it may include contemporary developments in art and science, for instance the fire-signaling perfected by Polybius himself (x, 47). It stands in contrast to the sensationalism of many of his predecessors, who confuse history with tragedy. His remarks on Phylarchus are characteristic (ii, 56, 7 ff.): "In his anxiety to excite his readers' pity and secure their sympathy for what he is describing, he introduces women clinging to altars, their hair dishevelled and their breasts uncovered, and crowds of both sexes together with children and aged parents weeping and lamenting as they are led away to slavery. . . . A historian should not try to astonish his readers by such sensationalism, nor, like the tragic poets, seek after men's probable utterances and enumerate all the possible consequences of the events under consideration, but simply record what really happened and was said, however commonplace. For the object of history is the very opposite of that of tragedy. The tragic writer seeks by the most plausible language to thrill and charm the audience temporarily, the historian by real facts and real speeches to instruct and convince serious students for all time. There it is the probable that counts, even though it be false, the object being to beguile the spectator; here it is the truth, the object being to benefit the student."

This attack on Phylarchus is not isolated. Similar faults are castigated in other historians guilty of sensationalism (cf. ii, 16, 13–15; iii, 48, 8; vii, 7, 1–2; xv, 34, 1–36). Nor are these their only weaknesses. Many historians are prone to exaggeration—and that for a special reason. As writers of monographs whose subjects are simple and monotonous, they are driven "to magnify small matters, to touch up and elaborate brief statements and to transform incidents of no importance into momentous events and actions" (xxix, 12, 3). In contrast Polybius stresses the universal character of his own theme, which is to narrate "how and thanks to what kind of constitution the Romans in under 53 years have subjected nearly the whole inhabited world to their sole government—a thing unique in history" (i, 1, 5). Apart from a general preference for a comprehensive view of history, Polybius had a particular reason for adopting it at that point. "Hitherto the affairs of the a-orld had been as it were dispersed . . . ; since this date (220 B C.) history has formed an organic whole, and the affairs of Italy and Africa have been interlinked with those of Greece and Asia. all tending towards one end" (i, 3, 3–4). Indeed, only universal history is capable of adequately treating Rome's rise to world power—the historian's synoptic view matches the organic character of history itself: "What gives my work its peculiar quality, and is nowadays most remarkable, is this. Tyche (Fortune) having guided almost all the world's affairs in one direction and having inclined them to one and the same goal, so the historian must bring under one conspectus for his readers the operations by which she has accomplished her general purpose. For it was chiefly this consideration, coupled with the fact that none of my contemporaries has attempted a general history, which incited and encouraged me to undertake my task" (i, 4, 1–2).

The role here allotted to Tyche is somewhat unusual. For clearly the value of history as a source of practical lessons is diminished if cause and effect are at the mercy of an incalculable and capricious power. Usually, although Polybius uses Tyche to cover a variety of phenomena ranging from pure chance to something very like a purposeful providence, much of the apparent inconsistency springs from his use of purely verbal elaboration or the careless adoption of current Hellenistic terminology, which habitually made Tyche a goddess. Here, however, Tyche seems to be a real directive power, which raised Rome to world dominion—because Rome deserved it. Normally Polybius lays great emphasis on causality, and his distinction (iii, 6) between the causes of an event (aitiai) and its immediate origins (*archai*) is useful up to a point, though it is more mechanical than that of Thucydides, and allows nothing for the dialectical character of real historical situations. An important place in Polybius' work is occupied by his study of the Roman constitution and army and the early history of the city in book vi. His analysis of the mixed constitution, which had enabled Rome to avoid the cycle of change and deterioration to which simple constitutional forms were liable, is full of problems, but it has exercised widespread influence from Cicero's De *republica* down to Machiavelli and Montesquieu.

Sources of **Information.**—Polybius defines the historian's task as the study and collation of documents, acquaintance with relevant geographical features and, finally, political experience (xii. 25e); of these the last two are the most essential. Polybius practised what he preached; he possessed good political and military experience and he traveled widely throughout the Mediterranean and beyond; as he explains, "I sustained the perils of journeys through Africa, Spain and Gaul and of voyages on the sea adjoining these lands on the outside, in order to correct the errors of my predecessors and make known those parts of the world also to the Greeks" (iii, 59, 7). He did not neglect written sources, however; indeed for his introductory books (i–ii), covering the period from 264 to 220, they were essential. His discussion of Aratus and Phylarchus, his sources for Greece, and of Fabius Pictor and Philinus, those for the First Punic War (i, 14–15; ii, 56. 2; iii, 26, 3–4), indicates his critical approach. For the main part of his history, from 220 onward, he consulted many writers, Greek and Roman; but following precedent he rarely names them. An exception is Zeno of Rhodes, whom he criticizes harshly (xvi, 14–19).

He had access to private sources, for instance Scipio Africanus' letter to Philip V of Macedonia, describing the capture in Spain in 209 B.C., of New Carthage (x, 9, 3) and that of Scipio Nasica to some Hellenistic king about the campaigns of the Third Macedonian War (xxix, 14, 3). He almost certainly consulted the Achaean record office (cf. xxii, 9, 10) and must have drawn on Roman records for such material as the treaty between Carthage and Philip V (vii, 9). That he had access to the Rhodian records has not been proved. His detailed figures for Hannibal's troop formations in Italy came from an inscription left by Hannibal, which he found in the temple of Juno on the Lacinian promontory (iii, 33, 18).

Polybius himself regarded oral sources as his most important, and questioning witnesses as the most vital part of a historian's task (xii, 4c, 2–5); indeed this is one reason why he chose to begin his main history at 220. Anything else would be "hearsay at one remove," a safe foundation for neither judgments nor statements (iv, 2, 3). Of the thousands whom he must have questioned few names can be isolated; but at Rome he had opportunities of meeting men from all parts, including internees, ambassadors and visitors.

His purpose was to ascertain the truth. "Truth is to history," he writes (i, 14, 6), "what eyesight is to the living creature"; and in the main Polybius achieves this standard. There are exceptions. His prejudice against Aetolia is easily detected and disallowed; and there is some rancour against Boeotia (xx, 5–7). But no serious charges can be leveled against his reliability; and he has stated his own position very frankly: "That historians should show partiality for their own country I would allow; but not that they should make statements about it that contradict the facts. There are enough errors of ignorance to which historians are liable and which a man may hardly avoid. But if we write falsely from intention—be it for country or for friends or for favour—what better are we than those who make their living by such means? . . . Readers should keep a watchful eye on this tendency, and historians themselves should be on their guard against it" (xvi, 14, 6–10).

Style and Qualities as a Historian.—Writing in the 1st century B.C. as a strict Atticist, Dionysius of Halicarnassus reckons Polybius among those who "have left behind them compositions which no one endures to read to the end"; that his successors shared this view of Polybius' style is confirmed by the failure of his works to survive except in an incomplete form. The infelicity of Polybius' Greek (which frequently reproduces the conventional phrases of the Hellenistic chancelleries familiar from contemporary inscriptions) lies in its awkward use of long and cumbersome circumlocutions, vague abstract nouns and pedantic repetitions. To the scholar his style is, however, no great obstacle; and though in his anxiety to improve his reader he moralizes and labours the obvious, the perennial interest and importance of his theme will always insure him a following among those who can enjoy a historian who is accurate, serious and sensible, understands the events of which he writes, and above all who asks the right questions.

POLYCARP *(c.* 69–*c.* 155), bishop of Smyrna and one of the Apostolic Fathers, derives much of his importance from the fact that he links together the apostolic age and that of nascent Catholicism. The sources from which we derive our knowledge of the life and activity of Polycarp are: (1) a few notices in the writings of Irenaeus, (2) the Epistle of Polycarp to the Church at Philippi, (3) the Epistle of Ignatius to Polycarp, (4) the Epistle of the Church at Smyrna to the Church at Philomelium, giving an account of the martyrdom of Polycarp. Since these authorities have all been more or less called in question and some of them entirely rejected by recent criticism, it is necessary to say a few words about each.

Sources.—I. The Statements of Irenaeus are found *(a)* in his *Adversus haereses,* iii. *3, 4, (b)* in the letter to Victor, where Irenaeus gives an account of Polycarp's visit to Rome, *(c)* in the letter to Florinus—a most important document which describes the intercourse between Irenaeus and Polycarp and Polycarp's relation with St. John. The genuineness of *(c)* is not uncontested, but it is generally accepted.

2. *The Epistle of Polycarp.*—Though Irenaeus states that Polycarp wrote many "letters to the neighbouring churches or to certain of the brethren" only one has been preserved, viz., the well-known letter to the Philippians. The epistle is largely involved in the Ignatian controversy (*see* IGNATIUS). The rehabilitation of the Ignatian letters in modern times has, however, practically destroyed the attack on the Epistles of Polycarp. The date of the epistle depends upon the date of the Ignatian letters and is now generally fixed between 112 and 118. The language in this letter is simple but powerful.

3. *The Epistle of Ignatius to Polycarp.*—This epistle has of course been subjected to the same criticism as has been directed against the other epistles of Ignatius *(see* IGNATIUS); the general criticism, may now be said to have been completely answered by the investigations of Zahn, Lightfoot and Harnack. Some modern scholars feel a difficulty about the peremptory tone which Ignatius adopts towards Polycarp. There was some force in this argument when the Ignatian Epistles were dated about 140, as in that case Polycarp would have been an old and venerable man at the time. But now that the date is put back to about 112 the difficulty vanishes, since Polycarp was not much over forty when he received the letter.

4. *The Letter of the Church at Smyrna* to the Philomelians is a most important document, because we derive from it all our information with regard to Polycarp's martyrdom. Eusebius has preserved the greater part of this epistle (iv. *15),* but we possess it entire with various concluding observations in several Greek mss., and also in a Latin translation. The epistle gives a minute description of the persecution in Smyrna, of the last days of Polycarp and of his trial and martyrdom; and as it contains many instructive details and professes to have been written not long after the events to which it refers, it has always been regarded as one of the most precious remains of the 2nd century. Certain recent critics, however, have questioned the authenticity of the narrative. The more moderate school of modern critics—*e.g.,* Lightfoot *(Ignatius and Polycarp,* 1589 *seq.),* Harnack (*Gesch. d. altchrist. Lit.* II. i. 341), and Krüger *(Early Christian Lit., 1897)—is* unanimous in regarding it as an authentic document, though it recognizes that here and there a few slight interpolations have been inserted. Besides these we have no other sources for the life of Polycarp.

Life.—Polycarp must have been born not later than the year 69, for on the day of his death (*c.* 155) he declared that he had served the Lord for eighty-six years (*Martyrium,* 9). Irenaeus tells us that in early life Polycarp "had been taught by apostles and lived in familiar intercourse with many that had seen Christ" (iii. 3, 4).

This testimony is expanded in the remarkable words which Irenaeus addressed to Florinus:

"I saw thee when I was still a boy (παῖς ἔτι ὤν) in Lower Asia in company with Polycarp . . . I can even now point out the place where the blessed Polycarp used to sit when he discoursed, and describe his goings out and his comings in, his manner of life and his personal appearance and the discourses which he delivered to the people, how he used to speak of his intercourse with John and with the rest of those who had seen the Lord, anrl how he would relate their words. And everything that he had heard from them about the Lord, about His miracles and about His teaching, Polycarp used to tell us as one who had received it from those who had seen the Word of Life with their own eyes, and all this in perfect harmony with the Scriptures. To these things I used to listen at the time, through the mercy of God vouchsafed to me, noting them down, not on paper but in my heart, and constantly by the grace of God I brood over my accurate recollections."

These words establish a chain of tradition (John-Polycarp-Irenaeus) which is without a parallel in early church history. Polycarp thus becomes the living link between the Apostolic age and the great writers who flourished at the end of the 2nd century. Recent criticism, however, has endeavoured to destroy the force of the words of Irenaeus. Harnack (*Chronologie,* i., 325–329), for instance, attacks this link at both ends. (*a*) The connection of Irenaeus and Polycarp, he argues, is very weak, because Irenaeus was only a boy (παῖς) at the time, and his recollections therefore carry very little weight. The fact, too, that he never shows any signs of having been influenced by Polycarp and never once quotes his writings is a further proof that the relation between them was slight. (b) The connection which Irenaeus tries to establish between Polycarp and John the apostle is probably due to a blunder. Irenaeus has confused John the apostle and John the presbyter. Polycarp was the disciple of the latter, not the former. In this second argument Harnack has the support of a considerable number of modern scholars who deny the Ephesian residence of John the apostle. But in spite of much modern criticism there seems to be no solid reason for rejecting the statements of Irenaeus and regarding Polycarp as the link between the Apostolic age and the first of the Catholic fathers.

Though Polycarp must have been bishop of Smyrna for nearly half a century we know next to nothing about his career. We get only an occasional glimpse of his activity, and the period between 115 and 155 is practically a blank. The only points of sure information which we possess relate to (1) his relations with Ignatius, (2) his protests against heresy, (3) his visit to Rome in the time of Anicetus, (4) his martyrdom.

His Relations with **Ignatius.**—Ignatius, while on his way to Rome to suffer martyrdom, halted at Smyrna and received a warm welcome from the church and its bishop. Upon reaching Troas he despatched two letters, one to the church at Smyrna, another addressed personally to Polycarp. In these letters Ignatius charged Polycarp to write to all the churches between Smyrna and Syria (since his hurried departure from Troas made it impossible for him to do so in person) urging them to send letters and delegates to the church at Antioch to congratulate it upon the cessation of the persecution and to establish it in the faith. The letters of Ignatius illustrate the commanding position which Polycarp had already attained in Asia. It was in the discharge of the task which had been laid upon him by Ignatius that Polycarp was brought into correspondence with the Philippians. The Church at Philippi wrote to Polycarp asking him to forward their letters to Antioch. Polycarp replied, promising to carry out their request and enclosing a number of the letters of Ignatius which he had in his possession.

Polycarp's Attack on Heresy.—All through his life Polycarp appears to have been an uncompromising opponent of heresy. We find him in his epistle (ch. vii) uttering a strong protest against certain false teachers (probably the followers of Cerinthus).

For every one who shall not confess that Jesus Christ is come in the flesh is antichrist; and whosoever shall not confess the testimony of the Cross is of the devil; and whosoever shall pervert the oracles of the Lord to his own lusts and say that there is neither resurrection nor judgment, that man is the first-born of Satan. Wherefore let us forsake their vain doing and their false teaching and turn unto the word which was delivered unto us from the beginning.

Polycarp lived to see the rise of the Marcionite and Valentinian sects and vigorously opposed them. Irenaeus tells us that on one occasion Marcion endeavoured to establish relations with him and accosted him with the words, "Recognize us." But Polycarp displayed the same uncompromising attitude which his master John had shown towards Cerinthus and answered, "I recognize you as the first-born of Satan." The steady progress of the heretical movement in spite of all opposition was a cause of deep sorrow to Polycarp, so that in the last years of his life the words were constantly on his lips, "Oh good God, to what times hast thou spared me, that I must suffer such things!"

Polycarp's Visit to Rome.—It is one of the most interesting and important events in the church history of the 2nd century that Polycarp, shortly before his death, when he was considerably over eighty years old, undertook a journey to Rome in order to visit the bishop Anicetus. Irenaeus, to whom we are indebted for this information (*Haer.* iii. 3, 4; *Epist. ad victorem, ap.* Euseb. v. 24), gives as the reason for the journey the fact that differences existed between Asia and Rome "with regard to certain things" and especially about the time of the Easter festival. Unfortunately all he says is that with regard to the certain things the two bishops speedily came to an understanding, while as to the time of Easter, each adhered to his own custom, without breaking off communion with the other. We learn further that Anicetus as a mark of special honour allowed Polycarp to celebrate the Eucharist in the church, and that many Marcionites and Valentinians were converted by him during his stay in Rome.

Polycarp's Martyrdom.—Not many months apparently after Polycarp's return from Rome a persecution broke out in Asia. A great festival was in progress at Smyrna. The proconsul Statius Quadratus was present on the occasion, and the asiarch Philip of Tralles was presiding over the games. Eleven Christians had been brought, mostly from Philadelphia, to be put to death. The appetite of the populace was inflamed by the spectacle of their martyrdom. A cry was raised, "Away with the atheists. Let search be made for Polycarp." Polycarp took refuge in a country farm. His hiding-place, however, was betrayed and he was arrested and brought back into the city. Attempts were made by the officials to induce him to recant, but without effect. When he came into the theatre, the proconsul urged him to "revile Christ," and promised, if he would consent to abjure his faith, that he would set him at liberty. To this appeal Polycarp made the memorable answer, "Eighty and six years have I served Him and He hath done me no wrong. How then can I speak evil of my King who saved me?" These words only intensified the fury of the mob. They clamoured for a lion to be let loose upon him there and then. The asiarch, however, refused, urging as an excuse that the games were over. When they next demanded that their victim should be burned, the proconsul did not interfere. Timber and faggots were hastily collected and Polycarp was placed upon the pyre. With calm dignity and unflinching courage he met his fate and crowned a noble life with an heroic death.

Eusebius in his *Chronicon* gives A.D. 166 as the date of Polycarp's death, and until the year 1867 this statement was never questioned. In that year appeared Waddington's *Mémoire sur la chronologie* de *la* vie *du rhéteur* Aelius *Aristide,* in which it was shown from a most acute combination of circumstances that the Quadratus whose name is mentioned in the *Martyrium* was proconsul of Asia in 155–156, and that consequently Polycarp was martyred on Feb. 23, 155. Waddington's conclusion has received overwhelming support amongst recent critics. His views have been accepted by (amongst many others) Renan (*Antéchrist,* 1873, p. 207), Hilgenfeld (*Zeitschr.* f. *wiss. Theol.,* 1874, p. 325), Gebhardt (*Zeitschr. f. hist. Theol.,* 1875, p. 356), Lipsius (*Jahrb.* f. *prot. Theol.,* 1883, p. 525), Harnack (*Chronologie,* i. 334–356), Zahn (*Zeitschr.* f. *wiss.* Theol., 1882, p. 227). Lightfoot (*Ignatius* and *Polycarp,* i. 629–702) and Randell (*Studia biblica,* 1885, i. 175). Against this array of scholars only the following names of importance can be quoted in support of the traditional view—Keim (*Aus dem Urchristentum,* p. 90), Wieseler (Die Christen-*verfolgungen* der *Caesaren,* 1878, p. 34) and Uhlhorn (Studia Biblica, 1890, ii., 105–156). The problem is too complex to admit of treatment here. There seems to be little doubt that the case for the earlier date has been proved.

The significance of Polycarp in the history of the Church is out of all proportion to our knowledge of the facts of his career. The violent attack of the Smyrnaean mob is an eloquent tribute to his influence in Asia. "This is the teacher of Asia," they shouted, "this is the father of the Christians: this is the destroyer of our gods: this is the man who has taught so many no longer to sacrifice and no longer to pray to the gods." And after the execution they refused to deliver up his bones to the Christians for burial on the ground that "the Christians would now forsake the Crucified and worship Polycarp." Polycarp was indeed, as Polycrates says, "one of the great luminaries" (*megala* stoikeia) of the time. It was in no small degree due to his staunch and unwavering leadership that the Church was saved from the peril of being overwhelmed by the rising tide of the pagan revival which swept over Asia during the first half of the 2nd century, and it was his unfaltering allegiance to the Apostolic faith that secured the defeat of the many forms of heresy which threatened to destroy the Church from within.

Polycarp had no creative genius. He was a "transmitter, not a maker." As Irenaeus says (iii. 3, 4), "Polycarp does not appear to have possessed qualifications for successfully conducting a controversial discussion with erroneous teachers . . . but he could not help feeling how unlike their speculations were to the doctrines which he had learned from the Apostles, and so he met with indignant reprobation their attempt to supersede Christ's gospel with fictions of their own devising." It is this that constitutes Polycarp's service to the Church, and no greater service has been rendered by any of its leaders in any age.

Bibliography.—J. B. Lightfoot, *Apostolic Fathers*, pt. ii. (2nd ed., 1889). Polycarp is dealt with in i. 417–459, 530–704; ii. 897–1086; G. Volkmar, *Epistula Polycarpi Smyrnaei genuina* (1885); *T*. Zahn, *Forschungen zur Geschichte des Kanons, &c.*, iv. 249, 279; J. M. Cotterill, "The Epistle of Polycarp to the Philippians," *Journ. of Philol.* (1891), xix., 241–285; Harnack, *Chronologie der altchristlichen Litteratur* (1897), and authorities quoted in the text. *See* also Apostolic Fathers. (H. T. A.; X.)

POLYCHAETA, a class of segmented, largely marine worms. The name refers to the serially arranged tufts of bristles at the sides of the body. Examples are *Nereis* and *Serpula*. *See* Annelida.

POLYCLITUS (Polycleitus), the name of two Greek sculptors of the school of Argos; the first belonging to the 5th century, the second to the earlier part of the 4th.

The elder, better known Polyclitus (fl. 5th century B.C.) was a contemporary of Phidias and in the opinion of the Greeks his equal. Whether he was a pupil of Ageladas is disputed; at least he carried on the Argive tradition. He made a figure of an Amazon for Ephesus which was regarded by later Greek writers as superior to the Amazon of Phidias made at the same time. His colossal Hera of gold and ivory which stood in the temple near Argos was considered as worthy to rank with the Zeus of Phidias. Balance, rhythm and the minute perfection of bodily form, which were the great merits of this sculptor, appealed especially to the Greeks of the jth century. Polyclitus worked mainly in bronze.

In regard to his chronology we have data in a papyrus published by B. P. Grenfell and A. S. Hunt containing lists of athletic victors. From this it appears that he made a statue of Cyniscus, a victorious athlete (464 or 460 B.C.), of Pythocles (452) and Aristion (452). He thus can scarcely have been born as late as 480 B.C. His statue of Hera is dated by Pliny to 420 B.C. His artistic activity must therefore have been long and prolific. His two great statues, ideal or heroic types rather than portraits, are the Diadumenus ("Man Tying on a Fillet") and the Doryphorus ("Spearbearer"), copies of both of which survive. The Doryphorus was known as "The Canon," because it embodied the correct proportions of ideal male form. The most complete copy is from Herculaneum. There are Roman copies in marble of the Diadumenus in London and New York, giving a good basic impression but only a general idea of the finish of Polyclitus' work in bronze. At Delos French excavators discovered a Diadumenus of more pleasing type and greater finish, a Hellenistic transformation of the Polyclitan type into a youthful Apollo. Among the bases of statues found at Olympia were three signed by Polyclitus, still bearing on their surface the marks of attachment of the feet of the statues. This gives us their pose, and critics such as A. Furtwängler identified several extant statues as copies of figures of boy athletes victorious at Olympia set up by Polyclitus. Among these the Westmacott athlete in the British museum is probably a copy of the "Cyniscus" mentioned above.

The Amazon of Polyclitus survives in many copies, among the best being the Lansdomne statue in the Metropolitan Museum of Art, New York. The masterpiece of Polyclitus, his Hera in gold and ivory, has totally disappeared, but coins of Argos give us the general type. A marble head in the British museum gives a Greco-Roman version of this type. treated in general terms.

The want of variety in the works of Polyclitus was brought as a reproach against him by certain ancient critics. Varro says that his statues were square and almost of one pattern. Excepting the statue of Hera, the work of his later years, he produced scarcely any notable statue of a deity. His field was narrowly limited; but in that field he was unsurpassed.

The younger Polyclitus (fl. 4th century B.C.) was of the same family as the elder. Sculptures by him have been difficult to identify among existing copies. Some bases bearing the name. however, are inscribed in characters of the 4th century, when the elder sculptor cannot have been alive. He was also an architect of note. His best-known buildings are the tholos (in ruins) and the theatre (now restored) of Epidaurus (360–330 B.C.).

Bibliography.—G. M. A. Richter, *The Sculpture and Sculptors of the Greeks*, 246 ff. (1950); G. Lippold. *Handbuch der Archäologie*, iii, 1, 162 ff. (1950); R. B. Bandinelli, *Policleto* (1938). (C. C. V.)

POLYCRATES, tyrant of Samos (c. 535–515 B.C.). Having won popularity by donations to poorer citizens, he took advantage of a festival of Hera, which was being celebrated outside the walls, to make himself master of the city (about 535 B.C.). After getting rid of his brothers Pantagnotus and Syloson, who had at first shared his power, he established a despotism which is of great importance in the history of the island. He equipped a fleet of 100 ships and so became master of the Aegean basin. This ascendancy he abused by numerous acts of piracy which made him notorious throughout Greece; but his real aim was the control of the archipelago and the mainland towns of Ionia. He maintained an alliance with Lygdamis of Naxos, and dedicated to Delos the island of Rheneia. He also defeated a coalition of two great naval powers of the Asiatic coast, Miletus and Lesbos. He made an alliance, probably commercial in object, with Amasis of Egypt. But the squadron he sent to Amasis' support against Cambyses of Persia, being composed of political opponents of Polycrates, suspected treachery and returned and attacked Polycrates. After a defeat by sea, Polycrates repelled an assault upon the walls, and subsequently withstood a siege by a joint armament of Spartans and Corinthians assembled to aid the rebels. He maintained his ascendancy until about 515, when Oroetes, the Persian governor of Lydia, who had been reproached for his failure to reduce Samos by force, lured him to the mainland and put him to death by crucifixion.

Beside the political and commercial pre-eminence which he conferred upon Samos, Polycrates adorned the city with public works on a large scale. He was also a patron of letters; he collected a library, and Anacreon lived at his court.

POLYCYTHEMIA VERA, a chronic disease of unknown cause usually affecting adults of northern European origin. The basic abnormality is overproduction of red cells, white cells and platelets by the marrow and to a lesser extent by other blood-forming tissues. The patient has a red-blue appearance and complains of dizziness and headaches due to the increase of red cells. Major causes of death and disability are hemorrhages and clots, especially in the skin, brain and gastrointestinal tract. These complications may be controlled by irradiation or radiomimetic drugs which depress the overactive blood-forming tissues. Irradiation of any type may be followed by acute leukemia (*q.v.*). Over the years, regardless of treatment. the spleen enlarges due to formation of a marrowlike tissue; the previously active marrow is replaced by scar tissue and bone. In this terminal "burnt-out" stage the overproduction of blood cells ceases. The patient develops weakness due to anemia: bleeding due to lack of platelets. malnourishment and infection. Treatment is then palliative. consisting of blood transfusions. (M. H. Bl.)

POLYDORUS, the name of two figures in Greek mythology.

1. Polydorus, youngest son of Priam and Laothoe (Homer, *Iliad* xxii, 46) or Hecuba (Euripides and later writers). In Homer, Polydorus is killed in battle by Achilles. Euripides (*Hecuba*) tells

how Priam sent Polydorus with great treasures to Polyrnestor, king of Thrace, who murdered the boy for the money and threw his body into the sea; the corpse was tragically discovered later by Hecuba. Virgil (Aeneid iii, 22 ff.) has Polymestor bury Polydorus, polluting Thracian soil against Aeneas' settlement.

2. Polydorus was the son of Cadmus, father of Labdacus and ancestor of Oedipus. (WM. S. A.)

POLYGALACEAE, a family of dicotyledonous herbs, shrubs and small trees, comprising 10 genera and about 700 species, not represented in New Zealand, Polynesia and the arctic zone, but otherwise cosmopolitan. In North America about 50 species are found, chiefly in the southern and western United States. Polygala *vulgaris* is the British milkwort (*q.v.*), and P. Senega, the Senega snakeroot, a North American medicinal plant.

POLYGLOTT or POLYGLOT, a book which contains side-by-side versions of the same text in several languages (Gr. *polys,* many, and glotta, tongue). The most important polyglotts are editions of the Bible, or its parts, in which the Hebrew and Greek originals are exhibited along with the great historical versions. The famous *Hexapla* of Origen (*q.v.*), in which the Old Testament Scriptures were written in parallel columns, probably suggested the later polyglotts, but though it gives six texts it is itself only in two languages. In the 16th and 17th centuries polyglotts became a favourite means of advancing the knowledge of eastern languages as well as the study of Scripture. See also BIBLE.

POLYGNOTUS (c 500–440 B.C.), Greek painter, son of Aglaophon, was a native of Thasos who soon moved to the Greek mainland and eventually acquired Athenian citizenship. His fame was based on large, monumental wall paintings in the severe style, admired by posterity but now totally lost. The following titles are mentioned by ancient writers: (1) Plataeae, entrance porch of the temple of Athena Areia: "Ulysses after the punishment of the suitors"; (2) Athens, Painted Hall ("Poikile"): "The taking of Ilium"; (3) Athens, Temple of the Dioscuri ("Anakeion"): "Wedding of the daughters of Leucippus"; (4) Athens, Acropolis ("Pinacotheca"): "Achilles in Scyrus"; (5) Same as no. 4: "Nausicaa"; (6) Delphi, Hall ("Lesche") of the Cnidians: "Departure of the Greeks from Ilium"; and (7) Same as no. 6: "Ulysses visiting Hades."

Pausanias left an account of the last two paintings (Paus. x, 25–31) from which, with occasional support of other sources, the following characteristics of Polygnotus' style are deduced. Figures approximating life-size were freely distributed within the composition, near the lower border and higher. In Greek painting of the first half of the 5th century B.C. this method represents an innovation, though precedents existed elsewhere, notably in Assyrian art. It constitutes a break with the ancient Greek principle of arranging figures on a single base line; Polygnotus replaced the horizontal base lines by irregular, mounting or descending terrain lines. Comparable representations can be found in contemporary vase paintings, perhaps under his influence. There was no unifying perspective in the modern sense: the individual figure remained the focus of interest even when several figures were grouped together. Stateliness was paired with subtlety of detail: delicate headdresses of women, transparent garments, mouths uith parted lips uncovering the teeth. Sharp foreshortenings were not lacking. Coloration consisted of four basic colours: black, white, red and ochre. None of the last named characteristics can be claimed for Polygnotus alone: he was merely the outstanding representative of the severe style in Greek monumental painting. The "ethos" which later critics, including Aristotle (Poetics, ch. 6), valued so highly in his work indicates a concept of character as an innate disposition, governing the actions and manifest in a person's outward bearing.

See Carl Weickert, "Studien zur Kunstgeschichte des 5. Jahrhunderts v. Chr. I., Polygnot," *Abhandlungen* der Deutsch. *Akademie* des *Wissenschaften,* vol. 1947, no. 8 (1950). (O. J. BL.)

POLYGONACEAE, the buckwheat family, a dicotyledonous family of about 40 genera and 800 species, consisting chiefly of herbs, although shrubs, vines and even trees occur. The stems are often swollen at the nodes (from whence comes the genus name *Polygonum,* referring to the many joints or knees). The leaves are alternate, usually simple and entire, and stipules at the base of the leaves usually form a highly characteristic sheathing growth (ocrea) around the stem. The flowers, often borne in clusters, are radially symmetrical, lacking petals, and usually small. The calyx generally consists of five or six separate or united sepals. These are usually green or white, but other colours such as rose and yellow also occur. The stamens vary in number from five to nine and the achenelike fruit is one-celled, one-seeded and usually three-carpellate and three-sided. The single seed is erect and attached at the base of the fruit. The flowers, usually bisexual, are wind- or insect-pollinated (depending on the genus), or sometimes self-pollinated. The family is so distinct from its nearest relatives that it is placed in a separate order. the Polygonales.

The apparently basic type of flower has six sepals (two whorls of three), nine stamens and three united carpels: such a flower is usual in Eriogonum. Although examples with the flower parts in fours occur, the usual variation is a reduction in number of one or all of the parts. Five sepals and five to eight stamens are frequent in *Polygonum;* two whorls of two (2 + 2) sepals and two united carpels characterize Oxyria.

The family occurs primarily in the northern hemisphere. As is true in many plant families, the geographic distribution of the genera often provides interesting problems. Polygonum (about 200 species) is widely distributed, whereas Rheum is strictly Asian, and *Muehlenbeckia* (15 species) is unusual because it is limited almost entirely to the southern hemisphere. Coccoloba, with 125 species, is confined to the American tropics and subtropics. Several small genera (*e.g.,* Gilmania, Hollisteria, Mucronea) are limited to California, while the one species of Koenigia, in addition to being circumboreal, is found also in the Himalayas and in Tierra del Fuego. Of the two species of *Brunnichia,* one occurs in the southeastern part of the United States, the other in west Africa.

The tribe Eriogoneae is strictly American and occurs almost entirely in the western portion of the United States. Besides several small genera, the tribe includes Chorizanthe (60 species) and *Eriogonum,* nearly 200 species. The tribe is unusual in lacking the ocreae so characteristic of the family.

To the Polygonaceae belong such wild plants as mountain sorrel (Oxyria digyna), smartweed and water pepper (several species of Polygonum), canaigre (*Rumex hymenosepalus;* see DOCK), whose root is a source of tanning material and dye, and California buckwheat (*Eriogonum* fasciculatum), an important bee plant in its native range.

Common weeds that belong to this family are knotweed (*q.v.*) or knotgrass (Polygonum aviculare); the vine, black bindweed (Polygonum convolvulus); and dock or sorrel (*qq.v.*) (several species of *Rumex*). In this last genus, the three inner sepals known as valves, enlarge and surround the fruit.

Among the important cultivated food plants in the family are buckwheat (*q.v.;* Fagopyrum esculentum) and rhubarb (*q.v.*) or pieplant (*Rheum rhaponticum*). Ornamentals include several old world species of *Polygonum* such as silver lace vine (P. auberti), coral vine (Antigonon) from Mexico and the sea-grape (Coccoloba uvifera) whose fleshy sepals form an edible berrylike structure. (G. J. G.)

POLYGONAL AND POLYHEDRAL NUMBERS: see FIGURATE NUMBERS.

POLYGONS. A polygonal line, also called a broken line, joining the point A, to the point A, is any finite set of points A_1, A„ . . . , *A,* and the segments A_1A_2, A_2A_3, . . . , $A_{n-1}A_n$. In this and the following definition of a polygon the phrase "a point A," means a point associated with the symbol *A,* and the phrase "a segment A_iA_j" means the segment whose ends are the points which are the associates of the symbols A, and A, respectively, associated with the symbol A_iA_j. A segment is the set of all points of any (straight) line which are between any two points of that line. Each of the latter points is called an end of the segment. A polygon is any finite set of points A_1A_2, . . . , A, and the segments A_1A_2, A_2A_3 . . . , A_{n-1} A„ A_nA_1. The points A, and segments A_iA_{i+1}, A_nA_1, $i = 1, 2, \ldots, n$, are called respectively the vertices and sides of the polygon; similarly for a polygonal line.

The terms polygonal line and polygon are used also with meanings which are different from, although closely related to, those given above. A polygon as defined may have one of two senses assigned to it so that the first end and the second end of each side is specified in such a way that the vertex A_i is either the first end of the side A_iA_{i-1} and the last end of the side $A_{i-1}A_i$, and if $i=1$, A, is the first end of A_1A_2, and the second end of A_nA_1, or vice versa. A polygon with such an assignment of a sense is called an *oriented* or a *sensed polygon*. In an obvious way an oriented polygonal line is defined. Thus two sensed polygons or polygonal lines are associated with each polygon or polygonal line. In the sequel the phrase the oriented (or sensed) side AB of a sensed polygon indicates that *A* is the first end of the oriented side ***AB*** of that oriented polygon, and B the second. Polygonal lines and polygons according to the first definition are referred to as *unoriented* or *unsensed polygonal lines* and *polygons* respectively. In formulating a third meaning of the terms polygonal line and polygon it should be emphasized that the elements involved in the above definition are points and segments associated with symbols so that an unoriented or oriented polygon is neither a set of points and segments nor a set of points. The word polygon also is used to signify either certain sets of points and segments or certain sets of points. The distinctions just pointed out although delicate are logically essential and even practically important. For the purpose of this article the single word "polygon" denotes any set of points which consists of the points which are the associates of the symbols $A_1, A_2, \ldots, A_n$ and the points which belong to the segments which are the associates of the symbols A_iA_{i+1}, $i=1, 2, \ldots, n$ and A_nA_1 of the first definition; *i.e.*, the definition of an unsensed polygon. Similarly in the case of a polygonal line.

The above definitions are of broad scope and define abstractions which are based on the phenomenon of the motion of a particle from point to point along intermediate rectilinear stretches. Important specializations of these ideas are the so-called *simple polygons* or polygonal lines according to any of the definitions given. A simple unoriented polygon is any unoriented polygon which is such that none of its vertices is an end of more than two of its sides and no side of the unoriented polygon contains a vertex or a point which belongs to another side of the unoriented polygon. The definitions of simple unoriented polygonal lines, simple oriented polygonal lines and polygons as well as those of simple polygons and polygonal lines in conformity with the third definition are apparent and consequently are not stated formally. Alternative definitions for the several concepts defined or indicated above may be given; for example a simple polygon may be defined as a finite set of points and segments such that *(a)* every point of the set is the end of two and only two segments of the set, *(b)* each end of every segment of the set is a point of the set, (c) no segment of the set contains a point of the set or a point of another segment of the set and (d) no (proper) subset of the given set satisfies (a), (b) and (c). It is easy to show that this definition is equivalent to the one indicated in introducing the third formulation of the idea of a polygon and it is valuable in that it admits of immediate generalization to the idea of a polyhedron in space.

Place of Polygons in Mathematics.— The theory of polygons as a special chapter in mathematics is chiefly concerned with the classification of unoriented and oriented polygons all of whose elements,—that is, vertices and sides,—are in the same plane. The corresponding question for space concerns polyhedrons and is taken up in the article on SOLIDS, GEOMETRIC. Polygons whose elements are not in one plane have not as yet formed the subject of any interesting theory. Such polygons, as well as plane polygons, however, serve as important aids, as in the study of continuous curves in general. This is largely because of the fact that any continuous arc contains the vertices of a polygonal line, the length of whose sides are all less than any preassigned positive number, and which is simple if the arc is simple. In particular, the length of an arc of a curve is defined by means of the lengths of the inscribed polygonal lines,—that is, polygonal lines which join the ends of the arc and whose vertices are on the arc and have an order which conforms to one of the two senses along the arc. In the geometry of the Euclidean plane, plane polygons,—that is, those having all of their points in one plane,—take on an added significance because of the fact that the Euclidean plane is separated into two regions by any simple polygon that is contained in it. This is a consequence of the basic fact that a line separates the Euclidean plane. Unless it is stated otherwise it is understood that in the following all configurations are in the Euclidean plane. A *region* is a set of points such that any point of the set is the centre of a circle which has only points of the set in its interior and such that the set is not composed of two sets having the latter property and also having no points in common. It follows easily that any two points of a region are joined by a simple polygonal line which is contained in the region. A precise statement of the important fact mentioned above is that if P is any simple plane polygon, then the plane is composed of P and two regions which have no points in common with each other or with P. One of these regions is of infinite extent and the other is not. A region such as the latter is referred to as a *polygonal region* and also as the *interior* of the polygon concerned and the latter is called the *boundary* of the polygonal region. Every circle which has a point of the boundary of the polygonal region as centre contains points of the region and any point which is such that any circle having it as centre contains points which belong to the region and also points which do not is a point of the boundary of the region. This property of the boundary of any polygonal region is used as the defining property of the boundary of a region in general. As a further consequence should be mentioned the fact that any polygonal region plus its boundary is composed of a finite number of triangles and their interiors, which have no points in common, and the vertices of the triangles are vertices of the bounding polygon. A region which is not a polygonal region is, however, approximated to by polygonal regions according to the following theorem: If Σ is any region, then there exists a sequence of polygonal regions $\Sigma_1, \Sigma_2, \Sigma_3, \cdots, \Sigma_n, \ldots$ such that *(a)* Σ_n and its boundary is contained in Σ and also in Σ_{n+1} for all (positive integral) values of n and (b) each point of Σ is contained in all but a finite number of the polygonal regions Σ_n. This theorem is easily proved by using as the polygonal regions regions which are composed of congruent squares which are formed by two sets of parallel lines, the lines of each set being equally spaced and intersecting orthogonally those of the other set. These acts indicate the importance of polygonal lines and polygons in the study of more general configurations.

THE THEORY OF PLANE POLYGONS

The Interior, Exterior and Peripheral Angles of a Plane **Polygon.**—We now proceed to the special theory of plane polygons. As remarked above, this theory concerns itself largely with unoriented and oriented polygons. In the case of a simple polygon the meaning of "an interior angle of a polygon" is immediate in virtue of the theorem concerning the separation of the plane by the polygon. This meaning leads to an interesting generalization in the case of an oriented polygon. In proceeding to this generalization and to related ideas it should be stated that all of the terms used are not defined with the mathematical completeness that would be possible with a greater allowance of space, but it has been aimed at least to indicate clearly the way to that completeness. Now it can be proved that if P is a simple oriented polygon and *A* any vertex of P then for the positive (counterclockwise) rotation of any side AB of P about its first end *A*, in accordance with the sense of P, which transforms the side ***AB*** into the other side of P having *A* as an end and which has a magnitude not exceeding 2π radians, then the points on the intermediate positions of AB which are within a certain distance of *A* are all in the interior of the polygon determined by P if the sense of P is the same as that of the rotation and all in the exterior in the contrary case. (Note that senses of oriented polygons are compared only in the case of simple oriented polygons.) Accordingly the *interior angle at any vertex* A_i of any oriented polygon P is defined as the positive angle (rotation) which has A_i as its vertex and whose initial side contains the side of P which has A_i

as its first end, say the side A_iA_{i+1}, whose terminal side contains the side with the ends A_i and A_{i-1}, if $i\neq 1$, and A_n if $i=1$, and whose magnitude does not exceed 2π. (See fig. 1.)

Further if A_i is any vertex of an oriented polygon P and the first end of the oriented side A_iA_{i+1} of P then there is a rotation about A_i of the half-line having A_i as its initial point and having the same direction as the oriented side $A_{i-1}A_i$ ($i-1\equiv n$ if $i=1$), that is the half-line of the line through A_{i-1} and A_i, which has A_i as its initial point and which does not contain A_{i-1}, into the half-line which contains the side A_iA_{i+1} which has a magnitude greater than $-\pi$ and less than or equal to π and there is another such rotation which is positive and has a magnitude not exceeding 2π. The former angle (rotation) is called the *exterior angle* and the latter the *peripheral angle* of the oriented polygon P at the vertex A_i.

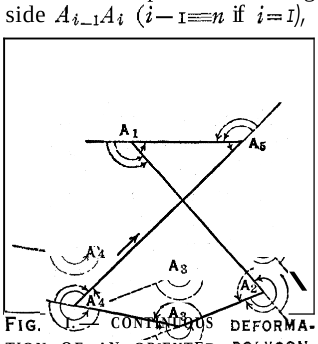

FIG. 1.— CONTINUOUS DEFORMATION OF AN ORIENTED POLYGON, WITH FIVE VERTICES

If α_i, β_i, γ_i are respectively the magnitudes of the interior, exterior and peripheral angles of the oriented polygon P at the vertex A_i then $\alpha_i+\beta_i=\pi$ and $\alpha_i+\gamma_i=\pi$ or 3π according as α_i is or is not less than π. If α_i is less than π then γ_i is and conversely. If the sum of all the β_i is set equal to $2a\pi$ and the sum of all the γ_i to $2a'\pi$ then a and a' are integers or zero as a simple consideration shows and $a'-a$ is the number of interior angles of P whose magnitudes are greater than or equal to π. If P' and P'' are two oriented polygons which differ only in orientation and if α_i', β_i', γ_i' and α_i'', β_i'', γ_i'' are respectively the magnitudes of the interior, exterior and peripheral angles of P' and P'' at the vertex A_i then $\alpha_i'+\alpha_i''=2\pi$, $\beta_i'+\beta_i''=0$ and $\gamma_i'+\gamma_i''=2\pi$. Hence the value of a for P'' is the negative of its value for P' while the value of a' for P'' is the number of vertices of P' (or P'') minus the value of a' for P'.

Classification of Plane Polygons.— In the classification of oriented polygons the numbers a and a' have been used to define the so-called types of such polygons. It is obvious how they may be used in the classification of unoriented polygons. There exist oriented polygons of any number n of vertices for which the value of a is any number whose absolute value does not exceed $\frac{1}{2}(n-1)$ except that for a triangle a cannot be zero. A more detailed scheme of classification is according to the values of a and $q=a'-a$. If all of the interior angles of an oriented polygon have magnitudes which do not exceed π then the polygon is called a *convex oriented polygon.* The unoriented polygon P is convex if and only if P with a sense assigned to it is convex. Both of these definitions are in conformity with the important notions of a *convex simple polygon* and a *convex polygonal region.* A *convex region* is a region such that all of the points of any segment whose ends belong to the region belong to the region also. A simple polygon is said to be convex if it is the boundary of a convex region, which is then a convex polygonal region. As theorems we have: A line which does not contain a side of a convex simple polygon contains not more than two points of the polygon and conversely. Also, no point of a convex simple polygon is on a particular one of the two sides of the line which contains any side of the polygon and conversely.

Another method of classification of unoriented and oriented polygons uses the notion of the continuous deformation of such polygons. Any one of two unoriented polygons with the vertices $A_1, A_2, \ldots, A_n$ and $B_1, B_2, \ldots, B_n$ respectively is deformable continuously into the other so that the vertex A_i corresponds to the vertex B_i and the side A_iA_{i+1} to the side B_iB_{i+1}. To obtain subclasses of unoriented polygons continuous deformations of such polygons, which satisfy any or all of the following conditions, are used: (1) no intermediate polygon of the deformation has two consecutive sides which lie in the same line and which have no points in common; (2) neither of two consecutive sides of any intermediate polygon of the deformation is contained in the other; and (3) no point is common to more than two sides of any intermediate polygon of the deformation. In the case of oriented polygons it is also required that sense be preserved by the deformation. Two oriented polygons that are transformable one into the other by a continuous deformation satisfying the first condition have the same value for a. If instead of the first condition the second is satisfied the oriented polygons have the same value for a'. If the deformation satisfies both the first and second conditions then the two oriented polygons are related so that if the magnitudes of one of two corresponding interior angles is less than π then the same is true of the other. Corresponding results for unoriented polygons follow easily. An interesting classification of unoriented polygons which satisfy the conditions on the intermediate polygons of the deformations satisfying all three conditions and which, in addition, have no vertex as the end of more than two sides and no side containing a vertex or a point belonging to more than two sides is that in which any unoriented polygon in one class is deformable into any other or into the symmetric image of any other in that class by a continuous deformation satisfying all three of the above conditions. For unoriented polygons of 4, 5 and 6 vertices there are respectively 3, 11 and 70 classes under this classification.

Non-metrical and Metrical Theories. Regular Polygons. Area of Polygons.— It should be pointed out that the above theory of the classification of unoriented and oriented polygons holds without essential modification in a more general plane than the Euclidean for only the order relations of the Euclidean plane are essential. Between this theory and the corresponding theory in the projective plane there are, because of the different kinds of linear order, some essential differences. but both theories are non-metrical. By making use of the metric properties of the Euclidean plane the consideration of regular polygons, oriented or not, becomes possible; also the question of the area of polygonal regions arises. An unoriented polygon is *regular* if any side is congruent to any other side and any angle of the polygon, *i.e.,* the figure consisting of a vertex and the two consecutive sides having that vertex as an end, congruent to any other "angle" of the polygon. The regular polygons are convex and there exists a circle circumscribed about and another inscribed in every regular polygon. Those regular polygons that are not simple also are called *star polygons.* If n points which are equally spaced on the circumference of a circle and numbered in order along that circumference are joined by segments so that the i-th point is joined to the $(i+d)$-th point, where d is a fixed positive integer, then the polygon resulting is a regular polygon for which the value of a, defined above, is d. Thus the number of "types" of regular polygons of n vertices is half of the number of positive integers which are less than and prime to n. Other kinds of regular polygons have been studied with particular reference to their classification along the lines explained above. For instance, there are the polygons which have the property that the figure composed of any vertex and the two sides of the polygon which have that vertex as an end is congruent to any other such figure and also the polygons which are such that the figure consisting of any side and two adjacent angles of the polygon is congruent to any other such figure. These polygons have an even number of vertices and a circle is circumscribable about any of those of the former kind and inscribable in any of those of the latter.

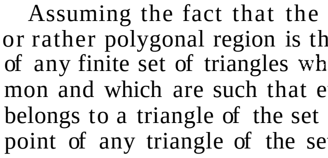

FIG. 2.— DEFORMATION OF A POLYGON OF FOUR VERTICES INTO THREE TYPES

Assuming the fact that the area of any plane simple polygon or rather polygonal region is the sum of the areas of the triangles of any finite set of triangles which have no interior points in common and which are such that every point of the polygonal region belongs to a triangle of the set or to the interior of one and every point of any triangle of the set or of the interior of any belongs to the polygonal region or its boundary the notion of the area of any plane unoriented or oriented polygon is approached. In the case of an unoriented or oriented polygon in general there is no region uniquely determined as in the case of simple polygons. In the following only the case of oriented polygons is considered for that essentially covers the case of unoriented polygons. If the area of a triangle according to the usual meaning is σ then the area of that triangle with a sense assigned to it is defined as σ or $-\sigma$ according as that sense is positive or negative; *i.e.*, the same or not the same as the counterclockwise sense along the circumference of a circle. Using the symbol $A_1A_2 \dots A_n$ to denote

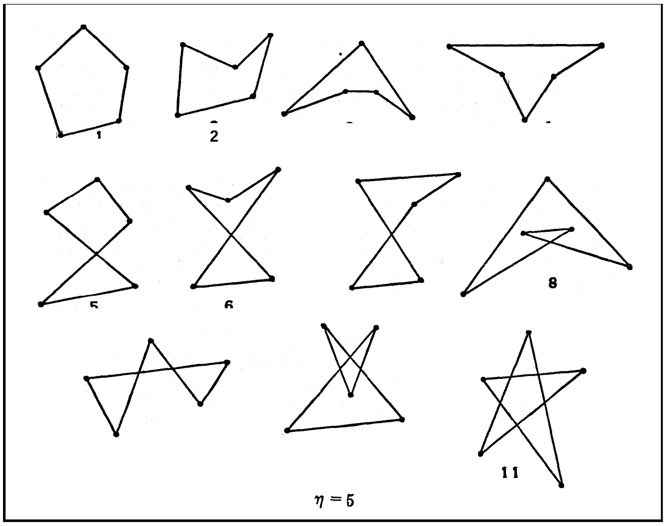

FIG. 3.— DEFORMATION OF A POLYGON OF FIVE VERTICES INTO 11 DIFFERENT TYPES

the oriented polygon with the vertices $A_1, A_2, \dots, A_n$ and the sensed sides A_iA_{i+1}, the area of the oriented polygon $A_1A_2 \dots A_n$ is defined as the sum of the areas of the oriented triangles $OA_1A_2, OA_2A_3, \dots, OA_nA_1$ where O is any point of the plane. It is, of course, proved that the value of the area thus defined does not depend on the position of O and that if $A_1A_2 \dots A_n$ is simple, this definition agrees with the area of a simple polygon according to the fundamental definition. An oriented polygon P determines a finite number of polygonal regions in its plane which have no points in common and whose boundaries are composed of points belonging to P. One and only one of these regions is of infinite extent. Now the following interesting facts pertain: let the regions, or cells, of finite extent be denoted respectively by $S_1, S_2, \dots, S_k$, and let the area of the cell S_i according to the fundamental definition of the area of a polygonal region be σ_i so that σ_i is a positive number; then there exists a set of numbers $c_1, c_2, \dots, c_k$ which are either integers or zero such that the area of the oriented polygon P is $c_1\sigma_1 + c_2\sigma_2 + \dots + c_k\sigma_k$. Further: c_i is the number of complete positive revolutions minus the number of complete negative revolutions made by the radius vector, having any point O of S_i as its initial point, as its terminal point describes once the oriented polygon P in the assigned sense. c_i is called the coefficient of the cell S_i. *See* TOPOLOGY, ALGEBRAIC.

POLYGRAPH, a device for simultaneously measuring and recording various bodily functions such as heart-beat, blood pressure, respiration rate, etc. Because these functions tend to fluctuate abnormally when a person attempts to lie or deceive, the polygraph is used extensively in the investigation of crime. Used in this manner it is popularly called a lie detector (*see* INVESTIGATION, CRIMINAL: *Detection of Deception*).

POLYGYNY, the system under which a man is married to several women at the same time, a type of polygamy or plural marriage. Polygyny is nowhere the exclusive form of marriage, and among most peoples who permit it the large majority of men live in monogamy. It may be modified in a monogamous direction both from the social and the sexual point of view. Frequently one of the wives: generally the one first married, holds a higher position than the rest or is regarded as the principal wife. In some cases this position implies certain sexual privileges; but more often it is the custom for the husband to cohabit with wives in turn, or this is actually required of him. How far theory and practice coincide is moot—one may be for a time the favourite.

Primitive Societies.—Among preliterate peoples polygyny does not seem to be practised on a large scale by the hunters and food-collectors, except some Australian and Bushman tribes, nor by any incipient agriculturists. On the other hand, a considerable number of these hunting and slightly agricultural tribes—such as some of the South American Indians, the aboriginal tribes of the Malay peninsula, most of the Andaman Islanders, the Veddas of Ceylon, certain tribes in the Malay archipelago, most of the Negritos of the Philippine Islands and some at least of the central African pygmies—are represented as monogamous. Among more well-to-do hunters polygyny is more frequent, although in the majority of their tribes it is practised only occasionally; and exclusive monogamy is rare, though perhaps not unknown. Among pastoral peoples there seems to be none that can be regarded as strictly monogamous; and both among them and the higher agriculturists polygyny is undoubtedly more frequent than among the hunters and incipient agriculturists, although cases of regular monogamy are more frequent among the higher agriculturists than among the higher hunters. The cases in which polygyny is represented as general are comparatively much more numerous among African than non-African pastoral peoples and higher agriculturists. Polygyny is at its height in Africa, both in point of frequency and in number of wives. King Mtessa of Uganda and the king of Loango are said to have had 7,000 wives.

Ancient Civilizations.—Polygyny, or a sort of concubinage hardly distinguishable from genuine polygyny, is found among most peoples of archaic civilization. In China there were, besides the legal principal wife, so-called wives "by courtesy" or lawful concubines. In Japan concubinage of the Chinese type existed as a legal institution until 1880. In ancient Egypt polygyny seems to have been permitted but to have been unusual, except in the case of kings. The Babylonian code of Hammurabi assumed that marriage should be monogamous; yet "if a man has married a wife and a sickness has seized her," he might take a second wife; and if she remained childless he might take a concubine. Among the Hebrews a man could in any circumstances have a plurality of wives, and there was no difference in the legal status of different wives, nor was there any limit to the number of wives a man might take. In Arabia Mohammed ordained that a man's legal wives should be not more than four. Polygyny has been permitted among many of the Indo-European peoples—among ancient Slavs and Teutons, the ancient Irish and the Vedic Indians—though it seems to have been as a rule confined to kings or chiefs or nobles. None of the Hindu lawbooks restricts the number of wives a man is allowed to marry; yet some preference is often shown for monogamy, and most castes object to their members having more than one wife, except for some cogent reason. On the other hand, there can be little doubt that monogamy was the only recognized form of marriage in Greece; concubinage existed in Athens, but it was well distinguished from marriage, conferring no rights on the concubine. Roman marriage was strictly monogamous; liaisons between married men and mistresses were not uncommon, but such a relation was not considered lawful concubinage.

Modern Times.—Polygyny has been found even in Christian Europe. No obstacle was put in the way of its practice by kings in countries where it had occurred in the times of paganism. In the middle of the 6th century Diarmait, king of Ireland, had two queens and two concubines. Polygyny was frequently practised by the Merovingian kings. Charlemagne had two wives and many concubines; and one of his laws seems to imply that polygyny was not unknown even among priests. In later times Philip of Hesse and Frederick William II of Prussia contracted bigamous marriages with the sanction of the Lutheran clergy. In 1650, soon after the peace of Westphalia, when the population had been greatly reduced by the Thirty Years' War, the Frankish *Kreistag* at Niirnberg passed the resolution that thenceforth every man should be allowed to marry two women. The Anabaptists and the

Mormons once advocated polygyny with much religious fervour.

Causes.—One cause of polygyny can be an excess of marriageable women in certain age groups. But while the existence of available women makes polygyny possible. the direct cause of it is generally the man's desire to have more than one wife. There are various reasons for this desire. Among many of the simpler peoples the husband has to abstain from his wife during her pregnancy. or at least during the latter stage of it, and after childbirth until the child is weaned. which often means an abstinence lasting for a couple of years or more. Other contributing factors are the attraction of youth and beauty, the desire for many children—which is one of the principal causes of polygyny in the east—and the fact that polygyny may contribute to a man's material comfort or wealth, and thereby his social importance. But it should also be noted that the paying of a dowry, the amount of which is influenced by economic conditions, makes it possible for certain men to acquire several wives while others can acquire none at all.

See MARRIAGE; POLYANDRY; SOCIAL ANTHROPOLOGY; SORORATE; see also references under "Polygyny" in the Index volume.

POLYMERIZATION, in chemistry, was originally considered to be any process in which two or more molecules of the same substance unite to give a molecule (polymer) with the same percentage composition as the original substance (monomer), but with a molecular weight which is an integral multiple of the original molecular weight. The special case that exists when the monomer and polymer are so easily interconvertible that their isolation and chemical distinction are difficult, is usually considered to be association (*q.v.*).

The term "polymerization" now applies when the monomer and polymer are easily distinguished; it applies also to preparations of some polymers which do not conform to the original definition (*see* below). Polymerization is the process by which plastics, resins and rubber are synthesized (see PLASTICS: RESINS; RUBBER: PRODUCTION AND MANUFACTURE). This article is concerned with the general principles of polymerization processes. and particularly with the much-studied. industrially important processes which produce polymers of high molecular weight (high polymers).

Addition Polymerization.— This process occurs when monomer units simply join together to form polymers. The process usually requires a double or triple bond in the structural formula of the monomer. Although a carbon-oxygen or carbon-nitrogen multiple bond will serve (see FORMALDEHYDE)! most examples involve carbon-carbon double bonds, particularly olefins with $>C=CH_2$ groups (see CHEMISTRY: Organic *Chemistry* for many terms used here). Some polymers contain only two or three monomer units (see TERPENES), some contain many, and some monomers yield more than one kind of polymer. Phosphonitrile chloride. $P\equiv NCl_2$, is an inorganic monomer yielding several addition polymers.

The polymerization of styrene (*q.v.*) illustrates addition polymerization. The monomer is a colourless, mobile liquid. On standing for several weeks at room temperature. for a few days at 100° C., or for a shorter time at higher temperatures, the liquid polymerizes, becoming first an increasingly viscous solution of polymer in monomer. and finally a clear, odourlcss, glassy solid. The polymer is a mixture of molecules of the formula $(C_6H_8)_n$, where n has a wide range of values and averages several thousand. When the monomer is warmed with 1% or less of an initiator such as benzoyl peroxide. $C_6H_5—CO—O—O—CO—C_6H_5$, a similar polymer is formed, but in minutes or hours instead of days or weeks. These processes are chain reactions, starting when styrene is activated thermally, or when the initiator decomposes, to give electrically neutral fragments of molecules. with free or unsaturated valences (free radicals with trivalent carbon atoms). Such a fragment, R —, adds easily to the double bond in the monomer

$$R - + H_2C = CH - C_6H_5 \rightarrow R - CH_2 - CH(C_6H_5) -$$

forming a larger radical with the free valence now on the styrene unit. This new free radical adds to another double bond, and so on, so that many monomer units become linked together in a linear (threadlike) polymer. Thousands of steps in a single reaction chain may occur in a second, the reaction ending when two radicals interact and mutually destroy their free valences.

Similar polymerizations are industrially important both with liquids (*e.g.*, vinyl acetate, acrylic esters, acrylonitrile) and with gases under pressure (*e.g.*, ethylene, butadiene and vinyl chloride). Such polymers have a wide range of physical properties (see PLASTICS; ETHYLENE; BUTADIENE). To avoid difficulties in handling large masses of hard or viscous polymer, large-scale polymerizations are frequently carried out in emulsion or suspension in water to produce synthetic latex or beads.

Initiators which do not produce free radicals may also be employed. Some metal halides (aluminum chloride or boron trifluoride), sulfuric acid, metal alkyls (from sodium, lithium or aluminum: see ORGANOMETALLIC COMPOUNDS) and strong bases (sodamide) also cause addition polymerization of some olefins. but here the growing chains are usually ion pairs. These initiators require anhydrous conditions since the polymer ions are destroyed by water. Although styrene and butadiene are polymerized by all the initiators mentioned, the choice of initiators for most monomers is limited.

Considerable heat is evolved when high polymers are formed, and the process can become violent. The driving force in the polymerization is the conversion of the double bond in each monomer to two single bonds in the polymer. In a sense, the strain in the double bond is thus relieved. However. in the polymer, the monomer units are crowded together and restricted in their motions. These restrictions become more important at increasing temperatures. and high polymers made from larger monomers begin to revert to monomer above 200° C. Polymers from smaller monomers hold together better, but at 300°–400° C. they also break up, yielding complex mixtures and rather little monomer.

When a mixture of two monomers is subjected to polymerization. the product may contain both monomers in each polymer molecule (*i.e.*, copolymerization of two monomers yields a copolymer), or it may contain only one kind of monomer in each polymer molecule, depending on the monomer and type of initiator. Many commercial polymers are actually copolymers. a wider range of properties being possible than with single monomers.

Two polymers may have atoms joined together in the same sequence. but still have different physical properties because of different spatial relations among the atoms (see STEREOCHEMISTRY: *The Stereochemistry* of Carbon). Lowering the temperature of polymerization for SBR synthetic rubber from 50° to about 5° C. has resulted in the improved "cold rubber." Natural rubber has been duplicated by polymerizing isoprene with specific organometallic catalysts. Similar catalysts have produced crystalline modifications of polystyrene and polypropylene which melt above 150° C.. instead of softening below 100°.

Condensation **Polymerization.**—This is the process of making products, commonly called polymers, with the formation of a small, easily removed molecule (often water) for each step in the process. For making high polymers, the general method is to choose a simple and clean organic reaction, to make it possible for this reaction to take place at each end of every molecule, and to force the reaction to completion by removing the water (or other volatile condensation product) from the reaction mixture. Reactions uhich give amides or esters are particularly useful. For example, a polyamide can be made either from an amino acid, $H_2N—(CH_2)_x—CO_2H$, or from an equimolecular mixture of a dibasic acid, $HO_2C—(CH_2)_y—CO_2H$, and a diamine. $H_2N—(CH_2)_z—NH_2$. Proteins are polyamides assembled from many amino acids in a very specific manner by enzymes. Starch and cellulose can be considered to be made similarly from glucose units. The condensation of a dihydroxysilane produces a silicone (*q.v.*) polymer. (See also AMIDES; ESTERS; PROTEINS; STARCH; CELLULOSE.)

For polymerization to occur, each molecule must contain two potential open ends and the monomer units must join end-to-end into linear polymers. Such polymers are usually soluble in suitable solvents, soften (reversibly) on heating, and are termed thermoplastic. However, if the monomers contain more than two sites of reaction (*e.g.*, butadiene, glycerol, phenol, tribasic acids), then netlike (cross-linked) instead of threadlike molecules result. When the networks grow large enough, they become equivalent to many linear polymer molecules joined together in a single network. At this stage, the polymers are insoluble and infusible and are termed thermosetting. See PLASTICS: Causes of *Resinification,* Synthetic Resin Plastics; RESINS: Synthetic Resins.

POLYMORPHISM. Many chemical substances, elements as well as compounds, crystallize in two or more distinct atomic arrangements which are differentiated by their X-ray diffraction patterns, outward crystal form, optical properties, energy content, volume, etc., and as such, are separate crystalline phases of the substance, according to the definition laid down by J. W. Gibbs (1876). The name "polymorphism" was applied to this property by E. Mitscherlich (1823), who discovered it in sodium phosphate and sulphur. Another term: "allotropy," attributable to J. Berzelius (1841), was proposed as a name for the supposed different conditions of the same element, both in the pure state and in compounds of which the element forms a part. Subsequent usage tended to confine the term to elements (W. Ostwald, 1893), and included such forms as gaseous oxygen and ozone, the mobile and viscous forms of sulphur, the different forms of phosphorus and the diamond and graphite forms of carbon. In the broadest sense, allotropy was applied by A. Smits (1911) to compounds in studies of "inner equilibria" prevailing therein between different molecular species. All cases of allotropy in the crystalline state are merely examples of polymorphism, and are best described as such. A polymorphic substance may be described as dimorphic, trimorphic, etc., according to the number of distinct crystalline forms.

Polymorphic substances may also be distinguished according to whether or not two given forms are reversibly transformable one into the other. When the transformation is reversible, the change is said to be enantiotropic; if it is found to be unidirectional only under all conditions investigated thus far, it is said to be monotropic. Two phases of one substance in equilibrium form a univariant system according to the phase rule; this means that if pressure and temperature are chosen as the external variables, the equilibrium temperature will depend upon the pressure, the composition being constant. The equilibrium temperature at constant pressure is known as the transition or inversion point. For example, rhombic sulphur is in equilibrium with monoclinic sulphur at 95.6° C., 1 atm., and at 129.9° C., 845 atm. The variation of the transition temperature with the pressure is expressed quantitatively by the Clapeyron equation in the form $dT/dp = T(v_{I}-v_{II})/L$ where T is the temperature on the Kelvin scale, p the pressure, L the latent heat absorbed and $v_{I}-v_{II}$ the difference in volume of the high- and low-temperature form, respectively, all per unit mass. dT/dp was measured for numerous enantiotropic transitions by G. Tammann, P. W. Bridgman and others. Since $v_{I}-v_{II}$ is usually small in comparison with L/T, high pressures are required to produce appreciable changes in the transition temperature; for sulphur in the above example, the average $dT/dp=0.034°$ per atmosphere. Other examples are: low to high quartz, 0.021; red to yellow HgI_2, 0.0016. Three phases of one substance in equilibrium form an invariant system; this means that the phases can coexist at some one constant pressure and temperature characteristic of the phases present. This invariant point is named the triple point. In polymorphism two of the phases must be different crystalline forms of the substance; the third phase may be another crystal form, or liquid or vapour. For sulphur the triple point rhombic-monoclinic-vapour is 95.6° C. (approx.), 0.00003 atm.; rhombic-monoclinic-liquid, 153.7° C., 1,400 atm. For water, which has seven crystalline phases, the triple point ice I—ice II—ice III is at −34.3° C., 2,100 atm. (see ICE).

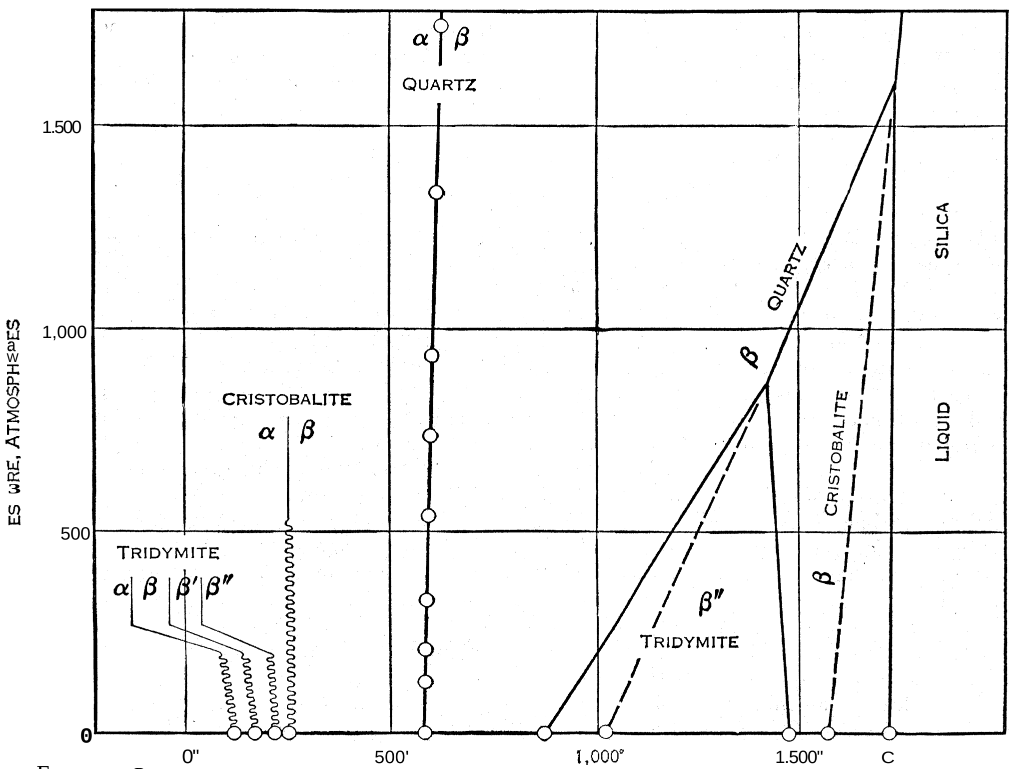

FIG. 1.— PRESSURE-TEMPERATURE PHASE DIAGRAM FOR SILICA. SOLID LINES REPRESENT TRANSITIONS OF PHASES STABLE IN THE RESPECTIVE ADJOINING REGIONS. BROKEN LINES REPRESENT TRANSITIONS OF METASTABLE PHASES. TRIDYMITE AND CRISTOBALITE IN THE REGION OF THEIR ALPHA-BETA TRANSITIONS ARE EACH METASTABLE WITH RESPECT TO ALPHA QUARTZ, WHICH IS HERE THE STABLE PHASE

A polymorphic substance, when mixed with one or more other substances and brought to equilibrium, may have its transition point changed. Both experimental evidence and deductions from the phase rule indicate that this occurs when the polymorph and the added substance form solid solution. If the polymorph crystallizes pure from the mixture or solution, the transition point remains unaltered. Thus, NH_4NO_3, which crystallizes pure from its aqueous solution, is found to invert at 32°, 84° and 125° C., whether alone or in the presence of its aqueous solution. KNO_3, on the other hand, forms solid solutions with NH_4NO_3, and equilibrium mixtures of the two invert at temperatures which depend on the composition of the system. Specifically, *e.g.*, 20% KNO_3 added to NH_4NO_3 lowers the 32° transition to near 0° C.

The enantiotropic transformations considered above are in many respects analogous to melting or freezing, with one important difference. In melting it is rarely observed that a crystal can be superheated above its melting point. although undercooling on freezing is common. Polymorphic transitions may be both superheated and undercooled; the aidth of the band of indifference (hysteresis band) varies from a few degrees for prompt transitions to unknonn values for very sluggish ones. Transitions in uhich only minor changes of crystal symmetry occur are often prompt, while those involving marked alterations of structure are usually more or less sluggish Both varieties of behaviour may be found in the same chemical substance, as in silica *(q v)*. *See* fig 1. The three main varieties of silica are quartz, tridymite and cristobalite. These differ considerably in their crystal structures, and are mutually transformed only with great difficulty. quartz to tridymite at 867° C and tridymite to cristobalite at 1,470° C., at the pressure of one atmosphere The sluggishness of these transformations is evidenced by the fact that these varieties of silica have been found in coexistence in certain volcanic rocks for geologic ages. On the other hand, there occur one or more relatively rapid transitions between high- and low-temperature forms of each of the main varieties, accompanied by only slight changes in crystal structures; namely, in quartz at 573° C., in tridymite at 118°, 163° and 230° C. and in cristobalite between 200° and 275° C. In the slow transformation of quartz to tridymite or to cristobalite, catastrophic changes in the structure occur which involve the breaking of Si-O-Si bonds. whereas only distortions of structure occur in the rapid transitions of the low- to high-temperature forms in quartz, tridymite or cristobalite.

The enantiotropic transformations may be contrasted with the monotropic transformations. for which no transition temperature had been found experimentally at mid-20th century. The classification is not particularly exact, inasmuch as it is usually based not on the knowledge of the actual stabilities of the phases but rather on empirical findings, usually at atmospheric pressure only. The tendency to transform may be held in abeyance by the same energy barriers that are responsible for the metastable existence of such enantiotropic forms as cristobalite at ordinary temperature. Many cases of monotropism at ordinary pressure occur among organic compounds, as in chloroacetic acid. which can crystallize in three different forms with melting points at 50.2°, 56.2" and 61.3° C., the two lower melting forms being unstable with respect to the highest melting form An instance of apparent monotropism is offered by calcium carbonate, which is found in nature as the stable calcite (*q.v.*) and as aragonite, which is unstable with respect to calcite at ordinary and higher temperatures. The transformation aragonite to calcite at these temperatures is truly unidirectional. A thermodynamic study of the stabilities of the two indicates. however, that belcw −60° C. aragonite becomes the stable form. At higher temperatures, the complex aragonite structure, although unstable, inverts only slowly to the simpler structure of calcite. Both aragonite and calcite have been found together in certain fossils. The influence of structure on transformability is shown even more strikingly in diamond and graphite, two forms of carbon (fig. 2). Diamond, the less stable torm,

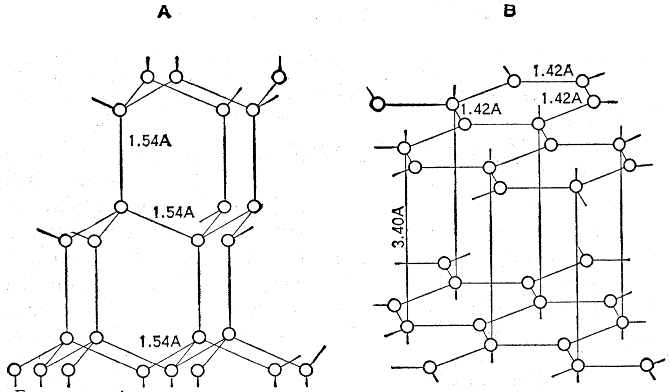

FIG 2 — ARRANGEMENT OF ATOMS IN THE LATTICE OF (A) DIAMOND, WITH (111) PLANE HORIZONTAL, AND (B) GRAPHITE. WHERE LINES LINK ATOMS OF SUCCESSIVE SHEETS WHICH ARE IN THE SAME VERTICAL COLUMNS. NOTE THE DIFFERENCES IN THE INTERATOMIC DISTANCES IN THE TWO TYPES OF CRYSTAL. SMALL CIRCLES INDICATE LOCATIONS OF CENTRES OF CARBON ATOMS, AND BEAR NO RELATION TO THEIR SIZE

has a very rigid cubic structure, with each carbon atom joined to four others by bonds of equal strength. whereas the rhombohedral graphite has one weak bond and three much stronger ones. These give it its layer lattice and lubricating properties. The two lattices have nearly the same energies of cohesion, about 170,000 cal. per mole, which differ by only joo cal. per mole; the difference is too small to provide the energy of activation for the necessary rearrangement in the strengths of the bonds, and there is no evident tendency to transform at ordinary temperatures. From measurements made at the national bureau of standards, it appears that high pressures and low temperatures increase the thermodynamic stability of diamond; very great pressures would. however: be required to produce artificial diamonds at temperatures high enough for the rate of transformation to become appreciable (much more than 50,000 atm. at 2,000° C.).

The occurrence of polymorphism and the formation of metastable modifications had not yet been satisfactorily explained in detail at mid-20th century. Qualitatively, the energy change in the transition of one form to another (*i.e.*, the heat of transition) is much smaller than the energy of formation of the individual lattices from the vapour. A number of atomic arrangements of nearly the same energy may be possible for a given substance, such that different lattices in turn become the more stable at different temperatures. The exact calculations are difficult, and only the lattice energies of the simplest crystals have been calculated. The various possible lattices of a substance may differ in the degree of order of arrangement of the atoms; the more symmetrical lattices, such as the cubic, may be considered as less highly ordered than the less symmetrical, such as the monoclinic or triclinic. It may be noted that the less highly ordered lattices tend to occur as stable phases at high temperatures where the disordering action of thermal vibrations is more violent. They often tend also to crystallize first from melts, from solutions or from the vapour, even though other forms may be more stable. Thus, KNO_3 crystallizes from solution in rhombohedra and only later inverts to the more complex orthorhombic stable form; silica almost invariably crystallizes from dry silicate melts as cubic cristobalite rather than as the more complex quartz. Such examples indicate the trend, but apparently there are many exceptions, and little can be said about cases where all the modifications have complex structures. The problem of polymorphism is further complicated by the occurrence of lattices with defects in the atomic arrangement. In the high-temperature forms of AgI, Ag_2S, Ag_2HgI_4 and certain related compounds, some or all of the metal ions are mobile in a still rigid anion lattice, whereas in the low-temperature forms of such substances all the ions are in ordered positions. In heating some alloys, an ordered arrangement of the metal atoms inverts to a random one (Cu_3Au, CuZn, AgZn), and in some other substances: certain radicals or whole molecules change from an ordered orientation to a random one (NH_4Cl, CH_4, NH_4NO_3, $NaNO_3$, HCl). A still further type of disordering is that suffered by quartz on changing from the low- to the high-temperature form, where bent Si-O-Si bonds are straightened. In such cases the final (abrupt) transition is often preceded by a gradual change in structure, volume: specific heat and other properties, extending over many degrees, as the temperature is raised.

Liquid crystals, turbid, viscous, structure possessing phases intermediate between true crystals and true liquids of some long-chain organic compounds. invert promptly to true crystals with a small heat of transition and a small volume change. About 250 examples are known.

Liquid phase transformations, as in sulphur or helium, may be mentioned as examples not of polymorphism but of allotropy in the broader sense. There is no sharp phase transition. but rather a gradual transformation evidenced by a change in physical properties of the liquid over a narrow range in temperature.

POLYNESIA, the islands scattered over the eastern Pacific ocean between 170° E., and 110° W. long., lying within the vast triangle formed by the Hamaiian Islands to the north, New Zealand to the south and Easter Island (Chile) to the east. Western Samoa, American Samoa (U.S.) and Tonga Islands (British) are located at the western base of this triangle and the Society Islands (French), with Tahiti the largest of the group, at the centre. Northeast of the Society Islands are the Marquesas Islands (French), and between them the Tuamotu archipelago (French) stretches eastward to the Mangareva (Gambier) Islands (French). The Cook Islands (New Zealand) lie to the west of the Society Islands and the Tubuai (Austral) Islands (French) to the south. (For the structure, geology, climate, flora and fauna, etc., see Pacific Islands.)

The Polynesian people. — The native inhabitants of Polynesia are a large-framed, soft-featured, brown people with black wavy hair and wide-open brown eyes, readily distinguishable from the small, fine featured, but also brown Micronesians north of the equator and to the west, and the small, dark, frizzly-haired Melanesians south of the equator and to the west. In bodily proportions, shape of the nose, thickness of lips and waviness of hair. they stand in contrast with the American Indians. Many Polynesians have streaks of blond hair and features akin to Caucasians. Therefore the racial classification of the Polynesians has been a difficult problem. They are compounded of elements observable around the Pacific and including the primitive Ainu of Japan, who have Caucasian traits. Some combination of these elements, producing the modern Polynesians, was isolated in a homeland from which they dispersed. The fact that a Polynesian population has not been found outside of Polynesia and some islands to the west settled by them raises the possibility that their formation took place within an island group of Polynesia itself, before dispersal. It would seem from their remarkable homogeneity that in their spread through the islands of Polynesia they encountered no other people different from themselves. This is not to say that all Polynesians look alike, but the same types reappear in the major island groups in much the same proportions.

If the racial classification and origin of the Polynesians is obscure this is not true of their languages. They speak dialects of Malayo-Polynesian, and islanders from one part of the region after short contact can readily converse with those from any other part. It is the close language affiliations with the islands to the west and the total absence of linkage with any American Indian language mhich has long convinced anthropologists of a western origin for the Polynesians. (*See* Polynesian Language.)

Origin of Domesticated Animals and Plants.—The pig, fowl and rat introduced by the Polynesians are of Malaysian origin, as well as nearly all of the introduced plants, such as taro, sugar cane and the breadfruit. A notable exception is the sweet potato, which botanists agree comes from South America.

American Indian **Influence.**—The presence of the sweet potato in Polynesia raises the question of what else may have been derived from America. It has been demonstrated that the balsa rafts such as were employed by the Incas of Peru could drift to Polynesia. Possibly one of these was responsible for the introduction of the sweet potato with a Peruvian Indian name. A number of cultural parallels between ancient Peru and eastern Polynesia may be the result of cultural diffusion from South America. Certain advocates of the theory of a basic American Indian origin for the Polynesians have selected details from myths and traditions, mhich, unfortunately, are too nebulous to be relied upon, and have seized upon cultural parallels from widely scattered parts of America and Polynesia for evidence. Most of this evidence will not bear careful scrutiny as demonstrating historical connections, but a residue cannot be lightly dismissed. People from the islands to the west, however, must have firmly established themselves first in Polynesia as far east as Easter Island, within 2,000 mi. of Peru; if this were not the case, language relationships would not be what they are. The argument that the islands of Polynesia could not be reached from the west because they lie in the face of prevailing winds and currents is untenable. For, if the hypothesis that they were reached from the west is not accepted, it is impossible to account for the presence at Easter Island of the Indonesian fowl and the China paper mulberry bush, imported to make bark cloth.

The Canoes and Their Origin. — The canoes of Polynesia are outrigger types. Ocean voyages were carried out in great double canoes based on the outrigger canoe, mhich is of Malayan origin in design and native terminology, and completely lacking in the Americas. It is a swift sailing, highly manoeuvrable, seaworthy craft, capable of sailing close to the wind, and was in the hands of bold and skilled navigators. Although the Indians on the west coast of the Americas had the advantage of winds and currents for reaching Polynesia, they also had the handicap of a vast and empty stretch of water before them, canoes inadequate for ocean voyages or clumsy rafts, and no foreknowledge of havens in the sea.

Date of **Arrival.**—Archaeologically, no clear traces in any part of Polynesia of a people possessing a culture radically different from the historical culture, which is so strongly western Oceanic in its affiliations, had come to light by the 1950s. The amount of local change in the language since the dispersal of the Polynesians to their present island homes indicates a separation of at least 1,000 years. A radiocarbon date of first settlement in the Hamaiian Islands is A.D. 1004. Indications are that the Hawaiian Islands were one of the last groups to be settled, that Tahiti received its first people about A.D. 200 and Samoa and Tonga to the west by at least 500 B.C.

Religion.—A Polynesian believed himself surrounded by gods who were personifications of nature, or presided over localities, or were spirits of men who had been experts in an art or a craft, or who were ancestor spirits. He sought their aid through offerings, prayers and auguries. Rites were performed at simple stone altars or open-air temples set with grotesque images. The worship of the greater gods was in the hands of an organized priesthood, serving the ruling chiefs. Some of these gods required human sacrifices.

Essential to religion and magic was the concept of *mana*, connoting supernatural pomer invested in gods and to varying degrees in some men. The chiefs, as descendants of the gods, possessed *mana*.

Social and Political Organization. — Kinship constituted the vital nucleus of the social organization, rather than locality. One family, by virtue of physical and mental prowess, rose to the ascendancy and remained in ruling power through maintaining the belief of descent from the creator gods. The head of this family was, normally, the eldest male and the ruling chief. His eldest surviving son succeeded him. All the land of the island or district under his jurisdiction was his. Over the people he had absolute power. The chief ruled through members of his family and trusted experts in a highly developed organization.

Economics. — Fishing and agriculture maintained the people. Their regular diet was supplemented by the flesh of dogs and fowls, and on special occasions by pork. In some of the islands human flesh was included at times. Taro was the favorite vegetable food and its cultivation, similar to that of rice, resulted in intricate irrigation systems. The sweet potato, bananas, breadfruit and sugar cane were grown around the houses. Goods and foods were exchanged through gifts. The chiefs received their taxes in the form of feathers, fine cloth, pigs, dogs and other valuables, which were redistributed among their followers.

Traditional Lore. — The Polynesians developed an unwritten literature consisting of myths, legends, traditions and poetry of vast extent and admirable quality. The creation myths, cast in chant form, conceive of the world evolving from darkness and chaos, through the mating of phenomena such as thunder and lightning until the earth and sky appear. Their union results in the birth of the gods, who separate their parents and thus emerge into the world of light. One of the gods marries a woman formed from sand and by her begets the first man.

Modern Polynesia.—All of Polynesia came under the dominance of foreign powers and outside contacts drastically altered the original life of the Polynesians. Modern Polynesians are nominally Christians and most of them have followed the ways of modern civilization. *See* also Easter Island; Hawaii; Pacific Islands; etc.; *see* also Index references under "Polynesia" in the Index volume. (K. P. E.)

POLYNESIAN LANGUAGE is spoken by fewer than 1,000,000 persons living among a group of Pacific islands which covers a larger segment of the globe than that encompassing the native speakers of any other single language. This one language has more than 60 closely related dialects and subdialects. but contrasts markedly with the many related Melanesian. Micronesian and Indonesian languages of the Austronesian (or Malayo-Polynesian) family of language, itself a member of the over-all Austric group. The Polynesian speech area is bounded by Kapingamarangi and Nukuoro Islands in the west through Hawaii to the north and New Zealand in the south through Easter Island to the east. The best known of the dialects include Hawaiian, New Zealand Maori, Samoan, Tongan, Tahitian, Niuean, Mangarevan and Tuamotuan.

Intensive exploration of the Pacific ocean by Capt. James Cook and his contemporaries of the last quarter of the 18th century accompanied a general awakening of interest in linguistic studies. The early discoverers collected vocabularies for both practical and scientific purposes. Following this period of discovery a world-wide expansion of Christian missionary activity and an accompanying need for translation of the Bible into native tongues led to a more systematic study of many of the Polynesian dialects. By the middle of the 19th century there were dictionaries, grammars and a full translation of the Bible for the most important island groups. Continuing interest in Polynesian history and culture has resulted in this language becoming one of the best known of the non-Indo-European languages from the standpoint of morphology and the techniques of translation.

Phonology.—Because of the paucity of consonants and the presence of at least ten meaningfully distinct vowel sounds, Polynesian is frequently termed a "vowel language," Each of the positional variant sounds /*a*/, /*e*/, /*i*/, /*o*/ and /*u*/ has about five recognizable variants of length in ordinary speech. For orthographic purposes these may be clustered together in two groups. distinguished by the use of the macron (¯) over the longer variants, as in New Zealand Maori *mata* "the face" and *mātā* "a heap." The many variant vowel lengths are patterned in relation to their linguistic environment, but exact rules of pronunciation have not been worked out. There are indications that the meaningful distinction between short and long vowels is a relatively recent phenomenon related to the loss of consonants uith or without the coalescence of two or more shorter vowels.

Considerable alternation exists between certain vowels, notably /*i*/ ⟷ /*u*/ and /*a*/ ⟷ /*e*/. This shift may be freely variable within one dialect, as Hawaiian *imu*⟷*umu* "earth-oven" Frequently it is fixed between dialects, as Rarotongan *nzeitaki* and Tahitian *maita'i* "excellent." but is never an established sound shift in the same sense that consonants are found to vary between dialects

A comparison of data from 50 dialects suggests the following reconstruction of the proto-Polynesian consonantal system:

	Bilabial	Labiodental	Alveolardental	Velar	Glottal
Continuant .	M	V	N	ŋ	
Stop . .	P		T	K	'
Fricative . .		F	S		H
Flap . . .			L/R*		

*Whether or not the sound was /L/ or /R/ or whether both existed as distinct meaningful sounds is not clear.

No modern dialect retains all of the original sounds, and there has been a marked tendency toward reduction in the number of consonants, especially in Eastern Polynesia. Only seven consonants appear to be present in Rurutuan, contrasting strongly with Tongan, the most conservative in the retention of consonants. Regular shift of consonants betneen dialects and the complete loss of certain consonants are characteristic of most dialects. Hence, the variations between dialects may be predicted and ancient or modern forms within one dialect may be derived with a fair degree of confidence. In Rarotongan when one finds that the term for proto-Polynesian (PPN) **ahi* "fire" is *a'i*, and that PPN **faka* the causative prefix is *'aka*, then it may be assumed that the term for PPN **tahi* "one" will be *ta'i*, as the shift from the PPS fricative to the glottal stop is obvious. Likewise, when it is determined that Rarotongan *taŋata* "person" and *tapu* "sacred, forbidden" are in Hawaiian *kanaka* and *kapu* then it may be predicted that Hawaiian *maka* "face" will be *mata* in Rarotongan.

In some cases the sound shift was only partially completed at the time of European arrival, as in Mangaian where the velar stop /*k*/ has shifted to the glottal stop /'/ only in certain words. In other cases there has been an irregular but complete loss of a sound, as in Hawaiian *'uala* and Mangaian *'uara* from PPN **kumara* "sweet potato." as well as in such words as PPN **tasi* "sea" which becomes *tai* in much of Polynesia.

There are no such distinctive voiced sounds as English /b/, /d/ and /g/, although in the past European recorders have misspelled terms such as *tapu* "forbidden" as *tabu*, and the island of *Porapora* as *Borabora*. Polynesians cannot distinguish between the English speaker's "bad" and "bat," "tab" and "tap." Other than the apparently mnemonic device of the controversial Easter Island "talking boards" there was no pre-European system of writing. Those English and French missionaries who developed the present Polynesian systems of writing attempted to use their own European orthography. In most cases they did not understand the significance of the distinction between short and long vowels and the importance of the glottal stop, hence these were not provided for in the alphabets. These omissions seriously affect the ability to read aloud or to translate from the literature in most areas other than New Zealand.

Many foreign words have been adapted by the various dialects. The sound changes involved bring the new words into conformance with the Polynesian sound system by shifting any voiced sounds to sibilants or stops and by adding vowels to closed syllables; hence English "broom" and "towel" become Tahitian *purumu* and *tauera*.

Morphology.—The seemingly inexhaustible vocabulary is derived from a relatively limited number of basic words. which are capable of being used individually or combined with other basic words and frequently also with a small number of prefixes and suffixes. These basic words are usually, but not invariably, disyllabic in nature. All syllables end in vowels although the initial sound may be consonant or vowel. Stress or "accent" varies between areas and appears to be absent from certain dialects, notably Tahitian; traditionally it is stated to be upon the penultimate syllable, with certain exceptions related to vowel length. The New Zealand Maori base word *tupu* "to grow" when combined with the causative prefix *whaka* becomes *whakatupu* "to cause to grow"; *turipona* "the knee joint" is derived from *turi* "the knee" and *pona* "a knot. joint"

Basic words and syllables are frequently duplicated to form diminutives, pluralatives, frequentatives, and other variants of the base. as *paki* "to pat," *pakipaki* "to pat frequently," *papaki* "to clap together"; or *manu* "a bird, small insect," *manumanu* "a very small insect." A few words are composed of a single sound or syllable, as New Zealand Maori *ā* "to compel, drive," *ki* "to be full."

Syntax.—Sentences are generally brief, and when spoken in full are composed of an initial predicative phrase followed by a subject, which may or may not be followed by one or more locative. directive or possessive phrases. The predication is the most significant part of the sentence and is spoken even when the nature of the situation permits the rest of the sentence to remain unsaid, as in Rarotongan E *kai!* E *kai ra!* "Eat! Eat on!"

Phrases are composed of one or more central "full words," usually (but not always) preceded and in some cases also followed by particles. Full words are those innumerable terms which have definable meanings within themselves. The very limited number of particles do not in themselves convey meaning, but serve only to place the predication or substantive as to identity, location and duration of the time. place or type of possession. A simple analogy would be to a brick wall, the bricks being similar to the full words of a sentence. the mortar similar to the particles which serve to bind the individual units into the whole structure. The Rarotongan base term *'aere* "to go" (without connotation of direction) and *au* "I ego" may be combined with particles as follows: *Kua 'aere au* "I went," *Ka 'aere au* "I shall go," *Tē 'aere nei au* "I am (in the process of) going."

Terms may be classified as full words or particles on the basis of specific meaning or function, but not individually as the traditional noun, verb and the like. A more useful classification relates to their use and position within the phrase or sentence. Many Polynesian full words may serve as predicative, substantive or the modifier of either. The initial full word of a phrase is invariably the most significant term with respect to meaning, and the words which may follow or the surrounding particles serve only to modify the basic concept. The first full word of the initial phrase of a sentence is the basis of the predication and the first full word of the second phrase is the subject, as *Kua tupu te taro* "The taro grew" and *Kua oti te tupu* "The growth stopped."

Polynesian predicatives lay greater stress upon the state of being than do English verbs and many of them must be preceded in translations by the phrase "was in the state of being." A particular source of confusion relates to the fact that a predicative may be either active or passive in nature as well as transitive or intransitive in any one of the four possible combinations. The full word involved may be modified by the passive suffix, one of a number of prefixes and by the intransitivizing particle. A secondary source of confusion relates to the sentence initial particle *E*, which is frequently mistranslated as equivalent to the English indefinite nominalizing particle "a, an," but in reality it is a predicative equational particle best translated as "is, am, was," as in Rarotongan *E taŋata tikai koe* "You are truly a man."

Polynesian full sentences may be analyzed as follows (particles are in small capitals, full words are italicized):

In Hawaiian

UA *ho'ohiu* 'IA / KA *moku* / I *luna* O KE *alahukinzoku*
predicative phrase / subject / locative phrase
The ship was liited (was liited the ship) on to (on top of) the marine railway.

In Tahitian

The letter was written (was written the letter) by me.

Semantics.—Studies utilizing the technique of glottochronology reveal that Polynesian is possibly the most changeless of languages known to scholars. During more than 2,000 years following the settlement of Polynesia about 90% of such basic vocabulary terms as "fish," "fire" and "water" have retained the same form as that of the proto-language. The recording and translation of Polynesian has been considerably hampered by the lack of adequate orthography, and many dictionaries give the false impression of lack of precision of terminology as a result of having entered meanings belonging to several orthographically separate words under a single form. Despite the conservatism and the preciseness of vocabulary meanings, Polynesian makes extensive and richly complex use of analogy and imagery in oratory, poetry and folk lore. Despite the lack of written language there was an elaborate oral literature, with great stress upon preciseness of memorization and usage. Feats of memory witnessed by early explorers and later by anthropologists seem little short of phenomenal. Much of the memorization involved ancient prayers, religious ceremonies, folk tales and legends, but the most significant of all (and still a vital force in court cases) was the recounting of genealogy and secret family chants. This type of knowledge was the sole patent to land rights and verbal knowledge ruled in the event of dispute.

Together with other Oceanic languages Polynesian utilizes a complex system of differentiating persons, with the individual distinguished from two persons as well as from a plurality, and the further differentiation of whether or not the person spoken to is included in the reference. Furthermore, the system of particles distinguishes persons and personified places or things from all others. All phenomena are divided into category of implicit and explicit connection when spoken of in the possessive sense, where for example one's blood kin are considered to be intimately a part of the speaker, hence are intrinsic, and one's wife is much less so and therefore explicitly "possessed."

Polynesian dialects, together with languages such as Javanese, utilize a form of courtesy reference or "chiefly language," as it is referred to in Samoa where its use is most elaborated. This separate vocabulary is used by commoners in addressing chiefs and their families and by the upper classes in discourse among themselves. The terms are frequently simple analogies, as when the chiefly women of Samoa are referred to as "flowers," but in other cases represent the retention of archaic terms. In central Polynesia a distinct vocabulary was also used for theological purposes by initiated priests, enabling them to perform ceremonies and render prayers not understood by noncommunicants. Learned aged men still are able to carry on conversations among themselves, to the bafflement of the younger generation.

BIBLIOGRAPHY.—Songs, tales, chants, genealogies have been preserved in the *Journal of the Polynesian Society*, Wellington, New Zealand; the *Memoirs* and *Bulletins* of the Bernice P. Bishop Museum, Honolulu, Hawaii; and in the *Bulletin de la Société des Etudes Océaniennes*, Papeete, Tahiti The most important dictionaries include C. M Churchward, *Tongan Dictionary* (1959); Herbert W Williams, *A Dictionary of the Maori Language*, 6th ed (1957); Mary Kawena Puki and S. H Elbert, *Hawaiian-English Dictionary* (1957); J. Frank Stimson with Donald Stanley Marshall, *A Dictionary of Some Tuamotuan Dialects of the Polynesian Language* (1960). (D. S. ML.)

POLYNOMIAL, in elementary algebra, an expression composed of two or more terms combined by operations of addition or subtraction. Thus $\frac{1}{2}a+7b+c$ and $2+a-\sqrt{(\frac{1}{2}xy)}+z^2$ are polynomials. A polynomial of two terms is called a binomial, and one of three terms is called a trinomial. An expression consisting of a single term is called a monomial.

The word polynomial is often used with a more technical meaning, particularly in higher mathematics, to characterize the manner of dependence of an expression on one or more quantities regarded for the time being as independent variables. Importance attaches then to the nature of the operations performed on the variables, rather than to the number of terms, and monomial expressions of suitable iorm are admitted as special cases. Under this interpretation, which will be adopted throughout the rest of the article, a polynomial in one variable is a sum of terms. each consisting, of a power of the variable multiplied by a coefficient independent of the variable, or, as an extreme case, a single such term; in a polynomial in several variables, each term contains a power of one of the variables or a product of powers of two or more of them. By a power in this connection is meant a power with exponent equal to a positive whole number or zero. The highest exponent that occurs, or, in the case of more than one variable, the highest value attained by the sum of the exponents in a single term, is the degree of the polynomial. Thus ax^2+bx+c is a polynomial of the second degree in x (if $a\neq 0$), and $x^5+3xy^2-8x^3y^4$ is a polynomial of the seventh degree in x and y. The latter is also said to be of the fifth degree in x, and of the fourth degree in y.

Having fundamentally a relative sense, the definition is applicable to charadterize the manner of dependence on quantities which may themselves be more or less complicated expressions of any iorm. Thus ax^2+bx+c, $a(1+\sqrt{x})^2+b(1+\sqrt{x})+c$, $a/x^2+b/x+c$, $a(\log x)^2+b\log x+c$ are polynomials with respect to x, $1+\sqrt{x}$, $1/x$, and $\log x$ respectively, though the last three are not polynomials with respect to x; and ax^4+bx^2+c, a polynomial in x, can also be regarded as a polynomial in x^2. The sum, difference, or product of two polynomials is a polynomial; their quotient in general is not. Polynomials and quotients of polynomials are known collectively as rational functions.

In elementary algebra, expressions coming under the more technical definition of polynomials are studied largely in connection with the equations formed by setting them equal to zero. If $f(x)$ denotes the polynomial

$$a_0x^n+a_1x^{n-1}+a_2x^{n-2}+\ldots+a_{n-1}x+a_n,$$

where $a_0\neq 0$, then the so-called "fundamental theorem of algebra" ensures the existence of a root r of the equation $f(x)=0$. The number r is a complex number. or as a special case a real number, and the fact that $f(r)=0$ implies that $(x-r)$ is a factor of $f(x)$. By a repetition of this argument one can show that $f(x)$ can be factored in the form

$$f(x)=a_0(x-r_1)(x-r_2)\ldots(x-r_n)$$

where the r_1 are the roots of $f(x)=0$. This factorization is uniquely determined. If the factor $(x-r)$ occurs exactly h times in the factorization then r is said to be a root of multiplicity h of the corresponding equation.

The resolution of a polynomial into linear factors makes essential use of the availability of all complex numbers as coefficients. If a more restricted system of coefficients is employed. such a factorization may not be possible. For example, x^2+1 is irreducible if real numbers only are allowed as coefficients. and x^3-x+2 is irreducible if rational numbers only are allowed. As these examples show, it is necessary in any discussion of factorization to specify the coefficient domain. If this domain is denoted as F it is customary to denote the system of all the polynomials in x with coefficients in F by $F[x]$, and more generally, the system of all polynomials in $x_1, x_2, \ldots x_m$ with coefficients in F by $F[x_1, x_2, \ldots x_m]$. If F is a field (*e.g.,* the set of all complex numbers. the set of all real numbers, the set of all rational numbers) then a polynomial belonging to $F[x]$ is called irreducible if it cannot be expressed as a product of polynomials in $F[x]$ of lower degree. Every polynomial in $F[x]$ which is not itself irreducible can be resolved into irreducible factors in this domain and apart from the order of the factors and from constant factors, can be so resolved in only one way. A similar definition of irreducibility can be used in the domain $F[x_1, x_2, \ldots x_m]$ and there, too, the unique factorization theorem holds. In a slightly modified form the theorem holds also for other polynomial domains. (*See,* for example. A. A. Albert's *Modern* Higher Algebra, 1937.)

It is an important fact in trigonometry that the cosine of n times an angle, where n is a whole number, can be expressed as a polynomial of the nth degree in terms of the cosine of the angle itself:

$$\cos 2x = 2\cos^2 x - 1,\ \cos 3x = 4\cos^3 x - 3\cos x,$$
$$\cos 4x = 8\cos^4 x - 8\cos^2 x + 1$$

The sine of nx can be expressed as the product of sin x by a polynomial of degree n − 1 in cos x; when n is odd. but not when n is even, it can also be expressed as a polynomial of the nth degree in sin x; *e.g.,*

$$\sin 2x = 2\sin x\cos x,\ \sin 3x = \sin x\,(4\cos^2 x - 1) = 3\sin x - 4\sin^3 x$$

The relation between algebra and trigonometry was emphasized by François Vieta (1540–1603), who contributed largely to the advancement of both branches.

Analytic geometry is largely concerned with the geometric interpretation of the equations obtained by setting polynomials in the co-ordinates equal to zero. In the plane, an equation of the first degree, of the typical form $Ax + By + C = 0$, represents a straight line; *i.e.,* if (x, y) are the rectangular co-ordinates of a point, all points whose co-ordinates satisfy the equation lie on a straight line, and all points of the line have co-ordinates satisfying the equation. The conic sections (*q.v.*)—ellipse, circle (which may be regarded as a special case of the ellipse). parabola, hyperbola (*qq.v.*), and certain "degenerate" forms (pairs of straight lines)—are represented by equations of the second degree, of the form

$$Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$$

where in particular cases one or more of the coefficients may be equal to zero. René Descartes (*Géométrie,* 1637) and his contemporary, Pierre de Fermat, are regarded as the founders of analytic geometry (*q.v.*). The curves represented by equations of the third degree were systematically studied by Sir Isaac Newton (1704). In three dimensions, an equation of the first degree, $Ax + By + Cz + D = 0$, represents a plane, and one of the second degree a quadric surface—ellipsoid, sphere (a special case of the ellipsoid), hyperboloid (of one sheet or of two sheets), paraboloid (elliptic or hyperbolic). cone. cylinder (*qq.v.*), or, as a degenerate form, a pair of planes.

The study of curves and surfaces defined by polynomial equations of arbitrary degree constitutes the field of algebraic geometry. A fundamental concept in the modern development of this subject is that of a polynomial ideal, defined to be a set **I** of polynomials such that (1) the difference of any two polynomials that belong to **I** also belongs to I, and (2) the product of any polynomial in **I** by any polynomial belongs to **I**. If $u_1(x,y)$, $u_2(x,y)$, $\ldots u_r(x,y)$ are fixed polynomials then the totality of polynomials of the form

$$f_1(x,y)u_1(x,y) + f_2(x,y)u_2(x,y) + \ldots + f_r(x,y)u_r(x,y)$$

where the $f_1(x,y)$ range independently over the polynomial domain. is an ideal. The polynomials $u_1(x,y), \ldots u_r(x,y)$ are said to form a basis for this ideal. An important theorem due to David Hilbert (1890) asserts that any polynomial ideal has a finite basis.

The theory of the transformation of homoneneous polynomials, or *forms* (see ALGEBRAIC GEOMETRY; TENSOR ALGEBRA), by linear substitutions in the variables, and of the invariants and covariants associated with such transformation, is an important branch of algebra with numerous applications. For example, if x,y in the polynomial $ax^2 + bxy + cy^2$ are expressed, in terms of a new pair of variables u, v, by the relations

$$x = \alpha u + \beta v, \qquad y = \gamma u + \delta v$$

where $\alpha\delta - \beta\gamma = 1$, it is found that $ax^2 + bxy + cy^2$ is identically equal to an expression of the form $Au^2 + Buv + Cv^2$, in which $B^2 - 4AC = b^2 - 4ac$, a fact which is of fundamental significance in analytic geometry. More generally, for any values of α, β, γ, 6,

$$B^2 - 4AC = (\alpha\delta - \beta\gamma)^2\,(b^2 - 4ac)$$

The expression $b^2 - 4ac$, itself a polynomial in terms of the coefficients a, b, c, is called an invariant.

Polynomials in one variable are the simplest class of functions from the point of view of the calculus, because the rules for their differentiationand integration are simple, and are obtained immediately from the definitions of these processes. The result of differentiating or integrating a polynomial with respect to its independent variable is always a polynomial. In the modern theory of functions (see FUNCTION), any polynomial is a continuous and analytic function of its variables. If a function of a single complex variable z is analytic for every finite value of z, and becomes infinite when z, represented by a point in a plane, goes to infinity in an arbitrary manner, the function is necessarily a polynomial.

Applications.--Apart from their specific properties, polynomials are of fundamental importance from their use in the approximate representation of other functions. The standard functions of elementary analysis can be represented by power series (see SERIES), of the form

$$c_0 + c_1x + c_2x^2 + c_3x^3 + \ldots \text{ (Maclaurin's series)}$$

or, more generally,

$$c_0 + c_1(x - a) + c_2(x - a)^2 + c_3(x - a)^3 + \ldots \text{ (Taylor's series)}$$

which reduces to the preceding when $a = 0$: the sum of an infinite series is by definition the limit approached by the sum of a finite number of its terms, as the number of terms is taken larger and larger, and the sum of a finite number of terms of a power series is a polynomial. Representation by power series can be made the basis for a systematic treatment of analytic functions of a complex variable. Another important form of development in series, theoretically applicable with greater generality, proceeds in terms of the polynomials of Adrien Legendre (1752–1833) or Legendre's coefficients. These may be defined as the coefficients of successive powers of r in the power series for $(1 - 2xr + r^2)^{-\frac{1}{2}}$. One of their most striking properties is that the product of any two of them, integrated over the interval from −1 to +1, gives zero. Legendre polynomials have been found to be of great value in mathematical physics. especially in quantum mechanics. Approximations in terms of the polynomials of Gustave Hermite (1822–1901) are of importance in the theory of probability. Karl Weierstrass (1885) proved that an arbitrary continuous function can be uniformly approximated by a polynomial with any assigned degree of accuracy.

The ordinary process of simple interpolation (*q.v.*), is equivalent to the replacement of the tabulated function by a polynomial of the first degree, over the interval in which the interpolation is performed. Formulas for interpolation by means of higher differences depend for their derivation on the fitting of polynomials of higher degree to the tabulated values. Formulas of numerical

$x = 0$	$y = 3$		
		$\Delta y = 8$	
1	11		$\Delta^2 y = 2$
		10	
2	21		2
		12	
3	33		2
		14	
4	47		2
		16	
5	63		

integration or mechanical quadrature likewise depend on the fitting of polynomial approximations. In connection with the use of polynomials for interpolation. it is an important fact that, if the values of a polynomial of the nth degree are tabulated for equally spaced values of the variable, the nth differences are constant. Consider the preceding table of values of the polynomial $y = x^2 + 7x + 3$. The first column contains values of x, and the second. the corresponding values of y. The entries in the third column, obtained by subtracting each y from the following. are the first differences. The last column is made up of the differences of the first differences. which are called second differences, and in the present instance are all equal. It is clear that by means of this property the table could be continued further, without direct substitution in the original formula. *See* CALCULUS OF DIFFERENCES.

POLYP, in medicine, is a general term used to designate any growth projecting from the wall of a cavity lined with a mucous membrane. This growth may have a broad base, in which case it is called sessile; or it may have a long narrow neck, the characteristic of a pedunculated polyp. The surface of a polyp may be smooth, irregular or multilobular. The commonest locations of polyps in the human body are the nose. the bladder and the gastrointestinal tract, especially the rectum and colon. Symptoms of polyps depend upon their location and size. There may be no symptoms, or there may be symptoms resulting from pressure or from mechanical obstruction of all or part of a lumen, such as the nose or bowel; they may occasionally bleed. Usually polyps are simple, benign growths, but a small percentage may be either precursors to cancers or may actually contain cancers. It is for this reason that it is best, when possible, to remove all polyps and examine them microscopically to determine whether further treatment is necessary. (J. A. RR.)

POLYP, in zoology. is the name commonly applied to animals that bear tentacles and that are in some way attached to the substrate. In its broadest usage, the name applies to the individuals of such diverse animal phyla as the Bryozoa (Ectoprocta), the Endoprocta, the pterobranch Hemichordata and the sessile members of the Coelenterata. More strictly the term is ordinarily applied only to members of the latter group. The word itself seems to have come into English from the French word *poulpe* ("octopus"). Polyps are illustrated and discussed in the articles COELENTERATA, HYDROZOA, SCYPHOZOA, ANTHOZOA and SEA ANEMONE.

In the phylum Coelenterata the polyp represents one of the two body forms known in that group. the other being the medusa. Polyps are of columnar form in general and with few exceptions are attached to the substrate or burrow into it. The attached end may be called the base and is the aboral end. The free end of the polyp has a mouth at its centre and is surrounded by tentacles in most instances. The parasitic hydroid Hydrichthys, found on fish, and the minute hydralike polyp Protohydra are examples of exceptional polyps that have no tentacles. Another hydroid (Monobrachiurn) has a single tentacle on each polyp; *Proboscidactyla* (another hydroid) has two; while most polyps have many tentacles. Some large sea anemones have thousands of tentacles.

The polyp. in the different groups of coelenterates, is not only morphologically different in the different classes but represents different stages in the life history of those animals. For example, the polyps of the Hydrozoa. the hydroids, are morphologically quite simple. They usually have small numbers of tentacles, are of small size and have a coelenteron (the gut) that is a simple sac. These polyps are usually the immature. attached stages of medusae. representing the adult, sexually reproducing form. Within the Hydrozoa. however, not all polyps bud off free medusae. and many polyps are known that are themselves the sexually reproducing stage. In almost all instances where hydroid polyps represent sexual adults, it can be shown nonetheless that the gonads develop in association with structures that represent reductions of the medusa. Thus it seems to be a safe generalization that the polyp of the Hydrozoa represents an immature stage in the life history of the members of that class.

Much the same seems to be true for the class Scyphozoa. whose members are the large medusae or jellyfish of marine waters. The polyps here are simple, but the coelenteron is divided into four compartments by four projections or mesenteries that arise along the inner body wall. These polyps bud off the sexual medusae (the adults) much as in the Hydrozoa, and the polyps seem to represent only an attached immature stage in the life history of the group. In the Anthozoa, on the other hand, no medusae are known and the polyps represent the adult individuals. Here the polyps may grow to very large sizes, up to about three feet in diameter, and internally become very complex through the possession of many mesenteries which subdivide the coelenteron into many radially distributed compartments.

Polyps may occur as solitary individuals as in the fresh-water Hydra and many sea anemones, or they may occur as colonial aggregations. These colonies result from asexual reproduction by budding from the original polyp. Buds may arise apically, laterally or from stoloniferous growths from the basal region. Associated with colony formation, in many instances, especially among the marine hydroids, individual polyps in the colony assume different morphologies and have differing functions. Thus some individual polyps may be specialized for feeding (gastrozooids), for protection (tentaculozooids and dactylozooids) or for reproduction (gonozooids). Colonies possessing more than one type of polyp are said to be polymorphic; a good example is the common hydroid Hydractinia or *Podocoryne.* Another excellent example of a polymorphic colonial coelenterate is to be found in such organisms as the Portuguese man-of-war or any other of its relatives (Siphonophora). Commonly among these free-floating colonial hydroids, having a number of polymorphic polyps present, medusalike individuals may also occur that function as locomotory structures for the colony.

Polyps may occur as naked individuals or colonies, or they may have skeletons of various sorts. Among the hydroids, tough but flexible chitinous exoskeletons are common, and in many cases the polyp can contract completely within the surrounding skeletal cup. Skeletons of calcium carbonate or lime are also known among marine hydroids; the colonial polyps possessing these are called hydrocorals. The true corals, which are anthozoan polyps. also have skeletons of lime (see CORAL). The polyps here, as in the hydrocorals, live in cups on the surface of the limey skeleton and when disturbed contract into these protective structures. In the Anthozoa a number of colonial polyps are known, such as sea fans and sea pens, that have an axial, internal skeleton around which the colony grows.

Coelenterate polyps possess nematocysts (see COELENTERATA), and with the aid of these are able to capture other animals as food. Contact of a potential food organism, such as a small worm, mollusk or fish, with the tentacles of a polyp causes the nematocysts to discharge. Once a food item has been caught the tentacles bend toward the mouth and the mouth opens in preparation to receive the food. Primary digestion of the food takes place in the coelenteron, where strong protein-splitting enzymes break the food doun to minute particles. The cells lining the coelenteron then engulf these particles and final digestion takes place within the individual cells.

Polyps are for the most part restricted to marine habitats. In fresh water abundant Hydras are found and occasionally the minute polyps of the fresh-nater medusa, *Craspedacusta.* The only other coelenterate polyp seen in fresh water is the widely distributed colonial hydroid, *Cordylophora,* which, while commonest in brackish waters, does occasionally appear in lakes and reservoirs. In marine habitats coelenterate polyps are abundant nearly everynhere. The open ocean supports many different siphonophores, while along the shores of the world hydroids, anemones and corals flourish, the latter, however, being most conspicuous in tropical waters. Somewhat below the reach of the lowest tides occur veritable gardens of sea fans and sea pens, particularly in warm waters. while even at the greatest depths of the oceans anemones and hydroids may still be found. In fact, the tallest hydroid polyp known, *Branchiocerianthus*, is usually restricted to waters more than one-half mile deep, and the largest specimens recovered have been more than six feet long: See JELLYFISH; *see* also references under "Polyp" in the Index volume. (C. HA.)

POLYPHEMUS, the most famous of the Cyclopes, son of Poseidon and the nymph Thoosa. Odysseus, having been cast ashore on the coast of Sicily, fell into the hands of Polyphemus, who shut him up with 12 of his companions in his cave and blocked the entrance with an enormous rock. Odysseus at length succeeded in making the giant drunk, blinded him by plunging a burning stake into his eye while he lay asleep, and with six of his friends (the others having been devoured by Polyphemus) made his escape by clinging to the bellies of the sheep let out to pasture. *See* ACIS; CYCLOPS; ODYSSEUS.

POLYPODIUM, an inclusive genus of ferns containing about 600 species. widely distributed throughout the world, but specially developed in the tropics. Sometimes it is divided into ten or more "natural" genera. The name is derived from Gr. *polys*, "many," and *podion*, "a little foot," on account of the foot-like appearance of the rhizome and its branches. The species differ greatly in size and general appearance and in the character of the frond; the sori or groups of spore cases (sporangia) are borne on the back of the leaf, are globose and naked, that is, are not covered with a membrane (indusium). The common polypody (P, *vulgare*) of Europe. Asia and western North America is widely diffused in the British Isles, where it is found on walls, banks: trees, etc.; the creeping. densely scaly rootstock bears deeply pinnately cut fronds. the fertile ones bearing on the back the bright yellow naked groups of sporangia. It is also known as adder's foot, golden maidenhair and woodfern. There are a large number of varieties, differing chiefly in the form and division of the pinnae; var. *cambricum* (originally found in Wales) has the pinnae themselves deeply cut into narrow segments; var. *serratum* has the pinnae serrate. Besides the well-known polypody of eastern North America (P. *virginianum*), very similar to the foregoing, several other species occur in the southern and western states.

POLYPTYCH: *see* ALTARPIECE.

POLYTECHNIC. This term, common to many languages, is ordinarily used, by itself or nith the word "institute" or, more rarely. "school." to denote an educational establishment equipped to teach many subjects (Greek *polus*, "many"). but mainly if not exclusively scientific and technological studies and processes (*technē*, "art" or "craft"). It has also been used occasionally to describe other kinds of establishment designed to encourage interest in the arts and sciences, and in one instance at least has been applied to a large shop with many departments.

In general, a polytechnic institute offers instruction to students beyond school age, though it may include a secondary school organized as a separate department. But the exact significance of the name varies almost with every establishment or, as in England, group of establishments. In France. where it appears to have been first used, the name *école polytechnique* was applied in 1795 to the Ecole des Travaux Publics, founded a year previously in Paris by the National convention to advance scientific knowledge and in particular to train engineers for the army. The sobriquet, originating by way of protest against the almost exclusive devotion to literary and abstract studies then common to French places of higher education. became and remained the institution's official title; but the École Polytechnique stayed predominantly a school of military and civil engineering and therefore, strictly speaking, rather a monotechnic than a polytechnic. Similarly, the Faculté Polytechnique of Mons, Belg., is restricted to engineering studies, though the range is wide; and the same applies to the Polytekniske Laereanstalt at Copenhagen, Den. The Istituti Politecnici at Milan and Turin. It.. and the Polytechneion at Athens, Gr., have faculties of architecture as well as engineering. The famous Eidgenossische Technische Hochschule (Swiss Federal Institute of Technology), frequently referred to as the Zurich Polytechnikum, is as good an example of a polytechnic in the literal sense as can be found. It is organized in 12 schdols which include, in addition to civil, mechanical, electrical and agricultural engineering, subjects as varied as forestry and pharmacy; and there is also a department of optional subjects embracing literature, history, economics, politics and philosophy. All the foregoing institutions are either universities in their own right or hold university status. The location, character and status of educational establishments in Communist Europe were liable to change at a moment's notice, but at mid-20th century there were reported to be polytechnic institutes in Poland at Warsaw, Gdańsk, Gliwice, Lodz and Wroclaw (Breslau) and in Rumania at Bucharest, Jassy and Timişoara. Most if not all of these appear to have been degree-granting institutions and mainly if not entirely devoted to technological studies.

London.—In England the title "polytechnic" is almost restricted to the members of a group of educational institutions founded in London during the latter part of the 19th century with the dual purpose of providing vocational and other educational facilities for young working people and of promoting definite religious, social and civic ideals. These London polytechnics and their distinctive aims and organization derive from the initiative of Quintin Hogg (1845–1903), who as a young man of 19 shortly after leaving Eton college began a lifetime of evangelistic and educational pioneering by teaching street urchins to read. His first "classroom" was under the archways of the Adelphi on the north side of the Thames. In 1871 he opened a Youths' Christian institute in Castle street (moved to larger premises in Long Acre in 1878) for young shop assistants and artisans between the ages of 16 and 21. This he developed to provide, in addition to the optional Bible classes and other religious exercises which were the basis of his enterprise, a wide range of educational, social and athletic activities including, despite lack of support from employers and opposition from trade unions, classes for instruction in the building and other trades.

So successful nas he that by 1880 he mas looking for larger premises. As it happened, about this time there was offered for sale a building in Regent street called the Royal Polytechnic institution. It had been opened in 1838 to advance "practical science" and for many years enjoyed much popularity as a resort where the demonstration of scientific novelties nas pleasantly tinctured with entertainment. Hogg bought it, retained the name and reopened his institute there in Sept. 1882, with accommodation for 2,000 members. By the end of the winter session there had been 6,800 applications for membership. As he refused to increase the modest fees or to accept any subventions which involved compromise of the religious principles on which he based his work, Hogg for some years incurred heavy financial losses. But this did not deter him from continuing to build up the "Poly," as it soon came to be affectionately called, into a many-sided educational and social institution, providing instruction "in subjects ranging from the domestic arts to carriage-building, photography, and goldsmith's work" (Ethel M. Hogg. *Quintin Hogg, a Biography*, London, 1904) and offering its members reading rooms, library, gymnasium, billiard room. refectory. concerts. country excursions and a wide range of athletic activities Members were also encouraged to co-operate in the management of the Poly and in the maintenance of good discipline From the start women were admitted to classes, and in 1885 a separate institute was opened for them under the direction of Mrs. Hogg. In 1856 a school was started for boys and girls which gave special attention to manual, domestic and commercial subjects

The resounding success of the Regent Street polytechnic naturally suggested the foundation of other establishments on the same model, and happily funds became available. In 1878 a royal commission had been appointed to inquire into the parochial charities in the City of London; it was felt that because of the increase in their value and the decrease. or disappearance, of the kind of beneficiaries whom they were founded to aid, the total annual income was far greater than was needed to provide adequately for all the designated objects of these charities. The outcome of the commission's report was the City of London Parochial Charities act. 1883. This provided that the charities in 107 of the city parishes (that is, in all save five of the largest) should after seven years be administered by a corporate body to be called the Trustees of the London Parochial Charities. A scheme was drawn up by the charity commissioners whereby that part of the income from the consolidated charities which was allocated to secular purposes was to go toward the establishment and maintenance of "industrial" and recreative institutes similar to Hogg's polytechnic and Walter Besant's People's palace in the Mile End road, for the benefit of the poorer classes of the working population of London. The commissioners' offer of these funds was made conditional upon the raising by voluntary effort of an amount approximately equal to the capitalized value of the endowment. Local committees were set up, valuable sites were given by private benefactors, and subscriptions were received from livery companies, charities and individuals. A total sum of more than £500,000, including grants made by the charity commissioners and the Trustees of the London Parochial Charities, was raised for capital expenditure. As a result. betneen 1891 and 1896 six new polytechnics opened their doors. Chelsea (1895), Woolwich (1891), Borough (1892), Battersea (1894), Korthampton (in St. John street; 1896) and Northern (1896).

A seventh was planned in the scheme, but lack of local support. delay in securing possession of the site and the incidence of World War I prevented the North-Western from opening before 1929.

The Trustees of the London Parochial Charities, as conditions for making grants toward the maintenance of the polytechnics, "laid down as their principles that the institutions which benefited should give instruction in the principles of the arts and sciences which underlie crafts and in the application of such principles to particular trades, that they should be a supplement and not in substitution for the workshop or place of business, that they might give instruction suitable for intending emigrants and hold lectures and concerts, encourage gymnastics, drill, swimming, and other forms of bodily exercise, and institute clubs and societies, libraries, museums and reading rooms, that their educational facilities should be equally open to both sexes, that the fees should be small, and that drinking, smoking and gambling should be prohibited" (R. L. Archer. *Secondary Education* in *the XIX Century*, Cambridge University Press, 4th impression, 1937). Membership was restricted, except in special cases (not to exceed 5% of the total), to persons between the ages of 16 and 25.

Large as they were, the funds available from the London Parochial Charities trust were quite inadequate to maintain the great establishments to which they were committed. But aid was at hand from another source In 1893 the London county council, empowered under the Technical Instruction act. 1889, to make limited grants in aid of technical education and also having had funds placed at its disposal for the purpose by the Local Taxation (Customs and Excise) act. 1890, devoted a considerable portion of the latter to the development and sustenance of the polytechnics. Thereafter an increasing percentage of their revenue came from public funds. The Education act, 1902 (as applied to London by its act of 1903), by making the council responsible for all education in its area, tended to diminish distinctions between the grant-aided polytechnics and the wholly maintained technical institutes set up by the council. The Education act, 1921, which empowered the council (in common with the other local authorities) to promote social and physical well-being and to co-ordinate all forms of education within its area, continued the process of assimilation; and the Education act, 1944, by transforming these powers into statutory duties. advanced it still further. The distinction between a polytechnic and a major technical college in London became increasingly managerial rather than educational.

The London county council from the start endeavoured to secure that the educational facilities in the polytechnics and technical institutes should be so disposed as best to meet the particular needs of any given district; and the governing bodies of the polytechnics from time to time accepted suggestions to this end from the council involving important revisions of their educational programs. For example, facilities for more specialized technologies were concentrated at individual establishments. Thus Battersea has in addition to important departments of engineering and chemistry one of hotel training and domestic science: Chelsea a department of pharmacy and a school of art; and the Regent Street Polytechnic schools of architecture and commerce and a department of management studies. The Borough houses the National College of Heating, Ventilating, Refrigeration and Fan Engineering, established in 1948 to give technological education at the highest level to selected persons in these industries. Similarly, the Northampton houses the National College of Horology and Instrument Technology (established 1947); and the Northern. temporarily, the National College of Rubber Technology (established 1948).

The location of these national colleges was a tribute to the outstanding work previously done by the respective polytechnics in the technologies concerned. The Northern contains also a department of radio and musical instrument technology, and the Northampton one of furriery.

Five of the polytechnics—Battersea: Chelsea, Northampton, Northern and Woolwich—prepare students in some subjects for internal degree examinations of the University of London. These polytechnics are not organically linked with the university, but the faculties concerned have on their staffs members whom it accepts as "recognized teachers." This arrangement dates from the reconstitution of the university in 1902. (H. C. D.)

United States.—The term "polytechnic" as used in the United States generally refers to a postsecondary educational institution offering various curricula in technology, science and possibly agriculture. There is no essential difference between a polytechnic institute and an institute of technology. One characteristic which differentiates a polytechnic institute from a liberal arts college is that the curricula in the institutes have been designed to prepare students for positions in engineering, applied science and agriculture upon graduation. The occupational objectives of the institutes' courses of training are thus more clearly defined than is the case with the liberal arts colleges. In the institutes a student spends as much as three-fourths to four-fifths of his time on technical and professional studies in the field of his specialization, and the remainder of the time is devoted to English and the social sciences.

The term was first given prominence in the United States by Benjamin Franklin Greene, second president of Rensselaer Polytechnic institute, who in 1849 wrote a report to his board of trustees entitled *The True Idea of a Polytechnic Institute*. In this he summarized the progress of technical education in Europe and made recommendations concerning the reorganization of Rensselaer. He envisioned a "series of special schools for the training of Architects; Civil Engineers, Mining Engineers and other Scientific Technists—all united under a common organization." The curriculum of this school was to be divided into two parts: a preparatory school which students would enter at 10 to 12 years of age and which would include the studies necessary to matriculation; and the polytechnic institute proper. The institute curriculum was to be three years in length and consisted of courses in the general school and the technical schools. The general school embraced mathematics, English, pure science and philosophy. The technical schools contained the applied subjects common to all the engineering specialties, as well as the specific subjects required in architecture, civil engineering and mining engineering.

In addition to suggesting the subjects to be included in the curriculum, Greene also suggested the addition of other schools, emphasized the importance of general education and went into detail regarding the residences for faculty and students, buildings for instruction and museum collections of many kinds. His report had widespread influence on the later development of Rensselaer Polytechnic institute.

The 1950–51 *Education Directory* of the U.S. office of education listed 12 institutions of higher learning including "polytechnic" as an integral part of the name. These schools varied widely in the number and level of curricula offered, type of control and number of students enrolled. Alabama Polytechnic institute with more than 7.000 students, for instance, is probably more like a university than a strictly technical institution. Curricula are offered which lead to degrees in agriculture, architecture, chemistry, education, engineering, home economics, pharmacy, science and literature and veterinary medicine. Contrasted with this would be Wyomissing Polytechnic institute, with about 400 students and a limited number of two-year vocational-technical curricula. The offerings of other institutes range between these two extremes. One factor common to these institutions, however, is the occupational emphasis of the curricula to the end that their graduates will be equipped to periorm successiully in the fields for which they are being trained.

See Federal Security Agency, Office of Education, *Education Directory, Part 3, Higher Education (1950–51)*; *The True Idea oj a Polytechnic Institute; A Facsimile Reprint from the Report of Benjamin Franklin Greene, Director of Rensselaer Polytechnic Institute, 1846–1858 (1949).* (L. F. SH.)

POLYTONALITY, a comparatively recent addition to musical terminology, signifying the simultaneous employment of conflicting keys. *See* HARMONY; KEY.

POLYXENA, daughter of Priam and Hecuba. The shade of Achilles appeared to the returning Greeks in the Thracian Chersonese and demanded Polyxena, who was put to death on his tomb. As a prominent leader he claimed a prominent female prisoner for his share of the booty, as Agamemnon did Cassandra (*q.v.*). Hence. in Philostratus, Dictys and other late authors, the story of a romantic affection between Achilles and Polyxena.

POLYZOA (BRYOZOA), a group of tiny aquatic animals in which the individuals bud and remain attached to each other to form colonies that are sometimes plantlike. See BRYOZOA.

POMBAL, SEBASTIÃO JOSÉ DE CARVALHO E MELLO, MARQUESS OF (1699–1782), Portuguese statesman, was born at Soure near Pomba, on May 13, 1699. In 1739 he was sent as Portuguese ambassador to London, where he remained until 1745. He was then transferred to Vienna. In 1749 he took up the post of secretary of state for foreign affairs and war. He reorganized Portuguese education, finance, the army and the navy. He also built up new industries, promoted the development of Brazil and Macao and expelled the Jesuits. His ascendancy over the mind of King Joseph dates from the time of the great Lisbon earthquake (Nov. 1, 1755). In Sept. 1770 he was made marquess of Pombal. Soon after the death of King Joseph, in 1777, Pombal was dismissed from office and was only saved from impeachment by the death of the queen mother, Mariana Victoria. On Aug. 16 a royal decree forbade him to reside within 20 leagues of the court. He died on May 8, 1782.

POME, a fruit in which the fleshy outer portion is formed by the undiverged bases of sepals, petals and stamens which surround the ovary, together with the carpels in whole or in part; the type of fruit characteristic of the apple, pear, quince, haw and juneberry. (J. M. BL.)

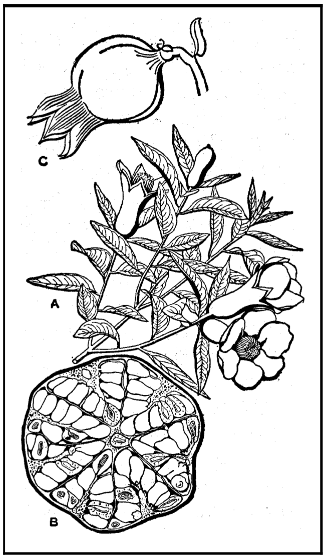
POMEGRANATE. Throughout the orient this fruit has since earliest times occupied a position of importance alongside the grape and the fig. It is produced by a bush or small tree, *Punica granatum,* only member of the family Punicaceae.

King Solomon possessed an orchard of pomegranates; and when the children of Israel, wandering in the wilderness, sighed for the abandoned comforts of Egypt, the cooling pomegranates were remembered longingly. Centuries later, the prophet Mohammed remarked sententiously: "Eat the pomegranate. for it purges the system of envy and hatred." It will thus be seen that this fruit is of exceptional interest because of its historic background. While the pomegranate is considered to be indigenous in Persia and perhaps neighbouring countries, its cultivation long ago encircled the Mediterranean and extended through Arabia. Afghanistan and India. There is something in the character of the juicy subacid pomegranate which makes it particularly agreeable to inhabitants of hot arid regions—which are precisely those in which it attains its greatest perfection.

The ancient Semitic name *rimmon* was adopted by the Arabs as *rumman,* from which the Portuguese in turn formed *romão* or *roman.* From the early Roman names *malum punicum* (apple of Carthage) and *granatum* have come the modern botanical binomial and the common name *granada,* used in Spanish-speaking countries.

The plant, which may attain 15 or 20 ft. in height, has elliptic to lanceolate bright green leaves about 3 in. long, and handsome axillary orange-red flowers borne toward the ends of the branchlets. The calyx is tubular, persistent, 5- to 7-lobed; the petals lanceolate, inserted between the calyx-lobes. The ovary is embedded in the calyx-tube and contains several locules in two series, one above the other.

The fruit is the size of an orange and often larger, obscurely six-sided, with a smooth leathery skin which ranges from brownish yellow to red in colour. Within it is divided into several cells, containing many thin transparent vesicles of reddish juicy pulp, each surrounding an angular elongated seed. A ripe pomegranate has a delightful subacid flavour.



POMEGRANATE (PUNICA GRANATUM), A. BRANCH WITH FLOWERS. B. TRANSVERSE SECTION THROUGH FRUIT SHOWING SEEDS, C. YOUNG FRUIT

Presumably the plant was introduced into the new world by the early Spanish colonists. It is commonly cultivated in gardens from the warmer parts of the United States to Chile. Small commercial plantings have been made in California. Though it will grow in a wide range of climates, good fruit is produced only where high temperatures and dry atmosphere accompany the ripening period. Deep, rather heavy loams are probably the best soils. Propagation is effected by seeds, cuttings and layers: the first-named can readily be grown, but choice varieties cannot be reproduced in this manner. Commercial propagation is by hardwood cuttings 10 to 12 in. long, which can be rooted in the open ground.

The varieties of the pomegranate are numerous. Ibn-al-Awam, a Moor who wrote in the 13th century, described some ten which were grown in southern Spain at that time. The three leading ones which have been cultivated commercially in the United States are Wonderful, Paper-Shell and Spanish Ruby. There are also dwarf forms which produce fruit of no value but are grown for their handsome scarlet flowers. (W. PO.)

POMFRET, JOHN (1667–1702), English poet, born at Luton, became rector of Maulden, Bedfordshire, in 1695, and of Millbrook in the same county in 1702. His poems were printed in Johnson's *English Poets* (1779, vol. xxi).

POMO. This group of American Indians, speaking Seven dialects of Hokan (*q.v.*) lineage, on Russian river and Clear lake, California, is noted for its basketry, which is perhaps the finest and most varied made on the continent. The general culture was central Californian as typified by the Maidu (*q.v.*).

POMONA, an old Italian goddess of fruit and gardens. Pomona had a special priest at Rome, the *flamen Pomonalis,* and a sacred grove near Ostia, called the Pomonal.

POMONA, a city of California, U.S., is located 30 mi. E. of Los Angeles (*q.v.*). A group of promoters purchased lands for town and agricultural development in 1875. The settlement, which the founders named Pomona for the Roman goddess of fruit, grew slowly until after 1880 when the sinking of deep wells provided a dependable source of irrigation water and made it the centre of a prosperous farming and fruit raising region. The southern California real estate boom of 1887 brought rapid growth; the town was incorporated in 1888 and the census of 1890 recorded a population of 3,634. Pomona remained the trading centre for a growing region which produced oranges, lemons and walnuts as well as deciduous fruits, field crops and livestock. The Southern Pacific, Santa Fe and Union Pacific railroads, which passed through or near it, gave a wide outlet for its crops. Pomona's agricultural character was recognized by the location of the extensive grounds of the Los Angeles County Fair there.

World War II and the years following brought major changes to Pomona. Its population, which had been 20,695 in 1930, grew to 67,157 in 1960. (For comparative population figures *see* table in CALIFORNIA: *Population.)* This was partly due to the expansion of Los Angeles which brought Pomona into commuting range of the city. It was even more the result of the industrialization of Pomona itself. There had been some manufacturing in Pomona since 1902, notably of water pumps necessary for the irrigation of the fruit groves. During and after the war, however, the number and size of industrial plants increased steadily. Naval ordnance, guided missiles, aircraft parts, pumps, paper products and tile were manufactured. Hundreds of acres of orange groves were replaced by single-family dwellings and citrus culture was no longer the prime activity of the region. The Kellogg-Voorhis campus of the California State Polytechnic college was established in 1938 just west of Pomona. The city has a council-administrator form of government, in effect since 1949. (J. H. K.)

POMONA or MAINLAND (the latter is the more correct name), the central and largest island of the Orkneys, Scot. Pop. (1951) 14,198. Area, including smaller adjacent islands, 201.6 sq.mi. It is irregularly shaped, and Kirkwall bay and Scapa Flow. cutting into the land on the north and south respectively, at one point reduce the width to less than 2 mi. The western coast is almost unbroken, but the eastern and southern shores are considerably indented. Ward hill (881 ft.) in the south is the highest peak in the island. There are numerous lakes, some of considerable size and most of them abounding in trout. Kirkwall (*q.v.*), the capital of the Orkneys, and Stromness (*q.v.*) are the only towns. Antiquities include Pictish *brochs,* chambered mounds and weems. or underground dwellings afterward roofed in. Northeast of Stromness, and within a mile of the standing stones of Stenness, lies the great barrow or chambered mound of Maeshowe. It is a blunted cone 300 ft. in circumference, and'at a distance of 90 ft. from its base is encircled by a moat. The ground plan shows that it was entered from the west by a passage, leading to a central apartment, the walls of which ended in a beehive roof. The barrow is variously ascribed to the Stone Age and to 10th-century Norsemen. The stone circles forming the Ring of Brogar and the Ring of Stenness, traditionally pagan temples, lie $4\frac{1}{2}$ mi. N E. of Stromness. The former stands on a raised circular platform of turf. surrounded by a moat and a grassy rampart. The ring originally comprised 60 stones. varying from 9 to 14 ft. in height. set up at intervals of 17 ft. Only 13 are now erect. The Ring of Stenness is of similar construction, and 150 yd. N. of it formerly stood the monolith called the Stone of Odin, pierced by a hole at the height of j ft., through which persons swearing a particularly binding oath clasped hands. At the bay of Skaill is the Neolithic village of Skara Brae (*q.v.*), where evidence has been found of more than one occupation, with perhaps hundreds of years between. On Marwick head stands the Kitchener memorial, erected to the memory of Lord Kitchener, drowned off Mainland in 1916. (*See* also ORKNEY ISLANDS.)

POMORZE (POMERANIA), a stretch of land extending from the lower Vistula on the east to the lower Oder on the west. The name is Slavonic and means "the country by the sea"; its Latinized form is Pomorania (later Pomerania), Pommern in German. Political developments contributed in extending the name west of the Oder as far as Stralsund with the island of Rügen (Rugia).

Physical Geography. — Pomorze is a flat country lying generally about 300 ft. above sea level, although its centre is traversed by a west-east range of morainic ridges rising in many places to 6jo ft., at some points over 975 ft. and at one, the Wiezyca hill (near Koscierzyna), to 1,066 ft. Off the west coast. which is irregular, lie the islands of Usedom (Uznam) and Wollin; the eastern coast is smooth in outline and is bordered with dunes and sandbanks. There are in Pomorze several small rivers, some of which flow north into the Baltic sea and some south into the Vistula or Notec rivers. The Leba, the Slupia and the Parseta are the most important among the former; the Brda, the Gwda and the Drawa among the latter.

The soil of Pomorze is for the most part thin and sandy. with patches of good land here and there. The principal crops are rye, oats and potatoes. Poland's ports are situated in Pomorze; in the chief ports of Gdansk (Danzig), Gdynia and Szczecin (Stettin) a shipbuilding industry is developing, while Kolobrzeg (Kolberg), Darlowo (Rugenwalde) and Ustka (Stolpmiinde) are mainly centres of fishing industry.

History. — In prehistoric times the southern coast of the Baltic seems to have been occupied by Celts, who made way for various tribes of Teutonic stock. These in turn were replaced, about the end of the jth century A.D., by Slavonic tribes. Pomorane or Pomorzanie settled between the Vistula and the Oder, while the Polabian Slavs — Lutycy (Veleti, Wilzen) and Obotryci (Obotriten) —were occupying the land between the Oder and the Elbe (Laba).

The whole of Pomorze was included in the territory of Mieszko I (d. 992), Poland's first historical ruler; so it was under King Boleslaw I the Brave (992–1025), who in the year 1000 founded a Polish bishopric at Kolobrzeg.

At that time there existed a local Slavonic dynasty that ruled over the whole of Pomorze and also in what was later known as Mecklenburg. Swiatobor or Svantibor, duke of Pomorze, who died in 1107, divided his land among his three sons: Boguslaw (Bogislaw or Bogislav) received the eastern part (Pomerania Ulterior, later known as Hinterpommern) with Gdansk; Warcislaw (Wratislaw) received the western part (Pomerania Citerior, or Vorpommern) with Wologoszcz (Wolgast); while Ratibor was the ruler of the central part with Szczecin.

Under King Boleslaw III, the Wry-Mouthed (1102–38), the dukes of Pomorze recognized the sovereignty of Poland. About 1125 eastern Pomorze was included in the Polish Kujawy diocese of Kruszwica. Later this episcopal see was transferred to Wloclawek. In 1140 a new bishopric for western and central Pomorze was created at Wollin, and about 1176 it was transferred to Kamien (Kammin), replacing that of Kolobrzeg.

In 1181 both western (Wolgast) and central (Stettin) Pomorze had to accept the protection of the German empire, and in 1225 the Wollin-Kamien diocese was transferred from the Polish archbishopric of Gniezno to the German archbishopric of Magdeburg. In the following five centuries these two parts of Pomorze were united under a single duke for two periods (1264–95 and 1478–1532) but generally remained separated under two branches of the same family. From the 13th century the country was opened to German immigrants, and this resulted in the Germanization of the towns and later of the nobility and of the countryside.

In 1294, on the death of Duke Mszczuj or Mestwin II, last duke of eastern Pomorze and stout opponent of the Germans, his land became an integral part of Poland. In 1308 it was conquered by the Teutonic order and reconquered by Poland in 1454, a reconquest recognized by the order in 1466.

Western and central Pomorze remained under the suzerainty of the German empire. In 1625 Boguslaw XIV once more united the duchies of Wolgast and Stettin. but he died without issue in 1637 and the whole dukedom passed to Brandenburg. At the peace of Westphalia in 1648 it was again divided with Sweden, which took its western part (Vorpommern), that is west of the Oder, with Stettin, leaving the remainder (Hinterpommern). as far as the frontiers of Poland, to Brandenburg. In 1720 Stettin and the southern part of Vorpommern, as far as the river Peene (Piana), was ceded to Brandenburg, but the northern part with Greifswald, Stralsund and Rügen remained Swedish until 1815.

In the meantime, Polish Pomorze was annexed by Brandenburg-Prussia in 1772 and renamed West Prussia. It was recovered by restored Poland in 1919 in somewhat smaller boundaries, and until 1939 constituted the province of Pomorze with chief town at Torun. Its area was 6,324 sq.mi. and in 1921 it had 939,000 inhabitants.

In 1815 Vorpommern and Hinterpommern were united in one Prussian province of Pommern with its chief town at Stettin. That province had an area of 11,663 sq.mi. and its population in 1926 was 1,897,166.

After 1945 almost the whole of historic Pomorze, except its section west of the Oder. became part of Poland. It was then divided into three provinces (*wojewodztwa*) of Gdansk, Bydgoszcz and Szczecin. On June 1. 1950, a fourth province of Koszalin (Koslin) was formed in the eastern part of that of Szczecin. The four provinces of Pomorze cover together an area of 24,098 sq.mi. Their total population in Feb. 1946 was 2,941,170, including 619,287

Germans. In 1955 it was estimated at 3,972,000, practically all Poles. (K. Sm.)

POMPADOUR, JEANNE ANTOINETTE POISSON LE NORMANT D'ÉTIOLES, Marquise de (1721–1764), mistress of Louis XV., was born in Paris on Dec. 29, 1721, and baptized as the legitimate daughter of François Poisson, an officer in the household of the duke of Orleans, and his wife, Madeleine de la Motte, in the church of St. Eustache; but she was educated at the charge of a wealthy financier and farmer-general of the revenues, Le Normant de Tournehem. He declared her "un morceau de roi," and specially educated her to be a king's mistress. This idea was confirmed in her childish mind by the prophecy of an old woman, whom in after days she pensioned for the correctness of her prediction. In 1741 she was married to a nephew of her protector and guardian, Le Normant d'Étioles, who was passionately in love with her, and she soon became a queen of fashion. The king met her at a ball given by the city to the dauphin in 1744, and he was immediately subjugated. She at once gave up her husband, and in 1745 was established at Versailles as "maitresse en titre." Louis XV. bought her the estate of Pompadour, from which she took her title of marquise (raised in 1752 to that of duchess).

She was hardly established firmly in power before she began to mix in politics. Knowing that the French people of that time were ruled by the literary kings of the time, she paid court to them, and tried to play the part of a Maecenas. Voltaire was her poet in chief, and the founder of the physiocrats, Quesnay, was her physician The command of the political situation passed entirely into her hands; she it was who brought Belle-Isle into office with his vigorous policy; she corresponded regularly with the generals of the armies in the field, as her letters to the Comte de Clermont prove; and she introduced the Abbé de Bernis into the ministry in order to effect a very great alteration of French politics in 1756. The continuous policy of France since the days of Richelieu had been to weaken the house of Austria by alliances in Germany; but Mme. de Pompadour changed this hereditary policy for the alliance with Austria which brought on the Seven Years' War, with all its disasters.

But it was to internal politics that this remarkable woman paid most attention. She made herself indispensable to Louis. She died on April 15, 1764, at the age of forty-tao.

See Capefigue, *Madame la marquise de Pompadour* (1858); *E.* and J. de Goncourt, *Les Maîtresses de Louis XV.*, vol. ii. (1860); and Campardon, *Madame de Pompadour et la cour de Louis XV. au milieu du dix-huitième siècle* (1867). Far more valuable are Malassis's two volumes of correspondence,*Correspondance de Madame de Pompadour avec son père M Poisson, et son frère M. de Vandières,* etc. (1878), and Bonhomme, *Madame de Pompadour, général d'arme'e* (1880), containing her letters to the Comte de Clermont. *See* also P. de Nolhac, *La Marquise de Pompadour* (1903).

POMPEII, an ancient town of Campania, Italy, near the river Sarnus, almost at the foot of Mt. Vesuvius. Its foundation was ascribed by Greek tradition to Heracles, in common with the neighbouring city of Herculaneum, but it was not a Greek colony. Strabo, in whose time it was a populous and flourishing place, tells us that it was first occupied by the Oscans, afterwards by the Tyrrhenians (*i.e.*, Etruscans), to whom it probably owes its rectangular ground plan, and Pelasgians, and lastly, by the Samnites. (See Campania.) No doubt, Pompeii shared the fate of the neighbouring cities, and afterwards passed in common with them under the yoke of Rome. But its name is only mentioned incidentally during the wars of the Romans with the Samnites and Campanians only when a Roman fleet landed near Pompeii in 309 B C. and made an unsuccessful marauding expedition up the river valley as far as Nuceria. At a later period, however, it took a prominent part in the Social War (91–89 B.C.), when it withstood a long siege by Sulla, and was one of the last cities of Campania that were reduced by the Roman arms. The inhabitants were admitted to the Roman franchise, but a military colony was settled in their territory in 80 B C by Sulla (*Colonia Cornelia* Veneria *Pompeianorum*), and the whole population was rapidly Romanized Before the close of the republic many Roman nobles acquired villas in the neighbourhood, among them Cicero, whose letters abound with allusions to his Pompeian villa. The same fashion continued under the empire, and during the first century of the Christian era, Pompeii had become a flourishing place with a considerable population. In A.D. 59 a tumult took place in the amphitheatre between the citizens and visitors from Nuceria. Many were killed and wounded on both sides. The Pompeians were punished for this violent outbreak by the prohibition of all theatrical exhibitions for ten years. A painting on the walls of one of the houses represents this event.

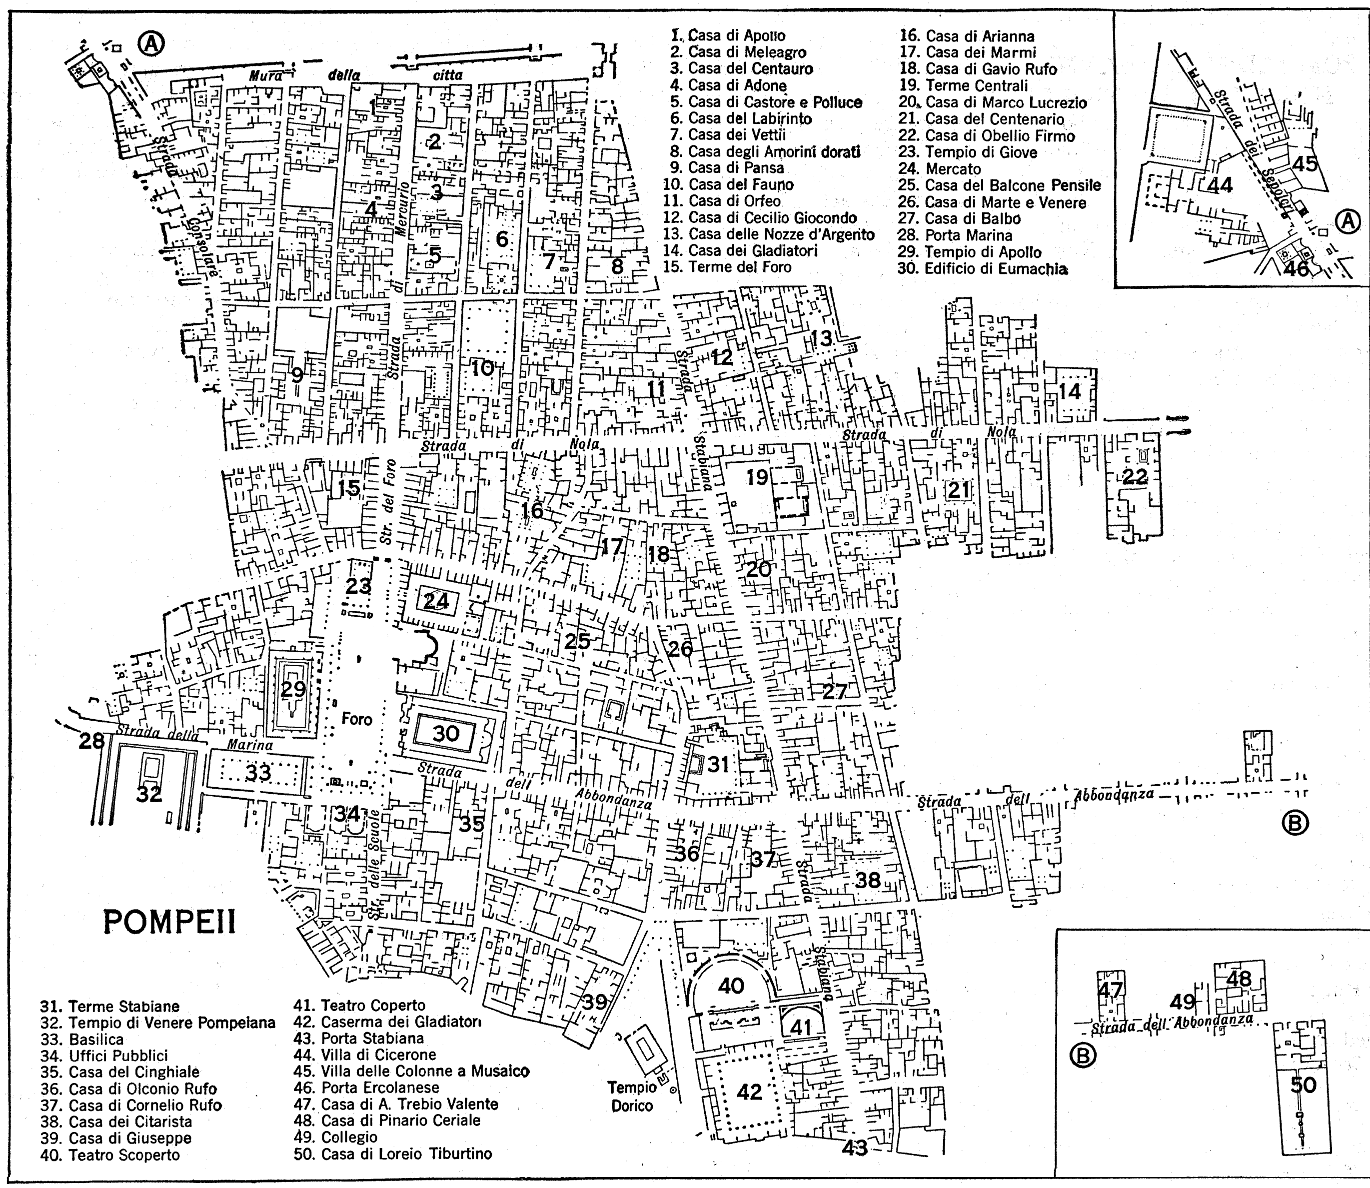
Four years afterwards (A.D. 63) an earthquake vented its force especially upon Pompeii, a large part of which, including most of the public buildings, was either destroyed or so seriously damaged as to require to be rebuilt. The inhabitants were still actively engaged in repairing and restoring it, when the whole city was overwhelmed by the great eruption of Vesuvius (*q.v.*), A.D. 79. Pompeii was merely covered with a bed of lighter substances, cinders, small stones and ashes, which fell in a dry state, while at Herculaneum the same substances, being drenched with water, hardened into a sort of tufa, which in places is 65 ft. deep. The whole of this superincumbent mass, attaining to an average thickness of from 18 to 20 ft., was the product of one eruption, though the materials may be divided generally into two distinct strata, the one consisting principally of cinders and small volcanic stones (called in Italian *lapilli*), and the other and uppermost layer of fine white ash, often consolidated by the action of water from above so as to take the moulds of objects contained in it (such as dead bodies, woodwork, etc), like clay or plaster of Paris. It was found impossible to rebuild the town, and its territory was joined to that of Nola. But the survivors returned to the spot, and by digging down and tunnelling were able to remove all the objects of value, even the marble facing slabs of the large buildings.

In the middle ages, however, the very site was forgotten. Ruins and inscriptions were found by the architect Domenico Fontana in making an underground aqueduct across the site in 1594–1600, but only in 1748 a more careful inspection of this channel revealed the fact that beneath there lay entombed ruins far more accessible than those of Herculaneum. Only in 1763 systematic excavations were begun; the work, which had received a vigorous stimulus during the period of the French government (1806–14), was prosecuted under the Bourbon kings (1815–61). Since 1861 it has been carried on under the Italian government on a system devised by G. Fiorelli, according to which the town is for convenience divided into 6 or 9 regions, which are subdivided into insulae (blocks), the gates, streets and houses being also named for convenience, though often incorrectly.

The town was situated on rising ground less than a mile from the foot of Vesuvius. This eminence is itself due to an outflow of lava from that mountain, during an eruption in prehistoric times, for we know that Vesuvius had been quiescent ever since the Greek settlements in this part of Italy.

The area occupied by the ancient city was of an irregular oval form, and about 2 m. in circumference. It was surrounded by a wall, which is still preserved for more than two-thirds of its extent, but no traces of this are found on the side towards the sea, and there is no doubt that on this side it had been already demolished in ancient times, so as to give room for the free extension of houses and other buildings in that direction. It consisted of two parallel stone walls with buttresses, about 15 ft. apart and 28 in thick, the intervening space being filled with earth, and there being an embankment on the inner side. These walls are strengthened at intervals by numerous towers, occupying the full width of the wall: They appear to have been added at a later period. probably that of the Social War. Similar evidences of the addition of subsequent defences are to be traced also in the case of the gates, of which five have been cleared, while at least one (and perhaps three) more are unexcavated.

The general plan of the town is very regular, the streets being generally straight, and crossing one another at right angles or nearly so. But exceptions are found in the south-west corner, where a small irregular group of streets represents the original Oscan settlement, and on the north-west in the street



FROM "GUIDA D'ITALIA DEL TOURING CLUB ITALIANO'

leading from the Porta Ercolanese (gate of Herculaneum) to the forum, which, though it must have been one of the principal thoroughfares in the city, was crooked and irregular, as well as very narrow, in places not exceeding 12 to 14 ft. in width. Another excention is to be found in the Strada Stabiana (Stabian Street) or Cardo, which, owing to the existence of a natural depression which affects also the line of the street just east of it, is not parallel to the other north and south streets. The other main streets are in some cases broader, but rarely exceed 20 ft. in width, and the broadest is about 32 ft., while the back streets running parallel to the main lines are only about 14 ft. (the standard width of a Roman highroad). They are uniformly paved with large polygonal blocks of hard basaltic lava, fitted very closely together, though now in many cases marked with deep ruts from the passage of vehicles in ancient times. They are also in all cases bordered by raised footways on both sides, paved in a similar manner; and for the convenience of foot-passengers, these are connected from place to place by stepping-stones raised above the level of the carriage-way. The careful investigation in recent years of the buildings in the eastern portion of the Strada dell' Abbondanza has shown that previous conceptions of the appearance of the exterior of the houses were entirely erroneous. The upper stories were diversified by balconies. open loggias, colonnades, etc., while the lower portions of the façades were painted, often with scenes of considerable interest. The streets were also diversified by fountains, small water-towers and shrines.

The first-mentioned of the two principal streets was crossed, a little before it reached the forum, by the street which led directly to the gate of Nola (Strada delle Terme, della Fortuna, and di Nola). Parallel to this last to the south is a street which runs from the Porta Marina through the forum, and then, with a slight turn, to the Sarno gate, thus traversing the whole area of the city from east to west (Via Marina, Strada dell' Abbondanza, Strada dei Diadumeni). These two east and west streets are the two decumani.

The population of Pompeii was mixed; both Oscan and Greek inscriptions are still found up to the last, and evidences of the presence of Jews are not lacking—such are a wall-painting, probably representing the Judgment of Solomon, and a scratched inscription on a wall, "Sodoma, Gomora." From the number of skeletons discovered, about 2,000 persons may have perished in the city itself in the eruption of A.D. 79.

The whole portion of the city which lies to the west of the Strada Stabiana, towards the forum and the sea, has been completely excavated. It is over one-half of the whole extent, and that the most important portion, inasmuch as it includes the forum, with the temples and public buildings adjacent to it, the thermae, theatres, etc. The greater part of that on the other side of the Strada Stabiana remains still unexplored, with the exception of the amphitheatre, a small space in its immediate neighbourhood and the buildings on each side of the Strada dell' Abbondanza and the Strada di Nola.

The forum at Pompeii was the centre of the life and movement of the city. Hence it was surrounded on all sides by public buildings or edifices of a commanding character. It was not, however, of large size. only 467 ft. in length by 126 in breadth (excluding the colonnades). The nature of its pavement, composed of broad flags of travertine, into which was let an inscription in large bronze letters, shows that it was only intended for foot-passengers. It was adorned with numerous statues. It was surrounded on three sides by a series of porticos supported on columns; and these porticos were originally surmounted by an upper storey, traces of the staircases leading to which still remain. Both this portico and the adjacent buildings were undergoing a process of restoration after the earthquake of 63, involving material changes in the original arrangements, which was still incomplete at the time of their final destruction. The north end of the forum, where alone the portico is wanting, is occupied in great part by the imposing temple of Jupiter, Juno and Minerva, or Capitolium. It was raised on a *podium* 10 ft. high, and had a portico with six Corinthian columns in front. This magnificent edifice had, however, been evidently overthrown by the earthquake of 63, and is in its present condition a mere ruin, the rebuilding of which had not been begun at the time of the eruption. On each side of it were two arches. affording an entrance into the forum, but capable of being closed by gates. On the east side of the forum were four public edifices. The first (from the north), is a *macellum* or meat-market, consisting of a rectangular court surrounded by a colonnade, with a twelve-sided roofed building (tholus) in the centre. On the south side were shops, and in the centre of the east side a chapel for the worship of the imperial house. Next to this comes the sanctuary of the Lares of the city, a square room with a large apse; and beyond this a small temple. Beyond this again, bounded on the south by the Strada dell' Abbondanza, is a large and spacious cloth-exchange, erected by a priestess named Eumachia. It is an open court, oblong, surrounded on all four sides by a colonnade; in front is a portico facing the forum, and on the other three sides there is a corridor behind the colonnade with windows opening on it. On the south side of the Strada dell' Abbondanza was the Comitium. At the south end of the forum are three halls side by side, similar in plan with a common façade —the central one, the curia or council chamber, the others the offices respectively of the duumvirs and aediles, the principal officials of the city; while the greater part of the west side is occupied by two large buildings—a basilica, which is the largest edifice in Pompeii, and the temple of Apollo, which presents its side to the forum. The former. a building of the 2nd cent. B.C., was an oblong edifice divided by columns into a central hall and a corridor running round all the four sides with a tribunal opposite the main entrance; and, unlike the usual basilicae, it had, instead of a clerestory, openings in the walls of the corridor through which light was admitted, it being almost as lofty as the nave. The temple was an extensive edifice, having a comparatively small *cella*, raised upon a podium, and standing in the midst of a wide space surrounded by a portico of columns, outside which again is a wall, bounding the sacred enclosure. Between this temple and the basilica the Via Marina leads off direct to the Porta Marina.

The remains of five other temples have been discovered. The most interesting, though the least perfect, is not only by far the most ancient edifice in Pompeii, but a true Greek temple (6th century B.C.). Unfortunately only the foundation and a few Doric capitals and other architectural fragments remain; they were coated with brightly painted stucco. The reverence attached to it in later periods is shown by its being left standing in the midst of a triangular space adjoining the great theatre, which is surrounded by a portico, so as to constitute a kind of forum (the so-called Foro Triangolare). Not far off, and to the north of the great theatre, stood a small temple, dedicated to Isis, rebuilt after the ruinous earthquake of 63. It is interesting as the only temple of Isis that has come down to us in a good state of preservation. The decorations were of somewhat gaudy stucco. The plan is curious, the internal arrangements being adapted for the performance of the peculiar rites of this deity. Close to this was the small temple of Zeus Milichius. The temple of the Fortune of Augustus (Fortuna Augusta), which stood north of the Forum, suffered very severely from the earthquake, but we learn from existing remains that its walls were covered with slabs of marble. and that the columns of the portico were of the same material. The fifth temple, that of Venus Pompeiana, to the west of the basilica, was in process of rebuilding at the time of the eruption. Before the earthquake of 63 it must have been the largest temple of the whole city. It was surrounded by a large colonnade, and the number of marble columns in the whole block has been reckoned at 296. Venus was the protectress of the young men of Pompeii, who had formed a society for gymnastics and other sports. They met in a hall (the Schola Iuventutis Pompeianae) in the Strada dell' Abbondanza.

All the temples above described, except that ascribed to Hercules, which was approached by steps on all four sides, agree in being raised on an elevated podium or basement—an arrangement usual with all similar buildings of Roman date. Among the other public buildings, the most conspicuous are the theatres, of which there were two, placed, as was usual in Greek towns, in close juxtaposition with one another. The largest of these, which was partly excavated in the side of the hill, was in great part cased with marble, with seats of the same material for about 5,000 spectators. It was erected in Roman times by two members of the same family, M. Holconius Rufus and M. Holconius Celer, both of whom held important municipal offices at Pompeii during the reign of Augustus. Their work was only a reconstruction of a more ancient edifice (probably 5th cent. B.C.), while its first alteration belongs to the "tufa" period, and three other periods in its history can be traced. The smaller theatre (for 1,500 spectators) was erected by two magistrates specially appointed for the purpose by the decuriones of the city, soon after the establishment of the Roman colony under Sulla. It was permanently covered.

Adjoining the theatres is a large rectangular enclosure, surrounded by a portico, at first the colonnade connected with the theatres, and converted, about the time of Nero, into the barracks of the gladiators. Remains of armour and weapons were found in some of the rooms, and in one, traces of the stocks used to confine insubordinate gladiators with three skeletons in them (63 were found in the whole building). The amphitheatre was erected by the same two magistrates who built the smaller theatre, C. Quinctius Valgus and M. Porcius when no permanent edifice of a similar kind had yet been erected in Rome itself, and is indeed the oldest structure of the kind known to us. It is in great part excavated in the surface of the hill, instead of the seats being raised on arches. Nor are its dimensions (460 by 345 ft.) such as to place it in the first rank, nor are there any underground chambers below the arena. The seating capacity was about 20,000 (for illustration see AMPHITHEATRE).

Among the more important public buildings of Pompeii were the public baths (thermae). Three different establishments of this character have been discovered, the first, the baths near the forum, though the smallest of the three, is in some respects the most complete and so well preserved that we trace without difficulty all the separate apartments described to us by Roman authors—the apodyterium, *frigidarium*, *tepidarium*, *caldarium*, and so on. (See BATHS.) The greater thermae (the so-called "Stabian" baths), which were originally built in the 2nd century B.C., and repaired about 80 B.C., are more extensive and combine a palaestra in the centre and other apartments for exercise or recreation. An inscription records the repair and restoration of the edifice after the earthquake of 63. These two establishments were inadequate to supply the wants of the inhabitants, and a third edifice, the so-called central baths, at the corner of the Strada Stabiana and the Strada di Nola, but on a still more extensive scale, intended for men only, was in course of construction in A.D. 79.

Far more interesting is the insight afforded us by the numerous private houses and shops into the ordinary life and habits of the population of an ancient town. The houses at Pompeii are generally low, rarely exceeding two storeys in height; the upper storey is generally of a slight construction, and occupied by small rooms, serving as garrets, or sleeping places for slaves. From the mode of destruction of the city these upper floors were in most cases crushed in and destroyed. The principal living rooms, as well as those intended for the reception of guests or clients, were all on the ground floor, the centre being formed by the *atrium*, or hall, which had an opening in the centre—the *compluvium*, so-called because the rain from the roofs was collected by it and fell into a basin (the *impluvium*). In the larger houses it was often surrounded with columns. Into this opened other rooms, the entrances to which, rarely protected by doors, were only closed by curtains. At the back was a garden. Later, under Greek influences, a peristyle with rooms took the place of the garden.

All the apartments and arrangements described by Vitruvius and other ancient writers may be readily traced in the houses of Pompeii, and in many instances these have for the first time enabled us to understand the technical terms and details transmitted to us by Latin authors. We must not, however, hastily assume that the examples thus preserved to us by a singular accident are to be taken as representing the style of building in all the Roman and Italian towns—in fact, the excavations at Ostia (*q.v.*) have shown us the contrary. We know from Cicero that Capua was remarkable for its broad streets and widespread buildings, and it is probable that the Campanian towns in general partook of the same character. At Pompeii indeed the streets were not wide, but they were straight and regular, and the houses of the better class occupied considerable spaces, presenting in this respect no doubt a striking contrast, not only with those of Rome itself, but with those of many other Italian towns, where the buildings would necessarily be huddled together from the circumstances of their position. Even at Pompeii itself, on the south side of the city, where the ground slopes somewhat steeply towards the sea, houses are found which consisted of three storeys or more, and with the inner walls painted black (with white designs on them) owing to the brilliancy of the light.

The excavations have provided examples of houses of every description, from the humble dwelling-place of the artisan or proletarian, with only three or four small rooms, to the stately mansions of Sallust, of the Faun, of the Golden Cupids, of the Silver Wedding, of the Vettii, of Pansa, etc.—the last of which is among the most regular in plan. But the general similarity in their plan and arrangement is very striking, and in all those that rise above a very humble class the leading divisions of the interior, the *atrium, tablinum, peristyle,* etc., may be traced with unfailing regularity. In all the more considerable houses in Pompeii the front, where it faces one of the principal streets, is occupied with shops, usually of small size, and without any communication with the interior of the mansion. In general the shop had a very small apartment behind it, and probably in most cases a sleeping chamber above it, reached by a staircase. The front of the shop was open to the street, but was capable of being closed with wooden shutters. Not only have the shops of silversmiths been recognized by the precious objects of that metal found in them, but large quantities of fruits of various kinds preserved in glass vessels, various descriptions of corn and pulse, loaves of bread, moulds for pastry, fishing-nets and many other objects too numerous to mention, have been found in such a condition as to be identified without difficulty. Inns and wine-shops appear to have been numerous; one of the latter we can see to have been a *thermopolium*, where hot drinks were sold. Bakers' shops are also frequent, though arrangements for grinding and baking appear to have formed part of every large family establishment. In other cases, however, these were on a larger scale, provided with numerous querns or hand-mills of the well-known form, evidently intended for public supply. Other establishments on a large scale were *fullonicae* (fullers' shops), where all the details of the business were illustrated by paintings still visible on the walls. Dyers' shops, a tannery and a shop where colours were ground and manufactured are of special interest, as is also the house of a surgeon, where numerous surgical instruments were found, some of them of a very ingenious and elaborate description, but all made of bronze. A blacksmith's shop was also found, with many tools that had been brought in for repair: here were discovered the remains of a *groma*, the instrument used by Roman land-surveyors, which has been successfully reconstructed (Della Corte in *Monumenti dei Lincei,* 1922). Another curious discovery was that of the abode of a sculptor, containing his tools, as well as blocks of marble and half-finished statues.

Of the numerous works of art discovered in the course of the excavations the statues and large works of sculpture, whether in marble or bronze, are inferior to those found at Herculaneum, but some of the bronze statuettes are of exquisite workmanship, while the profusion of ornamental works and objects in bronze and the elegance of their design, as well as the finished beauty of their execution, are such as to excite the utmost admiration—more especially when it is considered that these are the casual results of the examination of a second-rate provincial town, which had, further, been ransacked for valuables (as Herculaneum had not) after the eruption of 79. The same impression is produced in a still higher degree by the paintings with which the walls of the private houses, as well as those of the temples and other public buildings, are adorned, and which are not merely of a decorative character, but in many instances present us with elaborate compositions of figures, historical and mythological scenes, as well as representations of the ordinary life and manners of the people, which are full of interest to us, though often of inferior artistic execution. It has until lately been the practice to remove these to the museum at Naples; but the present tendency is to leave them (and even the movable objects found in the houses) *in situ* with all due precautions as to their preservation, which adds immensely to the interest of the houses; indeed, with the help of careful restoration, their original condition is in large measure reproduced. In some cases it has even been possible to recover the original arrangement of the garden beds, and to replant them accordingly, thus giving an appropriate framework to the statues, etc., with which the gardens were decorated, and which have been found *in situ.* The same character of elaborate decoration, guided almost uniformly by good taste and artistic feeling, is displayed in the mosaic pavements, which in all but the humbler class of houses frequently form the ornament of their floors. One of these, in the House of the Faun, well known as the battle of Alexander, presents us with the most striking specimen of artistic composition that has been preserved to us from antiquity.
