The architecture of Pompeii presents in general a transitional character from the pure Greek style to that of the Roman Empire. The temples (as already observed) have always the Roman peculiarity of being raised on a *podium* of considerable elevation; and the same characteristic is found in most of the other public buildings. All the three orders of Greek architecture—the Doric, Ionic and Corinthian—are found freely employed in the various edifices of the city, but rarely in strict accordance with the rules of art in their proportions and details; while the private houses naturally exhibit still more deviation and irregularity. In many of these indeed we find varieties in the ornamentation, and even in such leading features as the capitals of the columns, which remind one rather of the vagaries of mediaeval architecture than of the strict rules of Vitruvius or the regularity of Greek edifices. One practice which is especially picvalent, so as to strike every casual visitor, and dates from the early years of the empire, is that of filling up the flutings of the columns for about one-third of their height with a thick coat of stucco, so as to give them the appearance of being smooth columns without flutings below. The architecture of Pompeii suffers from the inferior quality of the materials generally employed. No good building stone was at hand; and the public as well as private edifices were constructed either of volcanic tufa, or lava, or Sarno limestone, or brick (the latter only used for the corners of walls). In the private houses even the columns are mostly of brick, covered merely with a coat of stucco. Marble was sparingly employed.

These materials are used in several different styles of construction belonging to the six different periods which Mau traces in the architectural history of Pompeii.

1. That of the Doric temple in the Foro Triangolare (6th cen-

tury B.C.) and an old column built into a house in Region vi., Insula 5; also of the older parts of the city walls—date uncertain (Sarno limestone and grey tufa).

2. That of the limestone atriums (outer walls of the houses of ashlar-work of Sarno limestone, inner walls with framework of limestone blocks, filled in with small pieces of limestone). Date before 200 B.C.

3. Grey tufa period; ashlar masonry of tufa, coated with fine white stucco; rubble work of lava. The artistic character is still Greek, and the period coincides with the first (incrustation) style of mural decoration, which (coming from Asia Minor or Greece perhaps by way of Sicily) aimed at the imitation in stucco of the appearance of a wall veneered with coloured marbles. No wall paintings exist, but there are often fine floor mosaics. To this belong a number of private houses (*e.g.,* the House of the Faun), and the colonnade round the forum, the basilica, the temples of Apollo and Jupiter, the large theatre with the colonnades of the Foro Triangolare, and the barracks of the gladiators, the Stabian baths, the Palaestra, the exterior of the Porta Marina, and the interior of the other gates—all the public buildings indeed (except the Doric temple mentioned under [1], which do not belong to the time of the Roman colony). Date, end of 2nd century B.C.

4. The "quasi-reticulate" period—walling faced with masonry not yet quite so regular as *opus reticulaturn,* and with brick quoins, coinciding with the second period of decoration (the architectural, partly imitating marble like the first style, but without relief, and by colour only, and partly making use of architectural designs framing pictorial scenes, which are conceived as seen through openings). It is represented by the small theatre and the amphitheatre, the baths near the forum, the temple of Zeus Milichius, the Comitium and the original temple of Isis, but only a few private houses. This style probably owes much to Hellenistic theatrical decoration. Date, from 80 B.C. until nearly the end of the Republic.

5. The period from the last decades of the Republic to the earthquake of AD. 63. No homogeneous series of buildings—we find various styles of construction (quasi-reticulate, *opus reticulatum* of tufa with stone quoins, of the time of Augustus, *opus reticulaturn* with brick quoins or with mingled stone and brick quoins, a little later); and three styles of wall decoration fall within its limits: the later stage of the second, already mentioned, the third or ornate, with its freer use of ornament and its introduction of designs which suggest an Egyptian origin (originating in the time of Augustus), and the fourth or intricate, with a return to architectural forms, dating from about A.D. 50. Marble first appears as a building material in the temple of Fortuna Augusta (*c.* 3 B C.).

6. The period from the earthquake of A.D. 63 to the final destruction of the city, the buildings of which can easily be recognized. The only wholly new edifice of any importance is the central baths.

Outside the Porta Ercolanese, or gate leading to Herculaneum, is found a house of a different character from all the others, undoubtedly a large villa; its remains are of interest as aiding us in understanding the description of ancient authors, such as Vitruvius and Pliny, of the numerous appurtenances frequently annexed to houses of this description.

In the cellar of this villa were discovered no less than twenty skeletons, and fourteen in other parts of the house. Almost all the skeletons and remains of bodies found in the city were discovered in similar situations, in cellars or underground apartments—those who had sought refuge in flight having apparently for the most part escaped from destruction, or having perished under circumstances where their bodies were easily recovered by the survivors. It has been found possible in many cases to take casts of the bodies found.

An interesting farm-house (few examples have been so far discovered in Italy) is that at Boscoreale excavated in 1893–94, which contained the treasure of one hundred and three silvrr vases now in the Louvre. The villa of P. Fannius Synhistor, not far off, was excavated in 1900; it had fine wall paintings, which were exported, and sold by auction in Paris (some now in the Louvre, while others are in New York). (*See* F. Barnabei, *La Villa pompeiana di P. Fannio Sinistore;* Rome, 1901.) Another, closer to Pompeii, in the so-called Villa Item, contains remarkable life size frescoes representing scenes of initiation into the mysteries of Dionysus or of Orpheus.

The road leading towards Herculaneum is bordered on both sides for a considerable extent by tombs, in many instances monuments of considerable pretension, and of a highly ornamental character, which present in the highest degree the advantage common to all that remains of Pompeii, their perfect preservation.

There appears to have been in the same quarter a considerable suburb, outside the gate, extending on each side of the road towards Herculaneum, apparently much resembling those which are now fouad from thence to Naples. Other suburbs were situated at the harbour and at the saltworks (*salinae*).

No manuscripts have been discovered in Pompeii. Inscriptions have been found in considerable numbers, and give much information concerning the municipal arrangements of the town, as well as the construction of various edifices and other public works. The most interesting of these are such as are written in the Oscan dialect, which appears to have continued in official use down to the time when the Roman colony was introduced by Sulla. From that time the Latin language was the only one officially employed. Still more curious are the numerous writings painted upon the walls, which have generally a semi-public character, such as recommendations of candidates for municipal offices, advertisements, etc., and the scratched inscriptions (*graffiti*), which are generally the mere expression of individual impulse and feeling, frequently amatory, and not uncommonly conveyed in rude and imperfect verses. In one house also a whole box was found filled with written tablets—diptychs and triptychs—containing the record of the accounts of a banker named L. Caecilius Iucundus.

POMPEIUS, GNAEUS, surnamed STRABO (squint-eyed), Roman statesman, father of the triumvir. He was successively quaestor in Sardinia (103 B C.), praetor (94), propraetor in Sicily (93) and consul (89). He fought with success in the Social War, and was awarded a triumph for his services. Probably towards the end of the same year he brought forward the law (*lex Pompeia de Gallia transpadana*), which conferred upon the inhabitants of that region the privileges granted to the Latin colonies. During the civil war between Marius and Sulla he seems to have shown no desire to attach himself definitely to either side. He set out for Rome; the engagement which he fought before the Colline gate, although hotly contested, was indecisive. Soon afterwards he was killed by lightning (87).

See Plutarch, *Pompey, 1;* Appian, *Bell. civ.* i. 50, 52, 66–68, 80; Vell. Pat. ii. 21; Livy, *Epit.* 74–79; Florus iii. 18.

POMPEIUS, GNAEUS, surnamed MAGNUS (c. 75–45 B.C.), the elder son of the triumvir. In 49–48 B.C. during the civil war he commanded his father's fleet in the Adriatic. After the battle of Pharsalus he set out for Africa nith the remainder of the Pompeian party, but, meeting with little success, crossed over to Spain. Having been joined by his brother Sextus. he collected a considerable army, the numbers of which were increased by the Pompeians who fled from Africa after the battle of Thapsus (46). Caesar. who regarded him as a formidable opponent, set out against him in person. A battle took place at Munda (*q.v.*) on March 17, 45, in which the brothers were defeated. Gnaeus escaped, but mas soon (April 12) captured and put to death.

See *Bellum hispaniense,* 1–39; Lucan. *Pharsalia,* ix, 120; Dio Cassius, xliii, 28–40.

POMPEIUS, SEXTUS, surnamed MAGNUS (75–35 B.C.), the younger son of the triumvir. After his father's death he continued the struggle against the new rulers of the Roman empire. From Cyprus, where he had taken refuge, he made his way to Africa, and after the defeat of the Pompeians at Thapsus (46) crossed over to Spain. After Caesar's victory at Munda (45), he abandoned Corduba (Cordova), though for a time he held his ground in the south, and defeated Asinius Pollio, the governor of the province. In 43 he was proscribed by the triumvirate and put himself at the head of a fleet manned chiefly by slaves or proscribed persons, with which he made himself master of Sicily, and from thence ravaged the coasts of Italy. Rome was threatened with a famine, as the corn supplies from Egypt and Africa were cut off by his ships, and it was thought prudent to negotiate a peace with him at Misenum (39), which was to leave him in possession of Sicily, Sardinia and Achaea, provided he would allow Italy to be freely supplied with corn. But the arrangement could not be carried into effect, as Sextus renewed the war and gained some considerable successes at sea. However, in 36 his fleet was defeated and destroyed by Agrippa at Naulochus off the north coast of Sicily. After his defeat he fled to Mytilene, and from there to Asia Minor. In the attempt to make his way to Armenia he was taken prisoner by Antony's troops, and put to death at Miletus.

See Dio Cassius, xlvi.–xlix.; Appian, Bell. civ. iv. 84–117, v. 2–143; Vell. Pat. ii. 73–87; Plutarch, Antony; Livy, Epit. 123, 128, 129, 131; Cicero, *Philippica,* xiii., and many references in Letters to *Atticus.*

POMPEY, the common English form of Pompeius, the name of a Roman plebeian family.

POMPEIUS, GNAEUS (106–48 B.C.), the triumvir, the first of his family to assume the surname MAGNUS, was born on Sept. 30, in the same year as Cicero. When only 17 he fought together with his father in the Social War. He took the side of Sulla against Marius and Cinna, but for a time, in consequence of the success of the Marians, he kept in the background. On the return of Sulla from the Mithridatic War Pompey joined him with an army of three legions, which he had raised in Picenum. Thus early in life he connected himself with the cause of the aristocracy, and a decisive victory which he won in 83 over the Marian armies gained for him from Sulla the title of *imperator.* He followed up his successes in Italy by defeating the Marians in Sicily and Africa, and on his return to Rome in 81, though he was still merely an *eques* and not legally qualified to celebrate a triumph, he was allowed by general consent to enjoy this distinction, while Sulla greeted him with the surname of *magnus,* a title he always retained and handed down to his sons. Latterly, his relations with Sulla were somewhat strained; after Sulla's death he resisted the attempt of the consul M. Aemilius Lepidus to repeal the constitution. In conjunction with A. Lutatius Catulus, the other consul, he defeated Lepidus when he tried to march upon Rome, and drove him out of Italy (77). He retained his army, and jockeyed the senate into sending him to Spain *pro consule* (though he had as yet held no magistracy) to deal with Sertorius. Pompey was fighting in Spain from 76 to 71. After Sertorius had fallen a victim to assassination, Pompey easily defeated his successor Perperna and put an end to the war. On his way back he met and cut up a body of slaves, part of Spartacus' defeated forces, in flight northwards. He demanded a triumph, and permission to stand for the consulate.

The Consul.—The senate was inclined to grudge it, so he entered into a coalition with Crassus, and as both had armies at the gates, there was no more to be said. Pompey and Crassus were consuls together in 70, and that year saw the work of Sulla undone; the tribunate and censorship were restored, and the administration of justice was shared between the Senate, the equites, and the *tribuni aerarii.*

Pompey rose still higher in popularity, and on the motion of the tribune Aulus Gabinius in 67 he was entrusted with an extraordinary command over the greater part of the empire, specially for the extermination of piracy in the Mediterranean, by which the corn supplies of Rome were seriously endangered, while the high prices of provisions caused great distress. He was completely successful; the price of corn fell immediately on his appointment, and in 40 days the Mediterranean was cleared of the pirates. Next year, on the proposal of the tribune Manilius, his powers were still further extended, the care of all the provinces in the East being put under his control for three years together with the conduct of the war against Mithridates VI., who had recovered from the defeats he had sustained from Lucullus and regained his dominions. Both Caesar and Cicero supported the tribune's proposal, which was easily carried in spite of some opposition in the senate. Pompey was entirely successful. Mithridates was beaten and driven into the Crimea, and there was a generai settlemen. of affairs in the East. Syria and Palestine were annexed in 64 and 63. Tigranes of Armenia submitted and was confirmed as a vassal king, and an agreement was reached with Phraates of Syria whereby the Euphrates marked the boundary between them.

Pompey, now in his 45th year, returned to Italy in 61 to celebrate the most magnificent triumph which Rome had ever witnessed, as the conqueror of Spain, Africa and Asia.

Politics.—This triumph marked the turning-point in his career. As a soldier everything had gone well with him; as a politician he was a failure. He found a great change in public opinion, and the people indifferent to his achievements abroad. The senate had a unique chance to secure his support, but refused to ratify the arrangements he made in Asia or to provide money and lands for distribution amongst his veterans. In these circumstances he drew closer to Caesar on his return from Spain, and became reconciled to Crassus. The result was the first triumvirate. He was married to Caesar's daughter Iulia, and as yet the relations between the two had been friendly. Pompey was now in fact ruler of the greater part of the empire, while Caesar had only the two provinces of Gaul. But being no political tactician, Pompey made no use of this advantage, and all this time the balance of power was steadily turning in Caesar's direction. The senate and the aristocracy disliked and distrusted Pompey, but they felt that, should things come to the worst, they might still find in him a champion of their cause. Hence the joint rule of Pompey and Caesar was not unwillingly accepted, and anything like a rupture between the two was greatly dreaded as the sure beginning of anarchy throughout the Roman world. In 55 Pompey was consul again, in accordance with the arrangement with Caesar when the triumvirate was renewed at Luca in 56. As proconsul he should have left for his province, but ne remained in charge of the corn-supply, virtually master of Rome, and governed Spain by his *legati.* With the death of Pompey's wife Iulia (54) and of Crassus (53) the relations between him and Caesar became strained, and soon afterwards he drew closer to the conservative party and married into the house of Scipio. In 52, in the utter disorder that followed the death of Clodius. he was elected sole consul, carried through the trial of Milo, and started a programme of administrative and provincial legislation threatening Caesar's position.

Civil War.—The crisis arrived with the approaching end of Caesar's command at the end of 50. Pompey nearly compromised by accepting the Parthian command and leaving Rome, but Marcellus forced his hand, and civil war began. Pompey, wisely or unwisely, abandoned Italy. His cause, with that of the senate and' aristocracy, was finally ruined by his defeat by Julius Caesar in 48 in the neighbourhood of Pharsalus. That same year he fled with the hope of finding a safe refuge in Egypt, but was treacherously murdered by one of his old centurions as he was landing. He was five times married, and three of his children survived him—Gnaeus, Sextus, and a daughter Pompeia.

POMPONAZZI, PIETRO (1462–1525), Italian philosopher, was born in Mantua on Sept. 16, 1462. He studied philosophy and medicine at Padua and taught philosophy in that university (1487–

1509, with interruptions), at Ferrara and finally at Bologna (1512–25), where he died on May 18, 1525. Thoroughly versed in Aristotle and his commentators, especially Averroes and St. Thomas, Pomponazzi was a leading representative of Renaissance Aristotelianism as it had developed at the Italian universities (*i.e.,* in conjunction with medicine rather than with theology) since the end of the 13th century. His questions and lectures on Aristotle are still for the most part unpublished 400 years after his death. His treatise on the immortality of the soul, *De immortalitate animae* (1516), was violently attacked but not officially condemned, and the author was allowed to defend his position in his *Apologia* (1518) and *Defensorium* (1519). He contended that the immortality of the individual soul cannot be demonstrated on the basis of Aristotle or of reason but must be accepted as an article of faith. In developing this view, he maintains that the end of human life consists in moral action and that virtue is its own reward, vice its own punishment. This moral virtue constitutes the peculiar dignity of man.

Pomponazzi's largest treatises, *De incantationibus* and *De fato,* were published posthumously (1556 and 1567). The former proposes a natural explanation of several reputedly miraculous phenomena. The latter defends the Stoic doctrine of fate against Alexander of Aphrodisias and adds a subtle philosophical discussion of predestination and free will.

(P. O. K.)

POMPOSA, an abbey of Emilia, Italy, in the province of Ferrara. 2 mi. from Codigoro. ahich is 30 mi. E. of Ferrara in the delta of the Po. The fine church, a nork of the 6th century, rebuilt in the llth, aith interesting sculptures and terra-cotta decorations on the façade and a splendid Romanesque. campanile 163 ft. high (1063), contains a good mosaic pavement (1036) and interesting frescoes of the 14th century—a "Last Judgment" of the school of Giotto, and others. There are also paintings in the refectory. The abbey was abandoned in 1650 because of malaria.

POMPTINE (PONTINE) **MARSHES,** an ill-drained area covering 300 sq mi. southeast of Rome and lying between Monti Lepini and a belt of coastal sand dunes. It nas apparently cultivated under the Volsci but later abandoned because of the prevalence of malaria. Attempts at drainage were made in Roman times, folloning the construction of the Via Appia in 312 B.C., and these were repeated at various times without much success. The draining was finally achieved under the Fascist government betneen 1930 and 1934. Previously, about one third of the land provided rough pasture for half-wild cattle and minter pasture for sheep brought down from the hills. There was also a little wheat cultivation by peasants who returned for a few days to harvest it. The rest of the land was covered with scrub. Some areas were under nater for most of the winter. A major canal nas made to carry drainage from the hills direct to the sea. and pumping stations were installed to drain the lowest lands.

Irrigation canals have made possible the cultivation of most of the area and healthful, well-planned towns. such as Littoria, Nettuno and Porto d'Anzio, have been established. Water supplies are drawn from wells. (T. HER.)

PONCA CITY, a city of Kay county, Okla., U.S., 90 mi. N E. of Oklahoma City. It was established in 1893. Prior to the opening of the historic Cherokee strip on Sept. 16 of that year (see OKLAHOMA. *History*). 2,300 $2 certificates were sold by a private group, entitling each holder to participate in forming the nea town and in acquiring a lot. More than 2,000 people gathered at the proposed site, and on Sept. 21 the drawing for lots was held and a provisional government nas organized by popular assembly.

The name is from the Ponca tribe of Indians, moved in 1879 to a reservation located south of the townsite. Although the name Ponca City had always been in popular use, the post-office name was Ponca until 1913. The city has a council-manager form of government, in effect since 1954.

Ponca City is an important petroleum centre; two large refineries have a combined daily capacity of more than 100,000 bbl. There is also an annual production of 75,000.000 lb. of carbon black. Other industries in the city process agricultural products; manufacture clothing, oil-drilling bits, farm equipment, ceramics, decorative wreaths and vacuum cleaners; and service diesel engines.

The city is the home of the famous "Pioneer Woman" statue and Pioneer Woman State park, presented to the people of Oklahoma by Gov. E. W. Marland, and is the location of the Pioneer Woman Historical museum.

For comparative population figures see table in OKLAHOMA: *Population.* (GE. H. S.)

PONCE, the largest and most important city on the southern coast of Puerto Rico and the second city in size and importance on the island. In 1960 the population of the city was 114,286 and of the municipal district 145,586. Ponce's official history dates from 1692 when a tonn council was established and a mayor appointed. In 1877, because of its growth and importance, the Spanish government elevated Ponce to the category of a city.

The warm, dry climate on the south coast is most agreeable. The average annual temperature is 79°, and the yearly rainfall is 36 in. Constant breezes coming off the mountains and from the Caribbean sea assure comfortable living. As Puerto Rico's principal shipping port on the Caribbean, Ponce trades with the islands of the Lesser Antilles, Colombia and Venezuela Extensive improvements of the excellent harbour were made under the direction of U.S. agencies. Cement, iron. shoes, candy, textiles and paper products are some of the more important industrial goods manufactured in Ponce. To the west on the coast is located a large oil refinery. To the east well-irrigated plains produce high-grade sugar cane. Five banking firms have offices in Ponce. There are four radio stations, two television stations and one daily newspaper.

Excellent highways connect the city with other coastal towns, and two well-kept paved roads lead up over the mountains to the interior and the north coast. The city is also connected with San Juan (*q.v.*) by regular commercial air service. Ponce's parks. plazas, public buildings and private residences are well-kept and attractive. In addition to first-class hotels, the city has an ultra-modern tourist hotel.

The Roman Catholic Church maintains the University of Santa Maria with facilities for over 3,000 students in the city.

(T. G. Ms.)

PONCE DE LEÓN, JUAN (*c.* 1460–1521), discoverer of Florida, was born in Servas, Spain, about 1460. He took part in the Moorish wars and then sailed for America with Columbus on his second voyage (1493). In 1509 he conquered Puerto Rico and was appointed governor. As soon as the island was under control and pacified he set out with three ships to search for the land of "Bimini," wherein, as the Indian legend told him, there was a fountain with waters of marvelous curative power. On Mar. 27, 1513, he discovered the mainland which he named Florida because the day was Easter Sunday *(Pascua Florida).* He landed north of the present site of St. Augustine on April 2 and on April 8 took possession in the name of the Spanish king. He afterward explored the coast southward to the cape and up the west shore of the peninsula to at least 27° 30' and perhaps to where the coast trended westward.

Ponce de León returned to Spain in 1514 and received an appointment from Ferdinand V as governor of "The Island of Florida." In 1521 he set out to conquer and colonize his possession, but the fierceness of the natives prevented his success.

In a sharp engagement Ponce de Leon was mortally wounded and his force driven to the ships. He died in Cuba in June 1521.

See F. A. Obcr, *Ponce de Ledn (1908);* Justin Windsor, *Narrative and Critical History of America,* vol. ii, chap. iv. *(1886);* "The Track of Ponce de Leon," *Amer. Geog. Soc. Bulletin, xlv.,* pp. 721–735 *(1913); Boletin histdrico de Puerto Rico, Año I;* pp. *118–161 (1914).*

PONCELET, JEAN VICTOR (1788–1867), French mathematician and engineer, one of the founders of modern synthetic geometry, was born at Metz on July 1, 1788. From 1808 to 1810 he attended the Bcole Polytechnique and afterward, until 1812, the *école d'application* at Metz. He then became lieutenant of engineers and took part in the Russian campaign during which he was taken prisoner and confined at Saratov, on the Volga, until 1814, when he returned to France. During his imprisonment he began his researches on projective geometry which led to his great treatise on that subject. This work, the *Traité des propriétés projectives des figures* (1822; 2nd ed., 2 vol., 1865–66), is occupied with the investigation of the projective properties of figures and entitles Poncelet to rank as one of the greatest of those who took part in the development of the new geometry of which G. Monge was the founder *(see* GEOMETRY: *History of Geometry).* Poncelet developed the principle of duality and discovered the circular points at infinity. From 1815 to 1825 .he was occupied with military engineering at Metz, and from 1825 to 1835 he was professor of mechanics at the *tcole d'application* there. In 1834 he became a member of the Académie; from 1838 to 1848 he was professor to the faculty of sciences at Paris and from 1848 to 1850 commandant of the Bcole Polytechnique, with the rank of ,general. He died at Paris on Dec. 22, 1867.

Poncelet's works include *Cours de me'chanique, appliquée aux Machines* (1826), and *Mémoire sur les roues hydrauliques à aubes courbes* (1826).

See Eric *T. Bell, Men of Mathematics* (1937). (O. OE.)

PONCHIELLI, AMILCARE (1834–1886), Italian musical composer, was born near Cremona on Sept, 1, 1834, and studied at the Milan conservatory. He attained his fame with *La Gioconda* (1876), written to a libretto founded by Arrigo Boito upon Victor Hugo's tragedy, *Angelo, Tyran de Padoue. La Gioconda* was followed by *Il Figliuol prodigo* (1880) and *Marion Delorme* (1885). He died at Milan on Jan. 17, 1886.

POND, JOHN *(c.* 1767–1836). English astronomer-royal, was born about 1767 in London. After leaving Trinity college, Cambridge, he settled at Westbury near Bristol, and began to determine star places with a fine altitude and azimuth circle of $2\frac{1}{2}$ ft. diameter by E. Troughton. His demonstration in 1806 *(Phil. Trans.* xcvi, 420) of a change of form in the Greenwich mural quadrant led to the introduction of astronomical circles at the Royal Observatory, and to his own appointment as its head. He was elected a fellow of the Royal Society on Feb. 26, 1807; he married and went to live in London in the same year, and in 1811 succeeded Nevil Maskelyne as astronomer-royal.

Under Pond the instrumental equipment at Greenwich was completely changed, and the number of assistants increased from one to six. The superior accuracy of his determinations was attested by S. C. Chandler's discussion of them in 1894, in the course of his researches into the variation of latitude *(Astron. Journ.* no. 313, 315). Pond received many academic honours. He published eight folio volumes of *Greenwich Observations,* translated S.-P. Laplace's *Système du monde* (in 2 vols. 8vo., 1809), and contributed 31 papers to scientific collections. His catalogue of 1,112 stars (1833) was of great value. He retired in 1835 and died at Blackheath on Sept. 7, 1836, and was buried beside Halley in the churchyard at Lee.

PONDICHERRY (Fr. *Pondichéry* from Tamil *puddu cheri,* "new village"); the name of a centrally administered state of India and of its capital, and of the chief settlement of former French India. On Nov. 1, 1954, on the basis of a vote of the elected representatives of French Indian municipalities, the administration of French India was transferred to the republic of India; central control was initiated through a chief commissioner with headquarters at Pondicherry; and on Jan. 6, 1955, the four settlements together were designated the state of Pondicherry. The distances from Pondicherry and relative locations of the isolated parts of the state are as follows: Karikal 70 mi. (Tanjore district, Madras); Mahé 285 mi. (Malabar dist., Madras); Yanoan 370 mi. (East Godavari dist., Andhra Pradesh). Total area 193 sq.mi.; total pop. (1955 est.) 330.688. Pondicherry territory itself (South Arcot district of Madras) has an area of 112 sq.mi. The town (pop., 1955 est., 62,716) is 122 mi. by rail (85 mi. direct) south-southwest of Madras city. Its roadstead is the best on the east coast.

Pondicherry was founded in 1683 by François Martin, on the site of a village given him by the governor of Gingee. In 1693 the Dutch took Pondicherry, but restored it, with the fortifications greatly improved, in 1697, at the peace of Ryswick. In 1761 it was taken by Col. Eyre Coote from the Comte de Lally. In 1763 it was restored to the French. In 1778 it was again taken, by Sir Hector Munro, and its fortifications destroyed. In 1783 it was retransferred to the French. and in 1793 recaptured by the English. The treaty of Amiens in 1802 restored it to the French, but it was retaken in 1803. In 1816 it was restored to the French.

(S. GL.)

PONDO, a Kafir people who have given their name to Pondoland, the country comprising much of the seaboard of Kaffraria, Cape province, immediately to the southwest of Natal.

PONDWEED, a popular name for *Potamogeton natans,* a cosmopolitan aquatic plant found in ponds, lakes and ditches, with broad, more or less oblong ovate, olive green, floating leaves. The name is also applied to other species of *Potamogeton,* one of the characteristic genera of lakes, ponds and streams all over the world but more abundant in temperate regions, embracing about 90 species. It is the principal genus of the family Potamogetonaceae and contains plants with slender branched stems and submerged and translucent, or floating and opaque, alternate or opposite leaves, often with membranous united stipules. The small flowers are borne above the water in axillary or terminal spikes; they have four stamens, which bear at the back four small herbaceous petallike structures and four free carpels, which ripen to form four small green fleshy fruits, each containing one seed within a hard inner coat; the seed contains a large hooked embryo. An allied genus, *Zannichellia,* occurring in fresh and brackish ditches and pools nearly throughout North America and in Great Britain, and also widely elsewhere in temperate and tropical regions, is known as horned pondweed, from the curved fruit.

FROM STRASSBURGER, "LEHRBUCH DER BOTANIK FUR HOCHSCHULEN" (GUSTAV FISCHER)
PONDWEED (POTAMOGETON NATANS), SHOWING FLOWERING STEM AND LEAVES

PONGEE, a plain weave fabric made of tussah or wild silk, originated with the Chinese in ancient times. Its sphere of usefulness has been broadened due chiefly to the increase in standard width from 18 to 36 or more inches, and the variety of colours extended. The Japanese buy from the Chinese the wild silk and work it up in their own plants.

Shantung, a variety of pongee, derives its name from the province which is the centre of the wild silk industry. It differs from true pongee in that the former must be a plain weave, while Shantung may include many types. even adding coloured threads for decoration. Because of the ease with which they can be laundered and their durability pongees are among the most practical of silks.

PONIARD, a dagger, particularly one of small size, used for stabbing at close quarters. The French word *poignard,* from which the English is a 16th-century adaptation, is formed from *poing,* fist, in which the weapon is grasped. *(See* DAGGER.)

PONIATOWSKI, the name of a Polish princely family of Italian origin, tracing descent from Giuseppe Torelli, who married about 1650 an heiress of the Lithuanian family of Poniatov, whose name he assumed.

STANISLAUS PONIATOWSKI (1677–1762), only belonged to the family by adoption, being the reputed son of Prince Sapieha and a Jewess. He was born at Dereczyn in Lithuania, and was adopted by Sapieha's intendant, Poniatowski. Attaching himself to the party of Stanislaus Leszczynski, he became major-general in the army of Charles XII of Sweden, who also employed him as diplomatic intermediary to the Sultan. He next became governor of the duchy of Zweibrücken, Bavaria. After the death of Charles XII in 1718 he visited Sweden; and was subsequently reconciled with Leszczynski's rival on the throne of Poland, Augustus II, who made him grand treasurer of Lithuania in 1724. On the death of Augustus II he tried to secure the reinstatement of Leszczynski, but presently gave his allegiance to Augustus III, by whom he was made governor of Cracow. He died at Ryki on Aug. 3, 1762.

His second son Stanislaus Augustus became king of Poland. *(See* STANISLACS II AUGUSTUS.) Of the other sons, Casimir (1721–80) was his brother's chancellor; Andrew (1735–73) became *Feldzeugmeister* in the Austrian service; Michael (1736–94) became archbishop of Gnesen and primate of Poland. Joseph Anthony (*q.v.*), Andrew's son. became one of Napoleon's marshals.

STANISLAUS PONIATOWSKI (1757–1833), son of Casimir, was grand treasurer of Lithuania, starost of Podolia and lieutenant-general of the royal army. In 1793 he settled in Vienna, and subsequently in Rome, where he made a magnificent collection of antique gems, subsequently sold. He died in Florence, Feb. 13, 1833, and the Polish and Austrian honours became extinct.

His natural, but recognized, son, JOSEPH MICHAEL XAVIER FRANCIS JOHN PONIATOWSKI (1816–1873), was born at Rome and in 1847 was naturalized as a Tuscan subject. He received the title of prince in Tuscany (1847) and in Austria (1850). He represented the court of Tuscany in Paris from 1848, and he was made a senator by Napoleon III., whom he followed to England in 1871. He also wrote numerous operas. He died on July 3, 1873. His son, Prince Stanislaus Augustus, married and settled in Paris. He was equerry to Napoleon III., and died in Jan. 1908.

PONIATOWSKI, JOSEPH ANTHONY (1763–1813), Polish prince and marshal of France, son of Andrew Poniatowski and the countess Theresa Kinsky, was born at Warsaw in 1763. He served with distinction in the imperial forces against the Turks in 1788, then becoming major-general and subsequently lieutenant general in the Polish army under his uncle, King Stanislaus. In 1789 he commanded the Ukrainian division; and after the proclamation of the constitution of May 3, 1791, was made commander-in-chief. Aided by Kosciuszko, he conducted the operations against Russia with much skill, but when the king acceded to the confederation of Targowica *(see* POLAND: *History),* at the same time guaranteeing the adhesion of the army, Poniatowski, and most of the other generals threw up their commissions and emigrated. During the Kosciuszko rising he again fought gallantly for his country under his former subordinate, and after the fall of the republic lived in retirement. After the evacuation of the Polish provinces by Prussia, Poniatowski became commander of the National Guard, and on the creation of the grand duchy of Warsaw he was nominated war minister.

During the war of 1809, he operated successfully against the Austrians. In Napoleon's campaign against Russia in 1812 Poniatowski commanded the fifth army corps; and after the disastrous retreat of the grand army remained faithful and formed a new Polish army of 13,000 men, with which he joined the emperor at Liitzen. In 1813 he guarded the passes of the Bohemian mountains and defended the left bank of the Elbe. As a reward for his brilliant services at Leipzig he was made a marshal of France and entrusted with the duty of covering the retreat of the army, in the course of which he perished, fighting heroically against overwhelming odds. His relics were conveyed to Poland and buried in Cracow Cathedral, where he lies by the side of Tadeusz Kosciuszko and Jan Sobieski. Poniatowski's *Mes souvenirs sur la campagne de 1792* (Lemberg, 1863) is of historical value.

See *Correspondence of Poniatowski* (ed. E. Raczynski, Posen, 1843); Bronislaw Dembinski, *Stanislaus Augustus and Prince Joseph Poniatowski in the light of their Correspondence* (Fr.; Lemberg, 1904); Szymon Askenazy, *Prince Joseph Poniatowski* (Pol.; Warsaw, 1905).

PONS, JEAN LOUIS (1761–1831), French astronomer, was born at Peyres (Hautes Alpes) on Dec. 24, 1761. He entered the Marseilles observatory in 1789, and in 1819 became the director of the new observatory at Marlia near Lucca, which he left in 1825 for the observatory of the museum at Florence. Here he died on Oct. 14, 1531. He spent his time searching for comets, of which he discovered a record number; some bear his name, *e.g.,* Pons-Winnecke's comet.

See M. R. A. Henrion, *Annuaire biographique,* i. 288 (1834); *Memoirs Roy. Astron. Soc.* v. 410; R. Wolf, *Geschichte der Astronomie,* p. 709; J. C. Poggendorff, *Biog. lit. Handwörterbuch.*

PONSARD, FRANÇOIS (1814–1867), French dramatist, was born at Vienne, Isbre, on June 1, 1814, and studied law. His translation of *Manfred* was published in 1837. His play *Lucrèce* was represented at the Théâtre Français on April 1, 1843. This date mprks a reaction against the romantic style of Dumas and Hugo. He received, in 1845, the Academy's prize for a tragedy "to oppose a dike to the waves of romanticism." Ponsard combined the liberty of the romantics with the sober style of earlier French drama. The success of his plays was aided by the impersonation of many of the principal rôles in them by Rachel. He followed up *Lucrèce* with *Agnès de Méranie* (1846), *Charlotte Corday* (1850), and others. *L'Honneur et l'argent*, one of his most successful plays, was acted in 1853, and he became an academician in 1855. In 1866 he obtained great success with *Le Lion Amoureux*, another play dealing with the revolutionary epoch. His *Galilée,* which excited great opposition in the clerical camp, was produced in 1867. He died in Paris on July 7, 1867.

His *Oeuvres complètes* were published in Paris (3 vols., 1865-76). *See* C. Latreille, *La Fin du théâtre romantique et François Ponsard d'après des documents inkdits* (1899).

PONSONBY OF SHULBREDE, ARTHUR AUGUSTUS WILLIAM HARRY PONSONBY, 1ST BARON (1871–1946), British author and politician, was born on Feb. 16, 1871, and educated at Eton and at Balliol college, Oxford. In 1894 he entered the diplomatic service, and after holding posts in Constantinople and Copenhagen, returned in 1902 to join the staff of the foreign office. In 1906 he became principal private secretary to Sir Henry Campbell-Bannerman, and in 1908 was elected Liberal M.P. for Stirling. He represented this constituency until 1918, and in 1922 was elected Labour member for the Brightside division of Sheffield, and held minor posts in the Labour governments of 1924 and 1929–31. He was raised to the peerage in 1930, and was leader of th'e opposition in the house of lords from 1931 to 1935. He died at Hindhead, Surry, March 24, 1946.

His works include *The Decline of Aristocracy* (1912); *Democracy and Diplomacy* (1915); *Wars and Treaties (1815–1914)* (1917); *Now is the Time* (1925); *Life Here and Now* (1936).

PONSONBY, English family. PONSONBY, JOHN (1713–1789), Irish politician, was born on March 29, 1713. In 1739 he entered the Irish parliament, where he became first commissioner of the revenue (1744), a privy councillor (1746), and in 1756 Speaker. Belonging to one of the great families which at this time monopolized the government of Ireland, Ponsonby was one of the principal "undertakers," men who controlled the whole of the king's business in Ireland, and he retained the chief authority until the marquess Townshend became lord-lieutenant in 1767. A struggle for supremacy between the Ponsonby faction and the party dependent on Townshend followed, which caused Ponsonby to resign the speakership in 1771. He died on Dec. 12, 1789. His wife was Elizabeth, daughter of William Cavendish, 3rd duke of Devonshire, a connection of advantage to the Ponsonbys.

Ponsonby's third son, GEORGE PONSONBY (1755–1817), lord chancellor of Ireland, was born on March 5, 1755, and educated at Trinity College, Cambridge. A barrister, he became a member of the Irish parliament in 1776 and was chancellor of the Irish exchequer in 1782, afterwards taking part in the debates on the question of Roman Catholic relief, and leading the opposition to the union of the parliaments Ponsonby represented Wicklow and then Tavistock in the united parliament; in 1806 he was lord chancellor of Ireland, and from 1808 to 1817 he was the official leader of the opposition in the House of Commons, He left an only daughter when he died in London on July 8,1817.

George Ponsonby's elder brother. WILLIAM BRABAZON PONSONBY, 1st Baron Ponsonby (1744–1806), was also a leading Whig politician, being a member of the Irish and, after 1800, of the British parliament In 1806, shortly before his death, he was created Baron Ponsonhy of Imokilly. On the death of his grandson, WILLIAM BRABAZON PONSONBY (1807–1866), the barony became extinct.

PONTA DELGADA, the capital of an administrative district, comprising the islands of St. Michael's and St. Mary in the Portuguese archipelago of the Azores. Pop. (1950) 22,706. Ponta Delgada is built on the south coast of St. Michael's. in 37° 40′ N. and 25° 36' W. Its mild climate and the fine scenery of its mountain background render it very attractive to visitors; it is the commercial centre and the most populous city of the archipelago. Great improvements in the harbour were effected after 1860 by the construction of a breakwater 2.800 ft. long.

PONT-À-MOUSSON, a town of northern France in the *département* of Meurthe-et-Moselle, 17 mi. N.N.W. of Nancy by rail. Pop. (1954) 10,872. Dating from the 9th or 10th century, Pont-à-Mousson constituted a lordship, which was made a marquisate in 1354. It was from 1572 to 1763 the seat of a well-known university. The Moselle, which is canalized, divides the town into two quarters, united by a 16th-century bridge. The church of St. Martin dates from the 13th, 14th and 15th centuries. The lower ecclesiastical seminary occupies the building of an old Premonstratensian convent.

PONTANO, GIOVANNI (JOVIANUS PONTANUS) (1422 or 1426–1503), Italian humanist whose voluminous and wide-ranging work illustrates the diversity of the Renaissance scene, was born at Cerreto, in Umbria, on May 7, 1422 or 1426. At about the age of 21 he went to Naples, where he spent the rest of his life. In 1471, on the death of the scholar Antonio Beccadelli (Panormita), he became head of the Neapolitan humanist academy, called after him Accademia Pontaniana. In 1461 he married Adriana Sassone, who bore him one son and three daughters and died in 1490. From 1486 until 1495 he was the effective political leader of the kingdom of Naples as adviser, military secretary and chancellor to the kings of the Aragonese dynasty. He died in Sept. 1503.

Pontano's extensive literary output, all in Latin, includes a historical work (De *bello Neapolitano*), philosophical treatises (*De prudentia, De* fortuna), an astrological poem (*Urania*), five dialogues dealing with such widely differing subjects as morals and religion, philology and literature (*Aegidius*, Actius, *Asinus, Antonius, Charon*) and many lyrics on love, nature, family life and scenes from Neapolitan life (*Lepidina*, *Amorum* libri, *Eridanus, Hendecasyllabi,* Dr *amore coniugali, Jambici, Tumuli*). His erudition embraced all fields of knowledge, but neither as a thinker nor ax a poet did he display a powerful personality. The importance of his work for the cultural and. even more, the social history of the Renaissance, lies not so much in its erotic originality as in the fact that it synthesizes and reproduces more completely perhaps than that of any other humanist the diverse elements of the period.

BIBLIOGRAPHY.—C. M. Tallarigo, *Giovanni Pontano e i suoi tempi (1873)*; M. Scherillo, "Il Rinascimento" in Le *origini e lo svolgimento della letteratura italiana,* parte i, pp. 76–122 (1926). (*G. P. G.*)

PONTARLIER, a frontier town of eastern France, 36 mi. S.E. of Besançon. Pop. (1954) 13,079. It is situated 2,750 ft. above sea level on the Doubs, about 4 mi. from the Swiss frontier, and forms an important strategic point at ,the mouth of the defile of La Cluse, one of the principal passes across the Jura. Pontarlier is the junction of railway lines to Neuchâtel, Lausanne, Lons-le-Saunier. Dôle and Besançon.

At Pontarlier the French army of the east made its last stand against the Prussians in 1871 before crossing the Swiss frontier. The distillation of herbs, largely grown for kirsch and other liqueurs. is the chief industry.

PONT AUDEMER, a town of northwestern France. in the *département* of Eure. 39 mi. N.W. of Evreux, on the railway to Honfleur. Pop. (1954) 6,380. The town owes its name to Audomar, a Frankish lord. who in the 7th or 8th century bridged the Risle there.

The church of St. Ouen, which has fine stained glass of the 16th century, combines the late Gothic and Renaissance styles; its choir is Romanesque. Manufacturing includes malleable metal founding, glue, leather goods and paper and cotton spinning. There is trade in flax, wool, grain, cattle, cider, paper, iron, wood and coal. The port has a length of more than one-half mile on the Risle, which is navigable for small vessels from this point to the Seine (10 mi.).

PONTCHARTRAIN, a lake in southern Louisiana, U.S., 40 mi. long and 25 mi. wide. with an area of 625 sq.mi. and a mean depth of from 10 to 16 ft. Lying due north of a bend of the Mississippi, it is in places only 5 mi. distant from the river. More a lagoon than a lake, since it connects eastward with the Gulf of Mexico by a narrow passage called the Rigolets, Pontchart-rain is brackish and teems with game fish. It was discovered by Sieur d'Iberville in 1699. New Orleans, founded on the Mississippi. now extends to the lake, on which there is a state park and many small resorts. Pontchartrain causeway. a 27-mi., multispan concrete bridge, crosses the lake north from New Orleans. (W. A. Ro.)

PONTE, JACOPO DA: *see* BASSANO, JACOPO.

PONTECORVO, a city of Lazio. Italy. in the province of Frosinone. about 48 mi. from Caserta. Pop. (1951) 5,207. The principality of Pontecorvo, once an independent state, belonged alternately to the Tomacelli and the abbots of Monte Cassino. Napoleon bestowed it on Bernadotte in 1806, and in 1810 it was incorporated with the French empire.

PONTÉCOULANT, LOUIS GUSTAVE LE DOULCET, COMTE DE (1764–1853), French politician, was born at Caen on Nov. 17, 1764. He entered the army in 1778. A moderate supporter of the revolution, he was returned to the convention for the department of Calvados in 1792 and became commissary with the army of the north. He attached himself to the party of the Gironde, and in Aug. 1793 was outlawed. He refused to defend his compatriot Charlotte Corday, who wrote him a letter of reproach on her way to the scaffold. He returned to the convention on March 8, 1795, and became its president in July; he was for several months a member of the council of public safety. He was elected to the council of 500, but was suspected of royalist leanings, and spent some time in retireinent before the consulate. Becoming senator in 1805, and count of the empire in 1808, he organized the national guard in Franche-Comté in 1811 and the defense of the northeastern frontier in 1813. He sat in the upper house under the restoration. He died in Paris on April 3, 1853.

PONTEFRACT, a market town and municipal borough in the West Riding of Yorkshire, Eng., 25 mi. S.S.W. of York and 13 mi. E.S.E. of Leeds by road; it is served by three railway stations. Pop. (1951) 23,185. Area 7.6 sq.mi. An ancient Brigantian settlement existed there, to be succeeded by the Saxon town of Kirkby; the name was changed to Pontefract at some date prior to 1140, when the death in the town of Archbishop Thurstan was recorded. The building of the famous castle was begun in 1069 by Ilbert de Lacy. After 240 years the much-altered castle and manor passed by marriage to Thomas, earl of Lancaster. Henry IV held his court there for many years after deposing Richard II, and within the castle dungeons Richard supposedly was murdered in 1400. There too, after Agincourt (1415), Charles, duke of Orléans, was imprisoned for over 20 years. In 1541 Henry VIII made a visit to the north with the object of pacifying the northern counties after the disturbances occasioned by the Pilgrimage of Grace, in the course of which the castle had been taken by Robert Aske. leader of the pilgrimage, in 1536. Elizabeth I also visited the castle and repaired the chapel. the remains of which can still be seen within the walls. During the civil wars the castle sustained three sieges. It was the last royalist stronghold to be reduced by Cromwell, who had it dismantled. Sufficient of its walls, towers and dungeons still remain to give some idea of its former grandeur.

The town was the site of several important monastic settlements, including the priory of St. John, which was later demolished upon the orders of Henry VIII. The material recovered from the demolition was used for the building of the New hall, about half a mile away, itself to be reduced to ruins (which may still be seen) during the course of the civil mar. In Southgate is an ancient hermitage and oratory cut from the solid rock and dating from 1396. The Butter cross in the market place was erected in 1734 by the widow of the Spaniard Solomon Dupier with whose collaboration Gibraltar had been taken by Adm. Sir George Rooke.

The church of All Saints', under the castle, dates from Norman times. Ruined in the civil war, it had its central portion repaired and it is still in use. The church of St. Giles, first mentioned in a charter of Henry I, became the parish church after the ruin of All Saints'.

There are several ancient almshouses; the earliest, that of St. Nicholas, having been founded before the Conquest. The old town hall (18th century) contains the original plaster cast from which was made the panel depicting the death of Lord Nelson, at the foot of the column in Trafalgar square, London. The King's school, whose foundation was confirmed by Edward VI in 1549, is now housed in modern buildings. Three miles away, at Ackworth, is the well known Society of Friends school, founded in 1778. Other principal buildings are the market hall, the courthouse, the barracks (of the York and Lancaster regiment), the assembly rooms and the municipal offices. There is a racecourse in the park.

The principal industries are those of liquorice confectionery, made from locally grown liquorice (the town being the home of the celebrated "Pomfret cakes," so named from the usual pronunciation of Pontefract), coal mining, furniture making. iron founding, tanning. textiles and engineering. The market rights are exercised under a charter granted by Roger de Lacy in 1194, while the first mayor was appointed pursuant to a charter of Richard III in 1484. From the end of the 13th century to the Reform act of 1832 Pontefract returned two members to parliament. In the mid-1950s the borough constituency of Pontefract, which includes Castleford and Featherstone urban districts. returned one member. The Pontefract court of quarter sessions has an unbroken history from 1640 to the present day, and the town gives its name to a bishop suffragan in the Wakefield diocese.

PONTEVEDRA, a maritime province of northwestern Spain. before 1833 a part of Galicia. Pop. (1950) 714.666; area 1,695 sq.mi., with a density of population 421.6 inhabitants per square mile. The surface is mountainous. The coast line is deeply indented; navigation is rendered difficult by fogs in summer and storms in winter. Large agricultural fairs are held in the chief towns, and there is export of cattle, hams. salt meat and fish, eggs, breadstuffs, leather and wine. Vigo is the chief port and there are harbours at Bayona, Carril, Marin, Villagarcia and elsewhere among the deep estuaries of the coast. At Tuy the Spanish and Portuguese railways meet.

PONTEVEDRA, the capital of the Spanish province of Pontevedra; on the Tuy-Corunna railway, and on the river Lerez, which here enters the Ria de Pontevedra, an inlet of the Atlantic. Pop. (1950) 41,828. The name of the town is derived from the ancient Roman bridge (pons *vetus*) of twelve arches, which spans the Lerez near its mouth. Pontevedra is mainly built of granite, and still partly enclosed by mediaeval fortifications. There is an active trade in grain, wine and fruit; cloth, hats, leather and pottery are manufactured.

PONTIAC (c. 1720–1769), famous chief of the Ottawa Indians and leader in the "Conspiracy of Pontiac" in 1763–64, was born about 1720, probably on the Maumee river, in what is now northwestern Ohio. His father was an Ottawa, and his mother an Ojibwa. By 1755 he had become a chief of the Ottawa and a leader of the loose confederacy of the Ottawa, Potawatomi and Ojibwa. As an ally of France, he possibly commanded the Ottawa in the defeat (1755) of Gen. Braddock. In 1760 he met Maj. Robert Rogers, then on his way to occupy Michilimackinac and other forts surrendered by the French, and agreed to let the English troops pass unmolested on condition that he should be treated with respect by the British. Like other Indians he soon realized the difference between French and English rule—that the Indians were no longer welcomed at the forts and that they would ultimately be deprived of their hunting grounds by encroaching English settlements. French hunters and traders encouraged Indian disaffection with vague promises of help from France; and in 1762 Pontiac enlisted the support of practically all the Indian tribes from Lake Superior to the lower Mississippi for a joint move to expel the British. He arranged for each tribe to attack the fort nearest to it in May 1763, and then to combine to wipe out the undefended settlements. Pontiac himself decided to capture Detroit, but his carefully laid plans for a surprise attack on May g were betrayed to the commanding officer, Maj. Gladwin, and he was forced to lay siege to the fort. The siege continued for five months, marked by desultory attacks and sorties. Schooners sent through Lake Erie with supplies and provisions were captured by the Indians, but Pontiac could not prevent reinforcements from Fort Niagara under Capt. Dalzell from reaching Detroit. However, when the besieged made a night attack on the Indian encampment, Pontiac, apprised of their coming, inflicted heavy losses on them at Bloody Run, July 31. The Indians were unused to making long sieges and, after a few months, several of the associated tribes made peace. With his own Ottawa, Pontiac continued to camp around Detroit until Oct. 30 when, hearing that no aid from the French could be expected owing to the signing of the peace treaty with the English, he withdrew to the Maumee river.

Pontiac's larger plan was more successful. Of the 12 fortified posts attacked by the Indians, all but four were captured; most of the garrisons were massacred; several relief expeditions were nearly annihilated, and the frontiers were desolated and plundered. Col. Bouquet, however, succeeded in defeating the Indians at Bushy Run, when on his way to relieve Forts Pitt and Ligonier, and in 1764, he led a second expedition into Ohio from Pennsylvania, and forced the Indian tribes to sue for peace and release their prisoners. Pontiac still hoped to arouse other tribes to continue the fight, but after another year he saw that the English were the real masters of the situation and, on behalf of the tribes lately banded in his league, he concluded a treaty of peace and amity with Sir William Johnson at Oswego, N.Y., July 25, 1766. Pontiac, laden with gifts from the enemy, returned to his home on the Maumee. He met his death in 1769 at the hands of an Illinois Indian bribed by an English trader to murder him at Cahokia (nearly opposite St. Louis). His death occasioned a bitter war among the Indians, and the Illinois group was all but annihilated by his avengers. Pontiac was one of the most remarkable men of the Indian race in American history, possessing a commanding energy and force of mind combined with subtlety and craft, and a power of organization.

BIBLIOGRAPHY.—*See* Francis Parkman, The Conspiracy of Pontiac (1851; 10th ed., 1905) ; Handbook of American Indians (Bureau of American Ethnology, vol. ii., 1910).

PONTIAC, the seat of Oakland county, Mich., U.S., 26 mi. N.W. of Detroit (*q.v.*) and within the Detroit metropolitan area, is an important automobile-manufacturing city in the midst of a resort region, with hundreds of lakes and numerous public parks Named for the famous Ottawa chief, Pontiac was settled in 1818 by the Pontiac company, organized in Detroit; the site was the intersection of the Clinton river and the Saginaw trail, which formed part of the Indian route from the Straits of Mackinac to northern Ohio. In the 19th century, Pontiac was the shopping centre for a prosperous agricultural area. It was chartered as a city in 1861; in 1877 its population of about 4,000 supported newspapers, banks, mercantile establishments, hotels, and blacksmiths, gunsmiths, mills, foundries and small factories.

Its river location made available water power essential to the rise of factories. Most important for its future were the wagon and carriage works, which, with the invention of the automobile, turned to production of cars and parts; in the 20th century, Pontiac's economy has depended largely upon the automobile industry. Pontiac has a commission-manager form of government, in effect since 1920. Pontiac State hospital is located in the city; nearby are the Cranbrook institutions (private schools, museum and art academy) and the Oakland branch of Michigan State university. The population of the city in 1960 was 82,233; for comparative population figures see table in MICHIGAN: Population.

(E. S. AD.)

PONTIANUS, pope from 230 to 235. He was exiled to Sardinia by the emperor Maximinus, and in consequence of this sentence resigned (Sept. 28, 235). He was succeeded by Anteros.

PONTIFEX. The collegium of the pontifices was the most important priesthood of ancient Rome, being specially charged with the administration of the *jus divinum; i e.,* that part of the civil law which regulated the relations of the community with the deities recognized by the state officially, together with a general superintendence of the worship of gens and family. The name is clearly derived from *pons* and *facere,* but whether this indicates any special connection with the sacred bridge over the Tiber (Pons Sublicius) cannot be determined. The college existed under the monarchy, when its members were probably three in number; they may be considered as legal advisers of the *rex* in all matters of religion. Under the republic they emerge into prominence under a *pontifex maximus,* who took over the king's duties as chief administrator of religious law, just as his chief sacrificial duties were taken by the *rex sacrorztm;* his dwelling was the *regia,* "the house of the king." During the republican period the number of pontifices increased. probably by multiples of three, until after Sulla (82 *B.c.)* they numbered 15; for the year 57 B.C. a complete list of them is given in Cicero *(Harusp. resp.,* 6, 12). Included in the collegium were also the *rex sacrorum,* the *flamines,* three assistant pontifices *(minores)* and the vestal virgins, who were all chosen by the *pontzfex maxımus.*

Vacancies in the body of pontifices were originally filled by cooptation; but from the second Punic war onward the *pontifex maximus* was chosen by a peculiar form of popular election, and in the last age of the republic this held good for all the members. They all held office for life.

The immense authority of the college centred in the *pontifex maximus,* the other pontifices forming his *consilium* or advising body. His functions were partly sacrificial or ritualistic, but these were the least important; the real power lay in the administration of the *jus divinum,* the chief departments of which may briefly be described as follows: (1) the regulation of all expiatory ceremonials needed as the result of pestilence, lightning, etc.; (2) the consecration of all temples and other sacred places and objects dedicated to the gods by the state through its magistrates; (3) the regulation of the calendar both astronomically and in detailed application to the public life of the state; (4) the administration of the law relating to burials and burying places, and the worship of the manes, or dead ancestors; (5) the superintendence of all marriages by *confarreatio; i.e.,* originally of all legal patrician marriages; (6) the administration of the law of adoption and of testamentary succession. They had also the care of the state archives and the lists of magistrates. and kept records of their own decisions *(commentarii)* and of the chief events *(annales).*

It is obvious that a priesthood with such functions and holding office for life must have been a great power in the state, and for the first three centuries of the republic it is probable that the *pontzfex maximus* was in fact its most powerful member. The office might be combined with a magistracy, and, though its powers were declaratory rather than executive, it may be described as quasi-magisterial. Under the later republic it was coveted chiefly for the great dignity of the position; Julius Caesar held it for the last 20 years of his life, and Augustus took it after the death of Lepidus in 12 B.C., after which it became inseparable from the office of the reigning emperor.

PONTOISE, a town of northern France, in the *dkpartement* of Seine-et-Oise, 18 mi. N.W. of Paris on the railway to Dieppe. Pop. (1954) 9,785. Pontoise existed in the time of the Gauls as *Briva Isarae* (Bridge of the Oise). It was destroyed by the Normans in the 9th century, united with Normandy in 1032 and acquired by Philip I in 1064. Capital of the French Vexin, it played a conspicuuus part in the wars between the French and the dukes of Normandy and in the Hundred Years' War. The English took it in 1419 and again in 1437. In 1441 Charles VII took it by storm after a three months' siege. After belonging to the count of Charolais down to the treaty of Conflans, it was given as a dowry to Jeanne of France when she was divorced by Louis XII. The *parlement* of Paris several times met in the town, and in 1561 the states-geneial convoked at Orléans removed thither after the death of Francis II. During the Fronde it offered a refuge to Louis XIV and Mazarin. Henry III made it an apanage for his brother the duke of Anjou. Later it passed to the duke of Conti. Down to the Revolution it remained a monastic town. Two churches alone remained in modern times: St. Maclou, a 12th-century church, restored in the 15th and 16th centuries, and containing a fine holy sepulchre of the 16th century; and Notre Dame, of the close of the 16th century, with the tomb of St. Gautier, abbot of Meulan in the 12th century. Trade is in grain and in flour ground by numerous water mills on the Viosne. Remains of the 12th-century Cistercian abbey of Le Val survived at Mériel, near Pontoise. Pontoise suffered damage during World War II.

PONTOPPIDAN, HENRIK (1857–1943), Danish writer whose novels and short stories present an unusually comprehensive picture of his country and his epoch, was born at Fredericia on July 24, 1857. His father was a clergyman, and it was partly in revolt against his environment that he began to study engineering in Copenhagen in 1873. In 1879 he broke off his studies and became for several years a teacher. His first collection of stories, *Staekkede Vinger,* was published in 1881, and thereafter he supported himself by writing, until 1900 partly as a journalist with various Copenhagen papers. In 1917 he shared the Nobel prize for literature with Karl Gjellerup. He died at Ordrup on Aug. 21, 1943.

Pontoppidan's output, mainly of novels and short stories, stretches over half a century and covers most aspects of Danish life and the social, political and religious problems of the period. As a poet he belonged to the naturalist school, though he showed a characteristically critical independence and an agile, dialectic, ironic mind. An individualist and an apostle of the cult of personality, he yet had strong ties with his nation and his compatriots, for whom he had great affection although he criticized them severely.

His first books were mainly descriptions of country-town life. *Landsbybilleder* (1883), *Fra Hytterne* (1887) and *Skyer* (1890) are all characterized by social indignation though also by ironic appreciation of the complacency and passivity of country people. The trilogy *Det forjaettede Land* (1891–95; Eng. trans., *Emanuel or Children of the Soil,* 1892, and *The Promised Land,* 1896) describes the religious controversies in country districts. The chief character is a pastor from Copenhagen, a dreamer who tries, unsuccessfully, to gain the confidence of the peasants. In the 1890s Pontoppidan wrote a number of short novels on psychological, aesthetic and moral problems (*e.g., Nattevagt,* 1894; *Den gamle Adam,* 1895; and *Højsang,* 1896). These were followed by a major work, the novel *Lykke-Per* (1898–1904), in which the chief character bears some resemblance to Pontoppidan himself. He is a clergyman's son who rebels against the puritanical atmosphere of his home and seeks his fortune in the capital as an engineer. But his religious background inhibits him and he loses interest in success and wealth, separates from his Jewish fiancée (who with her strength of will and pride probably represents Pontoppidan's ideal) and after an unsuccessful marriage ends his life in complete loneliness. The book's theme is the power of environment, and national tendencies toward daydreaming and fear of reality are condemned.

Deeper problems are touched on in the shorter novels *Borgmester Hoeck og Hustru* (1905) and *Den kongelige Gaest* (1908), after which follows a third great novel, *De Dødes Rige* (1912–16). This covers the first decade of the 20th century and shows dissatisfaction with political developments after the liberal victory of 1901, and anxiety for the future. It sounds a warning against the barrenness of the new era. Anxiety for the country's destiny also lies behind the bitter novel *Mands Himmerig* (1927), which describes neutral Denmark during World War I and attacks carefree materialism. The cold, aloof, epic style which Pontoppidan had developed during his career is also a feature of his last important work, the four volumes of memoirs which he published between 1933 and 1940 and which appeared in a collected and abridged version entitled *Undervejs til mig selv* (1943).

PONTORMO, JACOPO DA (JACOPO CARRUCCI) (1494–1556), Italian painter, one of the leading representatives of the late Florentine school, was born at Pontormo, near Empoli, on Rlay 24, 1494, the son of Bartolommeo Carrucci, a painter. He was apprenticed to Leonardo da Vinci and afterward to Albertinelli and Piero di Cosimo. At the age of 18 he entered the workshop of Andrea del Sarto and was remarked as a young man of exceptional promise. One of his earliest works extant, painted in 1516, is the fresco in the vestibule of SS. Annunziata, Florence, representing the "Visitation." Two years later he completed the altarpiece in the Church of S. Michele Visdomini. From this early period of the master date three small pictures painted for the mansion of Piero Franceschi Borgherini of Florence. One of these, representing "Joseph and His Kindred in Egypt." is now in the National gallery, London. It was regarded by Vasari as Pontormo's best picture. The other two panels, also of the story of Joseph, are also in Great Britain. In 1521 he was employed on decorative work in the Medicean villa at Poggio a Caiano. He was then at the height of his powers, and a fresco painted in a large lunette with mythological figures may be regarded as one of his most successful achievements. He then took to imitating Diirer, whose engravings and woodcuts were circulating in Italy. In 1522 he executed at the Certosa di Val d'Erna a series of frescoes founded on the Passion subjects of the German master. Pontormo's last works were a series of frescoes for the Church of S. Lorenzo, Florence. He had by then come under the influence of Michelangelo's style. After working on these for 11 years he left themincomplete. He died in Florence on Jan. 2, 1556.

PONTRESINA, a village in the upper Engadine valley, canton Graubiinden, Switz., 5 mi. E. of St. Moritz. It is an important winter sport centre. At its station travelers change from a branch of the Rhaetic railway from Samaden onto the Bernina line going into Italy. Pop. (1960) 1.067, all Romansh-speaking.

PONTUS, an ancient region of northeastern Anatolia, bordering on the Euxine (Black sea) or Pontus Euxinus. The cradle of the Mithradatic kingdom of Pontus, it was at first called "Cappadocia toward the Pontus" or "Pontic [*i.e.,* Maritime] Cappadocia," the name Pontus being a later simplification.

At the eastern end of the central Anatolian plateau Pontic Cappadocia begins as a series of fertile plains within the arc of the river Halys (the modern Kizil Irmak) and stretches northward and eastward to comprise the catchment areas of the Iris (Yesil Irmak) and of the Thermodon, with the basin of the lower Halys, as well as a long and narrow strip of coastland beyond the mountains toward the Caucasus. The kingdom of Pontus, however, eventually included not only this area but also part of inland Paphlagonia and Armenia Minor and extended its coast line westward to the Bithynian frontier and eastward into Colchis.

The ethnic affinities of the indigenous Cappadocians, whom the Greeks called Leucosyri or White Syrians, are a matter for conjecture; so too are those of the Chalybes, the Tibareni, the Mosynoeci and the Macrones, barbarous tribes who were still inhabiting the mountains in Strabo's time (see ASIA MINOR for general indications of the racial type anterior to the Hittite invasion). The Chalybes, however, were credited with being the first workers of iron (Greek, *Chalyps*), and the mines of the eastern mountains provided much of the ancient world's supply of that metal. The Milesian Greeks established colonies on the coast at Sinope (Turkish, Sinop) and at Amisus (Samsun) in the 7th century B.C.; and Cotyora, Cerasus and Trapezus (Trebizond) were colonized from Sinope. Trapezus exported iron from the hinterland; Sinope was an entrepôt for this trade and for the grain sent from the opposite shores of the Euxine. Inland, the great temples of Ma at Comana, of Men at Ameria and of Anahita at Zela were major centres of native settlement. Something of the conditions prevailing in the country at the end of the 5th century B.C. can be gathered from Xenophon's Anabasis.

Little is known of the early kings. The emergence of the region as a political unit of international importance dates from the end of the 4th century B.C., when Mithradates I Ctistes (*Ctistes,* the Founder), taking advantage of the situation created by the Wars of the Diadochi, established a new kingdom there. The capital was at first at Amasya (Amasia) on the Iris, where the rock-cut tombs of four of the new kings have been recognized; later it was transferred to Sinope. The dynasty reached the zenith of its power in Mithradates VI Eupator, later called the Great, whose sovereignty embraced not only a large Anatolian state but also the Greek colonies in what is now the Ukraine and the Crimea and who at one time came near to subduing Greece proper. For an account of these kings and of Pompey's conquest of Pontus for the Romans in 66 B.C., when the king was driven from his country at the end of the Third Mithradatic War, see MITHRADATES. Under Pompey's settlement the Ora Pontica or western part of the seaboard, from a point east of Heracleia (Eregli) to Amisus, was attached to Bithynia to form the province of Bithynia and Pontus; and the eastern part of the coast as far as Trapezus, with most of the hinterland, was assigned to the Galatians.

See the *Cambridge Ancient History,* vol. ix, ch. v, with bibliography (1932); W. M. Ramsay, *Historical Geography of Asia Minor* (1890); J. G. C. Anderson, E. and F. Cumont and H. Grégoire, *Studia pontica,* 3 numbers (1903–10). Strabo, one of the principal ancient authorities, was born at Amasya.

PONTYPOOL, an urban district in the Pontypool parliamentary division of Monmouthshire, Wales, 9 mi. N. of Newport by road. Pop. (1961) 39,879. Area 24.9 sq.mi. It is on the right bank of the Afon Llwyd, a tributary of the Usk, which divides the mountainous industrial country to the west from the low agricultural land to the east. Its growth is due to its situation on the eastern edge of the great south Wales coal field. The first ironworks were put up in 1577 by Edmond Brode, a partner of Richard Hanbury, whose family has played a big part in its iron industry. Pontypool Park house, built by Maj. John Hanbury in the 17th century, is now a convent school and the park is public property. Pontypool was the pioneer in sheet rolling and tin-plating and it became famous for wire, cast-iron gates, etc. Specially lacquered decorated ironware was known in the 18th century as Pontypool japan.

The old forges have given place to huge steelworks, a nylon yarn factory and other industries.

PONTYPRIDD, an urban district in the Pontypridd parliamentary division of Glamorganshire, Wales, situated on the Taff at its junction with the Rhondda and on the Glamorganshire canal, 12 mi. N.W. from Cardiff. Pop. (1961) 35,536. Area 12.7 sq.mi. It receives its name from a remarkable one-arch bridge spanning the Taff, erected in 1756. It was a village until the opening of the Taff Vale railway in 1840 and it owes its progress chiefly to the development of the coal areas of the Taff-Rhondda valleys. Pontypridd became the railway junction for the Merthyr, Aberdare and Rhondda valleys and a big centre for the inhabitants of these valleys. Though industrial it is also a residential town and in the centre is the Unysangharad park, subscribed by the public in 1923. Two miles away is the Treforest trading estate, with 70 factories in 1955.

PONY, a horse of a small breed (see HORSE).

PONY EXPRESS, the name applied in U.S. history to a system for providing fast mail service between St. Joseph, Mo., and Sacramento, Calif., from April 1860 to Oct. 1861. The pony express was established by the freighting and stagecoach firm of Russell, Majors and Waddell. Expert riders chosen from boys and small men rode fleet horses in relays. They carried half-ounce letters bearing a $5 pony express stamp and a 10 cent U.S. stamp. A specially designed square of leather, called a mochila, was thrown over the saddle, with a hole for the saddle horn and a slit for the cantle. The letters were carried in four sole-leather boxes attached to the corners of the mochila. The goal of ten-day service between St. Joseph and Sacramento was sometimes achieved.

The route at the outset covered 1,838 mi. and included 157 stations from 7 to 20 mi. apart. "Home stations" were located at intervals of 75 to 100 mi. Each rider changed horses from six to eight times on his scheduled ride from one home station to another. After a rest period he carried the mail in the other direction.

The route followed in general the Oregon-California trail and passed through Ft. Kearney, Julesburg, Ft. Laramie, South pass, Ft. Bridger, Salt Lake City and Carson City. Indians burned stations, killed employees and otherwise disrupted service in the summer of 1860 during the Paiute War.

Among the best-known pony express riders were William ("Buffalo Bill") Cody and "Pony Bob" Haslam. Joseph A. Slade was a hard-driving division superintendent. Russell. Majors and Waddell had introduced the pony express in the hope of winning a mail contract that would save their tottering transportation empire from bankruptcy. In this they failed. Sensational though it was, the pony express was a financial failure when completion of the transcontinental telegraph line in Oct. 1861 ended all need for it.

See Raymond *W.* and Mary L. Settle, *Saddles* and *Spurs* (1955); Arthur Chapman, *The* Pony *Express* (1932). (T. A. LN.)

PONZA (anc. PONTIA), the principal of a small group of islands belonging to Italy. Pop. (1959 est.) 5,105 (commune). The group is of volcanic origin, and includes Palmarola (anc Palmaria), Zannone (Sinonia), Ventotene (Pandateria) and Santo Stefano. It is about 20 mi. S. of Monte Circeo and 70 mi. W. of Naples. There is regular communication with Naples by steamer, and in summer with Gaeta.

The islands rise to a height of about 70 ft. above sea level. Ventotene has a convict prison, and the islands were a place of banishment in ancient times. Under fascism, Ponza became again a place of banishment for Italians opposed to Mussolini, among them General Bencivenga.

POOL: see BILLIARDS.

POOLE, REGINALD STUART (1832–1895), English archaeologist and orientalist, was born in London on Jan. 27, 1832, the son of Edward Poole and his wife née Sophia Lane. Poole acquired his taste for antiquities during a stay (1842–49) with his uncle, R. S. Poole, in Cairo. In 1852 he became an assistant in the British museum, and was assigned to the department of coins and medals, of which in 1870 he became keeper. In 1882 he helped to found the Egypt Exploration fund and in 1884 the Society of English Medallists. He retired in 1893 and died on Feb. 8, 1895.

His elder brother, EDWARD STANLEY POOLE (1830–1867), who was chief clerk in the science and art department at South Kensington, was an Arabic scholar, whose early death cut short a promising career. His two sons, Stanley Lane-Poole and Reginald Lane-Poole (1857–1939), keeper of the archives at Oxford (1909–27), lecturer in diplomatic and author of various historical works, carried on the family tradition of scholarship.

POOLE, WILLIAM FREDERICK (1821–1894), U.S. bibliographer, was a pioneer in U.S. periodical indexing and library administration. He was born in Salem, Mass., Dec. 24, 1821. As a student at Yale he became librarian of a literary society; his An Alphabetical Index to Subjects Treated in the Reviews and Other Periodicals, to Which No Indexes Have Been Published (1848) appeared a year before his graduation. A second edition of what became Poole's Index to Periodical Literature (1887–1908) appeared in 1853. Poole was an assistant in the library of the Boston Athenaeum in 1851; was librarian of the Boston Mercantile Library association (1852–56); of the Boston Athenaeum (1856–69); served two years as a library consultant; was librarian at the Cincinnati Public library, which he organized (1871–73); of the Chicago Public library (1874–87), building it to the largest circulation in the U.S.; and organized the reference library of the Newberry library, Chicago, where he remained until his death, March 1, 1894, in Evanston, Ill. History was his avocation and he published widely, especially in the *North* American Review.

POOLE, a municipal and parliamentary borough and county, holiday resort and seaport in Dorsetshire, Eng., 24 mi. E. of Dorchester by road. Pop. (1961) 88,088. Area 24.4 sq.mi. excluding 3.5 sq.mi. of tidal water and foreshore. The name alludes to the remarkable situation of the old town on a peninsula between the almost landlocked Holes bay and the tidal waterway (7 mi. by $4\frac{1}{2}$ mi.) to the north of Purbeck known as Poole harbour. A bridge to Hamworthy crosses the entry to Holes bay; on the east Poole includes Parkstone and Branksome and extends to Bournemouth. It is a great yachting centre and its good sands have gained it popularity as a holiday resort. The southeast coast is formed by chalk cliffs scored by several of the chines characteristic of those parts. Largest of the islands in Poole harbour is Brownsea (a bird sanctuary) where in 1907 was held the experimental camp from which sprang the Boy Scout movement. There is an old-established pottery, and other industries include boatbuilding, chemicals, agricultural implements and engineering. Coal, timber, oil and general merchandise are imported; exports include clay and tar. Poole, not mentioned until after the Domesday survey, was granted its charter in 1248. It is uncertain when the burgesses obtained their town at the fee-farm rent of £8 13*s*. 4*d*. mentioned in 1312. In 1372 they obtained assize of bread and ale and right to hold courts of the lord of the manor. Elizabeth I made it a separate county in 1569.

POOLS, IN INDUSTRY. Rival manufacturers or traders who, while still ostensibly in competition with each other, either allocate among themselves by agreement the amount or proportion of business each shall do, or agree as to who shall put in the lowest tender for a contract, frequently set up, as a part of their agreement machinery, a pooling system. One type is that adopted by those associations of manufacturers in the same industry which allot to each member a percentage of the output of the whole group and require that each member who exceeds his quota shall pay an appropriate sum into a pool and that each member who does not reach his quota shall receive an appropriate sum from it. In associations concerned with work for which tenders are asked, three kinds of pooling are known. In one the tenders prepared by members of the group are confidentially examined by the secretary of the association and a percentage added to each, to be subsequently paid by the successful tenderer into a pool and divided among the rest. In another a uniform tender price is decided upon which all shall quote on the understanding that the firm receiving the contract shall pay an agreed percentage into the pool. In another the tenderers are informed of the order in which the sums quoted run, from highest to lowest, in order that the lowest tenderer may hold out for his price; in which case also the successful tenderer pays an agreed percentage of his contract into a pool. Another arrangement is the profit pooling agreement in which the future profits of two or more businesses are for a specified period paid into a common fund and divided out in agreed proportions. (See also COMPETITION, ECONOMIC; MONOPOLY; TRADE ORGANIZATION.) (J. H.)

Finance and Commerce.—A pool on the stock exchange would work in some such way as follows, although the actual details naturally vary:

1. Its members would consist of the holders of a certain share, and while the pool organizers would not attempt to bring in every shareholder, the members of the pool would between them have to hold a substantial block of the total shares issued for the formation of the pool to be worth while.

2. The pool members would authorize the pool organizers to sell their shares on their behalf and would agree not to sell them themselves.

3. The pool organizers would agree not to sell these shares at less than a certain price. Thus the first third of the shares in the pool might be sold at a minimum of 21*s*., the next third at 22*s*. and the remainder at 23*s*. 6d. The proceeds of the sale as effected, less the charge for the pool's expenses, would be paid over to the pool members in proportion to the shares each held.

4. After six months from its date of formation, the pool would break up, and any shares still unsold would be retransferred to the members. to deal with as best they could.

The whole object of a pool is to control and regulate the supply of a certain share to the market. For a pool to be effective, it must have a big holding of the share, or it will be faced with competitive selling from outsiders and will be unable to obtain its minimum price.

If a new issue meets with an immediately unfavourable reception so that the bulk of it has to be taken up by the underwriters, it often happens that the underwriters form a pool.

A commercial pool in a commodity would work in very much the same way; it might be a buyer's pool—as the U.S. rubber pool—or a seller's pool, such as the Canadian wheat pool. a great nonprofit, co-operative marketing association in Canada. In either case, the buying and selling is done by the pool for its members, who agree to operate only through the pool. The object is to obtain by combined effort a reasonable price. (N. E. C.)

United States.—Pools among railway companies became widely prevalent throughout the United States between 1870 and 1887 and aroused so much opposition on the part of the public that the Interstate Commerce act was passed in 1887 making them illegal as regards interstate traffic. The act was not altogether successful, for division of traffic, especially in the shipping of cotton, fruit and grain, persisted without the usual pooling machinery being in evidence. Such agreements, however, being nonenforceable, were seldom of long duration. The wisdom of the Interstate Commerce act has been often called into question, and recommendations favouring legalization under government supervision have been made both in presidential messages and in the reports of the Interstate Commerce commission itself. A decision of the supreme court in 1911 making contracts not illegal unless in "unreasonable restraint of trade" eased the situation somewhat, while the modern tendency toward combination also tends to eliminate the conditions which cause pooling arrangements to be made.

POONA (PUNE), a city and district of Bombay state, India. The city is at the confluence of the Mutha and Mula rivers, 1.850 ft. above sea level and 119 mi. S.E. from Bombay. Pop. (1961) 721,134. It was the centre of the Maratha empire for more than 100 years and the monsoon capital of the Bombay presidency under British rule. The old government house at Ganeshkhind is now the home of the university (founded 1948).

The cantonments of Poona (pop., 1951, 59,011) and Kirkee or Khadki (pop., 1951, 48,552) adjoin the Poona city area. Kirkee contains a large ammunition factory. In the city of Poona itself and in the adjoining cantonments are a number of places of historical association; *e.g.,* the remains of the famous Shaniwarwada palace of the Peshwas and the Aga Khan's palace where Mohandas K. Gandhi was held in custody in 1942. There are a cotton mill, a paper mill and a few metal and engineering factories. The National Chemical laboratory and the meteorological department observatory are at Poona.

The DISTRICT OF POONA has an area of 6.032 sq.mi.; pop. (1961) 2,465,080. Toward the west the country is undulating and numerous spurs from the Western Ghats enter the district; to the east it opens out into plains. The district is liable to drought. The two most important irrigation works are the Mutha canal and the Nira canal. (D. G. K.)

POOR CLARES, otherwise CLARISSES, Franciscan nuns. so called from their foundress, St. Clare (*q.v.*). She was professed by St. Francis of Assisi (*q.v.*) in the Portiuncula in 1212, and two years later she and her first companions were established in the convent of St. Damian at Assisi. The nuns formed the "Second Order of St. Francis," the friars being the "First Order" and the Tertiaries (*q.v.*) the "Third."

Before Clare's death in 1253, the Second Order had spread all over Italy and into Spain, France and Germany; in England they were introduced about 1293 and established in London, outside Aldgate, where their name of Minoresses survives in the Minories; there were only two other English houses before the dissolution.

St. Francis gave the nuns no rule, but only a "Form of Life" and a "Last Will," each only five lines long and coming to no more than an inculcation of his idea of evangelical poverty. Something more than this became necessary as soon as the institute began to spread; and during Francis's absence in the east, 1219. his supporter Cardinal Hugolino composed a rule which made the Franciscan nuns practically a species of unduly strict Benedictines, St. Francis's special characteristics being eliminated. St. Clare made it her life work to have this rule altered and to get the Franciscan character of the Second Order restored; in 1247 a "Second Rule" was approved which went a long way toward satisfying her desires, and finally in 1253 a "Third," which practically gave what she nanted. This rule has come to be known as the "Rule of the Clares"; it is one of great poverty. seclusion and austerity of life.

Most of the convents adopted it, but several clung to that of 1247. To bring about conformity St. Bonaventura, while general (1264), obtained papal permission to modify the rule of 1253, somewhat mitigating its austerities and allowing the convents to have fixed incomes. This rule was adopted in many convents, but many more adhered to the strict rule of 1253. Indeed a countertendency toward a greater strictness set in, and a number of reforms were initiated, introducing an appalling austerity of life.

POOR LAW. This term denotes a particular system of giving alms to the destitute. To give alms had been recognized as a moral and ecclesiastical duty at least from the establishment of the Christian Church, but a poor law, in the sense of a secular and legal obligation to relieve destitution, was the creation of the 16th century. Though the secondary causes of this development were many, they were all basically connected with the breakdown of the mediaeval economy and social structure of western Europe, which both destroyed the traditional framework of charity and produced new types of poverty.

ENGLAND AND WALES

In mediaeval England poverty had been largely due to an underdeveloped economy in which famine and pestilence were recurring phenomena. By the beginning of the 16th century this kind of destitution was giving place to the "dearth in the midst of plenty" which so perplexed contemporaries. Enclosure for pasture was blamed for causing unemployment, depopulation and vagrancy. The rising price level, resulting from a complex combination of the influx of treasure from the new world and the disastrous monetary debasements of Henry VIII and Edward VI, was popularly attributed to the mania for sheep farming. The breakdown of the mediaeval rural economy. deplorable as it seemed to contemporaries, must not be exaggerated; the areas affected by enclosure for sheep were very limited. It was the expansion of the woollen industry, with its close dependence on foreign markets, which was often responsible for this kind of unemployment. The cycle of boom and slump had come to add a new permanent element of instability to the economic life of England. Of less importance in the creation of Tudor poverty is that cause which has loomed so large in early accounts of the origin of the poor law, the dissolution of the monasteries. By 1536 many of these were too embarrassed financially to do more than relieve the local beggars their presence attracted, while the legend that hordes of monks and nuns were turned adrift to beg their bread has not been substantiated by later research.

This new type of poverty was not confined to England; it was appearing in all the more economically advanced countries of western Europe. It is customary to attribute the pattern of early Tudor legislation to the influence of Juan Luis Vives' De *subventione pauperum* sive de *humanis* necessitatabus, published in 1526, and to the experiment of dealing with poverty by municipal action undertaken at Ypres in 1525, an account of which appeared in an English translation in 1535, but foreign influences may have been overestimated; similar causes were everywhere likely to suggest similar remedies. That the crown evinced any interest in the destitute was attributable to politics not compassion. Vagrants spread disaffection and might provide the raw material for a rebel army. The early efforts of the government, therefore, were directed to stamping out vagrancy. The relief of poverty was left. with some general directives, to local authorities. The first statute dealing specifically aith poor relief was that of 1531, which merely empowered justices to license aged and impotent persons to beg within their own neighbourhood. The interlocked problems of destitution, unemployment and vagrancy seem to have been under discussion in 1535, as in that year draft proposals outlined revolutionary suggestions for dealing with them, including the employment of the able poor on public works and the setting up of both central and local administrative machinery. The statute of 1536, as finally passed, was less drastic and concentrated largely on the organization of voluntary funds for the relief of those unable to work. Despite its lack of administrative machinery, it, like the previous draft, illustrates the new approach to the problem and for this reason is often regarded as the first English poor law. In line with coptinental opinion it prohibited begging and indiscriminate charity, and attempted to classify the poor into the aged and impotent needing relief: and poor children who should be apprenticed. In practice, lacking administrative machinery, it could be put into effect only where the municipal authorities had the organization to finance and implement its provisions. It was towns such as London, Norwich and York that were confronted with turning theory into fact.

In this London took the lead. A serious attempt to deal with the City's poor soon showed that funds provided by voluntary contributions were insufficient and in 1j47 the corporation decided to impose a compulsory poor rate. This was a momentous step forward; it introduced a new administrative device of the greatest importance and broke decisively with the mediaeval conception of charity as a religious duty. Other expedients of an equally modern character followed rapidly. By 1553 a comprehensive scheme for the treatment of the poor was in existence. They were now classified as the poor by impotency, the poor by casualty and the thriftless poor. and appropriate institutional treatment was to be provided, as far as resources would allow, for each group. Similar programs were initiated by other cities, particularly those nhose connection with the fluctuating fortunes of the woollen industry increased the instability of employment. By the end of the 1j70s many of them had evolved workable schemes based on classification, some measure of institutional treatment and compulsory rates.

Before 1572 the state provided little legislation to underpin this system and it looked as if the relief of poverty would become the responsibility of the towns rather than of the nation. Indeed a characteristic feature of the English poor law is the way in which national legislation followed! rather than initiated, local experiment. This, until the adoption of the ecclesiastical parish as the unit of poor law administration, was dictated by the fact that the central authority had no etiective machinery through which to administer statute law locally. It was only in the sphere of providing funds, therefore: that a few fumbling advances were made by the acts of 1551–52 and 1563. Not until 1572 was a straightforward, compulsory rate imposed on a national scale. By then it was clear that the state would have to take a more active part in enforcing on local authorities some responsibility for destitution. The .same act also ordered the compilation of a comprehensive register of persons needing relief and instructed justices in rural areas and mayors in towns to appoint collectors and overseers. It also, like the earlier draft of 1535, recognized the fact that not all the unemployed were work-shy; local authorities were now encouraged to use funds left over from the relief of the aged, sick and infant poor to set the able-bodied pauper "on work" (*i.e.*, provide work for the able-bodied). In 1j76 this permission was transformed into compulsion. All local authorities were to provide funds for the purchase of raw materials for this purpose.

The "Old Poor Law" (1601).—The codification of 1597–98, re-enacted in 1601 with minor changes and finally made permanent in 1623, completed the first stage of the poor law (sometimes known as the "old poor law" in contradistinction to the "new poor law" set up after 1834). The parish was finally and decisively acknowledged as the normal unit of administration. This was entrusted to overseers, 'appointed. annually by the local justices and forced to serve under penalty of a fine, who, together with the churchwardens, were to assess and levy a poor rate on all householders which, when ratified by the justices, was compulsory. With these funds the aged were to be relieved and provided, if necessary, with cottages on the waste, poor children were to be apprenticed and the able poor set "on work." This codification was at once a synopsis of previous urban experience and a break with urban experiments, since the parish, a smaller but ubiquitous unit, was now the basis of the national system. Though later the parish was to prove too small, it is difficult to see what else could have been done. Experience had shown that poor relief confined to the towns put too heavy a burden on them and distributed rather than relieved destitution.

The subsequent period, from 1597 to 1644, is of fundamental importance in the history of the poor laws; in these years the privy council succeeded in building up an administrative hierarchy to make it effective. It is easy for the modern citizen to forget how great was the gap between enactment and enforcement in Tudor England and to assign to early acts a practical importance which they could not possess. After 1597 the exertion of pressure on the justices and the sending of directives became more frequent. Sometimes these took the form of general orders, such as those sent to all high sheriffs and courts of quarter sessions in 1598 to explain the new legislation, sometimes they were concerned with particular problems and were sent to individual authorities. Until 1622 this kind of pressure was irregular, being called into being in response to a sudden crisis, either local or national. The failure of the harvests in 1621 and 1622 and in 1629–31 apparently converted an occasional expedient into a regular routine. In 1631 the privy council applied the experience it had gained since 1597 in dealing with the regulation of supplies of grain in scarcity conditions to the oversight of the local poor law authorities. The system was both practical and detailed. The justices of each county were to divide themselves into groups. so many being responsible for each hundred. They were to hold monthly meetings with the churchwardens and overseers of the parishes within their respective hundreds, to punish neglect by these officers of their statutory duty and to report what had been done every three months to the high sheriff. These reports were sent to the justices of assize and finally submitted to the privy council. In this nay it was possible, at least in theory, for the central government to get a picture of the way in which the local authorities mere carrying out their tasks.

The general impression is one of real but geographically patchy success. Where the pressure of work was not great, or where local charity and endowments were adequate. or the parish remote and difficult to supervise, the poor, if assisted at all. were helped without much reference to the letter of the law. For example, the parish of Sawston in Cambridgeshire levied no regular poor rates until 1658. In contrast. where towns and cities had long been grappling with the problem, or in those rural areas where the justices were accessible to pressure, parishes seem to have been relieving the aged and sick. apprenticing their children and even complying with the obligation to have a "town stock" of raw materials with which to set the poor "on work."

With the outbreak of civil war and the determined attack of the Long Parliament on the coercive power of the privy council. the situation altered. Authorities were once again left to their own devices. The statutory obligations remained but the encouragement and oversight disappeared, not to return until the creation of the poor law commissioners in 1834. Nevertheless. the pressure of the previous 40 years was not without results. The habit of appointing overseers, levying rates, relieving the poor, had become something of a social tradition. It might not be well done, and the difficult task of organizing employment was often dropped, but the laws, far from falling into abeyance. were gradually extended into parishes and areas where earlier they had been little observed.

Parish Organization of Poor Relief, 1662–1795.—The next milestone in the history of the English poor law came a-ith the restoration of the monarchy. There was no attempt to revive the control of any central authority, but in 1662 the responsibility of each parish was defined by an act usually known as the Law of Settlement and Removal. Its preamble contained the statement that "by reason of some defect in the law, poor people are not restrained from going from one parish to another, and do therefore endeavour to settle themselves in those parishes-where there is the best stock, the largest commons or wastes to build cottages and the most woods for them to burn and destroy." To remedy this defect that act provided that any person coming into a parish who neither rented a house of the annual value of £10. which was a rental completely outside the economic resources of the craftsman or labourer, nor was able to give security against becoming a burden on the rates at any future time, could be moved back to his or her place of settlement within 40 days on application made by the overseers to two local justices for a warrant of removal.

There was nothing very new. except in the precise definition of the occasion and method of removal, in this act. The piecemeal legislation of the Tudors, before the final codification of 1601, contained assumptions that the right to relief was a local one, that parishes were entitled to some defense against an influx of strangers and need not relieve, might indeed even remove. "aged, lame or impotent persons" of less than three years' residence. Sixteenth-century municipal authorities had been zealous in removing persons likely to become chargeable. Norwich. which had stringent settlement regulations, for example, ordered one Jane Thornton to leave the city because she "in summer live in the countrie but in wint charge the citie." As E. M. Leonard observes, the act of 1662 merely "stereotyped a custom that had long been in existence in the towns." (See Bibliography.)

The legal basis for the custom however had never been clearly defined,wthough most communities seem to have felt that people had a right to relief only where they lived and were known. Charity both began and ended at home. Even so, why the task of definition should have been undertaken just when it was has been something of a puzzle to historians. The general upheaval and unsettlement of the years after the Civil War and interregnum is usually adduced as the most likely cause. The growth of population may well have been an additional reason. Many of the rural poor lived from hand to mouth, eking out what they could earn by exploiting the resources of the uncultivated, or waste, land which in most parishes was still unenclosed. Such families, clinging to the skirts of economic subsistence, were clearly a potential liability which no parish would want to assume, but with any marked increase in population, unless industry and trade were also booming, which was not the case in 1662, they were just the people who would drift to the more extensive wastes. It is at least arguable therefore that the act of 1662 was passed in response to an overflow of population beyond that which could be absorbed by the immediate economic resources of the country.

Whatever the reasons for its enactment, the act of 1662 with its subsequent amendments was thenceforth the hub around which the administration of the poor law revolved. In 1685 the original act was amended so that the 40 days' residence necessary to gain a settlement only began from "the time of his or her Delivery of a Notice in Writing of the house of his or her Abode, and the Number of his or her Family, if he or she have any, to one of the Church ardens or Overseers of the said Parish." In 1693 the regulations were further tightened by the stipulation that the notice in writing had to be read in the parish church at the time of divine service. After this there was little chance of a stranger's gaining a settlement without the consent of the general body of the ratepayers. In an attempt to make the act work in a reasonable way, the same statute also defined other methods of gaining a settlement. These were by serving an apprenticeship within the parish, by being hired as a servant for a year, by executing some parochial office for the same period or by paying parochial rates. In addition. women gained a settlement on marriage, and legitimate children took that of their father until they reached the age of seven, when they could acquire one of their own. Illegitimate children were settled where they were born.

Betneen 1662 and 1795, after nhich date no person could be removed until he was actually chargeable, the attempts of parish officers to take advantage of the settlement laws distorted almost every aspect of the poor lams except the granting of relief to those aged and sick paupers who were. beyond all doubt, the settled poor of the parish. Despite the condemnation of Adam Smith, the purely economic effect of this legislation appears to have been slighter than might have been expected. Some elasticity was given by an act of 1697. which gave legal sanction to the existing practice, by which parishes gave testimonials to parishioners seeking nork elseuhere, which nere. in effect, promises to take them back should they ever become chargeable. Moreover it was clearly impossible to remove every newcomer, particularly where there was a demand for labour. In practice, able-bodied men, so long as they took no steps to obtain a settlement by presenting a notice in writing rarelv seem to have been removed unless they were actually chargeable. Rural parishes appear to have concentrated on removing married couples, particularly those "overburdened with children." Single women, women with children and orphans were equally unpopular. In industrial areas where young and old could be employed, the family unit was less economically vulnerable. Here women, particularly those with children, were the main victims. In any case the changing distribution of the growing population of the 18th century make it clear that mobility cannot have been unduly restricted.

If the economic consequences of the Law of Settlement were not notably harmful, the social consequences can be more justifiably condemned. Apprenticeship, originally intended to give a child a start in life, was now often used to change its settlement. Children could be compulsorily bound out in their own parishes or, with funds provided from the poor rate, elsewhere. In this case no one questioned the suitability of the master or the trade selected. or the treatment the child reckived. In this matter the urban parishes appear to have been the chief offenders. The result was many runaway apprentices and much misery. Another unfortunate result was the restriction on the building of new cottages, which led to overcrowding and the retarding of marriage. Unmarried mothers were treated with great harshness. An act of 1576 had made it an offense to beget an illegitimate child which was likely to become chargeable, and the father, if known, could be forced to give security "to save the parish harmless." Little proof beyond the woman's oath was required, and many men, guilty or innocent, found refuge in flight. In·such cases the overseers, faced with the responsibility for the child, forced or bribed the woman to take to the roads. Yet whether this widespread distortion of the poor laws really saved parish funds may well be doubted. Removals were expensive and often contested at quarter sessions; sometimes they were taken on appeal to higher courts. Moreover, though each parish struggled to save itself expense, it was in turn the victim of similar practices on the part of other parishes.

The best-administered part of the poor law appears to have been the relief of those aged and sick persons who were unquestionably settled inhabitants. Indeed, care had to be taken to keep this kind of relief within bounds. After 1693 none was to be given, except in case of emergency, without the authority of a justice, the names of such persons to be entered in a book and reviewed annually. Paupers whose claims were allowed received small monthly pensions, though by the act of 1697 they were ordered to wear a large red or blue P on their outer garment. Often their rent was paid and they got occasional gifts of fuel and clothes. Sick paupers were looked after, medical attention that ranged from a bonesetter to the local doctor was provided, and, if death followed, the parish paid funeral expenses.

The obligation to set the poor "on work" was perhaps the most difficult of all the burdens placed on the parish by the act of 1601. To manage a parish stock at a profit was well-nigh impossible. Municipal experiments on the lines of the London Bridewell tended to peter out, while the houses of correction, which an act of 1607 ordered to be set up in every county. were increasingly regarded as penal establishments for the idle rather than as places of employment. Because of the difficulties involved once the oversight of the privy council disappeared the first phase of the attempts to employ the poor came to an end in 1644, though town stocks for this purpose lingered on in some places. After the Restoration the increasing interest taken in political economy refocused attention on this failure to employ the poor. Emphasis was now placed on the loss to the national income sustained through the waste of labour, and many pamphleteers, among whom were John Bellars, Richard Haines and Thomas Firman, outlined schemes for the organization of corporations to employ the poor on a commercial basis. For this purpose stock was to be subscribed and workhouses erected. For the most part they remained on paper, being quite impracticable, but John Cary started a new chapter in poor law history when he persuaded the Bristol parishes to apply for a local act to set up a "Corporation of the Poor" in 1696. This was to be responsible for the poor of the entire city and provide employment for them in a well-run workhouse. At first the experiment appeared successful, and Bristol's example was followed by other towns. These early hopes were not maintained, but. though commercially unprofitable, the workhouse was discovered to have a useful deterrent value. In consequence in 1723 a permissive general act allowed parishes to build and manage workhouses and to refuse relief to those who would not enter them. Though useful in keeping down the poor rate, such workhouses made no effective contribution to setting the poor on profitable work.

Whether the original purpose for which individual workhouses had been promoted had been to punish the idle, deter applicants for relief, house the sick. aged and infant poor or provide work for the able-bodied. they everywhere rapidly degenerated into mixed receptacles of misery where every class of pauper, vicious or unfortunate, young or old. sick, well or lunatic, was dumped. Sometimes they were managed by parochial officials, often they were let out to contractors, either for a lump sum or on a capitation basis. Many parishes fluctuated from one method to the other but neither led to any satisfactory employment of the poor.

Meanwhile the growing humanitarianism of the 18th century was increasingly troubled by the abuses of the general mixed workhouse. At the same time the inadequacy of the parish as a unit for poor law administration was becoming apparent, partly because, particularly in the towns, it was too small for effective action, partly because its unpaid, annually appointed, untrained officers were either lazy or corrupt. Indeed, some parishes, though without legal sanction, were already employing a salaried overseer. In these circumstances Thomas Gilbert promoted the act known by his name in which, in 1782, parishes were permitted to unite for the purpose of building institutions to house all classes of the destitute, except the able-bodied. For these the overseers, in vague terms, were directed to provide relief or work outside the house. This meant a complete reversal of earlier policy in a revulsion from its failure.

Speenhamland System (1795).—Between 1782 and 1793 postwar depression, poor harvests, the frictional unemployment caused by agricultural developments and the early stages of the Industrial Revolution combined to make life difficult for the labouring poor. In many cases wages were traditional and bore little relation to changing conditions. Yet, to men steeped in mercantilist thought, to raise wages to meet what, to contemporaries, must have seemed a temporary crisis appeared plain folly. It had long been the practice to help poor men "overburdened with children" by making them some allowance from the parish. In the same way temporarily soaring prices, caused by a failure of the harvest, were commonly met by ad *hoc* emergency relief measures rather than by raising wages. In line with this tradition the justices of Berkshire. meeting at Speen in 1795, decided that wages below what they considered an absolute minimum should be supplemented by the parish in accordance with the price of bread and the number of dependents a man had. Their example was widely followed and the practice received parliamentary confirmation in 1796. Yet another phase of English poor law history, the so-called Speenhamland system, had begun. (D. Ml.)

The word "system" is misleading, for the Speenhamland decision was a makeshift, grounded in existing social theory and practice, rather than a deliberate proposal for a general poor law policy. Even in Berkshire itself. the decision did not result in any substantial changes in local administration. Parishes continued to maintain their own workhouses, to give or withhold casual relief, to distribute cheap food and to fix bread prices. During the Napoleonic Wars, however, there was a great extension of the allowance system. or various types of allowance systems, in the southern counties of England, and contemporaries found it convenient to describe the extension as part of one general process. Most histcrians have agreed with contemporary critics that the spread of the allowance system was "momentous" and "disastrous."

The "system" had three possible abuses. First. it might lead to the subsidization of wages out of the poor rate. In The State of *the* Poor (1797), Sir F. M. Eden claimed that the larger farmers were able to take advantage of the magistrates' benevolence by forcing the smaller ratepayers, who were not themselves employers of labour, to augment wages. The charge may have been exaggerated, for some tenant farmers were able to pass on the increase in poor rates to their landlords, but such a transfer was not general and did not prevent the poor rate from becoming a redistributive tax. Second, it might entail the general pauperization of large numbers of employed workers on the land. Opponents of the system argued that it made the poor careless and indifferent, checked their incentive to save, encouraged improvident marriages and engendered a large increase in population which. according to Malthusian theory. would inevitably create a new mass of poverty. Some opponents even went so far as to argue that any legal system designed to alleviate poverty was a threat to the well-being of the recipients of relief; as Thomas Chalmers put it. "the system which was working this mischief assumed to be founded on benevolence, but no evil genius could have designed a system of greater malignity for the corruption of the race." Third. it sharpened the contrast between industrial north and agrarian south and perpetuated the division of the labour market into two sectors, the one depending upon a contractual wages system. the other depending upon status and protection. Controversy centred around these points not only during the Napoleonic Wars but also in the period after 1815, when agrarian discontent was accompanied by industrial expansion.

Between 1815 and 1830 contemporaries were mainly concerned, however, with the burden of poor law expenditure, particularly in the area south of the Wash-Severn line. In 1785 the total cost of poor law administration was a little less than £2,000,000; by 1803 it had increased to a little more than £4,000,000; and by 1817 it had reached the total of almost £8,000,000. This final figure represented a cost of about 13*s*. 3*d*. per head of the population or about one-sixth of total public expenditure. Although the total fell a little in the subsequent 15 years, it did not fall as much as the price level, and in 1832 it stood at about £7,000,000, or 10*s*. per head of the population. Some parishes were particularly affected by the burden. One Buckinghamshire village, for instance, reported in 1832 that its expenditure on poor relief was eight times what it had been in 1795 and more than the rental of the whole parish had been in that year. In face of statistics of this kind, the Whig government decided to intervene, and in the year of reform, 1832, a royal commission was appointed to inquire into the whole "system." Its recommendations served as the basis of the reforms which were embodied in the Poor Law Amendment act. 1834.

New Poor Law (1834).—The new act was not merely a return to severity after a period of benevolence; it was inspired by new principles and set up new administrative machinery. Its guiding rule, strongly influenced by the theories of Benthamite political economists, was that poor relief should be granted only to able-bodied poor and their dependents in sell-regulated workhouses under conditions inferior to those of the humblest labourers outside. As the commissioners had argued "every penny bestowed that tends to render the condition of the pauper more eligible than that of the independent labourer is a bounty on indolence and vice." The machinery also was Benthamite. The hitherto independent parishes were grouped into unions, each under an elected board of guardians. with a strong central authority—the Poor Law commission—to enforce a uniform policy.

On paper, the act of 1834 introduced order into the poor law system; in the words of Nassau Senior, one of its chief architects, it was "a measure of social policy." Poverty was considered a crime, which merited a stigma, and the poor were poor not because Providence had ordained them to be so but as a result of their onn failings. Such a harsh philosophy, which was sharply criticized by traditionalists and helped to rouse the Chartist movement, was nonetheless better suited to the mood of an industrial age than Speenhamland. One of the purposes of the act was to stimulate free trade in labour by driving workers onto the labour market The abolition of outdoor relief was intended to provide an incentive to workers to seek regular employment. Unfortunately however, when the poor law commissioners attempted to apply the act in the north of England in 1837, there was much genuine industrial unemployment.

The inadequacies of the act were demonstrated very clearly during the subsequent 30 years. The first and most dramatic crisis in its administration came in 1847 at Andover. The workhouse there was so efficient in applying the principle of less eligibility (*i.e.*, that the condition of the poor should be made "less eligible" than that of the labourer) that labourers were willing to accept as little as js. or 6s. a meek rather than enter the workhouse, but work conditions imposed on inmates were intolerably cruel. A committee set up to investigate conditions at Andover condemned its internal administration and led to the setting up of a new Poor Law board (1847). directly responsible to parliament, in place of the Poor Law commission. The president of the board was now eligible to sit in parliament. Some improvement in workhouse conditions followed the Andover scandal, but in 1852 an experienced lawyer, Robert Pashley, maintained that "a single English workhouse contains more that justly calls for condemnation in the principle on which it is established than is found in the very worst prisons or public lunatic asylums that I have ever seen. The workhouse as now organized is a reproach and disgrace peculiar to England: nothing corresponding to it is to be found throughout the whole Continent of Europe."

There was an inevitable reaction in the middle of the century against the excessive harshness of poor law administration. The attempt to treat as one group all. children, women and men in need of assistance was bound to create social as well as administrative difficulties. To place under the same stringent discipline the young, the sick, the aged and the able-bodied proved as much of a strain to the administrator as it was a grievance to the poor themselves. The new poor law, in consequence, became almost as subject to local variation as the old poor law of the 17th and 18th centuries. In many parts of the country it proved impossible totally to abolish outdoor relief; in other parts, separate poor law institutions were created for the young and the sick; and in some districts, boards of guardians continued to pay small weekly doles to old men and women incapacitated from work. Such signs of "sentimentalism" were bitterly attacked by the faithful supporters of the principles of 1834. The development of democracy. however, associated as it was with the growth of humanitarian feeling. and, after 1880, the discovery of more scientific methods of dealing with destitution, helped to mitigate the harshness of poor law administration.

The extension of the franchise in 1884 was an important turning point in the approach to the poor. From that date onward a move away from the principles of 1834 can clearly be traced. In 1891 supplies of toys and books for workhouses were permitted; in 1892 tobacco and snuff could be provided; in 1893 visiting committees of ladies were allowed to inspect the workhouses; in 1894 guardians were given the right to distribute dry tea. milk and sugar for women to make their own afternoon tea; in 1897 trained nurses could be employed for the care of the sick poor; and in 1900 a government circular. recommended the grant of outdoor relief for the aged of good character.

In addition to these deviations from the principle of less eligibility, changes were made in the fiscal and administrative machinery for supervising the poor laws. In 1871 the Poor Law board was abolished and central authority passed directly to the Local Government board. The new body was as much concerned as the old one had been with fiscal surgery as nell as social policy, and throughout its existence it emphasized the most important social bulwark of 1834, the assertion that poverty deserved a stigma. Men and women in receipt of relief under the poor law were not only subject to a special discipline and compelled to wear pauper uniforms as a symbol of their inferiority; they were robbed of their civil and political rights, including the right to vote. The poor law treated the claims of the poor not as an integral part of the rights of the citizen. but as an alternative to them—as claims which could be met by society only if the claimant ceased to be a full citizen of the community. It was not until 1918 that the pauper disability of disfranchisement was removed, and even after that signs of the stigma still remained.

The changed approach both to poverty and to the poor law began with a new inquiry into the facts of destitution in the last 20 years of the 19th century. Charles Booth's *Life and Labour of the People in London,* the first volume of which was published in 1889, was the first great landmark. It was followed by other important books, such as Seebohm Rowntree's *Poverty: A Study of Town Life* (1901), which gave a new precision to the concept of poverty. Further evidence collected by official committees, particularly the Royal Commission on the Aged Poor, which reported in 189j, helped to direct attention both to existing practices and to basic presuppositions about the poor. The way mas prepared for setting up the Royal Commission on the Poor Laws in 1905.

Reports of the Royal Commission, 1909.—Unlike the commission of 1832. that of 1905 was not the outcome of any sustained agitation or vociferous opposition to the existing structure, nor did its members start with any common theory to apply to the contemporary situation. "There is no one directing purpose shaping the enquiry to a pre-determined end," wrote Beatrice Webb, one of the members, in the middle of the deliberations, "which of the many conflicting or diverging purposes will prevail remains to be seen." But the commission included many experts in dealing with the poor. Some. like Sir Charles Loch, had experience with both poor law and voluntary charity; some, like Charles Booth, Helen Bosanquet and Beatrice Webb herself. had been leaders in social study and research; others, like George Lansbury and Francis Chandler. were representatives of the new labour upsurge as well as experienced guardians; and finally there was Octavia Hill, who had done more than any other woman for the welfare of the London poor. If these distinguished members of the commission had been unanimous, they would, said Canon S. A. Barnett, have been invincible.

In fact no single purpose prevailed and t o reports were produced by the commissioners. The majority (16) recommended that the boards of guardians should be replaced by statutory committees of the county and county borough councils (which had been set up in 1888), and that the neu committees should be called "public assistance authorities" with a number of subordinate public assistance committees working under them in subareas. More important. the general workhouses should be abolished and different classes of the destitute should be relieved in specialized institutions. The able-bodied poor should, as far as possible, be found work, but outdoor relief could be provided after strict inquiry, under supervision and on a uniform basis.

The minority (four) were not content with this retreat from the principles of 1834. They argued that the poor law system was fundamentally bad. It was the business of the community to try to prevent destitution and not merely to palliate it when it occurred. In consequence, the poor law should be broken up, and in its place the state and the local authorities should provide specialized social services to deal with separate categories of poor people. Already administrators had been compelled to note the existence of the sick. the feeble-minded, the aged and pauper children as well as the able-bodied. Now the able-bodied should be placed in charge of a national unemployment authority and the other categories should be transferred to the appropriate local authorities.

Both majority and minority expressed themselves strongly against the views of the surviving supporters of 1834. particularly J. S. Davy, the principal officer of the poor law division of the Local Government board. There mas a remarkable measure of agreement in the condemnation of the past and the assessment of the present. There were two distinct views of the future, however, each of which was to prove influential. The minority report, drafted with skill and driven by passion, advocated optimum social services maintained by specialists, the boundaries of whose activities would be set by the boundaries of perfection in their own expert techniques. In the middle of the picture would be a registrar of public assistance for each local authority, co-ordinating the various schemes. The majority report, building on the social situation as it existed in 1905, was more concerned with minimum social security than with the optimum, and more conscious of the continued role of voluntary action, maintained by an army of trained general or family caseworkers. If the minority report seemed to point more clearly toward the welfare state, it was opposed to the insurance principle on which the welfare state was to be constructed.

Welfare Legislation and the **Poor.**—No action was taken in 1909 to implement the proposals of either the majority or the minority reports, although Beatrice Webb set up the National Committee for the Promotion of the Break-up of the Poor Lam, and Lord George Hamilton created an alternative National Poor Law Reform association. The first was renamed the National Committee for the Prevention of Destitution, and bitterly attacked not only lack of food, clothing and shelter but also the social degradation and "the moral malaria" of an acquisitive society.

The government did not respond to the arguments of this agitation and within the poor law structure itself undertook merely a mild so-called "revolution by administration" under the direction of John Burns, the president of the Local Government board. It did, however, herald a genuine revolution in welfare policy outside the poor law. The Provision of Meals act, 1906, empowered local authorities to supply meals in elementary schools to certain children; the Old Age Pensions act, 1908, provided pensions for the aged without their being punished "by the loss of political rights or the stigma of pauperism"; the Trade Boards act, 1909, regulated squalid conditions in the labour market; the Labour Exchanges act of the same year set up important new institutions designed to reduce local unemployment; and, above all, the National Insurance act, 1911, provided sickness and unemployment benefits on a contributory basis to a selected group of industrial workers. Insurance was extended in 1920 to include large numbers of additional workers. As a result of such piecemeal legislation, the place of the poor law as a relief agency was completely changed. Even during 1909 David Lloyd George, the radical chancellor of the exchequer, exclaimed in introducing his controversial budget, "this is a war budget for raising money to wage implacable warfare against poverty and squalidness. I cannot help believing that before this generation has passed away, we shall have advanced a great step towards that good time when poverty, and the degradation which always follows in its camp, will be as remote to the people of this country as the wolves which once infested its forests." This was a very different 'approach to the poor from that of the 18th and 19th centuries.

Breakup of the Poor Law.—Although new welfare proposals of many kinds were adopted, it was not until 1929 that the Local Government act implemented the main recommendation of both the 1909 reports by replacing the boards of guardians by local authorities. The number of authorities responsible for poor relief was thus reduced from 642 to 145. The Poor Law act, 1930, consolidated previous legislation. The minister of health was charged with the central direction and control of all matters relating to the administration of poor relief; in the localities, to deal with relief problems, most authorities appointed separate public assistance committees, consisting of elected members of the council plus (optionally) a number, not exceeding one-third of the total, of persons co-opted from outside the council. In addition there were subordinate guardians' committees for appropriate workhouse areas in the counties, although they had no power to appoint or dismiss officers without the approval of the public assistance committees. The chief local administrator of the poor law was the public assistance 'officer, who in some cases was also the clerk of the council. He was assisted by the district relieving officer, the direct descendant of the Elizabethan parish officer.

The reforms of 1929 and 1930 were secured only after a period of prolonged inquiry. In 1917 the ministry of reconstruction had set up a committee. under the chairmanship of Sir Donald Maclean, to reconsider the 1909 suggestions. The committee, which included representatives of both the majority and the minority of the 1905 commission, confirmed the earlier sentence of death on the guardians, recommended the transfer of their powers to local authorities and urged the extension of specialized services for special groups, such as the sick and the mentally deficient. Although these proposals were approved by the government and pledges were given that a bill to reform the poor law would be introduced as soon as opportunity offered, nothing was done. Even after the newly founded ministry of health had taken over the functions of the Local Government board in 1919, no reforms were introduced. It was not until 1925 that Neville Chamberlain, the Conservative minister of health, began to implement suggestions generally approved by experts and public alike.

In the 1920s, however, the administration of the poor law had entered on a new and alarming phase. An industrial depression, which had begun in 1920, resulted in a rapid and unprecedented increase of industrial unemployment. Trade-union funds, private savings. insurance benefits and relief works proved inadequate to meet widespread distress. Successive governments failed to meet the challenge of the situation, and. to their sharpest critics, even seemed to be encouraging recourse to the poor law in order to shift as much as possible of the cost of relief from the national taxes to the local rates. Before long the boards of guardians in the worst areas of distress were overwhelmed with applications for assistance, and by June 1922 nearly 2,000,000 persons—or about 1 in 21 of the population—were in receipt of poor law relief. In some unions the proportion was one in five. Despite a short-term recovery, there were pockets of large-scale unemployment in many districts throughout the 1920s, and in 1926, as a result of the coal dispute. there were 8 unions with a third and 14 others with a quarter of their populations in receipt of relief. In two unions, in particular weeks, mare than 50% of the population were paupers. The size of the poor rate reached an alarming figure in many of the crowded industrial districts. On Tyneside, for example, in 1926–27 the Gateshead poor rate was 11*s.* in the pound. Such a heavy burden meant that guardians in badly hit unions with low ratable value were compelled to borrow large sums, thereby further saddling the rates.

In some unions, the rise in poor law expenditure was not the result of fluster, as the parsimonious suggested, nor even of grim necessity, as some of the humanitarians suggested, but of design. Certain boards of guardians deliberately adopted the policy of granting outdoor relief on such a generous scale that there could be no pretense of making the lot of the pauper less eligible than that of the independent labourer. The guardians at Poplar. dominated by a Socialist majority, had long favoured this policy; in the 1920s, however, there was a more general spread of "Poplarism." The Poplar Borough council took the desperate course in 1920 of refusing to collect the rates for the London County council and certain other central bodies. Legal proceedings were taken and the high court ordered the collection of the rates. The borough council ignored the order and 29 of its members were imprisoned for contempt of court. Their imprisonment put the government in an awkward position and forced it to concede the legislation which Poplar had been demanding. The Local Authorities (Financial Provisions) act of 1921 provided for a large measure of equalization of poor rates in London: in particular it laid down that the cost of outdoor relief should be borne by a metropolitan common poor fund within the limits of a scale to be fixed by the minister of health. The fixing of a scale in Jan. 1922 did not satisfy the Poplar guardians. They pressed for a loan, and there was a special inquiry by the government into the circumstances of their case. The report uhich followed was unfavourable to the guardians. and declared that by more economical methods £100.000 a year could be saved. A conflict of principle as well as a financial question was at stake in this dispute. The Poplar guardians insisted that it was not only the right but the duty of the guardians to give adequate relief; the minister retorted that the Poplar conception of adequacy was extravagant and inflated. In 1922 the minister issued a peremptory order applicable to the Poplar union alone, providing that no relief to an able-bodied person or his family in excess of a scale laid down by him should be legal unless he specially sanctioned it. The guardians defied this order and in consequence were heavily surcharged by their auditors, but successive ministers of health were unable to enforce the order, which was finally withdrawn in 1924. Other boards of guardians continued to favour Poplarism and pursued a persistent guerrilla warfare with the ministry of health.

In 1925 the msin scene of the struggle shifted to West Ham, where the guardians, already £2,000,000 in debt, asked for a further loan of £350,000. The treasury and the ministry of health insisted on certain restrictions as a condition. The guardians refused to accept the conditions and, although they eventually yielded to threats, the struggle was not settled and finally they refused to amend their scales. This time the government took decisive action. Under a new act, the Boards of Guardians (Default) act, 1926, the minister superseded the West Ham guardians and handed over their functions to three paid administrators, nominated by himself. Under the new regime the number of outdoor paupers fell sharply, as did average expenditure upon them. The Default act was applied in other areas and succeeded in directing attention to the necessity of a general reform of the system. The basic reforms of 1929 and 1930 were secured only as a result of this bitter controversy.

Great Depression. — The passing of the new legislation coincided with an alarming increase in the number of unemployed and the darkest period of industrial distress in the whole of English history. For the three years 1931–33, the annual average total of unemployed workers was 2,785,000, the equivalent of one worker in every five. In face of this. the insurance scheme broke down, and for six years. from Oct. 1931, less than half the unemployed qualified for insurance benefit.

The financial and political crisis of 1931 was followed by drastic action to cut expenditure on the poor. *Ex gratia* benefits to those whose insurance rights had become exhausted were stopped, and the administration of state-financed relief for the off-insurance unemployed was handed over to the poor law authorities, who proceeded to apply more or less rigid means tests. In consequence the number of able-bodied persons on poor relief increased from 43,000 in the autumn of 1931 to 220,000 (with 440,000 dependents) at the end of 1934. Eventually, after a period of great confusion, a new state agency, the Unemployment Assistance board, was set up in 1934 and began to administer all state relief for the unemployed in Jan. 1935. The new board was an ad *hoc* body consisting of a chairman, a deputy chairman and three salaried part-time members. Its 300 local offices administered relief in accordance with a fixed scale of assistance, based on a household means test, and its area officers were given strict instructions to maintain uniformity. Inevitably this form of administration implied remoteness from an understanding of the real needs of the poor. Nonetheless the setting up of the board was an important step in the breakup of the poor law.

The breakup of social policy could be discerned in many areas. In the 1930s many groups of persons, of whom the unemployed were the most important. were being dealt with not by the poor law but by other welfare agencies. The Blind Persons acts, 1920 and 1938, for example, laid down that the blind were to be treated separately. As groups of this kind were separated from poor law jurisdiction. the public assistance committees of the local authorities became residuary legatees of the expanded but inadequate system of social services rather than agencies dealing with the poor as a whole. Their functions were miscellaneous rather than coordinated. The most important were to provide public assistance pending aid from other sources; to supplement amounts received from other sources) such as widows' pensions, workmen's compensation grants and national health insurance benefits; to grant assistance to those able-bodied persons who were not covered by national insurance legislation; to aid residual classes, such as widows not entitled to pensions, feeble-minded persons not requiring institutional treatment, dependents of imprisoned persons, dependents of persons admitted to hospitals or mental institutions and deserted wives and children; and, above all, to assist the sick poor. The National Health Insurance acts provided inadequate benefits, in respect of both size and duration, even for the insured person; more seriously they made no provision for dependents or for the chronically sick. Public assistance was essential, even though it was still frequently associated in the public mind with the stigma of pauperism.

The constant shrinkage of poor law functions and their replacement by services founded on a more popular basis made it increasingly difficult to justify the more archaic parts of the public assistance system or to resist the political pressure to abolish the poor law altogether.

***Abolition* of the *Poor* Law and Establishment *of the* Welfare State.**—World War II gave a powerful impetus to the demand for comprehensive social security in place of *ad hoc* services, supplemented by public assistance. At the same time the phrase "social welfare" began to be used more generally. The mood was caught in a sentence of the Ttmes in July 1940: "if me speak of democracy. we do not mean a democracy which maintains the right to vote but forgets the right to work and the right to live."

During the war many social services which had previously been tainted with the flavour of the poor law, such as the school meals service, became services for all. The Unemployment Assistance board dropped the word "unemployment" from its title in 1940 and was given the task of administering a new supplementary pensions scheme for old persons and widows over 60. Other relief services were handed over to it between 1940 and 1945, and by the end of the nar it was mainly concerned with widows and old persons rather than with the unemployed, who had in any case fallen to a minute fraction of the working population as a result of wartime full employment. In 1941 its household means test was abolished and was replaced by a more generous personal means test; at the same time various improvements were introduced in its allowance scales. The revelation that large numbers of persons who had been qualified for public assistance had not taken and were not taking advantage of it exposed the unpopularity of the surviving poor law structure. The deterrent element implied in the act of 1834 had left a powerful impression on opinion.

More important than the changed position of the Assistance board was the drafting of a comprehensive scheme of social insurance by Sir William (later Lord) Beveridge in 1942. It was based upon the conception that it was the duty of the state — in collaboration with the individual — to provide income-maintenance for all those families whose normal incomes had been interrupted, or were likely to be interrupted, by social contingencies outside their control. The notion of comprehensiveness or universality marked the greatest single departure from the old conception on which the poor law had been based. The poor as a whole were no longer to be treated as an inferior group within the nation, but rather as individuals and families whose interests were inextricably bound up with the interests of the whole community. The plan marked the end of the concept of divided citizenship.

In 1943 the government accepted the main outline of the Beveridge proposals, and in 1944 it published its own white paper setting out official plans for future social insurance and assistance. It stated clearly that "in a matter so fundamental" as social security "it is right for all citizens to stand in together, without exclusion based upon differences of status, function, or wealth." In 1944 the ministry of national insurance was set up. various legislative measures followed, and in 1948 a new National Assistance act achieved the final break with the old poor law.

The new system mas based upon a blend of insurance and assistance. Insurance. paid for by individuals, employers and the state, was supplemented by direct assistance from the state to persons whose needs were outside the scope of the contributory scheme and to those whose needs could not wholly be met by statutory benefits. Because of the continued rise in prices and the difficulty of adjusting benefits to the cost of living, there was a greater resort to assistance than had been expected. In consequence, the Assistance board, renamed the National Assistance board in 1948, had an important task to perform.

It operated through 11 regional offices and 350 area offices in various parts of the country. In addition, advisory committees were set up to deal with such general questions as rent allowances, although not with individual cases. The variety of cases covered by the board was large, and the general objective was not only to provide financial assistance but to offerhelp "in such a manner as shall best promote the welfare of the persons affected by the exercise thereof." This criterion contrasts plainly with the criterion of 1834. Nonetheless, there was evidence that some persons were still unwilling to apply for assistance because the stigma of the poor law had not finally been removed. During the textile depression of 1952 some Lancashire workers showed reluctance to apply for "charity," as they still tended to regard it. The survival of such attitudes within a welfare state indicated the inadequacy of legislation to remould opinion in such a short period as a generation. *See* also IRELAND; IRELAND, NORTHERN; IRELAND, REPUBLIC OF; SCOTLAND: *Social Services;* SOCIAL SECURITY. UNITED STATES

Any discussion of the laws which relate to the relief of the poor in the United States is much complicated by the wide variety of law and practice among the various states, the many laws within states covering the different types of public assistance and the present involvement of the three levels of government—federal, state and local. Prior to 1933 there was no federal agency where comprehensive data could be secured covering state relief laws, their administration or relief expenditures and the number of persons assisted. After 1933 progress was made in the collection of data covering the country generally on various types of outdoor relief. In addition, many important special studies on phases of public welfare were made by various federal agencies.

HISTORY PRIOR TO 1930

State Laws.—Few states had a "poor law" in the sense of a comprehensive statute regulating relief to the poor and its administration before 1930. In many states the subject was dealt with briefly and fragmentarily in sections scattered through the general statutes. In some states, local provisions so modified state law that it was difficult to know what the law really was.

State laws were based largely on the early English poor law. They had been only slightly altered since enactment. with no reflection of changing social conditions and increasing understanding of social prohlems. The most important changes had been effected by taking away certain functions from poor relief officials and not by reorganizing and improving the poor relief system. Under laws largely concerned with the control of vagrancy and able-bodied pauperism. officials attempted to care for the sick, aged and infirm. dependent children. destitute families and in some cases the insane and mental defectives.

Responsibility for Care of the Poor.—The principle of responsibility for the care of the poor by some governmental unit was found in the laws of all states. The legislation tended to be permissive. leaving to the responsible authorities the decision as to whether almshouses should he erected and whether outdoor relief should be granted.

Administrative Systems.—In the New England states the townships cared for the poor. Later, a special poor relief official, the overseer of the poor. was given responsibility. Cities usually had the same responsibilities as the towns. In southern states the county was the governmental unit and poor relief was on a county basis. These two systems. or some combination of them, formed the basis for the administrative systems of all the states. the governmental form adopted in the states depending largely on the system in vogue in the state from which most of the settlers came. In about half the states all poor relief was administered on a county basis. In states having mixed administrative systems the relation of the city and town to the county was complicated and varied greatly from state to state. City charters usually placed the responsibility for the care of the poor on a special official or board, either elected or appointed.

Authorized Relief.—The laws of every state except New Mexico authorized the establishment of almshouses by some governmental unit, either the town, city or county. The law, except in two states, was permissive. Outdoor relief was authorized at the discretion of the poor law authorities. either by specific statement or by implication. As a rule. the laws dealt briefly with outdoor relief! regarding it as a temporary expedient, and tended to place greater emphasis on almshouse care. Medical care was authorized at the discretion of the poor law officials as a form of poor relief.

Eligibility for Relief.—Practically all laws had some definition of what sort of persons were to be cared for by public relief. In about three-quarters of the states, care was to be given to "persons unable to support themselves" or "all poor, indigent, and incapacitated persons." The laws of most of the states established the liability of the community for support of a needy person on the basis of "settlement." a required length of residence in the community. As a rule, legal settlement was acquired by residence for a stated time in the particular governmental unit without receipt of relief. The usual requirement was for residence of one year, though some states required as much as five or seven years. Settlement was generally considered to have been lost in a state by absence for one year from that state.

Liability of Relatives.—The laws of most of the states were based on the principle that relief should be given only when there were no close relatives liable and able to support their dependents. Occasionally grandparents and grandchildren were made liable, but usually only parents and children.

State Supervision.—While 43 states had some central board or department with some degree of administrative or supervisory responsibility relating to some phases of the care of the dependent classes, comparatively few such state bodies had definite responsibilities in regard to the supervision of poor relief. In about one-quarter of the states, state authorities inspected almshouses, received financial reports and made recommendations to local authorities. The recommendations. however, could seldom be enforced. There was even less supervision of outdoor relief. and comparatively few states had accurate figures on expenditures.

Development of Poor Relief.—At first, the poor were cared for by outdoor relief, by indenture of adults or children or by boarding out. As the number of poor increased, the practice grew of auctioning the care of the poor as individuals or as a group. The first almshouse was established in Massachusetts in 1660, but it was not until after 1700 that any great number were established. During the 18th century and the first half of the 19th century the almshouse came to be looked upon as the best method of correcting the abuses inherent in the earlier systems of aiding the poor at home. It soon became a catch-all for all types of persons for whom no other care was available, such as the sick, aged and infirm! children, insane, feeble-minded, vagrants, etc. The period from 1870 was characterized by a growing realization of the failure of the almshouse to care adequately for its varied type of inmates. By steady effort! specialized care was secured for many of these cases. In particular, laws were enacted forbidding the care of children in almshouses and requiring the removal of the insane and feeble-minded.

A report of the United States census on Jan. 1, 1923, showed that there were 78,090 inmates in almshouses, showing a decrease since 1910 when there had been 84.198 inmates. In 1923, 47 states had 2.183 puhlicly owned almshouses. representing an investment of $150,485,230. The annual maintenance cost of the publicly owned institutions was $28,740,523. About 88% of the publicly owned almshouses were directly operated by public officials. The other 12% operated under a contract system whereby the public institution and care of the inmates was given to a private individual on various terms. As to public outdoor relief, very little was known prior to 1930, since no general study had ever been made and few states had even accurate information as to the amount expended by local officials for this purpose. From figures available from a few states. it was evident that many more persons were being aided by outdoor relief than through almshouse care. The administration of outdoor relief was subject to great criticism which certain special studies justified.

Children. — Poor relief officials were originally responsible for all public care given to dependent children, but this function was taken away from them in all but a few states, chiefly during the years following 1900. The inefficiency of almshouse care and the inadequate care given by poor law officials to children resulted in the establishment of new agencies for the care of dependent children. such as county boards of child welfare, boards of children's guardians, county children's courts, county children's homes and state institutions. In all except a few states the poor relief officials came to have practically no responsibility for children cared for away from their families.

Special Types of Assistance. — The inadequacies of the poor relief system also gave rise to statutory provision for special types of assistance, now commonly called categorical assistance, usually administered by other than poor law officials. These types included assistance to veterans, widows' pensions or mother's aid and assistance to the blind and the aged. Relief to war veterans was the earliest type of special assistance. The first state statute providing mother's aid, now known as aid to dependent children, was passed in 1911. Major development in the field of assistance to the blind began in 1910. A law providing for old-age assistance was passed in 1914, but was declared unconstitutional; the next such statute was enacted in 1923. By 1930 there had been substantial growth in all the special types of assistance.

Poor Law Administration. — Faulty administration was undoubtedly the chief weakness of the poor relief system in every state. In only a few states was there any evidence of public interest in poor law reform. Instead, the tendency had been to transfer poor relief functions to agencies caring for special groups of dependents. Some changes made in state laws were in the direction of establishing the county as the unit of administration, as, for example. the poor law passed in Pennsylvania in 1925 and the public welfare law passed in New York state in 1929. The New York public welfare law, replacing a statute which had not been significantly changed for 100 years, embodied the modern philosophy which was to mark later legislation in the relief field.

(H. Fs.)

HISTORY AFTER 1930

When the depression of the 1930s began, the country had a poor relief system based upon programs which were almost entirely locally administered and locally financed. Assistance programs ior special categories of the needy unemployable groups, such as the aged, mothers of young children and the blind, were established in some states, often not on a state-wide basis. Needy persons who were employable had not been numerous, and they mere a responsibility of the local poor law officials. The depression brought about a rapid increase in the number of needy persons willing to but unable to find work. This put an impossible burden on local, especially municipal finances. The first shift to take place as a result of this increase was to state responsibility, because of the financial strain on local government and because the deterrent philosophy underlying local poor law aid was inappropriate ior dealing with mass unemployment.

By 1933 about hali the states had enacted temporary relief lams designed to provide state funds for relief purposes. The state laws generally established separate governmental agencies, even in those states with state public welfare departments. Although local officials retained authority to give assistance, the main burden of providing relief was carried almost entirely by the temporary agency.

Federal Participation. — As the number of unemployed increased to an estimated 15,000,000 in 1933, it became apparent that state resources were insufficient. Already, limited federal aid had been made available to the states in the form of loans (later cancelled) by the Reconstruction Finance corporation, a government corporation established in Jan. 1932 to stimulate economic recovery. In 1933 the Federal Emergency Relief act was passed by the congress and direct grants mere made to the states for unemployment reliei. The iederal government participated in the cost of both direct relief and work relief. The Federal Emergency Relief administration was liquidated in 1935 at the time the Social Security act was adopted, and no more grants mere made to the states for assistance to the unemployed.

Under related legislation, the federal government accepted responsibility for providing work for the able-bodied through the Works Progress administration (later renamed the Work Projects administration). Through the Social Security act, grants-in-aid were made to the states tor public assistance (a term which became more generally used than "reliei") to three groups of needy unemployable persons, the aged, the blind and certain dependent children. Other provisions of the Social Security act were designed to provide income to persons who, except for such income, might need public assistance. These provisions included insurance compensation for the unemployed and old-age insurance (later broadened in 1939 to include benefits to survivors of deceased workers). Thus in 1935 the iederal government adopted a comprehensive plan ior dealing with poverty and with some of its causes.

Effect of Federal Relief. — Federal aid for direct relief had a lasting effect on poor law systems in some states. Not only were assistance standards raised, but a more humane attitude toward the needy was established, medical care was recognized as an essential requirement and efforts mere made to obtain workers qualified by social work training to administer the programs. The Federal Emergency Reliei administration influence did not endure in other states. Direct relief was returned to the localities as soon as iederal funds were withdrawn and standards were left to the decision of the local poor law officials In the poorer states there was an especially severe drop in the standards of care and administration.

World War 11.—The period from 1935 to the beginning of U.S. participation in World War II was marked by the gradual strengthening of state public assistance programs, particularly in the special forms or categories of assistance established bv the Social Security act. During these years there was also a constant, and generally a losing, struggle to maintain the standards for general assistance. Old-age assistance, aid to dependent children and aid to the blind grew in size as more states set up programs, while general assistance rolls declined gradually because oi the transfer of eligible persons to the categories and the increase in work opportunities. The federal government continued to provide work relief for employable persons, although at no time during this period were all of the employable workers eligible for direct relief able to find employment on the WPA. In this period state general assistance (or poor relief) programs varied widely in size and adequacy depending on the traditions and resources of the states.

United States entry into World War II in 1941 brought about a dramatic decline in the number of persons requiring public aid. Federal appropriations for the work reliei program were reduced and then discontinued in 1943. State general assistance loads declined sharply, well below the most optimistic forecast, as a result of the great demand for labour. During the war the number of persons receiving the special categories of assistance under the Social Security act also declined somewhat. Although such persons mere generally unemployable, the high employment level meant that relatives who previously had not been able to assist the needy were now able to do so.

The end of World War II in 1945 mas felt almost immediately by the public assistance agencies administering the special categories ior the needy. The number of persons receiving old-age assistance and aid to dependent children began to increase at once. General relief case loads also increased but less markedly because the high level of employment that had prevailed during the war continued afterward. The increase in the old-age assistance and the aid to dependent children case loads reflected in part the increase in the number of the aged and the very young in the population, the two groups most likely to become dependent.

Public Assistance Under the Social Security Act.—AS stated earlier there were three public assistance programs established under the Social Security act, aid to the needy aged and needy blind and to certain groups of dependent children. A fourth category, aid to the permanently and totally disabled, was added in 1950. Federal funds were made available to the states on the basis of a state plan which must fulfil the requirements stated in the Social Security act. Under the provisions of the Social Security act, the plans must be state-wide in operation, and there must be state financial participation. By the mid-1950s all the states had programs for the aged and for the blind, all states hut one had programs for dependent children and all but eight states had programs for the disabled. These programs were also operating in the District of Columbia and in the territories of Hawaii, Alaska, Puerto Rico and the Virgin Islands.

State definitions of who is needy vary; some states are more exacting than others, for example, in the degree to which relatives are required to support the needy, or in the amount of property a person may hold and be considered needy. Nearly all states require periods of residence in the state, but the poor law concept of settlement is not permitted. Citizenship is required by some states. Assistance is available to persons in their own homes, and usually in private institutions and, with some exceptions, public medical institutions. Aid to dependent children is available only to children in their own home or in the home of close relatives.

In nearly all states one state agency administers or supervises the administration of all four programs. In some of these states that agency either administers or supervises the administration of general assistance also. In all but a very few of the counties in the nation there is a local office serving applicants and recipients.

General Assistance.— In a few states general assistance is administered by the same agency that administers the categories and with the same standards. Frequently, however, different and lower standards apply. In about half the states the general assistance program is locally financed and administered. Eligibility requirements and assistance standards may vary widely within the state. For this reason detailed iniormation about the program may be too scattered to he available. Although some emergency aid is available in nearly all localities, it is often meagre in amount and uncertain in duration. Many states give no assistance to the families of persons who are considered able to work. Residence requirements also are severe in some states, and familiar poor law concepts such as settlement are imposed. General assistance, probably because its importance has not been recognized by the federal government and because the group served has less public appeal than the persons in the federally aided categories, has never achieved status equal to that of the categories.

Relations Between Public Assistance and Social Insurance.— Some economic risks are being insured against under the social insurance system. The effect is to provide income to some persons who otherwise would have to be given public assistance. Even though the old-age and survivors insurance program had not reached maturity in the 1950s, it was significantly reducing the number of persons dependent on the various public assistance programs for support. The major risks against which social insurance protection had been adopted were unemployment, old age and premature death. Formerly these had been major factors contributing to dependency. Prolonged unemployment, disability, family breakup and illness continued to be uninsured risks. Social insurance benefits also were sufficient to meet the needs of only the average person and assumed that he had some other resources. Persons with special needs or with low benefits often needed supplementary help. Social insurance had been accepted as a way to reduce dependency. Much progress had been made, but the goal of a society free from dependency was still far from being attained in the 1950s.

Statistics on Expenditures and Case Loads.— Before 1933 there mere no even approximately complete figures on relief expenditure for recipients. Special studies, however, showed a slight but steady trend upward before 1929 and a sharp upward trend after that year. The predecessor agencies of the Social Security administration of the United States department of health, education and welfare started to collect data on assistance expenditure in 1933, although general assistance data were not entirely complete since they are based upon voluntary reporting by the states. These figures show that expenditures for outdoor relief (public assistance), federal, state and local, increased from $1,223,329,000 in 1933 to a peak of $2,540,009,000 in 1953. Expenditures for the special types of public assistance under the Social Security act reached a peak that same year when $2,337,297,000 was spent from all sources.

As of Aug. 1954 about 700,000 persons were receiving general assistance. 2,578,712 were receiving old-age assistance, 584,720 families totalling 2,093,499 individuals were receiving aid to dependent children, 101,458 received aid to the blind and 217,427 received aid to the permanently and totally disabled. Expenditures for that month totalled $220,879,000 for these groups. It is estimated that in the federally aided programs federal funds comprised about 56% of the total; the remainder mas state and local. In general assistance about 49% was state and the remainder local funds.

Assistance payments in Xug. 1954 averaged 552.43 a case in general assistance (ranging from $13.77 in Mississippi to $77.47 in New Jersey) ; $51.55 in old-age assistance (ranging from $26.41 in Mississippi to $82.76 in Connecticut); $85.07 per family in aid to dependent children (ranging from $26.05 in Mississippi to $135.85 in Wisconsin); $55.94 in aid to the blind (ranging from $25.90 in Alabama to $92.47 in Connecticut); $53.53 in aid to the permanently and totally disabled (ranging from $24.57 in Mississippi to $101.31 in Connecticut). POORWILL, the name (from its cry) of a North American bird (*Phalaenoptilus nuttalli),* allied to the whippoorwill, nightjar and nighthawk (*qq.v.*), which it resembles in habits. It is about eight inches long, the smallest of the family; the primaries are rusty. barred with black. It breeds west of the Mississippi north to British Columbia and south to southern California.

Hibernation of the poorwill in rock crevices was demonstrated by Jaeger (*Condor*, vol. 51, 1949); the bird observed was torpid and aith redyced temperature for about 85 days. (K. P. S.)

POPAYAN, a city of Colombia, capital of the department of Cauca, about 240 mi. S.W. of Bogotá, on the old trade route between that city and Quito, in 2° 26' N., 76° 49' W. Pop. (1961 est.) 61.490.

Popayán is built on a great plain sloping northwest from the foot of the volcano Puracé, near the source of the Cauca and on one of its small tributaries, 5,712 ft. above the sea. Its situation is singularly picturesque, the Puracé rising to an elevation of 15,420 ft. about 20 mi. S.E of the city, the Sotara volcano to approximately the same height about the same distance south by east; behind these at a greater distance is the Pan de Azúcar, 15,978 ft. high. It has rail connection nith Cali.

Earthquakes caused much damage to Popayán, especially those of 1827 and 1834.

Popayán was founded by Sebastián Benalcázar in 1538 on the site of an Indian settlement, whose chief, Payán, had the unusual honour of having his name given to the usurping town. It is noted as the birthplace of Caldas, the Colombian naturalist, and of Mosquera, the geographer

POPE, an ecclesiastical title now used in the West exclusively to designate the head of the Roman Catholic Church. In the 4th and 5th centuries it was frequently used by any bishop (Du Cange, *s.v.*); but it gradually came to be reserved to the bishop of Rome, becoming official. In the East, the title became restricted to the patriarchs of Alexandria. Xntioch, Jerusalem and Constantinople, but is still given by popular usage to priests. Even in the case of the sovereign pontiff the word pope is officially only used as a less solemn style: though the ordinary signature and heading of briefs is, *e.g.,* "Pius P.P.X.," the signature of bulls is *Pius episcopus ecclesiae catholicae,* and the heading, *Pius episcopus, servus servorum Dei,* this latter formula going back to the time of St. Gregory the Great. Other styles met with in official documents are *Pontifex, Summus pontifex, Romanus pontifex, Sanctissimus, Sanctissimus pater, Sanctissimus dominus noster, Sanctitas sua, Beatissirnus pater, Beatitudo sua;* while the pope is addressed in speaking as "*Sanctitas vestra,*" or "*Beatissime pater.*"

Jurisdiction.—The pope is pre-eminently, as successor of St. Peter, bishop of Rome. Writers are fond of viewing him as representing all the degrees of the ecclesiastical hierarchy; they say that he is bishop of Rome, metropolitan of the Roman province, primate of Italy, patriarch of the Western Church and head of the universal Church. This is strictly correct, but, with the exception of the first and last, these titles are seldom to be found in documents. And if these terms were intended to indicate so many degrees in the exercise of jurisdiction they would not be correct. As a matter of fact, from the earliest centuries (*cf.* can. 6 of Nicaea, in 325), we see that the popes exercised a special metropolitan jurisdiction not only over the bishops nearest to Rome, the future cardinal bishops, but also over all those of central and southern Italy, including Sicily (*cf.* Duchesne, *Origines du culte,* ch. 1), all of whom received their ordination at his hands. Northern Italy and the rest of the western Church, still more the eastern Church, did not depend upon him so closely for their administration. His influence was exercised, however, not only in dogmatic questions but in matters of discipline, by means of appeals, petitions and consultations, not forgetting to mention spontaneous intervention.

Primacy.—The primacy of the pope, a primacy of honour and jurisdiction, involving the plenitude of power over the teaching, the worship, the discipline and administration of the Church, is received by the pope as part of the succession of St. Peter, together with the episcopate of Rome. The whole episcopal body, with the pope at its head, should be considered as succeeding to the apostolic college, presided over by St. Peter; and the head of it, now as then, as personally invested with all the powers enjoyed by the whole body, including the head. Hence the pope, as supreme in matters of doctrine, possesses the same authority and the same infallibility as the whole Church; as legislator and judge he possesses the same power as the episcopal body gathered around and with him in oecumenical council. Such are the two essential prerogatives of the papal primacy: infallibility in his supreme pronouncements in matters of doctrine (*see* INFALLIBILITY); and immediate and sovereign jurisdiction, under all its aspects over all the pastors and the faithful. These two privileges. having been claimed and enjoyed by the popes in the course of centuries, were solemnly defined at the Vatican Council by the constitution *Pastor aeternus* of the 18th of July 1870. For the history of the papacy, and associated questions *see* PAPACY. CONCLAVE, CURIA ROMANA, CARDINAL, VESTMENTS. For particulars of the lives of the different popes, *see* the separate articles.

POPE, ALEXANDER (1688–1744), English poet, was born in Lombard street, London, on May 21, 1688. His father, Alexander Pope, a Roman Catholic, was a linen-draper who afterwards retired from business with a small fortune and fixed his residence about 1700 at Binfield in Windsor forest. Pope's education was desultory. Before he was 12 he had obtained a smattering of Latin and Greek from various masters; by his 17th year excessive study had undermined his health and he had developed the personal deformity which later on largely distorted his view of life. Under the treatment, however, of the famous physician John Radcliffe, he recovered his health and continued his studies.

Pope was early an eager aspirant to the highest honours in poetry, and his connections with neighbouring Roman Catholic families of influence in the literary world gave direction to his ambitions. Pope was thus brought under the notice of Sir William Trumbull, a retired diplomatist, living at Easthampstead. Thomas Dancastle, lord of the manor of Binfield, took an active interest in his writings, and at Whiteknights, near Reading, lived another Roman Catholic, Anthony Englefield, "a great lover of poets and poetry." Through him Pope made the acquaintance of Wycherley and of Henry Cromwell, the former introducing him to William Walsh, then of great renown as a critic. Before the poet was 17 he was admitted in this way to the society of London "wits" and men of fashion, and was cordially encouraged as a prodigy.

Pope recognized soon that a long course of preparation was needed for the translation of *Homer* into English verse, on which he had decided. He learnt most, as he acknowledged, from Dryden, but the harmony of his verse also owed something to an earlier writer, George Sandys, the translator of Ovid. At the beginning of the 18th century Dryden's success had given great vogue to translations and modernizations. Dryden had rewritten three of the *Canterbury Tales;* Pope tried his hand at the *Merchant's Tale, Prologue to the Wife of Bath's Tale,* the *House of Fame,* and further experimented with translations from some Latin authors and the *Odyssey.*

Precocious Pope was, but he was also industrious; and he spent nine years in arduous discipline, before anything of his appeared in print. His first publication was his "Pastorals"; they appeared in May 1709 at the end of the sixth volume of Tonson's *Poetical Miscellanies,* containing contributions from Ambrose Philips, Sheffield, Garth and Rowe, with "January and May," Pope's version of Chaucer's "Merchant's Tale."

Pope's next publication was the *Essay on Criticism* (1711), written two years earlier, and printed without the author's name. The sales were slow until Pope caused copies to be sent to Lord Lansdowne and others, but its success was none the less brilliant for the delay. The town was fairly dazzled by the young poet's learning, judgment, and felicity of expressions, and Pope gained credit for much that might have been found where he found it, in the *Institutes* of Quintilian, in the numerous critical writings of René Rapin, and in René le Bossu's treatise on epic poetry. Addison has been made responsible for the exaggerated value once set on the essay, but Addison's paper (*Spectator,* No. 253) was not unmixed praise. He and Pope became acquainted and Pope's sacred eclogue, "Messiah," was printed as No. 378 of the *Spectator.* In the *Essay on Criticism* Pope provoked one bitter personal enemy in John Dennis, the critic, by describing him as Appius, who "stares, tremendous, with a threat'ning eye." Dennis retorted in *Reflections . . . upon a late Rhapsody . . .* (1711), abusing Pope among other things for his personal deformity; and Pope never forgot this brutal attack.

The *Rape of the Lock,* in its first form, appeared in 1712 in *Lintot's Miscellanies;* the "machinery" of sylphs and gnomes was an afterthought, and the poem was republished as we now have it early in 1714. William, 4th Baron Petre, had surreptitiously cut off a lock of Miss Arabella Fermor's hair, and the liberty had been resented; Pope hearing of this, caught at the hint, and treated the subject in mock heroic vein—the result being a poem which is generally admitted to be a masterpiece of airiness, ingenuity, and exquisite finish. It was followed by the publication in March, 1713, of *Windsor Forest,* which was begun, according to Pope, when he was 16 or 17. Hitherto, Pope had avoided politics, but this work appeared with a flattering dedication to the secretary for war, George Granville, Lord Lansdowne, and an opportune allusion to the Treaty of Utrecht. When the poem appeared, it was made the subject of an insidious attack by the Addison coterie, who about this time became estranged from Pope. Addison disavowed connivance of this coarse attack, but a coolness between the two friends ensued.

The attacks upon *Windsor Forest* appeared in a series of papers on "Pastorals" which were published in the *Guardian* (Nos. 22, 23, 28, 30 and 32). No mention was made of the poem, but everyone knew to whom the general principles referred. In the articles the introduction of Greek names, customs and deities was ridiculed and as *Windsor Forest* was fairly open to criticism on this ground, the real subject of the papers was manifest. The real sting of the criticisms, however, lay in their extravagant praise of the second-rate poet Ambrose Philips and the implied comparison with Pope. The latter characteristically succeeded in revenging himself. He secured the publication in the *Guardian* of an anonymous article which ostensibly attacked his own poems, but which actually, by quotation, disposed of the pretensions of Ambrose Philips, and ridiculed the *Guardian's* principles.

The links that attached Pope to the Tory party were strengthened by a new friendship. His first letter to Swift, who became warmly attached to him, is dated Dec. 8, 1713. Swift had been a leading member of the Brothers' Club, from which the famous Scriblerus Club seems to have been an offshoot. The leading members of this informal literary society were Swift, Arbuthnot, Congreve, Bishop Atterbury, Pope, Gay and Thomas Parnell. Their chief object was a general war against the dunces, waged with great spirit by Arbuthnot, Swift and Pope.

The estrangement from Addison was completed in connection with Pope's translation of Homer, which was definitely undertaken in 1713, and was published by subscription. Men of all parties subscribed, their unanimity being a striking proof of the position Pope had attained at the age of 25. But the unanimity was broken by a discordant note. A member of the Addison clique, Tickell, attempted to run a rival version. Pope suspected Addison's instigation; Tickell had at least Addison's encouragement. Pope's famous character of Addison as 'Atticus" in the *Epistle to Dr. Arbuthnot* (ii. 193–215) was, however, inspired by resentment at insults that existed chiefly in his own imagination.

The translation of Homer was Pope's chief employment for 12 years. The new pieces in the miscellanies published in 1717, his "Elegy on an Unfortunate Lady," and his "Eloisa to Abelard," were probably written some years before their publication. The *Iliad* was delivered to the subscribers in instalments in 1715, 1717, 1718 and 1720. Pope's own defective scholarship made help necessary. William Broome and John Jortin supplied the bulk of the notes, and Thomas Parnell the preface. For the translation of the *Odyssey* he took Elijah Fenton and Broome as coadjutors, who between them translated 12 out of the 24 books. (1, 4, 19 and 20 are by Fenton; 2, 6, 8, 11, 12, 16, 18, 23, with notes to all the books, by Broome.) It was completed in 1725. Opinions have varied on the purely literary merits of the poem, but with regard to it as a translation few have differed from Bentley's criticism, "A fine poem, Mr. Pope, but you must not call it Homer." In 1722 he edited the poems of Thomas Parnell, and in 1723–25 made a considerable sum by an unsatisfactory edition of Shakespeare, in which he had the assistance of Fenton and Gay.

Pope, who cleared £8,000 by the two translations. was thus rendered independent and enabled to live near London. The estate at Binfield was sold, and he removed with his parents to Mawson's buildings, Chiswick, in 1716, and in 1719 to Twickenham, to the house with which his name is associated. Here he practised elaborate gardening on a small scale, and built his famous grotto, which was really a tunnel under the road connecting the garden with the lawn on the Thames. He was constantly visited at Twickenham by his intimates, Dr. John Arbuthnot, John Gay, Bolingbroke (after his return in 1723), and Swift (during his brief visits to England in 1726 and 1727), and by many other friends of the Tory party. With Atterbury, bishop of Rochester, he was on terms of affectionate intimacy, but he blundered in his evidence when he was called as a witness on his behalf in 1723.

In 1717 his father died, and he appears to have turned to the Blounts for sympathy in what was to him a very serious bereavement. He had early made the acquaintance of Martha and Teresa Blount, having probably met them first at the house of his neighbour, Englefield of Whiteknights, who was their grandfather. Their home was at Mapledurham, near Reading. He began to correspond with Martha Blount in 1712, and after 1717, the letters are much more serious in tone. He quarrelled with Teresa, who had apparently injured or prevented his suit to her sister, but his friendship with Martha lasted all his life. So long as his mother lived he was unwearying in his attendance on her, but after her death in 1733 his association with Martha Blount mas more constant. His earlier attachment to Lady Mary Wortley Montague was apparently a literary passion, which perished under Lady Xfary's ridicule.

The year 1725 may be taken as the beginning of the third period of Pope's career, when he made his fame as a moralist and a satirist. Edward Young's satire, *The Universal Passion,* had just appeared, and been received with more enthusiasm than any thing published since Pope's own early successes. Swift was finishing Gulliver's *Travels,* and the survivors of the Scriblerus Club resumed their old amusement of parodying and otherwise ridiculing bad writers, especially bad writers in the Whig interest; four volumes of their *Miscellanies in Prose and Verse* were published from 1727 to 1732. According to Pope's own history of the *Dunciad, an Heroic Poem in Three Books,* which first appeared on May 28, 1728, the idea of it grew out of this. Among the Miscellanies was a "Treatise of the Bathos or the Art of Sinking in Poetry," which gave rise to a torrent of abusive falsehoods and scurrilities from those who thought themselves injured by it.

The *Dunciad* was Pope's answer to them, and among the most prominent objects of his satire were Lewis Theobald, Colley Cibber, John Dennis, Richard Bentley, Aaron Hill and Bernard Lintot, who, in spite of his former relations with Pope, was now classed with the piratical Edmund Curll. The book was published anonymously with the greatest precautions. When the success of the poem was assured, it was republished in 1729, and a copy was presented to the king by Sir Robert Walpole. Names took the place of initials, and a defence of the satire, written by Pope himself, but signed by his friend William Cleland, was printed as "A letter to the Publisher." Various indexes, notes and particulars of the attacks on Pope made by the different authors satirized were added. To avoid any danger of prosecution, the copyright was assigned to Lord Oxford, Lord Bathurst and Lord Burlington, whose position made them practically unassailable. The most unprovoked assault was on Richard Bentley, whom he satirized in the reconstruction and enlargement of the *Dunciad* made in the last years of his life at the instigation, it is said. of William Warburton. In the earlier editions the place of hero had been occupied by Lewis Theobald. who had ventured to criticize Pope's *Shakespeare.* In the edition which appeared in Pope's *Works* (1742), he was dethroned in favour of Colley Cibber; Warburton's name is attached to many new notes, and one of the preliminary dissertations by Ricardus Aristarchus on the hero of the poem seems to be by him.

The four epistles of the *Essay on Man* (1733–34) too were intimately connected nith passing controversies. The subject was suggested to him by Henry St. John, Lord Bolingbroke, nho had returned from exile in 1723 and was a fellow-member of the Scriblerus Club. Bolingbroke is said—and the statement is supported by the contents of his posthumous works—to have furnished most of the arguments. In this didactic work, as in his *Essay on Criticism,* Pope put together on a sufficiently simple plan a series of happy sayings, separately elaborated, picking up the thoughts as he found them in miscellaneous reading and conversation and trying only to fit them with perfect expression. His readers were too dazzled by the verse to be severely critical of the sense. Pope himself had not comprehended the drift of the arguments he had adopted from Bolingbroke, and was alarmed when he found that his poem was generally interpreted as an apology for the freethinkers. Warburton is said to have qualified its doctrines as "rank atheism," and asserted that it was put together from the "worst passages from the worst authors" The essay was soon translated into the chief European languages, and in 1737 its orthodoxy was assailed by a Swiss professor, Jean Pierre de Crousaz, in an *Examen de l'essay de M. Pope sur l'homme.* Warburton now saw fit to revise his opinion of Pope's abilities and principles—for what reason does not appear. In any case he now became as enthusiastic in his praise of Pope's orthodoxy and his genius as he had before been scornful, and proceeded to employ his unrivalled powers of sophistry in a defence of the orthodoxy of the conflicting and inconsequent positions adopted in the *Essay on Man.* Pope was wise enough to accept with all gratitude an ally who was so useful a friend and so dangerous an enemy, and from that time onward Warburton was the authorized commentator of his works.

The *Essay on Man* was to have formed part of a series of philosophic poems on a systematic plan. The other pieces were to treat of human reason, of the use of learning, wit, education and riches, of civil and ecclesiastical polity, of the character of women, etc. Of the ten epistles of the *Moral Essays,* the first four, written between 1731 and 1735, are connected with this scheme, which was never completed.

There was much bitter, and sometimes unjust, satire in the *Moral Essays* and the *Imitations of Horace.* In these epistles and satires, which appeared at intervals, Pope was often the mouthpiece of his political friends, who were all of them in opposition to Walpole, then at the height of his power. and Pope chose the objects of his attacks from among the minister's adherents. Epistle III., "Of the Use of Riches," addressed to Allen Bathurst, Lord Bathurst in 1732, is a direct attack on Walpole's methods of corruption and on his financial policy in general; and the two dialogues (1738) known as the "Epilogue to the Satires," professedly a defence of satire, form an eloquent attack on the court. Pope was attached to the prince of Wales's party and he did not forget to insinuate, what was indeed the truth, that the queen had refused the prince her pardon on her death-bed. The "Epistle to Dr. Arbuthnot" contains a description of his personal attitude towards the Scriblerus and is made to serve as a "prologue to the satires." The gross and unpardonable insults bestowed on Lord Hervey and on Lady Mary Wortley Montague in the first satire "to Mr. Fortescue" provnked angry retaliation from both. The descriptions of Timon's ostentatious villa in Epistle IV., addressed to the earl of Burlington, was generally taken as a picture of Canons, the seat of John Brydges. duke of Chandos, one of Pope's patrons. Epistle II , addressed to Martha Blount, contained the picture of Xtossa, which was taken to be a portrait of Sarah Jennings, duchess of Marlborough.

One of the worst imputations on Pope's character was that he left this passage to be published when he had in effect received a bribe of £1,000 from the duchess of Marlborough for its suppression through the agency of Nathanael Hooke (d 1763) As the passage eventually stood. it might be applied to Katherine. duchess of Buckingham, a natural daughter of James II. Pope may have altered it with the intention of diverting the satire from the original object. To appreciate fully the point of his allusions requires an intimate acquaintance with the political and social gossip of the time, but apart from their value as a brilliant strongly-coloured picture of the period, Pope's satires have a permanent value as literature. It is justly remarked by Mark

Pattison (in his edition of the *Satires and Epistles*, 1866), that "these *Imitations* are among the most original of his writings." The vigour and terseness of the diction is still unsurpassed in English verse.

Pope's wit had won for him the friendship of many distinguished men, and his small fortune enabled him to meet them on a footing of independence. He paid long visits at many great houses, especially at Stanton Harcourt, the home of his friend Lord Chancellor Harcourt; at Oakley, the seat of Lord Bathurst; and at Prior Park, Bath, where his host was Ralph Allen. He died on May 30, 1744, and was buried in the parish church of Twickenham. He left the income from his property to Martha Blount till her death, after which it was to go to his half-sister Magdalen Rackett and her children. His unpublished mss. were left at the discretion of Lord Bolingbroke, and his copyrights to Warburton.

If we are to judge Pope fairly there are two features of his times that must be kept steadily in view—the character of political strife in those days and the political relations of men of letters. The age of Queen Anne was pre-eminently an age of intrigue. The Government was almost as unsettled as in the early days of personal monarchy, but it was policy rather than force upon which men depended for keeping their position. Secondly, men of letters were admitted to the inner circles of intrigue as they had never been before and as they have never been since; and Queen Anne's statesmen paid their principal literary champions with social privileges and honourable public appointments. Hence men of letters were directly infected by the low political morality of the unsettled time.

Pope's own ruling passion was the love of fame, and he had no scruples where this was concerned. His vanity and his childish love of intrigue are seen at their worst in his petty manoeuvres to secure the publication of his letters during his lifetime. These intricate proceedings were unravelled with great patience and ingenuity by Charles Wentworth Dilke, when the false picture of his relations with his contemporaries which Pope had imposed on the public had been practically accepted for a century. After manipulating his correspondence so as to place his own character in the best light. Pope deposited a copy in the library of Edward, second earl of Oxford, and then had it printed. The sheets were offered to Curll by a person calling himself P.T., who professed a desire to injure Pope, but was no other than Pope himself. The copy was delivered to Curll in 1735 after long negotiations by an agent who called himself R. Smythe, with a few originals to vouch for their authenticity. P.T. had drawn up an advertisement stating that the book was to contain certain answers from various peers. Curll was summoned before the House of Lords for breach of privilege, but was acquitted, as the letters from peers were not in fact forthcoming. Difficulties then arose between Curll and P.T., and Pope induced a bookseller named Cooper to publish a *Narrative of the Method by which Mr. Pope's Private Letters were procured by Edmund Curll, Bookseller* (1735). These preliminaries cleared the way for a show of indignation against piratical publishers and a "genuine" edition of the *Letters of Mr. Alexander Pope* (1737, fol. and 4to).

Unhappily for Pope's reputation, his friend Caryll, who died before the publication. had taken a copy of Pope's letters before returning them. This letter-book came to light in the middle of the 19th century, and showed the freedom which Pope permitted himself in editing. The correspondence with Lord Oxford, preserved at Longleat, afforded further evidence of his tortuous dealings. But against Pope's petulance and "general love of secrecy and cunning" have to be set, in any fair judgment of his character, his exemplary conduct as a son, the affection with which he was regarded in his own circle of intimates, and many well-authenticated instances of genuine and continued kindliness to persons in distress.

BIBLIOGRAPHY.—Various collected editions of Pope's *Works* appeared during his lifetime, and in 1751 an edition in nine volumes was published by a syndicate of booksellers "with the commentaries of Mr. Warburton." In 1769–1807 an edition was issued which included Owen Ruffhead's *Life of Alexander Pope* (1769), which was largely inspired by Warburton. The notes of many commentators, with some letters and a memoir, were included in the *Works of Alexander Pope*, ed. W. L. Bowles (10 vols., 1806). His *Poetical Works* were edited by Alexander Dyce (1856); by R. Carruthers (1858) for Bohn's Library; by A. W. Ward (*Globe Edition*, 1869), etc. Materials for a definitive edition were collected by John Wilson Croker, and formed the basis of what has become the standard version, *The Works of Alexander Pope* (10 vols., 1871–98), including unpublished letters and other new material, with introduction and notes by W. Elwin and W. J. Courthope. The life of Pope in vol. v. was contributed by Prof. Courthope. The chief original authority besides Pope's correspondence and Ruffhead's *Life* is Joseph Spence's *Anecdotes*, published by S. W. Singer in 1820. Samuel Johnson gives a good estimate of Pope in his *Lives of the Poets*. The best modem lives are that by Prof. Courthope already mentioned; and *Alexander Pope*, by Sir L. Stephen, in the *English Men of Letters* series (1880). *See* also George Paston, *Mr. Pope: his Life and Times* (1909). The first check to the admiration that prevailed during Pope's lifetime was given by the publication of Joseph Warton's *Essay on the Genius and Writings of Pope* (vol. i., 1757; vol. ii., 1782). Thomas Campbell's criticism in his *Specimens of the British Poets* provoked a controversy to which William Hazlitt, Byron and W. L. Bowles contributed. For a discussion of Pope's position as one of the great men of letters in the 18th century who emancipated themselves from patronage, *see* A. Beljame, *Le Public et les hommes de lettres en Angleterre au dix-huitième siècle* (1881); a section of Isaac D'Israeli's *Quarrels of Authors* is devoted to Pope's literary animosities; and most important contributions to many vexed questions in the biography of Pope, especially the publication of his letters, were made by C. W. Dilke in *Notes and Queries* and the *Athenaeum*. These articles were reprinted by his grandson, Sir Charles Dilke, in 1875, as *The Papers of a Critic.*

POPE, JOHN (1822–1892), American soldier, was born at Louisville, Ky., on March 16, 1822. He graduated at the United States military academy in 1842 and was assigned to the engineers. He served in the Mexican War, subsequently engaged in engineering and exploring work, and was commissioned captain in 1856. Early in the Civil War he was placed, as a brigadier general U.S.V., in charge of the district of Missouri, which by vigorous campaigning against guerrilla bands he quickly reduced to order. In 1862, along with the gunboat flotilla (commanded by Commodore A. H. Foote) on the Mississippi, Pope obtained a great success by the capture of the defences of New Madrid and Island No. 10, with nearly 7,000 prisoners. Pope subsequently joined Halleck, and in command of the Army of the Mississippi took part in the siege of Corinth. He was now a major general (U.S.V.). The reputation he had thus gained as an energetic leader quickly placed him in a high command, to which he proved to be quite unequal. The "Army of Virginia," as his new forces were styled, had but a brief career. At the very outset of his Virginian campaign Pope, by a most ill-advised order, in which he contrasted the performances of the western troops with the failures of the troops in Virginia, forfeited the confidence of his officers and men The feeling of the Army of the Potomac (which was ordered to his support) was equally hostile, and the short operations culminated in the disastrous defeat of the second battle of Bull Run. Pope was soon compelled to realize the impossibility of retrieving his position, and resigned the command. Later, in command of the department of the North-West, he showed his former skill and vigour in dealing with Indian risings. In 1882 he was promoted to the full rank of major general, U.S. army. He died at Sandusky, O., on Sept. 23, 1892.

He was the author of various works and papers, including railway reports (*Pacific Railroad Reports* vol. iii.) and *The Campaign of Virginia* (Washington, 1865).

POPE, JOHN RUSSELL (1874–1937), U.S. architect, was born in New York city on April 24, 1874. In 1895 he was fellow of the American Academy at Rome and in 1896–97 held the Schermerhorn traveling fellowship in architecture. In 1900, after attending the École des Beaux-Arts in Paris, he began practice in New York city. In addition to many private residences he designed the Scottish Rite temple, Washington, D.C.; Plattsburg (N.Y.) city hall; the Terminal station, Richmond. Va.; the McDonough memorial at Plattsburg; and the Lincoln memorial at Hodgenville, Ky. He was chosen architect for the Roosevelt memorial and the Mellon art gallery in Washington and the Roosevelt memorial in New York city.

POPE, SIR THOMAS (*c.* 1507–1559). founder of Trinity college. Oxford. was born at Deddington, Oxfordshire. probably in 1507, and educated at Eton college. By 1532 he was holding a minor post in the court of chancery and in October he became clerk of briefs in the Star Chamber. Later he was warden of the mint (1534–36), clerk of the crown in chancery (1537), and in 1536 he was appointed treasurer and second officer of the new court of augmentations. set up to deal with the financial business arising from the dissolution of the monasteries. In this last office he mas superseded in 1541, but from 1547 to 1553 he was again employed as fourth officer.

He was enriched by grants of monastic lands, was knighted in 153j and made a privy councillor in March 1544. The changes made by Edward VI were repugnant to him, but at the beginning of Mary's reign he again became a member of the privy council, and he retained the royal favour under Elizabeth.

As early a s 1555 Pope had begun to arrange for the endowment of a college at Oxford. for which he bought the site and buildings of Durham college, the Oxford house of the abbey of Durham. He received a royal charter for the establishment and endowment of a college of the "Holy and Undivided Trinity" on March 8. 1555. The foundation provided for a president. 12 fellows and 8 scholars. The number of scholars was subsequently increased to 12. On March 28 the members of the college were put in possession of the site. and they were formally admitted on May 30, 1556. Pope died at Clerkenwell on Jan. 29, 1559.

POPISH PLOT: *see* OATES. TITUS.

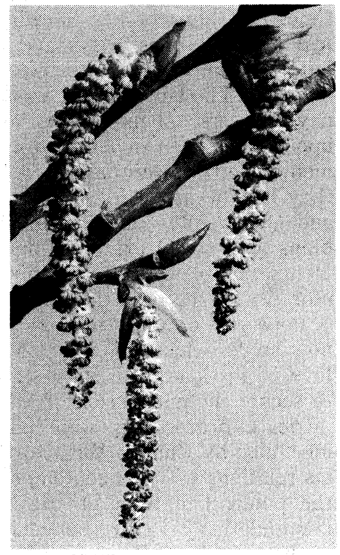
POPLAR, a metropolitan and parliamentary borough of London. Eng.. in the extreme east of the county of London, bounded north by Hackney. east by the Lea river (and the county borough of West Ham). south bv the Thames (and Greenwich). west by Stepney and Bethnal Green. The Blackn-all tunnel goes from between the East and West India docks to Greenwich. Pop. (1951) 73.579. Area 3.6 sq.mi. including 180 ac. water area in its docks. The Lea is believed to have been crossed toward the north by a Roman road. now recalled by the district of Old Ford; Bow acquired its name from the original arched bridge built over the Lea in the early 12th century at the direction of Queen Matilda. South of Bow lies Bromley; in the southeast. Blackwall; and a deep southward bend of the Thames encompasses the Isle of Dogs. In Blackwall and the Isle of Dogs, streets give place to the extensive India and Millwall docks system with shipbuilding. engineering. chemical and other works along the waterfront. Blackwall has been a shipping centre from early times.

The West India (opened in 1802). East India (1806) and Millwall docks have a total area of 515 ac.. of which 1jj ac. is nater: there are 8 mi. of quays. The capacity of the warehouses is about 93.000 tons; goods stored are principally hardwoods. sugar and grain. The central granary at the Millwall dock can accommodate 24.000 tons. Large quantities of green fruit are discharged at two new berths at the West India import dock. The West India docks include export and import docks covering a water area of 24.1 ac. and 27.j ac. respectively: a quayage length of 2.017 yd. and 2.289 yd.; and a maximum depth of 29 ft. In addition, these docks include Blackwall basin with an area of 7.2 ac. and a depth of 26 ft.; Junction dock. area 1.3 ac. and depth 25 ft.; South dock, area 36.3 ac.. maximum depth 30.j ft. and quayage 2,627 yd. Millwall docks are connected with the West India docks. The outer Millwall dock has a water area of nearly 25 ac. and quayage of 2,037 yd., while the inner dock area is 10.5 ac. with 1,638 yd. of quayage. Their maximum depth is 29.8 ft. The new entrance lock to these docks is jd4 ft. long and 80 ft. wide, with a depth of 3j ft. on the sill. The East India docks, to the east. consist of the import dock and a basin with total water area of 23.4 ac. and 2.047 yd. of quay: the depth in the dock being 28 ft. and in the basin 32 ft. Impounding stations raise water in these docks from 19 in. to 2 ft. above Trinity high water.

In the 19th century the district of Cubitt Town in the Isle of Dogs was laid out by Sir William Cubitt. for shipbuilding was then on a large scale (the "Great Eastern" of I. K. Brunel was built there) but by the end of the century the industry began to decline. The population of Poplar reached its height in 1901 (169,000) but by 1931 it had fallen to 155.000 and by 1951 to about half this figure. Northwest of the East India dock road lies the community unit of Lansbury, named in honour of Poplar's former mayor. labour leader George Lansbury (1859–1940), and constructed as part of the comprehensive Stepney-Poplar redevelopment scheme of the London county council after extensive devastation by bombs during World War II. Industries include the manufacture of matches, chemicals, clothing, steel and iron products, and general engineering.

For "Poplarism" *see* POOR LAW.

POPLAR, the name commonly applied to several species of trees comprising a subgeneric group of the genus *Populus,* belonging to the willow family, the Salicaceae (*q.v.*). Aspens (*q.v.*), also members of the genus *Populus,* comprise a second subgeneric group. Several of the poplars are better known in some areas as cottonwoods. This name alludes to their minute. air-borne, hairy-tufted seeds which are released in profusion, and which in accumulations suggest cotton. Others, with fragrant. balsamic-resinous winter buds are commonly called balsam poplars. (Buds of aspens are essentially nonresinous.)



JOHN MARKHAM

MALE CATKINS OF BLACK POPLAR (POPULUS NIGRA)

Populus comprises a group of about 35 species of trees. and a number of natural hybrids. These are widely distributed through the northern hemisphere and range from northern Africa through Eurasia and North America; a few species extend even beyond the Arctic circle.

The leaves of poplars are alternate, deciduous, and are mostly triangular to oval in outline. with finely to coarsely toothed margins and long, cylindrical and tapering, or laterally compressed petioles. The poplars are a dioecious (unisexual) group. with the flowers of both sexes borne in long drooping catkins (aments) in advance of leaf emergence. Flowers on staminate (male) trees consist of 12 to 60 stamens inserted in a cuplike disk subtended by a many-fingered bract (those of the aspens with but 6 to 12 stamens). Flowers from pistillate (female) trees are composed of a single two to four-cell ovoid to globular ovary surmounted by a large spreading stigma, and are similarly inserted on a disk with bract attached. The fruit, a thick-walled (thin-walled in aspens) two to four-valved capsule, contains many minute seeds clothed in cottony pubescence.

There are about a dozen poplars and cottonwoods; including stable varieties and natural hybrids, indigenous to and widely distributed through North America, exclusive of central and southern Mexico.

The eastern cottonwood (*P. deltoides),* a large tree with coarse! deeply furrowed bark and triangular-shaped leaves which are about as broad as long, often attains a height of 150 or more feet and a diameter of 48 to 96 in. Ranging from Quebec westward to Montana and south to Florida and Texas. it is not only a pulpwood and timber tree of major importance, but it is also planted in many localities as a street and shade tree. Numerous forms of this poplar are prized ornamentals in both Europe and America, several of which are hybrids with the European black poplar *(P. nigra)* or one of its varieties. Among these are the Carolina poplar (P. × *canadensis* [hybrid between *P. deltoides* × *P. nigra]),* a vigorous tree with strongly ascending limbs. widely used in parks and streets; and the Eugene poplar *(P. canadensis eugenei* [hybrid between *P. deltoides* × *P. nigra italica*]), a tree of narrow-pyramidal habit that originated in France in 1832. Pistillate trees of the two forms have never been found.

The black cottonwood (*P. trichocarpa*) is the largest of the American poplars. and not infrequently attains a height of more than 200 ft. and a diameter of more than 80 in. It is found along the Pacific slope from southern coastal Alaska to Lower California, and eastward in Canada to Alberta and in the United States to western Montana and Nevada, but is most abundant at low elevations. Reaching its maximum development on deep, moist alluvial or sandy soils, it is often the first tree species to become established on newly formed sand bars and food plains. While very abundant in some areas, its exploitation was retarded for many years, due in large measure to a preponderance of readily accessible softwood timber of quality throughout its range. Since the turn of the 20th century. however, it has been harvested in ever increasing quantities for use in the production of lumber. slack cooperage, excelsior, veneer and paper pulp.

The balsam poplar or the tacamahac (*P. balsamifera* [*tacamahaca*]), the "liard" of the early Canadian *voyageurs*, is a large tree of transcontinental distribution with a pyramidal crown and shallow root system. Essentially a Canadian tree, it occurs along the northern border of the United States from New England westward through the lake states and northern Rocky mountains to Oregon and Washington. Northward it ranges from Labrador westward across nearly all of Canada to beyond the Arctic circle in Alaska. The balm of Gilead poplar, once known botanically as *P. candicans* and widely used ornamentally throughout much of the northeastern United States and southern Canada. is now generally regarded to be either a clone from a pistillate tree of the heartleaf balsam poplar (P. *balsamifera* var. *subcordata*) or a hybrid between the balsam poplar and the eastern cottonwood.

The principal poplar of the swamps and river bottoms of the coastal plains and the blississippi river drainage basin is the swamp cottonwood (*P. heterophylla*). In the Mississippi valley where it reaches its maximum development, trees are often 80 to 90 ft. tall and 36 to 42 in. in diameter.

The plains cottonwood (P. *sargenti),* is one of the most frequently encountered trees in the essentially treeless areas of the central United States. Narrowleaf cottonwood (*P. angustifolia*) is a tree of the Rocky mountains and adjacent plains to the east. The ranges of these two species overlap, and at least one natural hybrid between them has become well established. This is known as the lanceleaf cottonwood (P. × *acuminata* [hybrid between *P. angustifolia* × *P. sargenti*]).

Fremont cottonwood (P. *fremonti)* and its variety, Rio Grande cottonwood (*P. fremonti* var. *wislizenii*), are two tree forms not infrequently found along the margins of streams and water holes in the semiarid areas of the southwestern United States. Palmer cottonwood (P. *palmeri*) is a little-known tree of central and the trans-Pecos regions of Texas and northern Mexico.

Of the European forms, the white poplar or abele (P. *alba*) is probably the most important. This is a large tree with rounded and spreading crown composed of several massive. curved branches which. like the trunk. are clothed with grayish-white bark. Its leaves are oval ovate to nearly circular. with deeply wavy or more or less lobed margins and heart-shaped bases. The foliage. although dark green above, is clothed below in dense. white pubescence. as are also the young shoots which. with the bark, give a rather hoary aspect to the tree. Of its several varieties. P. *alba* var. *pyramidalis* (Bolleana poplar). a tree of narrow columnar habit. probably enjoys the greatest ornamental use. 4 closely related species, the gray poplar (*P. canescens*). with grayish deltoid leaves, is equally well known. Some taxonomists. however, regard this form as a hybrid between the white poplar and the European aspen (P. *tremula*). Both trees have extended ranges through Europe and Asia. and often attain a height of 90 or more feet. Their white. soft. even-grained timber is employed by turners and toymakers, and is used in quantity in the construction of boxes and crates. Both also enjoy extended ornamental use, although the tendency of white poplar to produce root suckers some distance from the tree restricts its ornamental value in some areas.

The black poplar (*P nigra*) a tree of 100 or more feet in height. nith smooth, dark green. deltoid leaves and dark, deeply furroned bark, is a Eurasian species of wide distribution. Its almost universally known variety. the Lombardy poplar (*P. nigra* var. *italica*), is easily identified by its narrow-pyramidal crown composed of many closely appressed and vertically ascending branches. Its origin appears to have been in Iran or some adjacent country. for it was unknown in Italy in the days of Pliny. From remote times it has been an inhabitant of Kashmir. Punjab and Iran. where it is still commonly to be observed along road sites and in formal gardens. It was probably brought to southern Europe from one of these countries, and derives its common name from its abundant use along the rivers of Lombardy. It was introduced into Great Britain in the early 18th century. and somewhat later into the United States. Lombardy poplar's value lies chiefly in its ornamental use. since its rapidly tapering bole. densely clothed in branches for the greater part of its length, is incapable of producing any appreciable volume of utilizable lumber. This tree makes very rapid growth on a variety of sites. and often attains a height of 100 or more feet. The white, black and Lombardy poplars are widely planted in eastern United States and Canada; the first two of these have become naturalized in many areas.

P. euphratica, believed to be the weeping willow of the Scriptures. is a large tree remarkable for its variability in the shape of its leaves. It is a native of northern Africa and western and central Asia.

Yellow poplar (*Liriodendron tulipifera*), an unrelated species of the magnolia family, is one of the most important hardwoods of eastern United States. *See* TULIP TREE. (E. S. HR.)

POPLAR BLUFF, a city of southeastern Missouri, U.S., 156 mi. S. of St. Louis at the head of navigation on the Black river; the seat of Butler county. Situated in the Ozark perimeter above a broad alluvial plain that forms the rich delta land of one of Llissouri's most prosperous farming areas. Poplar Bluff is essentially a farm marketing centre with diversified light industries. It is located at the intersection of two main transcontinental highways and is served by two major railroads.

Founded in 1849 and named for a forest of yellow poplars on the bluffs of the Black river, the city nas almost destroyed by guerrilla and troop foragers during the American Civil War. Its subsequent development gained impetus with the construction of the St Louis, Iron Mountain and Southern railway (Missouri Pacific) in 1872. Agricultural growth followed a lumbering boom and reclamation of vast swamp lands betneen the St. Francis and Black rivers The county produces cotton. rice, grain. livestock and lumber. For comparative population figures *see* table in MISSOURI *Population.* (W. E. Ro.)

POPLIN, a fine and plain ribbed fabric produced from any class of textile material, comprising a variety of different textures and qualities, and containing fine ribs or cords of uniform size extending across the width of the fabric, from selvage to selvage; *i e*, in the direction of the weft. The ribbed effect in a poplin fabric is obtained by employing a relatively high number of warp threads of fine counts of yarn and interweaving these on the principle of the plain calico (q *v*) weave, with picks of weft of coarse counts Hence, during weaving, the finer and weaker narp threads bend or interlace quite freely under and over the coarser and stronger picks of weft which therefore, lie in a perfectly straight line across the entire nidth of the fabric and thus develop the fine ribs or cords that characterize all poplin fabrics. Cotton poplin fabrics are used for making blouses, dresses, shirts, jackets and other garments. Irish poplin, composed of silk warp and worsted weft, is used for ties. dresses, coats and other clothing.

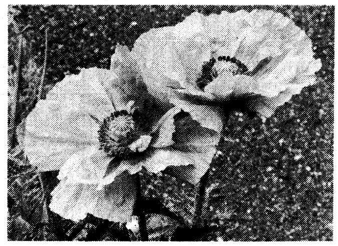
POPOCATÉPETL (Aztec *popoca* "smoke," *tepetl* "mountain'), a volcano nith a large bell-shaped crater approximately 2.008 by 1,312 ft., and a snow-covered cone rising to a height of 17.887 ft. in México state. central Mexico. Popocatépetl and its twin Ixtacihuatl (Ixtaccihuatl; *q.v*) dominate Mexico city, 45 mi. N.W. It is believed that Diego de Ordaz. one of Cortès lieutenants, was the first European to make the ascent. The last major eruption was in 1802 but there have since been minor ones. There is a road from the town of Amecameca to the foot of the volcano. *See* also MEXICO: *Physical Geography: Mountains.*

POPOV, ALEKSANDR STEPANOVICH (1859–1906), Russian physicist and electrical engineer, among the earliest scientific investigators of electromagnetic waves (as later used in wireless communication), was born on March 16, 1859, in a mining village in the Ural mountains where his father mas a priest. He graduated from St. Petersburg university in 1883 and became an assistant in the physics laboratory, later joining the staff of the torpedo school at Kronstadt. where he subsequently became head of the physics department. Popov became interested in the work of H. R. Hertz (*q.v.*), and began to develop a device for receiving electromagnetic waves (*q.v.*). To detect the oscillations resulting from these waves he made various modifications to the coherer, containing metallic filings, used by Edouard Branly and Sir Oliver Lodge. In particular, he added to his coherer an arrangement for automatically tapping back the filings to a sensitive condition after they had cohered on the reception of oscillations. By this means each received impulse of oscillations caused a bell to ring or a mark to be made on a simple recorder which could operate for 12 hours at a time. This apparatus was used for detecting lightning discharges at a distance and was demonstrated at a meeting of the St. Petersburg Physical society in May 1893. Later, it was set up at the meteorological observatory, the coherer being connected to a lightning conductor and used for the study of atmospheric electrical discharges received at distances up to almost 20 mi. In a second lecture before the society in March 1896. Popov showed the transmission of Hertzian waves between different parts of the university buildings. In June 1896. Guglielmo Marconi took out the first patent granted for wireless telegraphy based on the use of electric waves. The news of this aroused Popov to fresh activity, and working in conjunction with the Russian navy he effected ship-to-shore communication over distances of about 6 mi. by 1898. This was increased to about 30 mi. by the end of the following year. Unfortunately Popov's work was not sufficiently appreciated and supported by the Russian government. and in 1901 he returned to St. Petersburg as professor at the electrotechnical institute. of which, a few years later, he was elected director. Popov died on Jan. 13, 1906 (Dec. 31. 1905. by the old Julian calendar). (R. L. S.-R.; X.)

POPPY, common name for plants of several genera of the poppy family (Papaveraceae), especially the type genus *Papaver*. This genus comprises annual and perennial erect herbs containing a milky juice, with lobed or cut leaves and generally long-stalked regular showy flowers, which are nodding in the bud stage. The sepals, usually two in number, fall off as the flower opens; the four (very rarely five or six) petals. which are crumpled in the bud stage. also fall readily. Numerous stamens surround the ovary. which is surmounted by a flat or convex rayed disk bearing the stigmas. The ovary develops into a short many-seeded capsule, opening by small valves below the upper edge. The valves are hygroscopic, responding to an increase in the amount of moisture in the atmosphere by closing the apertures. In dry weather the valves open, and the small seeds escape through the pores when the capsule is shaken by the wind. The genus contains perhaps 90 species! mostly natives of central and southern Europe and temperate Asia. Five species occur in Great Britain; *Papaver* rhoeas, the corn poppy, found in fields and waste places also in the U.S. Cultivated forms of this, with exquisite shades of colour and without any blotch at the base of the petals, are known as Shirley poppies. P. *somniferum,* the opium (*q.v.*) poppy, with large white or blue-purple flowers, is native to Greece and the orient and widely cultivated for medical uses, although it is often grown illicitly.

The oriental poppy (P. orientale) and its many varieties are fine garden plants, having huge bright crimson flowers with black blotches at the base. Many hybrid forms of varying shades of colour have been raised, especially in the U.S. The Iceland poppy (P. nudicaulej is one of the showiest species, with gray-green pinnate leaves and flowers varying in colour from pure white to deep orange-yellow and orange-scarlet shades.

The Welsh poppy (*Meconopsis cambrica*) is a perennial herb with a yellow juice and pale-yellow poppylike flowers. It is found in the southwest and north of England, Wales, Ireland and western Europe. The prickly poppy belongs to the related tropical American genus Argemone. *A.* grandiflora is a popular Central American annual with large white flowers. The horned poppy *Glaucium flavum,* found on sandy seashores along the Mediterranean and characterized by the waxy bloom of its leaves and large golden-yellow short-stalked flowers is naturalized in the U.S. The plume poppies (*Macleaya*) are ornamental foliage plants of great beauty. The snow poppy (*Eomecon chionantha*) is a pretty Chinese perennial, having roundish slightly lobed leaves and pure-white flowers about 2 in. across. The Mexican tulip poppy or golden cup (*Hunnemannia fumariaefolia*), a perennial usually grown as an annual, has very showy yellow flowers. The celandine poppy is *Stylophorum diphyllum; Hydro*cleis *nymphoides* is the water poppy of ponds and aquaria.



J. HORACE MCFARLAND CO

ORIENTAL POPPY (PAPAVER ORIENTALE)

The poppy group is well represented in western North America, especially in California, where about 20 native species, together with numerous varieties, are found. The best known is the California poppy (*Eschscholtzia californica*) an annual with brilliant, orange-coloured flowers, widely grown in gardens and extensively naturalized in Australia and India. Other notenorthy Californian species. more or less cultivated, are the tree poppy (Dendronzecon rigida), a rigid, leafy shrub, 2 to 10 ft. high, with golden-yellow flowers, about 2 in. across; the Matilija poppy (Romneya coulteri), a widely branched subshrub, 3 to 8 ft. high, with large white fragrant flowers, 6 in. across; the cream-cups (*Platystemon* californzcus), a low, delicate annual, with light-yellow flowers, 1 in. across; and the flaming poppy or wind poppy (*Meconopsis heterophylla*), bearing brick-red flowers 2 in. across.

The cultivation of common garden poppies (*Papaver* species) is simple if the plants are provided with rich well-drained soil in an open sunny location and are watered during dry spells. Some varieties of P. *orientalis* have enormous flowers in nearly all colour shades, but are ephemeral and useless as cut flowers. Seed should be sown where plants are to grow, for poppies, especially the annuals, do not transplant well. (N. TR.; X.)

POPPY OIL (*Oleum* papaveris), a vegetable oil obtained by pressure from the minute seeds of the garden or opium poppy, *Papaver somniferum.* The white-seeded and black-seeded varieties are both used for oil pressing; but, when the production of oil is the principal object of the culture, the black seed is usually preferred. The qualities of the oil yielded by both varieties and the proportion they contain (from 50% to 60%) are the same. By cold pressing, seeds of fine quality yield from 30% to 40% of virgin or white oil (huile blanche), a transparent limpid fluid with a slight yellowish tinge, bland and pleasant to taste, and with almost no perceptible odour. On second pressure with the aid of heat an additional 20% to 25% of inferior oil (huile de fabrique or huile russe) is obtained, reddish in colour, possessed of a biting taste, and a linseedlike smell. The oil belongs to the linoleic or drying series, having as its principal constituent linolein; and it possesses greater drying power than raw linseed oil. Its specific gravity at 15° C. is 0.925.

Poppy oil is a valuable and much used medium for artistic oil painting. The fine qualities are largely used in the north of France (*huile* d'oeillette) and in Germany as a salad oil, and are less liable than olive oil to rancidity. The inferior qualities are principally consumed in soapmaking and varnishmaking, and for burning in lamps. The oil is used in the valley of the Ganges and other opium regions for food and domestic purposes. Ordinary poppy-oil cake is valuable feeding material. rich in nitrogenous constituents. with an ash showing an unusually large proportion of phosphoric acid.

POPULATION. The number of people in the world reached 3,000.000.000 during the year 1960, according to the estimates by the Cnited Nations secretariat. The world's population was then increasing at about 1.8% per year. This rate, which if continued would double the number in 40 years, or by 2001, was well above that prevailing in any previous epoch. According to widely accepted estimates, the average rate of increase rose from less than 0.1% per year in ancient and medieval times to about 0.3% at the beginning of the 18th century and about 0.6% during the

middle decades of the 19th century. The acceleration of population increase in the 20th century was the result of progressive and world-wide lowering of mortality.

Differences in population trends among the various regions of the world are strongly affected by differences in fertility. Estimates of population increases and projected trends, by continents, prepared by the Cnited Nations secretariat, are shown in Table I.

No population projections are prophetic. Projected trends for the continents having less-developed countries may be modified by social changes affecting births and deaths, the discovery of new techniques for the control of fertility or in other ways. Trends in the more-developed countries, where mortality at early ages is very low and fertility is already subject in large measure to voluntary control, are peculiarly sensitive to changes in economic conditions and cultural values. The projections merely show the expected effects of processes already in force if these continue without drastic modification. Projections were made on several sets of hypotheses; those shown in Table I follow from a central assumption of medium, or average, fertility and mortality.

Some idea about variations in population trends among particular countries is given by the information on countries with more than 30,000,000 inhabitants presented in Table II.

KNOWLEDGE ABOUT POPULATION

The scientific study of population, known as demography, began with investigations by John Graunt in the 17th century. Graunt was one of a group of associates in London who were fired with enthusiasm for observations and experiments and received a charter as the Royal Philosophical society, the first scientific academy in the modern world. Graunt, who was a haberdasher by trade. discovered many significant regularities in a series of periodic records of christenings and burials, with reports on the apparent causes of deaths. issued by parish clerks. He published his findings in a pamphlet, *Natural and Political Observations . . . Made upon the Bills of Mortality* of London (1662). This pamphlet. in which Graunt had sketched a hypothetical life table to show the proportions of persons born alive who live to successive ages and the expected years of future life at each age, attracted the attention of scientists in England and on the continent and stimulated other inquiries.

TABLE II.—*Population of Countries with 30,000,000 or More Inhabitants, 1960*

Country	Population (in 000,000)	Average per cent annual increase	Persons per square mile
China (mainland)	660	2.5	178
India	432	2.0	343

Poland	30	1.7	247
Spain	30	1.2	155

Source: *Population Index*, vol. 28, no. 1, Jan. 1962. The rates of increase refer to varying recent periods prior to 1960. The figures for China and Nigeria are subject to large errors.

In 1693 Edmund Halley, the astronomer, constructed the first empirical life table on the basis of information about deaths by age in Breslau, Ger.. which had been forwarded to the London Philosophical society by Leibnitz. The measurement and analysis of mortality, which involved study of the frequency of births and the distribution of persons by ages, engaged the attention of scientists in many countries through successive decades. Eventually their investigations led to the systematic exposition of possible interrelations among births, deaths and the age structure of populations. Alfred J. Lotka developed the classic formulation of these relations. Though most of his work was carried out in the United States. his definitive exposition was presented in French: *Théorie analytique des associations biologiques. II. Analyse démographique avec application particulière à l'espèce humaine* (1939).

Censuses.—The major source of basic information on population during the 18th century was the civil register of vital events, established in most European nations to supersede reliance in legal affairs on church records of christenings, marriages and burials. There had already been occasional countings of people in some nations, but these early censuses were sporadic. Usually there was neither a complete tabulation of the returns nor any publication of the results. Quite different opinions were often entertained about the population of a country, even as to whether its population was increasing or decreasing. Scientists investigating these questions experimented with new methods of observation and analysis.

The constitution of the United States prescribed representation in congress on the basis of a periodic census of the population beginning in 1790. Periodic censuses were initiated both in England and in France in 1801. Since that time censuses have gradually spread through the world and supply basic information on most of the world's inhabitants. The greatest gap was apparently closed by the census of China. 1953–54, though its results must be accepted with some reservation. Three-fourths of the population of Africa has been described by complete enumerations or national inquiries on the basis of scientific sampling. However, the scope and reliability of censuses differ greatly among nations. (*See* also CENSUS; *VITAL* STATISTICS.)

Information on births, deaths and migration is less satisfactory. In the United States, the registration of births and deaths was still very defective in most states at the beginning of the 20th century. Federal birth and death registration areas, initiated at that time, were first extended to include all states in 1933. Reliable vital statistics are still lacking for countries containing more than half the world's population; *i.e.*, Asia (except Japan. Taiwan, Ceylon and Israel). most of Africa and much of Latin America.

Estimates of fertility and mortality can sometimes be obtained by the systematic exploitation of indirect and fragmentary information. but even the critical and skilful use of incomplete information is not a satisfactory substitute for adequate basic data. The measurement of migration, especially within nations, is inherently difficult Census inquiries are used in many countries to obtain some Information on this subject.

MORTALITY

The risk of death varies with age and sex. In general the risk at any given age is less for females than for males, though under some conditions the death rates of women in the childbearing ages may be above those of men at the same ages. The risk of death is high immediately after birth and, with diminishing force, through early childhood; it decreases to a minimum at 10 to 12 years of age. The risk then rises again until at late ages it surpasses that in the first year of life. So the crude death rate of a population (usually expressed as deaths per year per 1,000 persons) is powerfully influenced by its age composition. For comparative purposes. the effect of age composition must always be taken into account in the measurement of mortality. Various standardized death rates have been devised for this purpose, but each is subject to certain technical objections. The expectation of life at birth, as given by a life table. is the most efficient index of the general level of mortality of a population. This is a hypothetical figure. It shows the average years of life to be expected at birth if the risks of death at particular ages in a specified year continue in effect. In Table III the calculated expectations of life at birth are shown for certain countries at particular times.

Mortality Levels.—The range in levels of mortality, shown in Table III, mainly reflects degrees of progress in technology. especially in sanitation and medicine. Prior to the 18th century, the range in levels of mortality was much narrower, except at times of famine, plague or war. In normal times the mean expectations of life at birth were then in the vicinity of 25 to 30 years.

The figures for Ceylon in 1954 are surprisingly high; a decade earlier, in 1945–47, the figures had been 46.8 for males and 44.7 for females. The change was due mainly to a campaign in that country, with the assistance of the World Health organization, for the control of malaria by DDT spraying and related advances in sanitation. Mortality can be substantially reduced in underdeveloped countries by mass programs without great changes in levels of living or education—and at a more rapid pace than the earlier gradual lowering of death rates in Europe. A great advance along this line has been in progress throughout the world

Class Differences.—There are still important differences among social classes within technically advanced nations in levels of mortality, especially in infancy and early childhood. This is indicated by the differences between the figures for whites and nonwhites in the United States (*see* Table III) and by other information concerning families at different economic levels. However, such differences have generally been narrowed in North America and in Europe. especially since World War II. On the other hand. differentials in mortality between males and females have generally widened—notably in the United States. Various reasons for this phenomenon have been advanced, but none has as yet won a clear consensus among scientists.

Life Expectation.—The lengthening of the span of life is due chiefly to the control of infectious diseases which are especially dangerous in infancy and early childhood Where the expectation of life at birth is only 30 years, about half of the newborn infants die before age 25 years; but where the expectation is 70 years, over 95% of those born alive pass the 25-year point. Past progress in lowering mortality and that now going on in underdeveloped countries, therefore, exerts a powerful influence on rates of population increase. Future progress in the extension of life in technically advanced countries, being largely dependent on the reduction of deaths at late ages, may be relatively slow. See also DEATH RATE.

FERTILITY AND REPRODUCTION

The word fertility is used to denote the actual production of offspring, whereas fecundity refers to biological capacity. The average capacity of a population for reproduction cannot be precisely measured; it varies to an unknown degree under different conditions and perhaps among different stocks. The average capacity of couples under widely prevalent conditions has been estimated at 8 5 to 10 or more births; some couples can have more than 20 births, but others in every society are sterile or become so after the birth of one or several children. In any case. reproduction in human societies is always influenced by customs affecting the frequency of and ages at marriage, divorce and separation, the remarriage of widowed and divorced persons, prohibitions against sexual intercourse under particular conditions. and in many other ways. Various practices. largely magical, both to promote fertility and under certain conditions to prevent conception or induce abortion, are found in most preliterate societies. but they usually have little effect on actual performance. Among technically advanced societies. variations in levels of fertility are determined mainly by attitudes and practices; they have little relation to possible variations in fecundity—though post-World War II increases of birth rates in Europe and North America may have been due in small part to a reduction in the frequency of complete or partial sterility.

Reproduction Ratios.—In most of Asia (except Japan), in Africa and in America from Brazil north through Mexico, each woman who lives through the childbearing years has on the average about six children—though there is. of course, some variation among regions. Between 48% and 49% of all babies are girls. So the average number of daughters born alive per surviving woman (gross reproduction ratio) under these conditions is about three. If the number of children which newborn female infants might eventually bear if all lived through the childbearing period is cut in half by deaths between birth and successive adult ages, there will still be about 150 daughters in each generation per 100 daughters in the previous generation (net reproduction ratio). The population will then tend to increase by 50% during an intergeneration interval. usually somewhere between 25 and 30 years. In past times, this tendency was checked by recurrent disasters. With the same gross reproduction ratio (three) but improvement in sanitation so that only one-third of the potential reproduction is lost by mortality, the net reproduction ratio becomes two. In other words, the population then doubles in each generation. Due to reductions in mortality and the persistence of high fertility, the population of the less-developed countries is generally moving toward. or has already exceeded, this reproductive level. This statement. in the absence of reliable vital statistics, is necessarily based on inferences from census data. investigations in various localities and other indirect evidence; but it is supported by cumulative evidence from many sources.

The general level of fertility in Europe prior to the Industrial Revolution. and perhaps throughout medieval times, was significantly below that now generally prevalent in Asia, Africa and Middle America. The moderation of fertility in preindustrial Europe was not due to the control of fertility within marriage but to social restraints on marriage or procreation at early ages—associated with an emphasis on the nuclear family (husband, wife and children) as contrasted with the larger kinship groups in many societies. These restraints on early marriage were eased among settlers in the open spaces of the new world, so that fertility in colonial America was much higher than in Europe. Different social conditions, also, led to some reduction of fertility in premodern Japan, but in this case by resort to abortion and infanticide.

Control of Fertility.—The growth of commerce, new opportunities for individuals to achieve higher levels of living, the withdrawal of children from economic production and provisions for their education stimulated a new interest in the control of fertility within marriage. At the same time. the lowering of mortality increased the probability that most infants would survive to maturity. Then, too. the progress of science and education fostered rationalistic behaviour in the pursuit of personal goals. Incidentally. it seems that men were at least equally and probably more insistent than women on the control of births. So a trend toward the regulation of births within marriage began in France and in the United States near the beginning of the 19th century. Later, but with long lags. it spread through all western and central Europe and then eastward and southward and from cities into rural areas. The control of fertility was at first achieved through an intensification of ancient folk practices, but it was later facilitated by mechanical and chemical means of contraception. It first gained momentum in professional and commercial classes and then spread more slowly through the families of skilled and unskilled workers. This pattern brought wide differences in fertility among the social classes.

As the regulation of fertility has become more nearly universal in Europe, North America. Australia and New Zealand, 'social class differentials in fertility have been narrowed. though they have not entirely disappeared. The trend toward the regulation of fertility in these regions was apparently approaching completion. in the sense of bringing fertility more or less into conformity with the personal interests of couples, when the world-wide economic depression generated a wave of anxiety to avoid. or at least to postpone. the enlargement of families. Wartime opportunities for employment and postwar prosperity brought a shift toward earlier marriages, a reduction in the frequency of childless or one-child families and some increase in the number of subsequent births to couples who already had t o children—notably in North America, Australia and New Zealand and, to a lesser extent, in Europe. Assuming 1.057 male births per female birth. with 95% of the female infants living to the centre of the childbearing period, of whom 90% marry, an average of 2.16 births per woman living through the childbearing years, or 2 4 births per ever-married woman. will maintain a constant population. Around 1960 fertility was well above this level in North America and Oceania

TABLE IV.—*Estimated Birth Rates by World Regions, 1954–58*

Region	Per 1,000 population per year	Region	Per 1,000 population per year
World	35	U.S.S.R.	26
Africa	45	Northern America.	25
Southwest Asia	42	Oceania	24
South central Asia	41	Southern Europe	21
Southeast Asia	46	Central Europe	19
Middle America	42	North and western Europe.	18
South America	40	Japan	18

Note: The general birth rate in Africa may be higher than in Southwest, Central, and Southeast Asia, but this is speculative. The estimate for "East Asia," which includes mainland China, is omitted.

and in some European countries; in some other European countries it was fluctuating in this vicinity. Fertility in the Soviet Union was then similar to, but slightly above, that in the United States. The rapid decline of fertility in Japan brought it into line with the low-fertility countries in Europe. In both instances, sharp declines mere initially effected by widespread resort to abortion. with a gradual shift toward increased reliance on contraception.

Meanwhile fertility remained at a fairly constant level in most of the underdeveloped countries. Except in periods of rapid change, crude birth rates usually give a fair indication of levels of fertility (in contrast to crude death rates, which are strongly influenced by differences in age composition). Estimated birth rates by world regions are shown in Table IV.

See also BIRTH CONTROL; BIRTH RATE.

AGE AND SEX STRUCTURE

The age and sex composition of a population is determined. apart from the effects of migration. by the frequencies of births in previous years. the sex ratio at birth and the proportions of male and female infants living to successive ages. The age and sex composition of a closed population (not affected by migration) in which the relative frequencies of vital events (births, deaths by age and by sex, and the sex ratio at birth) have been constant for a long time can be calculated mathematically from information on these vital rates. The effects of particular changes in vital rates can also be calculated, but such calculations are more complex.

A population with persistently high fertility has a large proportion of children and a small proportion of aged persons. A population. such as that of France, in which fertility has been low for a long time, has a smaller proportion of children and a larger proportion of aged persons. Changes in fertility have an immediate effect on numbers of children, but 15 years must pass before

TABLE V.—*Age Distribution of Enumerated Populations in Selected Countries*

Country and date of census	Per cent in specified classes: Under 15 years	15–59 years	60 years and over

the change affects the numbers above this age, and 60 years before it affects the numbers of older persons. Therefore, a population that has experienced a recent decline in fertility tends to have relatively small numbers both of children and of aged persons and a large proportion of adults in the middle ages. An upswing in births will again bring an increase in the proportion of children. Thus the rise of fertility in France during the post-World War II period increased the proportion of children in its population while the proportion of aged persons remained relatively high In technically advanced countries reductions in mortality at late ages may be expected to increase the proportions of aged persons. (A systematic exposition of these principles is given by Ansley J. Coale, "The Effect of Changes in Fertility and Mortality on Age Composition." *The Milbank Memorial Fund Quarterly, 34*:79–114 [Jan. 1956].)

The age distributions of population in different countries *(see* Table 5') are mainly due to differences in the levels and trends of fertility. They have also been influenced in varying ways by migrations, war losses and differences in mortality—though these effects are generally less important than the influence of variations in fertility. The migration of young adults. who bring children with them or soon have children in the area to which they move, is likely to swell the numbers both of adults in the middle ages and of children in the receiving country while the proportion of aged persons remain low—with reverse effects on the population of an area from which there is a large net out-movement.

The division by sex of a population. or of its component age classes. at any moment is determined quite simply. apart from the influence of migration, by the ratio of males to females at birth and the relative proportions of males and of females who have survived from birth to successive ages. See SEX; SEX RATIO.

MIGRATION

It is possible to distinguish three major kinds of spatial population movements: tribal wanderings and expansion by conquest into new lands—a process continued in the form of military occupation and colonization; forced transfers of people, including the acquisition of captives, the movement of slaves and the expulsion of minorities for political reasons; and the free movement of individuals. (The movement of indentured or contract labourers, which in some situations includes an element of force or fraud. is somewhat intermediate between the last two types.) Migration usually refers to the free movement of individuals; but other types of movement have been important forces in determining the present distribution of the world's population, and the 20th century has been plagued by forced movements on a large scale *(see* MINORITIES; REFUGEES).

The free movement of individuals is directed mainly toward the adjustment of people to economic opportunities—though it is influenced by diverse motives and has complex social and cultural aspects. Migration as a process of economic adjustment is often impeded by ignorance. attachment to habitual sites, the costs and risks of migration, and political barriers. Moreover, the sheer magnitude of population and the force of natural increase in the major regions of limited opportunity exclude the possibility that international migration can be a major factor in raising the levels of living of these regions. Migration seems to have been economically most effective when great resources held by small populations have been open to migrants, or there has been a great expansion of economic activities in which prospective migrants could be absorbed, and when migration has been associated with other transitional economic and demographic processes in the countries of origin.

The second of these relations is illustrated by the progressive shift southward and eastward of the areas of overseas emigration from Europe, with a spontaneous diminution of outflows from western and northern Europe as their industries expanded and their birth rates declined. It is also illustrated by the post-World War II movement of Puerto Ricans to the mainland of the United States, associated with the formation of new economic enterprises, progress in education and an initial trend toward modification of fertility.

Although migration varies greatly in magnitude and significance under different conditions. some approaches have been made to the formal analysis of internal migration (within nations) and the magnitudes of various streams of international migration at different times have been estimated. There is also much information about the characteristics of migrants and their adjustments. but this is not easily summarized. The total number of overseas migrants passing from Europe to the Americas. Oceania and Africa from 1800 to 1940 is estimated as being in the vicinity of 60.000,000 persons. of whom about two-thirds to three-fourths remained abroad. These immigrants and their descendants have increased more rapidly than the people in the countries of origin so that their number now approaches that of the population of Europe outside the Soviet Union. There were also smaller but important movements from China, Japan and India to other continents, as well as within Asia.

The partition of India in 1947 involved the forced movement of some 17,000,000 persons. World War II uprooted 25.000 000 to 30,000.000 people in Europe. There were 600.000 displaced persons on the rolls of the International Relief organization in 1946. These were absorbed in new situations; but, because of unresolved political conflicts, the Arabs displaced by the formation of Israel remained in refugee camps into the 1960s.

There was a net overseas migration of more than 4,000,000 persons from Europe during the first postwar decade. 1946–1955. The principal areas of origin and destination are shown in Table VI. Emigrants from Italy, Spain and Portugal went mainly to Latin America. Most of those from northern and western Europe, including Germany, went to the United States or to Commonwealth countries. Migrants from eastern Europe, mostly displaced persons, were widely dispersed; but they contributed a large contingent to the formation of the population of Israel.

THEORIES AND POLICIES

The movement and structure of a population involves the formation of new lives and their persistence through spans varying from a moment to a century. These demographic processes can be measured, and possible interrelations among them can be analyzed in abstraction; but they are essentially biological processes and in human societies they are largely controlled by economic, social and psychological conditions. Moreover, population movements in turn influence all other human affairs. They have social determinants and consequences. The objective study of population in its biological and social context, therefore, can aid in the formation of realistic public policies.

Turning to aspects of population theory that are related to social issues. mention still must be made of the century-old debate between the exponents of two conflicting dogmas, expounded by Thomas Malthus and by Karl Marx, about relations between population and economic conditions. Each of these dogmas contains sufficient truth to inspire enthusiasm in its disciples, but each is a gross oversimplification and distortion of actual situations.

Malthus, who in 1798 published the first edition of *An Essay on the Principle of Population as It Affects the Future Improvement of Society, wzth Remarks on the Speculations of Mr. Godwin, M. Condorcet, and Other Writers,* held that the increase of population enforced by "the attraction between the sexes" constantly tends to exceed the resources for its sustenance and is always subject to the "positive checks" of famine, war and disease. Each advance in the arts is absorbed by a consequent increase of population, thus preventing any rise in the general level of living. This is, indeed, a fair statement of the situation in much of the world prior to the time of his essay and in some areas at later times. But he proceeded on the fallacious assumption that increases in production could never exceed, or even equal. increases in population. He later modified this position by suggesting that under some conditions population might be brought into a more favourable balance with production through the "preventive check," by which he meant the postponement or avoidance of marriage and procreative activity. He repudiated M. Condorcet's suggestion that fertility might be controlled within marriage not only on moral grounds but also for economic reasons because he viewed poverty as a necessary stimulus to economic activity. Some later proponents of birth control who drew support from his economic doctrine called themselves Neo-Malthusians. Malthus applied his exposition of "the population principle" in opposing certain welfare measures which he viewed as futile and dangerous and, in general, repudiated the idea of improving the condition of mankind through changes in economic and social institutions. Marx viewed revolutionary changes in economic and social institutions as inevitable and as leading toward an ideal society. He violently attacked Malthusian theory, just as Malthus had attacked the utopian socialism of Condorcet and Godwin. He equated overpopulation with actual, or latent, unemployment; he described relative overpopulation in this sense as essentially and purely a phenomenon of the capitalist system. Exponents of Marxist doctrine view the control of population and changes in economic institutions as alternative and incompatible approaches to the advancement of levels of production and income.

Most contemporary demographers and economists view constructive changes in economic institutions. the advancement of education and the control of fertility as essentially complementary processes—none of which can be effective in the long run unless reinforced by the others. They point to specific ways in which rapid increase of population in low-income countries hampers economic and social development. This type of analysis was well summarized in the following quotation from a statement prepared by the United Nations secretariat.

To sum up, population enters into the problem of achieving satisfactory standards of living in the under-developed countries in three principal ways. First, their high birth rates create a heavy load of dependent children per adult. This makes it difficult to save enough, over and above what is required for the support of the workers and their dependents, for needed investments in equipment for economic development. It also seriously complicates the problem of providing the children with the education that is essential for social and economic progress in the long run. This aspect of the population problem is common to all the under-developed countries. Second, falling death rates with high birth rates bring about a rapid increase of population. Large investments must be made to keep the growing numbers of workers equipped even with the same inadequate amounts of working equipment per man as they have had in the past. So the possibilities for investments which would improve the equipment and raise productivity per worker are diminished. This speeding up of population growth, aggravating the shortage of capital, is now taking place in very many under-developed countries, wherever successful public health campaigns have greatly reduced death rates. Third, many of the under-developed countries have an excessive density of agricultural population in relation to the area of cultivated land. The average iarmer has too little land to make a satisfactory living for himself and his family. Not all under-developed countries face this difficulty, but it exists in some which have large amounts of unused land, as well as in those where nearly all the cultivable land is fully occupied. At least some of the countries now suffering from acute agricultural over-population might be able to employ all their numbers to good advantage, and benefit in the long run from a substantially larger population, if they were better equipped to utilize the land resources which they possess, or if they could industrialize. But neither the necessary improvements of agriculture nor the development of industry can easily be accomplished, and the difficulties are increased by high birth rates and rapid population growth. It appears that even in a country where population growth would be economically advantageous in the long run, economic progress will be hindered if the birth rate is so high and if the population grows so rapidly as to put an excessive strain on the economy. (From *Population Growth and the Standard of Living in Under-Deneloped Countries,* a summary of relevant chapters of UN Dept. of Social Affairs. *Tha Determinants and Consequences of Population Trends, UN* Population Studies no. 20 [1954].)

The social aspects of population have generally received much less attention than the economic aspects. though in some situations they may be even more important. For example, there are important relations between population trends and education. A high ratio of children to adults. characteristic of many poor areas with high fertility. requires a larger expenditure per adult to maintain a given standard of schooling than where the proportion of adults is higher and may hamper the recruitment of qualified teachers. Again, the-character of the adult population in areas of heavy inmigration, e g., most cities. is strongly affected by levels of education in other regions. This reinforces the thesis that education is not purely a matter of local concern. Moreover. if the less-educated elements in a population are more reproductive than those with higher education, the cultural force of education in successive decades is weakened. This trend may be largely a transitional phenomenon; but the extent to which it may reflect persistent conditions requires greater attention. On the other hand, the advancement of education may be a potent force in promoting the regulation of births. These brief comments suggest larger and more complex problems on which as yet there is little knowledge. The distribution of genetic factors is inevitably affected by differences in reproduction rates. But, again. this is a momentous issue on which present knowledge is sadly deficient. Some governments, including among others those of Sweden the Soviet Union. Japan and many of the state governments of the United States, have taken special measures (sterilization) to control fertility by persons handicapped by defects or diseases that frequently involve genetic factors.

During the late 1920s and the 1930s, when birth rates were falling rapidly in Europe, North America and Oceania, there was much alarm about "the retreat from parenthood"—reinforced in some countries by considerations of national security. Demographers were to some extent responsible for exaggerating the dangers in this situation through misplaced confidence at that time in the net reproduction ratio as an index of intrinsic population trends. Moreover, some economists viewed the slackening of population growth as tending to cause economic stagnation and chronic unemployment. It was. in any case, apparent that demographic changes were increasing the proportion of aged persons in the population.

These considerations led to the advocacy of measures for promoting the maintenance and growth of population as a matter of public policy. Quite different measures to this end were advanced in different countries and by different groups within the same country. In France concern about population trends. in conjunction with other interests, led eventually to a comprehensive system of family allowances and related measures, in which the government still makes a large investment each year, which actually offset at least in large part the costs of additional children in many French families Some programs of financial aid to families with children have been adopted in most European and many non-European countries, including Canada. These programs are usually designed to serve various ends, and it is often difficult to say to what extent they express population policies. Moreover, most governments have been reluctant to authorize expenditures on a scale comparable to that accepted in France. More blatant but less expensive pronatalist measures were inaugurated by the Italian Fascist and the German National Socialist regimes.

Laws against the promotion or sale of contraceptives, as such, as well as stringent legislation against abortion are supported in some countries by demographic as well as religious considerations. The qualitative aspects of population trends were taken explicitly and seriously into account in general population policies only in Sweden. And even there the early program. which included this emphasis along with other welfare features, has been revised in favour of direct subsidies to families with children. Many governmental programs designed to promote fertility without much expenditure of public funds had practically no effect. In some other countries, notably in France. it is impossible to say to what extent pronatalist programs may have influenced actual population trends.

Policies designed to promote the limitation of births have been officially adopted by the governments of Japan. India. Pakistan and Puerto Rico and have been proposed with various reservations in China, Ceylon and Egypt. The inauguration of the Japanese program was followed by a rapid decrease in births, but the method most widely accepted to achieve this end (abortion) is not acceptable in most countries. Governmental action in this field in Puerto Rico has been restrained by strong opposition, but there has been some lowering of fertility in the island. The government of India has intensified its efforts in this direction. with increased appropriations. Governmental action on this question in Pakistan dates from 1960. These programs may eventually influence actual population trends, but they encounter inherent difficulties under the conditions of rural life in the Indian subcontinent.

The importance of population questions is officially recognized in the councils of the United Nations. The 15-member Pooulation commission, a permanent expert body of the United Nations Economic and Social council, keeps population problems under continuous review. Areas of concern include population problems of underdeveloped countries, mortality, fertility and migration studies. age structure, labour supply and aging, and population estimates and forecasts.

POPULATION ECOLOGY. A relatively recent research interest among biologists is the study of groups of organisms as contrasted with the study of individuals. As is meli appreciated, much of biological knowledge rests upon the morphology, physiology and biochemistry of those units that comprise the organism (*e.g.,* cells, tissues, systems) and upon knowledge of the entire organism considered as a whole. However, it is becoming increasingly evident that significant problems and principles emerge when the reactions of animals considered as populations are investigated. This has many parallels in scientific inquiry including many areas of biology. Thus, in the study of tissues (histology). a cell as a single unit, groups of cells and the particular tissue itself all must be subject to analysis. This is equally true of population research. Not only is it essential to understand the interactions between an individual and its surroundings but, also, it is equally necessary to understand those new interactions that emerge when the group operates as a unit within its particular physical environment. This, once accomplished, is logically followed by consideration of different kinds of populations so that a body of general information about the subject is built. It is in this may that population biology grows as a unified science in its own right.

Population biology falls into two broad categories: population genetics and population ecology. The first, concerned with the processes of organic evolution, lies outside the scope of this article but is treated elsewhere (see EVOLUTION, ORGANIC; GENETICS OF POPULATIONS). The second forms the subject matter here to be discussed. A general distinction between the two subdivisions can be drawn as follows: The student of population genetics is concerned primarily with events within the population leading to qualitative hereditary differences—with the transmission in time of genes through the group and with those agents that affect this transmission such as mutation, selection (*q.v.*), isolation, breeding structure and so on. The student of population ecology on the other hand is concerned primarily with quantitative events within the population—with those environmental factors, regardless of type, which affect the group's size, its composition and its growth and life history. This distinction between these two major fields becomes somewhat arbitrary if carried too far. because actually both depend to a considerable extent upon each other.

The subject matter of ecology (see ECOLOGY, ANIMAL) can be considered under four categories, each of which represents a grade of biological organization of increasing functional and structural complexity. The four are: the individual organism, the single species population, the mixed or several species population and the community. Knowledge of the ecology of single organisms—that is, of the interactions between one animal and its immediate environment—is designated autecology and is fundamental for an understanding of populations. Similarly, information about populations is fundamental for an understanding of the ecology of communities (synecology), those complex plant and animal assemblages existing in nature as essentially self-sustaining units. Although, when investigating a population, the ecologist must be informed about the autecological relations of its members, he must also study the groups as such. It follows, too, when communities are studied, that, in addition to research on the component populations, a suitable synthesis cannot be formulated without analysis of the communities as wholes.

The primary focus of population research is on numbers. A population may be defined appropriately in several ways: "The organisms, collectively, inhabiting an area or region"; or, in another version, "A group of living individuals set in a frame that is limited and defined in respect of both time and space." These definitions have at least four implications: number of individuals, likeness of kind enumerated, aliveness and limitation of universe in space and time. In other words, the definition of a biological population deals with these questions: (1) How many organisms are there? (2) Are the forms counted biologically alike? (3) Are members of the group living? (4) Where do the forms live and in what places?

Census Methods.—Since the study of populations involves a count of those organisms present in a circumscribed area or volume, it follows that the single most significant technical procedure in population research is the taking of an adequate census. This assumes several forms, depending upon the particular situation. Population size is usually determined, or at least approximated, by one of the following methods:

Total Count of All Individuals of *All* Stages *or Classes.*—This is the only single census method that is completely accurate. It counts in a delimited environment every individual regardless of age, sex, stage of development or location. It is only occasionally that the method can be used because: (1) the number of animals usually is too great; (2) it is technically impossible or at best not feasible; and (3) the precision it affords is not worth the effort. Modern censuses of human populations for civilized countries approach the perfection the total census method demands.

Total *Count* of All Individuals of a Certain Stage or *Class.*—This method is used either because it is sufficient to know only how many members of a specified category are present within a population or else it represents the best that can be done under the circumstances. For example, in censusing an insect population the student may be concerned only with the number of adults and ignore, say, the number of eggs, larvae and pupae.

Method of Sampling.—This is the usual method employed in estimating population size. It assumes that the investigator can form a judgment about the entire group, however delineated, by withdrawing replicated aliquots. This method can be highly accurate when the pattern of distribution of the forms is understood and the samples are taken with this in mind. On the other hand, it is replete with pitfalls at the hands of the unskilled and can lead to gross errors of interpretation.

The successful application of sampling methods depends on firsthand information about the ecology of the group under study; on a knowledge of what constitutes an adequate sample, followed by appropriate statistical treatment of the data once collected; and, above all, on wisdom and judgment in 'evaluation of the findings.

Method of Biomass.—This method utilizes weights of population samples (biomass) instead of counts of individuals. The weights are always reported relative to some defined spatial unit and may be treated directly as such in analysis of the data or else converted into number of individuals.

Registration *Method.*—This method requires that, after an initial census has been taken, each birth, death, immigration and emigration within the population shall be recorded at stated time intervals. Population size is then enumerated as follows:

$$\text{population size} = \text{initial size} \pm ([\text{births} + \text{immigrations}] - [\text{deaths} + \text{emigrations}]).$$

This method is of minor practical importance because it frequently is difficult to obtain the requisite facts about births, deaths and dispersion, and because it is usually simpler to count the members directly.

Method of &farking.—This useful technique is gaining rapid adoption among students of insect and mammal populations. In one of its variants the procedure is as follows: a known number of marked animals is turned loose within the habitat. It is assumed that, since these presumably redistribute themselves as they were before being caught, then in a sample taken later the proportion of marked to unmarked forms can be determined with total population size estimated by solving this equation:

$$\frac{\text{total number of marked animals released}}{\text{total number of unmarked animals}} = \frac{\text{marked animals caught in census period}}{\text{unmarked animals caught in census period}}.$$

The unknown to be solved for is the denominator of the first fraction—a solution readily obtainable by simple algebra.

Indirect Methods.—Sometimes it is impossible to count numbers of animals at all but it is possible to approximate their abundance only by some product of their activity—the greater the product, the larger the size of the group. This is the poorest of all census methods and is, or should be, used only as an extension of other techniques or as a last resort. These are certain manifestations that have been utilized in estimating population numbers: the number of fecal pellets (rabbits, foxes); of shed antlers (deer); of tracks (rabbits, birds); pelt records (fur-bearing mammals of commercial significance); the frequency of vocalization (bird calls, howls, etc.), and so on.

In certain instances, as has been recommended, various methods can be combined to advantage.

Scope of Population Ecology.—Modern population research falls into the following practical categories:

1. Studies of natural (field) populations. These are both intraspecies (single species) and interspecies (several species) in character.
2. Studies of experimental laboratory populations (both intraspecies and interspecies).
3. Studies of human populations (intraspecies).

4. Epidemiological studies (interspecies, as interpreted in this article).
5. Theoretical population ecology (both intraspecies and interspecies).

Natural population studies usually deal with the distribution, total size, territorial relations, predation and other interspecies competitions and the relation of the population to its immediate physical environment. Insects, fishes and their planktonic foods, birds and mammals have been most studied as natural populations.

Laboratory population studies make their prime contribution through control of the physical and biotic environment. They attempt to analyze a specific group relationship that would be either extremely difficult or impossible to study in many natural populations. The objective of such research is to illuminate population operations by means of relatively simple, yet not artificial, models, and then to apply the results to groups in nature. In the laboratory these are the general problems most studied: at the intraspecies level, population growth form, analysis of population density and the effects of density on reproduction and death; at the interspecies level, competition for a shared food supply or niche in which to live, and the interactions between predators, parasites and prey. Microorganisms (protozoa, bacteria, yeasts), insects and certain rodents have been employed most extensively in such investigations.

Human population studies are treated elsewhere from other points of view (*see* SEX RATIO: *Human, at Birth and Death;* LONGEVITY).

Epidemiological studies as viewed here are limited to population aspects of host-parasite interactions, although some students refer to epidemics of single species. Many of these are statistical, deal with pathogenic organisms and hence are of clinical significance. Such diseases in epidemic form as tuberculosis, diphtheria, the common cold, influenza, acute anterior poliomyelitis, septic sore throat, typhoid fever, typhus, sleeping sickness and malaria have been investigated from this point of view. In these instances man is the host organism, but the findings are of distinct importance for population ecology. In a book by F. M. Burnet, himself a medical scientist, entitled *Biological Aspects of Infectious Disease,* the following pertinent statement appears:

> Other workers with an appreciation of modern developments in biology are finding that infectious disease can be thought of with profit along ecological lines as a struggle for existence between man and micro-organisms of the same general quality as many other types of competition between species in nature (by permission of the Cambridge University Press).

In addition to the studies with a clinical motivation there exist important laboratory studies of host-parasite interactions using insect materials.

Theoretical population ecology is still in an early stage of development. Workers have concentrated on three aspects: mathematical rationalizations, the problem of the origin and integration of social groups and synthesis of knowledge to build a conception of population integration, that is, how a group as such is controlled through its own functional organization.

Natality, Mortality and Dispersion.—In all scientific inquiry there are particular focal points of study. The physicist stresses the behaviour of atoms and molecules; the geneticist, the transmission and physiology of genes; the cytologist, the structure of the cytoplasm and the nucleus, and so on. The student of population ecology is always concerned in final analysis with three composite statistical factors—natality, mortality and dispersion—and those forces that affect them. These factors shape the course of population growth form, its composition and survival as to age, sex and stage of development, and its distribution in space and time. Natality has the effect of increasing the size of the group. Mortality, the total deaths exhibited by the population, has the effect of decreasing the size of the group. Dispersion can operate, at least temporarily, in either direction depending upon the form it assumes, numbers being increased by immigrations and decreased by emigrations.

Natality can be viened as either potential or realized. Potential natality is that maximum number of eggs that the species can produce; realized natality is the birth rate. Were potential natality realized, each individual member of the population would need to exist under ideally optimal conditions. Obviously, this situation is rarely if ever attained in nature, which suggests that populations characteristically produce many fewer offspring than their physiological capacities allow. A valid ecological generalization is that species with high natality potentials are subject to excessive mortality of their eggs. while the converse is typically true for species with lower natality potentials. For example, P. S. Galtsoff (1930) estimated that a single oyster has the capacity of producing 55,000.000–114,000,000 eggs during a lifetime, when it is clear that only a relatively few of these mature. Similarly, J. L. Hart and A. L. Tester (1934) reported that a population of 1,000,000–9,000,000 herring in certain areas of the Strait of Georgia produce annually 8,000,000,000–75,000,000,000 eggs, of which perhaps 95% hatch and less than 0 1% reach maturity. On the other hand, the potential natality of the human female is comparatively low but the realization of this potential in terms of reproductive effort is high.

It is meaningful also to view mortality as potential or realized. F. S. Bodenheimer (1938) defined the former, which he called physiological longevity, as ". . . the average longevity of individuals of a population living under optimal conditions and of genetically homogeneous stock," and the latter, which he called ecological longevity, as ". . . the empirical average longevity of the individuals of a population under given conditions" (*Problems of Animal Ecology,* Oxford University Press). If a population is studied under situations approaching potential mortality, and if these data, expressed as survival against time, are then compared with a similar population under known conditions of realized mortality, the difference between the two curves indicates that approximate part of the total mortality caused by a suboptimal environment and that part which would occur even under the most favourable conditions. In a sense, potential mortality connotes the best that a group can do in terms of its life duration. while realized mortality connotes how much a group actually is decimated when confronted with hazards of various sorts. Among these hazards may be mentioned such items as unfavourable climate, excessive cronding, adverse biotic pressures engendered by predatory and parasitic organisms and accidents.

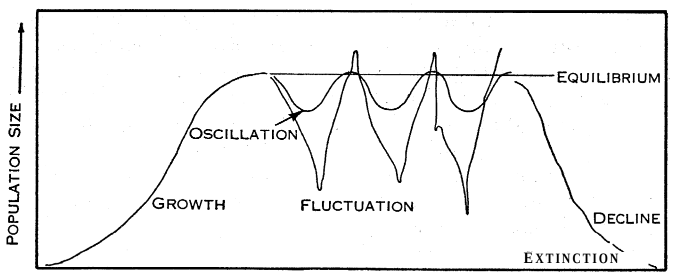
Obviously, great differences exist betneen species in the extent of ecological mortality to which they are subjected, some regularly having many deaths because of many causes and others having few deaths because of few causes. with numerous gradations between. Populations of grasshoppers living under exposed conditions in plain and prairie habitats exemplify a group with a high realized mortality; honeybees living protected in hives with a highly perfected social organization exemplify a group with relatively low realized mortality.

Cases of potential mortality that approach the theoretical conditions were reported by R. Pearl and S. L. Parker (1924) on *Drosophila melanogaster*, by B. Noyes (1922) and Pearl and C. R. Doering (1923) on the rotifer *Proales decipiens*, and by B. P. Wiesner and N. M. Sheard (1935) on laboratory populations of albino rats. Ecological mortality was assessed by Bodenheimer for natural populations of the locust *Schistocerca.* He reported these specific mortalities for the various stages of the life cycle: eggs 13%. nymphal period 67.5% and adult period 19.5%. Not all causes of death were accounted for, but it does seem clear that the eggs are particularly subject to insect parasitization and fungus disease, while the nymphs and adults are eaten by lizards, birds, small mammals and, sometimes, by man.

Although it is necessary to discuss natality and mortality as if they are single factors, it becomes immediately apparent, however, that it is their interaction that is significant in terms of the behaviour of the total population. Thus, a high birth rate taken by itself is of minor value without knowledge of the corresponding death rate reported for the same group over the same time interval. Such a birth rate might suggest that the population is vigorously expanding, while actually, as is so frequently true, the death rate could be so severe that members added by reproduction are canceled by deaths, uith the result that the population remains stationary. Similarly. a low birth rate does not necessarily indicate a declining population, because it may be associated with a correspondingly lower death rate. A single empirical statistic has been proposed, known as the birth-death ratio or vital index, which shows at a glance this relationship between natality and mortality. This is defined as 100 births ÷ deaths, and yields upon solution the number of births for each 100 deaths. In the absence of sustained immigration or emigration a vital index greater than 100 shows that the group is growing; less than 100, that the group is contracting; and equal to 100, that the group is stationary.

The interactions of natality and mortality are decisive in controlling the growth form of populations only when the group is not dispersing over its territory to any extent or when it is not adding to or subtracting from its membership as a result of migratory phenomena. Thus, as mentioned above, the pattern of movement of animals must be considered in all population studies, in addition to reproduction and death, whenever it effectively alters size or composition. Dispersion may take the form either of slight movements or rearrangements within the population, mass movements of the group itself or income from immigrations and outgo from emigrations. In nearly all natural populations such movements are occurring either sporadically or with considerable regularity. When these are of a magnitude to alter markedly the size of the population, internal adjustments must occur. Characteristically, but with exceptions, if a group loses constituents, the spaces thus made available are filled through more effective reproduction. If it gains members through the influx of new organisms, the pressure of competition for food, shelter, mates, etc., increases, and a higher death rate is brought about.

Population Growth Form.—As populations pass through their life history they assume certain patterns that are called, collectively, growth form. Knowledge of growth form is basic for the development of population ecology in that it provides a single numerical statement about how groups have behaved in time. It is obvious that a particular growth form is the product of the interactions between natality, mortality and dispersion. The following somewhat arbitrary phases constituting the growth form can be recognized and are stylized in fig. 1.



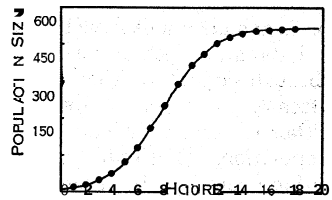
POPULATION LIFE HISTORY

FIG. I.—STYLIZED REPRESENTATION OF POPULATION GROWTH FORM

1. The period of positive growth (the population increasing).
2. The period of equilibrium (equilibrium is defined as mean numerical stability).
3. Oscillations and fluctuations (departures from equilibrium).
   A Oscillations (relatively symmetrical departures).
   B. Fluctuations (relatively asymmetrical departures).
4. The period of negative growth (consistent and progressive decline of the population below equilibrium or below the lower range of usual fluctuations and/or oscillations that jeopardize the population's survival).
5. Extinction (the disappearance of the population).

The growth (*q.v.*) of populations usually follows a sigmoid (S-shaped) curve when represented by number of organisms on the ordinate axis (vertical) against time on the abscissal axis (horizontal). This holds for many species of animals, including man, and abundant data have been accumulated for both laboratory and natural groups. In fact, a considerable segment of population biology has been concerned with fitting such data with a particular equation known as the logistic curve that, upon solution, yields a growth curve which is characteristically sigmoid. Fig. 2, from Pearl, The Biology of Population Growth (1930), illustrates this curve when applied to the multiplication of yeast cells within a spatially limited environment. The smoothed line is the calculated function, the dots are the actual census counts. The curve demonstrates that rate of growth is at first slow, then rapid, then slow again as the maximal number possible (asymptote) under the existing ecological conditions is approached.

After this asymptote is attained, assuming there are no marked changes in the exploitable potentialities of the environment, several courses are open to the population. It can maintain itself with slight variability at the mean maximal size (equilibrium); it can oscillate in even and regular dips and peaks about that maximum (oscillation); it can vary above and below the average equilibrium value in a more-or-less irregular fashion (fluctuation) or it can steadily contract (decline). If the contraction continues, the entire population dies (extinction).



ADAPTED FROM PEARL, THE BIOLOGY OF POPULATION GROWTH" (KNOPF)

FIG. 2.— THE LOGISTIC GROWTH OF A LABORATORY POPULATION OF YEAST

Initial sigmoid population growth is rarely demonstrable with any precision in nature, primarily because most groups have long since passed that original phase of their life history when censused. It can be demonstrated readily in the laboratory, however. Nor is equilibrium, oscillation. protracted decline or extinction often seen under field conditions. Most groups react so sensitively within themselves and with their surroundings that an even, sustained equilibrium is unusual. Oscillations demand such a regularity and repeatability of causal mechanisms that they too are rare events. A population decline that jeopardizes the future survival of the group is seen somewhat more often in nature, especially following an unfavourable climatic disturbance leading to increased mortality or decreased food supply or after exposure to a particularly virulent epidemic, but it too is exceptional. The extinction of definitive populations is likewise infrequent. Cases of species extinction are known, and occasionally the underlying reasons are understood; but as a rule populations are adaptable enough so that they compensate in one way or another for environmental vicissitudes before their contraction goes irreparably far.

Thus, by elimination, fluctuation remains the usual event so far as population growth form is concerned. Populations characteristically vary above and below an average equilibrium value. This variation may be caused by chance alone, but it is more likely to result from fundamental, yet temporary, adjustments between the group and its effective environment. The magnitude of the variation can be great or small in terms of total population size (ordinate axis). in terms of the time intervals between the fluctuations (abscissal axis) and in terms of the species involved.

Density-Independent and **Density-Dependent** Factors.—It is necessary to develop population ecology beyond a consideration of natality, mortality and growth form. While these aspects constitute the background for such studies in the sense that interactions of the first two induce a pattern of growth, it is clear that they in turn are influenced by factors of ecological origin. These, falling into two broad categories known as density-independent and density-dependent factors, merit brief definition and illustration (see bibliography, H. S. Smith).

It will be apparent from the discussion above that, as a population passes through the phases of growth form, the degree of crowding, or density, of its members characteristically varies to a considerable extent. Certain factors of the environment have virtually the same effect on the group's members regardless of this density relation. and these are called density-independent. Another set of factors, known as density-dependent, achieve notably different results when crowding is slight, as compared with the results obtaining when crowding is extreme. Thus, a particular unfavourable temperature might eliminate through mortality 60%, say, of a population, whether that population had a census of 100 or 1,000 members per unit area. On the other hand, this same population might not be vulnerable to predatory attack, or to disease in epidemic form, when composed of only 100 individuals but, alternatively, highly vulnerable when 10 times larger. These important distinctions can be clarified by actual cases.

Density-independent factors are largely products of the physical-chemical environment. Density-dependent factors stem primarily from biotic interactions between organisms. For terrestrial populations the more usual density-independent factors are the following: temperature (high, low and alternating), precipitation (both excess and deficient), wind and storms, atmospheric pressure. humidity, light and certain aspects of food supply. For aquatic populations, the' physical and chemical qualities of the water, water movements, light penetration, substratum effects and. again, selected aspects of food supply constitute the more characteristic density-independent agents.

A satisfactory illustration of a density-independent interaction between a particular environmental factor and a particular population is afforded by the report of Gordon Gunter (1941) on the relation of unusually low temperatures to mortality of fishes inhabiting the gulf waters of the Texas coast. The winter of 1939–40 was severe in that area, and on Jan. 18, 1940, an extremely cold wave brought about a drop in temperature within a few hours from 65° to 25° F., and then reached 16° that night. Many fish died from the cold, as was ascertained by experimental seining and the presence of corpses along the beaches. These deaths were also reflected in the fishery statistics reported annually for this region. For example, while the months of February–March–April for 1938 yielded 1,331,302 lb. of fish, and the same months for 1939 yielded 911,133 lb., the catch for 1940, subsequent to the cold spell mentioned above, was only 335,431 lb. Unquestionably. this decline reflected direct mortality caused by cold. When these statistics are broken down in various ways, as for example by localities and species, the same point holds. Of all the forms. the flounders were the most susceptible. The catch of these was 94.8% less after the cold days than it was for the winter months immediately preceding the unusual temperatures. This clearly illustrates a density-independent phenomenon in that the mortality is directly caused by temperature and appears to be unrelated to the density of the various fish populations.

Studies of the pollution of waters by industrial wastes, when coupled with the consequent effects of this chemical poisoning upon a particular population, offer further instructive examples of density-independent operations. This phenomenon is well kno n for a number of species, and frequently it can be shown that mortality stands in direct proportion to the kind and quantity of the pollutant but is primarily independent of the crowding of the group members. In general, the pollutants affect organisms in several ways. Acting directly, they can predispose to infection, increase egg and juvenile mortality. drive motile forms from their habitats and actually kill the adult members of the population subjected to them. Acting indirectly, they can reduce oxygen supply, harm or at least change the flora and further limit the habitats and food supply.

Although many examples could be selected to illustrate the density-independent action of pollution, a cogent one is that reported by P. S. Galtsoff, W. A. Chipman, A. D. Hasler and J. B. Engle (1938) concerned with oyster populations of the Tork river in Virginia. The years from the 1920s have seen a progressive decline of this population and the industry depending upon it. This started with the liberation of trade wastes into the river by a pulp mill. Apart from pollution, the York river is favourable for oyster culture. Careful comparative studies with ecologically similar neighbouring streams well populated with oysters show this to be true. This fact, along with the observed reduction of oysters follouing pollution, incriminates the latter as the causal agent. Experimental studies in the laboratory demonstrated that the wastes had a decided effect upon the mollusk's physiology. The pollutant induced a prolonged contraction of the adductor muscles with the consequence that the shells remained closed for undue periods of time, thus interfering with respiration and feeding. Also, the pollutant inhibits the ciliary activity of the gills, thereby preventing water from circulating with its customary efficiency. Such impairments of the oysters' physiology causes the individuals to be dwarfed, and they fail to store normal levels of glycogen. The entire case is proved, for when the oysters mere returned to clean water, and provided they had not been exposed to the poison for too long, their normal rate of growth was restored and glycogen was again deposited in adequate amounts.

Thus, a single density-independent factor, pollution, is identified, its effect on population decline is appraised and the physiological channels through which it acts are experimentally detected. It is interesting to note in passing that the authors found some oysters which resisted the pollution enough to continue to survive and reproduce and so maintain a relatively small population in the York river.

Although the above examples of density-independent operations deal with aquatic populations, it should be pointed out that terrestrial forms have also been actively studied from this point of view. In fact, much of the research along this line actually was developed by ecologically minded entomologists (see bibliography, B. P. Uvarov; A. J. Nicholson: H. S. Smith; W. R. Thompson).

Analysis of population density has been an active research interest of the population ecologist and leads, of course. into a consideration of density-dependent factors—those agents nhose effect upon the population varies with the crowding of its members. A systematic treatment of population density falls under three categories: the sorts of processes and events that are known to be influenced by density; the type of end result brought about by density regardless of the mechanisms involved (density as related to growth form) and the constitution of density per se.

A wide variety of processes are known to be affected by changes in density. Among these the following should be mentioned: the three primary variables governing population growth form—natality, mortality and dispersion—and such responses as the postembryonic development of insects; the individual growth of organisms; the rate of oxygen consumption; protection from noxious agents in the surrounding environment; resistance of marine forms to sea water diluted as to salt content; aggregating activity of bacteria and protozoa; sex determination and, occasionally, even the modification of anatomical characters.

Operating through reproduction and mortality, density affects the growth form of populations either by inducing decline or stimulating growth. The former aspect has been extensively studied and much is known of it. The latter aspect received the active attention of W. C. Allee (1931) and his associates, who marshaled many data showing that, under a wide variety of conditions, organisms crowded to some degree respond more effectively than others of their own kind that are either isolated, or nearly so, or else exist under extremely dense conditions. This optimal population effect has been advanced as evidence for an unconscious co-operation—an expression of the fact that, through its own integrative mechanisms. a group of certain size and composition is better adjusted within its environment, usually with reference to its survival, than is one either larger or smaller.

Analytical studies have shown that population density usually brings about an effect through one of two mechanisms. In some cases it is the actual behaviour relations between organisms that are responsible for the observed result, such interactions varying in their intensity with the degree of crowding. In other cases, density may operate through some secondary effect upon the environment as, for example, reduction of the available food supply or addition of waste products to the habitat, both of which obviously change with the size of the population. Two examples, the relation of crowding to production of eggs by cultures of the fruit fly (Drosophiln *melanogaster*) and the conditioning of flour by beetles (*Tribolium confusum*), illustrate these points.

The Drosophiln case was originally investigated by Pearl (1932) and was extended by F. IV. Robertson and J. H. Sang (1944). Pearl demonstrated that as the population density of adult flies increases, the number of eggs produced per individual female decreases. In other words, fecundity is inversely proportional to crowding. In an analysis of the causal factors underlying this effect, experiments were set up that varied the air volume in the culture bottles in the presence of initial fly densities ranging from 1 to 128 paired Drosophila, with the area of agar surface to which the flies were exposed the same in all cases. It was reported that, while this volume of air above the surface had no significant effect on oviposition, the degree of crowding of the flies on the agar was highly significant. That is to say, the real density effect is essentially limited to one niche within the system. Through a careful series of observations on the behaviour of crowded and uncrowded flies, Pearl concluded that Drosophila will not oviposit if they are in contact with, or disturbed by, other flies, and that individual flies do not obtain as much food under such conditions even though there is an ample supply available. This was called interference or collision, and it was suggested that the probability of collisions between flies on the surface of the agar plate increased with the density. This investigation thus links the population effect through egg production to two behaviour mechanisms — the inability of the flies to lay eggs and to feed adequately when disturbed by their fellows. The later experiments of Robertson and Sang showed that the reduced fecundity associated with crowding reported by Pearl could occur only when the flies were competing for food and therefore inadequately nourished because of this competition.

As suggested above, density can also affect a population by altering the habitat as well as by influencing the interactions between the component organisms. It was shown for the flour beetle (Thomas Park and Nancy Woollcott, 1937, and Park, 1941) that, as these beetles occupy their flour, which they never leave, they modify it through reduction of its nutritive value and the liberation of harmful waste products. This modification, designated environmental conditioning, is density-dependent because the degree of such conditioning is related in time to the number of beetles that have inhabited the flour. Conditioning thus emerges as a population product owing its existence entirely to the alteration of the habitat by the group activity. Studies have shown that flour beetle populations always decline when the medium (flour) is not renewed. that it thus becomes progressively more conditioned and that this is a cause of decline as well as an effect. It has been demonstrated that the conditioning operates primarily by reducing the beetles' fecundity and, secondarily, by extending the duration of their metamorphosis and increasing the mortality during this period.

Although density-independent and density-dependent factors have been treated as though they fall into discrete categories, the impression should not be left that this is always true. One environmental factor, or several in conjunction, frequently can operate in both ways at the same time. In fact, for natural populations this may be the rule rather than the exception.

Summary. — Even in so brief a treatment as that developed in this article, the following points should be apparent and are offered as a general summary:

1. Populations as such may be effectively studied in the field or laboratory either as intraspecies or interspecies units, using many sorts of species from widely divergent habitats.
2. Such study forms an integral part of ecology and is closely related to population genetics, evolution and biometry (*q.v.*).
3. The population constitutes a distinct level of biological organization and is to be thought of as a fundamental, responsive unit within its particular environment.
4. Since population size furnishes a convenient end index of many population phenomena and since size is usually determined by counting, census methods become the single most significant technique for population ecology.
5. The change in size of populations with time is divisible into certain continuous phases spoken of collectively as growth form.
6. Growth form is under the control of prior interactions between natality, mortality and dispersion. Natality as a single factor is related to population increase; mortality, to population decrease; and dispersion may induce either result depending upon the pattern it assumes.
7. Natality, mortality and dispersion are in turn influenced by ecological factors falling into two broad categories, density-independent and density-dependent.
8. Population density affects many responses in addition to natality, mortality and dispersion; it can favour both population growth and decline, depending upon local conditions, and it can operate either through actual behaviour interactions between constituent organisms or through modifications imposed upon the habitat.

Research Areas of Population Ecology. — In concluding this article it is meaningful to list those actual problems which characterize the significant research areas under study by population ecologists. These are as follows:

1. Numerical studies describing population growth form.
2. The effect of weather and other factors of the physical environment on growth form.
3. Analysis of population equilibria.
4. The problems of underpopulation, optimal population and overpopulation. This involves analyses of population density from various points of view.
5. The productivity of populations, and factors that influence it.
6. The problem of the optimum yield. Simply stated, this means to what extent can a group be exploited and still maintain itself?
7. Description and analysis of population cycles.
8. Analysis of dispersion within and between groups.
9. Analysis of ranges and territories established and inhabited by natural populations.
10. Epidemiological aspects of the interactions between host and parasite populations.
11. Intraspecies and interspecies competitions.
12. The organization of social populations; as, for example, the social insects, infra-human primate hordes and man.
13. Improvements and extensions of population census techniques.
14. Study of population integration; that is, those interactions between the factors that control population activities.

Several brief comments are appropriate about these problems. It is clear that some of them are primarily intraspecies, some primarily interspecies and some can be either, depending upon how the problem is specifically formulated. It can be stated didactically that all 14 problems have significant theoretical content for ecology generally and, also, that many of them have decided economic applications. Population studies assume a pragmatic value for man: (1) when a desirable species is not perpetuating itself to a great enough extent and something needs to be done about it; (2) when a species is so heavily exploited by man that he must intervene in an effort to counteract the exploitation by artificially stimulating the species to increase (this is a special case of [1] above and is illustrated by the fishing industry or by problems centring on the conservation of game and fur-bearing animals); (3) when a noxious form, for example an insect pest, endangers a particular crop or product and either must be exterminated or controlled; and (4) when a pathogenic population endangers the public health and, again, must be controlled or eradicated.

These situations as stated in the above four cases cannot be solved with any lasting validity, and without unforeseen complications, unless the entire population is viewed as an integral, functional part of its complete environment, the analysis then proceeding accordingly. Specifically, it could prove unwise to stimulate or decimate populations beyond their normal growth form solely on the grounds that the species were valuable or deleterious to man's interests. Such procedures may do more harm than good. For example, the indiscriminate use of such a potent insecticide as DDT in eliminating admittedly injurious organisms from an area might, by also eliminating locally necessary species, bring about irreparable damage even if measured only in terms of economic loss. It seems inescapable that real understanding of these applied problems of ecological character must rest upon extensive knowledge of the fundamental biology involved, and it is here that population ecology can contribute in a practical way to human well-being in addition to its more intangible, but equally exciting, contribution of a strictly intellectual nature.

POPULIST PARTY, a short-lived minor political party that flourished in the United States in the 1890s. Officially named the People's Party of the United States of America, it was founded at Cincinnati, O., May 21, 1891, by a mass convention of delegates representing the discontented farmers of the northwest and the south. Following another preliminary convention held at St. Louis. Mo., in Feb. 1892, the Populists met in national convention at Omaha, Neb., on July 4, 1892, and nominated James B. Weaver of Iowa for president and James G. Field of Virginia for vice-president. The platform of the new party demanded principally the free and unlimited coinage of silver at the ratio of 16 to 1; the repossession by the. government of unused lands it had given to the railroads; government ownership and operation of all railroad, telegraph and telephone facilities; and a graduated income tax. In the presidential election of 1892 the Populist ticket polled 22 electoral votes and more than 1,000,000 popular votes. By fusing with the Democrats in certain states the Populists mere able also to elect several members of congress, three governors and hundreds of minor officials and legislators. nearly all in the northwest. In the south most of the farmers refused to endanger white supremacy by voting against the Democratic party.

Populist gains in the midterm elections of 1894 were considerable, but when the Democrats nominated William Jennings Bryan in 1896 on a free silver platform, the Populists endorsed him, although nominating their own vice-presidential candidate, Thomas E. Watson of Georgia. After Bryan's defeat, most Populists became Democrats. A small residue known as "fusionists" endorsed Bryan, the Democratic candidate, again in 1900, while another element of the party nominated Wharton Barker of Philadelphia. A splinter group supported "middle-of-the-road" tickets, both state and national, as late as 1912.

See J. D. Hicks, *The Populist Revolt* (1931); Richard Hofstadter, *The Age of Rejorm* (1955). (J. D. H.)

POPULONIA, an ancient seaport town of Etruria, Italy (Etruscan Pupluna), at the north end of the peninsula of Monte hfassoncello, at the south end of which is situated the town of Piombino (*q.v.*). The place, almost the only Etruscan town built directly on the sea, was situated on a lofty hill now crowned by a conspicuous medieval castle and a poor modern village (Populonia). It commands a fine view, and Corsica is sometimes visible, though not Sardinia, as Strabo and, following him, Lord Macaulay erroneously state. Considerable remains of its town walls, of large irregular, roughly rectangular blocks (the form is that of the natural splitting of the schistose sandstone), still exist, enclosing a circuit of about $1\frac{1}{2}$ mi. The remains existing within them are entirely Roman—a row of vaulted substructions, a water reservoir and a mosaic with representations of fishes. Strabo mentions the existence there of a lookout tower for the shoals of tunny fish. There are numerous tombs outside the town, from the Villanova period (9th century B.C.) to the middle of the 3rd century B.C. Under heaps of ancient slag removed for resmelting in modern times, a considerable number of chambered inhumation tombs of the 8th–7th century B.C. were discovered; all were originally covered by circular mounds of earth; the roof was a false dome formed by the projection of each course of stones beyond the one below it. The remains of a temple, devastated in ancient times, were also found. The iron mines of Elba and the tin and copper of the mainland were owned and smelted by the people of Populonia; hot springs lay about six miles to the East (Aquae Populaniae) on the highroad—Via Aurelia—along the coast. At this point a road branched off to Saena (Siena). According to Virgil the town sent a contingent to the help of Aeneas, and it iurnished Scipio with iron in 205 B.C. It offered considerable resistance to Sulla, who took it by siege; and from this dates its decline which Straho, who describes it well, already notes as beginning. Four centuries later Rutilius describes it as in ruins The harbour continued to be of some importance and the place was still an episcopal see under Gregory the Great.

See A. Minto, *Populonia* (Elorence, 1922) for a full description.

PORBANDAR (properly PORBUNDER), a port on the south-western coast of Bombay state, India; pop. (1951) 58.824. The seaboard terminal of the railway line from central Saurashtra, Porbandar is also a centre for cement, silk and cotton manufactures and cotton ginning and pressing. It was the birthplace of Mahatma Gandhi.

The former princely state of PORBANDAR (area 642 sq.mi.; pop., 1941, 146,648) extended along the coast northwest and southeast of the port, its capital. It was within the Western Kathiawar States agency before its merger with Saurashtra on Feb. 15, 1948. Saurashtra merged with Bombay state in the reorganization of Nov. 1. 1956.

PORBEAGLE (Lamna *cornubica*), a species of shark, belonging to the Selachians (*q.v.*). The body is short and stout and contrasts strikingly with its much-attenuated tail, which is strengthened by a keel on each side and terminates in a powerful caudal fin. The porbeagle has formidable pointed teeth, but is a fish eater, not considered dangerous to man. It attains a length of 10 to 12 ft. and is a pelagic fish chiefly of warm seas but not rare in the North Atlantic and Mediterranean and frequently wandering to British and more rarely to North American shores as far as Nova Scotia. See SHARK.

PORCELAIN: see POTTERY AND PORCELAIN.

PORCELAIN ENAMELING. A porcelain enamel is a thin layer of glass fused to a metal to enhance its beauty, to prevent corrosion, or both. Porcelain-enameled iron is used extensively for both domestic and industrial articles. In addition to its use for kitchenware (see Enamel-wave, below), bathtubs and sinks, it is used extensively for table tops, refrigerators, washing machine tubs and stoves. Industrially, it is used for advertising signs, chemical and food tanks of large sizes, hospital furniture, grocery, meat market, supermarket and restaurant equipment, and has found application in architecture for the facing of the outsides of buildings. A porcelain enamel, being a glass, has the properties of glass; namely, its hard. glossy surface and resistance to solution, corrosion and scratching. The metal backing and design greatly influence its strength and resistance to damage. The quality of porcelain enamels varies greatly, depending upon the glass used, the design and the manufacturing technique.

History.—Although the term porcelain enameling (also called vitreous enameling or enameling) did not come into common use until about 1929, enamels were used far back in the early history of man, first as glass beads fused onto metal, later as medallions and finally, in the first half of the 18th century, as a protective surface". Although jewelry enamels, art pieces and photographs in enamels are still made and highly prized (for cloisonné, champlevé, etc., see ENAMEL; JEWELLERY). enamels on sheet steel and cast iron constitute the principal part of the modern industry.

Manufacture.—Although the early developments took many years, the transition of enameling from an art to an industry in the early part of the 19th century proceeded very rapidly. Cast-iron dry-process enamels were the first to be used on a large scale. In this process, the castings, such as bathtubs. mere first sand-blasted to give them a clean surface. The grip or ground coat was then applied. This ground coat consisted of a powdered glass, clay and water suspension uith a consistency about like that of cream. This was dipped, slushed or sprayed on the cool casting and allowed to dry. The ware was then introduced into a furnace at about 900° C. and allowed to come to the temperature of the furnace. The hot ware was withdrawn from the furnace and powdered glass dusted through a screen over it. This powdered glass melted as it fell on the hot ware and formed a continuous layer of enamel. Several applications were generally made, the ware being returned to the furnace for reheating before each application. This process is particularly applicable to the manufacture of heavy castings.

Another process which has come into common use is that of wet-process cast-iron enameling. This is used on lightweight or thin castings and has been adopted extensively in the stove industry. In this process, the ground coat is generally applied as a suspension of the glass with clay in water, dried and then fired in a furnace at about 750° C. The ware is removed from the furnace, cooled: the second coat applied and then refired. This process is sometimes known as the U.S. process for enameling cast iron.

Sheet-steel enameling has become the process most widely used for porcelain enamels. In this process, the sheet steel is fabricated and put through a cleaning and pickling process which prepares the surface for enameling. Sheet-steel enameling requires a ground coat containing a small percentage of cobalt to give it adherence. This ground coat is applied by the wet process, dried and then fired in a furnace at about 830° C. After the ware has been removed from the furnace and cooled, a second coat of cover enamel is applied by the wet process. This cover coat may be of any desired colour and may have special properties depending upon the use to which the ware is to be put. It is commonly sprayed or dipped onto the ware, allowed to dry and then fired at about 830° C. Additional coats of enamel are sometimes applied. and finally the decoration is applied and fired into the last coat.

Although enameling is an important industry in most countries, the use of automatic equipment. technical control and mass production is outstanding in the United States.

Enamelware. — Metal kitchenware, such as pots and pans, the surface of which is protected and decorated by a thin layer of porcelain enamel is known as enamelware. Prior to the advent of enamelware such utensils were made of pottery, copper, cast iron and to some extent tinned sheet iron. Aluminum and stainless steel, introduced in the 19th century, have come into common use.

In the kitchenware industry, enamelware is produced chiefly in large modern plants, with machine operations and a great deal of automation and control. Ware made in the second half of the 20th century is far superior to any of that made prior to World War II. In the manufacture of enamelware a good grade of low-carbon sheet iron is formed in the shape of the utensil by pressing or drawing, by spinning and by trimming; the handles, spouts and ears are welded in place by spot or resistance welding. The ware is then cleaned in a chemical detergent bath, rinsed in water, pickled in acid (usually 5% sulfuric acid), rinsed and neutralized in a bath of sodium hydroxide. borax or sodium cyanide. In some cases the ware is treated in a nickel sulfate bath prior to neutralizing to improve enamel adherence. The shapes are finally dried, sorted and inspected.

Enamel glasses are prepared by melting the raw materials together and quenching in a water spray and bath. These operations are called smelting and fritting, and the product, which is broken glass, is called frit. The frit is dried and weighed with mill additions such as water, clay and special suspending agents. This mill batch is charged into ball mills of about 1,000- to 3,000-lb. capacity and ground to a fineness of about 2% on a 200-mesh sieve. The product is a thick slurry called slip, the properties of which must be accurately controlled.

Enamel usually is applied in two coats each being fired separately. The first coat, called a ground coat, is an enamel containing cobalt. A typical composition is shown in the accompanying table. It usually is applied to the shapes by dipping, the properties of the slip being such that the excess drains off or is thrown off in the special handling of the ware just after it is removed from the slip bath. After drying it is fired, usually in a continuous conveyor furnace, at about 1,500" F., with four minutes in the hot zone of the furnace.

The ground-coated ware is next coated with the slip of the cover enamel (see table) in a similar manner, dried and fired. Where white is desired, the cover enamel is usually an acid-resistant titanium opacified enamel. Special compositions are needed for the colours, for the bead on the rim or for handles. In very special

Typical Enamel Compositions

Component	Ground coats (%)		White cover enamel (%)
	A	B	C
Borax	35.0	35.0	—
Feldspar	21.0	21.0	—
Quartz	28.0	21.0	41.5
Soda ash	4.5	6.0	—
Soda nitre	4.0	4.5	5.7

Cobalt oxide	0.5	0.5	—
Nickel oxide	0.5	0.5	—
Manganese dioxide	1.5	1.5	—
Dehydrated borax			22.6
Titanium dioxide			17.6
Potassium silicofluoride			8.0
Sodium silicofluoride			1.3
Monosodium phosphate (dehydrated)			3.3
Totals	100.0	100.0	100.0

Mill additions	Ground coat (parts)	Cover coat (parts)
Frit A	40% }100	
Frit B	60% }100	
Enamel clay	7	5
Water	40	40
Frit C	—	100
Electrolytes	Various	Various
Totals	147	145

cases a third firing is used for special decorations.

Enamelware is usually acid-resistant, withstanding fruit and vegetable acids to a high degree. When made under modern conditions, it is very resistant to impact. The enamel fails only when the piece is subjected to a deformation of the iron, which results in a cracking of the glass coating. Enamelware is very resistant to thermal shock, but cold water should not be put in a hot dry pan. Enamelware will withstand all temperatures used in cooking. It has a hard, scratch-resistant surface and can be cleaned with all common cleaning materials, but harsh abrasives such as sand should not be used as they scratch any glass surface.

PORCH, originally a roofed structure, usually open at the sides, to protect the entrance of a building; loosely used of any projecting portico, or even of any colonnade and, in the United States. of any roofed structure open at the sides and front, attached to a house or other building; synonymous with veranda or piazza. A sleeping porch is such a structure usually opening from an upper story.

ALINARI

PORCH OF SAN ZENO MAGGIORE. VERONA. 12TH-CENTURY ITALIAN ROMANESQUE

Of the porch proper there are few extant remains prior to the classic period. although Egyptian wall paintings seem to indicate their occasional use with houses. The most important Greek porches are those of the Tower of the Winds at Athens (1st century B.C.), in which two columns of a simple Corinthian order carried a pediment. A similar porch exists in the so-called villa of Diomed at Pompeii. Houses in Rome sometimes had long colonnades facing the street which served as porches. During the Romanesque period simple projecting porches covering the western doors of churches are found instead of the earlier basilican colonnaded narthices. Especially interesting are the projecting porches of the Italian Romanesque. such as that of S. Zeno Maggiore at Verona (12th century), in which the columns are carried on marble lions (as frequently in Lombard work) and at

Modena (12th century) and Parma (13th century). In Apulia there are many similar porches of distinct Lombard character

In France, especially in Burgundy, an even greater development of the porch occurred, in which it became a vaulted structure of great height and importance, two or more bays long and sometimes as wide as the entire church. The great porch of the abbey church at Vézelay (1132–40), sometimes termed an antechurch, is the largest and richest. In Norman work in England church porches are more frequently at the sides of the nave than at the west end. An interesting example is that at Southwell minster (early 12th century).

The English love of picturesqueness sometimes developed the porch to such an extent that it became almost a separate building which was called a "galilee," like that at Durham (1175). Galilees in medieval churches are supposed to have been used sometimes as a court of law, or a place where corpses were placed before interment, but the galilee probably served chiefly as a chapel for penitents before their admission to the body of the church. Many fantastically rich projecting porches occur in French Flamboyant churches. such as that of the church of Notre Dame at Alençon (c. 1500), the pentagonal porch of St. Maclou at Rouen (c. 1520) and the side entrance of the cathedral at Albi (early 16th century).

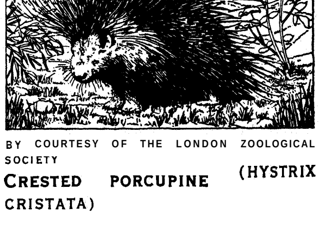
The same richness of porch design is not found in English Gothic churches. where western doors are often small and unimportant; an exception. all the more remarkable for its unique character, is the west front of Peterborough cathedral (c. 1220), in which the doors are deeply recessed within great arches, 81 ft. high, forming a most impressive porch. The other type of porch, the small projecting gabled feature projecting from the north or south walls of the nave, was, however, highly developed throughout the course of English Gothic. In small examples, in parish churches, the porches are usually of wood. with a richly decorated bargeboard running up the gable and often panels of intricate tracery at the sides.

In the larger city churches there was frequently a room over the porch, sometimes known as a porch chamber and sometimes incorrectly termed a parvis. These seem to have been used sometimes as vestries, sometimes as treasuries and sometimes as chantry chapels. Similar porches, with chambers above, occur occasionally in Tudor mansions, as in the house of Compton Winyates (c. 1520).

In Germany churches of the Flamboyant Gothic period are frequently decorated with western porches of the most fantastic richness, with a great use of cusping, pierced tracery and canopy work. Such are the double-arched entrance of the cathedral at Ulm (c. 1390) by Ulrich von Ensingen and the triangular porch of the cathedral at Regensburg by M. Roritzer (1482–86).

During the Renaissance the porch was usually treated as a portico (*q.v.*), but simple porches of two or four columns were exceedingly common features of the late 18th-century houses of England and the United States. (T. F. H.)

PORCUPINE, the name of the largest European terrestrial rodent, distinguished by the spiny covering from which it takes its name. The European porcupine (Hystrix cristata) is the typical representative of a family of old world rodents, the Hystricidae, all the members of which have the same protective covering. They range over the south of Europe, the whole of Africa, India and the Malay archipelago as far east as Borneo. They are all stout, heavily built animals, with blunt rounded heads, fleshy mobile snouts and coats of thick cylindrical or flattened spines, which form the whole covering of their body and are not intermingled with ordinary hairs. Their habits are strictly terrestrial. The common porcupine, which occurs throughout the south of Europe and north and west Africa, is replaced in south Africa by H. africaeaustralis and in India by the hairy nosed porcupine (H. *leucura*).



BY COURTESY OF THE LONDON ZOOLOGICAL SOCIETY
CRESTED PORCUPINE (HYSTRIX CRISTATA)

There are several smaller species with long tails in northeast India, the Malay region and Africa. In the new world the porcupines are represented by the family Erethizontidae. The spines are mixed with long soft hairs. They are less nocturnal in their habits, and with one exception live entirely in trees; certain of the species accordingly have long prehensile tails. They include three genera, of which the first is represented by the Canadian porcupine (Erethizon dorsatum), a stout, heavily built animal, with long hairs almost or quite hiding its spines, four front and five hind toes and a short, stumpy tail. It is a native of the greater part of Canada and the United States, wherever there is any remnant of the original forest left.

Coendou contains some eight or ten species, known as tree porcupines, found throughout tropical South America, with one extending into Mexico. They are of a lighter build than the ground porcupines, with short, close spines, often mixed with hairs, and prehensile tails The hind feet have only four toes as a result of the suppression of the first.

PORDENONE (GIOVANNI ANTONIO DE' SACHIS) (c. 1483–1539), a north Italian painter who, although basically influenced by Venetian painting, shows an element of violence which probably derives from Germany. He was born at Pordenone, in Friuli, in about 1483; however, the date of his birth rests only on the statement by G. Vasari that he died in 1540 (instead of 1539) at the age of 56. Pordenone was a pupil of Pellegrino da S. Daniele and other Friulian masters, but his style is founded on Venetian models and in particular on Titian; later he was influenced by Correggio and also by the Roman works of Michelangelo and Raphael and it is assumed, therefore, that he went to Rome, probably about 1515/16.

He worked in Treviso, Mantua, Genoa and Cremona as well as in Friuli and all over northern Italy. Even in Venice his work was so popular that for a short time he was a serious rival to Titian himself, and on one occasion the senate of Venice gave him the preference for a commission. Unfortunately, his frescoes in Venice have perished, but he painted a dome in Piacenza in the illusionistic manner of Correggio (1529–31). He was invited to Ferrara by Ercole II but died there soon after his arrival and was buried on Jan. 14. 1539. There are many documented and dated works by Pordenone, the earliest being a fresco at Valeriano, signed and dated 1506.

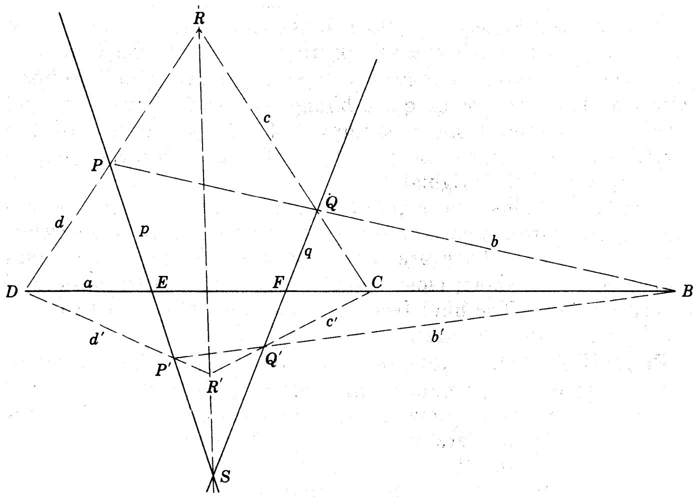
See C. Ridolfi, Le Maraviglie dell' Arte, etc. (1648; ed. by Hadeln, 1914–24); G. Fiocco, Giovanni Antonio Pordenone, 2nd ed. (1943). (P. J. MY.)

PORDENONE, a town of the province of Udine, Friuli-Venezia Giulia. Italy. 30 mi. W. by S. of Udine on the railway to Treviso. Pop. (1951) 21,895. It was the birthplace of the painter generally known as Pordenone (*q.v.*). Paintings from his brush adorn the cathedral (nhich has a fine brick campanile), and others are preserved in the Gothic town hall. Cotton industries are active. also silk and pottery.

PORI, formerly Bjorneborg, a seaport of Finland in 61° 29' N., 21° 43' E., on the Kumo river, 18 mi. from its harbours, Reposaari and Mantyluoto. Pop. (1950) 43,213. It imports coal, coke and flour. and exports timber and timber products. The river is 9 ft. deep. The town has ship-repairing yards. but vessels larger than 300 or 400 tons have to be careened. Reposaari, the "town harbour," used only for local traffic. is usually icebound from December to March. Mantyluoto is the new harbour, equipped with cranes, railroad tracks and quays for five large steamers, being ice-free until January.

PORIFERA, a phylum of the animal kingdom comprising the sponges. See SPONGES.

PORISMS, the title of a treatise written by Euclid (c. 300 B.C.), the author of the Elements. This book, no longer extant, is known only through the account given by Pappus (*q.v.*) of Alexandria (c. A.D. 320) in the seventh of the eight books of his Collection. The calibre of this material is such that Sir Thomas Heath characterized the Porisms as "a distinctly advanced work, perhaps the most important that Euclid ever wrote" (*The* History *of Greek Mathematics,* London. Oxford University Press, 1921). Translated from the Greek into Latin toward the close of the 16th century, this work of Pappus was the subject of study by scholars who endeavoured to reconstruct the original, an effort not unconnected with the development of projective geometry.



FROM B L VAN DER WAERDEN SCIENCE AWAKENING (P NOORDHOFF LTD)

ILLUSTRATION OF THE FIRST OF EUCLID S PORISMS SOLID LINES INDICATE THOSE THAT ARE FIXED IN POSITION. BROKEN LINES SHOW TWO POSITIONS OF THE VARIABLE LINES

The word porism (from *porizein,* "to carry" or "to produce") has several shades of meaning. In Euclid's *Elements* there are instances when a theorem (*q.v.*) is followed by the words "*Porism.* From this it is manifest that . . ." and a statement that is a corollary to the theorem. For example:

Euclid III, 1. *To find the centre of a circle. Porism* . . . if in a circle a straight line cuts a straight line into two equal parts and at right angles, the centre of the circle is on the cutting line.

Euclid IV, 15. *In a given circle to inscribe an equiangular and equilateral hexagon. Porism* . . . the side of the hexagon is equal to the radius

Euclid VII, 2. *Given two numbers not prime to one another, to find their greatest contmon measure. Porism* . . . ii a number measure two numbers, it will also measure their greatest common measure.

Pappus, quoting "older writers,' gave three classes of propositions:

A theorem is directed to *proving* what is proposed.
A *problem* is directed to *constructing* what is proposed.
A *porisnz* is directed to *producing* or *finding* what is proposed.

Heath suggests that the usual form of a porism was "to prove that it is possible to find a point with such and such a property or a straight line on which lie all the points that satisfy given conditions." Tobias Dantzig summarizes the matter in these terms: "The only thing certain about the *Book of Porisms* is the title, and even here there is no general agreement as to the sense in which Euclid used the term'! *(Bequest of the Greeks,* p. 36, Charles Scribner's Sons, New York. 1955).

As noted above, knowledge of Euclid's *Porisms* comes from the statements of Pappus of Alexandria, who has been characterized as a "belated geometer" because his work came at a time when higher geometry had been neglected for more than five centuries. He assembled materials dealing with many topics — higher plane curves, the trisection of an angle. the squaring of the circle, the duplication of the cube and others. From these he compiled a handbook and wrote a commentary to be read together with the classic that was being treated. In many cases, he described improvements on or extensions of the proofs in the original documents, and inserted additional theorems or lemmas. Since this is true of those works that are still extant, it may be assumed that it was true in the case of those which subsequently were lost.

Pappus states that the *Porisms* contained 171 propositions and 38 lemmas. He gives examples of a few of the propositions and adds 38 lemmas of his own. He begins by stating a proposition that he says epitomizes the first ten of Euclid's porisms. It reads:

If in a system of four straight lines which cut one another two and two, three points on one straight line be given, while the rest except one lie on different straight lines given in position, the remaining point also will lie on a straight line given in position.

Thus in the accompanying diagram, three points of intersection of the lines b, *c,* d lie on *a,* namely D, *C, B.* Two other points *P* and Q are on the fixed lines *p* and *q,* with *p* and *q* intersecting *a* at E and F, respectively. In a second position the variable lines *b', c', d'* intersect the lines *p* and *q* at *P'* and *Q',* respectively. It follows that the remaining point of intersection R' lies on the line that passes through the join of *p* and *q* and the point R. Pappus stated that this theorem is true of any number of straight lines intersecting two by 'two.

B. L. van der Waerden discusses the 13 lemmas that Pappus added to this porism, noting first that when two different positions of the variable lines are drawn, as is the case in the accompanying diagram, it is the theorem of Desargues (1636):

If two triangles are so situated that the lines joining pairs of corresponding vertices are concurrent, then the points of intersection of pairs of corresponding lines are collinear, or, as it appears in projective geometry, if two triangles are perspective from a point, they are perspective from a line, and conversely.

The lemmas that follow include the seeds of the ideas of the theorem of the complete quadrangle, of six points in involution, of four harmonic points and a special case of Pascal's hexagon.

Pappus' *Collection* was translated from the Greek into Latin by Federico Commandino (1509–75). Several editions of this work appeared, and in 1660 there mas a revision of it by Carlo Manolesse. The Latin and Greek text with notes was published by F. Hultsch in 1876–78.

The problem of reconstructing the *Porisms* from the evidence offered by Pappus is a challenging one. H. W. Turnbull describes it as being like trying to follow a chess game by listening to the comments of an intelligent onlooker. Pierre de Fermat (1601?–65) was one of the first to attempt the reconstruction, Michel Chasles (1860) was one of the latest. In the course of this work Chasles was led to the important idea of anharmonic ratios. In his opinion, the *Porisms* belong to the modern theory of transversals and to projective geometry. H. G. Zeuthen (1886) suggested that the *Porisms* may have been corollaries to a fully developed projective geometry of conics.

(V. SD.)

PORK. Pork is the flesh of the domestic pig used for food. It is the most popular meat in the American dietary, probably because its cost is usually lower than that of other meats and because of the variety of ways in which it can be used. Pork is used both fresh and cured. Because of its high fat content, pork is an energy food. The lean of pork is a good source of high-quality protein. phosphorus and iron. Pork is rich in vitamin B_1 or thiamin. Pork liver is one of the best sources of food iron.

Pigs are among the most efficient converters of grain and by-product feeds to fat. The majority of pigs are marketed during the winter and spring months. Since the major portion of the pork carcass is processed by curing. the marketing of pork products may be spread out over the entire year. Most pigs are marketed at 6 to 12 months of age and at weights ranging from 185 to 250 Ib. Pigs are usually dressed packer style; *i.e.,* head off, leaf lard and ham facings off and centre split. The average dressing yield is 69%.

Soft Pork. — The flesh of immature pigs and also that from pigs which have been fed feeds high in soft fats, is likely to be soft. Such pork does not firm up on chilling, is unattractive and, therefore, is discriminated against by consumers. Soybeans, peanuts, rice polish and mast! when used extensively, produce soft pork. The nutritive value of soft pork is as high as firm pork.

Pork carcasses are classified as butcher, packing and bacon hogs. Butcher carcasses are smooth, high-quality, well-finished carcasses suitable for choice, fresh and cured cuts. Packer hogs are usually coarse, low-grade, under- or over-finished carcasses which must be used for lower-priced products. A considerable number of sows which have been discarded from the breeding herds gravitate into this class. Bacon carcasses are light in weight, moderately finished and suitable for making Wiltshire sides (*see* BACON) or choice breakfast bellies.

Grades of pork carcasses and cuts are fewer in number than of beef and lamb. This is due to the fact that most pigs are slaughtered when they are relatively young and nearly all pigs are well-fattened at slaughter time. Consequently, there is less difference between grades. Grades are frequently designated numerically, No. 1, No. 2, No. 3 and cull; or choice, good, medium and cull.

The ideal pork carcass should be compact, straight-sided and thick-fleshed. The shanks should be short and the ham plump and the loin thickly-fleshed. The belly or bacon should be deep, long and smooth. The shoulder should be compact and should blend into the body smoothly.

A choice carcass should be well but not excessively fattened. The fat down the back should be about 1½ in. thick, although there will be some variation with different classes and weights of carcasses. Both excessive or deficient fat will cause a lowering of grade. The fat down the back should be uniform in thickness, firm, white and flaky, not rubbery.

Quality in a pork carcass is indicated by a thin, white skin free from wrinkles; fine joints and shanks. The lean should be a bright pink and fine-textured.

The most sought-after cuts of pork are ham, loin and belly or bacon. Hams are usually cured and may be sold regular (skin on), skinned, or boned. The loin is usually sold fresh, being used for roasts and chops. Heavy loins are sometimes boned out after the tenderloins are removed. The boneless loin strips are cured and smoked as Canadian style bacon.

The entire shoulder is called a long-cut or New York style shoulder which is used as a fresh cut. Many shoulders are cut in two, the lower half usually being cured as a picnic shoulder. The upper half has the layer of fat (clear plate) removed after which it is designated a Boston style of butt which is used for roasts and steaks. Sometimes the blade bone also is removed from the butt in which case the butt is known as a boneless butt. Boneless butts are usually cured and smoked.

The fat back, the covering over the loin, if more than 1¼ in. thick, may be cured in dry salt. If less than 1¼ in. thick, it is skinned and rendered for lard. The fatty covering over the shoulder is cured if sufficiently thick. The jowl or cheek also may be cured and smoked.

The belly or bacon if of choice quality, may be cured and smoked. Low-grade bellies are used for dry salt meats.

To a large degree, weight determines dollar-and-cents values of pork cuts. Within certain limits, the lighter-weight cuts are preferred because of their leanness.

The major portion of the pork carcass may be cured or processed. The proportion actually cured will depend upon price differentials between cured and fresh cuts. Pork trimmings are used for a wide variety of sausages and lunch meats. The fat of the pig is rendered into lard which is one of the most popular culinary fats. It is almost completely digestible, has a wide plastic range and produces very tender, flaky pastry. Lard is manufactured by three methods; kettle rendered, steam rendered and dry rendered. The best lard is made by the kettle-rendered process in which the hashed lard is cooked in an open kettle with constant stirring. Most of the commercial lard is made by the prime steam method whereby the stock is cooked in a tank by steam under pressure and in direct contact with the lard. Refined lard is prime steam lard which has beep bleached either with Fuller's earth or activated charcoal. Sometimes lard stock is hashed and rendered in a steam-jacketed cooker. This is known as dry rendering. About 13% of the live weight of a pig is lard.

Pork **By-products.**—The by-products of hog slaughter are less valuable proportionately than those of cattle or sheep. Aside from sausage and lard, there are edible offal such as livers, hearts, tongues, brains, pork feet, ears, lips, snouts, tails and chitterlings (made from the large intestine). Pigskin is a light but durable leather suitable for gloves, insoles and novelties. Some pigskin is used for gelatin manufacture. Hog casings are used for sausage. Pig stomachs are used for sausage containers and are a source of pepsin. Some of the glands are used in making pharmaceutical preparations. Pork fat not suitable for edible use is designated as grease. It is used for soapmaking and other industrial uses. Animal feeds are made from residues not suitable for human food. Hog hair is used for upholstery and insulation. (For diagram of cuts of pork see FOOD PREPARATION.)

POROS or PORO ("the Ford"), Greece, an island off the east coast of the Peloponnesus, separated at its western end by a narrow channel from the mainland at Troezen, and consisting of masses of limestone and trachyte connected by a sandy isthmus. Area 7 sq.mi. Pop. (1951) 4.141. The harbour town faces S. toward the mainland The English, French, and Russian plenipotentiaries met at Poros in 1828 to discuss the basis of the Greek government.

The ancient Calauria, with which Poros is idehtified, was traditionally given by Apollo to Poseidon in exchange for Delos; and in historic times was famous for a temple of the latter, the centre of an amphictyony of maritime states—Hermione, Epidaurus, Aegina. Athens, Prasiae, Nauplia, and Orchomenus, the distribution and legends of which suggest that their association goes back to Minoan times. Here Demosthenes took sanctuary with "gracious Poseidon," and, when this threatened to fail him, sought death. The temple of Doric architecture, excavated in 1894, lay on a ridge commanding a view of Athens and the Saronic gulf. Traces also of porticoes and other buildings remain.

Wide, in *Mitteilungen d. deutsch. Inst. Athen.* (1895), vol xx.

PORPHYRIA includes a group of genetic abnormalities with excessive formation and excretion of porphyrins or their precursors. Porphyrins are red pigments, of which protoporphyrin is most widely represented in nature, imparting the red colour to the circulating hemoglobin. Two main forms of porphyria are recognized, porphyria erythropoietica (bone marrow) and porphyria hepatica (liver). The former is characterized by greatly excessive porphyrin formation in certain of the developing red blood cells. The urine is dark red, bones and teeth reddish brown, due to uroporphyrin, normally present only in traces in the body and excreta. This is also responsible for light sensitivity appearing in early infancy, with blisters and eventual scarring and deformity of face and hands. Enlargement of the spleen and anemia are common. Removal of the spleen has benefited some cases. Protection from sunlight is essential.

The hepatic group comprises (1) an intermittent acute form represented by formation of colourless precursors in the liver, attacks of abdominal pain, nervousness, weakness or paralyses. at times fatal; (2) a late cutaneous form (commonly fourth to eighth decades of life, at times earlier) with marked porphyrin formation in the liver, photosensitivity and scarring; and (3) cases combining features of (1) and (2). (C. J. WA.)

PORPHYRY (Πορφύριος) (A.D. 233–*c.* 304), Greek scholar, historian, and Neoplatonist, was born at Tyre, or Batanaea in Syria. He studied grammar and rhetoric under Cassius Longinus (*q.v.*). His original name was Malchus (king), which was changed by his tutor into Porphyrius (clad in purple), a jesting allusion to the colour of the imperial robes. In 262 he went to Rome, attracted by the reputation of Plotinus, and for six years devoted himself to the study of Neoplatonism. Having injured his health by overwork, he went to live in Sicily for five years. On his return to Rome, he lectured on philosophy and endeavoured to render the doctrines of Plotinus intelligible to the ordinary understanding. His most distinguished pupil was Iamblichus. When advanced in years he mamed Marcella, a widow with seven children and an enthusiastic student of philosophy. Nothing more is known of his life, and the date of his death is uncertain.

Of his numerous works on a great variety of subjects the following are extant: *Life* of *Plotinus* and an exposition of his teaching in the Ἀφορμαὶ πρὸς τὰ νοητά (Sententiae ad *intelligibilia* ducentes, Aids to the study of the Intelligibles). The *Life* of *Pythagoras,* which is incomplete, probably formed part of a larger history of philosophy down to Plato. His work on Aristotle is represented by the Introduction (εἰσαγωγή) to and Commentary (ἐξήγησις, in the form of questions and answers) on the Categories. The first, translated into Latin by Boetius, was extensively used in the middle ages as a compendium of Aristotelian logic; of the second only fragments have been preserved. His Χρονικά, a chronological work, extended from the taking of Troy down to A.D. 270.

Other grammatical and literary works are Ὁμηρικὰ ζητήματα (*Quaestiones homericae*); and *De* antro *nympharum,* in which the description in the Odyssey (xiii, 102–112) is explained as an allegory of the universe. The Περὶ ἀποχῆς ἐμψύχων (De abstinentia), on abstinence from animal food, is especially valuable as having preserved numerous original statements of the old philosophers and the essence of Theophrastus' Περὶ εὐσεβείας (*On* Piety): It also contains a long fragment from the Cretans of Euripides. The Πρὸς Μαρκέλλαν is an exhortation to his wife Marcella to practise virtue and self-restraint and to study philosophy. The letter to the Egyptian priest Anebo, dealing with religious questions, was answered by a member of the school of Iamblichus, who called himself Abammon, in the *De mysteriis.* It is frequently referred to by Eusebius, Cyril and Augustine. Eusebius preserved fragments of the Περὶ τῆς ἐκ λογίων φιλοσοφίας (De *philosophia* ex *oraculis haurienda*), in which he expressed his belief in the responses of the oracles of various gods as confirming his theosophical views.

Porphyry is well known as a violent opponent of Christianity and defender of Paganism; of his Κατὰ Χριστιανῶν (*Adversus Christianos*) in 15 books, perhaps the most important of all his works, only fragments remain. Porphyry's view of the book of Daniel, that it was the work of a writer in the time of Antiochus Epiphanes, is given by Jerome. There is no proof of the assertion of Socrates, the ecclesiastical historian, and Augustine, that Porphyry was once a Christian.

BIBLIOGRAPHY.—There is no complete edition of the works of Porphyry. Separate editions: *Vita Plotini* in the *Enneades* of Plotinus (edit. R. Volkmann, 1883); *Sententiae* (edit. B. Mommert, Leipzig, 1907); *Vita Pythagorae, De antro nympharum, De abstinentza, Ad. Marcellam* (edit. A. Nauck, Leipzig. 1885); *Isagoge et in Arzstotelis categorias commentarium* in *Commentaria in Aristotelem graeca* (edit. A. Busse, 1887); *Boethii in Isagogen Commenta* (edit. S. Brandt, Vienna, 1906); fragments of the *Chronica* in *Fragmenta historicorum graecorum* (edit. C. W. Müller, 1849); *Quaestiones homericae* (edit. H. Schrader, 1880, 1890); *Letter to Anebo* in Iamblichus, *De mysteriis* (edit. W. Pharthey, 1857); *De philosophia ex oraculis Haurienda* (edit. E. Wolff, 1856); fragments of the *Adversus Christianos* (edit. G. Georgiades, Leipzig, 1891); English trans., Thomas Taylor, *De abstinentia, De antro nympharum* and *Sententiae* (1823), *De antro nympharum* (new ed. 1917); T. PORPHYRY, a beautiful red or purplish rock used by the ancients for ornamental purposes when cut and polished. The name porphyry (Greek *porphyreds,* "purple") was derived from the older name porphyrites, which in the time of Pliny was applied to purplish and reddish rocks mottled with light spots. Although most of this material was of igneous (volcanic or shallow intrusive) origin, the early Italian sculptors erroneously considered it a variety of marble, of metamorphosed sedimentary origin. The famous red porphyry (*porfido* rosso antico) came from Egypt where it was used in sculpture. Its beauty and decorative value were recognized by the Romans in the time of the emperor Claudius. It was obtained on the west coast of the Red sea, where it forms a dike 80 or 90 ft. thick. For a long time the knowledge of its source was lost, but the original locality of the ancient quarries was rediscovered at Jebel Dhokan.

In a dark red groundmass porphyry contains many small white or rose-red plagioclase feldspars, black shining prisms of hornblende and small plates of iron oxide. The red of the feldspars and of the groundmass arises from the partial conversion of the plagioclase feldspar into thulite (see ZOISITE) and manganese epidote (*q.v.*). These minerals also occur in thin veins crossing the rock. Many specimens show effects of crushing, which in extreme cases has produced brecciation.

Applications of Term.—In petrography the term porphyry is used to designate an igneous rock characterized by abundant relatively large crystals (phenocrysts) set in a matrix or groundmass of fine-grained to amorphous (apparently without crystal structure) material. The porphyries belong to a larger group of rocks, all of which possess a porphyritic texture (phenocrysts and groundmass). Thus, all porphyries have a porphyritic texture, but by no means are all porphyritic rocks true porphyries. Most generally perhaps, the term porphyry is restricted to those porphyritic rocks in which the phenocrysts abound or predominate and which consolidated at shallow depths beneath the earth's surface (hypabyssal rocks). Hence, the true porphyries are most commonly found in sills, dikes and other minor intrusive bodies. Not uncommonly, however, the term is also applied to certain highly porphyritic volcanic rocks, which may resemble the intrusive porphyries.

In the United States the term porphyry is used chiefly in a textural sense. A simple and rather precise scheme is to modify the term by prefixing the common rock name which the porphyry most closely resembles chemically or mineralogically. Thus, granite porphyry, diorite porphyry, etc., are porphyries, compositionally equivalent to the plutonic (coarse-grained) rocks, granite, diorite, etc., respectively. Rhyolite porphyry and andesite porphyry, for example, correspond in composition respectively to the volcanic rocks rhyolite and andesite.

A distinction is to be made, however, between such terms as porphyritic granite and granite porphyry. The former is a true granite; that is, its texture is phaneritic (constituent grains visible without magnification). The latter is not a granite, because its groundmass is aphanitic (constituent grains indiscernible without magnification). A similar distinction is to be made between such terms as porphyritic rhyolite and rhyolite porphyry. Generally the porphyritic rhyolite has a higher proportion of groundmass, which is in itself finer grained or richer in glassy constituents, than the rhyolite porphyry.

The early petrographers (particularly in Europe), in their studies of porphyries and related hypabyssal rocks, placed great emphasis upon the mineral composition of the large crystals, the geologic age of the rocks and the degree to which the rock had been altered. As a result a very complex and confusing nomenclature evolved. Some petrographers prefer to restrict the term porphyry to those types in which the large crystals are principally feldspar (with or without quartz) and to place those types with abundant, large crystals of olivine, pyroxene, amphibole and mica under the lamprophyres.

It is the general practice outside the United States to subdivide the highly porphyritic rocks with an aphanitic groundmass into two classes. Those in which potash feldspar is dominant are called the true porphyries, whereas the plagioclase feldspar types are called porphyrites. The porphyries, under this scheme, are essentially equivalent compositionally to the granites, syenites and nepheline syenites, whereas the porphyrites are compositional equivalents of the diorites and gabbros. In the United States the term porphyrite is nearly obsolete.

Origin.—Theories of origin of porphyries are manifold, and it is highly probable that different porphyries have formed in equally different ways. Many porphyries may have had an interruption in their course of crystallization. The phenocrysts may have formed largely at depth (intratelluric crystals), where cooling of the magma (molten rock material) proceeded slowly, permitting the growth of large scattered crystals. Before complete congelation, however, the magma, with its suspended crystals, was erupted to higher levels and injected as dikes and sills into colder rocks. The cooling effect upon these thin injected sheets was so marked that the liquid phase was rapidly transformed to a fine-grained or aphanitic groundmass.

In other porphyries the large crystals may have developed mainly subsequent to injection. Certain minerals may have developed well-formed crystals before the viscosity of the melt increased sufficiently to retard and restrict diffusion. Changes in pressure on the magma and the loss of dissolved volatiles may have contributed to the formation of porphyritic textures. The role of certain trace elements in controlling crystal growth rates is of possible importance and needs further investigation. Inoculation and incorporation of foreign crystals may explain the porphyritic character of some rocks. (For processes of crystallization see GEOCHEMISTRY: Geochemistry of the Lithosphere.)

Occurrences. — Porphyries occur abundantly as dikes and sills, satellitic to larger masses of compositionally equivalent plutonic rock. Thus, granite porphyry and quartz porphyry are exceedingly common in regions where granitic intrusive rocks occur, Nepheline and leucite rich porphyries, though rare, are associated with larger intrusions of nepheline syenite and leucite syenite. Diorite porphyries (porphyrites) accompany plutonic masses of diorite. Coextensive masses of porphyry may extend as veinlike projections and offshoots from larger parent masses of plutonic rock. Some porphyries, furthermore, appear as marginal phases of the larger intrusions. In such cases the plutonic masses and associated porphyries were probably derived from a common magma.

See A. Johannsen, *A Descriptive Petrography of the Igneous Rocks*, vol. iii (1937). (C. A. CN)

PORPOISE, the common name often applied to any of the smaller, round muzzled toothed whales, but properly restricted to the genus Phocaena. Porpoises, along with dolphins and whales, are included in the mammalian order Cetacea. There is no sharp scientific distinction between porpoises and dolphins, but, generally speaking, the porpoise is smaller and does not have the characteristic beak nose of the dolphin. In North America "porpoise" is generally used to indicate the bottle-nosed dolphin (see DOLPHIN).

Like most other mammals, these superficially fishlike forms breathe air directly and bear live young nhich they suckle. The adult porpoises mate in late summer, and the female bears a single calf, almost a yard long. in about a year. Their life expectancy has been estimated at 30 years. Porpoises feed on schoolin fish, such as herring and mackerel, as well as on squid and other marine animals.

The wide mouth is bounded by stiff, immobile lips, and the underjaw projects slightly. The teeth number betneen 80 and 100. In colour, the porpoise is black or dark gray above and white below, with black flippers. A single dorsal fin is triangular in shape and low.

The common, or harbour porpoise (Phocaena phocaena) attains a length of 4–6 ft. It prefers coastal waters to the open sea and inhabits the North Atlantic area, entering the Baltic in summer; it is rare in the Mediterranean. A distinct form of the common porpoise appears in the Black sea; one or two other species are found in the South Atlantic. The Pacific porpoise is a distinct species. The black finless porpoise (*Neophocaena pho*caenoides) inhabits the warm coastal waters of the Indian ocean.

Porpoise has been used for food — the flesh resembles pork but has a somewhat disagreeable odour to most persons. The oil obtained from the soft fat of the head and jaw of the common porpoise has been used as a lubricant in the manufacture of watches, clocks and other delicate mechanisms made of hard steel. The value of the oil lies chiefly in the fact that it is free from a tendency either to gum or thicken by oxidation, or to corrode metal, and in its ability to withstand exposure to very low temperatures without freezing or thickening to any great extent. The oil was also formerly used in lamps. (K P S.; X.)

PORPORA, NICCOLA [or NICCOLO] **ANTONIO** (1686–1766), Italian operatic composer and teacher of singing, was born in Naples on Aug. 19, 1686. His first opera, Basilio, was produced at Naples; his second, Berenice, at Rome. Both were successful. and he followed them up by innumerable compositions of like character; but his fame rests chiefly upon his unequaled power of teaching singing. At the Conservatorio di Sant' Onofrio and the Poveri di Gesu Cristo he trained Farinelli, Caffarelli, Mingotti, Salimbeni. and other celebrated vocalists. Unfortunately no written account of his method exists; all that remains is the tradition as handed down by his pupils In 1725 Porpora visited Vienna, but the emperor Charles VI disliked his florid style, especially his constant use of the trillo. He then settled in Venice, teaching regularly in the schools of La Pietà and the Incurabili. In 1729 he was invited to London as a rival to Handel; but his visit was unfortunate. Little less disastrous was his second visit to England in 1734, when even the presence of his pupil, the great Farinelli, failed to save from ruin the dramatic company of Lincoln's Inn Fields theatre, set up in opposition to that directed by Handel. The sequence of dates and visits in Porpora's life are variously stated by different biographers. The electoral prince of Saxony and king of Poland had invited him to Dresden to become the singing master of the electoral princess, Maria Antonia, and in 1748 he is supposed to have been made *Kapellmeister* to the prince. Difficult relations, however, with Hasse and his wife resulted in his departure, of which the date is not known. From Dresden he is said to have gone to Vienna, where he gave lessons to Joseph Haydn (*q.v.*), and then to have returned some time betaeen 1755 and 1760 to Naples. From this time Porpora's career was a series of misfortunes. His last opera, Camilla, failed; and he became so poor that the expenses of his funeral were paid by subscription.

PORRENTRUY (1,400 ft.), a town in the northern or French-speaking part of the canton of Bern, Switzerland, a station on the railways Basle-Delémont Delle and Altkirch-Mulhouse. It has famous schools and is an industrial centre; the great majority of the inhabitants are Roman Catholics. The castle overlooking the town was once the residence of the bishop of Basle.

Population of commune (1960) 7,095.

PORRES, SAINT MARTÍN DE (1579–1639), Peruvian Dominican lay brother, was born in Lima, the illegitimate son of a noble Spaniard, Don Juan de Porres. and a Negro woman, Ana Velázquez. As a youth. he was taken by his father to Ecuador and placed in school there. When official duties transferred the father to Panami, the boy returned to the care of his mother in Lima, and the remainder of his life was spent in that city.

When he was about 15 years old, Martin was apprenticed to a barber surgeon In 1601 he became a Dominican oblate, his first duties being to care for the sick friars in the monastery of Santo Domingo. It was not customary at that time to permit a mulatto to enter a religious order in Peru, but because of the exceptional qualities and virtue exhibited by Martin. he was ordered to become a lay brother in the Dominican order in 1610. As a friar. Martin was noted for his kindness to all persons but especially to the poor and the unfortunate; animals also found in him a friend of rare understanding. His greatest sympathy was won by the youth of Lima, for whom he established an asylum and a school, considered by some to be his monument. He died on Nov. 3. 1639. was beatified in 1837 and canonized in 1962; his feast is celebrated on Nov. 5. In 1939 the Peruvian government declared him the national patron of social justice.

See Cyril Martindale, ***Blessed Martin de Porres*** (1920). (A. S. TR.)

PORRIDGE (an altered form of "pottage," Fr. potage, soup, that nhich is cooked in a pot), a food made by stirring meal, especially oatmeal, in boiling water and cooking it slowly until the whole becomes soft. The dish and its name are particularly identified with Scotland; in Ireland it is commonly known as "stirabout." The former application to a broth made of vegetables or of meat and vegetables thickened with barley or other meal is obsolete, and the earlier "pottage" is the usual word employed. The form "porridge" apparently dates from the 16th century. In "porringer," a porridge bowl, the n is inserted as in "passenger" and "messenger."

PORSENA (or PORSENNA), **LARS,** king of Clusium in Etruria. He is said to have undertaken an expedition against Rome in order to restore the banished Tarquinius Superbus to the throne. He gained possession of the Janiculum, and was prevented from entering Rome only by the bravery of Horatius Cocles (*q.v.*). Porsena then laid siege to the city, but was so struck by the courage of Mucius Scaevola that he made peace on condition that the Romans restored the land they had taken from Veii and gave him 20 hostages. He subsequently returned both the land and the hostages (Livy, ii, 9–15; Dion. Halic., v, 21–34; Plutarch, *Poplicola,* p. 16–19). This story is probably an attempt to conceal a great disaster. According to other authorities, the Romans were obliged to surrender the city, to acknowledge Porsena's supremacy, to abandon their territory north of the Tiber, to give up their arms, and in future to use iron for agricultural purposes only. It is curious that, in spite of his military success, Porsena made no attempt to restore the Tarquinian dynasty. Hence it is suggested that the attack on Rome was merely an incident of the march of the Etruscans, driven southward by the invasion of upper Italy by the Celts, through Latium on their way to Campania. This would account for its transitory effects, and the speedy recovery of the Romans from the blow. With the departure of Porsena all traces of Etruscan sovereignty disappear *(see* Tacitus, *Hist.* iii, 72; Pliny, *Nat. Hist.* xxxiv, 39 [14]; Dion. Halic. v, 35, 36, vii, 5). The tomb at Chiusi described by Pliny (*Nat. Hist.* xxxvi, 19) as that of Porsena cannot have been his burial place *(see* CLUSIUM).

For a critical examination of the story, *see* Schwegler, *Romische Geschichte,* bk. xxi, 18; Sir G. Cornewall Lewis, *Credibility of Early Roman History,* ch. xii, 5; W. Ihne, *Hist. of Rome,* vol. i; E. Pais, *Storza di Roma,* i, ch. iv (1898); Macaulay's *Lays of Ancient Rome* gives a dramatic version of the story.

PORSON, RICHARD (1759–1808), English classical scholar, was born on Dec. 25, 1759, at East Ruston, in Norfolk, of humble parents. After attending the village school, he was entered on the foundation of Eton in 1774, and in 1778, through the generosity of Sir George Baker, the physician, entered Trinity college, Cambridge, of which he became a fellow four years later. The publication of his *Notae breves ad Toupii emendationes in Suidam* in 1790 established his fame as a scholar. During the same year, in the *Gentleman's Magazine,* he wrote the three letters on Hawkins's *Life of Johnson,* which have been reprinted in Kidd's *Tracts and Criticisms of Porson,* and in a volume of Porson's *Correspondence.* They are admirable specimens of his dry humour, and prove his intimate acquaintance with Shakespeare and the other English dramatists and poets. In the same periodical, in the course of 1788 and 1789, the *Letters to Archdeacon Travis, on the spurious verse i. John v. 7* (collected in 1790 into a volume), written in defense of Gibbon, had appeared. In 1792, his fellowship being no longer tenable by a layman, Porson moved to London, but in November of the same year was elected to the Greek professorship at Cambridge. Apart from his duties, the tragedians, Aristophanes, Athenaeus, and the lexicons of Suidas, Hesychius and Photius occupied most of his time.

In 1795 there appeared from Foulis' press at Glasgow an edition of *Aeschylus* in folio, printed with the same types as the Glasgow *Homer,* without a word of preface or anything to give a clue to the editor. Many new readings were inserted in the text with an asterisk affixed, while an obelus was used to mark many others as corrupt. It was at once recognized as Porson's work; he had superintended the printing of a small edition in two volumes 8vo, but this was kept back by the printer and not issued till 1806, still without the editor's name. There are corrections of many more passages in this edition than in the folio; and, though the text cannot be considered as what would have gone forth if with his name and sanction, yet more is done for the text of Aeschylus than had been accomplished by any preceding editor. It formed the substratum for all subsequent editions. It was printed from a copy of Pauw's edition corrected, which is preserved in the library of Trinity college.

Soon after this, in 1797, appeared the first instalment of what was intended to be a complete edition of Euripides—an edition of the *Hecuba.*

In the preface he pointed out the correct method of writing several words previously incorrectly written, and gave some specimens of his powers on the subject of Greek metres. The notes are very short, almost entirely critical; but so great a range of learning, combined with such felicity of emendation whenever a corrupt passage was encountered, is displayed that there was never any doubt as to the quarter whence the new edition had proceeded. He avoided the office of interpreter in his notes, which may well be wondered at on recollecting how admirably he did translate when he condescended to that branch of an editor's duties.

His work, however, did not escape attack; Gilbert Wakefield had already published a *Tragoediarum delectus;* and, conceiving himself to be slighted, as there was no mention of his labours in the new *Hecuba,* he wrote a "diatribe extemporalis" against it, a tract which for bad taste, bad Latin and bad criticism it would not be easy to match. Gottfried Hermann of Leipzig, then a very young man, who had also written a work on Greek metres, which Dr. Peter Elmsley styled "a book of which too much ill cannot easily be said," issued an edition of the *Hecuba,* in which Porson's theories were openly attacked. Porson at first took no notice of either, but went on quietly with his Euripides, publishing the *Orestes* in 1798, the *Phoenissae* in 1799 and the *Medea* in 1801, the last printed at the Cambridge press, and with the editor's name on the title page. But there are many allusions to his antagonists in the notes on such points as the final *v*, the use of accents, etc.; and on v. 675 of the *Medea* he holds up Hermann by name to scorn in caustic and taunting language. And it is more than probable that to Hermann's attack we owe the most perfect of his works, the supplement to the preface to the *Hecuba,* prefixed to the second edition published at Cambridge in 1802.

The metrical laws promulgated are laid down clearly, illustrated with an ample number of examples, and those that militate against them brought together and corrected, so that what had been beyond the reach of the ablest scholars of preceding times is made clear to the tyro. The laws of the iambic metre are fully explained, and the theory of the pause stated and proved, which had been only alluded to in the first edition. A third edition of the *Hecuba* appeared in 1808, and he left corrected copies of the other plays, of which new editions appeared soon after his death; but these four plays were all that was accomplished of the projected edition of the poet. Porson lived six years after the second edition of the *Hecuba* was published, but his natural indolence and procrastination led him to put off the work. He found time, however, to execute his collation of the Harleian ms. of the *Odyssey,* published in the Grenville *Homer* in 1801, and to present to the Society of Antiquaries his wonderful conjectural restoration of the Rosetta stone.

In 1806, when the London institution was founded (then in the Old Jewry, since removed to Finsbury Circus), he was appointed principal librarian with a salary of £200 a year and a suite of rooms; and thus his latter years were made easy as far as money was concerned.

Among his most intimate friends was James Perry, the editor of the *Morning Chronicle;* and this friendship was cemented by his marriage with Perry's sister, Mrs. Lunan, in Nov. 1796. The marriage was a happy one for the short time it lasted, as Porson became more attentive to times and seasons, and would have been weaned from his habits of drinking; but she sank in a decline a few months after her marriage (April 12, 1797), and he returned to his chambers in the Temple and his old habits. Perry's friendship was of great value to him in many ways; but it induced him to spend too much of his time in writing for the *Morning Chronicle;* indeed he was even accused of "giving up to Perry what was meant for mankind," and the existence of some of the papers he wrote there can be only deplored.

For some months before his death he had appeared to be failing: his memory was not what it had been, and he had some symptoms of intermittent fever; but on Sept. 19, 1808, he was seized in the street with a fit of apoplexy, and after partially recovering died on Sept. 25 at the age of 49. He was buried in Trinity college, close to the statue of Newton, at the opposite end of the chapel to where rest the remains of Richard Bentley.

In learning, Porson was superior to Valckenaer; in accuracy, to Bentley. It must be remembered that in his day the science of comparative philology had scarcely any existence; even the comparative value of mss. was scarcely considered in editing an ancient author. With many editors, mss. were treated as of much the same value, nhether they were really from the hand of a trustworthy scribe, or what Bentley calls "scrub manuscripts," or "scoundrel copies."

Thus, if we are to find fault with Porson's way of editing, it is that he does not make sufficient difference between the mss. he uses, or point out the relative value of early copies whether in ms. or print. Thus he collates minutely Lascaris' edition of the *Medea,* mentioning even misprints in the text, rather from its rarity and costliness than from its intrinsic value. And his wonderful quickness at emendation has sometimes led him into error, which greater investigation into mss. would have avoided; thus, in his note on Eur., *Phoem.* 1373 an error, perhaps a misprint (κε for με), in the first edition of the scholiast on Sophocles has led him into an emendation of v. 339 of the *Trachiniae* which clearly will not stand. But his most brilliant emendations, such as some of those on Athenaeus, or on the *Supplices* of Aeschylus are such as to convince the reader of their absolute certainty; and this pouer was possessed by Porson to a degree no one else had ever attained. No doubt his mathematical training had something to do with this; frequently the process may be seen by which the truth has been reached.

A few words are called for on his general character. No one ever more loved truth for its own sake; few have sacrificed more rather than violate their consciences, and this at a time nhen a high standard in this respect was not common. In spite of his failings few have had warmer friends: no one more willingly communicated his knowledge and gave help to others; scarcely a book appeared in his time or for some years after his death on the subjects to nhich he devoted his life without acknonledging assistance from him. And if it be remembered that his life nas a continued struggle against poverty and slight and ill-health, rather than complain that he did little. we should wonder hon he accomplished so much.

His library was divided into two parts, one of which was sold by auction; the other. containing the transcript of the Gale Photius, his books with ms. notes, and some letters from foreign scholars. was bought by Trinity college for 1.000 guineas His notebooks were found to contain, in the nords of Bishop Charles James Blomfield. "a rich treasure of criticism in every branch of classical literature — everything carefully and correctly nritten and sometimes renritten — quite fit to meet the public eye. without any diminution or addition" They have been carefully rearranged and illustrate among other things his extraordinary penmanship and poner of minute and accurate writing. Much remained unpublished. James Henry Monk. his successor as Greek professor. and Charles James Blomfield (both afterwards bishops) edited the *Adversaria,* consisting of the notes on Athenaeus and the Greek poets. and his prelection on Euripides: Peter Paul Dobree. afterwards Greek professor, the notes on Aristophanes and the lexicon of Photius.

Besides these. from other sources. Professor Thomas Gaisford edited his notes on Pausanias and Suidas and Thomas Kidd collected his scattered reviens. And. when Bishop Burgess attacked his literary character on the score of his *Letters to Travis,* Professor Thomas Turton (afterwards Bishop of Ely) came forward with a vindication (1827).

See Barker, *Porsoniana* (London, 1852); Kidd, "Imperfect Outline of the Life of R.P.," prefixed to his collection of the *Tracts and Criticisms;* the *Life by* J. S. Watson (1861): *Dict. Nat. Biog.;* and J. E. Sandys, *History of Classical Scholarship,* ii (1908). Porson's publications include: *Notae in Xenophontis anabasin* (1786); *Appendix to Toup* (1790); *Letters to Travis* (1790); *Aeschylus* (1795. 1806); *Euripides* (1797–1802); *Adversaria* (Monk and Blomfield, 1812); *Tracts and Criticism* (Kidd, 1815); *Aristophanica* (Dobree. 1820); *Notae in Pausaniam* (Gaisiord, 1820); *Photii lexicon* (Dobree. 1822); *Notae in Suidam* (Gaisford, 1834); *Correspondence* (Luard, edited for the Cambridge Antiquarian Society, 1867).

PORT: *see* PORT WINE; *see* also RULE OF THE ROAD AT SEA.

PORTA, GIACOMO DELLA (*c.* 1537–1602), Italian architect whose work represents the development in style from late mannerism to early baroque. was born and died at Rome. He was the chief Roman architect during the latter third of the 16th century. Della Porta continued two of Michelangelo's greatest architectural projects. the Piazza del Campidoglio and St. Peter's in the Vatican at Rome. whose dome, mith a more pointed profile than Michelangelo intended, became the prototype of the baroque dome.

In a similar manner the façade he added to Giacomo da Vignola's church of Il Gesu at Rome was the model for the typical baroque church façade. (D. R. CN.)

PORT ADELAIDE: *see* ADELAIDE.

PORTADOWN, a municipal borough (charter granted, 1947) in County Armagh, N.Ire., lies on the river Bann 26 mi. S.W. of Belfast by road. Pop. (1951) 17,202; (1961) 18,605. Area 2.9 sq.mi. An important road and railway junction, Portadown owed its origin to a ford on the river. Its wide Market and High streets are overlooked by the parish church of St. Mark (1824) with its war memorial tower. Fine business thoroughfares stretch from the town centre and there is a spacious covered market. The town hall (1890) and Carnegie library and museum (1903) are on Edward street.

Portadown has a college, two secondary intermediate schools and a maternity hospital. There is an annual music and drama festival. Two parks cater to most sports. The main industries are linen weaving, pottery, iron founding, bacon curing, flour milling, fruit canning and the manufacture of lace, furniture, clothing, carpets and metal cans. The renowned McGredy rose nurseries are located there. (WI. H. W.)

PORTAELS, JEAN FRANÇOIS (1818–1895), Belgian painter and teacher of art. was born at Vilvorde. Belgium. on April 30, 1818, and studied at the Brussels academy. In 1874 Portaels was appointed director of the academy of Brussels. His works include decorative paintings in the church of St. Jacques-sur-Caudenberg; biblical scenes and genre pictures, portraits, oriental scenes and pictures of fancy female figures, many of which are in the Brussels gallery. But it is as a teacher of art that Portaels is famous. He died at Brussels on Feb. 8, 1895.

PORTAGE LA PRAIRIE, a port of entry and the chief city of Portage la Prairie county, Manitoba, Can., 56 mi. W. of Winnipeg, on the Canadian Pacific and the Canadian National railways at an altitude of 856 ft. above the sea. Pop. (1961) 12,388.

The name had its origin in the fact that its situation on the Assiniboine is at the south end of a portage from Lake Manitoba used by the French fur traders. Industries include foundry and machine works and major brickyards.

PORTAEEGRE, a Portuguese district and a city on the Lisbon Madrid railway. City pop. (1960) 29,530 (mun.). Dist. pop. (1960) 192,706.

Portalegre is the Roman *Amaea* or *Ammaia,* and Roman and prehistoric remains have been discovered there.

PORTALES, DIEGO JOSÉ VICTOR (1793–1837), Chilean politician and *caudillo,* was born at Santiago on June 26, 1793. By 1824 he had built a profitable commercial firm that held a monopoly on tobacco in return for servicing a public loan contracted in England. When the Chilean government abrogated his contract he thren himself into politics as an ultraconservative. In 1830 the conservative Joaquin Prieto became president but Portales as chief minister ruled from behind the scenes and identified the objectives and defined the methods of the new power elite. He speedily silenced his liberal opponents. forced the military to submit to civilian dominance, and re-established Chile's credit standing abroad. The constitution of 1833. nhich reflected his political doctrines created a highly centralized state controlled by and for the landed oligarchy and the Roman Catholic church and provided 60 years of social stability and political order unequaled in Latin America. In 1836 he forced war on the Peru-

Bolivian confederation in order to distract attention from his repressive domestic measures. He was assassinated at Valparaiso on June 6, 1837, while reviewing troops preparing to embark for Peru. Hated and feared alive, in death he became a hero around whom the Chilean people rallied to win the war in 1839 and then to enter a period of aggressive nationalism and cultural flowering in the 1840s under Manuel Bulnes.

See also CHILE: *History.* (J. J. J.)

PORTALIS, JEAN ETIENNE MARIE (1746–1807). French lawyer and statesman, one of the chief architects of the *Code Civil,* was born at Bausset in Provence on April 1, 1746. He practised at the bar of Aix and in 1778–81 was one of the assessors or administrators of Provence. In Nov. 1793, after the republic had been proclaimed, he came to Paris and mas promptly imprisoned as the brother-in-law of Joseph Jérôme Simeon, the leader of the Federalists in Provence. Upon his release he resumed practice in the capital, but in 1795 was elected deputy to the *Conseil des Anciens,* later becoming its president. As a leader of the moderate party opposed to the Directory he was proscribed at the *coup d'état* of Fructidor and escaped to Switzerland. In 1800, when Napoleon became first consul, he returned to Paris and was appointed by Napoleon a *conseiller d'état* and a member of the commission charged with the drawing up of the *Code Civil.* As this body's most industrious member, he sought to permeate the code with the ideas of Roman law; many of the most important titles, notably those on marriage and succession, are his work.

In 1801 he was placed in charge of *cultes,* or public worship. and was chiefly responsible for drawing up the provisions of the concordat between Napoleon and Pius VII. He entered the French Academy in 1806 and died in Paris on Aug. 25, 1807. (L. N. B.)

PORTAL OF HUNGERFORD, CHARLES FREDERICK ALGERNON PORTAL, 1ST VISCOUNT (1893–), British air marshal and chief of air staff during World War II, was born at Hungerford in 1893 and educated at Winchester and Christ Church, Oxford. At the beginning of World War I he joined the royal engineers as a dispatch rider, and in 1915 he was commissioned in the royal flying corps. He distinguished himself as a fighter pilot by shooting down several enemy aircraft; for this he was awarded the Distinguished Service order and bar and the military cross. Between the wars his posts in the Royal Air Force included those of commander of the British forces, Aden; instructor at the Imperial Defence college; and director of organization and air member for personnel at the air ministry.

In 1940 for a short time he held the appointment of air officer commander in chief, bomber command. Soon after he became chief of the air staff, the highest post in the R.A.F., which he held with great distinction until 1945. In addition to his duties at the air ministry, directing the policy and operations of the R.A.F., he took a prominent part in all the important Allied conferences as a member of the chiefs of staffs committee. From 1946 to 1948 Lord Portal was responsible for work connected with atomic energy. He was appointed knight grand cross of the Order of the Bath in 1942, knight of the Garter and to the Order of Merit in 1946. He was created a baron in 1945 and a viscount in 1946. (E. B BN.)

PORT ARTHUR, a city and seat of Thunder Bay district in southwestern Ontario, Can., is on Thunder bay. a northwestern arm of Lake Superior. With its twin city Fort William (*q.v*). it is known as the lakehead. Port Arthur is a major transportation centre on the Canadian Kational and Canadian Pacific railways and the Trans-Canada highway. The passenger and freight ships of the Great Lakes transportation systems meet the rail lines of western Canada there.

There are important gold mines in the tributary area to the northeast. Extensive and rich hematite iron ore deposits at Steep Rock are tributary to the west, but most of the Steep Rock ore is shipped via special ore docks at Port Arthur. The city is noted for its large grain storage and shipment capacity.

There are extensive pulp and paper mills, shipbuilding and repair are important industries. and lumbering is a major activity. Pop. (1961) 45,276.

The Canadian lakehead is the gateway to a vast hunting and fishing area. (F. A. CK)

PORT ARTHUR (LÜ-SHUN), city and naval base in Liaoning province. China, at the southern extremity of the Kuantung peninsula of Manchuria. On the only part of the Manchurian coast line that is ice-free throughout the year. it occupies a strong strategic position, commanding the entrance to Po-hai wan a gulf of the Yellow sea Until the Chinese-Japanese war of 1894–95 Port Arthur was the chief Chinese naval base It fell in 1894 to Japan. which was. however. forced to return it to China under European pressure. Russia was anxious to obtain an ice-free port for its Pacific fleet. and the capture of Chiao-chou (Kiaochow) by the Germans in 1897 provided the occasion for Russian ships to occupy Port Arthur and the near-by commercial port of Dairen (q *v.*). In 1898. by agreement. Russia acquired from China the entire Kwantung peninsula for 25 years and the right to build a railroad to connect nith the Trans-Siberian railway. Port Arthur was made an apparently impregnable stronghold.

During the Russo-Japanese War (*q.v.*), Port Arthur was the scene of a victorious Japanese siege from the landward that undoubtedly had considerable influence on the outcome of the war. In May 1904 the Japanese 2nd army landed at P'i-tzu-wo and gained control of the isthmus that connects the Kwantung peninsula with the mainland. Dairen was seized without fighting and its port was used to debark the Japanese 3rd army in June The folloning month the Japanese broke through the outer defenses of Port Arthur and forced the Russians, under Gen. Anatoli M Stossel, to withdraw to the main defense norks of the base. Costly Japanese assaults were repeatedly frustrated during the next four months, until the key Russian position on 203-Metre hill nas finally overcome in late November. The Russian garrison capitulated Dec. 20, 1904. Even before the start of the siege. the Russian far eastern squadron, consisting of 7 battleships, 7 cruisers and 25 destroyers, had been bottled up in Port Arthur by a blockading Japanese naval force and fell to the Japanese at the time of the capitulation.

By the Treaty of Portsmouth (1905) Port Arthur mas transferred to the Japanese, who called it Ryojun. Japan retained control over the base and the entire Kwantung lease until the end of World War 1 Soviet forces seized Port Arthur in Aug. 1945. By treaty arrangements with the Chinese Nationalists and, later, with the Communists, the Soviet Union secured joint Soviet-Chinese control over Port Arthur until 1955. when the naval base passed to exclusive Chinese Communist use.

Port Arthur became part of the joint municipality of Port Arthur-Dairen, known in Chinese as Lüshun-Talien. or simply Lu-ta. with its seat at Dairen The population of Port Arthur in the 1953 census was 126,000; that of Lu-ta 1,200,000. (T. SD.)

SIEGE OF PORT ARTHUR, 1904

While the fortunes of the siege of Port Arthur had undoubtedly a considerable influence on the outcome of the Russo-Japanese war (*q.v.*), its execution was separated both in space and design from the main operations of the field armies. The first clash of the armies took place on the Yalu on May 1. 1904, and five days later. Gen. Oku's 2nd Army. which had been waiting at Chinampo for the ice to melt, landed near Pitszewo. By storming Nanshan Hill, he gained command of the isthmus which connected the Port Arthur peninsula with the mainland. This mission was a prelude to the siege, and to the 2nd Army's advance northward, its place being taken by the 3rd Army under Gen. Kogi.

Nogi landed on June 1. and his army (1st and 11th Divisions) gradually separated itself from Oku's and got into position for the advance on Port Arthur. Dalny, the commercial harbour. mas seized without fighting, and a month was spent in preparing a base there. But so far from retiring within his fort-line, the Russian commander. Gen. Stossel took up a strong position outside. Dislodged from this on June 26, the Russians checked Nogi's further advance on July 3–4. by a fierce, though unsuccessful. counter-stroke Having been reinforced by the 9th Division and two extra brigades of infantry, Nogi advanced again on the 26th The Russians, having had a month wherein to intrench themselves, held out all along the line; but after two days and one night of fighting amongst rocks and on precipitous hill-sides, the Japanese broke through on the night of July 27–28. Stossel then withdrew in good order into Port Arthur, which, in the two months he had gained by his fighting manoeuvre, had been considerably strengthened. Nogi had already lost 8,000 men.

The defences of Port Arthur, as designed by the Russians in 1900, and owing to the meagre allotment of funds only partially carried out before the war, had some tincture, but no more, of modern continental ideas. The main line of defence followed the outer edge of the amphitheatre of hills surrounding the harbour. These hills had their greatest development on the north-east side, their outer crests being some 4,000yd. from the Old Town. Running south-west and south back to the coast, the line gradually drew in quite close to the south-west end of the harbour. The total length from sea to sea was some 12 miles. Its most obvious weakness was that 5,000yd. N.W. of the harbour and New Town, the now famous "203-Metre Hill" overlooked both. Here it had been intended to construct permanent works, but consideration of expenditure had caused this to be deferred.

The permanent works along the main line were supplemented before the siege began by a prodigious development of semi-permanent works and trenches. Every knoll had its redoubt or battery, and the trenches were arranged line behind line, to give supporting, cross and enfilade fire in every direction. On the north-west front, 203-Metre Hill, in advance of the main line, was occupied by strong, semi-permanent works, with trenches and redoubts on either flank. Wire entanglements were disposed in repeated lines in front of the defences, but they were not of a strong type. The Russians, with the resources of the fleet at their disposal (just as at Sevastopol, in the Crimean War), used great numbers of machine guns and electric lights, and the available garrison at first was probably, including sailors, 47,000 men.

Such were the defences that the Japanese attacked, with a force at the outset (July 30) barely superior in numbers to the defenders, and an entirely inadequate siege train (18 6-in. howitzers, 60 4.7-in guns and howitzers, and about 200 field and mountain guns). They were imperfectly informed of the strength of the garrison and the nature of the defences. Recollections of their easy triumph in 1894 and perhaps thoughts of Sevastopol, German theories of the "brusque attack." the fiery ardour of the army, and above all the need of rapidly crushing or expelling the squadron in harbour, combined to suggest a bombardment and general assault. The bombardment began on Aug. 19 and continued for three days, while the infantry was spreading along the front and gaining ground where it could. The real assault was made on the night of the 21st on the two Pan-Lung forts (semi-permanent) on the centre of the north-eastern front. Although the stormers captured the two forts they were unable to make any further progress under the fire of the permanent forts Erh-Lung and Chi-Kuan on either side of, and the Wan-tai fort behind, Pan-Lung. Every attempt to bring up support to the captured positions failed. On the night of the 23rd–24th, just as the assault was being renewed, Stossel delivered a fierce counter-attack against the lost positions, and the result of an all-night battle was that though the forts were not recaptured, the assault was repulsed with over 5,000 casualties, and the Japanese in Pan-Lung were isolated. This sortie raised the spirits of the Russians to the highest pitch They seemed, indeed, to have broken the spell of defeat. On the Japanese side 15,000 men had been killed and wounded in three weeks, and their army had now to resign itself to a methodical siege. Small sorties, partial attacks[1] and duels between the Japanese guns and the generally more powerful ordnance of the fortress continued. The siege approaches were first directed against the Temple-Waterworks group, which was stormed on Sept. 19 and 20. Pan-Lung was connected with the Japanese lines by covered ways, approaches were begun towards several of the eastern forts, and on Sept. 20, 180-Metre Hill was stormed, though the crest was untenable under the fire from 203-Metre Hill. Further progress on the western side of the fortress was foiled after hard fighting, and the eastern forts remained the principal objective. Heavier howitzers had been sent for from Japan and on Oct. 1 the first batteries of 28-centimetre (11in.) howitzers came into action. They fired a shell weighing 485 lb. On the 12th, the Japanese took the trenches between the Waterworks Redoubt and the Erh-Lung, and from this time forward there was a desperate struggle at the sap-heads on the north front.[2] A lodgement on the counterscarp of Sung-Shu prepared the way for mining. On Nov. 17, seven mines were exploded.

On Nov. 26, another assault was made on the same lines as the earlier ones. By this time the besiegers were sapping under the escarps of the northern forts, and it would have been better to delay. But the situation was serious in the extreme. In Manchuria Kuropatkin's army had reasserted itself. From Europe Rozhestvenski's squadron was just setting sail for the Far East. Marshal Oyama sent his principal staff officers to stimulate Nogi to fresh efforts, and some exhausted units of the besieging army were replaced by fresh troops from Japan. With 100,000 men and this urgent need of immediate victory, Nogi and the marshal's staff officers felt bound to make a third general assault. The siege works had, indeed, made considerable progress. The ditches of Sung-Shu and Erh-Lung were partially filled. They held most of the ditch of Chi-Kuan Fort and were cutting down the escarp, and two parallels had been made only 30 yd. from the Chinese Wall at Pan-Lung.

The general attack was made at one o'clock in the afternoon. At Sung-Shu the stormers got into the fort, but suffered much from the artillery on the western side of the Lun-ho valley, and were beaten out of it again in 20 min.; 2,000 men tried in vain to get up the Lun-ho valley to take Sung-Shu in rear. At Erh-Lung they could not get over the outer parapet. At "G" they took a portion of the Chinese Wall and lost it again, other trenches with a cross fire being behind. At Pan-Lung the machine guns on the wall prevented them from leaving the parallel. At Chi-Kuan Fort the *terreplein* of the fort had been covered with entanglements defended by machine guns on the gorge parapets, and the Japanese could make no way. Briefly, there was a furious fight all along the line, and nothing gained. On Nov. 27, after losing 12,000 men, the assault was abandoned. On the north front the Japanese returned to mining.

But so urgent was the necessity of speedy victory that the fighting had to continue elsewhere. And at last, after every other point had been attempted, the weight of the attack was directed on 203-Metre Hill. A battery of 11-in. howitzers was established only one mile away. On Nov. 28 and 30, assaults were made and failed. On Dec. 1, there was a fresh bombardment by the big howitzers, which obliged the Russians to take shelter in the rear of the ruined works. On Dec. 2, the Russians tried a counterattack. During the next two days the artillery was busy. The engineers sapped up to the ruins of the western work, saw the shelters on the reverse slope and directed artillery fire by telephone. Thirty-six guns swept the ground with shrapnel. Finally, on Dec. 5, the Japanese attacked successfully. Their losses in the last 10 days at 203-Metre Hill had been probably over 10,000. Those of the Russians were about 5,000, chiefly from artillery fire.

This was the turning point of the siege. At once the 11-in. howitzers, assisted by telephone from 203-Metre Hill, opened upon the Russian ships; a few days later these were wholly hors *de* combat, and at the capitulation only a few destroyers were in a condition to escape. The siege was now pressed with vigour by the construction of batteries at and around 203-Metre Hill, by an infantry advance against the main western defenses, and by renewed operations against the eastern forts. The escarp of Chi-Kuan was blown up, and at the cost of 800 men, General Sameyeda (11th division), personally leading his stormers, captured the great fort on Dec. 19. The escarp of Ehr-Lung was also blown

[1] A feature of these constant night-fights was the effective use of the defenders' searchlight, both to show up the enemy and to blind him.

[2] Hand grenades and extemporized trench mortars were used on both sides with very great effect. The Japanese hand grenades consisted of about 1-lb. of high esplosive in a tin case; the Russian cases were all sorts, including old Chinese shell. The Japanese employed wire-netting screens to stop the Russian grenades. Various means were tried for the destruction of entanglements. Eventually it was found that the best plan was to sap through them.

up, and the ruins of the fort were stormed by the 9th division on Dec. 28, though a mere handful of the defenders prolonged the fighting for eight hours and the assailants lost 1,000 men. Sung-Shu suffered a worse fate on Dec. 31, the greater part of the fort and its defenders being blown up, and on this day the whole defense of the eastern front collapsed. The Japanese 7th and 1st divisions were now advancing on the western main line; the soul of the defense, the brave and capable General Kondratenko, had been killed on Dec. 15, and though food and ammunition were by no means exhausted, Anatoli M. Stossel surrendered on Jan. 2, 1905, with 24,000 effective and slightly wounded and 15,000 wounded and sick men, the remnant of his original 47,000. The total losses of the 3rd Japanese army during the siege were about 92,000 men (58,000 casualties and 34,000 sick).

PORT ARTHUR, a major deepwater port of east Texas, U.S., is on the northwest shore of Sabine lake, 9 mi. from the Gulf of Mexico. The city is 16 mi. S.E. of Beaumont (q v.) and 17 mi. S.W. of Orange (*q.v.*), the three points of the Golden Triangle, site of an important petrochemical industry. Port Arthur's population in 1960 was 66,676; for comparative population figures see table in TEXAS: Population.

The area, known in 1840 as Aurora, was an important base for a considerable illegal African slave trade into Texas during the mid-19th century. In the 1890s Arthur E. Stilwell, for whom the city was named, decided to use the port as the southern terminus for the Kansas City Southern railroad which he was promoting. Stilwell bought 53,000 ac. of land in the area in 1895, organized a town and arranged in 1899 for the dredging of a deep-sea canal to bring vessels directly to the city's docks.

In 1901 oil prospectors discovered the remarkable oil well known as Spindletop a few miles from Port Arthur. This event marked the birth of the Texas oil industry. James Stephens Hogg, a former governor of Texas, and the promoter and financier John W. ("Bet-a-Million") Gates stepped in to exploit the area and the port became a major sea outlet for a fabulous oil industry. Gates, in gratitude for a fortune made in the area, left the city funds for a library, art gallery, hospital and an industrial college.

Port Arthur has a council-manager form of government, in effect since 1932. (E. W. F.)

PORTATIVE ORGAN, a small mediaeval organ, not to be confounded with the positive (or portable) organ (*q.v.*). These miniature organs, used during the 14th and 15th centuries, were revivals of those used by the Romans, of which a specimen excavated at Pompeii in 1876 is preserved in the museum at Naples. The case measures $14\frac{1}{2}$ in. by $9\frac{1}{3}$ in. and contains nine pipes, of which the longest measures but $9\frac{3}{4}$ in.

PORT AUGUSTA, at the head of Spencer gulf, an arm of the sea which penetrates far toward the interior of South Australia. This position lends Port Augusta a potential importance which, however, is somewhat impaired by a shallow approach and a channel which requires dredging. It is the natural port for the wheat-growing areas to the east, and for the pastoral areas to the north and northwest. After the construction of the east to west transcontinental line (Perth-Brisbane), Port Augusta became a break-of-gauge station. Pop. (1954) 6,704. The rainfall (93") is too low for crops in the immediate vicinity.

PORT-AU-PRINCE, capital, chief port and commercial centre of the republic of Haiti, situated on a magnificent bay at the apex of the Gulf of La Gonbve which strikes inland for about 100 mi. between the two great peninsulas of the west coast, with its upper recesses protected by the island of Gonbve (30 mi. long and 2 mi. broad). Pop. (1950) 134,117. The National palace, rebuilt in 1918, the army barracks and an itnposing statue of Jean Jacques Dessalines dominate the Champs-de-Mars in the centre of the city. The most picturesque site is the Iron market where the merchants are almost exclusively women. Other notable buildings include the National archives, the National library and the National museum. It is the centre of the political and intellectual life of the nation and is the seat of the University of Haiti (established 1944), but Haiti's poverty makes the city one of the most unsanitary and backward capitals in the western hemisphere. During the U.S. occupation. 1915–34, sanitary conditions were

PUBLIX PICTORIAL SERVICE, INC.

GATE OF THE IRON MARKET (MARCHÉ FER), BUILT IN LATE 19TH CENTURY, PORT-AU-PRINCE

improved. The climate is warm and humid, average 81° F. with little seasonal change.

Port-au-Prince is linked by railroad to Saint-Marc, about 45 mi. N.W., and by paved road to Cap-Haïtien; buses run on irregular schedules to all parts of the country. There are air services to most of the Caribbean islands and to New York. During the 1950s several luxury hotels were built to accommodate tourists. Textiles, cottonseed oil, flour and sugar mills are located in or near the capital.

The city was first laid out in 1749 by the French and its bicentenary was commemorated in 1949 by an international exposition, the site of which is now a pleasant palm-fronted promenade. In 1751, and again in 1770, it was destroyed by earthquakes; in subsequent years the city was ravaged frequently by fire. (R. W. LN.)

PORT AUTHORITY. For Great Britain the discussion of the constitution and powers of the different port authorities will be found in the articles on the various ports, *e.g.,* London, Liverpool, etc. The U.S. port authority, in many respects peculiar, calls for special discussion. The American Association of Port Authorities issued a port authorities directory for North America which indicated the adoption by an increasing number of American ports of some modification of the form of government established at European ports, notably at London and Liverpool.

Ownership of all facilities on the San Francisco, Calif., waterfront was acquired by the state of California and operated by the board of state harbour commissioners, the state guaranteeing the bonds issued, the principal and interest of which are payable from harbour revenue. No funds were to be raised by taxation and the harbour was self-supporting from its inception.

Under the 1925 charter for the city of Los Angeles, Calif., the board of harbour commissioners obtained possession and control of the entire waterfront. It might collect rates or charges for the use of facilities in connection with Commerce and navigation, might acquire and operate such facilities and secured power to regulate and control the construction, maintenance, operation or use of any such facility.

An act approved on March 14, 1911, authorized the establishment of port districts in the various counties of the state of Washington, and the port of Seattle came into existence under this act a municipal corporation with power to levy taxes and to issue bonds. It might acquire lands, etc., and exercise the right of eminent domain. Commissioners are elected.

The port of Portland, Ore., was established and incorporated by the laws of 1891. It acquired broad powers, among them full control of the Willamette and Columbia rivers between Portland and the sea to the extent of the state's control, the right of eminent domain, the power to levy regular and special taxes on the property within the district and to bond the district to provide funds for carrying on its operations.

Operation of the port of Houston, Tex., was entrusted to the navigation and canal commission controlling the commercial activities of the port and the maintenance and construction of the terminal facilities. The board of commissioners of the port of New Orleans was created by a Louisiana statute enacted in 1896 to administer the public wharf system, construct and operate a public cotton warehouse, public grain elevator, public coal and bulk commodity handling plant and the great inner harbour navigation canal. The Virginia assembly in 1926 created the state port authority of Virginia, superseding the Hampton Roads port commission.

The board of harbour commissioners for the city of Wilmington, Del., an agency of the mayor and council of Wilmington, was created in 1917 by an act of the general assembly, which act was amended in 1921 and 1925. The board was given authority to fix rates and charges for wharfage and other services rendered in the loading and unloading of vessels, as well as warehouse and storage charges.

The Albany, N.Y., port district commission was created by the legislature of New York in 1925, with broad powers to lease or construct and maintain and operate port facilities, to acquire real property, to contract with municipalities for the construction of port facilities, issue bonds, fix rates, charges and wharfage for the use of all port facilities and collect charges for facilities owned by the district. Provision for tax in the several municipalities in the port district was made.

(J. H. Co.; X.)

The Port of New York is unusual in that it lies within the boundaries of two states, New York and New Jersey, each an independent sovereignty. As early as 1834 the two states found it necessary to enter into a treaty settling the jurisdiction of each over the harbour's waters.

In 1917, in its decision in the New York harbour case involving freight rates and other points of conflict between the harbour's New York and New Jersey sides, the Interstate Commerce commission held that "historically, geographically and commercially New York and the industrial district in the northern part of the State of New Jersey constitute a single community" and recommended that immediate steps be taken to reorganize and coordinate the terminal facilities at the port. In 1920 the New York-New Jersey Port and Harbor Development commission, organized to study the problem, recommended creation of a port authority and a port district. This was accomplished when, on April 30, 1921, the two states entered into a compact or treaty. The consent of congress was given by joint resolution approved Aug. 23, 1921.

By the compact, which supplemented the treaty of 1834, the two states pledged, "each to the other, faithful cooperation in the future planning and development of the Port of New York." The port authority operates under the direction of 12 unsalaried commissioners, 6 from each state, appointed by the governors for overlapping terms of 6 years. It has full authority to purchase, construct, lease and operate any terminal or transportation facility within the port district; to own, hold, lease and operate real or personal property; to borrow money and secure it by bonds or by mortgage on any property held or to be held by it. It has no powers of taxation and must be entirely self-supporting. No property held by any municipality within the port district, or by either state, may be taken by the port authority without the owner's consent. In 1922 the legislatures of both states adopted a plan for the comprehensive development of the port, as provided for in the compact, and this was approved by congress. Under these and subsequent statutes, the two states authorized the construction or operation of additional transportation and terminal facilities, beginning with the Goethals bridge and Outerbridge crossing across the Arthur Kill between Staten Island and New Jersey, opened to traffic in 1928. Within the next 25 years there were added to port authority operations four more interstate crossings: the Bayonne, N.J., bridge across the Kill van Kull between Staten Island and New Jersey, and the George Washington bridge and Holland and Lincoln tunnels across the Hudson river between Manhattan and New Jersey; two air terminals, La Guardia airport and New York International airport in New York city and two in New Jersey, Newark airport and Teterboro airport; two union motor truck terminals, one in New York city and one in Newark, N.J.; a less-than-carload railroad freight terminal and a union bus terminal in Manhattan; the city of Newark's seaport; and a grain terminal in Brooklyn.

To finance its extensive operations the port authority had issued $711,701.258 in revenue bonds by 1952, including numerous refunding issues. The debt outstanding on March 31, 1952, was $228,172,000. The port authority's credit had improved so that the interest costs on long-term bonds had dropped from $5\frac{1}{4}\%$ to 2%.

The port authority's actual investment and commitments in facilities as of March 31, 1952, totaled $395,395,396. Retirement of bonds was provided for out of revenues from the vehicular crossings and terminals.

The building and operation of transportation and terminal facilities represents only part of the port authority's work. It is charged by statute with the protection of port commerce and appears before such regulatory bodies as the Interstate Commerce commission, the Civil Aeronautics board and the Federal Maritime board in the interest of the welfare of the unified port area. It established branch offices in Washington, D.C., Chicago, Ill., Cleveland, O., and Rio de Janeiro, Braz., to promote commerce through the Port of New York.

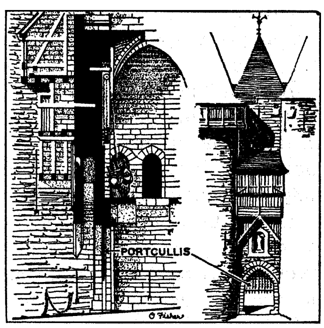
(L. K. J.)

PORT BLAIR, capital of the Andaman and Nicobar islands (*q.v.*), India, in the Indian ocean, lies on the southeast shore of the South Andaman Island, in 11° 42′ N., 93° E. Pop. (1951) 8,014. Occupied in 1789 by Capt. Archibald Blair, R.N., it was named Port Cornwallis. The site was abandoned after two years, but was resettled in 1857 and named Port Blair.

It possesses one of the finest harbours in Asia. From 1858 to 1945 there was a penal settlement on the islands and Port Blair was the headquarters. In World War II it was in Japanese occupation from 1942–45.

PORT CHESTER, a village in Westchester county, N.Y., U.S., on Long Island sound at the mouth of the Byram river, which separates it from Connecticut. Port Chester's earliest history began with Peter Disbrow's purchase of the southern part of its present site on Jan. 3, 1660, from the Siwanoy Indians, a Mohegan tribe. In 1661 he and his associates proclaimed Charles II their lawful monarch in defiance of the claims of the Dutch West India company (*see* LONG ISLAND: *History*). As early as 1732 the settlement was known as Saw Pit because of the important shipbuilding trade that had developed there. On March 11, 1837, the name was changed to Port Chester, and the village was incorporated under that name on May 14, 1868. Although Port Chester is a residential suburb, there were in the 1960s more than 600 business firms and manufacturing establishments making or selling such products as candy, cough drops, bread products, plastics, porcelainized products, nuts and bolts, women's hats and men's shirts. For comparative population figures see table in NEW YORK: *Population.*

(M. D. HH.)



A PORTCULLIS: LEFT, A SECTIONAL VIEW SHOWING OPERATION; RIGHT, FRONT VIEW

PORTCULLIS, a strong-framed grating of wood, the lower points shod with iron, and sometimes entirely made of metal, counterbalanced, and hung so as to slide up and down in grooves, and intended to protect the gateways of castles, city gates, etc. The defenders, having opened the gates and lowered the portcullis, could send arrows and darts through the gratings. The Romans used the portcullis in the defense of gateways. It was called *cataracta* (from the Gr. *katarraktes,* "a waterfall"). Vegetius speaks of it as an old means of defense. Remains of a *cataracta* are clearly seen in the gateway of Pompeii.

PORTE, THE SUBLIME, the name once given to the Turkish government. derived from the high gate giving access to the building in Constantinople where the offices of the principal state departments were situated.

PORT ELIZABETH, a seaport situated 436 mi. E. of Cape Town by sea, in the Cape of Good Hope, South Africa, in latitude 33" 58' S. and longitude 25° 37' E. The population in 1960 was 245,985, of whom 84,505 were Europeans, 51,453 coloured (mixed), 3,865 Asians and 106,162 natives.

Port Elizabeth is the third port of South Africa. midway between Cape Town and Durban. The area south of the harbour has developed into a seaside resort with one of the finest beaches in South Africa and extensive residential development has also taken place there.

The main business centre of Port Elizabeth is situated immediately inland from the harbour with further residential areas stretching about 7 mi. inland. To the north of the town more than 1,500 ac. of land have been developed with industries, the largest establishments being those of the automotive industry. Projects for further industrial expansion over an area of more than 600 ac. have also been planned.

The harbour, with a water area of 314 ac., is enclosed and has two main quays, one 3,540 ft. long and the other 1,700 ft. long. The depth of the water in the harbour is 36 ft. above low water ordinary spring tides and is capable of taking any ocean-going liner. In 1951 it handled more than half the imports for the Rhodesias by virtue of its excellent rail communication system with the hinterland. Ample cold storage facilities have been installed in the harbour to handle products of the increasing citrus industry. After World War II Port Elizabeth developed more rapidly industrially than any other town or city in South Africa and by the mid-1950s there were more than 400 factories engaged in about 80 different types of industrial activity.

History. — Algoa bay was discovered by the Portuguese explorer Bartolomeu Dias in 1488. In 1754 the Dutch settlement at the Cape was extended eastward to this point. With the arrival of 3.000 British settlers in 1820 — known as the 1820 settlers — Port Elizabeth was established under the supervision of Sir Rufane Donkin. At first Port Elizabeth was merely a commercial and shipping centre, but after 1925 its industrial development leaped forward and by 1953 it had become the largest municipality in South Africa, with an area of 106 sq.mi.

PORTEOUS, JOHN (d. 1736), captain of the city guard of Edinburgh, whose name is associated with the riots of 1736, was the son of an Edinburgh tailor. Having served in the army, he was employed in 1715 to drill the city guard for the defense of Edinburgh in anticipation of a Jacobite rising, and was promoted later to the command of the force. In 1736 a smuggler named Wilson, who had won popularity by helping a companion to escape from the Tolbooth prison, was hanged; and, a disturbance occurring at the execution. the city guard fired on the mob. Porteous, who was said to have fired at the people with his own hand, was brought to trial and sentenced to death. The granting of a reprieve was hotly resented by the people of Edinburgh, and on the night of Sept. 7, 1736, an armed body of men in disguise broke into the prison, seized Porteous and hanged him on a signpost in the street. It was said that persons of high position were concerned in the crime; but although every effort was made for the apprehension of the perpetrators, no one was ever convicted of participation in the murder.

PORTER, DAVID (1780–1843), U.S. naval officer who commanded the frigate "Essex" on her famous expeditions during the War of 1812, was born in Boston, Mass., on Feb. 1, 1780. His father. David, commanded U.S. ships in the American Revolutionary War. In 1796 he accompanied his father to the West Indies; on a second and on a third voyage he was impressed on British vessels, but he escaped. He became a midshipman in the U.S. navy in April 1798; served on the "Constellation" and was midshipman of the foretop when the "Constellation" defeated the "Insurgente"; was promoted lieutenant in Oct. 1799 and was in four successful actions with French ships in that year.

In 1803, during the war with Tripoli, he was first lieutenant of the "Philadelphia" when that vessel grounded, he was taken prisoner and was not released until June 1805. He was commissioned master commandant in April 1806; from 1807 to 1810 he served about New Orleans, where he captured several French privateers, and in 1812 was promoted captain. He commanded the "Essex" in her famous voyage (1812–14). In the Atlantic he captured seven brigs, one ship, on Aug. 13, 1812, the sloop "Alert," the first British war vessel taken in the War of 1812. Without orders from his superiors he then (Feb. 1813) rounded Cape Horn, and in the South Pacific captured many British whalers and took formal possession (Nov. 1813) of Nukuhiva, the largest of the Marquesas Islands. The United States, however, never asserted any claim to the island, and in 1842. with the other Marquesas, it was annexed by France. During most of February and March 1814 he was blockaded by British frigates in the harbour of Valparaiso. and on March 28 was defeated. Released on parole, he sailed for New York.

He was a member of the new board of naval commissioners from 1815 until 1823, when he commanded a squadron sent to the West Indies to suppress piracy. One of his officers, who landed at Fajardo (or Foxardo), Puerto Rico, in pursuit of a pirate, was imprisoned by the Spanish authorities on the charge of piracy. Porter, without reporting the incident or awaiting instructions, forced the authorities to apologize. He was recalled (Dec. 1824), court-martialed and suspended for six months. In Aug. 1826 he resigned his commission, and until 1829 was commander in chief of the Mexican navy, then fighting Spain. Pres. Andrew Jackson appointed him consul general to Algiers in 1830, and in 1831 created for him the post of chargé d'affaires at Constantinople, where in 1841 he became minister. He died in Pera on March 3, 1843.

He wrote a *Journal* of a *Cruise Made to the Pacific Ocean in the U.S. Frigate "Essex" in 1812–13–14* (1815; 2nd ed., 1822), and *Constantinople* and *Its Environs* (1835), which is a valuable guidebook.

See the *Memoir of Commodore David Porter* (1875), *by* his son, Adm. David D. Porter.

PORTER, DAVID DIXON (1813–1891), U.S. naval officer, who held important commands during the American Civil War, was born in Chester, Pa., on June 8, 1813. His first voyage, with his father, Capt. David Porter, in West Indian waters (1823–24), was terminated by the Fajardo affair *(see* PORTER, DAVID). In April 1826 he entered the Mexican navy, of which his father was commander in chief, and which he left in 1828 after the capture by the Spanish of the "Guerrero," on which he was serving under his cousin, David H. Porter (1804–28), who was killed before the ship's surrender. He became a midshipman in the U.S. navy in 1829 and was in the coast survey (1836–42). Porter became a lieutenant in Feb. 1841 and served at the naval observatory from 1845 to 1846, when he was sent to the Dominican Republic to report on conditions there. During the Mexican War he served as lieutenant and then as commanding officer of the "Spitfire." a paddle vessel built for river use, and took part in the bombardment of Veracruz. In 1855 and in 1856 he made trips to the Mediterranean to bring to the U.S. camels for army use in the southwest. In April 1861 he was assigned to the "Powhatan," and was sent under secret orders from the president for the relief of Ft. Pickens, Pensacola. Porter was promoted commander on April 22, and on May 30 was sent to blockade the Southwest pass of the Mississippi. Upon his return to New York in November he urged an expedition against New Orleans (*q.v.*), and recommended the appointment of Comdr. D. G. Farragut (*q.v.*), his foster brother, to the chief command.

In the expedition Porter himself commanded the mortar flotilla, which, when Farragut's fleet passed the forts on the early morning of April 24, 1862, covered the passage by a terrific bombardment that neutralized the fire of Ft. Jackson. At Vicksburg Porter's bombardment assisted Farragut to run past the forts (June 28). On July 9 Porter was ordered, with ten mortar boats, to the James river, where McClellan's army was concentrated. On Oct. 15 he took command of the gun vessels and had a share in the capture of Arkansas Post (Jan. 11, 1863). In the operations for the capture of Vicksburg in 1863 unsuccessful attempts were made by Porter's vessels to penetrate through connecting streams and bayous to the Yazoo and reach the right rear of the Confederate defenses on the bluffs, but the fleet ran past the Vicksburg batteries, mastered the Confederate forts at Grand Gulf and made it possible for Grant's army to undertake the brilliant campaign which led to the fall of the place (*see* AMERICAN CIVIL WAR and VICKSBURG). Porter received the thanks of congress for "opening the Mississippi river" and was promoted rear admiral. He co-operated with Maj. Gen. N. P. Banks in the Red river expeditions in March–May 1864, in which his gunboats, held above Alexandria by shallow water and rapids, narrowly escaped isolation. On Oct. 12, 1864, he assumed command of the North Atlantic blockading squadron, then about to engage in a combined military and naval expedition against Ft. Fisher, N.C. Porter claimed that his guns silenced Ft. Fisher, but Maj. Gen. B. F. Butler, in command of the land forces, refused to assault, asserting that the fort was practically intact.

After Butler's removal, Porter, co-operating with Maj. Gen. Alfred H. Terry and commanding the largest fleet assembled at any one point during the war, took the fort on Jan. 15, 1865; for this he again received the thanks of congress. From 1865 to 1869 he was superintendent of the U.S. Naval academy, Annapolis, which he greatly improved, his most notable change being the introduction of athletics. On July 25 he became vice-admiral. From March 9 to June 25, 1869, while Adolph E. Borie (1809–80) of Pennsylvania was secretary of the navy in President Grant's cabinet, Porter was virtually in charge of the navy department. In 1870 he succeeded Farragut in the grade of admiral. He died in Washington, D.C., Feb. 13, 1891.

Porter wrote a *Life of Commodore David Porter* (1875), gossipy *Incidents and Anecdotes of the Civil War* (1885), a none too accurate *History of the Navy During the War of the Rebellion* (1887), two novels, *Allan Dare* and *Robert le Diable* (1885; dramatized, 1887) and *Harry Marline* (1886), and a short "Romance of Gettysburg," published in *The Criterion* in 1903.

See J. R. Soley, *Admiral Porter* (1903).

Admiral Porter's three brothers were in the service of the United States: WILLIAM DAVID PORTER (1809–64) commanded the "Essex" on the Tennessee and the Mississippi in the Civil War and became commodore in July, 1862; THEODORIC HENRY PORTER (1817–46) was the first officer of the U.S. army killed in the Mexican War; and HENRY OGDEN PORTER (1823–72) resigned from the U.S. navy in 1847, after seven years' service, fought under William Walker in Central America, returned to the U.S. navy, was executive officer of the "Hatteras" when she was sunk by the "Alabama" and received wounds in the action from the effects of which he died several years later.

PORTER, ENDYMION (1587–1649), English royalist, born at Aston-sub-Edge in Gloucestershire, was brought up in Spain—where he had relatives—as page in the household of Olivares. He afterward entered successively the service of Edward Villiers and of the marquis (later duke) of Buckingham, and through the latter's recommendation became groom of the bedchamber to Prince Charles, who then and after his accession employed him on diplomatic business, including negotiations connected with the Spanish marriage. About 1620 Porter married Buckingham's niece, Olivia Boteler. During the Civil War he remained a faithful servant of the king.

At the end of 1645, when the cause of the king was finally lost, Porter abandoned England, and resided successively in France, Brussels and the Netherlands. He returned to England in 1649, after the king's death, and was allowed to compound for what remained of his property. He died shortly afterward, and was buried on Aug. 20, 1649, at St. Martin's-in-the-Fields. Porter had a great reputation in the world of art and letters. He wrote verses, was a generous patron of Sir William Davenant, of Dekker, Gervase Warmstrey, Thomas May, Herrick and Robert Dover, and was included among the 84 "essentials" in Edmund Bolton's "Academy Royal." He was a judicious collector of pictures, and as the friend of Rubens, Van Dyck, Daniel Mytens and other painters and as agent for Charles in his purchases abroad he had a considerable share in forming the king's magnificent collection. He was also instrumental in procuring the Arundel pictures from Spain. The authorship of Εἰκὼν πιστή (1649), a vindication of the Εἰκὼν Βασιλική, has been attributed with some reason to Porter.

See D. Townshend, *Life and Letters of Mr. Endymion Porter* (London, 1897); *Dictionary of National Biography,* vol. xlvi (London, 1896) and authorities there cited.

PORTER, FITZ-JOHN (1822–1901), American soldier, was born at Portsmouth (N.H.) on Aug. 31, 1822. He was the son of a naval officer, and nephew of David Porter of the frigate "Essex." He graduated at the U.S. Military academy in 1845; in the Mexican War he won two brevets for gallantry. He served at West Point as instructor and adjutant (1849–55), and at the outbreak of the Civil War in 1861 he was employed on staff duties in the eastern States. He became colonel of a new regiment of regulars on May 14, and soon afterwards brig.-general of volunteers. Under McClellan he commanded a division of infantry in the Peninsular campaign, directed the Union siege operations against Yorktown, and was soon afterwards placed in command of the V. Army Corps. When the Seven Days' battle (*q.v.*) began Porter's corps had to sustain alone the full weight of the Confederate attack, and though defeated in the desperately fought battle of Gaines's Mill (June 27, 1862) the steadiness of his defense was so conspicuous that he was immediately promoted maj.-general of volunteers and brevet brig.-general. His corps, moreover, had the greatest share in the successful battles of Glendale and Malvern Hill. Soon afterwards, the V. Corps was sent to reinforce Pope in central Virginia. Its inaction on the first day of the disastrous second battle of Bull Run (*q.v.*) led to the general's subsequent disgrace; but it made a splendid fight on the second day to save the army from complete rout, and shared in the Antietam campaign.

On the same day on which McClellan was relieved from his command, Porter, his friend and supporter, was suspended and tried by court-martial on charges brought against him by Pope. On Jan. 21, 1863, he was sentenced to be cashiered "and for ever disqualified from holding any office of trust under the Government of the United States." In 1878 Porter's friends succeeded in procuring a revision of the case by a board of distinguished general officers. General Grant had now taken Porter's part, and wrote an article in vol. 135 of the *North American Review* entitled "An Undeserved Stigma." Against much opposition, a relief bill finally passed Congress, and Porter was on Aug. 5, 1886, restored to the United States army as colonel and placed on the retired list, without compensation. After the Civil War he was engaged in business in New York, and held successively many important municipal offices. In 1869 he declined the offer made by the khedive of the chief command of the Egyptian Army. He died on May 21, 1901, at Morristown (N.J.).

See, besides General Grant's art., Cox, *The Second Battle of Bull Run as connected with the Porter Case* (Cincinnati, 1882); Lord, *A Summary of the Case of F. J. Porter* (1883), and papers in vol. ii. of the pub. of the Military Hist. Soc. of Mass.

PORTER, HENRY (*fl.* 1596–1599), English dramatist, author of *The Two Angry Women of Abingdon,* may probably be identified with the Henry Porter who matriculated at Brasenose

College, Oxford, on June 19, 1589. From 1596 to 1599 he was writing plays for Henslowe for the Admiral's Men, and his closest associate seems to have been Henry Chettle. None of the plays mentioned by Henslowe as being written by him are extant, unless, as has been suggested, *Love Prevented* is another name for *The Pleasant History of the Two Angry Women of Abingdon* of which Gayley says: "No play preceding or contemporary yields an easier conversational prose, not even the *Merry Wives.*"

Alexander Dyce edited the *Angry Women* for the Percy Society in 1841; and it is included in W. C. Hazlitt's edition of Dodsley's *Old Plays* (1874). It was edited by Havelock Ellis in *Nero and other plays* (1888, "Mermaid Series,") and in *Representative English Comedies* (1903), with an introduction by the general editor, Professor C. M. Gayley.

PORTER, HORACE (1837–1921), American diplomatist and soldier, was born in Huntingdon, Pa., on April 15, 1837; son of David Rittenhouse Porter (1788–1867), governor of Pennsylvania in 1839–45. During the Civil War he served in the Army of the Potomac until after Antietam; took part in the battles of Chickamauga and Chattanooga; and in April, 1864, became aide-de-camp to Gen. Grant, in which position he served until March 1869. From Aug. 1867 to Jan. 1868, while Gen. Grant was secretary of war *ad interim,* Porter was an assistant secretary, and from March 1869 to Jan. 1873, when Grant was president, Porter was his executive secretary. He resigned from the army in Dec. 1873, when he became vice president of the Pullman Palace Car Company and held other business positions. From March 1897 to May 1905 he was United States ambassador to France. At his personal expense he conducted (1899–1905) a successful search for the body of John Paul Jones, who had died in Paris in 1792. For this he received (May g, 1906) a unanimous vote of thanks of both Houses of Congress. In 1907 he was a member of the American delegation to the Hague Peace conference. He died in New York city on May 29, 1921. His publications include *West Point Life* (1866) and *Campaigning with Grant* (1897).

PORTER, JANE (1776–1850), British novelist, daughter of an army surgeon, was born at Durham in 1776. Her life and reputation are closely linked with those of her sister, ANNA MARIA PORTER (1780–1832), novelist, and her brother, SIR ROBERT KER PORTER (1775–1842), painter and traveller. After their father's death, in 1779, the mother removed from Durham, their birthplace, to Edinburgh, where the children's love of romance was stimulated by their association with Flora Macdonald and the young Walter Scott. Mrs. Porter moved to London, so that her son might study art, and the sisters subsequently resided at Thames Ditton and at Esher with their mother until her death in 1831. Anna Maria Porter published *Artless Tales* in 1793–95, the first of a long series of works of which the more noteworthy are *The Lake of Killarney* (1804), *The Hungarian Brothers* (1807), *Don Sebastian* (1809) and *Barony* (1830).

Jane Porter—whose intellectual power, though slower in development and in expression, was greater than her sister's—had in the meantime gained immediate popularity by her first work, *Thaddeus of Warsaw* (1803), which was translated into several languages and procured her election as canoness of the Teutonic order of St. Joachim. In 1810, four years before the appearance of *Waverley,* she attempted national romance in her *Scottish Chiefs.* The picturesque power of narration displayed by Miss Porter has saved the story from the oblivion which has overtaken the works of most of Scott's predecessors in historical fiction. Her later works included *The Pastor's Fireside* (1815), *Duke Christian of Lüneburg* (1824), *Coming Out* (1828) and *The Field of. Forty Footsteps* (1828). In conjunction with her sister she published in 1826 the *Tales round a Winter Hearth.* She also wrote some plays, and frequent contributions to current periodical literature. On Sept. 21, 1832, Anna Maria died, and for the next ten years Jane became "a wanderer" amongst her relations and friends. She died at Bristol on May 24, 1850.

Robert Ker Porter painted altar-pieces and battle-scenes of imposing magnitude. He went to Russia as historical painter to the emperor in 1804, travelled in Finland and Sweden, where he received knighthood from Gustaws IV. in 1806, and accompanied Sir John Moore to Spain in 1808. In 1811 he returned to Russia and married a Russian princess. He was knighted by the Prince Regent in 1813. In 1817 he travelled to Persia by way of St. Petersburg (Leningrad) and the Caucasus, returning through Bag. dad and western Asia Minor. He examined the ruins of Persepolis, making many valuable drawings and copying cuneiform inscriptions. In 1826 he became British consul in Venezuela. He died at St. Petersburg on May 4, 1842.

His works include: *Travelling Sketches in Russia and Sweden* (1808), *Letters from Portugal and Spain* (1809), *Narrative of the late Campaign in Russia* (1813), and *Travels in Georgia, Persia, Armenia, Ancient Babylonia, etc., during the years 1817–1820* (1821–22). After leaving Venezuela (1841) he again visited St. Petersburg, and died there on May 4, 1842. Jane Porter, who had joined him in Russia, then returned to England and took up her residence with her eldest brother at Bristol, where she died on May 24, 1850.

PORTER, KATHERINE ANNE (1894–), U.S. writer of fiction, was born May 15, 1894, at Indian Creek, Tex., and educated at southern convent schools. For many years she lived abroad—in Mexico, where she did much to stimulate interest in Mexican art and culture, and in Paris and Berlin. These experiences as well as those of her girlhood in the south are reflected in her stories. Though she wrote early and voluminously, she made no attempt to publish until about 1925. The appearance in 1930 of her first collection of stories, *Flowering Judas,* won her immediate critical acclaim. *Hacienda* followed in 1934 and in 1939 *Pale Horse, Pale Rider: Three Short Novels.* This volume established her as one of the foremost short-story writers of the period. Critics praised her for the extraordinary purity and concentration of her style, but her style never becomes a mere preciosity: it is made to serve her vision of life whether her theme is the individual's fight to maintain spiritual integrity or the vicissitudes of growing up or the attempt to discover the meaning of one's past. Other works by Miss Porter include *The Leaning Tower, and Other Stories* (1944) and *The Days Before* (essays and reviews) (1952).

See Edward Schwartz, *Katherine Anne Porter: a Critical Bibliography* (1953). (C. Bs.)

PORTER, NOAH (1811–1892), U.S. educationalist and philosophical writer, of Puritan ancestry, was born in Farmington, Conn., on Dec. 14, 1811. He graduated at Yale college in 1831, for two years taught in the New Haven grammar school, was for two years a tutor at Yale, then becoming a Congregational minister. He was elected professor of moral philosophy and metaphysics at Yale in 1846, and from 1871 to 1886 he was president of the college. His best-known work is *The Human Intellect, With an Introduction Upon Psychology and the Human Soul* (1868), abridged as *The Elements of Intellectual Science* (1871). He died in New Haven, March 4, 1892.

See *Noah Porter, a Memorial,* ed. by G. S. Merriam (1893).

PORTER, WILLIAM SYDNEY: *see* HENRY, O.

PORTES GIL, EMILIO (1891–), Mexican statesman and provisional president (Dec. 1, 1928, to Feb. 5, 1930), was born at Ciudad Victoria, Tamaulipas, on Oct. 30, 1891. He studied in the law school of the National university and was graduated in 1915 at the peak of revolutionary disorders. He took a prominent part in the revolutionary movement, serving in a judicial capacity in Sonora during P. E. Calles' administration as governor and in the legal section of the war department while Gen. Alvaro Obregon was secretary of war. In 1919 he worked in favour of the candidacy of Obregon and was imprisoned for a time for his activities. Following the overthrow of V. Carranza in 1920, Portes Gil acted as provisional governor of Tamaulipas and subsequently was elected a deputy from that state for four terms. He took office as elected governor of Tamaulipas in Feb. 1925 and held this post until appointed secretary of the interior and head of the cabinet by President Calles in Aug. 1928. While governor, he worked on behalf of labour legislation. The number of schools in the state was increased from 280 to more than 600, and special attention was given to agricultural and industrial instruction. He also abolished gambling and established partial prohibition.

Portes Gil was elected provisional president of Mexico by a unanimous vote of the Mexican congress (Sept. 25, 1928) to fill a temporary gap caused by the assassination of President-elect Obregon. His selection was supported by President Calles as well as the powerful Agrarian party. His brief administration was marked by a revolt in Veracruz and northern Mexico, and he retired in 1930 after the election of Pascual Ortiz Rubio. In 1931 and 1932 he was minister to France and from 1932 to 1934 attorney-general of Mexico. He was secretary of foreign affairs, 1934–36, and president of the National Athenaeum of Science and Art in 1949.

PORT GLASGOW, a large burgh of Renfrewshire, Scot., on the south bank of the Firth of Clyde, 19 mi. W.N.W. of Glasgow by road. Pop. (1961) 22,551. Area 1.8 sq.mi. It is continuous with Greenock. The industries include large shipbuilding and engineering works and sawmills. The area of the docks. both wet and graving, is $16\frac{1}{2}$ ac. The graving dock (1762) was the first dock of the kind in Scotland. The first Clyde steamship, the "Comet," was built at Port Glasgow in 1812. In 1775 it was made a burgh of barony. Nearby are the ruins of 16th-century Newark castle.

PORT HARCOURT, the second port of Nigeria. Africa, lies about 41 mi. from the sea on the Bonny river. an eastern distributary of the Niger, in an area of mangrove swamps and rain forest. The climate is hot and humid with an annual rainfall of 94 in.. largely between April and November. The most congenial months are January and December. Pop. (1960 est.) 42,553. It covers about 12 sq.mi. between the Bonny river (W.), the Amadi (E.) and Nwatugbo (S) creeks. First marked out in 1912 on a derelict site known as Obomotu, and linked by rail in 1916 with the Enugu coal fields, the port has continually expanded. The main streets are wide, with modern-style buildings and the principal commercial and residential houses are grouped around a central area known as The Circle. though there are new residential quarters to the northwest and southeast. The many open spaces include Jubilee Memorial park and a sports stadium.

Port Harcourt is in the Eastern Region and is the terminus of the eastern branch of Nigerian railways; it is linked by road and internal air services with the rest of the federation. The airport is 7 mi. N.E. on the Aba road. Local industries include cement, cigarette and metal window frame and door manufacture. The port has deepwater berths and bulk palm oil storage plants, and its increasing traffic necessitated a further large expansion of the facilities in the late 1950s. Its exports, mainly palm oil and kernels, cocoa. coal. tin and peanuts, were extended in 1958 by mineral oil from the newly developed oil fields of the Niger delta.

(W. H. I.)

PORT HUDSON, a village in East Baton Rouge parish, La., U.S., on the left bank of the Mississippi, about 135 mi. above New Orleans. At the sharp turn of the Mississippi there the Confederates in 1862 built on the commanding bluffs powerful batteries covering a stretch of about 3 mi., their strongest fortifications along the Mississippi between New Orleans and Vicksburg. On the night of March 14, 1863, Adm. David Farragut, with seven vessels, attempted to run past the batteries, commanded by Brig. Gen. William M. Gardner, but four of his vessels were disabled and forced to turn back, one, the "Mississippi" was destroyed, and only two, the "Hartford" and the "Albatross" got past. Gen. N. P. Banks's land attack on May 27 was unsuccessful. the Union loss, nearly 2,000. being six times that of the Confederates. A second attack on June 14 entailed a further Union loss of about 1,800 men. But on July 9, two days after the news of the surrender of Vicksburg, after a siege of 45 days, General Gardner surrendered the position to General Banks with about 6.400 men, 50 guns. 5,000 small arms and ammunition, and two river steamers. The Union losses during the siege were probably more than 4.000; the Confederate losses about 800. The capture of Vicksburg and Port Hudson secured to the Union the control of the Mississippi.

PORT HURON, a city of southeastern Michigan, U.S., 57 mi. N.E. of Detroit at the lower end of Lake Huron on the St. Clair river. opposite Sarnia, Ont.. with which it is connected by a railway tunnel and the Blue Water International bridge. It is a port on the St. Lawrence seaway. Port Huron, the seat of St. Clair county, the centre of a thriving agricultural community, has many industries and is a popular summer resort. It has a commission-manager form of government and a public junior college, established in 1923. (For comparative population figures see table in MICHIGAN: Population.)

In 1686 Ft. St. Joseph was built within the present city limits by Daniel Greysolon, Sieur du Lhut (Dulhut), a French trader and explorer; the British took possession in 1761 and the Americans built a fort on the site in 1814, naming it Ft. Gratiot for Capt. Charles Gratiot, who supervised its construction. The settlement which had grown up around the fort was incorporated as the village of Fort Gratiot in 1840; in 1893 it joined the other communities along the St. Clair river which had formed the city of Port Huron in 1857. Thomas A. Edison (*q.v.*) lived there as a boy; a boulder in Pine Grove Park stands near the site of his home.

(V. A.)

PORTICI, a town of Campania, Italy, in the province of Napoli, 5 mi. S E. of Naples by rail, on the shores of the bay. and at the foot of Vesuvius. Pop. (1957 est.) 42,285 (commune). The palace, erected in 1738, once contained the antiquities from Herculaneum, later removed to Naples (with the exception of some mosaic pavements), and in 1873 it became a government institute of agriculture.

Just beyond Portici. on the southeast, is Resina (commune pop. [1957 est.] 44,571). on the site of the ancient Herculaneum. with several fine modern villas.

The inhabitants are engaged in fishing, silk growing and silk weaving. The town was completely destroyed by the eruption of Vesuvius in 1631.

PORTICO, in architecture, a term loosely applied to many types of structure in which columns or colonnades are the most important part. Thus an entrance porch with columns is called a portico, and the colonnade at the end of a classic temple is also so named.

In Rome an arcaded and colonnaded building surrounding an open space or temple. and built for a public covered promenade mas termed a *porticus,* like the portico of Octavia (built by Augustus and restored by Septimius Severus and Caracalla, 203), of which there are extensive remains.

PORT JACKSON: see SYDNEY.

PORT KEMBLA, a town and port of New South Wales, Austr., lies 55 mi. S. of Sydney and forms part of Greater Wollongong (see WOLLONGONG). Pop. (1954) 6,570. Since the establishment of iron and steel works in 1926, Port Kembla has developed into an important industrial centre, producing about 2,600,000 tons of steel ingots annually.

Other industries include the smelting and refining of copper and other metals, and the manufacture of tin plate, wires and cables, sulphuric acid, fertilizers and metal products. There is also a large power station.

The artificial harbour has grown from a jetty built in 1883 to ship coal mined at Mount Kembla in the Illawarra range to the west; after 1960 a new harbour was built to provide many more berths, with a depth of 32 ft. at low water. The chief imports are ironstone, limestone and liquid fuels; iron and steel products and coal are the chief exports.

PORTLAND, EARLS OF. The English title of earl of Portland was held by the family of Weston from 1633 to 1688, and by the family of Bentinck from 1689 to 1716, when it was merged in that of duke of Portland.

Sir Richard Weston (1577–1635), according to Clarendon "a gentleman of very good and ancient extraction by father and mother," was the son and heir of Sir Jerome Weston (c. 1550–1603) of Skreens in Roxwell. Essex. his grandfather being Richard Weston (d. 1572), justice of the common pleas. He was lord high treasurer from 1628 until his death on March 13, 1635. He received the earldom in 1633.

The title became extinct in 1688. In 1689 it was revived by William III, who bestowed it upon William Bentinck (*q.v.*).

Sir Richard Weston must be distinguished from two contemporaries and namesakes: Sir Richard Weston (c. 1579–1652), baron of the exchequer; and Sir Richard Weston (1591–1652), who introduced notable improvements in English agriculture and was mainly responsible for introducing locks on the Wey which made this river navigable. Another family of Weston produced Robert Weston (c. 1515–73), lord chancellor of Ireland from 1566 until his death on May 20, 1573.

PORTLAND, WILLIAM BENTINCK, EARL OF (1649–1709), English statesman, was born on July 20, 1649. The son of Bernhard Bentinck of Diepenheim, he was descended from an ancient and noble family of Gelderland. As page of honour and gentleman of the bedchamber to William, prince of Orange, he secured the friendship of William, which he justified by his prudence and ability.

In 1677 he was sent to England to solicit for the prince of Orange the hand of Mary, daughter of James, duke of York, afterward James II, and he was again in England in 1683 and in 1685. When, in 1688, William was preparing for his invasion, Bentinck went to some of the German princes to secure their support, or at least their neutrality, and he was also a medium of communication between his master and his English friends. He superintended the arrangements for the expedition and sailed to England with the prince.

The revolution accomplished. Bentinck was made groom of the stole, first gentleman of the bedchamber and a privy councilor; and in April 1689 he was created Baron Cirencester, Viscount Woodstock and earl of Portland. He fought at the battle of the Boyne (1690), the battle of Landen and at the siege of Namur, but his main work was of a diplomatic nature. He helped to arrange the peace of Ryswick (1697); he negotiated with Louis XIV for a partition of the Spanish monarchy and, as William's representative, signed the two partition treaties. Jealous of the rising influence of Arnold van Keppel, earl of Albemarle, Portland resigned all his offices in the royal household in 1700, but he did not forfeit the esteem of the king, who continued to trust and employ him.

He received 135,000 ac. of land in Ireland, and only the strong opposition of a united house of commons prevented him from obtaining a large gift of crown lands in north Wales. For his share in drawing up the partition treaties he was impeached in 1701, but the case against him did not proceed.

He was occasionally employed on public business under Anne until his death at his residence, Bulstrode in Buckinghamshire, on Nov. 23, 1709.

Portland's eldest surviving son Henry (1682–1726) succeeded as 2nd earl. He was created marquess of Titchfield and duke of Portland in 1716.

BIBLIOGRAPHY.—M. E. Grew, *William Bentinck and William III* (1924); N. Japikse (ed.), *Correspondentie van Willem III en van Hans Willem Bentinck,* 6 vol. (1927–37); A. Turberville, *History of Welbeck Abbey,* vol. ii (1939).

PORTLAND, WILLIAM HENRY CAVENDISH BENTINCK, 3RD DUKE OF (1738–1809), prime minister of England, son of William, 2nd duke (1709–62), and grandson of the 1st duke. He was born on April 14, 1738, and was educated at Oxford. Under the marquess of Rockingham he was, from July 1765 to Dec. 1766, lord chamberlain, and on the return of Rockingham to power in April 1782 he was made lord lieutenant of Ireland. After the short ministry of the earl of Shelburne, succeeding the death of Rockingham, the duke of Portland was selected by Charles Fox and Lord North as a "convenient cipher" to become the head of the coalition ministry, to the formation of which the king was with great reluctance compelled to give his assent. The duke held the premiership from April 5, 1783, until the defeat of the bill for "the just and efficient government of British India" caused his dismissal from office on Dec. 17 following. Under William Pitt he was, from 1794 to 1801, secretary of state for the home department, after which he was, from 1801 to 1805, president of the council. In 1807 he was appointed a second time prime minister and first lord of the treasury. Ill-health caused him to resign in Oct. 1809, and he died on Oct. 30. He owed his political influence chiefly to his rank, his mild disposition and his personal integrity.

He married in 1766 Lady Dorothy Cavendish (1750–94), daughter of the 4th duke of Devonshire, and was succeeded by his son William Henry (1768–1854). The 4th duke married a daughter of the famous gambler, Gen. John Scott. His son, the 5th duke, William John Cavendish Bentinck-Scott (1800–79), died unmarried.

PORTLAND, the largest city in Maine, the seat of Cumberland county and a port of entry, is located on Casco bay 110 mi. N.E. of Boston. The city is built largely on two hilly peninsulas which command arresting views of Casco bay and its many islands. Pop. (1960) city 72,566; standard metropolitan statistical area (the cities of Portland, South Portland and Westbrook and the towns of Falmouth and Cape Elizabeth) 120,655. (For comparative population figures see table in MAINE: Population.)

Portland was first settled in 1632 by the Englishmen Richard Tucker and George Cleeve. During its early years it was known by several names and suffered various disasters. It was destroyed in 1676 by Indians and in 1690 by French and Indians. In 1775 a British fleet bombarded the settlement as punishment for patriotic activities. It was rebuilt and then mas incorporated as a town in 1786, when it took the name of Portland. When Maine became a state in 1820 Portland served as the capital until 1832. It also was incorporated as a city in 1832. A fire which resulted from an Independence day celebration destroyed much of the centre of the city on July 4 and 5, 1866. Reconstruction soon took place, however, and the city continued to grow. Portland's traditional fishing, shipping and commercial activities were increasingly supplemented by the development of manufacturing industries. The city was important in the building and operation of naval ships in both World Wars I and II. It has a council-manager form of government which it adopted in 1923.

Portland is the transportation and commercial centre of southwestern Maine. It has an excellent harbour, which is served by several steamship lines. It is a major petroleum port and is the eastern terminus of the Portland-Montreal oil pipeline. The metropolitan area has a diversified manufacturing base. Among the chief products are pulp and paper, a variety of canned and processed foods, textiles, lumber and wood products, furniture, footnear, chemicals, metal goods and various types of machinery. There is also considerable shipbuilding, printing and publishing in the area. Fishing is an important source of employment.

Educational facilities include a branch of the University of Maine and Westbrook, a private junior college for women. Two museums, an art gallery and music and drama groups contribute to the area's cultural activities. (H. A. PE.)

PORTLAND, the largest city of Oregon, U.S., and the seat of Multnomah county. is in the northwestern part of the state. Its original site was a shallow bench of land between low but steep wooded hills and the west bank of the Willamette river, 10 mi. from its entrance into the Columbia river. This remains the financial and commercial centre of the city. Zoned residential, commercial and industrial developments have spread out to occupy the plain on the east side of the Willamette, extending to the Columbia. From the city's heights, to the east, can be seen an encirclement of low foothills climaxed in the snow-capped summit of Mt. Hood, 75 mi. away, and in the farther distance, the peaks of Mt. St. Helens and Mt. Adams in Washington. To the west lie the Tualatin valley, the Coast Range mountains and beyond, less than 100 mi. away, the Pacific ocean. Pop. (1960) city 372,676; standard metropolitan statistical area (Multnomah, Washington and Clackamas counties in Oregon, and Clark county, Washington) 821,897.

History. — Portland was founded in 1845 and was named for the city in Maine. Deep water for ocean-going vessels and the opening of a road to the wheat producing farms of the Tualatin valley in the early 1850s gave it commercial advantages over rival town sites. By 1860, when its population was less than 3,000, it was the largest town in the Pacific northwest and remained so until outstripped by Seattle at the turn of the century. Between 1850 and 1870 Portland was the outfitting point and supply centre for northwest gold rushes and interior settlement. Thrifty and conservative businessmen, many originally from New England, invested capital earned during these prosperous times in real estate and transportation facilities. Locally owned stern-wheelers navigated the rivers and carried agricultural traffic to Portland; after 1880 it became one of the nation's chief grain exporting ports In the 1860s and 1870s Portland's residents invested heavily in railroad lines to California and in the Northern Pacific Railway company which gave them their first transcontinental connection in 1883. By 1910 all major western steam railroad lines entered Portland.

In 1889 a local company brought electric power to Portland from Oregon City, 14 mi. up the Willamette. over the world's first long-distance transmission line. With the completion of Bonneville dam on the Columbia in 1940 the availability of hydroelectric power began to attract metallurgical and chemical industries to the metropolitan area.

Local residents early advertised Portland as the city of homes as well as "the city of roses," celebrated in an annual rose festival Multiple-unit dwellings mere slow to develop until the mid-20th century. when long-range urban renewal projects, a new airport and the building of an express highway also began to change the appearance of the city.

Government. — Portland is governed by an elected. nonpartisan board of five commissioners and a mayor. It operates only minimum public utilities A port commission with taxing powers and a public dock commission supervise harbour facilities.

Education and Cultural Activities. — Institutions of higher education in the city include Cascadia, a private interdenominational college chartered in 1918 as the North Pacific Evangelistic institute; Lewis and Clark, a Presbyterian college founded in 1867; Reed, a private nonsectarian college founded in 1904; the University of Portland, a Roman Catholic coeducational institution established in 1901; Multnomah opened in 1897 and organized as a junior college in 1931; Portland State college (which grew out of Vanport Extension centre, established in 1946) became a degree-granting college in the Oregon state system of higher education in 1955, and the medical and dental schools of the University of Oregon. Wealthy and influential patronage supported such cultural institutions as a library, art museum and school, historical society and symphony by the turn of the 20th century In 1925 one of the first junior symphonies in the nation nas founded in Portland. The Multnomah county library, with headquarters in Portland, operates a number of branches and several bookmobiles.

The city school district, a separate taxing agency, operates elementary and high schools and a radio station and provides special programs for exceptional children.

Parks and Recreation. — Portland has over 100 park and recreational areas, including rose and zoological gardens, totaling over 6,000 ac. Forest park. 3,500 ac., is a primitive area within the city limits. (D. O J.)

PORTLAND, ISLE OF, a peninsula on the coast of Dorset, Eng., connected to the mainland by the Chesil bank, or beach, an unbroken ridge of shingle that stretches as far as Bridport. Pop of urban district (1951) 11,377. Four miles long and nearly $1\frac{3}{4}$ mi. in extreme breadth, it has an area of 4.5 sq.mi. Its precipitous shores are inaccessible from the sea except toward the south, and its highest point is the Verne hill in the north. A raised beach is seen at Portland Bill. The substratum of the island is Kimmeridge clay, overlain by beds of sand and strata of oolitic limestone — the famous Portland stone. In the dirt bed on the oölitic strata are numerous specimens of petrified wood, some of great size. A freight railway runs south from Weymouth to Portland and Easton; passengers travel by omnibuses. The island is a royal manor whose court leet still functions.

On the isle are the famous prison buildings, now a Borstal, and the Verne prison, formerly a barracks. Portland castle, built by Henry VIII in 1520, is open to the public. The remains of a Norman fortress. Bow and Arrow or Rufus castle, are on a rock on the eastern side, in the grounds of Pennsylvania castle, built by John Penn, governor of the isle and grandson of William. founder of the state of Pennsylvania.

Portland harbour was built by the admiralty in 1847–62. A breakwater stretching northward from the northeastern corner of the island partially enclosed a large area of water naturally sheltered on the south and west. An inner arm ran nearly east from the island to a masonry head and fort, and an outer detached arm bent north to a circular fort, a narrow entrance for shipping being left between the two. Two new breakwaters, built after 1895, closed the gap between the end of the outer breakwater and the Bincleaves rocks near Weymouth. The completely enclosed harbour covers 2.200 ac. to the one-fathom line. of which 1,500 ac. have a depth of not less than 30 ft at low water. After World War II there was further naval building toward Portland Bill.

PORTLAND CEMENT: *see* CEMENT.

PORTLAOIGHISE (MARYBOROUGH), the county town of Laoighis. Republic of Ireland. lies on the Triogue river 52 mi S.W. of Dublin Pop (1956) 3.196. Area 8 sq mi. One of the sand and gravel ridges called eskars runs northward from the town to Mountmellick and thence to Tullamore Portlaoighise, established as Fort Protector during the reign of Mary I (hence its common English name), was granted its charter in 1570. and a bastion of the castle still remains. The main industries are flour milling and the manufacture of worsted goods. On the Rock of Dunamase (the fort of Masg), 3 mi. E.. are the ruins of an old castle. the former seat of the kings of Leinster (*q v.*). It was destroyed in 1650 by Oliver Cromwell's army.

PORT LOUIS, the capital and port of Mauritius, is built round a small, well-sheltered harbour on the northwestern coast, and backed by an almost semicircular ridge of mountains which form part of an extensive range stretching toward the centre of the island. Because of these protective mountains. the town and harbour are almost entirely cut off from the normal east and southeast trade winds, and this makes Port Louis one of the hottest places in Mauritius in summer. The town covers an area of 2.1 sq.mi. Pop. (1952) 69,693.

Port Louis was founded in about 1736 by the French governor, Mahé de La Bourdonnais, and considerably improved in 1770. In appearance it seems a curious and fascinating assemblage of ancient and modern, oriental and European, shabby and luxurious. Its streets are laid out in a rectangular netnork and it is dominated by an old fortress, the Citadel (1838), built on a hill almost in its centre. Port Louis also possesses two cathedrals and two fine Roman Catholic churches, a stately town hall, a natural history museum and art gallery, two public libraries, a theatre, a large public hospital and several colleges. A little race course lies on the southeastern extremity and a public park on the northeastern seaboard. The Grand River North West, which runs on the outskirts, furnishes part of the fresh water supply.

The port, mhich is the main harbour on the island, has one deep-sea quay. From the Central railway station and clearing yard lines branch off to all parts of the island. Port Louis contains no large industrial establishment. Its industrial activity, besides that connected with docks and warehousing, is restricted to minor mechanical workshops, small food and wine manufactures, oil extraction and refining, sawmilling, printing, etc. On the outskirts of the town proper, however, there are a big tobacco warehouse, a modern cigarette factory, a thermal power station and a railway workshop. As the central collecting and clearing ground for all merchandise imported or exported from the island, the commercial activity of Port Louis is extensive in wholesale and retail sales. The main export is sugar (98% of domestic exports in value). (M. V. M. H.)

PORT MAHON (MAHÓN), capital and principal seaport of Minorca (*q.v.*) in the Spanish province of the Balearic Islands. Pop. (1950) 15,732 (mun.). Mahón is on the east coast, at the head of a deep inlet which extends inland for $3\frac{1}{2}$ mi. It is an important harbour. Mahon is the ancient Portus Magonis, which under the Romans was a *municipium* (Mun. *flavium magon*tanum) and probably included the whole island under its authority. As the name suggests, it had previously been a Carthaginian settlement. The Moors, who occupied Minorca in the 8th century, were expelled by James I of Aragon in 1232. Khair ed-Din Barbarossa besieged and captured the city in 1535; and in 1558 it was sacked by a corsair called Piali. The British seized the island in 1708 and in 1718 declared Mahon (which they called Port Mahon) a free port. In 1756 it fell into the hands of the French. Restored to the British in 1762, it was recovered by the Spanish in 1782. In 1802 it was finally ceded to Spain by the treaty of Amiens.

Many of the houses date from the British occupation. The King's Island is so called as the landing place of Xlphonso III of Aragon in 1287; farther southeast on the shore is the village of Villa Carlos or George Town; and at the mouth of the port, on the same side, are the remains of Fort San Felipe, originally erected by Charles V and twice the scene of the capitulation of British troops. Opposite San Felipe is the easily defended Peninsula of La Mola (256 ft. high) where extensive Spanish fortifications were established.

PÔRTO ALEGRE, a city and port in southern Brazil, the capital of the state of Rio Grande do Sul. Pop. (1960) 617.629. It is located 670 mi. S.W. of Rio de Janeiro and 150 mi. N.N.E. of the seaport, of Rio Grande at the entrance to the lake. Pôrto Alegre is at the northern end of the Lagôa dos Patos on an arm of the lake known as the Rio Guaiba. Into this end of the lake five short but deep rivers empty their waters: the Gravataí, Sinos, Cai, Jacui and its tributary the Taquari. Since the lower courses of these rivers are all navigable, Pôrto Alegre has become the most important centre of inland navigation in all of Brazil. The outlet of the Lagôa dos Patos, near Rio Grande, is too shallow to accommodate ships of more than 16½-ft. draft. The lake and rivers, however, provide a fine system of inland waterways to serve the chief area of concentrated settlement in the state. The city is built on a ridge of high ground on the edge of the lake. It is located about 30° south of the equator and its climate is one of mild winters and hot summers, with abundant rainfall (average of 50 in.). In winter cold waves from the south bring occasional frosts.

In addition to its function as administrative centre of the state PBrto Alegre is also the chief commercial centre serving the whole of this southernmost part of Brazil. From the rural hinterland come a variety of agricultural and pastoral products: meat and hides, wool, rice, tobacco, grapes, cereals, manioc meal and maize. From the forests lumber is produced. In the city are many business and financial establishments serving this economically active region. Educational institutions include two universities, a medical school, a normal school and a school of agronomy and veterinary medicine. The city also ranks high among the industrial centres of Brazil. Manufacturing industries are chiefly those engaged in processing the products of the farms, forests and ranches; they include meat packing, lard refining, leather tanning, the weaving of woolen yarn and cloth and the manufacture of clothing, the brewing of beer and the manufacture of cigarettes, furniture. soap, candles, macaroni, farinha (manioc flour) and a variety of preserves and wines. There are also metal factories producing stoves, furnaces and iron safes and a shipbuilding and ship repair works. The city is provided with electric power by a large steam-electric plant making use of coal from the nearby mines at São Jerônimo, brought to PBrto Alegre by river barge. Although this coal has a high ash content and requires the use of especially designed grates, it is cheaper than imported coal.

The city is connected by rail with the Uruguayan railroads at Sant'Anna do Livramento and with the Argentine railroads at Uruguaiana. From the junction of Santa Maria, a rail connection exists all the way to São Paulo and Rio de Janeiro. Modern all-weather highways also connect PBrto Alegre with the rest of Brazil and with neighbouring countries. Regular air connections tie the city to these same countries and regions.

PBrto Alegre was founded in 1742–43 by immigrants from the Azores and was first known as PBrto dos Cazaes. In 1825 the first German immigrants were settled in the country north and northwest of the city; later Italian settlers also came into this region. The administrative centre of Rio Grande do Sul was moved from Rio Grande to PBrto Alegre in 1773; it was officially named capital of Rio Grande do Sul in 1807. (P. E. J.)

PORTO BELLO (PUERTO BELLO), a village on the Caribbean, 18 mi. N.E. of Colón, Panamá. Columbus named its site "beautiful harbour" in 1502; the city was founded March 20, 13'97, by Francisco de Valverde y Mercado. As a point of transshipment and exchange for the colonial merchandise of Spain and South America it was famous for its annual fairs and notorious for its high prices, congested quarters and tropical fevers. Once the busiest city in the new world and target of concentrated wealth, it was attacked by the English buccaneers Sir Francis Drake (who mas buried in Porto Bello bay), William Parker. Sir Henry Morgan and Edward Vernon. In 1713 Spain opened it to the trade of one British ship annually. The abandonment by Spain in the 18th century of the fleet system and fairs, the building of the Panama railroad in the 1850s and the opening of the Panama canal brought about its eclipse. It has ruins of great historic interest. Pop. (1960) 591. (A. R. W.)

PORT OF SPAIN, the capital city and chief port of Trinidad, the West Indies, lies on the west coast of the island, below the northern peninsula, on the Gulf of Paria which separates Trinidad from the northeastern coast of Venezuela. Pop. (1946) 92,793; (1960) 91,596.

On the hills behind Port of Spain there are residential suburbs, such as Goodwood Park, and the city itself is beautifully laid out with parks and squares. U'00dford square is the principal one, in the business section, near Holy Trinity cathedral. Queen's Park Savannah is at the centre of the city and from it radiate many of the most important streets, such as Frederick street, the main shopping thoroughfare. Charlotte street, with its markets and small shops. Cipriani boulevard, Marli street and St. Clair avenue, which are' residential.

Around Queen's Park savannah there are several buildings of historical and architectural interest: Government house, standing in the grounds (63 ac.) of the Royal Botanical gardens; the palace of the Roman Catholic archbishop of Port of Spain; Knowsley house, which accommodates certain government ministries; All Saints church; and the Princes' building. The Royal Victoria institute nearby houses a museum, concert hall and the federal supreme court.

The principal administrative building is the Red house near Woodford square. It was decided in 1957 that the legislative body of the federation should meet there until the federal capital of the West Indies was built in Trinidad. Among educational institutions in Port of Spain are Queen's Royal college, Fatima college, St. Mary's college and an extramural department of the University College of the West Indies.

Industries. — Port oi Spain is the market town and the centre of the commerce and industry of the island. The main industries of Trinidad, apart from those concerned with oil and cement, are the production of sugar, cocoa, citrus fruits, coconuts and bananas, and are all situated deep in the country. There are secondary industries within a 16-mi. radius to the east of the city; these include the production of rum, bitters, beer, margarine and oils, cigarettes, plastics, building blocks, prefabricated culverts and tiles. There are sawmills, textile mills and citrus-fruit canning works.

Communications. — Although situated in the extreme north, Port of Spain is linked by good roads with other parts of the island. From Queen's Park Savannah, St. Clair avenue joins the Western Main road leading out to the northern peninsula; Maraval road passes through various suburbs and valleys to the north and reaches Maracas bay, a very beautiful bathing beach. A highway has been cut through the southern hills of the St. George range giving access to Piarco airport and to the remainder of the country. Transport within the city is by diesel buses and numerous privately owned taxis which ply as public service vehicles at regular charges.

Port of Spain is a key port on the world's shipping routes and a centre of trade within the West Indies. The sheltered harbour accommodates medium-sized ships anchoring alongside the eight berths; there are several smaller wharves and jetties and two slipways. The harbour basin is 32 ft. deep and has a mean width of 900 ft. and a length of 5,500 ft. It is approached by a dredged channel 350 ft. wide marked by automatically lighted beacons.

The airport at Piarco, 16 mi. east of the city, is used by the principal airlines operating in the western hemisphere. (H. E. CN.)

PORTOLÁ, GASPAR DE (c. 1723–c. 1784), commander of the expedition sent from New Spain to colonize Upper California, was born about 1723 in Balaguer, Catalonia. At the age of 11, according to his military record, he became an ensign in the dragoon regiment of Villaricosa. He was promoted to lieutenant of dragoons and grenadiers in the Numancia regiment, where he served 21 years, and later was made captain of the España regiment and took part in the campaign against Portugal.

After José de Galvez was sent to New Spain in 1765 as *visitador,* he became aware of British and Russian interest in the Pacific coast of North America, an area which Juan Rodriguez Cabrillo' in 1542 and Sebastián Vizcaino and Bruno Heçeta later had visited and partially charted in behalf of Spain. He secured the appointment of Portolá, then of noble rank and unmarried, as governor of the Californias. Portolá took office in Oct. 1767 and after organizing an expedition, sailed from San Blas and landed at La Paz, Lower California, on July 6, 1768.

For the colonization of Upper California he prepared both a land and a sea expedition with the intention that both were to rendezvous at San Diego and later advance to Monterey, a harbour which had been reported in 1603 by Vizcaino. Portolá led the land force, taking with him Fathers Junipero Serra, Juan Crespi and several other priests to establish missions. He arrived at San Diego on July 1. 1769, after an arduous journey of four months from Loreto. On July 14 Portolá began the trip to Monterey but. failing to recognize the bay. he passed on to San Francisco bay. There, realizing that the party had gone too far, he turned back on Nov. 11 and arrived in San Diego on Jan. 24, 1770. Within a few months he tried again and was successful in reaching and identifying Monterey. He returned by sea to Mexico. surrendering his governorship in Sept. 1770.

He became governor of the city of Puebla on Feb. 23, 1777. In 1784 the viceroy of New Spain reported that he had advanced Portolá 12 salary payments in order to permit him to return to Spain, but whether or not the trip was attempted remains unknown.

BIBLIOGRAPHY.—"Diary of Gaspar de Portolá during the California Expedition of 1769–70," *Academy of Pacific Coast History*, i, 33–89 (1909); "Narrative of the Expedition by Miguel Costansó," ibid., i, 93–159; Francisco Palóu, *Historia de la Vida del Fray Junipero Serra* (Mexico, 1787); F. PORTO MAURPZIQ: *see* IMPERIA.

PORTO NOVO, a town on the Coromandel coast in South Arcot district, Madras state, India, 30 mi. S. of Pondicherry. Pop. (1951) 15.084. It is famous for the battle of July 1781, in which Sir Eyre Coote with 8,000 men defeated Hyder Ali with 60,000 and thus saved the Madras presidency.

PORT OPERATION. The term "port operation" includes the receiving of ships in harbour, putting them in position to discharge or load their cargoes, the handling of the cargo and its dispatch to or reception from inland destinations. The primary aim of all modern dock operation is to give ships quick dispatch; *i.e.*, to keep down the time in port.

Before the cargo can be distributed it has to be landed, sorted to the various bills of lading, passed by the customs officers, customs and port charges paid and the goods released by the shipowner to the merchant.

The shipper when dispatching goods receives from the master of the ship a bill of lading. which is a negotiable document of title and which he sends to his consignee. While the goods are in the ship they are by law the property of the shipowner, and he has a prior lien on the goods for his freight. This lien is removed by the consignee's taking the bill of lading to the shipowner and paying the freight, receiving in exchange a release, which is the authority to the port authority or wharfinger to deliver the goods. But in order that the discharge of the ship shall not be delayed while the consignees are obtaining releases. the discharge of the goods is commenced at once into the transit sheds alongside. These transit sheds are, in the eye of the law. part of the ship. So long as the goods are in the transit shed the shipowner retains his lien for freight, and the port authority cannot allow the goods to leave the transit sheds until a release has been produced.

In the case of goods liable to customs duty for which it is not desired to pay the duty at once, they are after being released passed under customs guard into bonded warehouses. In the case of goods of high customs value, such as wines and tobacco, the goods usually remain in bond until passed into consumption, the owner thus being relieved from the premature payment of heavy duty. Both transit sheds and bonded warehouses have, therefore, to be under double locks of the customs and wharfinger respectively, so that goods can be handled only in the presence of both parties.

To protect the customs, goods can by British law be landed only at duly authorized landing places called legal quays and sufferance wharves, the only difference between these terms being that the first receives a permanent licence issued by the treasury and the second a restricted licence issued by the commissioners of customs. The services of the officers of the customs for watching goods in course of discharge in ordinary hours are paid for by the state, but all overtime is at the cost of the ship, and as customs hours do not coincide with port hours, a ship working the ordinary hours has to pay at least one hour of customs overtime, and more if she is herself working overtime.

Rough cargoes such as ores, timber, etc.. which do not require shelter, are landed at open quays, and the limitation of the shipowner's lien sometimes gives rise to difficult questions.

In the days before free trade, when nearly all goods were dutiable, it was the British custom to constitute a customs area of the whole dock estate and to secure it within high walls and massive gates. These will still be found in the older ports, but in modern times it has become the practice to localize the control at sheds and wharves, and transit beyond these limits is free.

Custom of the Port.—A shipowner by his contract of carriage undertakes to deliver to the consignee the goods according to the bill of lading, which implies that he has to separate each man's goods from other people's goods and deliver them in one parcel. But this general rule of law is materially affected by the local custom of the port which varies everywhere and is a cause of much dispute and litigation. In some ports the custom ordains that the ship shall put the goods on the quay indiscriminately, and the work of sorting and removal is at the charge of the merchant; in some cases, goods are removed from the crane sling by one party, sometimes by the other, or sometimes shared by both parties. In some exceptional cases the cost of craning the goods from the hold is held to be on account of the merchant. For these reasons comparison of the working charges of different ports is alwavs difficult.

Large cargoes carried and the very mixed nature of the commodities necessitate in most cases landing on the quay for sorting before delivery. This requires much floor area, and led to the introduction of two or more floor transit sheds to avoid excessive congestion of the cargo when landed. And for the subsequent delivery of these goods by rail or road, special facilities are needed. A single cargo of 8,000 tons of general cargo, if all had to be dispatched by rail, would require 1,000 freight cars to take it away. These freight cars would occupy 3.000 yd. of railway, which is some measure of the amount of siding accommodation which has to be provided for the efficient working of a discharging berth and also the great relief obtainable when a large part of the work is done by barge. The movement of these freight cars has to be performed without interference with the work at adjacent wharves; hence the proportions which the three methods, barging, railway and road transport, bear to each other must largely affect the design of the shore equipment of a port.

The quick and economical movement of cargo is now largely obtained by the provision of mechanical appliances in substitution for manual labour, and the main staples when arriving or being dispatched in whole cargoes, or in large quantities in mixed cargoes, are usually dealt with by special machinery. For example, specially designed conveying machinery is installed at every port where the tonnage is sufficient to justify the expenditure to deal with the export of coal and the import of grain, timber, meat and provisions. Mixed cargoes are discharged either by cranes on the shore or by the ship's gear. Such equipment is usually provided by the port authority.

The Provision of Port Machinery.—As ships are often required to receive and deliver cargo in the open roadstead or at ports abroad not equipped with shore appliances, they must necessarily be fitted with booms and winches, and it is, therefore, often economical to make use of these appliances even when shore plant is available. In practice, however, competitive reasons compel port authorities to provide cranes and in many cases more specialized working plant. Coal is shipped by means of: (1) tips or hoists in which the freight car is lifted to a height above the ship's deck, the contents tipped into a chute to fall into the hold; (2) staithes, when the configuration of the ground permits, where the freight car is pushed to above deck level and the contents tipped into the hold; and (3) conveyors, in which case the freight car at quay level is discharged onto a conveying band to the hatch. Grain is mostly imported in bulk and is discharged by means of elevators which lift it in a continuous stream from the hold, convey it to the quay and there deposit it onto conveying bands which carry it to silos where it is either stored or delivered by gravity into sacks for inland transport. Pneumatic elevators have largely replaced the older bucket-type elevators in quayside granaries. When grain is imported in sacks the modern practice is to cut the bags in the ship and "start" the contents into bulk for discharge by this more economical method.

Grain elevators may be either movable shore appliances or mounted on floating pontoons. The latter, though more costly, have the advantage of greater mobility. The development of transport of grain in bulk, by rail or road, has led to the provision of vehicles with bottom doors, end doors or tippler devices. Among apparatus developed to facilitate the unloading of cargoes, mention may be made of fork-lift trucks, which, operated by gasoline, diesel or electricity, can pick up, raise, transport and pile suitable packages or palletized loads, and can also unpile loads and transport them to outgoing vehicles. They may be fitted with platforms to deal with goods in cases or with forks for lifting cargo in bags.

Ores are generally discharged by grab cranes which are self-filling and save the labour of loading into tubs. Iron is largely discharged by means of an electrified block on a crane which attracts the iron and when over the selected site releases by cutting off the current.. Petroleum is usually discharged through pipelines from the shore storage to the quays. The pipe is connected by means of a flexible hose to the ship's tank and pumped to the storage tanks. The same method is employed for vegetable oils where the volume of trade is sufficient to justify the cost of the installation.

There is an increasing modem tendency for the importing merchant to sell his goods "ex ship," and for goods to pass at once on discharge into consumption, but raw materials are still largely stored in dock warehouses or in adjacent warehouses of private owners for later consumption. Such deliveries are largely of a retail nature, and many of the chief ports have provided elaborate facilities for the storage, sampling, handling and accounting of warehoused goods. This branch of activity prevails in British and in some U.S. ports more than on the continent of Europe.

Rail Terminals and **Docks.**—At ports where barging is not the predominant method of handling cargo and at all modern ports to a greater or lesser degree the railway facilities are an important feature as affecting the cost of distribution. There is great variety of method. At some railway-owned ports the docks are treated as a terminal goods station under main line control. At others, the railway working is self-contained under the docks superintendent. This affects the design of the railway system and the methods of working. In nonrailway docks in some cases the railway company is given running powers to the quays; in others the port authority conducts its own railway operation. As in every properly conducted dock the first and principal aim is to give the ship dispatch and with that object to avoid, by its rapid removal, the congestion of cargo at the ship's side, modern practice is to confide the control to the auth'ority responsible for the dispatch of the ship, providing an area away from the ship where the traffic is interchanged with the main line railway. In the United Kingdom this area is called the exchange sidings; in the United States the belt line. One or more such points of interchange may be provided in accordance with the physical conditions of the main railways serving the port.

The development of road transport introduced a new problem into the question of dock layout, and the need for providing facilities for economical loading to road vehicles in docks equipped only for loading to barge and rail called for many modifications of design.

Port Ownership.—The several types of port ownership and operation may be classified under the following heads: (1) national ownership; (2) trust ownership; (3) municipal ownership; (4) railway ownership; (5) private ownership.

1. Examples of national ownership are Rotterdam and all the larger French ports. None are to be found in the United Kingdom and the United States except naval dockyards which do not come within the scope of this article.

2. Examples of *trust* ownership, are in England, London and Liverpool; in Canada. Montreal and Vancouver; in the United States. New York and New Orleans; in Australia, Sydney and Melbourne.

3. Examples of municipal ownership are, in England, Bristol and Preston; on the continent, Hamburg, uhich is the property of the Free City of Hamburg and might perhaps be classed under national ownership; and Antwerp, the financing of which is divided between the state and the city.

4. Railway *Ownership.*—Before the amalgamation of the railways of Great Britain in 1921 a number of docks were railway owned, some having been acquired by railways when they had difficulty in maintaining themselves as independent authorities. Examples are Southampton and Hull. Others were constructed by companies which, though nominally railway companies, were mainly ports (examples, Cardiff and Newport) to serve the surrounding coal fields. By provision of the Transport act, 1947, the former railway-owned docks in Great Britain passed into the ownership of the British Transport commission, together with the country's railways, inland waterways and some road haulage concerns.

An outstanding example of railway ownership is South Africa where all the ports are worked as part of the state-owned railways. A few examples may be found in the United States, but the tendency in that country is to separate the port and railway ownership.

5. Private Ownership.—In the United Kingdom few ports are to be found in this class, but the Manchester ship canal and the Gloucester Docks and Canal company may be instanced.

The acceptance as a national liability of a larger or smaller proportion of the cost of construction, maintenance and working of a port prevails on the continent much more widely than in the United Kingdom. For example, at Rotterdam and Antwerp the construction, dredging and maintenance of the harbour up to quay level are carried out by the state as a national charge against the general revenues of the country, only the superstructure above water level being provided by the municipality and being the only portion of the charges to be recovered from the trade passing through the port. This is a potent cause of the lower charges prevailing on the continent as compared with the United Kingdom. Under the policy which has generally prevailed in the United Kingdom of nonintervention by the state, economic forces have been allowed free play.

Public Ownership.—In the British dominions the policy of state or national ownership is almost universal, but the methods differ widely. In Australia the ports are financed by state loans and administered by nominated commissioners under the control of the minister for public works. In South Africa they are combined with the state-owned railways under the general manager of the latter. In New Zealand and in India the ports finance themselves, but with the government guarantee behind them, and are administered by a state-appointed chief commissioner assisted by commissioners elected by the users of the port with. in some cases, representatives of the local inhabitants. In Canada ownership and administration are with the several states through the agency of nominated commissioners.

Port trusts are statutory bodies not working for a profit but they are obliged, in order to keep themselves solvent, to levy charges high enough to cover all their outgoings. The capital account has to bear all the cost of construction and of equipping the port, and the revenue account has to bear the interest and sinking fund on such capital expenditure. Charges, therefore, have to be fixed so as to bring in sufficient revenue to pay this interest and sinking fund in addition to current working expenses. Surplus revenue is applied either to improving the facilities or reducing the charges of the port.

Municipal ports can, if the owners so desire as a matter of policy, be subsidized out of the general rates of the city, and in England these are the nearest analogy to the national ports of the continent. As port works from their nature take a long time to construct, and as new trade offering naturally cannot wait while facilities are being provided, it is necessary if a port is to maintain its position to provide facilities in advance of the current demand. It is, therefore, in the power of a municipality. if it is prepared to accept a present burden upon its rates in the hope of being eventually recouped, to provide for the future to an extent which private enterprise cannot afford. In some cities of the United States the practice prevails of levying a specific rate on houses and property in aid of port improvements, and an early example in England is the case of Bristol, the largest municipally owned port, which from 1849 to 1897 levied a rate of £4,000 a year on houses for port purposes. Since the last date this levy has been merged in the general rate-in-aid to balance the revenue account which, however, for many years has been less than the annual contribution toward the sinking fund for the extinction of the capital.

Before the nationalization of the railways, railway-owned docks were enabled, subject to certain provisions of the 1921 Railways act, to meet any shortage of earnings out of their general revenues. The 1947 Transport act sought to integrate all the activities of the British Transport commission and to make them pay as a whole, and the nation at large rather than a group of shareholders became responsible for the financial position of all undertakings managed by the commission. The Transport act, 1953, although modifying the commission's activities, did not affect this arrangement.

Private Ownership. — In the case of the fifth class of ports, the property of private companies, the same end can only be obtained by the shareholders' foregoing their dividends during a long fructifying period, which has actually been the experience of both the ports named above. In fact, in the case of the Manchester Ship Canal company, the outstanding example of a successful company port, the period of fruition was so long delayed that its capital and credit were exhausted and the Corporation of Manchester had to come to its aid by the provision of additional capital on which it had for a period to forgo interest, and in consideration of which it was entitled to representation on the board of directors. But as the management is still with the company's directors, the classification of the undertaking here adopted remains correct.

The decadence of so many English ports under private ownership may be traced to this natural law. Ports constantly tend to become out of date as a result of the increasing size of ships, and are faced with the alternative of seeing their trade depart or of undertaking expenditure on which the return must be far distant and which often proves to be beyond their unaided resources. London and Bristol. Southampton and Hull are examples of company-owned undertakings which were becoming derelict when they obtained outside aid. The first was absorbed by a powerful trust under the direct aegis of the government, the second by the local authority, and both became self-supporting. The last two, though returning large profits to the railway companies which owned them, never directly gave a commensurate return on their cost. Immingham and Fishguard, both railway owned from the beginning, were never remunerative undertakings to their owners or any great advantage to the trade of the country. The relation between the several classes of ports in the United Kingdom was largely affected by the Railways act of 1921 under which the great railway systems became great port proprietors in competition with others dependent on their own resources. This implied a combination of the two systems of extraneous subsidy and self-containment, each of which had been applied successfully in some countries but never before both in the same country.

Functions of Port Authority. — The functions of a port authority may be classified as conservancy and dock ownership. The first head comprises all operations connected with making the port available for shipping, maintenance of navigation channels, surveying the same. buoying and lighting, removal of wrecks, signal service, pilotage service, supervision of foreshore to prevent interference with navigation channels.

The conservancy boundaries of a port are laid down in its acts of parliament, or in the case of ancient ports may be derived from royal charters, and if any portion of those waters forms a highway to other ports, the lighting and charting of that portion is usually undertaken by the state. *e.g.*, Trinity House for English waters and the commissioners of northern lighthouses for Scottish waters.

As dock owner the authority provides the equipment necessary for the accommodation of ships, their loading and discharging and the movement of their cargoes, including the provision of transit sheds, cranes and other cargo working machinery, power plants, railway lines and roads, etc.; facilities. as working of lock gates (if any), lighting, berthing masters and everything necessary to enable a ship to get with safety to a position to discharge and load its cargo; and services, which include everything connected with the handling of cargo, discharging or loading, receiving, sorting, dispatching and storing. Facilities are necessarily provided by the dock owner. In regard to the rendering of services, the practice varies within wide limits. In some ports these are rendered by the dock owners in whole or in part. In others the policy is to leave the services to private enterprise. The port of Manchester is the only example in the United Kingdom of a statutory monopoly of all the services within the dock area, but all ports have power under their acts to provide services and to make "reasonable" charges therefor. The policy, however, differs materially in the various ports, some encouraging departmental working and others favouring separate private enterprise. The principle of a complete monopoly of all the services within the port limits is more prevalent in foreign ports.

The growing tendency to provide large-scale equipment for handling staple commodities makes it seem possible that in the future, despite the objection that it would deprive the shipowners of the advantage of competition, economic reasons will force the more general undertaking of services by dock owners and the acceptance of the position by shipowners. In the case of Manchester the powers giving the authority the exclusive right are coupled with the proviso that their charges to their customers must not provide more than a 10% profit, and it is a generally accepted principle of port finance that the several departments, viz., conservancy, facilities and services, should each be separately self-supporting, though many exceptions to this rule may be found.

In some cases the two functions of conservancy and dock ownership are combined in one authority; in others they are under separate ownership and administration. There is considerable difference of opinion as to which is the better system, but it is perhaps more generally held that more satisfactory co-ordination can be secured and therefore better efficiency and economy obtained when both functions are combined in the same authority. This is the case in most of the larger authorities of the United Kingdom. Examples of ports where the conservancy authority is separate from the dock-owning authority are Southampton, Glasgow and Newport.

Port Revenues. — The revenues of port authorities are principally obtained under the following heads: as conservancy authority, light dues, pilotage dues and sometimes tonnage dues levied entirely on the shipping; as dock authority, dues on shipping calculated on the net register ton, import and export dues on the cargoes. Subsidiary but sometimes very important items of revenue are: profits on the handling of cargo, warehousing, railway working round the docks and rents of lands.

Most ports endeavour to obtain sufficient land to establish industries in the immediate neighbourhood of the docks and, because of the high cost of inland transport and the fact that with most commodities the finished article weighs less than the raw material required to produce it, the tendency is to move industries more and more from inland centres to the coast in the immediate neighbourhood of the great ports, and when possible to obtain the economic advantage of establishment within the dock area to avoid the cost of haulage either by railway or road between such an inland centre and the port.

A problem in port economics which has always been the subject of much difference of opinion is the proper distribution of the burden as between the ships and the goods they carry. The principle generally accepted is that the burden should be divided as equally as can be between the two, but this has many exceptions. Some ports adopt the policy of making the charges on shipping very light with a view that thereby freights will be kept low, greater cargoes obtained and the revenue recouped from the tonnage of those cargoes. Other ports hold the view that the incidence of the port charges on the total expenses of a voyage is so small that it cannot affect the freight, and low charges on goods encourage manufacturers and merchants to use the port This is the policy of all the railway-o ned ports where dues on goods are not only fixed on a low basis but which frequently render services for less than cost, recouping the amount of the cost from the profits on railway haulage.

Important factors affecting the quantum of port and harbour dues are the nature and the cost of the works necessary under the particular physical conditions of each harbour. In the United Kingdom, because of the great variation of tides. it is in most cases necessary for the efficient working of ships to maintain a constant level in the docks by impounding the water within lock gates (a notable exception is Southampton, uhich has been favoured by nature with four tides in the 24 hours, reducing the difference between high and low water to a few feet). The Pacific and Indian oceans and the Mediterranean sea, on the other hand, with their low rise and fall of tide, enable their ports to dispense with such expensive equipment, and at the great ports of these oceans. Sydney, San Francisco, Singapore, Marseilles, etc.. the features of the port as left by nature have been almost entirely retained. For this reason the capital cost, as measured by the accommodation afforded, is much lower and is reflected in the lower scale of dues which can be imposed.

The working expenses of a port are for the greater part in the nature of fixed charges, e g., interest and depreciation on the capital cost of the accommodation and working of the entrances nhich are the same whether they lead to few or to many berths and whether the berths are occupied or not. Those expenses have to be distributed, as a rate per ton, over the shipping using the port. Hence economy of port charges can be obtained by concentrating the trdde of a country into a few ports. But this may involve a longer and more expensive carriage to point of origin or destination, and there is constant play of these contending forces. England is a small island with a comparatively large number of ports. On the continent of Europe, on the other hand, the area of distribution or collection runs into many thousands of square miles served in almost all cases by water ays concentrating in the mouths of a few great rivers. The number of ports is, therefore, fewer and the tonnage concentrated in each to a much greater extent than in Great Britain, thus allowing of lower dues per ton to obtain the necessary revenue.

In England, again, transport inland has mainly to be made by road or rail. On the continent of Europe the goods are carried for the most part on waterways of a width and depth to take barges sometimes nearly as large as ocean-going ships.

Comparison is frequently made of the charges in English and continental ports to the disadvantage of the former. The explanation can be found in the foregoing paragraphs, and may be summarized as: (1) substantial national expenditure not brought onto the port's accounts; (2) concentration of a greater tonnage over which to spread the fixed charges; and (3) the larger units and therefore the lower cost of transfer from ocean to land transport. (D. R.-J ; X.)

UNITED STATES

United States ports are on three coasts: the Atlantic. Pacific and Gulf of Mexico; they are also on the inland waterways. principally the Great Lakes and the Mississippi river system. Because of the size of the Great Lakes and the vessels employed on them, lake ports have many of the characteristics of ocean ports. Ports of the Mississippi and its tributaries are accessible by barges of up to nine feet of draught. Most United States ports have a much higher proportion of domestic—coastwise, intercoastal and internal—traffic in proportion to foreign traffic than is characteristic of ports throughout the world.

Harbours.—United States harbours are diversified in physical type. Few have tidal ranges comparable with those of major harbours of northwestern Europe: fluctuations in water level are generally not sufficiently great to impede cargo operations, making locked wet docks unnecessary. Low water depths at major ocean ports vary irom about 27 to 40 ft., at Great Lakes ports irom 18 to 25 ft. (except for ports handling traffic through the proposed St. Lawrence seaway) and 6 or 9 ft. at Mississippi river system ports accessible by barges.

With few exceptions, channels are improved and maintained by the U.S. army corps of engineers under specific project authorization and appropriation by congress.

Port Administration. — Although channels are generally maintained by the federal government, planning, financing, constructing and operating of port terminal and auxiliary facilities is for the most part by private interests or by local. state or interstate ad *hoc* agencies. Unified development and operation of all iacilities of a port is relatively uncommon.

Some ports, such as Gary, Ind., are private facilities of a single industrial establishment. Many port facilities are operated by railroads, nhich offer free berthage to vessels with full or partial cargoes moving over the lines of the respective companies, in competition with other privately and publicly operated facilities at the same and other ports.

In the first half of the 20th century, public development and ownership of port terminal facilities, in order to make them available to all carriers on equal terms. became increasingly common. Public port authorities which operate facilities are municipal departments as in New York city. Philadelphia and Milwaukee, state agencies as in North Carolina, Georgia, Alabama and in Boston and San Francisco, and interstate authorities, the oldest and largest of uhich is the Port of New York authority. In some instances, as in New York. two or more public authorities may own different port terminal iacilities, often with competition from privately owned facilities including those of the railroads.

Port Finance. — Use of harbours and channels maintained by the federal government is free. Terminal facilities operated by industries and carriers for their own traffic are maintained as part of their capital plants. Other private terminals and public terminals charge a berthage fee against vessels, as well as demurrage and special service charges as for heavy lifts. Berthage and other charges are customarily absorbed by the carriers.

Although some public port agencies receive tax revenues, most are supported entirely by receipts from operation of their facilities either directly or through leases to private operators. The specialized-function port authority is a popular device for relieving municipalities, counties and states of financial obligations with respect to their port terminal developments by having specific responsibility for amortizing its bonds from revenues derived from operation of the port facilities. Many port terminals have been financed by revenue bonds. In some instances the bonds are amortized by rentals paid for operation of the facilities by private companies which, in turn, assess berthage and other charges against the carriers. Commonly, the port authorities are authorized to issue bonds independently of the legal debt limit imposed upon municipalities and other public jurisdictions, the geographic boundaries of nhich may coincide with those of the port authority.

Many port terminals, although meeting out-of-pocket costs by user charges, cannot cover their full costs, including depreciation and amortization, aithout direct or indirect subsidy. In some instances the port authority is also a general transportation authority, operating river crossings, inland terminals and airports, some of which produce revenues in excess of amortization and operating costs the excess being used in part to finance port terminals.

Port Competition. — The success of a port in capturing the trade beyond its immediate metropolitan area is the result of the efficiency of its facilities in fast turn around of vessels, thereby attracting liner and tramp services; the strength of its own metropolitan and regional economic base in providing minimal traffic to justify regular shipping services; freedom from work stoppages by strikes and other disturbances; promotional activities by local port agencies; easy access to and from the hinterland by land and inland waterway carriers; and the structure of inland freight rates.

Beyond the local area there is a noncompetitive hinterland in which the port has rate advantages. Beyond is a competitive hinterland, in which rates to and from groups of ports are equal or nearly so, in which the frequency and dependability of services will determine routings. Ocean rates are generally equalized for all ports of a "range," as, for example, the transatlantic rates via the North Atlantic range which includes all ports from Portland, Me., to Norfolk, Va. Ports within that range have differential land rates. For example, to and from the midwest, transatlantic rates are equalized. but land rates via Philadelphia are lower than via New York and Boston, and via Baltimore are lower than via Philadelphia. Rates via Gulf of Mexico ports are also competitive with North Atlantic ports. Port equalization has been an issue before regulative bodies for many years.

The foreign trade zone or free port has, from 1937, been used to stimulate traffic, without outstanding success. In a foreign trade zone goods may be received, sorted, traded, processed and transshipped without payment of import duties unless and until passing the barrier which surrounds the zone. Such zones in New York, New Orleans, Los Angeles harbour, San Francisco and Seattle include small areas of terminal facilities together with adjacent land, under lease to private operators.

Terminal Design.--Older portions of United States coastal ports are characterized by piers at right angles to the shore line with inadequate landward access. congestion on the piers and marginal streets. wharf aprons too narrow for easy movement of modern mechanical handling equipment such as fork-lift trucks, slips of inadequate width for easy berthing of ships without tugs and for handling of barges and lighters alongside and unavailability because of high land costs and congestion of nearby sites for industrial plants requiring direct access to deep-draught shipping. Most modern port developments are of the marginal quay type, in which the vessels tie up parallel to the shore line, usually without aid of tugs. Such quays typically have paved aprons of 40 to 50 ft. width with access by rail and truck, transit sheds parallel to the wharf and at least 120 ft. wide. adequate marginal streets and a marginal belt railroad with adequate capacity in nearby holding yards, and nearby warehouses and open storage areas. Such developments meet the need for more shoreward area for cargo handling and less lineal footage of berths for vessels, resulting from larger but fewer vessels and faster turn arounds than were heretofore common. Such modern port developments are best accommodated at some distance from the older sections of cities, and there has been a tendency for newer port terminals to be located downstream and upstream from the older ones as a result of the necessity to provide larger space for sorting and classifying inbound and outbound shipments, as well as the warehousing and open storage. These tracts are generally in proximity to extensive. areas available for industrial sites.

United States port terminals are generally not provided with large cranes. as are European terminals! relying rather upon ships' tackle for transfer of cargoes between vessel and wharf and upon tractors and fork-lift trucks for movement between wharf and transit shed or storage areas. Pallets are extensively used for transfer of general cargo. Many ports are provided with floating cranes for heavy lifts. Except for lighterage in New York harbour, direct transfer of cargoes between ocean and inland vessels is not common. (H. M. M.)

PORTO-RICHE, GEORGES DE (1849–1930), French dramatist, born on May 20. 1849, at Bordcaux. In 1873 his pieces in verse began to be produced at the Parisian theatres; he also wrote some books of verse which met with a favourable reception. hut these early works were not reprinted. In 1898 he published *Théâtre d'amour,* which contained four of his best pieces, *La Chance de Françoise* (1888). *L'Infidèle* (1890), *Amoureuse* (1891) and *Le Passé* (1897). The title given to this collection indicates the difference between the plays of Porto-Riche and the political or sociological pieces being written by many of his contemporaries.

In Germaine, the passionate and exacting heroine of *Amoureuse,* Mme. Réjane found one of her best parts. In *Les Malefilâtre* (Odéon, 1904), also a drama of passion, the characters are drawn from the working classes. Later plays are *Le vieil homme* (1911) and *Le Marchand d'Estampes* (1917). He published in 1920, under the title *Anatomie sentimentale,* extracts from his works, which well illustrate his sense of the inevitableness of the continual duel between men and women.

Porto-Riche was a member of the French Academy, and a director of the Bibliothèque Marazine. He died in Paris on Sept. 5, 1930.

PORT PHILLIP: *see* MELBOURNE.

PORT PIRIE, a seaport of South Australia situated on the eastern shore of the northern portion of Spencer gulf. Pop. (1954) 14,223. The harbour is poor, and Pirie won its place as the second port of the state because it is the nearest convenient maritime outlet for all the exports and imports for Broken Hill (*q.v.*) in New South Wales. 205 mi. inland to the northeast. The Broken Hill ores have been smelted at Port Pirie since 1897 to produce lead bullion which is later refined. Coal from Newcastle, New South Wales. is used for the smelters which are on a large scale. The main exports are lead. ores and wheat and in 1952–53 they totalled 586.859 tons. The imports for the same period were 239,905 tons.

PORTRAIT PAINTING. A portrait is a record of certain aspects of a particular human being as seen by another. The sitter may be deified or merely flattered by the painter, satirized or even maligned but. as long as some sense of his individuality remains, a painting of him will be a portrait. The artist may be interested only in the sitter's physical appearance, his social position, his soul or his unconscious problems, but again. as long as the sitter's identity remains, the artist will have painted his portrait. Finally the painter may paint him with a concern for precision of detail or with apparent abandon, with an interest in photographic realism or with a composition of cubes; but still, whatever the style is, as long as the artist can suggest some aspect of a particular person. the work will be a portrait. (It may not be a very good portrait but that is another problem.)

The Portrait **and** History. — By its very nature the portrait grows out of a respect for the differences between human beings; therefore it is only in periods primarily interested in individual differences that portrait painting thrives. In classical Greece, where the ideal mattered more than human particularities, portraiture had no place. In the middle ages, when man should ideally have lost his identity in the contemplation of God. again portraiture had an insignificant role. In the 20th century, portrait painting, with certain exceptions, has not been an important art form, perhaps because photography has provided an inexpensive substitute or perhaps because the norm is worshipped more than specific human characteristics.

The reasons for a concern with the individual and a subsequent desire for portraits vary according to the period. The wish to have a portrait may be for religious reasons; *e.g.*, the ancient Egyptians needed a durable portrait in stone enough like the body of the dead person with which it was buried to suggest his authority and thus deceive his ka (or double) so it would not haunt the survivors. At other times the moving force may have been a conviction of the importance of the individual to the family's prestige, as it was for the noble Romans or for the great of Georgian England. The cult of the hero, whether knight or courtier, grew up in the late middle ages and was developed in the Renaissance; his individual virtues had to be recorded. In contrast to this, the 19th and 20th centuries have observed the human being realistically, almost critically; portrait painters (as well as novelists) have emphasized his physical peculiarities and his psychological problems. Circumstances such as these have helped determine the character of the portrait historically.

The Painter and the Sitter.—In a portrait the personality of the sitter is obviously of primary importance. It may not be equally apparent that the personality of the painter is just as significant. and that the character of the relationship between them is perhaps most relevant of all. When a fashionable patron commissions a portrait from a fashionable painter the relationship between painter and sitter may be a formal one, and the work will reflect that formality. When an artist instead chooses to paint a portrait from his own affection or interest the relationship between the painter and the sitter becomes intimate and revealing. A portrait may reveal the shyness, the apprehension, the arrogance, the amusement or the casualness with which the sitter regarded the artist.

The great moments in the history of portraiture are probably those when the personality of the artist can most completely comprehend his sitter's—when a Hans Holbein is capable of identifying himself with the Merchant Gisze or a Diégo Velázquez can meet the challenge of the realism of an Innocent X or a Jean Ingres can love the vulgarity of a Mme. Moitessier. Out of such a rapport the greatest portraits are painted.

HISTORY

The beginning of the Renaissance, about 1400, introduced the first consistent tradition of portrait painting in the west. The Egyptians and the Romans who, unlike the Greeks, were portraitists, preferred sculpture. During the middle ages interest in the individual's mortal life had a lesser place; it was only toward the end of this period that a donor felt a need to have his individual piety recorded—not just by a symbol, his coat of arms perhaps, used to decorate some object he had given—but by having his own features reproduced as he knelt in devotion before the Virgin Mary.

The Sitter's Piety.—In the late middle ages Richard II (1367–1400) of England was painted kneeling, under the protection of his three patron saints, before a Madonna and Child surrounded by a circle of angels who look and point to ard the suppliant king (Pl. II, fig. 1). There is some question whether this work, the "Wilton Diptych," was painted during Richard's lifetime or was commissioned by some admirer after his death. Whatever the circumstances were, the artist was not interested in visual probability; rather he imposed upon the scene the traditional conception of religious decorum by making the Virgin Mary appropriately larger than the three patron saints, who are bigger than the king, and by isolating Richard and the three saints in the left of the two panels which form the diptych.

The artist imposed the same medieval conventions in the portrait of Richard that he did in the arrangement of the whole. Richard's kneeling body has no apparent existence under the heavy robes which enclose it. All that is exposed are the head and the hands. The hands are held apart in a rather uncertain suppliant gesture before the Madonna to emphasize the humility of the king. That he is king is indicated by his crown and his gold brocaded robes, that he is Richard by the white hart with which his robe is decorated and which also hangs as an emblem around his neck. Finally, instead of using the three-quarter view of the face as he did for most of the other figures, the artist chose the position in which a person's features are most easily remembered—the profile. Richard's face is smooth, bland and young, its features delicate and somewhat pointed, his expression content. As long as he was identifiable, perhaps as much by the heraldic symbols as by his features, the purpose of the painting was served. The artist had clearly achieved the suggestion of the piety of this particular king.

RENAISSANCE

The Sitter Seen.—The convention of including the portrait of a donor in a religious work continued into the 17th century. but early in the 15th century during the Renaissance in both Italy and northern Europe independent portraits became common as an expression of the renewed interest of the Renaissance in the individual human being. One of the greatest portrait painters of the time was the Flemish artist Jan van Eyck (1385?–1441), and his most remarkable portrait was of an Italian merchant, "Jan Arnolfini and His Wife" (see EYCK, VAN). It has been shown that, more than a double portrait, this is a witness to the marriage of the Arnolfinis which Van Eyck shows taking place. The painting is full of late medieval symbolism referring to the event. The single candle in the candelabra burning in daylight represents the unity of marriage. The fruit, so casually placed on the chest by the window sill, suggests the state of man before the fall. Even the dog represents domestic bliss.

However, as a portrait "The Marriage of Giovanni (?) Arnolfini and Giovanna Cenami (?)" is more important because it is a rare attempt in the 15th century to paint a full standing figure and because both these figures are placed in their own familiar setting, no matter how fraught with symbolism it may be.

Although the garments the Arnolfinis wear are full they do not conceal their figures entirely; so Jan van Eyck, more than the artist of the "Wilton Diptych," makes use of their bodies to enrich his interpretation. The Italian merchant has narrow, sloping shoulders, he stands with his legs apart and his feet outspread; there is no suggestion of classical beauty or power. His body is, still in medieval terms, unimportant. He holds himself erect like an ascetic. somewhat aloof from his wife at whom he does not look, his head and his lifted right hand concentrating upon the troth he is pledging. Jeanne, his wife, is a gentler figure; her shoulders are bent, her head is modestly lowered in her husband's direction. Although Jan van Eyck proved here that full figures could be used meaningfully in a portrait it was another hundred years before the practice became common.

The Arnolfini portrait is also remarkable in its effort to make the figures seem very natural in their environment. Their slippers, the wooden planks of the floor. the bed, the opened window with the warm sunshine streaming through it, the obvious details of a prosperous 15th-century home can be seen. Although the Arnolfinis are quite large for the scale of the room, the slippers and the dog in front of them seem to place them convincingly back into it. This position, combined with the visual interest demonstrated in the textures, in the quality of light and shadow and even in the reflection of the mirror (all of which the new technique of oil painting made more possible), makes this work a step toward a greater naturalism, a desire to give the illusion of the Arnolfinis as they might actually be seen in their own drawing room. This interest in the thing seen is apparent in Van Eyck's choice of the three-quarter view of the heads, which also brings the two sitters, particularly Jan, into a closer relationship with the spectators.

This portrait is in some respects essentially a tour de force which had no imitators; however, it displays a visual realism, characteristic of all Jan van Eyck's work (*e.g.*, Pl. II, fig. z), which became an integral part of northern Renaissance painting, particularly in the work of such gifted followers of Van Eyck as Rogier van der Weyden (c. 1400–64), Petrus Christus (1420?–73) and Hans Memling (c. 1430–94).

The Sitter of Authority.—In Italy in the 15th century portraiture took a somewhat different form. Federigo da Montefeltro, duke of Urbino (1444–92), might have the Umbrian painter, Piero della Francesca (c. 1418–92), paint him kneeling piously before the Madonna and Child but he also felt quite free to have himself painted as the symbol of authority over the world he ruled, without any of the implicit humility which Van Eyck's work still possessed (Pl. II, fig. 3). Like the painter of the "Wilton Diptych," Piero imposed relationships upon the work which are rational rather than visual. However, the basis for his reasoning was quite unlike the medieval painter's. The duke of Urbino is exaggeratedly and imposingly large in relation to the countryside, his own territory, behind him; Piero has made it quite clear that his sitter was master over nature rather than, like Richard, small and humble before God. In describing the silhouette of the

duke's head and shoulders Piero used firm, clear contours which grow even more abrupt in the face — quite unlike the delicate, continuous lines which describe the figure of Richard. Their very severity suggests the harshness of the duke whose portrait is being painted to record his power rather than his piety. At the back of this small panel painting there is another study of the duke as part of a classically inspired triumphal procession; this makes the motivation for the portrait quite clear since, crowning the duke of Urbino, is the allegorical figure of Fame.

This portrait is a profile portrait. Since the duke had lost his right eye in the same tournament which had given his nose its distinctive shape, a profile portrait was probably mandatory. However, it was the position most characteristically chosen for Italian 15th-century portraits. One reason it was so popular may have been the authority of classical medals and gems. It is also possible that these artists may have felt, like the painter of the "Wilton Diptych." that the profile could most clearly characterize the distinctive features of a sitter's face. The profile places the emphasis upon the head as we know it or remember it to be rather than upon the visual impression which interested Jan van Eyck. Consistently the head is built up of separate facts, like the features revealed in the profile or in each curling strand of hair, rather than upon the visual unity of the whole; the imperfections of the moles and wrinkles, for example, do not destroy the alabaster smoothness of the skin.

Although the duke possessed the supreme kind of self-confidence which did not demand that a painter flatter him, indeed permitted Piero to enumerate any facts with brutal honesty, the ultimate purpose was not a record of his appearance — but rather of his authority. And it is generally true of 15th-century Italian portraiture that. although the painter recorded the anatomical features of his sitters as he knew them to be, he was primarily concerned with the ideal to which these sitters aspired. Therefore as Piero in painting the duke suggested his worldly power, Domenico Ghirlandajo (1449–94) in painting Giovanna Tornabuoni degli Albizzi would emphasize her female dignity or Gentile Bellini (c. 1429–1507) in painting a doge would show his keen intelligence—always qualities represented in their most perfect form.

The Sitter Idealized. — In Florence. at the turn from the 15th to the 16th century, painters and sculptors were not so interested in Piero's unequivocal realism of detail. An artist as renowned as Leonardo da Vinci (1452–1519) was seldom willing to paint a portrait and, when he did, it seems to have been because his sitter could be made to represent an ideal rather than a particular human being. The most famous portrait painting by his hand is of the wife of Francesco del Giocondo. the "Mona Lisa." This work, from 1504, not only makes it clear that Leonardo was interested in idealization but also that he was perhaps sufficiently tempted by the technique of oil painting to want to achieve the illusionary effects for which Jan van Eyck had also strived.

More even than Van Eyck, Leonardo, in his portrait. makes the transitions so subtle that the illusion of a body of flesh and blood occupying space is almost complete; however, in spite of the fact that she seems so physically convincing, the "Mona Lisa" remains aloof. Her dress is simple but the bearing of her head, the position of her hands and the triangular form she occupies make her seem imposing and regal. The face which, more than mere flesh and blood, seems to radiate with an inner warmth is so provocative. so eternally enigmatic in its expression that it has tantalized the millions who have seen it in the Louvre or in reproduction. The landscape behind her increases the mystery; it is so much sheer fantasy that it seems related to the world of imagination rather than fact. The "Mona Lisa" is so generalized that it is perhaps not even a portrait; rather she is characteristic of the short-lived High Renaissance desire to concentrate upon the ideal rather than the particular.

The ideal which the "Mona Lisa" represents, no matter how illusive it is, is certainly a matter of inner life rather than physical externals; it radiates through her flesh and skin. The best portraits by Raphael (1483–1520) have somewhat the same quality. However, the inner spirit within a Raphael is neither so enigmatic nor so timeless; *e.g.*, in the portrait of "Julius II" (1443–1513) in the Uffizi the inner spirit can show the effects of age and care (Pl. II, fig. 7). Raphael's ideal, at least in this portrait. was of a dignified and noble maturity. The weary shoulders, the head weighed forward, the white beard, the shadows under the eyes, the wrinkles enhance that effect. And the simple pyramidal composition, of the kind Raphael had studied in Leonardo's work, contributes to the sense of the pope's dignity.

In Venice about 1520 Titian (*c.* 1477–1576) painted a portrait of an unknown young man which shows another aspect of the search for the ideal in the portraiture of the Renaissance (Pl. II, fig. 6). This young man, whose elegance Titian proclaimed in the relaxed pose, the long fingers, the gloves and particularly by the extended "V" of his white shirt. has at the same time a youthful vulnerability. Instead of idealizing the dignity of old age. as Raphael did in his "Julius II," Titian is reminding us of the potentialities of youth; this is a man who may yet form himself into a maturer ideal. Although it is this suggestion of anticipation that makes this work most characteristic of the High Renaissance, it is the elegance of the man and the visual beauty of the arrangement within the painting that had most influence. Artists later in the 16th century, in the style called Mannerist rather than Renaissance, developed this self-conscious grace in paintings of polished and affected beauty. The type spread throughout Europe so that such Italians as Jacopo da Pontormo (1494–1556), Parmigianino (1504–40) and Bronzino (1503–72), such Frenchmen as François Clouet (d. 1572), such Flemings as Anthony More (c. 1512–75) and such Englishmen as Nicholas Hilliard (c. 1537–1619) painted Mannerist portraits.

During the Renaissance artists like Leonardo, Raphael and Titian had positions as courtiers rather than as artisans. This increase in social prestige helped to make the artist more conscious of his own personality. This consciousness accomplished two things: it encouraged the artist to paint portraits of himself and it made him impose himself in some fashion upon portraits he painted of others. Leonardo, Raphael and Titian did not efface themselves before their sitters as did Piero or Van Eyck; instead they revealed their own preoccupations by making these men conform to their particular ideals.

The Self-Conscious Sitter. — The same change in the social position of the artist took place in the north, with the same effects. The German Albrecht Durer (1471–1528), at 13, was sufficiently aware of himself to make an exquisite silverpoint self-portrait. He later revealed his personal ambitions in paintings of himself. The self-portrait in Madrid (1498) shows Diirer in the costume of an elegant young man (Pl. II, fig. 4). Proudly displayed in the background are the Alps the painter had crossed on his way to Italy. In 1505, conscious of the religious troubles of his time, Dürer painted a self-portrait which showed another ideal — the desire to lead a ljfe in imitation of Christ.

Durer's compatriot, Hans Holbein the Younger (1497–1543), excelled in superb and rather detached portrait drawings and paintings. His paintings show a desire for elegance, an enjoyment of the description of textures and a delight in the surface of the panel. 4 portrait such as that of the "Merchant Gisze" may at first seem cold and objective (Pl. II. fig. 5). Like Van Eyck in the portrait of the Arnolfinis, Holbein indicates the man's environment, his occupation (he is a Hanseatic merchant in the Steelyard in London) and even his habits by the details of the setting, and suggests his dignity and his position by the merchant's bearing and costume. However it soon becomes evident that Holbein is as much concerned with the nature of this man as with such externals. Here there is none of the easy grace of Titian's "Man With a Glove." Indeed Gisze holds himself rather tensely; he looks far to his right, well beyond us, not casually but with an expression which shows apprehension. Holbein uses the ingredients of the setting masterfully, building them around the Merchant Gisze in space so that he is hemmed in one corner. This position, combined with the dark shadow he casts, makes even the gesture of his opening the envelope a furtive one. On the wall is inscribed his appropriate motto: "No Joy Without Sorrow." Holbein tries to remain objective but within the formal restraint he gives his portraits strong emotional overtones which ask the spectator to respond as he once presumably responded before his sitter.

El Greco (c. 1542–1614) did not feel as much need to discipline his responses to his sitters some 66 years later. A comparison of his "Cardinal Guevara" (Pl. II, fig. 9) with Raphael's "Julius II" shows how differently from a Renaissance artist this painter approached an important ecclesiastic. El Greco does everything to destroy the pyramidal order and calm of Raphael's work by choosing an elongated canvas, emphasizing its verticality, showing the figure full length and by giving the red silk of the robe an independent life by the angular and dynamic play of the folds. The cardinal does not sit with the heavy gravity of the pope; instead he perches on the edge of his chair, his feet nervously protruding from beneath his robes, his right hand conspicuously relaxed, the left toying with the arm of the chair. The piece of paper at his feet helps destroy any sense of self-containment. Nor is there any suggestion of spiritual contemplation, for the cardinal looks out with great wariness through his black-rimmed spectacles. He has more in common with Holbein's "Merchant Gisze" although he is painted more freely and the emotions are much intensified. In the works of both El Greco and Holbein, like the best 16th-century portraiture after 1530, the emotions in the relationship between sitter and artist predominate.

Baroque and Rococo

The Whole Man.—The artists of the late middle ages were interested in man as a symbol; those of the early Renaissance in the facts of his appearance and position; those of the High Renaissance in him as an expression of an ideal and the Mannerist painters of the 16th century in his emotional responses. But it was not until the 17th century, in the period called the baroque, that any artist tried to embrace all these approaches in a single portrait. Certainly the Flemish Peter Paul Rubens (1577–1640) and the Dutch Frans Hals (1580?–1666) accomplished this—but it was the Spaniard, Diégo Rodriguez Velbzquez (1599–1660), who succeeded most impressively in his portrait of "Innocent X" (Pl. II, fig. 8). The pope in his dress, in his throne and in his bearing is a symbol of papal authority if not of infallibility. The facts of his appearance, no matter how ugly, are recorded here although they in no sense destroy the total impression. The ideal that Innocent X represents is far from the Renaissance ideal—but it is a magnificent expression of the physical and intellectual and moral force to which the baroque aspired. Velazquez is as much concerned as Holbein or El Greco with emotional relationships, but his are not so subtle or so strained; Innocent X challenges us with his penetrating look. Velázquez, with his remarkable ability to give the illusion of this dynamic man in space, has made a characteristically baroque effort to present the total man.

Velázquez' contemporary in Protestant Holland, Rembrandt van Rijn (1606–69), normally painted far gentler, humbler people but also tried to arrive at the synthesis of the complete man or woman. One of his late paintings, "Lady With a Pink," records the facts of his sitter's weariness and age and, by the position of her head and hands, suggests her shyness and humility (Pl. III, fig. 1). Like Leonardo, Rembrandt was interested in the spirit within such a woman, but here this radiates warmly and not coquettishly through a physical shell which in itself is a revelation of this woman's experience. Her beauty seems completely spiritual, the result of a moral life rather than of a physical ideal; Rembrandt expresses it in the gentle, worn face, the large, tender eyes and particularly in the light which seems to be the equivalent of her soul. Rembrandt's judgment of his sitters is ultimately a moral one.

One of the most influential portrait painters in Europe in the 17th century was the Flemish Sir Anthony Van Dyck (1599–1641). Like Rembrandt and Velázquez, Van Dyck was interested in an illusion of the total man revealed in a moment of contact. However, his ideal mas more like that of the early Titian whose work he admired.

As can be seen in his portrait of Charles I of England (1600–49), to whom Van Dyck was court painter, he could suggest the easy grace, the elegance and the arrogance of this man through the swing of the body, the texture of the dress, the haughty expression of the features (Pl. III, fig. 2). The casual landscape setting, the grooms with the horse, also contribute to the sense of the grace of the king, so accidentally discovered with them. Van Dyck brought this tradition of the courtly portrait from 16th-century Venice to England where it was developed in the 18th century by such painters as Sir Joshua Reynolds and Thomas Gainsborough.

The Sitter Romanticized.—France had several artists in the 18th century, including Jean Siméon Chardin (1699–1779), Maurice Quentin de La Tour (1704–88) and Jean Baptiste Perroneau (1715–83), who drew sensitive heads in pastel (*q.v.*) which show a lightness of touch which was appropriate for the period called rococo. But it was England that had the most substantial sequence of portrait painters; their names form an imposing list: William Hogarth, Sir Joshua Reynolds, Thomas Gainsborough, Joseph Highmore, Allan Ramsay, Sir Henry Raeburn and George Romney. Of these, Reynolds (1723–92) was the most verbally articulate and, before the Royal Academy of which he was the first president, he made a series of discourses about art in general with several asides on portraiture which he, like his age, regarded as a form of art inferior to history painting. During his fourth discourse he said of the portrait painter: "He cannot make his hero talk like a great man, he must make him look like one." And essentially this was the attitude of most of these English portrait painters—to emphasize, with certain visual conventions and exaggerations, the stature of the sitter. Reynolds did it himself, most convincingly in his portraits of such men as Samuel Johnson.

Gainsborough (1727–88) was perhaps the most gifted of these painters and, although many of them were influenced by Van Dyck, his style mas closest. He applied paint with the fluidity of Van Dyck. His work has a similar luminosity which seems, in itself, to give his portraits great distinction. Like Van Dyck he normally painted his sitters out-of-doors—although for the landed aristocracy of 18th-century England those parklike settings probably had more meaning in terms of prestige than they had had a century earlier. And he took certain conventions which Van Dyck had used to flatter his sitters and exaggerated them further to give the most aristocratic impression. In his portrait of "Mrs. Graham," for example, Gainsborough emphasized her proud dignity by elongating her body and by emphasizing the vertical through her long, graceful throat, the right arm and even the supporting pillar (Pl. III, fig. 3). She is spatially and psychologically sufficiently removed to remain appropriately remote. Her beauty is suggested by her exquisite features and by the shimmer of her garments, echoed in the romantic light of the sky. Finally the casualness of such an aristocratic ideal is indicated by the informal way Mrs. Graham leans on the pillar and looks without concern in another direction.

Eighteenth-century England was invaded periodically by American artists. Two talented portrait painters remained there. One of them, Benjamin West (1738–1820), became president of the Royal Academy. The other, John Singleton Copley (1737–1815), painted good, straightforward paintings which seem far removed from Gainsborough's romanticized portraits. When Copley painted "Mrs. Seymour Fort" he may have used the device of the baroque red curtain in the background and shown her in a position of considerable dignity—but with the crocheting in her hand, her solid body and good-humoured face, she represents all the most sensible middle-class virtues, presented without flattery, satire or rationalization (Pl. III, fig. 5).

19th and 20th Centuries

Realism.—In France during the first half of the 19th century there were two strains in painting comparable with those Gainsborough and Copley had represented in the 18th. Eugène Delacroix (1798–1863), when he painted his 21-year-old friend, the Baron Louis Schwiter (Pl. III, fig. 4), continued the strain in European painting which runs from the Venetians through Van Dyck to Gainsborough. Consistently he painted the full figure of this rather elegantly dressed young man, standing in a park with a poetic light breaking across the sky. However at the same time with a characteristically 19th-century realism Delacroix portrays the baron's essential vulnerability. His hands and the position of his feet, the untidy hair and collar convey his helplessness. And because he stands so simply and directly and because Delacroix has raised the horizon so that, unlike a portrait by Van Dyck or Gainsborough, the viewer is put almost on a level with him, the impression is given that this rather gentle, shy figure of Baron Schaiter has been exposed because he has been too passive to resist or to care. In the very lack of assertiveness or definition. which makes it possible for him to be such a harmonious part of the idyllic setting, the baron seems to represent at least one romantic ideal.

Just as Copley's "Mrs. Seymour Fort" is the antithesis of Gainsborough's "Mrs. Graham," so "Mme. Moitessier" (Pl. III, fig. 6) by Jean Auguste Dominique Ingres (1780–1867) is the antithesis of Delacroix's "Baron Schaiter." As substantial as Mrs. Fort and as elaborately dressed, Mme. Moitessier is decisive, assertive and meets our eyes with a challenge. Ingres, with the examples of Roman painting and of Raphael in mind, found every excuse for curves which would emphasize the firmness and roundness of her body; these combined with the relaxed pose make Mme. Moitessier essentially seductive. Throughout his career Ingres painted and drew many portraits as meticulous and direct.

The portraitist in the second half of the 19th century in France who perhaps most completely understood both Delacroix and Ingres, and learned from each, was Edgar Degas (1834–1917). His early portrait of his sister and brother-in-law, "Duke and Duchess of Morbilli" (Pl. III, fig. 8), shows an indebtedness to Ingres in the relative precision and boldness of the work but also something of the quality of Delacroix in the hesitancy of both husband and wife before the spectators. However, Degas was most conscious of the psychological complexities and tensions in the relationship of two human beings to each other—and in their relationship to the world. Although the work possesses almost the formality of a daguerreotype, Degas makes use of the positions of the figures in relation to each other and in space, their expressions and particularly their gestures to make the nature of their adjustment to each other and to society quite clear. Later Degas found a more personal visual vocabulary to convey the same kind of meaning in his portraits, which influenced such painters as Vincent Van Gogh (1853–90) and Henri de Toulouse-Lautrec (1864–1901).

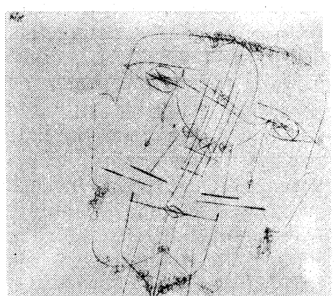
Degas' contemporary and friend Edouard Manet (1832–83) painted portraits which are psychologically uncomplicated, straightforward, but most remarkable, like all his paintings, for their sheer visual beauty (Pl. III, fig. 7). Like Manet. other painters associated with the Impressionists were less concerned with subject matter than with certain visual problems. Even Paul Cézanne (1839–1906), who painted some beautiful portraits, was only incidentally concerned with recording the appearance, personality or virtues of any particular person; his paintings had another function. It might be argued that the decline in the interest of the finest painters in portraiture was a result of the decline in patronage.

However, at the same time that Degas and his friends were receiving little encouragement, there were fashionable portrait painters throughout Europe who made fortunes from this form of art.. Perhaps the best of these was the U.S. expatriate, John Singer Sargent (1856–192j).

Sargent may have suffered somewhat from his generous patronage; indeed he eventually reacted against it and refused to paint more portraits. Whereas the most creative artists of the 19th century. Francisco Goya y Lucientes (1746–1828), Jacques Louis David (1748–1825), Jean Baptiste Corot (1796–1875), Honoré Daumier (1808–79), Jean François Millet (1814–75), Gustave Courbet (1819–77), James Abbott McNeill Whistler (1834–1903), Thomas Eakins (1844–1916) and Pierre Auguste Renoir (1831–1919) besides those already mentioned. revealed an underlying realism and a desire to present the sitter as unpretentiously as possible, Sargent fulfilled his sitters' desires to be ravishingly beautiful or forcefully handsome. In such paintings as "The Wyndham Sisters" he succeeded in giving an illusion of the most beautiful and animated of young women in a work of great brilliance and bravado (Pl. IV). Sargent has survived the criticisms of the 20th century more satisfactorily than such fashionable rivals as Giovanni Boldini (1845–1931) or Philip Alexius Laszlo de Lombos (1869–1937). However, a market for their kind of portraiture still exists.

The 20th Century.— In the first half of the 20th century, even more than during the 19th, the most penetrating portraits have not been the result of commissions of the kind Sargent received. Amedeo Modigliani (1884–1920), an Italian living a poverty-stricken and bohemian life in Paris, painted many of the most successful portraits of this period—but usually of his friends; they might pay him, but he only demanded a paltry sum. Jacques Lipchitz (1891–   ), the sculptor, has written that when he was newly married and he and his wife decided to have their portrait painted by Modigliani, the painter asked ten francs a sitting and insisted it was finished after the first. Lipchitz, in his embarrassment, persuaded Modigliani to work on it longer; however, the sculptor acquired his portrait for a modest sum (Pl. III, fig. 9).

Lipchitz has also written that the pose for this double portrait was inspired by their wedding photograph; this makes it particularly appropriate to compare it with Degas' portrait of the Morbillis which must have been based upon some daguerreotype. Probably a comparison of the photographs, as much as a comparison of the painting. would reveal how much more casually and informally the Lipchitzs were living than the Morbillis had half a century earlier. It is not just that the sculptor wears a turtle-neck sweater or has a hand cockily in his pocket or that the picture behind him on the wall is tilted precariously. It comes out in their perfect ease with the spectators, and even more tellingly in their casual intimacy with each other. Lipchitz places his hand protectively on her shoulder and she leans her head back on his chest with supreme confidence in him and in herself. None of the tensions of the Degas portrait seems to exist.



BY COURTESY OF THE PASADENA ART MUSEUM
"A FIRST SKETCH FOR THE SPECTRE OF A GENIUS" BY PAUL KLEE (1879–1940), SWISS

There is nothing photographic about this double portrait even if a photograph was the source for the composition. Modigliani makes use of visual abstractions, particularly pattern, to interpret this husband and wife. The beautiful oval of the woman's face opens up sensually whereas the features of the husband's face are smaller, cramped and more ingrown. In depending upon such abstractions Modigliani was able to eliminate irrelevant detail. to simplify the work and therefore to concentrate upon those essentials which could suggest their separate personalities, their relationships to each other and to the rest of the world more perfectly than any wedding photograph could.

Twentieth-century portraiture, like all 20th-century art, has been affected by the Freudian analysis of the personality, as is seen in "A First Sketch for the Spectre of a Genius" (see fig.) by the Swiss painter. Paul Klee (1879–1940). The work is a pathetic commentary upon the lack of balance in emotional. physical and spiritual gromth of the genius.

Of all 20th-century painters Pablo Picasso (1881–   ) has been the most creative in the discovery of new visual vocabularies to convey the character of a sitter. He has drawn and painted as meticulously and as representationally as Ingres or he has departed as far from the conventional as it seems possible for a painter to do without losing a sense of the thing portrayed His responses to people in his portraits have been sentimental, cynical, calm. analytical or morally indignant. in each case representing an attitude characteristic of a part of 20th-century society.

In his "Portrait of a Lady" (1937) Picasso continued, as he had for 30 years, to destroy the conventional integrity of the body for his own expressive purposes (Pl. I). With color, pattern, line and important allusions to anatomy, Picasso makes it apparent that a classically beautiful woman is seated. with a certain aplomb, in brilliant sunshine. She seems a typical 20th-century sophisticate in her informality, the smart dress. the lacquered nails and the hand which toys with her long hair. But Picasso was not content to describe her only socially; he designed her dress so that her jacket opens to reveal lines like stamens fanning out to her petal-like breasts; this floral motif seems carried out in the hands. It does not seem improbable that Picasso, with great restraint, is suggesting her sexual urges. But the most startling area is the face. The eye on the left is the strange and frightening red of something possessed; the quieter green eye on the right seems to have turned on itself to regard the other with disturbance and surprise. It is as if this woman, so suave externally, has suddenly become aware of the unknown world of her unconscious. Picasso, like the 20th-century novelist or psychologist, makes the accepted breakdown of the barriers between the normal and the abnormal, the unconscious and the conscious quite explicit. The Surrealists, such as Giorgio de Chirico (1888–), Max Ernst (1891–) and Yves Tanguy (1900–54) delved even more obviously into Freudian realms.

The Judgment of Quality in Portraiture.— How can the quality of a contemporary portrait be determined without the selective critical process of generations? A great portrait painting must be, first of all, a great work of art; this means that every brush stroke will have a structural role in the total painting and will, at the same time, express the attitude of artist toward sitter.

The abstract elements must have a vitality of their own which seems to be the consequence of the creative activity of a painter whose whole being is absorbed in the process. As completely different as such artists as Piero della Francesca, Velázquez or Picasso may be, every part of their work operates in producing visual relationships which make their sitters seem physically and spiritually alive. The portrait, a very difficult form of art, presents other problems about which it is perhaps rash to generalize. However. in all great portrait paintings the suggestion of the intelligence of the sitter seems to surmount the handsome costumes, elaborate settings or an unusual style. Even in Picasso's portraits from the most difficult of all his periods, analytical Cubism, the sense of the particular intelligences of sitters, as in his portraits of Ambroise Vollard, Wilhelm Uhde and Daniel Henry Kahnweiler, is finally triumphant. The great portrait. whatever the period. seems to be the product of the painter's imagination before a sitter whom this painter. because of his temperament and background, is fully able to understand. Being the product of the painter's imagination, it is thus strange to his contemporaries and impossible to anticipate.

PORT ROYAL, an island of Beaufort county, S.C., U.S., 50 mi. S.W. of Charleston, one of the Sea Islands. It is about 13 mi. long and 7 mi. wide. The principal city is Beaufort, a port of entry and seat of Beaufort county. The town of Port Royal is on the southern tip of the island, 5 mi. S. of Beaufort; its population is about 800. Major occupations of the area include fishing, shrimp and crab processing, cypress and pine lumbering, cattle and cotton farming and employment at nearby Parris Island. a U.S. marine corps installation devoted primarily to the basic training of enlisted personnel. Old plantation homes, vast oaks covered with Spanish moss and nearby beaches make Port Royal an exotic resort area.

The port was named Santa Elena by Spanish explorers in the early 16th century. In 1562 the French Huguenot. Jean Ribaut, seeking a haven for French Protestants and a privateering base against Spanish shipping, renamed it Port Royal and left 30 settlers on Parris Island, three miles from the present town of Port Royal. Neglected by Ribaut, after two years the settlers killed the commander he had left in charge, built a tiny ship and returned to Europe. The Spanish occupied the area more or less continuously from 1566 to 1650, maintaining garrisons and Indian missions. English claims to Carolina grew with the settlement of Charleston in 1670, and in 1684 Henry Erskin (Lord Cardross) led 51 Scottish Covenanters to Stuart's Town, 1 mi. N. of the present town of Port Royal. Charlestonians looked upon the Scots as trade rivals and ignored pleas for help when Stuart's Town was destroyed by Spanish and Indians in 1686. Gradually planters moved into the area, and in 1710 Henry Somerset (Duke of Beaufort) established the present town of Beaufort. In Jan. 1779, during the American Revolution, the British occupied the area but were dislodged the following month. After the Revolution the Port Royal environs became the centre of opulent rice and cotton plantations, and scores of magnificent ante-bellum homes attest to this golden age. Early in the American Civil War, on Nov. 6–7, 1861, a fleet of 56 Union vessels, and 12,000 men under Gen. Thomas W. Sherman, reduced the Confederate fortifications and used the port as a Union coaling and repair station for the remainder of the war. Northern abolitionists, supported by the U.S. government, conducted the Port Royal experiment during and immediately after the war, confiscating the lands abandoned by white planters and seeking, with mediocre success. to educate the ex-slaves of the area and give them control over local lands and government. (G. H. CT.)

PORT ROYAL, a celebrated Cistercian abbey, occupied a low and marshy site in the thickly wooded valley of the Yvette, at what is now known as Les Hameaux near Marly, a few miles southwest of Paris. It was founded in 1204 by Mahaut de Garlande, wife of Mathieu de Montmorenci-Marli in 1204; the church was built in 1229. During the three succeeding centuries its discipline became relaxed; reform was only attempted when Angélique Arnauld (*q.v.*) was appointed coadjutor to the abbess in 1598. Angélique's reforming energy soon brought her into contact with Jean du Vergier (*q.v.*) abbot of Saint Cyran, and chief apostle in France of the Jansenist revival.

In 1626 ague drove the nuns to Paris; they settled at Port Royal de Paris, at the end of the Faubourg Saint Jacques. The deserted buildings of Port Royal des Champs were presently occupied by "hermits," laymen, mostly relatives of the abbess, who wished for a semimonastic existence, though without taking formal vows. In 1648, however, some of the nuns returned, and the hermits retreated a short distance from the abbey. Here they set up a "little school" for the sons of Jansenist parents; and here Racine received his education. But in 1653 Innocent X condemned Jansenism and in 1656 "the hermitage" and school were broken up, and the nuns forhidden to receive new members.

In 1660 Louis XIV condemned the order and, between 1664 and 1669, the archbishop of Paris laid under an interdict those nuns who refused to subscribe to the papal censure on Jansen. In 1669, however, came the so-called "Peace of Clement IX," when the Jansenists generally were admitted to grace, and the interdict was removed from Port Royal, though the authorities broke up the convent into two distinct communities. The conformist nuns were gathered together at Port Royal de Paris, under an independent abbess, their Jansenist sisters at the original building in the country. Thereupon followed ten years of peace, through the protection of the king's cousin, Mme. de Longueville. But in 1679 she died, and Louis at once ordered the nuns to send away their novices and boarders and to receive no others. Finally, in 1705, he got from Clement XI a new condemnation of the Jansenists, which the few remaining nuns, all of whom were over sixty, refused to sign; and on the 29th of October 1709 they were forcibly removed from Port Royal by the police, and distributed among various conformist convents. In the next year the buildings were pulled down. The land on which the convent had stood was made over to Mme. de Maintenon's college of St. Cyr; in 1825 it was bought by some descendants of Jansenist families, who have done their best to restore the grounds to their original appearance, and have built a museum rich in Jansenist relics. Port Royal de Paris was secularized at the French Revolution, and is now a maternity hospital.

For a classified list of the chief hooks, ancient and modern, dealing with Port Royal, *see* the *Abrégé de l'histoire de Port Royal*, by Jean Racine, ed. by E. Gazier (Paris, 1908). *See* also C. A. Sainte-Beuve, *Port Royal*. 6 vol. and index (Paris, 1882); Charles Beard, *Port Royal*, 2 vol. (London, 1861); H. Reuchlin, *Geschichte von Port Royal*, 2 vol. (Hamburg, 1839–44); and the hooks recommended under the articles ARNAULD; JANSENISM; and PASCAL, BLAISE.

PORTRUSH, an urban district and seaside resort of County Antrim, Northern Ireland, terminus of a branch line from Coleraine. Pop. (1961) 4,263. Area 0.8 sq.mi. It is situated on the basaltic peninsula of Ramore head. with a deep bay on either side and a harbour. Out to sea lie the small rocky islands called the Skerries. The Giant's Causeway lies 7 mi. E. along the coast. Close beside Portrush the extensive ruins of Dunluce castle stand on a rock separated from the mainland by a chasm spanned by a bridge. Portrush has a salmon trade.

PORT SAID, a seaport of Egypt, at the entrance of the Suez canal, in 31° 15′ 35″ N., 32° 19′ 20″ E., and 145 mi. N.E. of Cairo by rail. pop. (1957) 212.973, lies on the western side of the canal on the low, narrow and treeless strip of land which separates the Mediterranean from Lake Menzala, the land at this point being raised and its area increased by the draining of part of the lake and by the excavation of the inner harbour. The outer harbour is formed by two breakwaters which protect the entrance to the canal; altogether the harbour covers about 570 ac. and accommodates ships drawing 28 ft. The port possesses a floating dock 295 ft. long, 85 ft. broad and 18 ft. deep, capable of lifting 3,500 tons, and a patent slip taking 300 tons and ships drawing 9 ft. 9 in. of water. On the western breakwater is a colossal statue of Ferdinand de Lesseps by E. Fremiet, unveiled in 1899, and a lighthouse 174 ft. high. Among the few buildings of note in the town are the offices of the Suez Canal company and the British barracks. the last having been built by Prince Henry of the Netherlands (d. 1879) as a dépot for Dutch trade.

Port Said dates from 1859. Originally it depended entirely upon the traffic of the canal, being the chief coaling station of all ships passing through and becoming the largest coaling station in the world. In 1902, however, a new industry was added in the export of cotton from the eastern provinces of the delta, the cotton being brought from Mataria by boat across Lake Menzala. In 1904 the opening of a standard gauge railway to Cairo placed Port Said in a position to compete with Alexandria for the external trade of Egypt generally, besides making it a tourist route to the capital from Europe.

PORTSMOUTH, EARLS OF. In 1743 John Wallop (1690–1762) of Farleigh-Wallop in Hampshire was created earl of Portsmouth. He belonged to an old Hampshire family and had been a lord of the treasury from 1717 to 1720, when he'was created Baron Wallop and Viscount Lymington. Gerard Vernon Wallop (b. 1898) became the 9th earl in 1943; he had been Unionist member of parliament for Basingstoke (1929–34) and was the author of several books, including *Alternative to Death* (1943).

PORTSMOUTH, LOUISE DE KÉROUALLE, DUCHESS OF (1649–1734), mistress of the English king Charles II, was placed early in life in the household of Henrietta. duchess of Orléans, Charles's sister. whom she accompanied during the negotiation of the treaty of Dover in 1670. Charles soon placed her among the queen's ladies in waiting. Her intrigue with him was vigorously pushed by the French ambassador, Charles Colbert de Croissy. aided by the secretary of state, Lord Arlington, and his wife. Louise, who concealed great cleverness and a strong will under an appearance of languor and a rather childish beauty (Evelyn the diarist speaks of her "baby face"), yielded only when she had already established a strong hold on the king's affections. Her son, ancestor of the dukes of Richmond (*q.v.*), was born in 1672.

The support she received from the French envoy was given on the understanding that she should serve the interests of her native sovereign. The bargain was confirmed by gifts and honours from Louis XIV and was loyally carried out by Louise. The hatred openly avowed for her in England resulted as much from her own activity in the interest of France as from her notorious rapacity. The titles of Baroness Petersfield, countess of Fareham and duchess of Portsmouth were granted her for life in 1673. Her pensions and money allowances of various kinds were enormous. In 1677 alone she received £27,300. Soon after the king's death she retired to France, where, except for one short visit to England during the reign of James II, she remained. Her emoluments were lost in her later years, which were spent on her estate at Aubigny (raised to a duchy in 1684), but she was protected from her creditors by Louis XIV. She died in Paris on Nov. 14, 1734.

See H. Forneron, *Louise de Kéroualle* (Paris, 1886).

PORTSMOUTH, a city, county and parliamentary borough, seaport and naval base of Hampshire, Eng., 70 mi. S.W. from London by road. Pop. (1961) 215.198. Area 14.5 sq.mi. The city suffered heavy air raids during World War II. About 93% of the houses were damaged and the guildhall (1890), both the main shopping centres and many public buildings were gutted.

Portsmouth owes its origin to the retreat of the sea from Portchester. No town existed there until the 12th century, when its strategical advantage induced Richard I to build one. The borough is governed by a charter granted by Charles I in 1627, modified by the municipal acts of the 19th century. The market, dating from 1194, is held on Tuesday, Thursday and Saturday.

The naval station and arsenal (known to seamen as "Pompey") is an aggregate of four towns, Portsmouth. Portsea, Landport and Southsea, and occupies the southwestern part of Portsea Island, which lies between Portsmouth harbour and Langstone harbour, two inlets of the English channel. Road and railway bridges connect the island and mainland. Portsmouth harbour opens into Spithead. the eastern end of the Solent (*q.v.*) which separates the Isle of Wight from the mainland. The harbour widens inward in bottle form, Portsmouth lying on the east shore of the neck, with Gosport (*q.v.*) opposite to it on the west side. Hayling Island is east of Langstone harbour. Portsmouth proper may be distinguished as the garrison town; Portsea as the naval station with the dockyards; Landport is occupied chiefly by the houses of artisans; and Southsea is a residential quarter and a holiday resort. There is a modern Roman Catholic cathedral. The cruciform church of St. Thomas Becket dates from about 1180 and in 193j extensions were begun consisting of the nave and aisles because in 1924 the foundation of a new diocese of Portsmouth and the Isle of Wight, taken from that of Winchester: was approved, and St. Thomas's was designated as the procathedral. The see was created in 1927. The garrison chapel originally belonged to the hospital of St. Nicholas. a foundation of the 13th century. Among interesting buildings which survived World War II is the Dickens museum (393 Commercial road) in which Charles Dickens was born in 1812. Other distinguished natives of Portsmouth are George Meredith. Sir Walter Besant and Isambard Brunel.

Passenger steamers from Portsmouth harbour serve Ryde on the Isle of Wight. A ferry and a floating bridge connect with Gosport. The civil airport is at Hilsea, immediately northeast of Portsmouth. The parliamentary borough is divided into Langstone, South, and West divisions, each returning one member. The county borough was created in 1888 and raised to the dignity of a city (1926) with a lord mayor in 1928.

Lord Nelson's flagship. H.M.S. "Victory," on which he met his death at Trafalgar in 1805, is in drydock in Portsmouth and is the flagship of the admiral of the station. The Victory museum has relics of Nelson.

The dockyard dates in its earliest form from 1496, though the town was already of importance as a naval station. Its later rise began with the building of one dry and two wet docks in 1698. Portsmouth royal dockyard covers more than 300 ac. and includes four large drydocks, 75 ac. of fitting and repairing basins and a vast conglomeration of workshops and other installations. There is a gunnery establishment on Whale Island and barracks, including those of the royal marine artillery at Eastney, beyond Southsea. Admiralty establishments provide employment for a large proportion of the population. Other industries are shipbuilding and aircraft engineering and the manufacture of corsets, cardboard boxes, brushes, refrigerators, etc. There are industrial estates at Fratton, Drayton and Farlington.

PORTSMOUTH, a city of New Hampshire, U.S., named after Portsmouth, Eng., is New Hampshire's oldest settlement, second oldest city, first capital and only seaport. Situated on the Piscataqua river near its entrance into the Atlantic ocean, it is about 60 mi. N. of Boston, Mass., and about 50 mi. S.W. of Portland, Me. Known as the Old Town by the Sea and the Queen of the Piscataqua, it is rich in historic associations and on its winding streets, tree-shaded and narrow, there are still examples of prerevolutionary architecture, ranging from the earliest simple salt-box style to the dignified 18th-century mansions, tall and square, built on the profits of the city's 18th-century shipbuilding and sailing trade.

Only three years after the Pilgrims settled at Plymouth a fishing settlement was planted 2 mi. E. of the present city. The next year (1624) settlement was made at Portsmouth proper, called successively Piscataqua and Strawberry Bank and finally in 1653 incorporated under its present name. Portsmouth was the seat of the provincial government of New Hampshire and the home of the famous Wentworth family which furnished two royal governors. Adjacent Newcastle was the scene of one of the earliest military events of the Revolution in the patriot capture of Ft. William and Mary from the British in 1774.

In the first half of the 19th century Portsmouth suffered a gradual decline of its commerce and settled down to its present status of a trading centre and home of small industry. The continuance and growth of one of the first U.S. navy yards, dating from the 1790s, has been important as a major economic support for the area. Although it is actually on Seavey's Island in the river (and so in Kittery, Me.) the establishment is known as the Portsmouth Navy yard. There in 1905 treaty negotiations ended the Russo-Japanese War. In the 20th century the yard became a centre for the building and repair of submarines. Connected with it are a naval hospital and a naval prison. The development of the large Pease air force base in Newington, just outside Portsmouth, has also been of great economic advantage to the area.

Portsmouth is located on a famous coastal highway, and for more rapid travel north and south the New Hampshire and Maine turnpikes are easily accessible. The city has a council-manager form of government, in effect since 1948. For comparative population figures *see* table in NEW HAMPSHIRE: *Population.* (A. R. F.)

PORTSMOUTH, a city of southern Ohio, U.S., on the Ohio river at the mouth of the Scioto; the seat of Scioto county. The city is protected by a $10,000,000 flood wall 27 ft. above the flood stage of the Ohio river, which was completed in 1950. Founded in 180'3 by Maj. Henry Massie, a land speculator from Goochland county, Va., Portsmouth was incorporated as a town in 1815 and as a city in 1851. While it shared in the down-river flatboat trade in agricultural produce from the beginning, its real importance dates from the opening of the Ohio and Erie canal in 1832, when it became a point of transfer from canal barges to river packets. During the remainder of the steamboat era, it was a typical river town. When steamboating declined, it became an important railway centre. From the industrial point of view, it has been noted for the manufacture of pottery, shoes and especially iron and steel. There are large sandstone quarries in nearby ravines which have supplied material for many important structures, including the Canadian parliament buildings at Ottawa. After 1952 Portsmouth's economy was greatly stimulated by the building and operation of a gaseous-diffusion plant of the Atomic Energy commission near Piketon, 25 mi. N. Some notable earthworks of the mound builders are in and near Portsmouth. There is a branch of Ohio university in the city. Portsmouth has a council-manager form of government. in effect since 1930. For comparative population figures *see* table in OHIO: *Population.* (R. L. J.)

PORTSMOUTH, a port city in southeastern Virginia, U.S., on the south shore of the Elizabeth river (an estuary of Hampton Roads), opposite the city of Norfolk (*q.v.*), with which its history has been closely associated; the seat of Norfolk county but politically independent of it. The normal annual temperature of Portsmouth is 60.7" F. It was settled in 1752 by people interested in trade but after the American Revolution the town refused to permit the settlement of British merchants. The Norfolk naval yard was established in Portsmouth by the U.S. government in 1801. In 1855 the population was decimated by yellow fever. When Federal troops evacuated the navy yard in 1861 the South fell heir to great stores of equipment and built the Confederate ironclad "Virginia" from the hull of the scuttled U.S.S. "Merrimack." The yard was recaptured by the Federals in 1862. Portsmouth received a city charter in 1858 and has a council-manager form of government, in effect since 1917.

Portsmouth, a part of the port of Norfolk, has oil and railroad terminals and enjoys steamship connections with world ports. The giant navy yard is the principal industrial employer but private shipbuilding yards and railroad shops are important. Portsmouth's manufactures include chemicals, plastics, fertilizer, machine tools, railroad equipment and peanut butter. The Intracoastal waterway runs southward past Portsmouth to the Great Dismal swamp, a haven for hunters and naturalists. The city has a Little Theatre group, a concert association, three swimming lakes, supervised public playgrounds and a naval museum, and is the site of Frederick college, a junior college for men, founded in 1958. Pop. (1960) 114,773. For comparative population figures *see* table in VIRGINIA : *Population.* (G. M. BE.)

PORTSMOUTH, TREATY OF, peace treaty that ended the Russo-Japanese War (*q.v.*). By June 1905 Japan realized that, despite an almost unbroken series of victories, it was no match for Russia in a long war. Russia, meanwhile, having suffered stinging defeats in a conflict which was unpopular with its people, was also looking for a way to end hostilities. Thus, when the president of the United States, Theodore Roosevelt, offered to mediate their differences, both sides accepted. Representatives from the warring nations met at Portsmouth, N.H., on Aug. 9, 1905, and on Sept. 5 signed a treaty providing that Russia would surrender its lease of the Kwantung peninsula and Port Arthur; that both nations would evacuate Manchuria and return it to China; that Japan's sphere of influence in Korea would be recognized by Russia; and that the island of Sakhalin would be divided at lat. 50° N. between Japan and Russia. Japan also was to have fishing rights in the Bering and Okhotsk seas. Acclaimed for his successful efforts to end the war, President Roosevelt was awarded the Nobel peace prize in 1906.

PORT SUDAN, a town and harbour of Sudan, on the west coast of the Red sea, in 19° 39' N. lat. and 37° 14' E. long., approximately 700 mi. by sea south of Suez and approximately 497 mi. by rail northeast of Khartoum and 295 mi. east of the Nile valley, which the railway joins at Atbara. Pop. (1956) 47,562. The coral reefs fringing the coast are there broken by a straight channel with deep water giving access to the harbour from which a short arm branches off westward close within the entrance. Depth 10 to 14 fathoms; at the main quays 33 ft. On the northeast side of the inlet are the main quays fitted with electric cranes, etc. There are the customs house, import clearance sheds and the warehousing area. The town proper lies on the southwest side of the inlet connected with the main quays by a causeway. Besides government offices, the public buildings include a hospital and schools.

The port dates from 1908. It owes its existence to the desire of the Sudan administration to find a harbour more suitable than Suakin for the commerce of the country. The railway (which has termini both at Port Sudan and Suakin) was opened in Jan. 1906. Port Sudan immediately attracted a large trade and became a regular port of call of British, German, Italian and other steamers. The imports are largely cotton goods, coal, oil, petroleum, provisions, machinery, timber and cement; the exports cotton lint, gum, sesame, durra, ivory, senna, coffee, sheep and goatskins, etc. Eighty miles north of Port Sudan is Mohammed

Gul, the port for the mines of Gebet.

PORT TALBOT, a municipal borough in the Aberavon parliamentary division of Glamorgan, Wales, on the Avon (Afan) near its mouth in Swansea bay, 31 mi. W.N.W. of Cardiff by road. Pop. (1961) 50.223. Area 36.6 sq.mi. Port Talbot docks were opened in 1837 and enlarged in 1898 when, after the coming of the railmays, coal from the Afan valley was carried by rail for export from the docks. With the passing of the Railways act in 1921, the Great Western Railway company took over the docks, and Port Talbot became one of the south Wales chain of ports for coal from the Rhondda and other valleys. It suffered severely in the depression of the 1930s. The docks are now used for the export of coal and coke. iron and steel, tin plate, etc., and the import of iron ore, timber and other mainly heavy-class goods. In 1947 the gigantic Abbey steel works at Margam were built by four companies as a reconstruction project for bringing up to date the sheet steel and tin plate industries of south Wales. This led, in turn, to the adaptation of the docks to meet the additional traffic. The steel works are named after Margam abbey, a Cistercian foundation of 1147, on which land they are built near the ruins of the abbey and also near Margam castle and the docks. hlargam urban district and Aberavon town were amalgamated in 1921 under the name of Port Talbot.

Besides workers in steel, oxygen, industrial solvents, etc., and on the docks. Port Talbot has a farming community. Two agricultural shows and a horticultural show are held annually as well as open and local shows of the Port Talbot Cage Birds society. The Aberavon fair (formerly a flannel fair) is held twice yearly under the 13th-century charter of Hugh le Despenser. On the beach, with its fine stretch of sand, is a pleasure fair near the promenade. A sea mall was being built in 1956. On reclaimed marshland to the west of the town the large housing estate of Sandfields was constructed. Open spaces include the Talbot and Vivian Memorial parks, each of 12 ac.

PORTUGAL, a republic of southwestern Europe, forming part of the Iberian peninsula and bounded on the north and east by the Spanish provinces of Galicia, León, Extremadura and Andalusia and on the south and west by the Atlantic ocean. For administrative purposes Portugal includes the Azores (about 700 mi. W. of Lisbon) and the Madeira group of islands. The total population amounted to 7,722,152 in 1940 and to 9,130,410 in 1960: the figures for continental Portugal were 7.185.143 in 1940 and 8,510,799 in 1960. The area of continental Portugal is 34.139 sq.mi., that of the Atlantic islands 1,201 sq.mi. In shape the country is a rough rectangle, its parallel sides running from east to west about 362 mi. apart and its breadth varying from 140 mi. in the north to about 70 mi. in the southern Alentejo.

Portugal's land frontiers are partly defined by mountains and by its four principal rivers. In the northwest the lower course of the Minho divides Portugal from Galicia, but from its middle course to Miranda do Douro the frontier usually follows mountain ranges. From Miranda to Barca de Alva the Douro marks the limit. which then drops raggedly to the level of the Tagus. The frontier follows the Tagus westward for a little way, then cuts across country to the Guadiana. ,From Mourão southward Portugal extends beyond the Guadiana and there is no natural feature to divide it from Spanish Extremadura. In its lower course the Guadiana again forms the frontier.

The Portuguese seaboard is about 500 mi. long. The only islands near the coast are the dangerous Farilhões and Berlings (Portuguese Berlengas) off Cape Carvoeiro. Most of the Portuguese coast is a series of long and gradual curves, with few indentations. Long sandy beaches are general, but Cape Rock (Cabo da Roca; *i.e.,* the Distaff) and Cape Espichel are rocky headlands north and south of the Tagus where the mountains reach the sea. Sines is another headland, and Cape St. Vincent (Cabo de São Vicente), the southwestern extremity of the country, has rough cliffs. There are sandy islands off the coast of the Algarve. The estuaries of the Tagus and Sado form considerable indentations. The former contains a small inland sea, the Mar da Palha. separated from the ocean by the narrows of the "Lisbon river"; the capital, on the north shore, is also the country's largest port. The Sado estuary lies before the port of Setúbal. The estuary of the Douro contains the great city of Oporto (though the port installations are outside the estuary at Leixões). The Mondego estuary has the small port and resort of Figueira da Foz. A number of other ports scattered round the coast are important for sardine and tunny fishing, but their harbours are almost all suitable only for small ships.

The "Atlantic Islands"—that is the Azores and Madeira (*qq.v.*) but not the Cape Verde Islands—have since 1832 formed part of metropolitan Portugal. The nine islands of the Azores have an area of 894 sq.mi. and a population (1960) of 336.933; the Madeira group. consisting of Madeira itself, Porto Santo and the uninhabited Desertas and Selvagens (Salvages) islands. has an area of 307 sq.mi. and a population of 282,678 (1960).

Physical Features.—The scenery of Portugal is rather diverse in relation to its limited area; both fauna and flora vary considerably within small distances. A broad distinction may be made between the area north of the Tagus, which is hilly (about half of it above 1,300 ft.), and that to the south, which is flat (97% of it below 1,300 ft.) except for the hills of Monchique which divide the Algarve from the Alentejo. Generally speaking, Portugal begins at the western edge of the Spanish meseta and shelves away from Spain and down to the Atlantic seaboard.

Northern Portugal comprises the provinces of Minho and Douro Litoral, which form the humid coastal region of pinewoods, maize fields and "green wine" (vinho verde), and the more mountainous interior province of Trbs-0s-Montes e Alto Douro, which includes bare ranges of mountains interspersed by forests of oak and chestnut and valleys in which cereals, olives and root crops are grown. The upper Douro valley where the river has cut through a deep stony gorge forms the celebrated wine country (*pais* do ***vinho)*** from which port wine derives its special qualities.

South of the Douro there is a coastal strip. the province of Beira Litoral. similar to the coast farther north, with fields of cereals and root crops and pinewoods; Aveiro, with its salt-water lagoon and canals. has an ancient salt industry. Inland, Beira Alta and the northern part of Beira Baixa share the Serra da Estrêla. the highest range of mountains in Portugal, which falls away in rough scrubby slopes toward the Spanish frontier. The folds of middle Beira form a transition area that produces good wine. The region of Castelo Branco in Beira Baixa is suitable for extensive agriculture with olives and cork trees. The Tagus valley, round which is formed the province of Ribatejo, is a rich alluvial region, and the flat and fertile fields known as *lezírias* bear cereals, fruits, rice and market produce, which form the wealth of the district of Santarém. To the southeast of Ribatejo is Alto Alentejo, where frontier areas of cork oaks and olives are broken by extensive stretches of sparsely inhabited heath. This country gradually merges into the extensively cultivated wheat-growing district of Beja in the province of Baixo Alentejo. The mountains and heath of Monchique divide this area from the seaboard of the Algarve, which partakes rather of the character of Andalusia or northwest Africa, being rich in fruit trees, especially the almond, fig and carob.

As has been mentioned. the highest mountains of Portugal are in the Serra da Estrêla (6,532 ft.), which forms the backbone of Beira. The next highest land is the Transmontane system on the Galician frontier. whose ranges are usually continuations of those in Spanish terrıtory. the Serra do Gerez reaches 4,944 ft.; Larouco, adjoining Gerez, j 003 ft.; Peneda. overlooking the river Minho, 4.646 ft.; Marão. betneen the Douro and Tâmega, 4,642 ft.; and Nogueira, near Braganza. 4,324 ft.

Between the Douro and the Mondego, the chief ranges are the hlontemuro (4,534 ft.). the Serra da Arada 13.661 ft.), the Serra do Caramulo (3.514 ft.) and the Serra da Lapa (3.127 ft). The Serra da Estrêla is continued in the Serra de Lousd (3,950 ft.). Betneen Lisbon and the sea rise the charming hills of Cintra (Sintra), which nith the Serra da Arrábida (1.644 ft.) form an amphitheatre round the capital, broken by the Tagus valley. South of the Tagus on the Spanish frontier there are several blocks of high land or single ridges, including Sdo Mamede (3.363 ft.), Ossa (2,142 ft) and Monfurado (1,391 ft.). The Monchique range in the northern Algarve reaches 2,959 ft.

The rivers of Portugal comprise four large streams, which have their sources in Spain, and a number of shorter ones. The Douro (Spanish Duero), Tagus (Portuguese Tejo. Spanish Tajoj, Guadiana and Minho (Spanish Miño) are the main rivers (see DOURO; GUADIANA; TAGUS). All four form for part of their courses sections of the frontier. but none of them is navigable in an international sense: Portugal is consequently not the natural port for the wares of western Spain. The Minho, 210 mi. long, can take small coasters for about 20 mi. The Lima (Spanish Limia) rises in Galicia, but its main course is in Portugal; on its estuary is the port of Viana do Castelo. The Cávado and Ave flow into the sea at Espozende and Vila do Conde. South of the Douro, the main rivers are the Vouga, rising in the Serra da Lapa and flowing into the lagoon at Aveiro; the Mondego, 137 mi. long, the longest river wholly in Portuguese territory, which rises in the Serra da Estrêla. runs first northeast, then turns back to flow through the picturesque gorge of Penacova, round the foot of the hill on which Coimbra is built and to the sea at Figueira da Foz. The Zézere, rising north of the Serra da Malcata, is a tributary of the Tagus from the north. The Sorraia flows into the Tagus estuary from the south. South of the Tagus, the Sado rises near Ourique and flows northward into a large bay on which is the port of Setúbal.

Portugal abounds in hot springs, often known as caldas (*e.g.*, Caldas da Rainha, Caldas de Monchique, etc.). These springs are used for medicinal purposes, and the resorts are much frequented.

On the Spanish frontier the scenery is rough and somewhat monotonous, rising to grandeur only in the gorge of the Douro and on the heights of Alto Alentejo; but the interior and coast are varied and pleasantly coloured. On the northern coastal area the effects of mist are attractive, and the softness of the light is in contrast with the dazzling summers of the extreme south. Where the soil is good, a wide variety of temperate and semitropical vegetation can be grown. and in Portugal the regions of palm and pine come close together. Although these favoured areas give the impression of a "garden planted by the sea," it is also true that much of the soil is poor and the rocky hillsides are often unproductive.

For the geology of Portugal, as part of the Iberian peninsula, see SPAIN.

Climate.—The climate of Portugal is usually mild, equable and temperate. The mean temperatures of the four cities of Lisbon, Oporto, Coimbra and Evora are between 60° F. and 61.5° F., and the daily variation nowhere exceeds 23° F. At Lisbon snow is almost unknown, and the heat of summer is tempered by a breeze which blows every evening (nortada). At Oporto the temperatures are a little lower and the whole year is damper, while the Algarve is sufficiently far south to experience considerable heat in August. In the interior the climate is affected by the Spanish meseta, and the northern and central frontier zones are hotter in summer than the seaboard and bleaker in winter; the deeper valleys are shielded by the mountains from cool winds and are sometimes oppressively hot in summer! while the summits of the mountains overlooking them remain fresh. The coldest place in Portugal is the high range of the Serra da Estrêla, where the annual mean temperature is less than 45° F. Heavy snowfalls lie on the mountain tops for several months of the year, but perpetual snow is unknown.

Rainfall varies considerably and reaches as much as 110 in. in the Serra da Estrêla and the northern coastal area. In the interior, drought is not uncommon and sometimes seriously affects crops, whose production may consequently vary considerably from year to year. Fog is common off the coast and is sometimes dangerous to shipping. Violent storms are infrequent, but earthquake tremors are felt from time to time. Several severe earthquakes are on record in historic times; by far the most violent was that of Lisbon (*q.v.*) of Nov. 1, 17jj.

Fauna **and** Flora.—For the fauna of the Iberian peninsula as a whole, see SPAIN. Wolves are found in the wilder and more mountainous areas, notably the Serra da Estrêla, and wild boars are preserved in certain districts. Bears existed in historic times but have long been extinct. The birds of Portugal are varied, but their distribution is often restricted to certain limited areas and they are rather inadequately protected.

A mixture of temperate and semitropical vegetation is characteristic of Portugal, where many of the plants of northern Europe flourish side by side with others introduced from Africa, the Americas and the east; thus, the slopes of Cintra are covered with pines and familiar deciduous trees, interspersed with specimens of cacti, palms, aloes and tree ferns. This is in contrast with Spain, where the vegetation, though its variety is almost equally great, is divided among zones that are rather severely demarcated. The difference is caused by the higher rainfall of Portugal, which is brought in on winds from the Atlantic and dropped before the Spanish frontier. In a number of places there are fine stretches of forest, among which the woods of Bussaco (see BUSSACO, SERRA DO) deserve to be mentioned. North of the Tagus the lime, elm, poplar and pine are common; the chestnut is grown for its fruit, and the Barbary oak (Quercus bellota, Portuguese *azenheiro*) for its acorns and charcoal, which is widely used as fuel. The cork oak is widely distributed, and the cork is of great importance in Portugal's export trade; the most important cork-bearing region is the Alentejo. The olive is also widely distributed and of no less economic importance. The carob (Ceratonia *siliqua,* Portuguese *alfarrobeira*) produces edible seed pods. Numerous conifers are grown for their timber and resin; they include the *Cupressus lusitanica*, probably a native of the Azores. Other common trees are the ilex. araucaria, myrtle and magnolia. The Australian eucalyptus flourishes, being remarkable for the rapidity of its growth. Also to be found are the agave, the Mexican opuntia, the American maple, the jacaranda and other witnesses of Portuguese enterprise in the four corners of the earth. Among specialized flora the Serra de Estrêla may be mentioned for its alpines and the lagoon at Aveiro for its aquatic plants.

HISTORY

Portugal has existed as an independent state since the 12th century, when it finally detached itself from León. Possibly even two centuries earlier there was a county of Portugal; but before this the area that is now so called had no consecutive political history independent of Spain's, nor indeed a distinctive name. An account of the common experience of the Iberian peninsula in Roman, Visigothic and Moslem times is given in the article SPAIN. but it should be remembered that the lack of independent administrative records does not disprove the ethnical and geographical dissimilarity of early Portugal from neighbouring territories. The Lusitanians, a tribe of what is now northern Portugal with relatives in adjacent Spain, fiercely resisted the Romans not only in their own tribal territory but as far afield as Andalusia. Their leader Viriatus being killed by treachery, they were subdued; but their name was later given to the westernmost of the three provinces into which M. Vipsanius Agrippa divided the peninsula (27 B.C.). The Roman Lusitania included most of modern Portugal but also spread eastward, its capital being at Mérida in Spain.

After the Germanic invasions (409–418), the Suebi maintained for a time an independent kingdom in the northwest, but this was incorporated into Visigothic Spain in 585. From this time until the Moslem invasion of 711 Portuguese history is undifferentiable from the little that is known of the Visigothic kingdom. With the fall of this power, the whole of Portugal passed under Moslem rule; but there was little Arab or Berber settlement in the north, and within half a century the expansion of the Christian kingdom of Asturias and León put an end to Moslem power north of the Douro.

The County and the Kingdom **(to 1383).**—It was in this early period of reconquest and resettlement that the phrase terra *portucalis* was first used. Derived from the name of a Roman settlement on the shore of the Douro, Portus Cale, it came to be applied to a wider area from the Douro to the Galician frontier, the Minho. This area became in the 10th century an hereditary county, when the first known governors were Dona Mumadona and her husband Mendo Gonçalves. Half a century later a member of this family was tutor and later father-in-law to Alphonso V of León, but under Ferdinand I, "the Great", of Castile and León it appears to have lost its influence. In 1064 Ferdinand carried the reconquest down to the Mondego, capturing Coimbra and appointing a separate governor there.

Under Alphonso VI of León (1065–1109) and Castile (1072–1109), the county of Portugal reappears and incorporates the district of Coimbra, to form the domain of Alphonso's illegitimate daughter Teresa and her husband Henry, brother of Duke Odo (Eudes) I of Burgundy. From 1095, therefore, Count Henry and Queen Teresa, as she sometimes called herself, governed Portugal and held the Coimbra frontier as vassals of León. On the death of Alphonso VI, when León passed to his legitimate daughter Urraca, Henry attempted to invade her domains, but little had been accomplished when he died in 1112. His son Alphonso (Afonso) I, called Henriques, was an infant; and his widow, actuated by jealousy of her half-sister, vainly endeavoured to intervene in the affairs of León and Galicia. Her association with her Galician favourite Fernão Peres, count of Trava, lost her the esteem of the Portuguese nobility and clergy. In 1128, after she had again embroiled Portugal in a futile conflict with León, supporters of her young son defeated her followers in the battle of São Mamede, and she and Fernão Peres were exiled.

Already in 1124 Urraca's son Alfonso VII had armed himself knight and been declared king of León. His cousin Alphonso Henriques similarly armed himself knight (a privilege usually confined to kings) a year later and, on the banishment of his mother, became count of Portugal. During his first years Alphonso Henriques fought vigorously on all frontiers, invading Galicia in the north and repelling the Moslems in the south. On July 25, 1139, he defeated the Moslems in the battle of Ourique (probably not the modern town of the same name). Soon after. he assumed the royal style (1140). In 1143, as a result of his campaigns and of negotiations with his cousin, his independence was admitted by León, and he placed Portugal under the direct protection of the Holy See, promising to pay an annual tribute. In March 1147 he carried the frontiers of Christian Portugal south to the Tagus with the capture of Santarém, and the arrival of a band of English, French, Flemish and German crusaders bound for Palestine enabled him to form a temporary alliance and to undertake the siege of Lisbon, which fell on Oct. 24, 1147. An English crusader, Gilbert of Hastings, became the first bishop of the restored see of Lisbon.

In Alphonso's later years, from 1179 to 1184, the Moslems, stiffened by the African Almohades, regained some ground in the south but failed to take Santarém or Lisbon; and when he died on Dec. 6, 1185, Alphonso had not only gained Portugal's independence but doubled its national territory. The military orders, especially the Templars, but also those of Santiago and Calatrava and later the Hospitallers, assisted in the defense and resettlement of the frontier areas regained from the Moslems, and the Cistercians introduced good agriculture and architecture into central Portugal, making their headquarters at Alcobaça.

Although Alphonso Henriques began to grant charters to new settlements it was his son Sancho I (1185–1211) who enfranchised many municipalities (*concelhos*), especially in eastern and central Portugal. The privileges of these communities were embodied in charters (forais). which attracted settlers from the more feudal north. Even Moslems were enfranchised, though on the other hand many of them were enslaved. Assisted by paaaing crusaders, Sancho captured Silves in the Algarve (1189); but in the folloning year an army from Africa advanced as far as the Tagus and, although Lisbon, Santarém and Tomar stood firm, the Moslems recovered Silves in 1191 together with most of the land below the Tagus. In his later years Sancho was involved in a quarrel nith the bishop of Oporto and with the papacy; but peace was made before his death, and it was left to his son Alphonso II, "the Fat", (1211–23) to endeavour to strengthen the power of the throne at the expense of the church.

Though Alphonso II himself was an unwarlike king, his followers were beside the Castilians at the great Christian victory of Las Navas de Tolosa in 1212 and, again assisted by crusaders, recovered Alcácer do Sal in 1217. Meanwhile Alphonso repudiated the bequests of large estates made by his father to his brothers and accepted those to his sisters only after a war with León. In the first year of his reign, Aiphonso called a meeting of the *cortes* at Coimbra, to which the nobility and prelates were summoned (representatives of the commoners were not to appear till 40 years later). On this occasion the barons and, especially, the clergy obtained important concessions; in fact the position of the church and the orders was now so strong that Alphonso 11 and his successors were involved in recurrent conflicts with Rome. Alphonso himself instituted *inquirições* or royal commissions to investigate the nature of holdings and recover whatever had been illegally taken from the crown. In his last years Alphonso defied the papacy and was excommunicated, but he was reconciled shortly before his death in 1223.

His son Sancho II (1223–48) succeeded as a boy of 13. Little is known of his reign, but the reconquest of the Alentejo was now completed and much of the Algarve was reduced. On his accession, Sancho found the church in full ascendancy as a result of the agreement made before his father's death. Conflicting reports exist of Sancho's own government, but in his later years the kingdom seems to have slipped into anarchy. At all events his younger brother Alphonso, who had become count of Boulogne by his marriage with the countess Matilda, was granted a papal commission to take over the government, and Sancho was ordered to be deposed by papal bull. When Alphonso reached Lisbon in 1246, he received the support of the church and of the inhabitants of Lisbon and other towns. After a civil war lasting two years, Sancho II retired to Toledo, dying there in Jan. 1248.

On his arrival the count of Boulogne had already declared himself king as Alphonso III, and the death of Sancho without issue gave his usurpation the mantle of legality. He brought together the divided kingdom, completed the reconquest of the Algarve, transferred the capital from Coimbra (*q.v.*) to Lisbon and, fortified by the support of the towns, summoned cortes at Leiria at which for the first time commoners representing the municipalities made their appearance (1254). Although still the husband of Matilda of Boulogne, Alphonso married Beatriz de Guzmán, daughter of Alphonso X of Castile, receiving the disputed territory of the Algarve as a fief of Castile. This marriage led to a dispute with the Holy See, in which Alphonso was placed under an interdict. Despite his early connection with Rome, Alphonso refused to give way, and in 1262 the bigamous marriage was legalized and his eldest son, Denis (Diniz), legitimized. Shortly afterward, Alphonso launched *inquirições*, as a result of which the church was deprived of much property. The prelates protested and most of them left the country. Although Alphonso was excommunicated and threatened with deposition, he defied the church until shortly before his death early in 1279.

The achievements of Alphonso's reign—the completion of the reconquest, the assertion of the royal power before the church and the incorporation of the commoners in the cortes—indicate important institutional advances. Under his son Denis (1279–1325) Portugal was to come into closer touch with western Europe and to acquire a university, the elements of a national literature and a navy. The chartering of fairs and the increased use of minted money bear witness to the growth of commerce, and the planting of pine forests to hold back the sand dunes near Leiria illustrates Denis' concern for shipbuilding and agriculture. In 1317 Denis engaged a Genoese admiral, Emmanuele di Pezagna (Manoel Pessanha), to build up his navy, having already adopted various measures to stimulate foreign trade. He founded the Cniversity of Coirnbra (at first in Lisbon) in 1290 and was both a poet and patron of literature. Yet he was especially famed as the "farmer king" (*rei* lavrador) for his interest in the land.

Despite his attachment to the arts of peace, Portugal was several times involved in strife during the reign of Denis. In 1297 the treaty of Alcafiices with Castile confirmed Portugal's possession of the Algarve and provided for an alliance between Portugal acd Castile. In the later years of his reign, his son, the future Alphonso IV, rebelled more than once, being persuaded to submit by the influence of his mother Isabella, daughter of Peter III of

Aragon. This remarkable woman, later canonized as St. Elizabeth of Portugal and popularly known as "a Rainha-Santa," successfully exercised her influence in favour of peace on several occasions.

Alphonso IV (1325–57) was also involved in various disputes with Castile. Isabella, who had retired to the convent of Santa Clara at Coimbra, continued to intervene in favour of peace; but on her death in 1336 war broke out, and terms were not made till 1340, when Alphonso himself with a Portuguese army joined Alphonso XI of Castile in the great victory over the Moslems on the Salado river in Andalusia. Alphonso IV's son Peter (Pedro) was married to Constance, daughter of the Castilian infante Juan Manuel de Peñafiel, but soon after the marriage he fell in love with one of her ladies, Inez de Castro (*q.v.*), by whom he had two sons. Alphonso IV was persuaded to countenance the assassination of Inez in 1355, and one of Peter I's earliest acts on his accession was to take vengeance on her murderers. During his short reign (1357–67), Peter devoted himself to the dispensation of justice; his judgments, which he executed himself, were severe and often violent, and his iron rule was tempered only by fits of revelling.

Peter's son by Constance, Ferdinand (1367–83), inherited a wealthy throne almost free of external entanglements; but the dispute between Peter the Cruel and Henry of Trastamara for the Castilian throne was raging, and on the murder of the former, several Castilian towns offered their allegiance to Ferdinand, which he was unwise enough to accept. Henry of Trastamara duly invaded Portugal in 1369, and by the peace of Alcoutim (1371) Ferdinand was constrained to renounce his claim and to promise to marry Henry's daughter. However, he instead took a Portuguese, Leonor Teles, although she was already married and in spite of the protests of the commoners of Lisbon. He also made alliance with John of Gaunt, who had married the elder daughter of Peter the Cruel and claimed the Castilian throne. In 1372 Ferdinand provoked Henry of Trastamara, who invaded Portugal and besieged Lisbon. Unable to resist, Ferdinand was forced to repudiate his alliance with John of Gaunt and to act as an ally of Castile, surrendering various castles and persons as hostages. It was only on the death of Henry that Ferdinand dared openly to challenge Castile again. In 1380 the English connection was resumed, and in the following year John of Gaunt's brother, Edmund of Langley (earl of Cambridge and afterward duke of York), took a force to Portugal for the invasion of Castile and betrothed his son Edward to Ferdinand's only child, Beatrice. In mid-campaign Ferdinand came to terms with the enemy (Aug. 1382), agreeing to marry Beatrice to a Castilian prince. She did in effect become the wife of John I of Castile, and when Ferdinand died, prematurely decrepit, Leonor Teles became regent and Castile claimed the Portuguese crown.

Leonor had long been the lover of the Galician João Fernandes Andeiro, count of Ourém, who had intrigued with both England and Castile and whose influence was much resented by Portuguese patriots. Opponents of Castile chose as their leader an illegitimate son of Peter, John, grand master of Avis, who killed Ourém (Dec. 6, 1383) and, being assured of the support of the populace of Lisbon, assumed the title of defender of the realm. The regent fled to Santarém, and the king of Castile sent an army to her aid; Lisbon was besieged for five months, but an outbreak of plague obliged the Castilians to retire.

The House of **Avis.**—The legitimate male line of Henry of Burgundy came to an end with the death of Ferdinand. and when the *cortes* met at Coimbra in April 1385 John was declared king and became the founder of a new dynasty. This result was not unopposed, for many of the nobility and clergy still considered the queen of Castile the rightful heiress; but popular feeling was strong, and John I had valuable allies in Nuno Álvares Pereira, "the Holy Constable," his military champion, and João das Regras, his chancellor and jurist.

A number of towns and castles still held out for Castile when in Aug. 1385 John I of Castile and a considerable army made their appearance in central Portugal. Although much outnumbered, the Portuguese won the great battle of Aljubarrota (Aug. 15, 1385) in which the Castilian chivalry was dispersed and John of Castile himself barely escaped. The victory, followed by secondary successes won by Nuno Álvares, assured John of Avis of his kingdom and made him a desirable ally. A small force of English archers had been present at Aljubarrota. Now the treaty of Windsor (May 9, 1386) raised the Anglo-Portuguese connection to the status of a firm, binding and permanent alliance between the two crowns. John of Gaunt duly went to the peninsula and attempted an invasion of Castile in conjunction with John of Avis. This was not successful, but the Portuguese king married Gaunt's daughter Philippa of Lancaster (1387), who introduced various English usages into Portugal and became the mother of four princes, the *inclita geração*. The truce arranged with Castile in 1387 was prolonged at intervals until peace was finally concluded in 1411.

The victory of John of Avis may be regarded as a victory of the national spirit against the feudal attachment to established order. As much of the older nobility had adhered to Castile. John rewarded his followers at their and at the crown's expense. Meanwhile, commerce prospered, and the marriage of John's daughter Isabella to Philip the Good of Burgundy was to be followed by the growth of close trading relations between Portugal and Flanders. With the conclusion of peace with Castile, John found an outlet for the activities of his frontiersmen and of his own sons in the conquest of Ceuta (1415), from which may be dated the great age of Portuguese expansion.

During the short reign of John's eldest son Edward (Duarte), "the Philosopher King" (1433–38), an unsuccessful attempt was made to conquer Tangier in 1437 by Prince Henry the Navigator and his younger brother Ferdinand, "the Constant Prince," who was held by the Moors as a hostage and died, still unransomed, in 1443. On Edward's death his son Alphonso V was still a child, and his brother Peter, duke of Coimbra, had himself made regent instead of the widow, Eleanor of Aragon. But Peter's own regency was later challenged by the powerful Braganza family, descended from John of Avis and Nuno Alvares Pereira. This family continued to set the young king against his uncle, who was forced to resign the regency, driven to take up arms and killed at Alfarrobeira (May 1449). Alphonso V (1438–81) proved unable to resist the demands of the Braganzas, who now came to own about a third of all Portugal. Having married Joan. daughter of Henry IV of Castile, Alphonso laid claim to the neighbouring throne and became involved in a lengthy struggle with Ferdinand and Isabella in the region of Zamora and Toro, where he was defeated in 1496. He sailed to France to entreat the aid of Louis XI, in which he failed, and on his return concluded the treaty of Alcácovas (1479) abandoning the claims of his wife Joan, after which she retired to a convent. Alphonso V, sometimes known as "the African" because of his Moroccan campaigns, never recovered from this reverse, and during his last years his son John administered the kingdom.

John II (1481–95) was as cautious. firm and jealous of the royal power as his father had been openhanded and negligent. At the first *cortes* of his reign he exacted a grovelling oath which displeased his greatest vassals. A suspicion of conspiracy against him enabled him to arrest Ferdinand II, duke of Braganza. and many of his followers; the duke was sentenced to death and executed at Evora, and John himself stabbed James (Diogo), duke of Viseu. In addition to his onslaught on the power of the nobility, John contrived to lessen the effects of the uniavourable treaty with Castile. Calculating and resolute, he received the epithet of "the Perfect."

John II was predeceased by his legitimate son and therefore succeeded by his cousin Manoel, duke of Beja. known as "the Fortunate" (1495–1521). Manoel I, who assumed the title of "lord of the conquest, navigation and commerce of India, Ethiopia, Arabia and Persia," inherited, thanks to the work of John II, a firmly established autocratic monarchy and a rapidly expanding overseas empire. Drawn toward Spain by the common need to defend their overseas interests as defined by the treaty of Tordesillas (*see* below), Manoel nourished the hope of joining the whole peninsula under the house of Avis; he married Mary, eldest daughter of Ferdinand and Isabella, who, however, died in giving birth to a son, Miguel da Paz. This child was recognized as heir to

Portugal, Castile and Aragon but died in infancy.

As a condition of the marriage, Manoel was required to "purify" Portugal of Jews. John II had admitted many Jewish refugees from the persecution instituted by Isabella in Castile and had exacted from them a heavy poll tax, but was also to supply ships for them to leave Portugal within eight months. This was not done, and Manoel now ordered all Jews to leave by Oct. 1497. On their assembly in Lisbon, every effort was made to secure their conversion by promises or by force. Some who resisted were allowed to go, but the rest were "converted" under promise that no inquiry should be made into their beliefs for 20 years. As "Christians" they could not be forced to emigrate, and they were indeed prohibited from leaving Portugal. In April 1506 a large number of these "new Christians" or marranos were massacred during a riot, but Manoel afterward protected them and allowed many to emigrate to Holland, where their experience of Portuguese trade was put at the service of the Dutch. It was only in 1536, again through Spanish pressure, that the Inquisition was established in Portugal; the first auto-da-fe was held in 1540.

If Manoel failed to realize his dream of ruling Spain, his son John III (1521–57) lacked the power to resist Castilian influence. A pious, dull man, he was ruled by his wife, Queen Catherine, sister of the emperor Charles V, and encouraged the installation of the Inquisition and the Society of Jesus, which soon controlled education in Portugal. In 1529 the settlement of the Moluccas dispute removed an obstacle to Portuguese-Spanish understanding, and the line of Tordesillas was matched by a similar line in the Pacific; all the new countries were in theory divided between Spain and Portugal. while the Reformation (as well as the discoveries) had come between the latter and its English ally.

John III was succeeded by his grandson Sebastian (1557–78), then a child of three. As a boy Sebastian became obsessed with the idea of a crusade against Morocco. Fanatically religious, he had no doubts of his own powers and listened only to flatterers. He visited Ceuta and Tangier in 1574 and began in 1576 to prepare a large expedition against Larache (El Araish); this departed in June 1578 and on Aug. 4 was utterly destroyed by the Moors. Sebastian himself was killed, 8,000 of his men are said to have died and 15,000 were captured. Only a handful escaped.

On the news of Sebastian's death, his great-uncle: Cardinal Henry, a brother of John III, became king. His age and celibacy made it certain that the Portuguese throne mould soon pass from the direct line of Avis. Philip II of Spain, nephew of John III and husband (by his first marriage) of his daughter Mary. had already made his preparations and, on the death of the cardinal-king (Jan. 31, 1580), summoned the authorities to obey him. An army under the great duke of Alba (*see* ALBA, FERNANDO ALVAREZ DE TOLEDO) entered Portugal in 1581, the resistance of the prior of Crato (illegitimate son of John III's brother Louis), acclaimed Antonio I at Santarém, collapsed, and Philip II of Spain became Philip I of Portugal. The claims of the duchess of Braganza (Catherine, daughter of John's brother Edward) were disregarded.

The Discoveries and the Empire.—The idea of expansion into Africa was a logical result of the completion of the reconquest in the peninsula, and the conquest of Ceuta in 1415 may be regarded as the source of the discoveries. The simple idea of fighting the hfoslems on their own soil was linked with more complicated motives: the search for a Christian ally, Prester John; the desire to explore in a scientific sense; the hope of finding a way to the rich spice trade of the Indies; and the impulse to spread the Christian faith. These purposes were gradually moulded together into a national enterprise, though at first they represented the hopes and aspirations of one man, Prince Henry (*see* HENRY OF PORTUGAL). The third son of John of Avis and Philippa of Lancaster, known rather inaccurately as "the Navigator" (he himself never went farther afield than Tangier), Henry became master of the Order of Christ, which King Denis had founded on the suppression of the Templars in 1319. The resources of the order were used to draw together skilled geographers and navigators and to provide and equip a series of expeditions that only gradually began to bear fruit. When Prince Henry died in 1460 his explorers were still about 8° short of the equator.

The date of Prince Henry's earliest expedition is not exactly known, but appears to have been about 1418, when Porto Santo was visited; the first call at Madeira probably dates from 1419. An attempt was made to settle in the Canaries, and between 1427 and 1431 the Azores were visited by Portuguese seamen. Both the Azores and Madeira were then uninhabited, and their colonization proceeded fairly rapidly from c. 1445. Sugar was exported to Europe and gave the islands great economic importance. Meanwhile, Prince Henry's ships were probing the African coast, passing Cape Bojador in 1434 and Rio de Oro (1436). The unsuccessful expedition against Tangier was followed by a break in the discoveries; but in 1439 Prince Henry was authorized to people the Azores, and from 1440 further expeditions equipped with a new and lighter ship, the caravel, reached Arguin, Senegambia (1444), Cape Verde and a point 100 leagues beyond (1446). This last point, near Sierra Leone, seems to have been the limit of the discoveries at the time of Prince Henry's death.

Under Alphonso V three military expeditions were sent against Morocco (1458, 1461 and 1471); by the last of them Tsngier and Arzila were captured. The African explorations were not entirely neglected, but it remained for John II. with his sharp sense of the national interest, to found a fortress and trading post in the Gulf of Guinea at Elmina (São Jorge da Rfina, 1481–82). Diogo Cam (Cão) discovered the mouth of the Congo in 1482 and then advanced to Cape Cross, 200 leagues beyond (1486). In 1488 Bartholomeu Diaz de Novaes at length rounded the Cape of Good Hope and reached the East African coast, and the seaway to India lay open. His return was followed in 1492 with the surprising news that Christopher Columbus had, as he thought, discovered the Indies by sailing west across the Atlantic. Much as this news must have perturbed the Portuguese, Columbus brought no news of the spiceries or the cities of the east, and John II ordered the preparation of an expedition to India by way of South Africa, though this, as it turned out, sailed only after his death, by order of Manoel I. John also contested the Spanish claim to all lands discovered beyond the Atlantic, and by the treaty of Tordesillas (June 7, 1494) Spain's rights were limited to what lay more than 370 leagues west of the Cape Verde Islands. By reason of this the territory that was to become Brazil was reserved for Portugal.

The treaty of Tordesillas had confirmed Portugal's rights to the exploration of Africa and the seaway to India. In July 1497 Vasco da Gama set sail with four ships on the first expedition to India. They reached Calicut the following spring, and the survivors put into Lisbon in the autumn of 1499 with specimens of oriental merchandise. A second fleet was at once prepared under Pedro Álvares Cabral, who touched the Brazilian coast (April 22, 1500) and claimed it for Portugal. One of Cabral's ships. under Lourenço Marques, discovered Madagascar in 1501; João da Nova discovered Ascension in the same year, and St. Helena in 1502. Tristão da Cunha sighted the islands named after him in 1506 and went on to explore Madagascar. Meanwhile, trading posts had been established by Cabral at Cochin and Calicut (1501) and by João da Nova at Cannanor. In 1502 Vasco da Gama made tributary to Portugal the ruler of Kilwa in East Africa.

In 1joj Francisco de Almeida arrived as viceroy of India, strengthening the African station at Kilwa and supporting the ruler of Cochin against the *samorin* of Calicut. The control of sea trade now instituted became the chief source of Portuguese wealth in the east. It nas assured by the defeat of Moslem naval forces off Diu in 1509. Almeida's successor Alphonso d'Albuquerque conquered Goa (1510), nhich he made the seat of Portuguese poner, and Malacca (1511); sent two expeditions to the Moluccas (1512 and 1514); and captured Ormuz in the Persian gulf (1515). Soon after Ferniio Pires de Andrade reached Canton; in 1542 Portuguese merchants were permitted to settle at Liampo and in 1557 they founded the colony of Macao (Macau).

Alphonso d'Albuquerque (q v.) was responsible for the establishment of Goa as the capital of the Portuguese east and to a large extent for the conception of a system of strong points which secured the trade of the orient to Portugal for nearly a century. Goa. seized from the sultan of Bijapur. soon became the chief port of western India; Ormuz controlled the Persian gulf and Malacca the gateway from the Indian ocean to the South China sea. while a string of fortified trading posts secured the coast of East Africa, the gulf and the shores of India and Ceylon. Farther east, less fortified settlements were set up with the consent of the native rulers from Bengal to China, and the trade of the principal spice islands nas in Portuguese hands. The preservation of the whole system was entrusted to a governor, who sometimes held the rank of viceroy. at Goa; and although Portuguese arms liad both triumphs and reverses, their control of the oriental trade remained substantial, if never complete, until the 17th century, when the Dutch. at war with the joint crown of Portugal and Spain and deprived of their traditional trade with Lisbon, began to seek spices from their source and effectively demolished the Portuguese monopoly.

The "Captivity," 1580–1640.—After Philip II had occupied Portugal, the island of Terçeira in the Azores held out for Antonio of Crato. who himself sought alliances in England and France. In 1582 a French expedition to establish him in the Azores was defeated, and in 1589 an English attempt upon Lisbon, led by Sir Francis Drake and Sir John Norris, failed dismally. But although Antonio died in Paris in 1594, the true symbol of Portuguese independence was not the prior of Crato but Sebastian himself. The Portuguese populace refused to believe that he was dead and nourished a messianic faith in his reappearance, of which no fewer than four pretenders sought to avail themselves, the last as late as 1600 and as far afield as Venice.

Meanwhile, Philip II arrived in Portugal, was crowned king and, by virtue of the *cortes* of Tomar (1581), undertook to preserve Portuguese autonomy, to consider the union as a personal one like that of Aragon and Castile under Ferdinand and Isabella, to appoint only Portuguese to the administration, to summon *cortes* frequently and to be accompanied by a Portuguese council in Madrid. These undertakings were adhered to by Philip II (I of Portugal, 1580–98), neglected by Philip III (II, 1598–1621) and completely violated by Philip IV (III, 1621–40).

The resentment of the Portuguese against Spanish rule was increased by the failure of the kings to visit Portugal, lack of redress, the appointment of Spaniards to Portuguese offices, the loss of trade consequent on Spain's foreign wars and the levying of taxation to sustain these. The final straw was the count of Olivares' policy of setting the Portuguese against the equally discontented Catalans. Two Portuguese insurrections in 1634 and 1637 failed to attain dangerous proportions, but in 1640 Spain's powers were extended to the utmost by war with France and revolt in Catalonia. Richelieu already had agents in Lisbon, and a leader was found in John, duke of Braganza, a grandson of the duchess Catherine whose claims had been overriden by Philip II. Taking advantage of the unpopularity of the governor, Margaret of Savoy, duchess of Mantua. and her secretary of state Miguel de Vasconcelos, the leaders of the party of independence carried through a nationalist revolution on Dec. 1, 1640. Vasconcelos was almost the only victim of the movement; the Spanish garrisons were driven out; and on Dec. 15 the duke of Braganza was crowned as John IV.

The House of Braganza.—Although the *cortes* confirmed the accession of the dynasty of Braganza and John's coronation on Jan. 28, 1641, the success of the new regime was not finally assured till 1668, when Spain at last recognized Portuguese independence. Faced with the threat of a Spanish invasion, John had at once sent missions to the courts of Europe in quest of alliances. France now refused a formal treaty. The Dutch, having seized Brazil, accepted a truce in Europe and proceeded to capture Angola. In England John made a treaty with Charles I, which was almost at once voided by the regicide. Meanwhile, the Portuguese defeated the Spaniards at Montijo (May 26, 1644) and warded off several invasions. In 1654 they negotiated a treaty with the English commonwealth, obtaining promises of aid in return for very considerable commercial and other concessions. By a secret article of the treaty of the Pyrenees (1659) France promised Spain to give no further aid to Portugal, but in 1661 negotiations began for a treaty with the restored English monarchy. In 1662 Charles II of England married John's daughter Catherine of Braganza and, in return for a large dowry, including the cession of Bombay and Tangier. provided arms and men for the war with Spain. Portuguese defense was organized by the count-duke of Schomberg; in June 1663 Sancho Manoel, count of Vila Flor. defeated Don John of Austria and on June 17, 1665. António Luis de Meneses, marquis of Marialva, won the important victory of Montes Claros. Peace was negotiated by Sir Robert Southwell and Sir Richard Fanshawe (the translator of the *Lusiads*) and signed on Feb. 13, 1668.

On the death of John IV his second son Alphonso VI (1656–83) was 13. His mother, Luisa de Gusmão, acted as regent until on June 23, 1662, he began to rule. Alphonso himself was feeble-minded, but the country was capably governed by Luis de Vasconcelos e Sousa, count of Castelo-Melhor, until 1667. The French princess Maria-Francisca of Savoy, who had married Alphonso in the previous year, now entered into an intrigue with his more personable brother Peter. They contrived to dismiss Castelo-Melhor and to have Maria-Francisca's marriage annulled. She at once married Peter, who was declared regent. Alphonso was imprisoned until his death in 1683.

During the reign of Peter II (1683–1706), Portugal recovered from the strain of the Spanish wars and began to feel the effects of the discovery of gold and precious stones in Brazil. The first strike of gold in Minas Gerais took place in 1692, and in the last years of the 17th century considerable wealth was being extracted; however, it was not until 1728 that diamonds were discovered and the wealth of Brazil came to form an appreciable part of the revenue of the Portuguese crown.

The struggle for the Spanish succession saw Portugal's recent friends, England and France, on opposing sides; and although Peter sought at first to remain neutral, Portugal joined the Grand Alliance in 1703, by which it afforded a base for the archduke Charles to conduct his war for the Spanish throne. In the same year (Dec. 27) John Methuen also concluded the brief treaty which bears his name, by which the exchange of port wine for English woollens became the basis for Anglo-Portuguese trade. Although the treaty of 1654 had secured great privileges for English merchants in Lisbon, neither it nor the treaties of 1642 and 1661 by which the traditional alliance was restored had created trade. This was now done, and by reason of the wealth that soon poured into Lisbon from Brazil, the English merchants gained a commanding position in the trade of Portugal. The political treaties of 1703 proved less fruitful. The marquês das Minas (Antonio Luis de Sousa) entered Madrid in 1706, but French and Spanish forces were victorious at Almansa, and in 1711 the French admiral René Duguay-Trouin sacked Rio de Janeiro. At the end of the war Portugal was not included in the peace of Utrecht, but at length in Feb. 1715 Portugal concluded peace with Spain at Madrid.

Under Peter's son John V (1706–50) Portugal attained a degree of prosperity unknown since the restoration. The royal fifth levied on the precious metals and stones of Brazil gave the monarchy an independent source of wealth. *Cortes*, which had met irregularly since the restoration, were no longer summoned, and government was carried out by ministers appointed by the king. John V himself showed little interest in administration, though he did not fail to convert his wealth into papal and other dignities. The archbishop of Lisbon became a patriarch and the king of Portugal "his most faithful majesty"; and royal academies, palaces and libraries made their appearance. But in the second half of the reign the ministers proved inadequate and the kingdom sank into stagnation. However, on John's death his son Joseph (1750–77) appointed as minister Sebastião José de Carvalho e Mello, later count of Oeiras and marquis of Pombal (*q.v.*), who soon gained a complete ascendancy over the king and endeavoured to replace the stagnant absolutism with a more active type of despotism which, with some qualifications, deserves the epithet "enlightened." His full powers date from his efficient handling of the crisis caused by the disastrous Lisbon earthquake of Nov. 1755; but even before this he had reformed the sugar and diamond trades, set up a national silk industry (1752) and formed one chartered company to control the sardine- and tunny-fishing industry of the Algarve and another to trade with northern Brazil.

In 1756 he founded a board of trade with powers to limit the privileges enjoyed by the English merchants under the treaties of 1654 and 1661 and set up the General Company for Wine-Culture to control the port wine trade. Industries for the manufacture of hats (1759), cutlery (1764) and other articles were set up with varying success; the University of Coimbra was reformed (1772), and the royal board of censorship (1768) directed lower education from 1771.

Pombal's methods were arbitrary and his enemies numerous. His reform of the wine industry provoked a riot in Oporto (1757) which was savagely repressed; but his principal victims were the Jesuits, expelled in 1759 from all the Portuguese dominions, and the nobility, in particular José Mascarenhas, duke of Aveiro, and the Távora family, who were accused of an attack on the king (Sept. 3, 1758), condemned and executed (Jan. 12, 1759).

While Pombal succeeded in modifying the ascendancy of the British merchants in Portugal, he invoked the alliance in 1762 when Spain, prompted by the Family Compact, invaded Portugal. The Portuguese army was reformed by Count William of Lippe-Bückeburg, under whom John Burgoyne served as brigadier general, and an English force was led by James O'Hara, second Lord Tyrawley, and John Campbell, fourth earl of Loudoun. Peace was signed in Feb. 1763 at Fontainebleau. Only the death of Joseph (Feb. 24, 1777) ended Pombal's regime. After the accession of Joseph's daughter Maria I (1777–1816), who had married his brother, her uncle Peter III, the aged dictator was dismissed and eventually condemned on several charges. His successors restored the Jesuits and made peace with Spain by the treaty of San Ildefonso (1777).

Maria I suffered from fits of melancholia after the loss of her consort (1786) and eldest son. In 1792 her mental balance was further disturbed, probably by the news of the French Revolution, and she ceased to reign. Her son, who on her death was to ascend the throne as John VI (1816), became prince regent. In 1793 Portugal joined England and Spain against France, sending a naval division to assist the English Mediterranean fleet and an army to the Catalan front. The peace of Basle (July, 1795), by which Spain abandoned its allies, left Portugal still at war. Although subjected to pressure from the Directory and from Manuel de Godoy, Portugal remained unmolested until 1801, when an ultimatum was delivered and Godoy invaded the Alentejo. By the peace of Badajoz (June 6, 1801) Portugal lost the town of Olivenza and paid an indemnity. From the peace of Amiens (1802) until 1807 Portugal was once more immune from attack, though subjected to continuous pressure to break off the English connection. By the Berlin decree of Nov. 21, 1806, Napoleon sought to close all continental ports to British ships. Portugal endeavoured to maintain neutrality, but the secret treaty of Fontainebleau (Oct. 1807) provided for its eventual dismemberment by Napoleon and Godoy. Already Gen. Andache Junot was hastening across Spain with a French army, and on Nov. 27 the prince regent and the royal family and court embarked on a fleet lying in the Tagus and were escorted by British vessels under the command of Sir Sidney Smith to Brazil. Junot declared the Braganzas deposed. but his occupation of Portugal was challenged in Aug. 1808 by the arrival of Sir Arthur Wellesley (later duke of Wellington) and 9,000 British troops at the mouth of the Mondego. Winning the victories of Roliça (Aug. 17) and Vimeiro (Aug. 21), Wellesley enabled his superiors to negotiate the so-called convention of Cintra (Xug. 30) by which Junot was allowed to evacuate Portugal with his army. A second French invasion threatened early in 1809, when Sir John Moore's force uithdrew to Corunna to re-embark. In February William Carr Beresford was placed in command of the Portuguese army, and in March Marshal Soult advanced from Galicia and occupied Oporto. Wellesley returned in April, drove Soult from northern Portugal and cleared the Tagus valley with the victory of Talavera de la Reina at the end of July. The third French invasion followed late in Aug. 1810 when Marshal André Masséna with Marshal Michel Ney and Junot entered Beira. Defeated by Wellington at Bussaco near Coimbra, the French found themselves facing the prepared lines of Torres Vedras, where they wintered amid great privations. By the spring of 1811 they could only retreat and, on March 5, began the evacuation of Portugal, beset all the way by English and Portuguese attacks and crossing the frontier after ihe defeat of Sabugal (April 3).

Portugal made peace with France on May 30, 1814. It was represented at the congress of Vienna but did not play a prominent part in the settlement. However, the series of Anglo-Portuguese treaties concluded between the years 1809 and 1817 was important in so far as it extended many of the conditions of the Anglo-Portuguese alliance to Brazil and had an influence on the future of Africa. England's efforts to get Portuguese collaboration in suppressing the slave trade resulted in the treaty of Jan. 22, 1815 (signed in Vienna), and in the additional convention of 1817, by reason of which Portugal's claims to a considerable part of Africa were admitted. Although England had agreed in 1809 and in 1810 to try to recover Olivenza for Portugal and was to receive part. of Portuguese Guinea should it succeed, Spain nevertheless held and continues to hold this frontier town.

Constitutionalism.—The Napoleonic campaigns had caused great devastation in Portugal, and the absence of the royal family and the presence of a foreign commander (Beresford) combined with revolutionary agitation and the influence of Spanish liberalism to produce an atmosphere of discontent and restlessness. On Dec. 16, 1815, Brazil was raised to the rank of a kingdom united with Portugal, and John, who succeeded to the throne in March 1816, showed no desire to return though in anticipation of his arrival George Canning was sent as ambassador to Lisbon to welcome him. In 1817 Beresford suppressed a conspiracy in Lisbon, and the Masonic leader Gen. Gomes Freire de Andrade was executed. Unrest increased, and when Beresford himself went to Brazil to press John to return, a constitutionalist revolution began in Oporto (Aug. 24, 1820), spread over the country and led to the formation of a junta in Lisbon (Oct. 4). On Beresford's return he was not allowed to land, and British officers were expelled from the army. A constituent assembly was summoned which drew up a very "democratic" constitution. thus confronting John VI with an accomplished fact. His reluctance to return was at last overcome, and he left his elder son Pedro to govern Brazil, landing at Lisbon on July 4, 1821. He swore to uphold the constitution, but his wife, Carlota Joaquina, and their second son, Miguel, refused to take the oath and were duly sentenced to banishment, though this was not carried out. The Portuguese constitutionalists, not appreciating the determination of Brazil not to yield up its status as a kingdom, sought to compel Pedro to return; but he, rather than sacrifice the rule of the Braganzas in Brazil, declared for Brazilian independence (Sept. 7, 1822) and became emperor of Brazil as Pedro I. This enabled his brother Miguel to appeal to absolutist forces in Portugal to overthrow the constitutionalists, and an insurrection led by the prince almost succeeded (April 30, 1824); but through the action of the foreign ministers John VI was restored and Miguel went into exile in Vienna (June 1824).

John VI acknowledged the independence of Brazil in 1825, assuming pro *forma* the imperial title and then yielding it to Pedro, but when he died (March 10, 1826) no provision had been made for the succession except that his daughter Isabel Maria was now named regent. Pedro, as Peter IV of Portugal, issued a constitutional charter, drawn up by himself, providing for a parliamentary regime by the authorization of the monarchy and not based on the sovereignty of the people. He then made a conditional abdication of the Portuguese throne in favour of his daughter Maria da Gloria, aged seven, provided that she should marry her uncle Miguel and that he should swear to accept the charter. This compromise could not be effective. The absolutists had hoped that Pedro would resign all rights to the Portuguese crown, and the council of regency hesitated to publish the charter until Gen. João Carlos de Saldanha, later duque de Saldanha, forced their hand. In October Miguel took the oath and was appointed regent, landing in Lisbon in Feb. 1828. His supporters at once began to persecute the liberals. A form of *cortes* met in Lisbon, and in July 1828 repudiated Pedro's claims and declared Miguel rightful king.

Only the island of Terceira in the Azores sustained the liberal cause, but when the liberal refugees in England tried to repair there they were intercepted by a British ship (Jan. 1829). In June 1829, however, a regency on behalf of Maria da Glória was set up in Terceira, and in 1831 Pedro, having abdicated the Brazilian throne, came to Europe and began to raise money and men for the conquest of Portugal. In Feb. 1832 the expedition sailed to the Azores, and in July the liberals disembarked at Mindelo near Oporto, which city they soon occupied. However, the rest of the country stood by Miguel, who besieged the liberals in Oporto for a year (July 1832–July 1833). 'By now Miguelite enthusiasm had waned, and António José de Sousa Manoel, duke of Terceira, and Capt. Charles Napier, who had taken command of the liberal navy, made a successful landing in the Algarve. Terceira advanced on Lisbon, which fell on July 24, 1833, and Miguel capitulated at Evora-Monte on May 26, 1834.

The War of the Two Brothers ended with the exile of one and was soon followed by the death of the other (Sept. 24). Maria da Glória (Maria II) was now queen at the age of 15. She was twice married: to Augustus, duke of Eeuchtenberg, in Jan. 1835; and to Ferdinand of Saxe-Coburg in April 1836. While Maria necessarily came under the influence of the successful generals of the civil war, her chief aim was to defend her father's charter (which had been octroyke) from those who demanded a "democratic" constitution like that of 1822, asserting the sovereignty of the people. In Sept. 1836 the latter, thenceforth called Septembrists, seized power. The chartist leaders rebelled and were exiled, but by 1842 the Septembrist front was no longer united and António Bernardo da Costa Cabral restored the charter. In May 1846 the movement of Maria da Fonte, a popular rising in which almost all parties joined, put an end to Costa Cabral's government but left Portugal divided between the Septembrists, who held Oporto, and Saldanha, now in Queen Maria's confidence, in Lisbon. Saldanha negotiated for the intervention of the Quadruple Alliance, and a combined British and Spanish force received the surrender of the Oporto junta in June 1847 and ended the war with the convention of Gramido (June 29, 1847). Saldanha governed until 1849, when Costa Cabral resumed office only to be overthrown on April 7, 1851. Saldanha then held office for five years (1851–56), and the period of peace at length permitted the country to settle down.

When Maria II died she was succeeded by her eldest son, Peter V (1853–61), who married Stephanie of Hohenzollern in 1857. He promised to be a capable and conscientious monarch, but died of cholera on Kov. 11, 1861. His brother Luis (1861–89) seemed to have inherited a country that had recovered from the Napoleonic invasions and from civil wars, political strife and pronunciamentos. But although the main parties were now defined as Historicals (*i.e.,* radicals) and Regenerators (or moderates), the alternation of governments gradually ceased to reflect popular feeling, and in the last years of Luis' reign republicanism was already gaining ground. With the accession of Carlos (1889–1908) there occurred a serious dispute with Great Britain. Portugal's possessions in Africa had been recognized by Great Britain in the treaty of 1815; but more recently the entry of Germany and Leopold of the Belgians into the colonial field had led to the definition of effective occupation as the basis for possession of colonial territories (conference of Berlin, 1885). A colonial movement had gained momentum in Lisbon, and Portuguese claims to the "Rose-Coloured Map," a colony stretching across Africa from Angola to Mozambique. were recognized by France and Germany (1886). Although Lord Salisbury registered a protest (1888), the Portuguese foreign minister Henrique de Barros Gomes sent Maj. Alexandre de Serpa Pinto to the Shiré highlands with a view to their annexation. He became involved in a fight with the Makololos, who were under British protection, and a series of communications between London and Lisbon ended in the dispatch of the British ultimatum of Jan. 11, 1890, demanding the withdrawal of all Portuguese from the Shiré. Amid great popular excitement Barros Gomes had no alternative but to comply, and the government resigned. The incident caused the deepest resentment in Portugal, not only against the ancient ally but also against the monarchy, which was menaced by a republican revolution in Oporto (Jan. 31, 1891).

During the following years, the Portuguese African colonies were defined as a result of the treaty of May 1891, but the financial position of the country was so bad that it seemed unlikely that the efforts to consolidate the African colonies would succeed. In 1897 it became clear that Portugal would require a considerable loan, and Germany demanded to partake in any assistance that was offered. On Aug. 30, 1898, Lord Balfour concluded an Anglo-German convention assigning spheres of influence in the Portuguese colonies to Great Britain and Germany in the event of such a loan. In 1899 the Germans endeavoured to persuade the Portuguese to accept a loan, and this and the imminent danger of a conflict in the Transvaal caused an Anglo-Portuguese approximation. On Oct. 14, 1899, the ancient treaties of alliance were reaffirmed in a secret declaration, later made public.

Meanwhile, the financial situation showed little improvement, and the republicans continued to progress. In 1906 João Franco, formerly a Regenerator, came to power as champion of the failing monarchist cause. Unable to obtain the support of the other monarchists, he began to govern by decree (May 19, 1906). Although Franco bravely undertook to reform the finances and administration, he was accused of illegally advancing money to the king. These scandals were followed by rumours of plots, and on Feb. 1, 1908, Carlos and his heir, Luis Felipe, were assassinated as they rode in an open carriage in Lisbon. Whether or not the regicides were isolated fanatics or agents of a wide organization such as the *Carbonários,* the deed was applauded by the republicans, who now prepared for a final attack on the monarchy. King Manoel II (1908–10) found no unity among the monarchist politicians, who continued to squabble till the last minute. The general election of Aug. 1910 showed republican majorities in Lisbon and Oporto, and on Oct. 3 the murder by a madman of one of the republican leaders, the distinguished physician Miguel Bombarda, offered the pretext for a rising that was already organized. Armed civilians, soldiers and the men aboard some ships in the Tagus began the republican revolution on Oct. 4 and, after faltering, their movement succeeded on Oct. 5. Manoel escaped to Ericeira and thence by sea to Gibraltar and to England, where he resided at Twickenham. On his death in 1932 his body was returned to Portugal.

The Republic. — The new regime formed a provisional government under the presidency of Theophilo Braga, a well-known writer. This in turn issued a new electoral law giving the vote to all adult Portuguese and presided over the election of a constituent assembly which opened on June 19, 1911. The constitution was passed on Aug. 20, and the provisional government surrendered its authority on Aug. 24 to the new president, Manoel José d'Arriaga.

Although a monarchist invasion was unsuccessfully attempted by Henrique de Paiva Couceiro in Oct. 1911, the main danger to the new regime came from its internal divisions. For the moment, it was fairly united in denouncing monarchism and persecuting the church. The religious orders were expelled (Oct. 8, 1910) and their property confiscated. The teaching of religion in primary schools was abolished, the marriage of priests legalized and the Roman Catholic Church disestablished. The conditions under which Catholics and monarchists were imprisoned attracted attention abroad, and it was only gradually that this legislation was modified. New universities were founded at Lisbon and Oporto, but the task of destruction proved easier than that of construction, and before long the republicans were divided into Evolutionists (moderates), led by Antonio José de Almeida; Cnionists (centre party), led by Manoel Brito Camacho; and Democrats (the left wing), led by Afonso Augusto da Costa. A number of prominent republicans had no specific party. The whirligig of republican political life offered little improvement on the monarchist regime, and in 1915 the army showed signs of restlessness. Gen. Pimenta de Castro formed a military government and permitted the monarchists to reorganize, hut a Democratic revolution (May 14) led to his arrest and consignment to the Azores. President Arriaga resigned and was succeeded by Braga ad interim and then by Bernardino Machado (Oct. 5, 1915–

Dec. 8, 1917). The Democratic regime, in which Costa was paramount, was ended by the revolution of Maj. Sidónio Pais, who established a "New Republic" of a right-wing tendency, supported at first by the Unionists, but on their separation driven to found its own National Republican party. Sidónio Pais' "presidentialist" regime was abruptly ended with his assassination on Dec. *14. 1918,* when, after the provisional presidency of Adm. João de Canto e Castro. power passed gradually back to the Democrats.

Meanwhile, on Aug. *7.* 1914, Portugal had proclaimed its adhesion to the English alliance, and on Nov. *23* committed itself to military operations against Germany. On Sept. 11 a first expedition left to reinforce the colonies, and there was fighting in northern Mozambique, on the Tanganyika frontier and in southern Angola, on the frontier of German South-West Africa. In Feb. *1916* Portugal seized German ships lying in Portuguese ports and Germany declared war (March 9). A Portuguese expeditionary force went to the western front in 1917, under Gen. Fernão Tamagnini de Abreu; on April *9, 1918,* they mere under heavy German attack in the battle of the Lys. In the peace treaty Portugal received 0.75% of the indemnity payable by Germany and the Kionga area captured by Portuguese forces in East Africa.

Almeida completed his term of office as president (Oct. 5, 1919–Oct, 5, 1923), but ministries succeeded one another in rapid succession. In *1921* the founder of the republic, António Machado Santos, was among those murdered by enemies of Sidónio Pais; and although António Maria da Silva contrived to govern in the Democratic interest for a year and nine months, his fall in 1923 was followed by a number of short-lived ministries.

Revolutionary movements grew more frequent as the Democratic party lost its cohesion, and there were signs of impatience with the political turmoil on the part of the army. Although the Democrats obtained a clear majority in *1925* and Manoel Teixeira Gomes (1923–25) yielded the presidency to Bernardino Machado without incident, a military revolt occurred in Lisbon on Feb. 2, 1926. It was quelled. but on May 28 Commander Joaquim Mendes Cabeçadas and Gen. Manoel de Oliveira Gomes da Costa rebelled at Braga. Machado was deposed, and a provisional government was formed.

The "New State." — At first Cabeçadas was head of the provisional government and Gomes da Costa minister of war; but the former was regarded as too close to the politicians, and Gomes da Costa unseated him. Within a few weeks he too was deposed and his place taken by his foreign minister. Gen. António Oscar de Fragoso Carmona (July 9, 1926). Carmona was elected president of the republic in March *1928* and re-elected in *1935, 1942* and *1949,* in each case without opposition; he remained president until his death in April *1951.* After an attempt at revolution in Feb. *1927.* which resulted in considerable bloodshed, Carmona's government was not seriously interrupted. The program of the military regime was merely to restore order. To remedy the financial plight of the country, it had been proposed to borrow money from the League of Nations. but the conditions offered included supervision of the finances. which was regarded as offensive to national sovereignty. The loan was therefore rejected. and Carmona called on António de Oliveira Salazar to take the ministry of finance. Salazar (born at Santa Comba Dão, *1889).* professor of law at Coimbra. obtained full powers over all expenditure and revenue and embarked on a complete overhaul of the administration. As minister of finance from *1928* to *1940* he produced an unbroken series of budgetary surpluses. which restored Portugal's financial credit. As prime minister from *1932* he ushered in the new constitution of *1933;* as minister of colonies in *1930* he prepared the Colonial act governing the administration of Portugal's colonial empire; and as minister for foreign affairs from *1936* he guided Portugal through the difficulties caused by the Spanish Civil War and practised a form of neutrality compatible with the Anglo-Portuguese alliance during World War II On the death of Carmona in *1951,* Salazar assumed under the constitution the attributes of the presidency, until Gen. Francisco Craveiro Lopes mas snorn in as president on Aug. 9. *1951.*

By *1953* Salazar had been a member of the government for 25 years. His "New State," as defined by the constitution of 1933, provided for a president, elected for a period of seven years, who appointed a prime minister and a variable number of ministers; a national assembly of deputies elected quadrennially as a block, meeting for at least three months annually; and a corporative chamber consisting of representatives of trades and professions and acting as a consultative assembly. At the general elections of Nov. *1953* there were *28* opposition candidates, but all *120* seats went to the government (National Union) party. India's attempts to absorb Goa having been rebufied throughout 1954, the Indian government severed diplomatic relations with Portugal in July *1955.* This was followed, in August, by mass invasions of the Portuguese colonies in India by "passive resisters" These were repelled, with some losses. In Dec. *1955* Portugal became a member of the United Nations and in Feb. *1956* referred the question of free access through Indian territory to the enclaves of Dadra and Nagar Havili (Aveli) to the International Court of Justice which, in April *1960,* recognized Portugal's right to the enclaves and also recognized India's right to control access to them through Indian territory Finally on Dec. *18, 1961.* India sent troops into Goa. Diu and Damão, and the next day the Portuguese surrendered. Rear Adm Américo Deus Rodriguez Tomás succeeded Craveiro Lopes as president in *1958.*

On Jan *22, 1961,* the Portuguese cruise ship "Santa Maria" was seized in the Caribbean sea by insurgents who had embarked as passengers The seizure was said to have been planned to coincide with the uprisings against the Salazar government in Angola and other Portuguese colonies. No uprisings occurred, however. and after cruising about the Atlantic for nearly two weeks the "Santa Maria" put into Recife. Braz., where its passengers were released. The ship was returned to its owners and the rebel crew. led by Henrique M. Galvão, was granted political asylum in Brazil.

POPULATION

The population of continental Portugal was 8,510,799 in *1960;* it was 7,185,143 in *1940* and *6.360.347* in *1930.* With the Azores and Madeira it was 9,130,410 in *1960* and 7,722,152 in *1940.* The colonies with an area of 803,835 sq mi, have a population of 11 *861 591* (1950) A decrease in the rate of emigration in the early years of World War II was reflected in a rather steep increase of population and the urban population grew more rapidly than the rural because of internal migration In 1960 the population of the chief towns was: Lisbon 818,382; Oporto 310,474; Setúbal 59,024 (mun); and Coimbra 112,199 (mun).

The Portuguese population increased rapidly in relation to the size of the country. The birth rate, at 23.6 per 1,000 in 1961, is one of the highest in western Europe. The death rate (10.7 per 1 000) is also high. The population is unevenly distributed, all but one-seventh inhabiting the provinces north of the Tagus. The density of population (1960) in continental Portugal reaches 1 380.2 per square mile in the district of Oporto but only 71.6 in that of Beja. The average for the whole country is *258* 4 per square mile. The island of Madeira is more thickly peopled than the mainland (except for the districts of Oporto and Lisbon), with 920 8 per square mile; the Azores have 376.9 per square mile.

Areas such as the Minho are seriously overpopulated. The division of land has proceeded so far that it is often uneconomically cultivated. The less populated areas, on the other hand, will not bear any very considerable increase because of poor soil. There has long been a considerable emigration of Portuguese, principally to Brazil but also to the United States, other parts of Latin America and Africa The emigrants are hard-working and vigorous. but nhile their unskilled labour commands a ready market in Brazil they find little opportunity in the Portuguese colonies, where unskilled work can be done by the natives

Religion and Education. — Roman Catholicism is the religion of the majority of the people. though other creeds compatible with good order are tolerated. The position of the Roman Church in Portugal is determined by the concordat of May *1910.*

Statistics of the school year *1952–53* for continental Portugal showed that there were *12.481* state-run establishments giving primary education, *40* giving secondary. *78* giving technical. *5* giving artistic and *22* giving advanced. as well as *11* training teachers; at the same time there were 9jj private or ecclesiastical establishments giving instruction of various grades. Pupils at these establishments, both state-run and private or ecclesiastical, in continental Portugal numbered 3,657 in infant schools, 859,468 in primary. 50,894 in secondary. 38,393 in technical and 1.028 in artistic, as n-ell as 10,440 receiving advanced education. 1,824 being trained to teach in state schools and 5,040 seminarists.

Racial Composition. — The original Portuguese stock has received transfusions of blood from many races: Romans, Goths, Arabs and Berbers, settlers from northern Europe. Jews, Negroes, etc. In general, however, the typical Portuguese stock is rather short, dark and sturdy, and among the peasantry the strain seems to be remarkably pure. The type is thought by some to be characteristically Iberian and by others to represent Mediterranean man. It is in any case not dissimilar from the prevalent type in Galicia or Asturias.

Although the Romans stamped the country with their language, institutions and civilization, they appear to have had little influence on the racial composition of the people. which may have been fairly constant from their arrival until their departure. The Suebi and Visigoths, who arrived in the jth century A.D.. left traces of more northern physical characteristics. which are especially common in the north. A number of Gothic place names indicate settlements or colonies of these people.

The overthrow of the Visigothic kingdom by the Moslem invasion of 711 introduced a new stock and a new religion. The so-called Moors included Arabs (some from Syria') and Berbers, and they deeply influenced the language, life. architecture and handicrafts of the Portuguese. This influence varied from region to region. North of the Douro it was negligible. since this region was shortly reconquered by the Christians. South of the Douro there was a Mozarabic civilization centred on Coimbra, in which Portuguese stock, still professing the Christian faith. adopted Arab ways and, to some extent, the Arabic language; mixed proper names are common. and it is not unusual to find records even of priests bearing Arab names.

With the reconquest, the Mozarabic civilization was again gothicized, but farther south the Arabic element persisted and is strongest in the Algarve. There were Jews in Portugal in Visigothic times, and they flourished under the Moslems. During the middle ages there were many Jewries, some of them extremely prosperous. Under the influence of Queen Isabella of Spain. King Manoel I (1495–1521) was persuaded to expel the Jews. Many were forcibly converted and. in some cases, intermarried into the population, but others retained their racial and cultural traits. From the foundation of the kingdom to modern times there has been a gradual introduction of other European stocks by settlement. Negroes from Africa were introduced as slaves in fairly considerable numbers after 1450 and left their mark especially in the south, where they were employed on the land, and in such towns as Lisbon, where they were drawers of water or performed similar tasks.

Customs. — The staple diet of the Portuguese people is one of fish, vegetables and fruit; the fish includes dried cod (*bacalhau*), which is prepared in many ways. Cooking is usually done in olive oil, and meat is rarely eaten by the labouring classes. Rice, maize bread and beans are characteristic of the popular diet. Wine is consumed generally but sparingly.

A great variety of picturesque costumes are worn. These may be seen at their best at the *romarias*, or pilgrimages. which combine religion with the attractions of a fair. A characteristic male dress is a white shirt and black trousers with a red sash. In the Alentejo this is accompanied by a stocking cap. and a copper-tipped quarterstaff is carried. Elsewhere a broad-brimmed hat is worn. In the north an umbrella is usually carried by countrymen. and in places short capes are made of reeds. Fishermen may wear a check or tartan shirt.

The female peasant dress is extremely varied, though above a certain age black is usually worn. A white blouse and a full black skirt is a common dress, and a daily clean apron is a general practice. On holidays girls wear brightly coloured cotton dresses decorated with gold or silver filigree ornaments. Headgear ranges from kerchiefs, to round felt or straw hats according to the season and locality.

The sport of bullfighting is conducted without the bull's being killed. Duelling with staves and rowing are other sports; football is popular. Dancing and singing play a prominent part in the life of the people. Almost every village has its *terreiro*, or dancing floor of beaten earth, and band. The traditional songs are of a slower rhythm than the Spanish. but the melody is robust and generally lyrical. The usual popular instruments are the gaita or bagpipe (commonly used in the north for dancing), the pipe, fiddle and drum. The gaita has been to some extent ousted by the accordion. but the Portuguese guitar, which is quite distinct from the Spanish guitar (known in Portugal as the *viola*), maintains its popularity. In Lisbon the *fado* is a ballad of crime or jealousy; a more lyrical form comes from Coimbra. Genuine popular ballads are still composed and recited to celebrate or commemorate local events.

Many curious superstitions survive in rural Portugal. Some are concerned with witches (*bruxas* or *feiticeiras*); there are also enchanted Moors (*mouras* encantadas), mermaids (sereias) who lure fishermen to destruction and werewolves (*lobis-homens*).

There are considerable regional variations in Portugal, and local differences are quite strongly preserved: but regionalism is less pronounced than in Spain and is almost devoid of political implications.

ECONOMICS, DEFENSE AND COLONIES

Agriculture, Livestock and Fishing. — Portugal is primarily an agricultural country, and 60% of the population of continental Portugal is engaged in agricultural pursuits.

Approximately two-fifths of Portugal is arable, and the main cereal crops are maize; wheat, rye, oats, barley and rice. Maize is grown especially in the north (districts of Oporto and Braga) and the coastal zone, while wheat, the most valuable crop, is produced in large quantities in the districts of Beja, Évora and Portalegre (Alentejo).

The consumption of wheat increased considerably in the 20th century, and Portugal can rarely grow enough to meet its needs. An energetic wheat campaign led to a year or two of self-sufficiency in the early 1930s, but thereafter importation again became normal as it seems to have been for centuries, though on a smaller scale than before. The olive tree is widely distributed, and olive oil is Portugal's second most valuable crop; Portugal is the world's third largest producer.

Grapes are grown over most of northern and central Portugal. The most valuable part of the vintage is port wine, which has been Portugal's principal export, but table wines are exported in considerable quantities to the colonies and to some extent to Brazil and other markets. Rice is grown in the valleys of several rivers. Fruit. abundant almost everywhere, is exported in its natural state, or dried or candied. The Algarve is famous for almonds and figs, Setúbal for oranges and Elvas for plums. (See Table I for some principal crops.)

TABLE I.—Agricultural Production
(in 000 metric tons; for olive oil and wine in 000 hl.)

Crop	1930–34	1948–50	1952–54	1955
Wheat	493	445	673	394
Barley	43	94	101	69
Oats	92	112	130	71
Rye	118	148	177	131
Maize	381	360	370	342
Rice	36	97	138	180
Potatoes	604	979	1,075	1,034
Olive oil	513*	722†	820	...
Wine	7,888*	8,030‡	11,410§	...

*1934–38. †1947–50. ‡1948–52. §1953–54.

Other important rural products are cork, of which Portugal is the world's largest producer and which is exported either crude or manufactured, and the products of the country's pine forests, including resin, turpentine. pit props and sann wood. Resin, a comparatively recent industry, had risen to be Portugal's fourth most important export by the end of World War II.

Oxen are widely used for plowing, especially in the north.

Sheep are numerous in eastern Portugal. The donkey is the usual beast of burden. Pigs and mules are bred in the Alentejo, as are bulls for the ring.

In 1955 cattle numbered 903.562: sheep 4,796,675; pigs 1,418,-615: goats 707,107; donkeys 232,497; mules 126,286; and horses 68.175.

Fishing villages are found at frequent intervals along almost the whole Portuguese coast. A fleet sails annually from Lisbon to the Newfoundland banks to procure the cod from which the staple *bacalhau* is made. The most valuable catch is the sardine, always a main export and occasionally the leading one. The centres of the sardine industry are at Setubal and at Matozinhos (near Oporto). The tunny is fished off the Algarve.

Industry and Mining.— Much of Portugal's industry is connected with the preparation of export products—the manufacture of cork and of glass for wine bottles, the canning of sardines. the extraction of resins and turpentine. etc. In addition, textiles of good quality are manufactured with home-grown wool or colonial cotton: other industries include cement and other construction materials. paper, soap, fertilizers. etc.

Various minerals occur in Portugal. including tin. wolfram, copper. sulphur. uranium, titanium, manganese. lead, zinc and kaolin. Tin. wolfram and copper are exported. Coal is found in a few places, but production is insufficient for domestic consumption. Iron ore exists in considerabie quantities but is little exploited.

Foreign Trade.— Portugal's principal exports are cork and cork manufactures (representing 18% of the total value of exports for the years 1951–54), fish, canned and in brine (10%), cotton fabrics (10%) and wine (8%). During World War II a great boom was produced by the competitive buying of rare ores by both belligerents. Wolfram was in especially great demand and remained so in the post\\-ar decade. Pyrites constitute another valuable mineral. Wood and wood products and fruit (principally almonds) are also exported in considerable quantities.

The principal imports are machinery. vehicles, etc. (26% of the total value for the years 1951–54), coal and petroleum and their products (11%), iron and steel and their manufactures (9%) and raw cotton (8%). In these circumstances, as other foodstuffs and raw material have also to be imported, there is normally an unfavourable balance of trade. The true extent of the gap, however, nas exaggerated by official figures until World War II. when the method of evaluation was altered. The deficits were met by agiotage on colonial goods, remittances from emigrants, services to shipping, etc. (See Table II.)

TABLE *11.—Foreign Trade*
(in 000,000 escudos)

Item	1948	1950	1952	1953	1954	1955
Imports (c.i.f.) . .	10,362	7,882	9,991	9,547	10,085	11,445
Exports (f o b) . .	4,295	1	6	6,284	7,297	8,144

The overseas territories together constitute the largest customer and supplier of continental Portugal. Between 1951 and 1954 the proportion of Portuguese exports to them increased from 23% to 25.1%, while the proportion of Portuguese imports from the overseas territories rose from 11.7% to 17%. Among other countries the main destinations of exports are the United States. the United Kingdom and the German Federal Republic. Main sources of imports, after the overseas territories, are the Cnited Kingdom, the German Federal Republic and the United States.

Finance.——Until Salazar became minister of finance in 1928. the Portuguese budget showed a deficit regularly. the only surplus for generations having occurred in one of the early years of the republic. Foreign indebtedness was high, and between 1917 and 1923 the escudo had dropped in value from 4*s*. to 2½*d*. When Salazar came to power, he applied a severe system of financial orthodoxy and produced a balanced budget in his first year. This feat was repeated annually, and the considerable surpluses garnered were used to promote public works. education, colonial development, equipment of the armed forces, etc. The foreign debt was greatly reduced. Revenue and expenditure are shown in Table III.

TABLE III.—*National Budgets*
(in 000,000 *escudos*)

Item	1951*	1952*	1953*	1954†	1955†	1956†

Expenditure . . .	5,605	5,855	6,407	6	7,331	7,671

*Actual. †Estimated.

Communications.— The Portuguese roads were greatly improved and extended by Salazar's government and are usually well maintained. There are about 2.250 mi. of railway line, mostly of the broad or Spanish gauge. Part of this is state-owned, part privately owned. The Companhia dos Caminhos de Ferro Portugueses administers some private and some state-owned lines. The principal line is that running from Lisbon to Oporto via Coimbra. Lisbon is connected with Madrid by the Tagus valley. with Seville and Madrid via Elvas and Badajoz and with northern Spain and France by Guarda and Salamanca. From Oporto one can go to Salamanca via the Douro valley and into Galicia by the line crossing the Minho at Valença-Tuy.

Defense.— In peacetime, the ministry of defense co-ordinates the activities of the ministries for the army and the navy through a general secretariat for national defense under the direction of the chief of the general staff of the armed forces.

There is a supreme national defense council whose ex-officio president is the president of the cabinet of ministers. but which may be presided over by the president of the republic when necessary.

The Portuguese army consists of 16 infantry regiments. 3 independent battalions. 10 battalions of chasseurs and 3 machine-gun battalions; j motorized regiments of light artillery. 3 of heavy artillery and 1 of coastal artillery; 1 regiment and 3 independent groups of anti-aircraft artillery; 1 regiment of mountain artillery; 4 mechanized regiments; 2 regiments of engineers, each with telegraphists and sappers; 1 railway battalion: and 1 group of motor convoy companies, pontoon units and other services. The permanent effectives, including officers. total about 30.000 men in peacetime.

The national republican guard. comprising infantry and cavalry, has a total effective of about 7,000 men. The total effective of the fiscal customs guard is 5,400 men. The Portuguese legion (Legião Portuguesaj is a voluntary patriotic organization nith about 50,000 men. Military service is compulsory and involves 18 months' preliminary training, a period of 8 years on the active strength and a period of 12 years in the reserve, followed by 5 years in the territorial army. Service normally ends at the age of 45. In the colonial forces; service is normally for ten years in the active army and five in the territorial reserve. Members of the home army can be seconded to the colonial army for shorter periods, and reductions are made for volunteers.

Continental Portugal is divided into five military regions: Oporto. Coimbra, Tomar. Évora and Lisbon. There are separate commands in Madeira and the Azores. In the colonies there are commands in Angola. Rlozambique and Cape Verde and military departments in Guinea. India. Macao and Timor.

The air force consists of offensive and defensive groups, a bombing and an observation group and a training and depot squadron. The air service includes a command headquarters and inspectorate, aeroplane and balloon departments, anti-aircraft defense and flying schools.

The Portuguese navy in 1954 consisted of five destroyers, eight frigates and escort vessels and three submarines. with numerous auxiliary craft. The normal complement is 860 officers and 6,37j ratings.

Colonies.— The Portuguese colonial empire consists of seven separate colonies of which five are in Africa, one in Asia and one in Oceania. The two large colonies of the African mainland. Angola (Portuguese West Africa) and Mozambique (Portuguese East Africa). represent more than 90% of the empire by area. Third in size is Portuguese Guinea. Almost opposite Guinea lie the Cape Verde Islands. while in the Gulf of Guinea the tropical islands of St. Thomas (São Tome) and Prince's (Principe) form the fifth of the African colonies. The Portuguese "state of India," which consisted of Goa, Damão and Diu, was forcibly taken over by India in Dec. 1961. In China, the promontory of Macao (Macau) on the Pearl river lies between Canton and Hong Kong. Timor, the largest of the Lesser Sunda Islands, is divided between Portugal and Indonesia (formerly Dutch). All these are described in separate articles.

The Colonial act of 1933 formulated the rights and duties of the colonies and the main outlines of colonial policy. The minister for colonies in Lisbon is assisted by a supreme colonial council and other advisory committees. The governor of each colony has a colonial council, and there are periodical meetings of governors in Lisbon. For a time after 1921 there were parliamentary institutions in the colonies, but under the corporative regime these organs of sovereignty disappeared and colonial policy was coordinated in Lisbon.

BIBLIOGRAPHY.—For geography *see* A. Amorim Girão, *Geografia de Portugal* (Coimbra, 1942); H. Lautensach, *Portugal,* 2 vol. (Gotha, 1932–37); Américo Costa, *Dicionário corográfico de Portugal continental e insular,* 10 vol. (Oporto, 1949).

General histories of Portugal in English are Charles E. Nowell, *A History of Portugal* (New York, 1952); H. V. Livermore, *A History of Portugal* (Cambridge, 1947), and H. Morse Stephens, *Portugal* (London, 1891; with additional chapter, 1908). In Portuguese the most complete modern history is the monumental *História de Portugal,* ed. by Damião Peres and others, 8 vol. (Barcelos, 1929–38); Fortunato de Almeida's *História de Portugal,* 6 vol. (Coimbra, 1922–27), is valuable for its bibliography.

Other general works covering various aspects of Portuguese history are: Fortunato de Almeida, *História da Igreja em Portugal,* 4 vol. (Coimbra, 1910–22), and Padre Miguel de Oliveira, *História eclesiástica de Portugal* (Lisbon, 1940); J. Lúcio de Azevedo, *Épocas de Portugal económico* (Lisbon, 1929); the *História da expansão portuguesa no mundo,* 2 vol. (Lisbon, 1937–42). *See* also E. Prestage, "The Anglo-Portuguese Alliance," in *Transactions of the Royal Historical Society* (1934) and *Chapters in Anglo-Portuguese Relations* (Watford, 1935).

Early and Mediaeval Portugal: José Leite de Vasconcelos, *Religiões da Lusitania* (Oporto, 1924); Adolf Schulten, *Viriato,* Port. trans. by A. Ataíde, 2nd ed. (Oporto, 1940); A. A. Mendes Corrêa, *Raizes de Portugal,* 2nd ed. (Lisbon, 1944); Damião Peres, *Como nasceu Portugal,* 2nd ed. (Coimbra, 1942).

For the early monarchy, *see* Alexandre Herculano, *História de Portugal,* 4 vol. (Lisbon, 1846–73), 7th ed., 8 vol. (Lisbon, 1914–16), going to the death of Alphonso III in 1279; Padre Luis Gonzaga de Azevedo, *História de Portugal,* 5 vol. (Lisbon, 1935–42). For the documents of Alphonso Henriques' chancery *see* Abiah E. Reuter, *Chancelarias medievais portuguesas,* vol. i (Coimbra, 1938). The English narrative of the conquest of Lisbon is edited and translated by C. W. David, *De expugnatione Lyxbonensi* (1936). Carl Erdmann, *Papsturkunden in Portugal* (Berlin, 1927), deals with early relations between Portugal and Rome. Sources are dealt with by Gonzaga de Azevedo.

E. Prestage, *Royal Power and the Cortes in Portugal* (Watford, 1927), and Visconde de Santarém, *Memórias para a história e theoria das cortes geraes . . .* (1827; Lisbon, 1924), deal with early institutions. H. da Gama Barros, *História da administração pública em Portugal nos séculos XII a XIV,* 4 vol. (Lisbon, 1885–1922), new ed. by T. de Sousa Soares (1945 *et seq.*), deals with administration. *See* also A. de Sousa Silva Costa Lobo, *História da sociedade em Portugal no século XV* (Lisbon, 1903); Virgínia Rau, *As sesmarias medievais portuguesas* (Lisbon, 1946).

The Age of the Discoveries: For the domestic history of Portugal, *see* the general histories already mentioned and the chronicles of John II by Rui de Pina, Damião de Gois and Garcia de Resende; of Manoel by Damião de Gois; of John III by Frei Luiz de Sousa and Francisco de Andrade; and of Sebastian by Frei Bernardo da Cruz. *See* also Alfredo Pimenta, *D. João III* (Oporto, 1936); J. D. M. Ford (ed.), *Letters, 1521–1557* of the court of John III (1931); J. M. de Queiróz Veloso, *D. Sebastião* (Lisbon, 1935), and *A Perda da independência,* vol. i, *O Reinado do Cardeal D. Henrique* (Lisbon, 1946).

Alexandre Herculano, *História da origem e estabelecimento da inquisição em Portugal,* 3 vol., 10th ed. by David Lopes (s.d.), can be consulted in translation (1926). Mário Brandão, *O Colégio das Artes,* 2 vol. (Coimbra, 1924–33), and Cardinal M. Gonçalves Cerejeira, *Clenardo* (Coimbra, 1926), afford useful introductions of the Renaissance in Portugal.

For the Portuguese in the east, *see* C. R. Boxer, *Fidalgos in the Far East, 1550–1770* (The Hague, 1948), *The Christian Century in Japan, 1549–1650* (1951) and chapter in *Portugal and Brazil,* ed. by H. V. Livermore and W. J. Entwistle (Oxford, 1953).

The Late 16th, 17th and 18th Centuries: J. M. Queiróz Veloso, *Reinado de D. Henrique;* Dánvila, *Don Cristóbal de Moura* (Madrid, 1900); Miguel das Antas, *Les Faux Sébastian* (Paris, 1866); J. Lúcio de Azevedo, *A Evolução do Sebastianismo,* 2nd ed. (Lisbon, 1947).

For the restoration *see* E. Prestage, *Diplomatic Relations of Portugal: 1640–1668* (Watford, 1925), and contemporary authorities such as Luis de Meneses, *História de Portugal restaurado,* 2 vol. (1679–98). For the life of D. Luisa de Gusmão *see* Hipólito Raposo's biography (Lisbon, 1947). António Baião studied the marriage of Alphonso VI in his *Causa de nulidade* (Coimbra, 1925), and Virgínia Rau has written on Catherine of Braganza in *O Instituto,* vol. 98 (Lisbon, 1941). Damião Peres, *A Diplomacia portuguesa e a sucessão de Espanha: 1700–14* (Barcelos, 1931), deals with Portugal in the War of the Spanish Succession; Eduardo Brazão, *Relações externas de Portugal: reinado de D. João V,* 2 vol. (Oporto, 1938), with the reign of John V. For the age of Pombal *see* Marcus Cheke, *Dictator of Portugal* (London, 1938); the most convenient introduction in Portuguese is J. Lúcio de Azevedo, *Marquês de Pombal e a sua época* (Lisbon, 1909 and 1922). *See* also Caetano Beirão, *D. Maria I: 1777–92,* 2nd ed. (Lisbon, 1934).

The 19th and 20th Centuries: C. K. Webster (ed.), *Britain and the Independence of Latin America, 1812–1830,* 2 vol. (Oxford, 1938); M. de Oliveira Lima, *D. João VI no Brasil,* 3 vol., 2nd ed. (Rio de Janeiro, 1945); Marquês do Lavradio, *D. João VI e a independência do Brasil: últimos anos do seu reinado* (Lisbon, 1937); Oliveira Lima, *D. Miguel no trono 1828–1833* (Coimbra, 1933); Maria Amélia Vaz de Carvalho, *Vida do duque de Palmela,* 3 vol. (Lisbon, 1898–1903); W. Bollaert, *Wars of Succession in Portugal and Spain,* vol. i (London, 1870); John Smith, *Memoirs of Field-Marshal the Duke of Saldanha,* 2 vol. (London, 1880), a rather flattering portrait; Júlio de Vilhena, *D. Pedro V e o seu reinado,* 3 vol. (Coimbra, 1921); Luis Vieira de Castro, *D. Carlos I,* 3rd ed. (Lisbon, 1943); Jesús Pabón, *La Revolución Portuguesa,* 2 vol. (Madrid, 1941–45).

For the regime of Salazar, *see* F. C. C. Egerton, *Salazar, Rebuilder of Portugal* (London, 1943); Antonio Ferro, *Salazar: Portugal and Her Leader,* Eng. trans. (London, 1939); Luis Teixeira, *Perfil de Salazar* (Madrid, s.d.); also Salazar's own *Discursos* and *Doctrine and Action,* Eng. trans. (London, 1939). Michael Derrick, *The Portugal of Salazar* (London, 1938), is a general account.

Descamps, *Le Portugal* (Paris, 1935); F. Cotta, *Economic Planning in Corporative Portugal* (London, 1937). (H. V. L.)

PORTUGUESE EAST AFRICA or MOZAMBIQUE (officially PROVINCIA DE MOÇAMBIQUE), the most populous and second largest of the five Portuguese African possessions, is bounded on the east by the Indian ocean, on the north by Tanganyika, Nyasaland and Northern Rhodesia, on the west by Southern Rhodesia and the Transvaal and on the south by Natal (Tongaland). Its area is 297,846 sq.mi., and its length from north to south about 1,300 mi. Because of the great irregularity of the frontier the territory varies in width from 56 mi. in the south to 480 mi. It takes its name from the town and island of Moçambique or Mozambique (*q.v.*), formerly the capital and a way station on the voyage to India.

Physical Features.—The coast line extends from 10° 40′ S. to 26° 52′ S. and makes a double curve on a northeast-southwest axis. Its length is about 1,600 mi. In the extreme south, about 40 mi. N. of the Natal frontier, is the great basin of Delagoa bay (*q.v.*) on which stands the capital, Lourenço Marques. North of this the coast is low-lying and sandy or swampy as far as the deep indentation of the Zambezi delta. From the Zambezi northward the coast is studded with small islands, mainly of coral formation, on one of which is Mozambique. North of this there are high rocky headlands and rugged cliffs. Pôrto Amélia stands on the great natural harbour of Pemba bay. The territory is rich in rivers, about 50 of which flow into the Indian ocean. The Zambezi divides the province in two: to the south the coastal plain is much deeper and only a small part of the high plateau falls in Portuguese territory. In the centre the Gorongoza reaches 6,600 ft., and farther north there are several ranges: Nampula district has more than 20 groups of mountains more than 4,000 ft. high and Namuli peak is 8,858 ft. high. Southeast of Lake Nyasa there is a high range which drops 3,000 ft. in 6 mi. to the level of the lake. The highlands along the Southern Rhodesian border reach about 9,000 ft.

Geology.—The central plateau consists of gneisses, granites and schists of the usual East African type which in part or in whole are to be referred to the Archaean system. Rocks of the Karroo period occur in the Zambezi basin, where at Tete they contain workable seams of coal and have yielded plant remains of Upper Carboniferous age. Sandstones and shales, possibly of Upper

Karroo age, form a narrow belt at the edge of the foot plateau. Upper Cretaceous rocks crop out from beneath the superficial deposits along the coast belt between Delagoa bay and Mozambique. The highest Cretaceous strata occur in Conducia, where they contain the huge ammonite *Pachydiscus conduciensis.* The Eocene formation is well represented in Gazaland by the nummulitic limestone which have been found to extend for a considerable distance inland. Basalts occur at several places in the Zambezi basin. On the flanks of Mt Milanje there are two volcanic cones which seem to be comparatively recent; but the most interesting igneous rocks are the rhyolitic lavas of the Lebombo range.

Climate and Health. — In most parts of Mozambique there is a hot, wet season (October–March) and a cooler, dry season (April–September), though rainfall is irregular. The climate of Lourenço Marques resembles that of Durban, South Africa, with an average temperature of 72° F. In the centre Quelimane on the coast has an annual mean temperature of 85.1°, with a maximum of 106.7° and a minimum of 49.1°. At Tete, about 260 mi up the Zambezi, the annual mean is 77.9°, the hottest month being November, 83.3°, and the coldest July, 72 3°. The range is similar in the north. On the uplands and plateaus the climate is more temperate. Rainfall (average over many years in inches) is: Lourenço Marques 30.6; Beira 60.4; Quelimane 56.4; Mozambique 31 4; Tete 21 2; Shiré 72 2.

Malarial and other diseases occur in Mozambique. especially on the lower ground. Great progress has been made in making Lourenço Marques and the other main centres healthful. and medical and preventive services have been much extended, especially in combating the malarial mosquito at its breeding grounds. Endemic focuses of sleeping sickness have been verified at various places. and the tsetse fly is found in several districts.

Flora and Fauna. — The coconut is common in the coast regions and often attains 100 ft.; the date palm, mostly in marshy ground and near rivers, is seldom more than 20 ft. in height; four other palms occur A kind of cedar is found in the lower forests; ironwood and ebony are common. The large *Kkaya senegalensis,* found in ravines and by riverbanks, affords durable and easily worked timber; there are several varieties of *Vitex* and of *Ficus,* notably the sycamore fig *(Ficus sycomorus).* which bears edible fruit and is the "sycamore" of the Bible.

Excellent hardwood is obtained from a species of *Grewia.* Other characteristic trees are the mangrove (along the sea shore), sandalwood, gum copal, baobab and bombax, and, in the loner plain, dracaenas (dragon trees), and many species of creepers and flowering shrubs, and several prickly shrubs. Acacias are numerous. including the gum-yielding variety, while *Landolphia* rubber vines grow freely in the forests Coffee, cotton indigo and tobacco plants, castor oil, bananas, mangoes and pineapples are found. The bamboo is common and spear grass with its waving, snowy plumes grows to 12–14 ft. and is abundant along the river banks and along the edges of the marshes.

The lion, of both the yellow and the black-maned varieties, leopard spotted hyena, jackal, serval. civet cat, genet, hunting dog and mongoose occur in the Rfozambique district. The elephant and the black rhinoceros are common, and south of the Zambezi are a few specimens of white rhinoceros (*Rhinoceros simus*). The rivers and marshes are the home of hippopotamuses, which have however deserted the lower Zambezi. The wart hog and the smaller red hog are common. A species of zebra is plentiful, and herds of buffalo are numerous in the plains and in open woods. Many antelopes are found, but the giraffe does not occur. Scaly anteaters are fairly numerous, and rodents are common. There are several kinds of monkeys and lemuroids, but the anthropoids are absent.

Crocodiles, lizards, chameleons. land and river tortoises are all very numerous, as are pythons (about 18 ft. long). cobras, puff adders and vipers. Centipedes and scorpions and insects are innumerable. Among insects mosquitoes, locusts, the tsetse fly, the hippo fly, cockroaches, phylloxera. termites. soldier ants and flying ants are common plagues. As has been indicated. the Zambezi forms a dividing line not crossed by certain animals, so that the fauna north of that river presents some marked contrasts with that of the south.

Flamingoes are common in the Mozambique district. Cranes, herons, storks. pelicans and ibises are numerous. including the beautiful crested crane and the saddle-billed stork (*Ephippiorhynchus senegalensis)*; the last-named is comparatively rare. The eagle, vulture, kite, buzzard and crow are well represented, though the crested eagle is not found. The guinea fowl. partridge, bustard, quail. wild goose, teal, widgeon. mallard and other kinds of duck are all common. A small green parrot is found.

HISTORY

Between the 11th and 1 jth centuries the east coast of Africa as far south as Sofala was linked politically with Arabia and India. Although the main centre of Arab influence was to the north of what is no Mozambique, Arab trade and to a lesser extent civilization had influenced the coastal peoples down to the Zambezi. Mozambique was first opened to European influences by Vasco da Gama who, on rounding the Cape of Good Hope in 1497, put in at what he called the Rio dos Bons Sinaes (River of Good Tokens). where he first found signs of oriental influence: this is now the Quelimane river, the northern outlet of the Zambezi, discovered on Feb 25. 1498.

Gama also put in at Mozambique (March 1), before sailing north for Malindi Mombasa and India. Sofala was seen in July 1500 by Pedro Álvares Cabral on his way to India, and on his return it was visited by one of his ships under Sancho de Toar, who made inquiries about the legendary gold trade of the place. Soon afterward. António de Campo visited Delagoa bay. A Portuguese settlement was made at Sofala in 1505. Despite its supposed commercial attractions Sofala was difficult to maintain and unsuitable as a way station for the Portuguese Indiamen, and the port of Mozambique was therefore annexed and fortified soon after. Within a few years the Portuguese had ended Arab influence in the area. Attempts to reach the *monomotapa,* the potentate who owned the supposed gold and silver mines of the interior, were disappointing. though a convict named Antonio Fernandes explored much of Monomotapa (Mashonaland) before 1514. The desire to find an easier route to the interior led to the founding of a settlement near Quelimane in 1544. In the same year Lourenço Marques explored the Delagoa bay area, and a station was set up near Catembe.

As a result of Fernandes' explorations the Zambezi was adopted as the main route into the interior. Sena. 160 mi. from the sea, was established in 1531, and Tete. 321 mi. upstream, soon after. In 1560 the Jesuit father Gonçalo da Silveira set out to convert the *monomotapa,* and guided by a Portuguese trader reached the chief's kraal in a year Although he found a compatriot living with the chief, he himself and his converts were strangled in March 1561.

The death of Silveira was followed by the dispatch of an expedition from Lisbon to seize the *mononzotapa's* mines. Its leader, Francisco Barreto, after losses from disease turned back and himself died. Barreto was followed by \-asco Fernandes Homem who travelled from Sofala to Manica and negotiated with the *monomotapa* near Umtali: he was disappointed with what he saw. and, although the great amount of valuable information about the interior he and his predecessors had collected was incorporated in João dos Santos' *Ethiopia oriental* (1609), the idea of conquering it for the crown of Portugal seems to have been abandoned in view of the limited possibilities of trade.

In the 17th century the Dutch wrested control of the eastern seas from the Portuguese. but. though they thrice attempted to seize the port of Mozambique, they were beaten off. The Portuguese settlers had now come to rely largely on the slave trade, which played an essential part in the development of Brazil. When the Dutch for a time seized the main sources of slaves in Angola, the Portuguese fell back on Mozambique, among other places. The slave trade continued until the middle of the 19th century, slavery was abolished in the colony in 1878.

In the early part of the 18th century the Arabs again expanded in east Africa and the northern limits of Portuguese influence were fixed at roughly the modern frontier of Mozambique. In

1752, Portuguese East Africa, after being subordinated to the Portuguese administration at Gba, was separated and given an independent governor.

The most remarkable of the colonialists of Mozambique was Francisco José Maria de Lacerda e Almeida, a Brazilian, who had explored the interior of his own country and Angola. He was made governor of Rios de Sena in 1797, and carried out the expedition to Cazembe on which he died in the following year. The distress caused in Portugal by the Peninsular War and the separation of Brazil left their mark on the administration of Mozambique, whose inhabitants felt their whole existence threatened by the abolition of slavery. Much of the country was also threatened in the 19th century by the raids of savage tribes of Zulu origin.

In the partition of Africa Portugal maintained rights based on the discovery of most of the African coast in the face of the doctrine of effective occupation. Cntil the Congress of Berlin Portugal hoped to preserve a continuous belt of territory from coast to coast uniting modern Angola with Mozambique. The acquisition of British rights in this area, especially to the south of Lake Nyasa and in the Shiré highlands, caused the Portuguese to prepare a counterexpedition. but when Maj. A. de Serpa Pinto came into conflict with peoples under British protection, the marquess of Salisbury, then British prime minister, delivered an ultimatum in Lisbon (1890). This was followed by a treaty defining the frontiers of British and Portuguese possessions and the creation of the Mozambique and Niassa companies for the development of the area. Under the Portuguese republic a measure of autonomy was granted to the colony, and this was extended in 1920. After the Portuguese revolution of 1926 this system was ended, and within the provisions of the Colonial act a much more centralized system mas adopted.

The building of the railways led to a rapid expansion of Mozambique's economy, and conventions with the countries of the hinterland were signed governing the question of transit trade, the recruitment of natives from Portuguese territory for work in the Rand mines and other matters. The original Mozambique convention which had been concluded with the Transvaal government in 1909, lapsed in 1923 and was replaced in 1934 by a new treaty that ran until 1939; thereafter it remained in force subject to 12 months' notice of termination of either party. The Companhia de Moçambique was wound up in 1942 and Mozambique was designated as an oversea province of Portugal in 1951.

THE PEOPLE

Populations and Towns. — The population of Portuguese East Africa shown in the census of Sept. 1950 was 5,732,317 as compared with 5,085,603 at the census of 1940. The number of civilized inhabitants was given as 92,404, of whom 48,910 were whites and 24,898 half-castes; there were small numbers of Indians and Chinese, and 4,377 Negroes were described as "assimilated"; *i.e.*, living as whites.

All the natives are Bantu-speaking, and the main tribal groups from north to south are: in Niassa, the Yao (*q.v.*); in Pbrto Amélia, Nampula and Quelimane, the Makwa or Macua; in Beira and Quelimane, the Basenega; in Tete, the Baangoni and Basenega; in Lourenço Marques and Inhambane, the Baronga, Batonga and Bachopi. The Yao occupy the area between Lake Nyasa and the Msalu river. The Makwa are divided into four groups — the lower Makwa, the Lomwe or upper Makwa, the Maua and the Medo. They have come into contact with Arabs, Banyai and Battia in the coastal districts, and their language has been much altered, though they have kept their purity of race. Between the Zambezi and the Mazoe most of the tribes are of Zulu origin, and in the area south of the Pungwe river, known as Gazaland, the ruling peoples are of Zulu origin, and all other tribes of difierent stock are known as Tsonga (Thonga). They include the Batonga (Inhambane) and Baronga (Lourenqo Marques), peaceful stock raisers and farmers akin to the Basuto. The Bachopi are a Bantu-speaking people of different origin and language.

The most important towns are: Lourenco Marques (*q.v.*), the capital, where about half the white population lives; Beira (*q.v.*), the headquarters of the former Mozambique company's territory; Mozambique (*q.v.*), established as a Portuguese post in 1508 and the capital of the territory until 1897; Quelimane, Inhambane and Chinde (*qq.v.*). Sofala (*q.v.*) is now of little importance, and its fort, founded in 1505, has collapsed into the sea. Other European settlements are (from north to south) Ibo, Pbrto Amélia, Vila Cabral, Nampula. António Enes (Angoche. formerly Parapato), Tete, Sena, Zumbo, Macequece (Masikesi, Vila Manica) and Vila João Belo. Ibo is a small port on one of the many Cabo Delgado islands and was formerly the capital of the district. It is picturesque and has ancient fortifications. Pôrto Amélia, the port for the districts of Cabo Delgado and Niassa, stands on the natural harbour of Pemba bay, which is 1½ mi. wide at the entrance and covers an area 7 mi. long by 5 mi. broad. Nampula, the capital of Niassa and seat of a bishopric, has a European population of about 300 and is the centre of a native population of 100,000. António Enes, 95 mi. southwest of Mozambique, dates from the 17th century and was rebuilt after suffering severely from cyclone damage in 1939. It exports copra. peanuts, sisal, etc., from an important area.

The Zambezi towns, some of which date from the 16th century, represent the limits of Portuguese penetration into the interior until the 20th century. They had considerable economic importance until the 18th century after which they declined. The development of the Rhodesias and the consequent building of railways restored their former importance. Tete, founded in 1531, is the centre of a mineral-bearing district and of an important transit trade with the British territories, since it is on the main road from Salisbury (Southern Rhodesia) to Blantyre (Nyasaland). Its district covers 65,000 sq.mi. and has a population of 336,000. Sena, halfway between Tete and the sea, is an ancient town, now about 2 mi. from the Zambezi. From it the Trans-Zambezi bridge crosses the river to Dona Ana on the north bank.

Macequece, on the railway line from Beira to Rhodesia, is 15 mi. from the frontier. It is pleasantly situated at 2.300 ft. and as it is healthful for most of the year it is a resort for those who live on the coast. It is the capital of Manica district and the centre of the small Manica gold fields. Vila Pery and Vila Machado are other settlements on the same line. Vila João Belo, 23 mi. from the mouth of the Limpopo, the chief town of the district of Gaza, is the centre of a rich farming area producing sugar, rice, maize and timber. A group of settlements in the neighbourhood of Lourenço Marques includes Moamba and Ressano Garcia, both on the railway from the capital to the Transvaal.

Education and Religion. — The predominant faith is Roman Catholic; the position of the church is defined by the Portuguese concordat and missionary agreement of 1940. This created a metropolitan see at Lourenqo Marques, to which two dioceses of Beira and Nampula are suffragan. There is freedom of worship and in addition to the modern Roman Catholic cathedral Lourenço Marques has an Anglican procathedral, a Methodist church, a synagogue, a mosque and a Chinese temple. Anglicans in Portuguese East Africa are subject to the archbishop of Cape Town: the Delagoa bay region and the district of Sul do Save form the Lebombo diocese with see at Lourenço Marques; Anglicans in the north come within the diocese of Southern Rhodesia. Other Christian missions are the Church of Scotland, Swiss and American Free Methodist.

The educational system of the colony is supervised by the department of education in collaboration with that of health. There is no university in Mozambique and students who wish to work for a degree usually go to Portugal. A large new secondary school, the Liceu Salazar, was built in Lourenco Marques in 1951 to serve the whole province.

There is a school for training native teachers run by the Roman Catholic Church and a special school for the children of native chiefs. The usual school for natives provides a primary education lasting four or five years. The age of entry varies greatly, and the subjects are reading, writing and arithmetic. There are also three arts and crafts schools for natives. Under the agreement of 1940 most of the native primary schools are entrusted by the state to Roman Catholic missionaries. There are also several foreign missionary schools. All instruction is given in Portuguese. Lourenqo Marques has various private and community schools for the English-speaking community. and for Hindus. Moslems and Chinese. In 1952 the number of primary schools was given as 1,261 with 174,320 pupils. There were 21 lyceal and other secondary schools (1950) with 1,885 pupils; and 3 teachers training colleges (1951) with 21 j students.

Administration. — The head of the province's government is the governor general who is appointed by the council of ministers in Lisbon for a four-year term, subject to reappointment, and who is directly responsible to the minister for overseas provinces in Portugal. Although he may be overruled in Lisbon on important matters, the governor general exercises wide powers in the province. He resides in Lourenqo Marques. He is assisted by an advisory government council.

There are no representative institutions, the only elected officials being the five unofficial members of the government council. who are elected by certain economic organizations such as the chambers of commerce, and the elected members of the town councils in the few municipal areas designated as communes. The five unofficial members of the government council are more than offset by the seven official members who sit on the council by reason of their position in the local administration. The council normally holds but one short session each year and is strictly consultative. The administration of the province is carried out through four lesser provinces and nine districts as follows (from south to north): province of Sul do Save, consisting of the districts of Lourenqo Marques, Gaza and Inhambane; province of Manica and Sofala, districts of Beira and Tete; province of Zambézia, district of Quelimane; province of Niassa, districts of Nampula. Cabo Delgado and Lago. The provincial capitals are Lourenqo Marques, Beira. Quelimane and Nampula respectively.

The districts are in turn divided into subdistricts (*circunscrições* civis) each under an administrator, and each subdistrict is redivided into one to four administrative posts, in which are the post offices, police stations, etc. The provinces are headed by provincial governors who can be overruled by the governor general. An administrator heads each district. A judicial system, comprising a court of appeals and courts of preliminary investigation in ten judicial divisions, maintains separate sections for native cases and applies the Portuguese law (cddigo civil).

The Mozambique company (Companhia de Moçambique) was incorporated by royal charter in 1891 for a term of 50 years. Much of its capital of £1,500,000 was foreign, and it exercised sovereign rights over the territories of Manica and Sofala, an area of 59,315 sq.mi., until its rights reverted to the Portuguese government in 1941, when they were not renewed, and the territory was formally restored to direct Portuguese administration on July 19, 1942. In this territory the company had control of agriculture, commerce, industry, mining, communications and transport, taxation and customs. and issued its own currency and postage stamps. The main interests of the company were in agriculture and transport, and after the restoration of the territory to the provincial government extensive schemes were adopted for developing it.

The Niassa company (Companhia do Niassa) acquired a charter for the administration of territories north of the Lurio river in 1894. Its capital was at Pôrto Amélia. Development under the company was comparatively slow, and in 1929 the Portuguese government resumed administration of the area.

ECONOMY

Agriculture. — Although much of the province consists of thinly populated bush country, it has also areas of high fertility. The most important of these are the southern lowlands between Catuane and Inhambane. which contain the lower reaches of the Limpopo and other rivers; the valleys of the Save and Zambezi; Quelimane; the coastal area of Mozambique and Nacala and its hinterland; and the Macondes highlands on the Tanganyika frontier. These include the main areas of native population. The main types of agriculture are the indigenous; the native-produced cash crop; and the European-owned plantation. There are few white small farmers, though it was hoped in the 1950s that the drainage and irrigation of the Limpopo valley would provide suitable soil for the settlement of Portuguese immigrant small holders.

The main crops gro n by European (and other non-native) cultivators are: copra, sisal, sugar cane, tea, rice. potatoes, sunflower, maize. tobacco and wheat — together contributing one-third of the province's exports. Sugar is grown on estates in the Zambezi, Sul do Save and Manica areas; and there are very extensive plantations of copra-producing coconut palms in the coastal area of Zambézia, with about 6,000,000 trees. Sisal is produced as a plantation crop in Zambézia, Niassa and Manica. Tea is an increasingly valuable plantation crop.

The most valuable single export of the province is raw cotton, which accounted for between one-fifth and one-quarter of total exports between 1946 and 1950. It is produced by the natives, and its development has been accomplished to some extent by sacrificing staple crops. Both cotton and rice, which latter meets the territory's needs and leaves a surplus for export, are cultivated under European supervision, under a concessionary system.

Native-produced crops include cashew nuts, which are collected all over Mozambique. copra, peanuts. sesame (all of which are usually exportable), maize, tobacco and vegetables. Maize normally suffices for consumption in Mozambique, but in 1949, 1950 and 1951 crops were poor, and imports were necessary. Tobacco, which is grown in the north, and coffee, which has a rather bitter taste popular in Mozambique, are produced for local consumption.

Forestry, Stockraising and Industries. — There are considerable resources of timber, including a large area of forest behind Beira.. The export of timber and wood-products increased greatly during World War II, from 10,960 tons in 1939 to 80,596 in 1946.

The most important timbers produced are: African mahogany (Khaya senegalensis) ; ebony or grandilha; mussacossa or pod mahogany (Afzelia quanzensis), called *chanfuta* in the south of the province, used for furniture, vehicles, etc.; m'bila (*Pterocarpus*) or bloodwood; *pau-ferro* (Swartzia), suitable for high-class furniture; African sandalwood for furniture and wagon work, etc.; ziba, a valuable hardwood; *moanjwa* (Cordyla); *m'zimbiti* (*Andro*-stachys), impervious to white ants, and used for railway sleepers and piles; *panga-panga* (Lonchocarpus), suitable for furniture; muanga or chuanga (Ormosia), used for bridge building, being impervious to white ants; *monhé* or gone (Adina), similar to teak; and messanda (Erythrophloeum), a very hard red wood, suitable for railway sleepers.

There is little industrial development in the province, but the government's policy is to encourage local production by the use of protective tariffs and the concession of monopolies for the manufacture of certain products. A textile factory has been built at Vila Pery, and cement is made near Lourenqo Xarques, where production is nearly 50,000 tons a year, and Beira. A large fibrous cement factory at Dondo, near Beira, makes irrigation pipes and prefabricated houses. Bricks, ceramics and other construction materials are produced in the province. A rubber factory makes rubber-soled footwear from the latex of a wild tree, and jute sacks and bags are also manufactured. In 1955 there were 6 tobacco factories and 32 producing oils and soaps. There are factories for the preparation of foodstuffs. including milling and the decortication of rice and cashew nuts. There are several breweries and mineral-water factories.

Minerals and Mining. — The mineral resources of the province are still inadequately known, though the mines department was undertaking a full survey in the mid-1950s. Although the region of Sofala was according to legend rich in gold and was identified with Ophir (*q.v.*), the quantity now extracted is small. It is mined near Vila de Manica and Tete, and there are alluvial deposits near Vila de Manica and Alto Zigonha (Quelimane). Coal is mined, though not on a large scale, in the Zambezi valley near Tete, and surveys confirm the existence of an extensive basin estimated to contain 700,000,000 tons. The Companhia Carbonifera de Mocambique. uith Belgian capital, supplies the railways and the port of Beira and exports some coal to Nyasaland. Southern Mozambique imports coal from South Africa.

The Alto Ligonha company, with exclusive rights over part of Zambézia, mines beryl, mica, colombite and bismuth. Quantities of graphite exist near Nacala and in Angónia, but extraction is irregular. Prospecting for petroleum was undertaken in Sul do Save under a contract for ten years (1948–58) between the Portuguese government and the Moçambique Gulf Oil company. Radioactive minerals exist in the Tete district; prospecting concessions are granted only through the Portuguese government and independent prospecting is prohibited.

Finance and Trade. — Unlike Angola, which for several years absorbed large quantities of capital without any return, Mozambique has enjoyed a long period of prosperity, largely as a result of a steady income from the supply of services and native labour to the territories to its west. At the end of 1951 the province's exchange account shoued reserves of about £3,500,000 in foreign currencies and £4,500,000 in gold. There was a surplus of income over expenditure after 1937, so that large sums were devoted to extraordinary public works, amounting to nearly £7,000,000 between 1946 and 1950. In 1947 the Portuguese government made a loan of 1,000,000,000 escudos to Mozambique.

The chief sources of revenue are customs duties. income tax and licence and stamp duties. The monetary unit is the Mozambique escudo of 100 centavos, equal in value to the Portuguese escudo. The Banco Nacional Ultramarino is the bank of issue.

The development of the province has been greatly facilitated by the profitable transit trade of the Transvaal, the Rhodesias, Nyasaland and Belgian Congo, though this has in some ways hindered the growth of internal communications within Mozambique. The hiring of a large number of native labourers to the Rand mines has similarly contributed very greatly to the territory's prosperity, though the absence of so large a proportion of its labour is unfavourable to its own agriculture. However, the advantages of these arrangements far exceed the disadvantages, and the construction of railways to the interior has led to the appearance of new townships in the hinterland of the capital and of Beira.

The requirements of the transit trade have led to a continuous development of the railways and port installations, while agricultural production has steadily increased. and Portuguese industrialists have introduced a number of manufactures. British and South African interests are represented in transport services, distribution. agriculture, etc. There is also U.S., French, Belgian and German capital.

The foreign trade of the province normally shows an excess of imports over exports. In 1950 imports were valued at 1,654,000,000 escudos and exports at 944,000,000 escudos. Re-exports, largely minerals from South Africa, were 604,000,000 escudos and transit traffic 7,936,000,000 escudos. Nearly 30% of both imports and exports were trade with Portugal. Twenty per cent of the province's imports came from the United Kingdom, but only 2% of its exports were sent there. Thirteen per cent of imports came from the United States which took 6% of Mozambique's exports. and the corresponding figures for South Africa were 13% and 18%.

The chief imports are cotton textiles (about one-sixth of the whole), railway material, agricultural and other machinery, table wines and vehicles. Other main items are iron and steel, wheat flour, gasoline and milk.

The cost of living in Mozambique doubled between 1939 and 1950.

Communications. — The province is served by some 40 shipping lines, which link Lourenço Marques with the main south and east African, European. Indian and American ports. In 1953, 1,197 ships with a net tonnage of 7,932,985 were handled at Lourenqo illarques. At Beira 669 ships of 2,582,979 tons entered in 1952. In each case more than half were English. The number of entries by coastal shipping in 1949 was 1,042, of which Lourenço Marques accounted for 171, Beira 179, Quelimane 136, Inhambane 112, Chinde 86, Mozambique 80, António Enes 79 and Pôrto Amélia j6.

The road system is satisfactory in the settled areas. though many parts of the province are still inaccessible by road, and much surfacing and bridge-building is necessary to make the existing roads suitable for use all the year round. Of 23,200 mi. of road in the province in 1952, 2,560 mi. were described as main roads. Metalled roads are limited to the capital and Beira, but the main towns are linked by good gravel roads. The following roads are the main international routes: Lourenço Marques to Goba for Swaziland; Lourenqo Marques to Ressano Garcia for Johannesburg; Beira to Macequece for Salisbury; Tete to Zôbué for Nyasaland; Tete to Vila Gamito for Fort Jameson (Northern Rhodesia); Quelimane to Milanje for Blantyre (Nyasaland); Mozambique to Nampula and Mandimba for Blantyre: and Mandimba to Vila Cabral and Côbué (Kabué) for Tanganyika.

The province's railway system owes its existence to the transit trade of the neighbouring English-speaking territories, and although these lines have contributed much to the opening up of Mozambique. there is still no rail connection between the chief centres of the province. From Lourenço Marques there are lines to Ressano Garcia (for the Transvaal frontier and Johannesburg), to Goba (for Swaziland); to Xinavane for the Komati (Incomati) valley; and to Marracuene (Vila Luisa) and the Limpopo valley. There is a short line from Vila João Belo to its hinterland (85 mi.), and from Inhambane to Inharrime (55 mi.). In central Mozambique the port of Beira is connected with Blantyre by the Trans-Zambezi railway, while a branch goes up to Moatize, near Tete. The line from Beira to Umtali for Salisbury (190 mi.), also connects Macequece, Vila Pery and Vila Machado with the coast. Quelimane has a port railway to Mocuba (go mi.); and a line from the port of Lumbo (Mozambique) connects with the new port of Nacala and runs through Nampula and up toward the Nyasaland frontier at Cuamba (335 mi.).

The Lourenqo Marques-Transvaal line carried 449.892 passengers and 3,455,945 tons of freight in 1950, and the Beira-Umtali line 237,710 passengers and 1,724,736 tons of freight.

The Zambezi is navigable by light-draught steamers throughout its course in Portuguese territory with a break at the long Kebrabasa (Quebrabaqa) rapids, 400 mi. from its mouth. There is direct steamer and railway connection with Lake Nyasa by the Shiré (Chire) river (*q.v.*).

The province belongs to the South African postal union. It is connected with Europe by telegraph via South Africa and via Zanzibar. A cable connects Mozambique with Madagascar, and it is linked with the British-owned Aden-Durban cable. There are land lines between Lourenqo Marques and Johannesburg, and Beira and Salisbury, an internal radio system for communication between the main administrative centres, and an external radio system for Lisbon and other towns in Portugal. The Radio Club of Mozambique controls five transmitters which broadcast in Portuguese, and also in English for South Africa. (H. V. L.)

PORTUGUESE GUINEA, a Portuguese overseas province on the Guinea coast of west Africa, extending from just south of Cape Roxo to the Cajet river (the northern arm of the Cogon estuary). Its coastline is extremely indented but extends about 150 mi. as the crow flies. Its area is 13.948 sq.mi. It is enclosed by Senegal on the north and Guinea on the southeast.

Physical Features. — Almost all the country is lowland. Off the coast there are many islands separated from the mainland only by creeks. although the Bijagós (Bissagos) archipelago consists of about 25 islands and islets lying 15 to 30 mi. offshore. The main rivers are the Cacheu (upper course called Farim), the Mansôa, the Geba and the Corubal (Rio Grande; upper reaches in French territory called Komba). the two last uniting in the deep inlet of the Rio Grande or Geba estuary. Other deep inlets are the Rio Tombali, the Rio Grande de Bolola and the Rio Cacine (which are not rivers but gulfs). There are fairly numerous swamps and pools. except in the southeast, the only high ground in the territory (328 ft.).

Climate. — There are two seasons, the dry from December to

May, and the wet from June to November. During the former the hot northerly harmattan (*q.v.*) blows from the desert, and the maximum monthly mean temperature is 85° F. in May. There is no rain at all between January and April, and the whole rainfall of up to 75 in. is therefore confined to the wet season, about one-third of the total occurring in August. The minimum mean monthly temperature occurs in January (77°). The difference between the two seasons is less marked in the interior.

Flora and Fauna. — The coastal region and the islands are covered with palm trees; the rest of the country, interspersed with swamps, is only lightly forested. The chief trees are the cotton tree, the African mahogany (Khaya senegalensis), the great ironwood or balsam tree (*Copaifera*), the baobab and innumerable varieties of acacia. Fruit trees include the papaw. guava, mango, banana and orange. Coffee trees, cotton bushes and indigo may be found. Peanuts, rice and millets are cultivated and are, besides the products of the palm. the chief staples of the native population. The fauna includes water buffaloes, deer, antelopes, lions, leopards. monkeys and many varieties of snake; occasionally elephants stray in from French territory; crocodiles and sharks abound in the estuaries. Birds include the pelican, heron, marabou, egrets, the trumpet bird and yellow parrots.

History. — According to João de Barros, Portuguese Guinea was first reached by Nuno Tristão in 1446, though it is still uncertain whether in fact Nuno Tristão passed the Gambia river. It was next visited by Diogo Afonso, Alonso Fernandes and Alvise Cadamosto (1456), who described it at some length. The colonists of Santiago in the Cape Verde Islands were later granted trading rights in Guinea, but the only settlers seem to have been isolated traders living among the natives. In the middle of the 16th century foreign interlopers began trading in Guinea: by 1588 the Cape-Verdeans had established a village at Cacheu, and in 1624 the overseas council decided to send royal officials there and to other parts with instructions to administer and defend them. Some of the early settlements such as São Felipe and Porto da Cruz were later abandoned, but others still exist, among them Farim, Geba and Buba. With the Portuguese restoration of 1640, a captain-major and factor was appointed to Cacheu from Lisbon, and the old dependency on the Cape Verde Islands gradually declined, till in 1879 all formal connection was dissolved. In 1676 the Cacheu company was given a virtual monopoly of the Guinea trade, but it was soon dissolved.

The expansion of the French Senegal company led to the building of a Portuguese settlement at Bissau in 1687, and this was created a captaincy in 1692, the duty of maintaining it being transmitted to the second Cacheu company. The main export of Guinea was slaves for Spanish America, and the second Cacheu company won the Spanish asiento or monopoly from the French Senegal company. However the company's contract was terminated in 1703, and Bissau was abandoned to be refounded in 1753 under the influence of the marquess of Pombal's Graõ-Pará company. In 1792 an English expedition led by Lieut. Philip Beaver tried unsuccessfully to establish a settlement at Bolama. This attempt led to a dispute between Portugal and Great Britain about the possession of Bolama, which was finally awarded to Portugal by the arbitration of Pres. Ulysses S. Grant of the United States (April 21, 1870). Bolama was then made the capital of the colony. The Franco-Portuguese frontier was defined in 1886. when the Portuguese lost the southern bank of the Casamance estuary in the north in return for the Cacine district in the south. The demarcation was completed in 1902–05.

Until the 19th century the colony had been at once dependent on the slave trade and unable because of it to attain orderly development. It was only after its abolition that the Portuguese were able to reduce the interior, between 1890 and 1915, in which year Capt. Teixeira Pinto finally pacified it. Even after this there was some resistance by the Bissagos, but after 1936 the colony developed steadily and peacefully. It was designated an overseas province in 1951.

Peoples. — The population of Portuguese Guinea at the 1950 census was 510,777 (including 502,457 Negroes. 4,568 *mestiços* [mixed], 2.263 Europeans).

The African inhabitants of the province consist of about a dozen peoples. Some of the tribes of the interior are Moslems, while those of the coastal regions (the majority) have retained their traditional religions. The first group includes the Fula or Fulani (*q.v.*), the Mandingo (*q.v.*) and the Biafada or Biafar; the first two of these groups are among the most industrious and intelligent peoples of the territory. Of the non-Moslem peoples, the Balante are the largest group in the province and are regarded as hard-working and shrewd, but litigious. The Manjako or Mandjak have proved readiest to accept Portuguese ways and the Palel most recalcitrant. Other non-Moslem peoples are the Fulup or Felupe north of the Cacheu river, the Bissago or Bijago of the islands and the Nalu in the extreme south. All the native peoples are agriculturists. although the Fula are also cattle breeders. Several thousand urbanized Africans live in the towns of Cacheu, Bolama and Bissau. There are about 2.500 whites and appreciably more half-breeds, including a large proportion of creoles from the Cape Verde Islands, who act as minor officials and storekeepers.

Education. — Native education is left largely to the natives themselves and the missions. There were in 1950 a small central (secondary) school in Bissau, four vocational schools and 59 primary or rural schools, with 3,295 pupils.

Administration. — The capital was shifted to Bissau from Bolama in 1942. It is the seat of a governor appointed from Lisbon and responsible to the minister for overseas; he is aided by a small cabinet of officials. The whole province is divided into ten *circunscrições* (subdistricts), which are in turn subdivided into *postes*. Native administration is left in the hands of dependable tribal chiefs.

Economy. — The currency is the Portuguese escudo, and the Banco Nacional Ultramarino is the bank of issue within the province. A gradual development of the province's economy has taken place, and the total value of exports rose from 64,000,000 escudos in 1941 to 118,000,000 escudos in 1950. The chief products are native crops, such as peanuts, palm oil, and rice; hides, wax and timber are other exportable commodities. A wide range of consumer goods, including especially cotton piece goods, wines and foodstuffs and equipment, is imported; imports were valued at 128.000.000 escudos in 1950. Bissau is the leading port, followed by Bolama and Cacheu. The deep estuaries provide easy communications with parts of the interior. (H. V. L.)

PORTUGUESE LANGUAGE, one of the Romance languages (*q.v.*), is the language of Portugal, including the Madeiran and Azorean archipelagos, and of Brazil. It is also the official language of Portugal's overseas provinces in Africa and the east. Spoken by about 70.000.000 persons, it is the end product of the evolution of the Romance dialect that was spoken in the county of Portugal, awarded by the king of León and Castile at the end of the 11th century to County Henry of Burgundy. Henry's son became the first king of an independent Portugal and advanced the area of his rule southward at the expense of the Moslem Moors who then governed the region. The language spoken by the Portuguese displaced the Mozarabic presumably spoken by Christians or their descendants who were living under Moorish domination; displaced, the Mozarabic undoubtedly influenced the emerging Portuguese to such an extent that the new national language is perhaps better considered the resultant of a Portuguese force from the northwest and a Mozarabic force from the south. By the middle of the 13th century Portugal had attained boundaries that are substantially those of the present day, and Portuguese became the language of the entire country. There is slight dialectal differentiation. Except for an occasional border dialect on the Spanish frontier, however, the *falares regionais* portugueses, as they are now called, are mutually comprehensible. The language of the nation's capital, Lisbon, and of the ancient university city, Coimbra, has provided the basis of the standard national language.

Portuguese was first written at the end of the 12th century. A standard written language was quickly formulated. It has changed little since the 13th century, virtually not at all since the 16th.

Portuguese was established as the official language of Brazil soon after Pedro Álvares Cabral's discovery of the continent in 1500. In its subsequent development it proved to be, on the whole, more conservative than the language of Portugal. Although regional pronunciations have developed, they do not hinder intercommunication. Moreover, the Brazilians and Portuguese communicate with ease despite an instantly recognizable accent. The influence on the Portuguese of Brazil of native American languages, African languages of imported slaves and Spanish of adjacent countries to the south has probably been negligible except for certain items of vocabulary.

Vasco da Gama initiated the Portuguese influence in the orient. The language of the Portuguese discoverers, colonizers, merchants and missionaries spread rapidly and Portuguese words are today far more disseminated than the area of Portugal's political control would suggest. They are found on Ceylon, for example, and even in Japan. Thus in the latter country the Portuguese *têmporas* "Ember days" is used for fried seafood.

In its evolution since the establishment of the Portuguese monarchy, Portuguese has developed more or less independently of the Romance dialects that ultimately became the language of Spain. In Galicia, however. the local dialect was originally very similar to Portuguese and has occasionally been used as a literary language. Several features of Portuguese distinguish it markedly not only from Spanish but also from other Romance languages.

Phonology.— There are five distinctive nasal vowels. as in *sim, lenço, sã* and *lanço, som* and *dom,* and *durn,* and a series of nasal diphthongs, as in *pão, põe* and *bem.* Final *em,* as in the latter word, is pronounced [ẽĩ] in standard Portuguese but as [ẽ] in many regions of Portugal and in Brazil. Among the oral vowels the distinction between closed and open *e* and *o* is meaningful: *sê-sé, pôde-pode,* the circumflex indicating closeness. the acute accent openness. Final unstressed vowels are weak and tend to disappear, especially in Portugal. In most regions *s* before a consonant is [ʃ] or [ʒ], depending on whether the consonant is voiceless or voiced (*casta, Lisboa);* intervocalic *s* is [z]. In the Rio de Janeiro area *t* and *d* before [i] become affricates approaching [tʃ] and [dʒ]. Historically, Latin intervocalic *l* and *n* have in many situations disappeared (*só,* Spanish *solo; lua,* Sp. *luna*). Because of the history of *l* and *ll,* the Portuguese definite article is simply *o, a, os* or *as.* Although the intervocalic *n* tended to disappear as a consonant, it often nasalized a preceding vowel. Thus, the singular noun ending *ão,* as in *mão, alemão, nação,* corresponds to three plural endings. *mãos, alemães, nações.* Comparison with Sp. *manos, alemanes, naciones* clarifies the endings and confirms that today's *ão* represents a convergence of earlier *ão, am* and *om.* Latin stressed *e* and *o* did not diphthongize *(pi, terra, roda, porta,* contrasted with Sp. *pie, tierra, rueda, puerta*), nor has initial *f* disappeared (*filho,* Sp. *hijo*).

Forms.— Portuguese is most different from Spanish in the verb system. It retains the Latin pluperfect as a pluperfect (1st and 3rd sg. *cantara,* used alternatively with a compound *tinha cantado).* It has a conjugated or personal infinitive and a future subjunctive. They have identical endings, those of the former being added to the infinitive, those of the latter to the preterite stem (3rd pl. *cantarem,* but *fazerem-fizerem*). Portuguese has two forms for "two," masc. *dois* and fem. *duas,* and maintains vow-el harmony in such groups of words as demonstrative *isto,* a neuter pronoun, and *êste* and *esta,* masculine and feminine demonstrative adjectives, respectively, the *e* of *esta* being [ɛ].

Syntax.— As suggested above, *ter* (Lat. *tenere*) is today the normal verbal auxiliary, and not *haver* (Lat. *habere*). Object pronouns are normally placed after the verb in Portugal, although in spoken Brazilian they usually precede. In the future tense. today used chiefly in the written language, they are inserted between infinitive and ending (*dar-lhe-ei o livro* "I shall give the book to him"). The combination of preposition and article is common *(do, da, dos, das,* for *de* + *o,* etc., and similarly *no, em* + *o,* and *pelo, por* + *o*). Forms of direct address are elaborate, ranging from *V.ª Ex.ª* (*Vossa Excelência*) through *o Senhor* and *a Senhora* and a more familiar *Você* to *tu;* all but the latter take the so-called "third-person" verb forms. In Brazil *V.ª Ex.ª* is restricted to the most formal discourse, its use otherwise being considered distinctly Portuguese.

Vocabulary.--An outstanding feature of Portuguese is the use of the church's designations for the days of the week, Monday *segunda-feira,* Tuesday *têrça-feira,* Wednesday *quarta-feira,* Thursday *quinta-feira* and Friday *sexta-feira.* Saturday and Sunday are the common *sábado* and *domingo.* Portuguese shares with Spanish many words of Arabic origin, yet also has several not found in standard Spanish, such as *alface* "lettuce," *alfaiate* "tailor." The language of Brazil contains many words. particularly designations for native animals, flowers, foods and the like, that have not entered the language of Portugal or other Romance languages.

PORTUGUESE LITERATURE. The literature of Portugal is distinguished by the wealth and variety of lyric poetry which have characterized it from the beginning, by the mediaeval lack of and later achievement in the national epic. the nealth of historical writing. and the relative slightness in drama, biography and the essay The early *cancioneiros* evidence a school of love poetry which spread, with the language. to Spain at a time when Spanish was as yet undeveloped for lyrical purposes. The *romanceiro* or balladry on the other hand was much influenced by that of Spain, though not sharing the latter's predilection for the heroic. *Amadís de Gaula,* prototype of the romance of chivalry, was in its primitive version almost certainly Portuguese, as was, later, the *Diana* of Jorge de Montemor (Montemayor), the masterpiece of the pastoral novel.

The *Lusíadas* may be held at once the most successful of the many Renaissance epics cast in the classical mould and the most national of great poems in any modern literature, and the many outstanding works of history and travel of the 16th and 17th centuries are worthy of a race of explorers who carried their flag. their faith and their speech to the ends of the earth. Gil Vicente, in the early 16th century. was a dramatist of great gifts. but no other appeared until Almeida Garrett in the 19th, and Portugal never developed a national drama.

This literature. which until the 19th century lay largely unstudied and unknown. has from the beginning been much exposed to foreign influences. The earliest was Provençal, and Provencal taste ruled for more than a century. Then came Castilian. with a court poetry which provided models until the Renaissance saw triumph that of Italy and the classics of antiquity. In the 17th century with political domination Spain again imposed its literary standards. followed in the 18th century by France. The Romantic movement reached Portugal from both France and England. two countries whose influence, joined in a lesser degree by that of Germany. persisted long after. The closeness of contacts with Spain, reinforced by dynastic marriages which often brought to the court at Lisbon a predominantly Spanish atmosphere, explains why for two centuries and more from 1450 nearly every Portuguese writer of note was bilingual and wrote also in Spanish. so that some, like Montemor and Manuel de Mello. are numbered among the classics of Spanish letters. Portuguese literature retains nonetheless a distinct individuality which contrasts strikingly with that of Spain alike in the nature of its development and in the divergent kinds where lie its major achievements; in it may be seen reflected the differing ethnical constitution of its people and the distinctive paths along which their lot has been cast. The mediaeval lyric! the chronicles of Fernão Lopes, the plays of Gil Vicente. the *Histdria trágico-marítima*, the bucolic verse and prose of the 16th century and. above all. the *Lusíadas*, are several expressions of a clearly defined national temperament which early carved out for itself original expression.

Early Period.— Though no literary documents belonging to the first century of Portugal's history as a nation have survived. there is evidence of the existence of an indigenous popular poetry both sacred and profane. Provencal influences were for a long time to mould the manifestations of poetical talent. but they did not originate them. A few compositions dating from before the year 1200 survive: one. attributed to Sancho I, is the earliest extant *cossante,* the name now given to brief lyrical poems, parallel-strophed, almost immobile in their repetitiveness and instinct with that *saudade* or wistful sadness which is never wholly absent from Portuguese literature. The accession in 1248 of Alphonso (Afonso) III. who had lived 13 years in France and returned home, bringing poets in his train, to play the role of patron of letters, inaugurated a period of poetic activity illustrated in the *Cancioneiro do Ajuda*, the oldest collection of Peninsular verse. Soon all the forms of Provence and of northern France were current, subtlety of form and device taking precedence in them over thought or emotion. Three main types of *cantiga* were recognized. all often practised by the same poet: *de amor*, *de amigo* and *de maldizer*. The second, put into the mouth of the lady lamenting her lover's absence. commonly betrays a truer feeling than the first; in the third the poet vents satire on his rival or enemy.

The apogee of this palace poetry dates from the early years of the reign of Dinis (1279–1325). who had been educated by a Frenchman, Aymeric of Cahors. Dinis. grandson and imitator in his services to culture of Xlphonso the Learned of Castile, founded his country's first university in Lisbon (later to be removed to Coimbra) in 1290. and stimulated the translation into Portuguese of outstanding works from Spanish, Latin and Arabic. He thus ranks as the founder of vernacular prose in Portugal; but he was also a true poet, technically accomplished and endowed with genuine feeling and esteemed the best poet of his age in the peninsula. To his court came troubadours and *jograis* from Leon. Castile and distant Aragon to enjoy the last afterglow of a cult already dying or dead elsewhere. and about 2.000 poems by its 200 poets are preserved in the three great *Cancioneiros da Ajuda, da Vaticana* and *Colocci-Brancuti*. In the main this poetry forms monotonous reading today, because of its poverty of ideas and conventionality of metrical form and expression: in it poets served an apprenticeship to their craft. and the language developed its rare musical qualities against the birth of more individual inspiration.

In contrast with the restricted horizons of courtly verse, themes of adventure. war and chivalry mingled with love, religion and the sea in the considerable collection of ballad poetry known as the *romanceiro*. Differing in subject matter from the ballad in Spain, which drew heavily on the native epic tradition. the *ronzanceiro* still derived in all probability from across the border and exploited the popularity of the form — the octosyllable with assonance in alternate lines — in more congenial directions. Few if any *romances* can be dated earlier than the 1jth century; they belong to the close of the middle ages, an anonymous collective poetry kept alive by oral transmission. with a late artificial flowering, from the pens of known poets. in the 16th and 17th centuries. Heroes and incidents of the French and Spanish epos were reflected in numerous derivative ballads: of native Portuguese epic we can point at most to a *Poema da batalha do Salado* (1340) by one Alphonso Giraldes concerning which the brief surviving fragment allows no firm inferences.

Prose literature took much longer than verse to perfect its instrument. Religious writings — fragments of the Bible: lives of saints and monastic rules — brief annals of the early kings and *livros de linhagens* or books of descent constitute the earliest texts; they date from the late 12th century onward and interest the student of language rather than of literature. The *Livro de linhagens* of Pedro, count of Barcelos (1289–1350), raised the last-named kind to the confines of literature. and therein constitutes a landmark, by a concern that went beyond genealogy to history and legend. The early popularity of the *matière de Bretagne* is attested both here and elsewhere, as in the five songs based on Breton *lais* with which the *Cancioneiro Colocci-Brancuti* opens: the ideals of chivalry and the spirit of sentimental adventure associated with the knights of the Round Table clearly made strong appeal to the Portuguese temperament. The *Histdria dos cnvaleiros da Mesa Redonda e da demanda do Santo Graall,* an adaptation from the French dating from the early 14th century. is the chief relic of a considerable activity in this field. out of which derived *Amadís de Gaula,* progenitor of a long succession of romances of chivalry in Spain and Portugal. While the authorship and country of this are still in debate, the balance of probability inclines to a Portuguese original. at least for the first three books of *c.* 1350, from the pen possibly of one Vasco de Lobeira.

The 15th Century.— Under John (João) I (1385–1433), founder of the new dynasty of Aviz. the court became once again a centre of literary culture. The king himself wrote a *Livro da montaria* or treatise on the chase. His son Duarte collected a rich library of the ancients. some translated by his order. as was also John Gower's *Confessio amantis,* and of mediaeval poems and histories. and composed a moral treatise. *Leal Conselheiro, c.* 1430, which revealed a great and conscious stylist. His brother Pedro's *Trauctado da Uirtuosa Benfeyturia* was a version of Seneca's *De beneficiis;* Cicero and Vegetius were among other authors translated by this much-travelled prince or at his instance. But the great distinction of the age was its chronicles, for which much credit falls to Duarte who as king created in 1434 the office of Cronista Maior do Reino and appointed to it Fernão Lopes (*q.v.*), the father of Portuguese historiography — Robert Southey called him the best chronicler of any age or nation — and author of chronicles of the first ten kings of Portugal, of which only those of Peter (Pedro) I. Fernando and John I survive. Earlier he had written the biography of the hero of Aljubarrota. the Constable Nun' Álvares Pereira. Vividness of style and character portrayal combined with serious documentation and a high sense of principle and responsibility to produce in Lopes the finest achievement of mediaeval Portuguese prose.

His successor in office, Gomes Eanes de Zurara (*q.v.*), adding to the seriousness a constant parade of erudition, continued the chronicle of John I on a lower level of artistry with an account of the 1415 expedition to Ceuta and the early period of expansion in North Africa. His chief work, born of admiration for Prince Henry the Navigator, was his *Crdnica do descobrimento e conquista da Guiné*. Rui de Pina (*c.* 1440–*c.* 1523), if likewise not of the stature of Lopes either as historian or as artist, was free from the rhetorical defects of Azurara. and his chronicles of Duarte, Alphonso V and John II were characterized by a notable frankness: the people. who in Lopes had occupied the foreground, here yielded pride of place to the monarch. To Pina's reworking of Lopes' narratives of the six reigns from Sancho I to Xlphonso IV is owed the irreparable loss of the original text; his own chronicle of John II was in its turn reworked, and spiced with much anecdotal gossip, by Garcia de Resende (*q.v.*).

Poetry had suffered a long eclipse after the spate of activity reflected in the *cancioneiros,* and when in the mid-15th century it was once more cultivated, much had changed. The dominant influence came now from Spain. and where once Spanish poets had, written in Galician-Portuguese, Portuguese poets initiated the long chapter of fealty. in theme and language alike, to Spain. Apart from the *romances,* popular poetry had disappeared along with that of the troubadours, whose legacy stood reduced to a set of metrical devices and another of conceits on the topic of courtly love. The constable Dom Pedro de Portugal (1429–66), son of the prince of that name already referred to, was led by the accidents of his own storm-tossed life—he lived for seven years in exile in Castile and died as king of Aragon—to imitate the fashion of writing in Castilian. As one of the first likewise to adopt the new Spanish trend away from the Provençal manner in favour of allegory and the cult of classical antiquity derived from Italy, his influence on his compatriots was doubly important. His own poems were inspired by deep feeling and much reflection on life. It was to him that the marques de Santillana addressed, *c.* 1449, his historic letter dealing with the origins of Peninsular verse. The constable was one of almost 200 poets represented in the *Cancioneiro geral* (1j16) of Garcia de Resende, covering the preceding three-quarters of a century. The main subjects of these 1,000-odd poems, in Portuguese and Castilian, are love, satire and epigram. Discovery and conquest in the east hardly find an echo, even in the verse of those who had taken part in them. Instead theme and tone are predominantly trivial and treatment artificial; the compositions that reveal genuine feeling or serious intent are very few. Resende was himself a better poet than most of his contributors. notably in his stanzas on the death of Inês de Castro. Some names were destined notwithstanding to count among the foremost in Portuguese literature: Bernardino (Bernardim) Ribeiro, Cristóvão (Christovam) Falcão, Gil I'icente, Francisco de Sá de Miranda (*qq.v.*). These typify the transition from the 1jth-century Spanish school to the Italianate school of the 16th. Ribeiro and Falcão, introducers of the bucolic style. proved successful in pouring new life into old forms and by their eclogues and *redondilhas* gave models which later writers worked by but rarely equalled.

Gil Vicente and Early Drama.— The emergence of the drama from its mediaeval swaddling-clothes to the threshold of the modern play may be traced in the works of Gil Vicente (*q.v.*), court dramatist and greatest name in the Portuguese theatre, who, having no forerunners in Portugal. drew for his first pastoral-religious *autos* on Spain. chiefly on Juan del Encina (*q.v.*). Eleven of his 44 plays were written wholly, and another 17 partly, in Spanish. The trilogy of the *Barcas* revealed his dramatic power in serious vein. but even here can be seen his fondness for comic relief, by way of which he arrived at pure comedy and the study of character. In this lay his strength, in construction his weakness; and the latter consideration, not remedied by his successors, had its bearing on the phenomenon of a potential national theatre that may be said to have died with its founder. His real influence was felt in Spain. In centres where Yicente's plays were known and acted writers for the stage did spring up, in number sufficient to allow afterward the term *Escola Velha* or old school of Gil Vicente, but none had the talent to compare with his achievement. The best known were Afonso Álvares in the religious vein, António Ribeiro Chiado, an unfrocked friar who wrote farces with a strong satirical bent, and his brother Jerónimo Ribeiro, likewise a satirist. António Prestes evinced in his plays more knowledge of folklore than dramatic competence. Baltasar Dias, a blind poet from Madeira. wrote simple religious *trutos* which for long retained their popularity. One of the last of the school was Simão Machado, whose *Comidia de Dio* and *Comédia da pastora Alfea* possessed something of Vicente's lyrical facility and skill in portraying peasant scenes.

By the time of Vicente's death, *c.* 1536, court favour had been withdrawn from the stage. The Inquisition. introduced into Portugal in that year, early declared war on the popular theatre on the charge of grossness, to counter which the Jesuits encouraged the writing of Latin tragicomedies or dramatized allegories for performance at religious or scholastic festivals. Vicente's own plays, which figure on the Spanish Index of 1559, were reduced in number to 35 and sadly mutilated in the second edition of 1j86, and no new edition appeared for another 250 years.

The Renaissance.— The movement commonly called the Renaissance reached Portugal both indirectly through Spain and directly from Italy. with which country there had been close cultural relations through the 1jth century. Xlphonso V had Matthew of Pisa as tutor and summoned Justui Balduinus to his court to write the nation's history in Latin. while John II corresponded with Politian. In the following century many famous humanists took up their abode in Portugal, Nicolas Cleynaerts taught Prince Henry. later cardinal and king. and lectured on the classics at Braga and Evora; Vassaeus directed a school of Latin at Braga: and George Buchanan accompanied other foreign professors to Coimbra when in 1547 John III reformed the university. Many distinguished Portuguese teachers returned from abroad to assist the king in his task. among them Aires Barbosa from Salamanca, André de Gouvêa of the Parisian college of St. Barbe, whom Montaigne called "sans comparaison de plus grand principal de France." Aquiles Estaço and Diogo de Teive.

At home Portugal produced its scholars of note, André de Resende (*q.v.*), author of *De antiquitatibus Lusitaniae,* Francisco de Holanda, painter, architect and author of *Quatro Diálogos da pintura antiga,* and many another. Women took a share in the intellectual movement of the time. The sisters Luisa and Angela Sigêa, Joana Vaz and Paula Vicente, daughter of the dramatist, constituted an informal female academy under the presidency of the infanta Maria. daughter of King Manoel. Luisa Sigêa was both orientalist and poetess in Latin; Lianor de Noronha, of noble family, served letters by her encouragement of translations.

The Italianate School.— The return in 1526 of Francisco de Sá de Miranda (c. 1485–1558) after a six years' stay in Italy initiated a literary reform of far-reaching effect, though his *Obras* only appeared posthumously in 1595. Like his contemporary Garcilaso in Spain. he introduced and acclimatized the new poetic forms of sonnet. canzon. ode and epistle in hendecasyllabic *ottava rima* and in tercets. At the same time he gave fresh vigour to the national octosyllable or *medida velha* through his *Cartas* and *Sátiras* which, with the *Églogas,* some in Portuguese, others in Castilian. are perhaps his most successful compositions. His chief disciple, António Ferreira (*q.v.*), a convinced classicist. wrote sonnets superior in form and style, along with odes and epistles too obviously reminiscent of Horace. Pero de Andrade Caminha. Diogo Bernardes, Frei Agostinho da Cruz and André Falcão de Resende continued the erudite school which, after some opposition, definitely triumphed with Luiz Vaz de Camdes (*q.v.*). The *Lima* of Bernardes (1596) contains beautiful eclogues while the religious poems of his brother Frei Agostinho are full of charm. Camdes, for all his eminence in the epic. was greater still as' a lyric poet: were the *Cem melhores Poesias líricas da lingua portuguesa* true to its title, wrote the compiler. D. Carolina Michaëlis de Vasconcelos, it would contain no other name. Here a profound classical education combined with perfect mastery of his instrument and a lifetime of checkered experience on which the poet had reflected deeply to produce in sonnets, eclogues, odes, elegies and *canções* the greatest poetry in the language. *Os Lusíadas* ("The Portuguese"), his epic narrative of Portuguese achievement in the east. with which was interwoven the whole story of the nation and much else, took rank on its appearance in 1572 as the national poem par excellence and the greatest of all Renaissance epics after the Virgilian pattern. Of the many who were moved to emulation by its success none approached Camdes in inspiration or poetic gifts. The least unsuccessful was perhaps Jerónimo Côrte-Real (Jeronymo Corte-Real; *q.v.*) with his long prosaic accounts of the *Segundo Cêrco de Dio* (1574) and the *Naufrágio de Sousa de Sepúlveda* (1594). Most of these poems, like the *Eleginda* of Luis Pereira Brandão (1588) on the disaster of Al Kasr al Kebir, the *Primeiro Cêrco de Dio* of the chronicler Francisco de Andrade (1589) and even the *Afonso Africano* of Vasco Mousinho de Quevedo (1611), for all their futile allegory. contain vigorous descriptive passages.

In the drama Sá de Miranda and his followers protested against the name *auto,* restored that of comedy and subitjtuted prose for verse. Taking Terence commonly as their model, they produced not Portuguese characters but conventional Roman-Italian types. This revived classical comedy, artificial alike in subject and style, won the favour of humanists and the nobility, though its influence was to be short-lived. Plautus and Ariosto were present as well to Sá de Miranda when, avowedly to combat the school of Vicente, he wrote *Os Estrangeiros,* the first prose comedy, and *Os Vilhalpandos,* both actions being set in Italy. His *Cleópatra,* a first classical tragedy. is lost. António Ferreira (*q.v.*), a greater dramatist, likewise attempted both kinds: *O Cioso,* Italian even to the names of the personages. came nearer to being a comedy of charatter, but his fame rests chiefly on *Inês de Castro,* which treated the most moving tragic theme in the nation's history by reference not to Seneca but to Sophocles and Euripides. From Jorge Ferreira de Vasconcelos *(c.* 1515–8j) came a "new invention" of another kind with *Eufrosina:* written under the influence of the *Celestina,* which enjoyed a great vogue in Portugal, it was close kin to the Spanish school though essentially Portuguese in characters and general atmosphere. This and his other plays, *Ulissipo* and *Aulegrafia,* resemble novels in dialogue and contain a treasury of popular lore and wise and witty sayings introduced with a moral purpose.

Sixteenth-century History. — Discovery and conquest in Africa, Asia. America and on the ocean inspired historians as well as poets. and many achieved distinction in narrating these events. The best had themselves seen Portugal's new greatness in the building and were moved by patriotism to write of it, so that their records gain in vividness what they may lose in scientific detachment. In the three "Decades" of his *Ásia* (1 jjz–63) João de Barros *(q.v.),* the Livy of his country, told in simple, vigorous language the deeds of his compatriots overseas down to 1526. His first decade undoubtedly influenced Camões, and together, one by his prose, the other by his verse, the two fixed the written language. This work. continued by the more critical and incisive Diogo do Couto (1542–1616), may claim to rank as the noblest historical monument of the century. The manuscript of do Couto's *Décadas 4–12,* carrying the story to the end of the century, suffered shipwreck, fire, theft and official delays and reached publication piecemeal in partial and very unequal form. In his *Soldado prático* he added some acute observations on the causes of Portuguese decadence in the east. Ten years of investigation in India underlay the *Histdria do descobrimento e conquista da Índia* (1552–54 and 1 j61) of Fernão Lopes de Castanheda, covering the first 40 years, a work which ranks close to those of Barros and do Couto. António Galvão, a governor of the Moluccas who died at home a pauper. left a brief *Livro dos descobrimentos das Antilhas e fndia* (1563) full of curious observations cast in the form of annals. Gaspar Correia likewise embodied intimate knowledge of the manners and customs of India in the picturesque prose of his *Lendas* or *Crdnica dos feitos da Índia* (1551), a work remarkable for the vividness of its effects. Among other historical works dealing with the east were the *Comentcirios de Afonso d'Albuquerque* (1557), an account of the great captain and administrator by his son, and the *Tratado das cousas da China e de Ormuz (* 1570) of the missionary Frei Gaspar da Cruz.

From this spate of writing on expansion overseas attention returned, by way of chronicles of the monarchs who presided over it, to the history of Portugal itself. Damião de Gois *(q.v.),* diplomatist, traveller, humanist and intimate friend of Erasmus, possessed an encyclopaedic mind and one of the most critical spirits of the age: his *Crdnica* (1566–67) of Manoel the Fortunate, preceded by one of his son, later John II, is most valuable where the author's oun feelings or experience come into play. Like Francisco de Andrade's uncritical *Crdnica de D. Jocio III* (1613), it still allowed eastern affairs to overshadow events at home; so too did Jerónimo Osório "the Portuguese Cicero," whose *De rebus Emmanuelis regis Lusitaniae* (1571), based on Goes and written in Latin in order to make the story known *per omnes reipublicae Christianae regiones,* achieved considerable fame abroad. Frei Bernardo da Cruz, who was with his king at the disaster of Al Kasr al Kebir. told the story of the reign in a *Crdnica de D. Sebasticio,* while Miguel Leitão de Andrade, taken prisoner in the battle, related his experiences along with many popular traditions and customs in his wide-ranging *Miscelânea.*

Works of travel likewise abounded and derive a particular importance from the fact that their authors were often the first Europeans to visit or at least to study the countries in question. Among the more noteworthy were the *Verdadeira informação das terras do Preste Jocio* by Francisco Álvares (Alvarez) (1540), the *Itinerários* (1560) of Antonio Tenreiro and Martim Afonso (1565), the *Itinerário da Terra Santa* (1593) by Frei Pantaleão de Aveiro, the *Etiopia oriental* by Frei João dos Santos (1609), and a much-translated classic, the *Histdria da vida do padre Francisco Xavier* (1600) by Padre João de Lucena. Important both as history and as human documents were the *Cartas* written home by Jesuits in China and Japan, of which collections were published in 1570 and 1598. An anonymous *Descobrimento da Frolida* or Florida and the *Tratado descritivo do Brasil em 1587* of Gabriel Soares de Sousa are reminders that Portugal was also present and active in the new world to the west. In all this literature of travel the palm is still held for curious interest by the *Peregrinação* (1614) which Fernão Mendes Pinto *(q.v.),* prince of adventurers throughout the east, composed in his old age for his children's reading, and for tragic pathos by the *Histdria trágico-marítima,* a collection first printed as such in 1735–36 of 12 contemporary narratives, told by survivors or based on their accounts, of the more notable disasters which befell Portuguese ships between 1552 and 1604, among them the stories of the "São João" wrecked on the Natal coast in 1552, which inspired Côrte-Real's epic poem as well as some poignant stanzas in the *Lusiadas,* and of the "São Bento" which foundered when homeward bound in 1554 after carrying Camões to India.

The Novel and Other Prose. — Bernardim Ribeiro (1482–1 j52), whose five eclogues introduced pastoral poetry to Portugal, was equally an innovator in the pastoral novel with his *Saudades,* better known by its opening words *Menina e moça* (published 1554–57). This tale of rustic love and melancholy, chivalresque elements mingling with the pastoral and lyric songs with the prose, transferred themes and emotions previously held the preserve of poetry to a new medium and explored them with scant concern for plot. From it Jorge de Montemor (Montemayor; *q.v.*) drew some part of his inspiration for the *Diana* which, written in Spanish, started a fashion subscribed to by Cervantes and Lope de Vega among many others and represents one of the outstanding contributions of Portugal to the neighbouring literature. Both countries shared in the new enthusiasm of the 16th century for the romance of chivalry, in an age when imperial enterprise to east and west was such as to blur the dividing line between fact and the most improbable flights of the imagination. . The first work of João de Barros, historian of empire, was in fact his *Histdria do Imperador Clarimundo* (1520), written purposely to develop his style for more serious tasks and serving, through the adventures of this fictitious progenitor of the kings of Portugal, his consistent aim of glorifying his native land. In the *Palmeirim de Inglaterra* (1544) Francisco de Morais *(q.v.)* naturalized one branch of the Spanish descent of Amadís with an imaginative luxuriance and a purity of style which caused Cervantes to bracket it with the works of Homer. Its own Portuguese progeny, the *Dom Duardos* (1587) of Diogo Fernandes and Baltasar Gonçalves Lobato's *Dom Clarisol de Bretanha* (1602), were of an inferior order. The dramatist Ferreira de Vasconcelos kept alive memories of the Arthurian cycle with his *Sagramor* or *Memorial da segunda Tdvola Redonda* (1567). A very different type of fiction entered with the *Contos de proveito e exemplo* of Fernandes Trancoso, containing 38 tales derived from tradition or imitated from Boccaccio and others, which won and held favour for over a century.

Among moralists three at least rank as masters of prose style: Frei Heitor Pinto for his *Imagem da vida christã* (1563), Bishop Amador Arrais for his ten *Diálogos* (1589) on religious and other topics and Frei Tomé de Jesus for his mystic and devotional treatise *Trabalhos de Jesus* (1602–09). The maxims of Joana da Gama entitled *Ditos da freira* (1 j55) form a curious if unsubtle psychological document. The roll of scientists includes the cosmographer and mathematician Pedro Nunes (Nunez), inventor of the nonius, and the botanist Garcia da Orta, whose *Coldquios dos simples e drogas* (Goa, 1563) was the first book to be printed in the east, while the form of Aristotelian scholastic philosophy professed at Coimbra had a succession of learned exponents, mainly in Latin, in which language also Francisco Sanches wrote his notable treatise *Quod nihil scitur* (1581).

The 17th Century. — From a literary as from a political point of view the new century found Portugal in a lamentable state of decadence. Long before the loss of independence to Spain in 1580 Spanish influence had brought about the introduction of the Inquisition, and with it censorship of books and the preparation of an Index; among its early victims was George Buchanan, at the instance of the Jesuits, into whose hands passed between 1552 and 1j55 control of higher education. Cultism. inseparable at bottom from classical education. was already present—as in Camões and Ferreira de Vasconcelos—before Luis de Góngora y Argote; but with the exhaustion of the national spirit that underlay political eclipse the influence of Gongora penetrated deeply. Its extent may be seen in the five volumes of the *Fenix renascida* (1716–28), which anthologizes the poetic production of the preceding century and reveals in the very titles of poems the emphatic futilities to which good talents could devote themselves. The trend. reiniorced by the new fashion out of Italy of literary academies. survived the throwing-off of the Spanish yoke in 1640; Portuguese editions of Góngora appeared in 1646, 1647 and 1667. In 1649 there was founded the Academia dos Generosos, numbering many illustrious by rank and learning. in 1663 the Xcademia dos Singulares.

In the bucolic vein a worthy disciple of Bernardim Ribeiro arose in Francisco Rodrigues Lobo (*q.v.*), whose long pastoral romance *A Primavera* (3 parts. 1601–14) showed. with the same delicate perception of nature. a gentler melancholy still and even more sluggish action. interspersed with songs which, with his *Églogas* (160j). earned him the title of the Portuguese Theocritus. Livelier and more varied interest attaches to the same author's *Côrte na aldeia e noites de inverno* (1619), a late flowering of Castiglione's *Cortegiano.* The foremost literary figure of the age was the encyclopaedic Francisco Manuel de Melo (*see* MELO, FRANCISCO *MANUEL* DE), at once a classic of Spanish and—with his *Epanáforas de vária história portuguesa* and *Apólogos dialogaes* —of Portuguese literature. who strove hard, more successfully in prose than in verse. to free himself from subservience to Spanish form and style. Most lyricists of the period remained steeped in Gongorism or, writing in Spanish. have no place here. It suffices to mention Soror Violante do Ceo, an exalted mystic praised as "the tenth muse," or the poems of Frei António das Chagas. who is better represented by his *Cartns espirituais* (1684–87). Satirical verse had two cultivators of merit in Tomás de Noronha and António Serrão de Castro, author of *Os Ratos da Inquisição,* a facetious fruit of his imprisonment by the Holy Office; the adherents of Gongorism were pilloried by Diogo de Sousa Camacho. Epic poets continued active! but few of their productions were more than rhymed chronicles. Their works span the century. from the *Condestabre de Portugal* (1610) of a poet already mentioned. Rodrigues Lobo, to the *T'iriato trdgico* of Brbs Garcia de Mascarenhas, published posthumously in 1699; those falling between include the *Ulissea* of Gabriel Pereira de Castro (1636), the *Malaca conquistada* of Francisco de Sá de Meneses (1634) and the *Ulissipo* of Sousa de Macedo (1640).

History, Oratory and Drama.—Frei Bernardo de Brito, beginning his ponderous *Monarquia lusitana* (1597–1606) with the creation, reached only to the founding of the monarchy. His work is a mass of legends lacking in foundation or critical sense, but both here and in the *Crdnica de Cister* (1602) he proved himself a great stylist. Of the four continuers of the former work, the last three were no better equipped: the first, Frei Antonio Brandão, who covered the period from Afonso Enriques to John II, wrote as a man of high intelligence and a learned and conscientious historian; his parts three and four appeared in 1632, parts five to eight between 1650 and 1727. Other historical works deserving of mention are the *Discursos vários politicos* of Manuel Severim de Faria (1624), the *Crdnica da Companhia de Jesus* of Padre Baltasar Teles (1645–47) and the *Portugal restaurado* of Luis de Meneses, conde de Ericeira (1679–98). Baltasar Teles also edited in 1660 an *Histdria geral da Etiopia a alta ou Preste João* of his fellow-Jesuit, the missionary Manuel de Almeida; and, although travel literature compares ill with that of the preceding century. note should be made of the *Itinerário da fndia por terra* (1611) of Frei Gaspar de S. Bernardino and of the *Relação do novo caminho através da Arabia e Siria* (1665) of Padre Manuel Godinho. Frei Luis de Sousa, a typical monastic chronicler, won lasting fame as a stylist with his *T'ida de Frei Bertolomeu dos Mártires* (1619) and the *Histdria de S. Domingos* (1623). Another notable biography, one of the best-known works of the century, was Jacinto Freire de Andrade's *Vida de D. Jocio de Castro* (1651). Manuel de Faria e Sousa, a voluminous writer on Portuguese history and commentator of Camões, wrote in Spanish, as did Melo in his classic account of the 1640 *Guerra de Cataluña.*

The Jesuit António Yieira (*q.v.*), missionary and diplomatist and held in his *Cartns* one of the greatest of all writers in Portuguese, repeated his triumphs of Bahia and Lisbon in Rome. which proclaimed him the prince of Catholic orators. Dying, Yieira considered the language safe in the hands of Padre Manuel Bernardes (1644–1710), a humble priest and recluse whose sermons and oratorical works *Luz e calor, Nova Floresta* and *Exercícios espirituais* breathed a calm serenity and naturalness alien to the other and exerted a powerful influence in freeing the language from the now outworn conceits of the *culteranos.* Among the most human documents of the age were the *Letters of a Portugese Nun,* which first appeared in French in 1669 and were long attributed to Mariana Alcoforado (*q.v.*). Padre Ferreira de Almeida's translation of the Bible (*Novo Testamento* [1681], *Velho Testamento* [1748–53]) has considerable linguistic importance.

The popular theatre lived on obscurely in the *comédias de cordel,* mostly anonymous and never printed. Such *autos* as have survived are mainly religious and show the common Gongoristic abuse of metaphor and conceit. All through the century dramatists who aspired to be heard wrote, like Jacinto Cordeiro and João de Matos Fragoso. in Castilian. with an occasional exception such as Melo's witty *Auto do fidalgo aprendiz* (1646). The court after 1640 preferred Italian opera, French plays and Spanish *zarzuelas* to dramatic performances in the vernacular, to. the detriment alike of native drama and of acting.

The 18th Century.—The new century, in Portugal as in Spain, was to be predominantly prosaic, even in poetry. In the opening decades bad taste was still rampant, but gradually signs appeared of a literary revolution which developed eventually into the Romantic movement. Men of liberal ideas went abroad to France and England. and to their exhortation and example were largely due the reforms which by degrees invaded every branch of letters. Of such were Alexandre de Gusmão, Xavier de Oliveira, Ribeiro Sanches. Correia da Serra. Avelar Brotero and Manuel do Nascimento (*see* NASCIMENTO, FRANCISCO MANOEL DO). Earlier, Luis Antonio Verney had poured scorn on prevailing methods of education in his *Verdadeiro método de estudar* (1746). New literary societies. variously called academies or arcadias. co-operated in the task of reform. In 1720 John V, an imitator of Louis XIV, established the Academia da História; in its *Memórias* (15 vol., 1721–36) may be seen the excellent work done by its members. who included Manuel Caetano de Sousa. author of a colossal *Histdria genealógica da casa real portuguesa* (1735–49), Barbosa Machado, compiler of the invaluable *Biblioteca lusitana* (1741–58), and Soares da Silva, chronicler of the reign of John I. The Academia Real das Ciências, founded in 1779 by the duque de Lafões, showed particular interest in language and literature and initiated specialized research and the study of Portuguese literary history (*Memórias de literatura, 8* vol. [1792–1812]). In its ranks were found nearly all the scholars of note at the end of the century. such as the ecclesiastical historian Frei Manoel do Cenbculo. the scientist of many parts Ribeiro dos Santos, Caetano do Amaral, a patient investigator into the origins of Portugal. João Pedro Ribeiro, who has been called his country's first modern historian, and the critics Francisco Alexandre Lobo, bishop of Vizeu, Cardinal Saraiva, and Frei Fortunato de S. Boaventura.

The **Arcadias.**—In 1756 António Dinis da Cruz e Silva (*q.v.*) established with others the Arcádia Clissiponense, its first aim being the uprooting of Gongorism and Spanish influence generally; an indifferent poet himself in odes, elegies and sonnets: his mock-heroic *O Hissope,* inspired by N. Boileau's *Le Lutrin,* was a telling satirical document. Antonio Correia (Correa) Garção, the most prominent Arcadian. was a devotee of Horace and technically accomplished rather than inspired. The bucolic verse of Domingos dos Reis Quita signified a return to the native tradition of two centuries earlier. Sincerity and suffering spoke in the justly more famous *Marília,* a volume of love lyrics in a pastoral setting, of Tomás (Thomaz) António Gonzaga (*q.v.*). In 1790 a Tova Arcádia came into being, its two most distinguished members the rival poets Manuel Maria Barbosa de Bocage (*q.v.*), a would-be second Camões in his life and in his lyrics who overspent himself and lives by a few sonnets, and José Agostinho de Macedo (*q.v.*), in whom inspiration fell below a notable industry, chiefly in the epic. Curvo Semedo was the only other New Arcadian of merit. Outside the Arcadias stood the "Dissidents," who numbered at least two writers of distinction. Few Portuguese satirists have possessed such equipment for the office as Nicolau 'Tolentino de Almeida (1740–1811), who painted the customs and follies of his day with devastating accuracy and distributed attacks or begged favours in the same sparkling verse. Francisco Manuel do Nascimento addressed himself perseveringly. at home and through 40 years of exile, to the purifying and enrichment of the language and to restoring the cult of the *quinhentistas*. 4 convert to romanticism shortly before his death, he prepared the way for its triumph in Portugal.

Early in the century authors sprung from the people attempted a revival of the drama at the Bairro Alto and Mouraria theatres in Lisbon. where numerous pieces of low comedy were staged. The Operas *portuguesas* of António José da Silva (*q.v.*), produced between 1733 and 1741, owe the name to the interspersing of the prose dialogue with arias. minuets and modinhas; if unremarkable in plot, style or language. they have a certain comic force of invention. Nicolau Luis was a fertile adapter from the Spanish and Italian. his best play. on the ever-appealing tragic theme of D. *Inês* de Castro (1772), being an imitation of Vélez de Guevara; lifeless characters and conventional passions notwithstanding, his comedies long held the stage. Meanwhile the Arcadia sought to raise the tone of the stage. finding its ideals in the classics of antiquity or of the 16th century but immediate inspiration in the contemporary French theatre. Its efforts failed from lack of dramatic talent and of popular appeal. Correia Garção led the way with two satirical comedies in blank verse. Teatro *novo* and *Assembléa* ou *partida*, but did not persevere. Manuel de Figueiredo. setting out to write pieces "morally and dramatically correct," produced 14 volumes of plays in prose and verse (Teatro, 1804–15) on national subjects; utterly lacking in life. they were never acted. The three Greek tragedies of the bucolic poet dos Reis Quita, *Astarto, Megara, Hermione*, proved likewise stillborn; to them he added yet another *Inês* de Castro, reduced to the three unities, and a pastoral drama Licore.

Romanticism and After.—The 19th century witnessed a general revival of letters; again the initial stimulus came from abroad, but this time it proved more congenial to the native temperament. The chief exponents of rpmanticism were in poetry and the drama João B. de Xlmeida Garrett (*q.v.*) and in prose Alexandre Herculano (*q.v.*), both formed in exile, the price of their political liberalism. Almeida Garrett read contemporary foreign literature in England and France and. imbued with patriotic fervour, introduced his fellow-countrymen to the new movement through two epics, *Camões* (182j) and *Dona Branca* (1826). His poetry, subjective in the short lyric. historical in longer compositions, remained always sincere and natural. António Feliciano de Castilho (*q.v.*), a gentle romantic who still looked back to the Arcadias and beyond. exercised much influence over a younger generation of poets: João de Lemos and the group associated with him in *O trovador* (1848), Soares de Passos and Tomás Ribeiro. who won fame with his ardently patriotic D. Jaime (1862). Mendes Leal, outstanding in the heroic vein. Francisco Gomes de Amorim and Raimundo António de Bulhão Pato belong more or less to the same school.

In 1865 romanticism received a frontal attack in a revolt against the primacy of Castilho led by Antero (Anthero) de Quental (*q.v.*), a student of German philosophy and poetry, and Teofilo (Theófilo) Braga (1843–1924), disciple of Auguste Comte and author already of an epic of humanity. *Visão* dos *tempos* (1864). Literature gained considerably therefrom. and especially poetry. Quental enshrined his metaphysical pessimism and agony of thought in finely wrought sonnets. *Odes modernas* (1865), Sonetos (1881), which place him near to Heinrich Heine and Giacomo Leopardi. The *Campo* de pores (1893) of João de Deus (*q.v.*) contains some of the finest short poems in the language, of a spontaneous simplicity. Abílio Manuel Guerra Junqueiro (1850–1923), heir to Victor Hugo, was a would-be social revolutionary swayed by grandiose ideas and overprone to grandiloquence (A *Morte* de D. *João*, A *Velhice* do Padre *Eterno*, Finis *patriae*); in *Os* Simples (1892) he turned to the portrayal of peasant life in sonorous stanzas that, lit by his powerful imagination and pantheistic tendencies, constitute his finest poetry. Akin to him on a lower level was Duarte Gomes Leal (1848–1921), a militant anti-Christian in *Claridades* do *sul* and antimaterialist in *O anti-Cristo*, whose declamatory excesses could likewise yield to a quiet sincerity on humble themes. Cândido Gonqalves Crespo (1846–83), in his slender harvest of delicately chiselled verse, *Miniaturas* and *Nocturnos*, stood out as the first of his country's Parnassians. By contrast Cesário Verde (1855–86) addressed himself in unaffected style to surprising the poetic essence of common realities; through the posthumous Livro de *Cesário Verde* he became one of the rediscoveries of a later generation. The *Só* (1892) of António Nobre (1867–1900) was intensely Portuguese in themes. mood—an all-pervading *saudade*—and rhythms; he typifies. with the sincere but nebulous pantheist Teixeira de Pascoais (1877–1953), a cult of *saudosismo* that was to inspire a whole school of northern poets, and his influence went deep. French Symbolism found an enthusiastic adept in Eugénio de Castro (1869–1944); in a long series of volumes from Oaristos (1890) to *Camaféus romanos* (1921) and beyond he sought to fill his verse with imagery and colour while emptying it of all personal element, and was admitted for a period, after the death of Junqueiro. as the greatest of contemporary poets. Afonso Lopes Vieira (1878–1946) brought the rhythm of the sea as well as many traditional notes into his *Ilhas* de *bruma* (1918) and showed a rare artistry in his retellings of two earlier classics, *Amadís* and Diana.

Drama, the Novel, and History.—Almeida Garrett, seeking early to reinvigorate the drama. found that he had to create alike theatre. plays. actors and audience. In *Um Auto* de Gil *Vicente, O Alfageme* de *Santarém* and especially *Frei Luís de Sousa*, a tragedy of fatality and pathos. all written in prose as admirable as his poetry, he proved himself. after Vicente, his country's most notable dramatist. The historical bent was continued by José Mendes Leal (1818–86), Gomes de Amorim (1827–91) and Manuel Joaquim Pinheiro Chagas (1842–95), all three inclined to ultraromanticism. António Enes (1848–1901) dramatized questions of the day in a spirit of combative liberalism, Ernesto Biester (1829–80) wrote social drama and Fernando Caldeira (1841–94), also no mean lyric poet, comedy. Good dialogue and sparkling wit marked the comedies of Gervásio Lobato (1850–9j), some of the most popular of them written in collaboration with João da Câmara (1852–1908), who for his plays historical, social and fanciful—Afonso *VI, A Rosa* engeitada, *Os Velhos*—was accounted the outstanding dramatist of his day. Other historical playwrights include Henrique Lopes de Mendonça, Marcelino Mesquita and the admirably gifted Júlio Dantas (1876–1962), remarkable for the wit, lightness of touch and sense of atmosphere with which he reconstructed the past (A *Severa*, Santa *Inquisição*, A Ceia dos cardenis, Rosns de *todo* o *ano*). With these plays of the early 20th century may be mentioned António Patrício's *Dinis e* Isabel (1919) and D. *João e* a *máscara* 11024), the *Egas Moniz* (1918) of Jaime Cortesão, and *O Gebo e a sombra* (1923), a tragedy of unrelieved gloom and considerable power by Raúl Brandão.

Herculano. returning from exile with an enthusiasm for the *Waverley* Novels, launched the historical romance with *O Monástico* (1844–48) and *Lendas* e *narrativas* (1851). Many took up the kind. Oliveira Marreca, Arnaldo da Gama, Pinheiro Chagas, the most popular successes being A *última* corrida de *touros em Salvaterra* and *A Mocidade de* D. *João V* by Rebelo da Silva and João de Xndrade Corvo's *Um* Ano *na côrte*. This was the great age of the novel: Camilo Castelo Branco (see CASTELO BRANCO. CAMILLO), J. G. Gomes Coelho (1839–71), Jose Maria Eça de Queiros (*q.v.*) are names which would stand high in any country. The first, a great impressionist, described to perfection the domestic and social scene (*Amor* de *perdição, Amor* de *salvação*, the various *Novelas* do *Minho*). Gomes Coelho. better known by his pseudonym Júlio Dinís, depicted country life and scenery with much charm, as in *As Pupilas do Snr. Reitor; Uma família inglesa* describes English society in Oporto with a detail suggestive of Charles Dickens. Eça de Queirós introduced naturalism with his powerful novel *O Crime do Padre Amaro,* followed by *O Primo Basílio* and *Os Maias;* he was the greatest of the realists, though materialism was always tempered by a sensitive imagination, and his last novels, *A ilustre Casa de Ramires* and *A Cidade e as serras,* place him rather with the regionalists. Naturalism claimed too Lourenço Pinto, Luís de Magalhães and the much greater Francisco Teixeira de Queirós (1849–1919), who sought to lay bare contemporary society in the 15 volumes of his two series *Comddia do campo* and *Corne'dia burguesa.* Antero de Figueiredo, a stylist who excelled in regionalist sketches *(Jornadas em Portugal, Senhora do Amparo),* showed historical imagination of a high order in his fictionalized biographies *D. Pedro e D. Inês* (1913), *Leonor Teles* (1916), *D. Sebastiiio* (1925). Raúl Brandão in *Os Pobres* (1906) and *Os Pescadores* (1923) brought a poignant realism to the description of the sufferings of humble folk.

With his magnum opus the *Histdria de Portugal* (1846–49), on a scale which allowed it to reach only to 1279, and the *Histdria da Inquisição em Portugal* (1854–59) Herculano established himself as the leader of modern Peninsular historians; in 1856 he initiated the important series *Portugaliae Monumenta Historica.* Historiography flourished with names such as the visconde de Santarém, historian of the Cortes, José Simão da Luz Soriano of constitutionalism, L. A. Rebelo da Silva of the period of Spanish rule under the Philips, and José Maria Latino Coelho of the dictatorship of Pombal; if all four have been overtaken by later research, the two latter still rank highly as stylists. Henrique da Gama Barros (1833–1925) and António da Costa Lôbo (1840–1913) followed in the footsteps of Herculano, the first with his erudite *Histdria da administração pública em Portugal nos séculos xii a xv,* the second with the unfinished *História da sociedade em Portugal no século xv,* both monuments of scientific objectivity. The works of J. P. de Oliveira Martins, if not similarly grounded in original research, gave proof of psychological imagination, a notable capacity for general ideas and the gift of picturesque narration; at once the most artistic and most philosophically minded historian of his generation, he left in his numerous writings a vast portrait gallery of the great figures of his country *(Histdria da civilisação ibérica, História de Portugal, Portugal contemporâneo, Os Filhos de D. João I, A Vida de Nun'Álvares).* The 20th century has seen accentuated the trend toward scientific documentation and objectivity. Fortunato de Almeida followed up an *Histdria da igreja em Portugal* with a masterly *História de Portugal* (6 vol., 1922–37). The monumental *História de Portugal* edited by Damião Peres and others (8 vol., 1928–38) provides an exhaustive treatment of the whole field.

The Contemporary Period.—The passage from monarchy to republic in 1910 was accompanied by a revisionary urge in literature associated chiefly with Oporto and self-styled, in token of serious purposes, the *Renascença portuguesa.* Leonardo Coimbra (1883–1936; *O Criacionismo,* 1912) was its philosopher, António Sérgio de Sousa (b. 1883; *Ensaios,* 1920–24) its critic and historian. Its poets—Mário Beirão *(O último Lusíada,* 1913), Augusto Casimiro (A *Vitória do homen,* 1910; A *Evocação* da *vida,* 1912) and João de Barros *(Oração à pátria,* 1917)—adopted the *saudosismo* of Teixeria de Pascoais as key to the nation's soul and so to the recovery of greatness, though the inadequacy as a principle of action of mere nostalgic regret for the past was soon realized. Against this the "Integralist" school reacted from 1913 in favour of Catholic monarchist tradition, under the leadership of the historian and poet António Sardinha (1888–1925; *Tronco reverdecido,* 1910, *A Epopeia da planície,* 1915) ; among his followers were the conde de Monsaraz *(Musa alemtejana,* 1908) and Hipólito Raposo *(Dois Nacionalismos,* 1929). The formula of Afonso Lopes Vieira, another sensitive traditionalist, *reaportuguesar Portugal tornando-o europeu,* synthesized in some degree the objectives of both schools and received a powerful impetus from Portugal's intervention in World War I. Less was heard thereafter of the cult of the past, and poetry, while responsive to developments abroad, grew again personal and introspective in a vein that proclaimed its affinity with Cesário Verde and António Nobre of the preceding century. Fernando Pessoa (1888–1935) published in his lifetime only *Mensagem;* posthumously, in four volumes of which three appeared under pseudonyms *(Poesias de Fernando Pessoa,* 1942, *Poeinas de Álvaro de Campos,* 1944; *Odes de Ricardo Reis,* 1946; *Poemas de Alberto Caeiro,* 1946), he stood revealed as a complex personality responsive to all the winds that blew and gained acceptance as the most inspired poet of his generation. Pessoa's influence was profound and enriched the moods and resources of subsequent poetry without imposing any suggestion of a school. José Régio and Miguel Torga are prominent among more recent names. Régio, poet, novelist and dramatist, has established himself in a dozen volumes from *Poemas de Deus e do diabo* (1925) to *El-Rei Sebastido* (1949) as a religious if sorely perplexed poet of power and the most significant of contemporary dramatists; Torga's works, numbering twice as many from *Ansiedade* (1928) to *Portugal* (1950), reflect in poems, short stories and volumes of autobiography a less introspective mind possessed of a robust faith in the primitive virtues of mankind.

Among novelists may be mentioned Aquilino Ribeiro *(A Via sinuosa,* 1916; *Estrada de S. Tiago,* 1922; *Quando ao Gaviiio cai a pena,* 1935), Mário de Sá Carneiro *(A Confissão de Lúcio,* 1914; *Céu em fogo,* 1915; *Indícios de oiro,* 1938) and J. M. Ferreira de Castro (*Emigrantes,* 1928; *A Selva,* 1930; *Eternidade,* 1935). But the field of contemporary prose achievement is to be found rather in history (Damião Peres, J. M. Queirós Veloso, Luis Gonzaga de Azevedo, David Lopes) and in literary criticism (Fidelino de Figueiredo, Manuel Rodrigues Lapa, Hernâni Cidade) ; thanks to the patient investigations of these and other scholars Portugal's long and distinguished record in the twin spheres of action and letters is at last becoming adequately known.

PORTUGUESE MAN-OF-WAR, scientific name Physalia, is a hydrozoan coelenterate belonging to the group Siphonophora (*see* Coelenterata; Hydrozoa). Physalia has a large gas-filled float that may be as long as 10 or 12 in. and is commonly seen in tropical or subtropical waters of all oceans. These animals are sometimes blown ashore in large numbers, and their bright blue, red and sometimes greenish coloured floats can hardly be overlooked. Beneath the float of Physalia there hang numerous polyps of a highly polymorphic nature; they may be described as protective, nutritive and reproductive (*see* Polyp).

The protective polyps (dactylozooids) are of two sorts, large ones with very long tentacles and more numerous small ones with small tentacles. The large dactylozooids possess tentacles specialized as fishing or food-catching tentacles that may be from several feet to several yards long. It is these fishing tentacles, heavily armed with nematocysts, that enable the Portuguese man-of-war to capture animals, including fish, up to as large as itself. The nematocysts of Physalia are larger than most coelenterate nematocysts and contain potent toxins. The sting of Physalia is extremely painful and, in the extreme, can cause death in man.

The feeding or nutritive polyps (gastrozooids) occur in clusters, and the individual zooids do not have tentacles. Once food has been captured by the fishing tentacles, those tentacles contract and carry the food up beneath the float where the gastrozooids can reach it. The gastrozooids apply their mouths to the surface of a food item and will swallow the item if it is small. If it is a large food organism, such as a fish, the mouths of many gastrozooids will spread out over the surface of the captured animal, sometimes completely covering the whole organism. Digestion is believed to be similar to that in other coelenterates.

FIG. 1.—YOUNG SPECIMEN OF PHYSALIA

(A) Float; (B) growing region of stem; (C) crest of float; (D) large protective polyps (dactylozooids) with fishing tentacles; (E) smaller dactylozooids and nutritive polyps (gastrozooids)

The remaining zooids, the reproductive ones, are more complex than the others. They are complexly branched structures, perhaps representing many individual zooids. These structures, called gonodendra, are made up of clusters of male reproductive units (male gonophores), clusters of female reproductive units (the medusoid female gonophores), long gelatinous processes called gelatinous zooids and short finger-like processes called gonopalpons. Sometimes, but apparently not always, the medusoid female gonophores may be released at sexual maturity. The early stages in the development of Physalia are not known, but once the first polyp appears, part of it becomes the float while an intermediate position, presumably homologous to the stem of most siphonophores, differentiates as a budding region from which the rest of the colony develops.

The zooids of Physalia are set at an angle beneath the float and act like the keel of a ship; thus, instead of simply blowing about the ocean's surface with the wind, these animals tack at an angle to the wind. The relationship of the float to the zooids is different in northern and southern hemisphere representatives of this animal, such that those in the north tack to the left of the wind and those of the south to the right of the wind. The same phenomenon is also known for the colonial hydroid Velella (the by-the-wind sailor), whose sail is differently set in the two hemispheres.

FIG. 2.—CLUSTER OF POLYPS FROM SEXUALLY MATURE PHYSALIA

(A) Large dactylozooid showing partial length of fishing tentacle; (B) gastrozooid; (C) smaller dactylozooids; (D) reproductive branches (gonodendra); (E) cluster of reproductive units (gonophores) and accessories (gonopalpons); (F) gelatinous processes (zooids)

The float of Physalia has a pore through which the contained gas may escape, allowing the animal to sink. In a short while, the gas-secreting tissues of the float will refill it and the animal will again return to the surface.

The Portuguese man-of-war commonly is accompanied by a fish, Nomeus, which lives among the tentacles of the hydroid and is said to share the food Physalia catches. Nomeus has also been reported to eat the tentacles of Physalia. As long as Nomeus is healthy and has no wounds it is not harmed by Physalia, and the presence of the fish does not cause discharge of the nematocysts. However, once wounded, Nomeus too falls prey to its host just as does any other fish. The nature and origin of the immunity of this fish to the potent nematocysts of Physalia is not understood.

PORTULACACEAE, the purslane family containing 16 or more genera and more than 500 species of widely distributed rather fleshy annual or perennial herbs or subshrubs with simple entire, often terete leaves and bisexual flowers with usually two green herbaceous sepals and from four to six petals (sometimes fewer).

A few are grown for ornament or as potherbs, among them *Portulaca, Montia, Claytonia* and *Talinum.* A very troublesome weed in many sections of the United States is the garden purslane or pusley (*Portulaca oleracea*). *See* Purslane. (J. M. Bl.)

PORTUNUS (Portumnus), in Roman cult originally a god either of gates and doors (from *porta*) or harbours (from *portus*), eventually associated with both. In the former capacity he was probably connected with Janus (*q.v.*), but the degree of their association is conjectural. At Rome he had his own priest, the *flamen Portunalis,* and a festival, the Portunalia, celebrated on Aug. 17 in his temple near the *pons Aemilius.* He was similarly worshiped at Ostia. The conjecture that he is the god of the gates and keys of granaries may explain the location of his shrine near the storehouses of the Tiber and his festival in the harvest season. He was, however, definitely connected with the guiding of ships to harbour (Virgil, *Aeneid,* v, 241; cf. Cicero, *Nat. deor.,* ii, xxvi) and he came to be associated with the Greek marine deity Palaemon-Melicertes. He is represented as a youth bearing keys.

Bibliography.—W. W. Fowler, *Roman Festivals,* pp. 202–204 (1899); H. Papenhoff in Pauly-Wissowa, *Real-Encyclopädie,* s.v.; Platner-Ashby, *Topographical Dictionary,* s.v. *Portunium.*

(R. B. Ld.)

PORTUS, an ancient harbour of Latium, It., on the right bank of the Tiber, at its mouth. For its origin *see* Ostia.

Claudius constructed the first harbour there, 2½ mi. N. of Ostia, enclosing an area of 170 ac., with two long curving moles projecting into the sea and an artificial island, bearing a lighthouse in the centre of the space between them; the harbour thus opened directly to the sea on the northwest and communicated with the Tiber by a channel on the southeast. The object was to obtain protection from the prevalent southwest wind to which the river mouth was exposed. Though Claudius, in the inscription which he caused to be erected in A.D. 46. boasted that he had freed the city of Rome from the danger of inundation, his work was only partially successful. The Via Portuensis (15 mi.) ran over the hills as far as the modern Ponte Galera, and then straight across the plain. An older road, the Via Campana, ran along the right bank of the Tiber. In A.D. 103 Trajan constructed another harbour, still well preserved in modern times, farther inland—a hexagonal basin enclosing an area of 97 ac. It communicated with the harbour of Claudius and with the canal constructed by him (though it bears the name Fossa Trajana), later forming the navigable arm of the Tiber (reopened for traffic by Gregory XIII and again by Paul V). It mas surrounded by extensive warehouses; the fineness of the brickwork of which they are built is remarkable. The perforated travertine blocks to which the ships were made fast survived in modern times. Farther to the east was built a circular building in brick with niches called the temple of Portumnus.

Portus eventually captured the main share of the harbour traffic of Rome, and though the importance of Ostia did not at once decrease Portus was already an episcopal see in Constantine's time not very long after Ostia, and the only harbour in the time of the Gothic wars. Its abandonment dates from the partial silting up of the right arm of the Tiber in the middle ages, which restored to Ostia what little traffic was left.

To the west of the harbour is the cathedral of S. Rufina (10th century, but modernized except for the campanile) and the episcopal palace, fortified in the middle ages, and containing a number of ancient inscriptions from the site. On the island (Isola Sacra) just opposite is the church of S. Ippolito, built on the site of a Roman building, with a picturesque 13th-century campanile: 2 mi to the west is the modern village of Fiumicino at the mouth of the right arm of the Tiber, 21 mi. W.S.W. by rail from Rome. It is a portion of the commune of Rome. Three miles to the north a pumping station was built to keep the lowland (formerly called Stagno di Maccarese, reclaimed and traversed by many drainage canals) drained.

PORT WINE is a rich, blended and fortified wine which comes from a specific area in the Douro valley in northern Portugal. It is made according to certain principles designed to conserve part of the natural sweetness in the wine; it is thus, generally, a dessert wine.

Port is fortified with grape brandy before the fermentation has finished; it will contain more or less natural sweetness according to the moment when the brandy is added. Although in France a comparatively dry port is popular as an *apéritif*, port is ordinarily sweet and rich.

Wines from the Douro began to be popular in England from 1670 onward; at first they were fortified after their arrival in England. Fortification in Portugal (at the time of the fermentation) was only developed in the 18th century. In England larger quantities of port were drunk than of any other wine from the early 18th century until the end of the 19th. Port trade was exclusively English in origin, and it was not until the 19th century that other countries (such as France and Norway) imported the wine on any scale.

There are two main types of port: vintage port, which is the finest wine from a single very good year, and wood port, which is blended from the wines of different years. With judicious blending (generally of about 12 varieties of grape) not only can any style of wine be produced, but that style can be maintained year in, year out, in spite of the vagaries of climate. Quality apart. the two main types differ in the way they are matured. Wood port is fully matured in wood, for 5 to 15 years; it is bottled only for convenience of sale. Vintage port is bottled after two or three years so that it will complete its maturation in bottle. where it will take longer than in wood, and where it will throw a deposit or crust.

Crusted port or vintage character is neither wood port nor true vintage port, but a blended wine bottled after five or six years to complete its maturation. It resembles vintage port, and like it requires decanting off its crust before it is consumed.

Vintage port is never white, but wood port may be white, ruby or tawny. When port is young, it is generally ruby. but it takes on a tawny hue; for this reason colour should be an indication of its age. Ruby port is not necessarily inferior to tawny because of its youth—a fuller-bodied wine may be preferred to a mellower one—but it is usually cheaper.

In 1916 the United Kingdom agreed by a treaty with Portugal not to permit the sale of any wine as port except that produced in a defined area of about 1,800 sq.mi. in the Douro (actual area under vine cultivation is now about 600 sq.mi.) and shipped from Oporto or its sister port of Vila Nova de Gaia. Other countries produce port-style wines by following methods similar to that used in the Douro, but the results are never like true port. Newfoundland port is true port matured in Newfoundland.

(C. C. H. F.)

PORUS (4th century B.C.), an Indian prince, ruler of the country between the Hydaspes and Acesines rivers at the time of the invasion of Alexander the Great. In the battle on the banks of the Hydaspes he offered a desperate resistance, and Alexander. struck by his independent spirit, allowed him to retain his kingdom, which he increased by the addition of territory. From this time Porus was a loyal supporter of Alexander. He still held the position of a Macedonian satrap when assassinated some time between 321 and 315 B.C.

See Arrian, v, 18, 19; Plutarch, *Alexander*, 60; Quintus Curtius, viii, 14.

PORVOO (Swed. BORGÄ), a seaport in the province of Uundenmaan, republic of Finland, situated at the entrance of the Borga river into the Gulf of Finland, about 33 mi. E.N.E. of Helsinki by rail. Pop. (1950) 8,534.

Once a city of great dignity, it was eclipsed by the rapid growth of Helsinki. In 1809, when the estates of Finland were summoned to a special diet to decide the future of the country, Porvoo was the place of meeting, and it was in the cathedral that the tsar Alexander I pledged himself as grand duke of Finland to maintain the constitution of the grand duchy.

POSADA, JOSÉ GUADALUPE (1852–1913), Mexican print maker. was born on Feb. 2, 1852, in Aguascalientes. As a child he worked as a farm labourer and in a pottery factory. He taught school for a short time and then began to draw, inspired largely by posters for the Rea circus. Gradually he was attracted to print making and became a kind of pictorial journalist with the publication of thousands of broadside illustrations and popular book and song covers. He may be regarded as one of the greatest popular artists of all time. Contrary to belief, most of his works were not executed in woodcut, but engraved or etched in relief on type metal.

Posada died Jan. 20, 1913, in Mexico City.

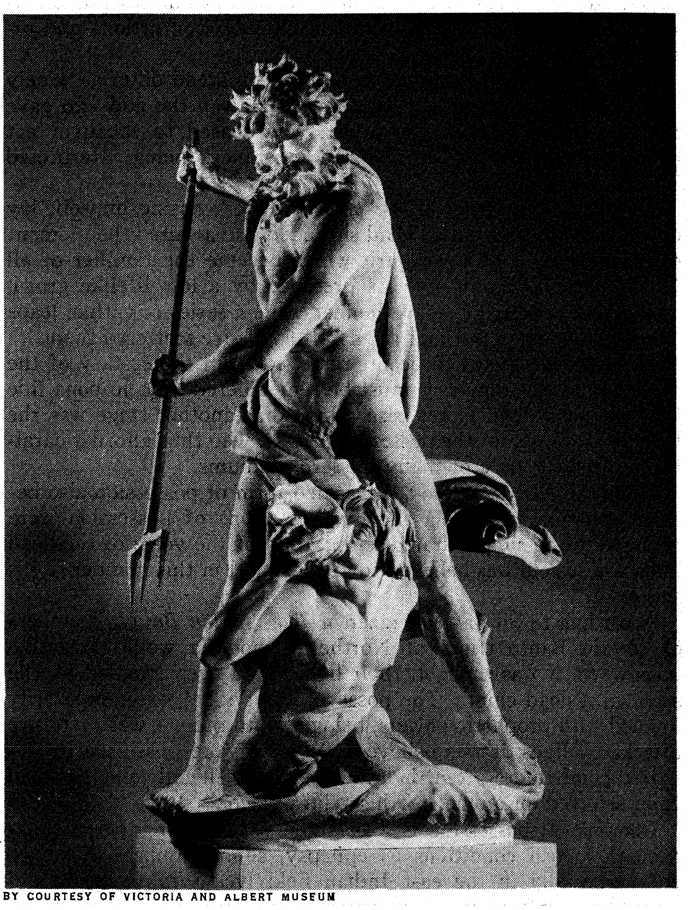
See Carl O. Schniewind and Hugh L. Edwards, *Posada: Printmaker to the Mexican People* (1944). (H. Es.)

POSEIDON, in Greek mythology, god of the sea and of water generally, son of Cronus and Rhea and brother of Zeus and Pluto (perhaps "lord of moisture," or connected with the Greek words for "drink," "a river").

When the three brothers deposed their father Cronus, the kingdom of the sea fell by lot to Poseidon. His home was in a golden palace in the depths of the sea near Aegae in Achaea. In his hand he bore a trident, wherewith he lashed the sea into fury, split the rocks and caused horses and fountains to spring from them. But, while he caused storms and shipwrecks. he could also send favouring winds; hence he was known as *Soter*, "the preserver." Another of his titles was *Gaieochos*, "holder (*i.e.*, encircler?) of earth."

He mas the god of navigation. and his temples stood especially on headlands and isthmuses. Every occupation connected with the sea was under his protection, and seafaring people, especially the Ionians, regarded themselves as his descendants. As god of the sea he disputed with other deities for the possession of the land. Earthquakes were thought to be produced by Poseidon shaking the earth — hence his epithet of *enosichthon,* "earth shaker" — and he was worshipped even in inland places which had suffered from earthquakes. Several striking seismic and other phenomena in historical times were attributed to him. Poseidon was also the god of springs, which he produced by striking the rock with his trident, as he did on the acropolis of Athens when disputing with Athena for the sovereignty of Athens. As such he was called *Nymphagetes,* the leader of the nymphs of springs and fountains, a god of fresh water, probably his original character, and in this connection was a god of vegetation, frequently associated with Demeter.

At Athens he is closely associated with Erechtheus (*q.v.*), with whom many identify him. As he gave, so he could withhold, springs of water; thus the waterless neighbourhood of Argos was supposed to be the result of his anger. Black bulls were sacrificed to him and often thrown alive into rivers; in Ionia and Thessaly bullfights took place in his honour; at a festival at Ephesus cupbearers were called bulls, and he was surnamed "Bull Poseidon."



BY COURTESY OF VICTORIA AND ALBERT MUSEUM

"NEPTUNE AND TRITON" BY G. L. BERNINI (1598–1680). ITALIAN

Several legends represent him as creating the first horse; horses were occasionally sacrificed to him; and he is called *Hippios* ("lord of steeds"). In the deme of Colonus Poseidon was worshipped with Athena, the reputed inventor of the bridle.

Various explanations of the title *Hippios* have been given: (1) that the horse represented the corn spirit; (2) the resemblance of the crested waves to horses; (3) the impression of horses' hoofs near the god's sacred springs, and the shaking of the earth by them when galloping. In the Trojan War he takes the side of the Greeks, because he had been cheated of his reward by Laomedon, king of Troy, for whom he had built the walls of the city. The blinding of his son Polyphemus by Odysseus brings upon the hero the wrath of Poseidon. He is famous for his numerous amours; his offspring were mostly wild and cruel, like the sea — the Laestrygones, Polyphemus, Antaeus, Procrustes and the like.

He was worshipped as a national god by the Ionians, who took his worship with them from Peloponnesus to Asia Minor. His chief sanctuary was at Mycale, where the Panionia, the national festival of the Ionians, was held. Other seats of his worship were in Thessaly, Boeotia and Peloponnesus. At Taenarum in Laconia he had a famous cavelike temple with an asylum, and on the island of Tenos he was worshipped as the physician, probably in reference to the health-giving properties of the sea air.

By far the most famous of his festivals was that celebrated every alternate year on the Isthmus of Corinth, at which the Isthmian games were held. The horse, the dolphin (the symbol of the calm sea) and the pine tree. with wreaths of which the Isthmian victors were crowned, were sacred to him. His attributes are the trident and dolphin or tunny fish. As represented in art, Poseidon resembles Zeus, but possesses less of his majestic calm. In modern Greece St. Nicholas has taken the place of Poseidon as patron of sailors. But the Zacynthians have a special sea god, half man, half fish, who dwells under the sea, rides on dolphins or in a car drawn by dolphins and wields a trident. By the Romans Poseidon was identified with Neptune (*q.v.*).

POSEIDONIUS (Posidonius) (*c.* 135–*c.* 50 B.C.), nicknamed "the Athlete," Stoic philosopher, the most learned man of his time and perhaps of all the school. A native of Apamea in Syria and a pupil of Panaetius, he spent many years in travel and scientific researches in Spain (particularly at Gades), Africa, Italy, Gaul, Liguria and Sicily and on the eastern shores of the Adriatic. When he settled as a teacher at Rhodes his fame attracted numerous scholars; next to Panaetius he did most, by writings and personal intercourse, to spread Stoicism in the Roman world. and he became well known to many leading men, such as Marius, Rutilius Rufus. Pompey and Cicero. The last-named studied under him (78–77 B.C.) and speaks as his friend.

The titles and subjects of more than 20 of his works, now lost, are known. In common with other Stoics of the middle period. he displayed eclectic tendencies, following the older Stoics, Panaetius, Plato and Aristotle. Unquestionably more of a polymath than a philosopher, he appears uncritical and superficial. His inquiries, however, were criticized by Strabo as alien to the Stoic school. In natural science, geography, natural history, mathematics and astronomy he took a genuine interest. He sought to determine the distance and magnitude of the sun and to calculate the diameter of the earth and the influence of the moon on the tides.

The history by Poseidonius of the period 146–88 B.C., in 52 books, must have been a valuable storehouse. Cicero made much use of his writings.

POSITION ANALYSIS: *see* Topology, Geseral.

POSITIVE (or Portable) **ORGAN,** a medieval chamber organ, known as the *Positivs,* which could be carried from place to place without being taken apart.

When played it was placed on a table or stool and required a blower for the bellows, as well as a performer. It was larger and more cumbersome than the portative organ (*q.v.*), or *Portativs,* with which it has often been confused.

The positive usually had only one kind of pipe, the open diapason of two-foot tone, and in the 16th century the best types had three registers by means of which each note could be sounded with its fifth and octave, or each by itself, or again in combinations of twos.

The positive differed from the regal (*q.v.*) in having flue pipes, whereas the latter had beating reeds in tiny pipes, one or two inches long, concealed behind the keyboard. During the early middle ages most of the pneumatic organs belonged to that type.

A well-known example of an early positive or portable organ of the 4th century is that on the obelisk erected to the memory of Theodosius the Great, on his death in A.D. 395. Among the illuminated miniature manuscripts acquired by the British Museum abound representative, interesting varieties of the portable organ, including examples of the 14th and 15th centuries.

The little organs were found at every kind of civil and religious function; they were used in the dwellings and chapels of the rich; at banquets and court functions; in choirs and music schools; and in the small orchestras of Jacopo Peri and Claudio Monteverdi at the dawn of the musical drama or opera.

(See ORGAN.)

POSITIVE RAYS: see MASS SPECTROSCOPY.

POSITIVISM, a philosophical term used (1) in a broad and (2) in a narrow sense.

1. The term positivism may be applied to any system that confines itself to the data of experience and excludes a priori or metaphysical speculations. In this sense the term is commonly applied to the empirical philosophers, although in fact reservations ought to be made (John Locke and David Hume accept mathematics, Eocke and George Berkeley accept a knowledge of the soul and of God, on nonempirical grounds). John Stuart Mill's "experience philosophy" is positivistic in this sense. Positivists have usually held that theological and metaphysical questions arise but cannot in fact be answered by any method available to men. Others, however, have dismissed such questions as meaningless. This second view connects with pragmatism and with logical positivism (*qq.v.*) and also with the hints to be found in Berkeley and in Hume of an experience test of meaning. Positivism emphasizes the achievements of science; but questions arise even within the sciences which do not seem to be answerable by experimental methods. Ernst Mach attempted to assign an experience meaning to such theoretical questions and to relate theories directly to the evidence for them.

2. More narrowly, the term describes the philosophy of Auguste Comte (*q.v.*), who held that human thought had passed inevitably through a theological stage into a metaphysical stage and was passing into a positive or scientific stage. Comte held that the religious impulse would survive the decay of revealed religion and ought to have an object. He projected a worship of man, with churches, calendar and hierarchy. Disciples (F. Harrison, R. Congreve et *al.*) founded such a church in England, but Mill, who inclined to accept the religion, repudiated Comte's organization.

See Thomas Whittaker, Comte *and* **Mill** (1908). (K. W. B.)

POSSE COMITATUS, an ancient English institution consisting of the shire's force of able-bodied private citizens summoned to assist in maintaining public order. This "power of the county." originally raised and commanded by the sheriff, became a purely civil instrument as the sheriff's office early lost its military functions. From time to time legislation gave authority to other peace officers and magistrates to call upon the poner of the county. While Blackstone stated that liability to serve extended to every person over the age of 15 and under the degree of peer. judicial interpretation (of a riot act of Henry IV) excluded also women, clergymen and the infirm. Failure to respond to the call subjected one to fine and imprisonment. The English sheriff ceased in the 19th century to be a police officer, but an act of 1887 still required every person in the county to be ready and apparelled (*i.e.,* armed) at the sheriff's command to arrest a felon or to assist if there were resistance to the execution of a writ. In the U.S., the posse comitatus was perhaps most important on the frontier. but it has been preserved as an institution in many states through the middle of the 20th century. Statutes confer on sheriffs and other peace officers authority to summon the power of the county. Some have made it a crime to refuse assistance. In general, its members have been privileged to use force if necessary to achieve a posse's legitimate ends, but states' laws differ as to the legal liability of one who in good faith aids an officer himself acting beyond his authority. (V. No.)

POSSESSION, the supposed control of a human body and mind by an alien spirit, human or nonhuman; or the occupation by an alien spirit of some portion of a human body, causing sickness, pain, etc.

The term "obsession" (Lat. for "siege") is sometimes used as equivalent to possession; sometimes it denotes spirit control exercised from without, or it may mean no more than a maniacal monoideism. The spirit is held to have entered the person in order to foretell the future or to proclaim the will of a god; the god himself may be regarded as speaking through the mouth of his devotee. Hence the authority of a prophet. Among peoples in primitive stages of culture, possession by spirits, of the dead is common and is related to ancestor worship. This kind of possession is found in Africa, Polynesia and Asia. Many of the classical oracles were regarded as divinely inspired. The manifestations are often voluntarily induced and are provoked in many different ways; in classical times the eating of laurel leaves, the inhaling of fumes which ascended from a cleft in the rocks of Delphi, the drinking of intoxicating liquors or of a more widely found means of inducing the phenomena—blood—wereall in use. Hypnosis was produced by drugs, drafts of animal blood or, as in Siberia, America and many parts of Africa, by drumming, contortions and orgiastic dancing.

The symptoms of supposed possession by a god differ as widely as do those of the hypnotic trance. In Hawaii the god Oro gave his oracles by inspiring the priest, who ceased to speak or act as a voluntary agent, his frenzied utterances being interpreted by the attendant priests.

In the Malay peninsula the *pawang*, after censing himself, lay down on his back, with his head shrouded and awaited the moment of inspiration. The tiger spirit which became the familiar of all Malay *pawangs* manifested its presence by a low lifelike growl, and the *pawang* scratched at the mat. gave a series of catlike leaps and licked up from the floor the handfuls of rice scattered there.

But his state seems to be far removed from the ecstasy of the Hawaiian priest, though it must be remembered that no bona fide test was possible in either case. In Tahiti another stage was the lofty declamation of the possessed priests, who thus afford a parallel to the utterances of many modern mediums.

Finally in Africa, where the frenzied form of possession also became common, at Sofala the manifestations of possession were confined to the simple dramatic imitation of the voice of the dead king, whose soul was believed to give counsei in this manner to his successor.

According to Sir James Frazer in *The* Golden Bough, members of certain Bantu tribes of Northern Rhodesia would roar like lions when, it was thought. their bodies had been invaded by the spirit of a dead chief. The possessed individual was temporarily imbued with prophetic powers. being able to predict war or future attacks by lions. it was believed. Women were possessed by departed chiefs more often than men, and occasionally the deceased chief selected an animal for his reincarnation.

Demoniacal possession is a common explanation of such psychopathological conditions as epilepsy, somnambulism, hysteria, etc.; especially in the east Indian field lycanthropy (*q.v.*) and magical power (for evil) are commonly attributed to possession. Demoniacal possession is familiar to us from the New Testament narratives, in which those possessed are stated to live among the tombs, to be deaf and dumb or blind, to be possessed by a multitude of evil spirits or to suffer from high fever as a result of possession; the demons are said to pass into the bodies of animals or to reside in uaterless places.

The facts recorded are explicable either as symptoms of mental disease or as results of suggestion.

In the primitive stages of culture diseases are explained as caused by the invasion of the body by spirits (see ANIMISM), but the effects are supposed to be physiological, not psychical. The wrath of an ancestor or other dead person or the malice of a spirit, such as the Malay *hantus*, or of any nonhuman spirit, may set up pathological conditions.

Such cases may be distinguished from the inspirational form by their invariably involuntary character and are dealt with by a variety of means such as spells, purifications, sacrifices to the possessing spirit, etc.

Among the Shilluk of the Anglo-Egyptian Sudan, for example, the possession of a person by the spirit of a dead king was regarded as a common cause of illness. Hence sacrifices were offered to the unwelcome royal spirit to induce it to leave the body of the afflicted person (see NILOTES).

POSSESSION (IN LAW), a term derived from Roman law. It has been said to be either a right or a fact conferring a right, or both together. The latter is the view of Friedrich Karl von Savigny, a leading authority upon the subject (Dm Recht des Besitzes). The definition of W. A. Hunter may be accepted: "Possession is the occupation of anything with the intention of exercising the rights of ownership in respect of it" (Roman Law). Possession is inchoate or incomplete ownership; it is on its way to become ownership.

In both Roman and English law the possessory tended to supersede the proprietary remedies from their greater convenience—that is to say, the plaintiff based his claim or the defendant his right upon possession rather than property. The English possessory action may have been directly suggested by the interdict. Henry de Bracton (103b) identifies the assise of novel disseisin, the most common form of possessory action, with the interdict unde *vi*.

In England ejectment had practically superseded other real actions before the latter were (with the exception of dower, writ of dower and *quare impedit*) expressly abolished by the Real Property Limitation act, 1833, s. 36. The action for the recovery of land, introduced by the Judicature acts, is the modern representative of the action of ejectment.

Possession gives in English law, speaking generally, much the same rights as in Roman law. Thus it serves to found a title (see LIMITATION, STATUTES OF; PRESCRIPTION), and to throw the onus of proof upon the claimant. In an action for the recovery of land the defendant need only allege that he is in possession by himself or by his tenant, and (where such an allegation is necessary) that he had no notice to quit. In English law the doctrine of possession becomes practically important in the following cases:

1. Possession serves as a convenient means of division of estates. (See LAWS OF REAL PROPERTY AND CONVEYANCING.) One of the divisions of estates is into estates in possession and estates in reversion or remainder. It also serves as a division of personal property (*q.v.*). A chose in action is said to be reduced into possession when the right of recovery by legal proceedings has become a right of enjoyment.

2. Possession gives a title against a wrongdoer. In the case of real property it is regarded as prima facie evidence of seisin.[1] In the case of personal property the mere possession of a finder is sufficient to enable him to maintain an action of trover against one who deprives him of the chattel.[2]

3. What is called "unity of possession" is one of the means whereby an easement is extinguished.

4. Possession is very important as an element in determining the title to goods under 13 Eliz. c. 5, the Bills of Sale act, 1878, and the Bankruptcy acts, 1883 to 1890.

5. Possession of goods or documents of title to goods is generally sufficient to enable agents and others to give a good title under the Factors' acts. (See FACTOR.) W

6. In criminal law the question of possession is important in founding the distinction between larceny and embezzlement. (See Sir James Stephen, *Digest* of the *Criminal* Law, note xi.)

7. Actions of possession of ships fall within the jurisdiction of the admiralty division. This jurisdiction in the case of British vessels depends upon the Admiralty Court act, 1861 (24 Vict. c. 10, s. 8), in the case of foreign vessels (in which the jurisdiction is rarely exercised) upon the general po ers of the court as a maritime court. Under the Statutes of Limitation the only question became not whether possession has been adverse or not, but whether 12 years have elapsed since the right accrued.

Scotland.—In Scotland possessory actions still exist eo *nomine*. Actions of molestation, of removing and of maills (payments) and duties are examples. A possessory judgment is one which entitles a person who has been in possession under a written title for seven years to continue his possession (Watson, *Law Dict.*, *s.v.* "Possessory Judgment").

United States.—In U.S. law possession carries much the same important significance that it does in English law. Except in Louisiana, where the civil law prevails, possession is commonly divided into actual and constructive possession. The former concerns actual occupancy or the exercise of dominion over a thing; the latter occurs where there is no actual possession but simply ownership and the possession is either vacant or consistent with the outstanding ownership, such as possession by a servant or bailee.

The doctrine of possession has an outstanding importance in practically every branch of the law, especially in the numerous cases where ownership to realty or personalty is in issue. Especially significant are the doctrines of adverse possession, where long continued and uninterrupted possession of chattels or realty under a claim of right and hostile to the true owner ripens after the statutory period into indefeasible ownership.

In addition to the authorities cited may he mentioned W. A. Hunter, *Exposition of Roman Law*, 4th ed. (1903); O. W Holmes, *The Common Law* (1882); F. Pollock and R. S. Wright, *Possession in the Common Law* (1888); W. Markby, *Elements of Law* (1905); T. H. Holland, *Elements of Jurisprudence*, 13th ed. (1924).

POST, GEORGE BROWNE (1837–1913), U.S. architect of many commercial buildings, was born in New York city on Dec. 15, 1837. He graduated with a degree in civil engineering from New York university in 1858 and was a draftsman under Richard Hunt until 1860, when he and Charles D. Gambrill formed a partnership. His buildings include the Williamsburgh Savings bank, New York city (1874), in Renaissance style; the original New York Times building (1889), Romanesque; the St. Paul building, New York city (1897–99), a 22-story structure using applied classic orders; and the New York Stock exchange (1904). Post died on Nov. 28, 1913, at Bernardsville, N.J.

POST, GEORGE EDWARD (1838–1909), U.S. physician and clergyman, who translated a number of scientific works into Arabic, was born on Dec. 17, 1838, in New York city. Graduated from the New York Free academy (later the College of the City of New York) in 1854, Post studied at the New York university medical school, where he received his medical degree in 1860, and the Union Theological seminary, where he was graduated the following year. During the Civil War Post served as chaplain of a New York regiment and graduated from the Baltimore (Md.) College of Dentistry in 1863.

In the same year he was sent as a missionary for the American Board of Commissioners for Foreign Missions to Tripoli, Syria. Four years later illness forced his return to the United States, but he returned to Syria in 1868. He became professor of surgery and of eye and ear diseases at the Syrian Protestant college (later the American University of Beirut) and later was appointed dean of the medical department.

Post, whose classes were conducted in Arabic, translated a large number of English medical and other scientific textbooks into that

---

[1] "Seisin" *and "possession" are used sometimes as synonyms, as generally by* Bracton; *at other times they are distinguished: thus there can he possession of a term of years, but no seisin* (Noy, *Maxims*, p. 2). *It seems doubtful, however, how far* in *English law a* tenant *for years has true* possession, *for he is in law only a bailiff or servant of the landlord. But he certainly has possessory remedies.*

[2] Compare *the* **Code** *Napoleon, art.* 2,279: *"En* fait *de meubles la* **pos***session vaut* titre."

language. He was editor of *Al-Tabib,* an Arabic medical journal, for five years and served as a surgeon at the Johanniter hospital in Beirut.

In addition to his works in Arabic, including a translation of Butler's *Physiology* and, nith C. V. A. Van Dyck and Eli Smith. a biblical concordance. he published *Plantae Postianae* (Lausanne, Geneva, 1890–19001. He also contributed articles on various scientific topics to James Hastings' *Dictionary of the Bible.*

Post died on Sept. 29, 1909.

POST, MELVILLE DAVISSON (1871–1930), **US.** author. best knonn for his mystery stories. was born at Romines Mills. near Clarksburg. W.Va., April 19. 1871. Post practised criminal law and later corporate law in West Virginia. He became active in politics and in 1898 was named chairman of the Democratic congressional committee in West Virginia.

In 1896 he published *Tlze Strange Schemes of Randolph Mason,* a collection of short stories featuring a lanyer who unscrupulously took advantage of loopholes in the law. In the folloning year a sequel. *The Man of Last Resort,* was published. Post's Randolph Mason worked for the ends of justice in *Randolph Mason, Corrector of Destinies* (1909).

Post became best knonn for his series of magazine stories about a rural sleuth in early Virginia. In 1918 a selection of the tales was published as a book entitled *Uncle Abner: Master of Mysteries.* Other mystery stories include *The Sleuth of St. James's Square* (1920); *Monsieur Jonquelle* (1923): *The Bradmoor Murder* (1929); and *The Silent Witness* (1930) He also nrote *Dwellers in the Hills* (1901) a story of West Virginia cattlemen: *Tlze Gilded Chair* (1910) an adventure story; and *The Mountain School-Teacher* (1922) an allegory based on Christ's life

On June 29. 1903. Post was married to Ann Bloomfield Gamble of Roanoke. W Va.. who died in 1919. He died at Clarksburg on June 23. 1930.

POST, PIETER (1608–16691, Dutch architect and painter. one of the principal architects of the Dutch golden age. nas born at Haarlem and died at The Hague. He nas a contemporary of Rembrandt and secretary to Constantijn Huygens Though Post began his career as a painter. he had by 1633 in collaboration nith Jacob van Campen. designed the exquisite Mauritshuis at The Hague. thus shoning his mastery of the typical Dutch baroque style. In 1645 he became architect to the stadholder Frederick Henry. With Campen he designed the House in the Wood (Huis ten Bosch) at The Hague (1645–47) and, independently Snanenburg house (1645), Nieuwkoop almshouses at The Hague (1658) and the weighhouse in Leyden (1658). Post's town hall at Maastricht (1656 ff.) is one of the outstanding buildings of the 17th century in the Netherlands. Post and Campen are notable for anticipating some of the architectural refinements of 18th-century France and for the influence they exerted on English architecture.

BIBLIOGRAPHY.—*Les Ouvrages* de *Pierre* Post, engravings (1715); G A. C Blok, *Pieter* Post (1937); F. A J Vermeulen, Handboek tot de *geschiedenis* der *Nederlandsche bouwkunst,* vol. iii (1941).

(H. MN.)

POST, WILEY (1899–1935), one of the most colourful figures of the early years of U.S. aviation. was born on Nov. 22. 1898. on a farm near Grand Saline, Tex.. and grew up in the oil country of Texas and Oklahoma. Of natural mechanical bent. young Post worked first on well-drilling rigs. then became interested in gasoline-driven engines and in the airplane flights of the barnstormers who performed at county fairs. While working as an oil driller he lost his left eye in an accident, but this did not prevent his learning to fly. Backed by a wealthy Oklahoma oilman. F. C. Hall, for nhom he became personal pilot. Post purchased the Lockheed monoplane "Winnie Mae" and proceeded to set an astonishing series of records, culminating in his solo round-the-world flight July 15–22, 1933. He covered a total of 15.596 mi. in 7 days. 18 hr. and 49 min. On this flight Post proved the value of navigation instruments, including the automatic pilot, that later came into common use in airline service. He had made an earlier round-the-norld trip in the same airplane June 23–July 1, 1931. On that flight he had been accompanied by Harold Gatty as navigator. Post also did pioneering work in high-altitude flying, having designed and tested a prototype of a pressurized suit similar to those later used by military pilots.

In Xug. 1935, while flying in Alaska accompanied by the humorist Will Rogers, Post and his famous passenger were killed in a plane crash near Point Barrow.

See W. Post and H. Gatty, Around the World *in* Eight Days (1931).

I. UNITED STATES

A. HISTORY

The first postal system in the United States was legalized in 1639 by the general court of Massachusetts. The ordinance directed that all mail brought from overseas was to be left at the home of Richard Fairbanks in Boston, who would have it transmitted onward to destination. Fairbanks was allowed a penny for the transmission of each letter. In 1672 Gov. Francis Lovelace of New York established a monthly post between New York city and Boston over what later became the Boston post road—U.S. highway route no. 1. In 1683 Gov. William Penn of Pennsylvania established a post office in Philadelphia, where Henry Waldy, the first postmaster, was authorized to send mail weekly between Philadelphia and Newcastle, Del., and to supply the riders with horses to serve the routes. A post route extending from Maine to Georgia was established in this same year; these old routes later became the trunk highways serving the eastern U.S. seaboard.

In 1691 Andrew Hamilton of Edinburgh, Scot., was appointed by the British crown as postmaster general for the American Colonies. The first advance toward an organized intercolonial service was made by the granting of a patent to Thomas Neale on Feb. 17, 1692, to establish post offices in North America. An office was established at Philadelphia and rates were fixed to most of the Colonies, but receipts did not cover expenses and in 1707 the government wurchased the rights.

SORTING MAIL AT A METROPOLITAN POST OFFICE

In 1753 Benjamin Franklin became joint postmaster general for the North British Colonies in America and served until 1774, wheh he was dismissed by the crown because of his sympathies with the cause of the American colonists. Many improvements in the colonial postal system were made under his administration. Despite poor roads and great distances between centres of population, Franklin made the postal service an efficient and reliable means of communication.

Service between New York city and Philadelphia was increased from once to three times a week in summer and from twice a month to once a week in winter; post roads were in operation from Maine to Florida and from New York to Canada, and mail between the Colonies and the mother country was operated on a monthly schedule.

Franklin was appointed head of the American postal system by the Continental Congress on July 26, 1775, at a salary of $1,000 a year, and served until Nov. 7, 1776. To Franklin, in great measure, belongs the credit for the establishment of a sound U.S. postal system.

Following ratification of the constitution, George Washington on Sept. 26, 1789, appointed Samuel Osgood of Massachusetts to serve as postmaster general. At that time the postal service was a part of the treasury department and it remained so until 1829, when the postmaster general became a member of the president's cabinet. In 1789 there were only 75 post offices; by mid-20th century there were approximately 40,000 post offices. In 1790 there were only 1,875 mi. of post routes; by the 1950s there were more than 2,100,000 mi. of post routes.

The postal grant under the constitution gave to congress much wider powers, and a vast and important public service was established and developed. Post offices were established as rapidly as possible, speedy transportation of mails was provided and service was extended to distant parts of the country.

In colonial times the policy was to make a profit from the postal service. But after the post office was made a separate department of government this policy was changed; it was felt that the department should render good service to the public consistent with due regard for cost, but it was maintained that such service should not always be self-sustaining. Deficits, therefore, became common in the conduct of the department throughout the years. By mid-20th centurv revenues of the U.S. post-office department began to exceed $1,500,000,000 annually. Expenditures amounted to more than $2,100,000,000, resulting in gross operating deficits of accrual ranging from $500,000,000 to $727,000,000.

Early in 1953, when it had become evident that the annual postal deficit had attained proportions seriously affecting adversely the efforts to balance the federal budget, a program designed to effect rigid economy and increased efficiency was instituted. The gross operating deficit for the government's fiscal year ending June 30, 1955, was $362,673,654, representing a reduction of 47% from the all-time high deficit of approximately $727,000,000 in fiscal year 1952.

Post offices are established in every city, town and village in the United States for the receipt and delivery of mail matter and the performance of such special services appropriate to their size and importance. These offices, each with a postmaster, are of four classes. Postmasters of the first three classes are appointed by the president with the advice and consent of the senate and those of the fourth class by the postmaster general. On Jan. 1, 1956 there were 8,623 first-class, 6,625 second-class, 13,113 third-class and 14,502 fourth-class postmasters.

One of the first major advances in the postal service was the use of adhesive postage stamps for prepayment of postage on mail matter. Legislation was enacted on March 3, 1847, authorizing the postmaster general to issue stamps, and they were first placed on sale in New York city on July 1, 1847. Until that time the rate of postage for a letter weighing less than one ounce and composed of a single sheet of paper for a distance not exceeding 30 mi. was six cents. A maximum rate of 25 cents was charged for more than 400 mi.

B. TRANSPORTATION

The earliest methods of transportation were by horseback riders, stagecoaches and steamboats. The opening of the west and the movement of settlers to new lands broadened the scope of the postal service, and in the following years services were inaugurated which became an integral part of the postal establishment. The advent of railroads in 1834 marked the beginning of a vast change in mail transportation. By the mid-1950s mails were carried over 120,000 mi. of railroads.

With the discovery of gold in California in Jan. 1848 and the rush of thousands westward, the postal service kept pace by sending mail overland to Monterey, Calif., by way of Fort Leavenworth, Kan., and Santa Fe, N.M.; the first overland mail arrived in Los Angeles in May 1848. The pony express, a private enterprise, was inaugurated between St. Joseph, Mo., and Sacramento, Calif., on April 3, 1860, to give faster mail transportation to and from the Pacific coast. The first mail took 10½ days and 75 ponies were used: the fastest time made was 7 days 17 hours to deliver the inaugural address of Pres. Abraham Lincoln in 1861. The company charged $5 for each one-half ounce at the beginning of the pony express, but later reduced the rate to $1. Service was discontinued in Oct. 1861. "Buffalo Bill" Cody was one of the early pony express riders.

C. EXPANSION OF SERVICES

Following adoption of adhesive postage stamps for prepayment of postage on mail matter, the next new service to be adopted by the post office mas the registry system, established in 1855 to afford greater security in sending money and valuables through the mails.

The system was applied to first, second and third classes of mail matter and extended to foreign as well as domestic mails; domestic third- and fourth-class matter could also be insured. This insurance service was established on Jan. 1, 1913. Domestic third- and fourth-class matter and sealed domestic mail matter of any class bearing postage at the first-class rate could be sent collect-on-delivery (service inaugurated on July 1, 1913) on the payment of a special fee.

In 1858 street letter boxes were introduced so that postal patrons would not have to call at post offices to mail their letters. In 1863 free delivery of mail was inaugurated in 49 cities, with 440 carriers so employed the first year. By 1956 there were more than 5,000 communities throughout the country enjoying this service, with 91,427 carriers. Village delivery service was established at certain second- and third-class offices in 1912 and was developed rapidly until most such services were consolidated with city services. Rural free delivery, generally regarded as one of the most far-reaching developments in the mail service, was inaugurated Oct. 1, 1896. when five routes were placed in operation in West Virginia. During the first week patrons on the routes received 214 letters, 290 papers, 33 postal cards and 2 packages. By 1956 there were more than 32.000 routes. 35,282,118 individuals and rural letter carriers were travelling more than 1,540,000 mi. daily.

Until 1862 all mail carried on trains was distributed in post offices; in that year the postmaster of St. Joseph, Mo , tried out a method of sorting and distributing mail on a moving train between Hannibal and St. Joseph, in an attempt to avoid delays in mail departures for the west. The experiment was successful, and on Aug. 28, 1864. the first officially sponsored test of a railway post-office car was made between Chicago, Ill., and Clinton, Ia. On Dec. 22 of that year the post-office department appointed a deputy in charge of railway post offices and railway mails. This marked the beginning of the railway mail service.

There had long been a demand for means of sending funds safely through the mails, and in 1864 the money order system was placed in operation in 139 post offices, mainly to accommodate soldiers who were desirous of sending money to their homes. Money order service was extended to foreign countries in 1867.

Postal notes, which were placed on sale for the first time at post offices throughout the country on Feb. 1, 1945, as an experiment as to whether card money orders would be feasible, were withdrawn from sale on March 31, 1951. It was found that the method of bookkeeping that had been employed to keep track of postal notes received and sold at post offices was too complicated to make their continuance desirable.

Under an order issued by the post-office department money orders could be cashed at any post office throughout the country instead of the initiating office. This resulted in greater convenience to those sending and receiving money orders in the transaction of their business.

Postal cards were first used in 1873. In 1885, to accommodate persons who wanted prompt delivery of mail upon receipt at the post office, the special-delivery service was established. One million of these transactions were handled the first year.

The postal savings system was established in 1911 as a convenient and safe depository for the accumulation of savings and to encourage thrift. Originally the maximum that could be placed in a postal savings account was $500; at mid-20th century the maximum was $2,500. Postal savings depositors in 1955 numbered about 2,700,000, with deposits of more than $2,000,000,000 and accrued interest of more than $95,000,000. Postal savings certificates were on sale at 7,775 depositories, including about 1,000 branches and stations, and savings stamps were on sale at all post offices and practically all branches and stations.

Parcel post, one of the most widely used services of the postal establishment, was inaugurated in 1913 and resulted in a greatly increased exchange of farm products and goods between the rural and urban areas. By 1956 the post-office department was handling approximately 972,928,000 parcels annually. Other categories of fourth-class mail boosted the total for this year to about 1,173,000,000 items.

D. AIR MAIL

The aeroplane, since the days of its humble beginning at Kitty Hawk, N.C., in 1903, when the Wright brothers flew the first heavier-than-air machine, was integrated into the transportation scheme of the United States postal system in ever-increasing measure. Air mail became commonplace—an essential link in communications and a vital part of the economy. Established on May 15, 1918, in co-operation with the war department, which furnished the planes and the pilots, the mails were first flown between Washington, D.C., and New York city, a distance of 216 mi. Great interest was aroused, and Pres. Woodrow Wilson left the White House to witness the departure of the first mail plane from the nation's capital.

On May 15, 1919, service was established between Cleveland, O., and Chicago, with a stop at Bryan, O., the first step in what later became the initial transcontinental route linking New York city and San Francisco, Calif. By May 15, 1920, it was possible to send a letter by air from New York city to San Francisco. The first transcontinental night flight started from San Francisco on Feb. 22, 1921, and ended at Hazelhurst field on Long Island, N.Y., 33 hr. 21 min. later. By July 1924 regular 24-hr. transcontinental air mail was in operation. Shortly after the completion of the coast-to-coast air route, the postal service awarded its first contract for the carriage of mails to a foreign country. The route ran between Seattle, Wash., and Victoria, B.C., a distance of 74 mi., and the service was inaugurated on Oct. 15, 1920, although it was not until 1927 that regular foreign air-mail service was in operation. In 1935 another milestone in overseas air transport was marked with the inauguration of transpacific air-mail service, from San Francisco to the Philippine Islands by way of Hawaii, Midway, Wake and Guam. This route was extended to Hong Kong on April 21, 1937, and to Singapore on May 3, 1941. Transatlantic air-mail service was inaugurated on May 20, 1939, from New York city via Bermuda and Portugal to Marseilles, Fr. Another route between New York city and Great Britain by way of Canada and Newfoundland began operation on June 24, 1941. Direct air service to Africa was made possible by the establishment of a route from Miami, Fla., to the Belgian Congo. After World War II there was a tremendous increase in foreign air transport, and direct air-mail service to every continent was afforded by United States carriers.

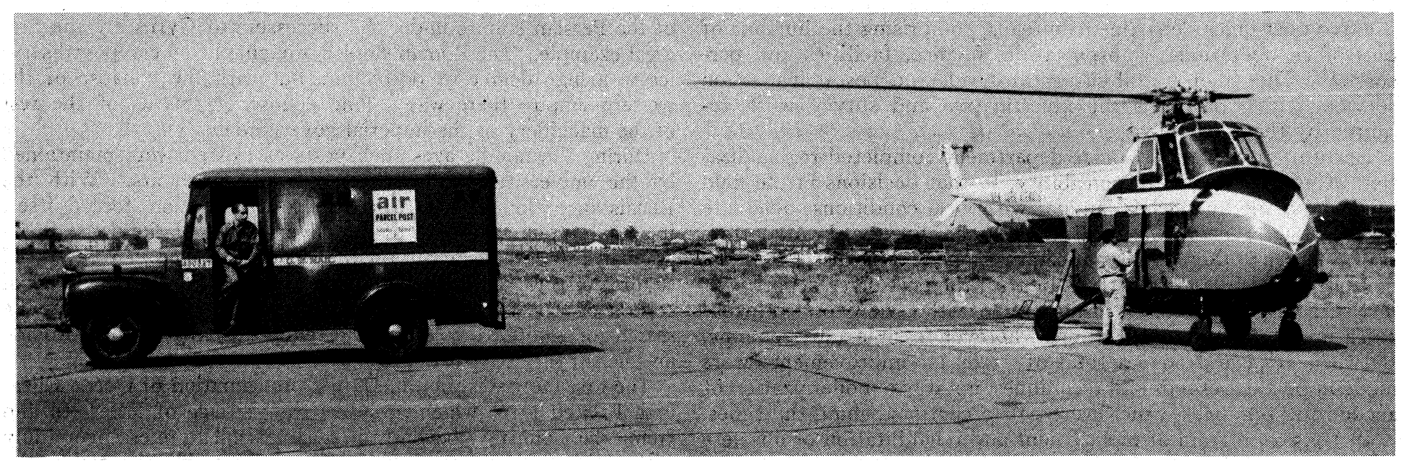
MAILBAG FOR RAILWAY PICKUP THE MAIL CAR OF THE TRAIN IS EQUIPPED WITH A CATCHER ARM, A DEVICE THAT PICKS UP THE MAIL POUCH AS THE TRAIN SPEEDS THROUGH SMALL TOWNS

To increase the use of air-mail routes, overseas postage rates to foreign countries were materially reduced. With the exception of Mexico and Canada, where a six-cent-an-ounce rate was in effect, air mail in 1956 could be sent to all countries in the western hemisphere for ten cents a one-half ounce. To Europe and countries surrounding the Mediterranean the rate was 15 cents per one-half ounce, and to all other countries a rate of 25 cents per one-half ounce was in effect. On April 29, 1947, the ten-cent air letter sheet, mailable to any country in the world, was made available to postal patrons by the post-office department as a convenient, economical means of sending communications to foreign lands.

Large metropolitan areas continued to present a problem in dispatching mail to and from the airport. In numerous instances the time saved in sending mail long distances by air was



BY COURTESY OF U.S. POST OFFICE DEPARTMENT

HELICOPTERS PROVIDE FAST SHUTTLE SERVICE OF AIR MAIL FROM AIRPORTS TO METROPOLITAN AND SUBURBAN AREAS

lost by the time consumed in surface transportation. It was thought that the helicopter, because of its ability to land in a small area, on the ground or rooftop, might prove the solution to the problem, and exhaustive tests of the carriage of mail by helicopter were conducted in the Los Angeles area in July 1946. Further tests were made at Chicago in Oct. 1946 and at New York city in Feb. 1947. As a result, the world's first experimental helicopter air-mail service was inaugurated in the Los Angeles, Calif., area on Oct. 1, 1947, over a route linking communities to the north directly with the airport. Shuttle service between the airport and the Los Angeles terminal annex post office was instituted the same day. The route was expanded until by 1956 it served approximately 50 cities and towns in the Los Angeles metropolitan area. Similar service was inaugurated in the Chicago area on Aug. 20, 1949 and in the New York area in Oct. 1952.

International air parcel-post service was inaugurated March 15, 1948. between the United States and 21 countries in Europe and the North Atlantic area. Service to South America was instituted on Sept. 4, 1948, and to the Pacific area on Sept. 11, 1948. Air parcel-post service became available to more than 60 countries throughout the world. Hundreds of planes flown by United States carriers at the end of 1955 were operating over 258,980 mi. of foreign routes, carrying air mail to every corner of the globe and transporting in a matter of hours mail that less than 15 years before took weeks to deliver.

Domestic air parcel-post service to the United States and its territories and possessions was begun Sept. 1, 1948, including all mail carried by air weighing more than 8 oz. and not more than 70 lb. Zone rates varied from 60 cents to 80 cents for the first pound, and from 48 cents to 65 cents for additional pounds, according to the distance flown.

Late in 1953 the post-office department initiated the experimental carrying of regular 3-cents letter mail by air on a space available basis, between New York city and Chicago and Washington. D.C. In Feb. 1954, this experiment was broadened to include Jacksonville, Tampa and Miami, Fla. By 1956 this experimental service had been further expanded to provide such mail transportation between all major cities of the Pacific coast.

E. OTHER DEVELOPMENTS

In 1943 the postal zoning system was placed in operation in many of the larger post offices. At present the zoning system is operative in 106 cities of the U.S. This method of addressing mail had been in use in other countries, and it was found that it permitted faster distribution and sorting of the mail, especially by less experienced personnel, and particularly during the Christmas season when large numbers of temporary clerks were employed at the larger post offices throughout the country.

As early as 1930, officials of the post-office department, anticipating the continuing withdrawal of trains and foreseeing the need of providing an effective substitute for railway post-office service, prevailed upon congress for the necessary legislation to establish highway post offices throughout the country. Operated on the same basis as the railway mail service, the mails on these highway post offices are transported in large bus-type vehicles and equipped with all facilities for sorting, handling and dispatch of mail that are found in railway postal cars. The first route, established Feb. 10, 1941, was between Washington, D.C., and Harrisonburg, Va. By 1956 there were 172 highway post offices. The system proved satisfactory in every respect and justified its continued existence and growth.

F. MAIL MATTER

The act of 1792, first after the adoption of the constitution, recognized letters, packets and newspapers as mail matter. Magazines and pamphlets were recognized in 1799 and unbound journals of the several states in 1825. Lithographed circulars, handbills or advertisements and every other kind or description of printed or other matter were recognized as mailable in 1845. In 1851 bound books were made mailable, with an early weight limit of four pounds. In 1861 maps, engravings, photographic prints, photographic paper, letter envelopes, cards, blanks, seeds and cuttings were made mailable and the weight limit was fixed at four pounds. The act of 1863 excepted books circulated by order of congress from the weight limit.

Mail matter was classified in 1863 and again in 1872 into three classes; in 1879 it was reclassified into four classes as follows: first class, written matter; second class, periodical publications; third class, miscellaneous printed matter; and fourth class, merchandise and matter not included in the other classes and not in form or nature likely to injure the contents of the mailbag or harm those engaged in the postal service, and not exceeding four pounds in weight for each package.

By the Parcel Post act of Aug. 24, 1912, the scope of fourth-class matter was enlarged. On third-class mail matter circulars and other miscellaneous printed matter and merchandise weighing not more than eight ounces were admitted to the mails. On fourth-class mail matter the limit of weight was increased to 70 lb., with the limit of size not more than 100 in. in length and girth combined, except at first-class post offices, where the limitations later were set at 72 in. and from 20 to 40 lbs., the latter depending upon the zone to which the parcel-post matter is shipped.

Congress vested in the post-office department a monopoly in the conveyance of letters, but did not extend this monopoly to any other class of mail matter.

G. ADMINISTRATION AND OPERATIONS

1. Staff.—The post-office department is administered by the postmaster general, who is also a member of the president's cabinet. He is assisted by a deputy postmaster general, five assistant postmasters general and a chief postal inspector.

The deputy postmaster general executes and performs by delegation all powers, functions and duties conferred by law upon the postmaster general. The five assistant postmasters general head the five post-office department bureaus, comprising the bureaus of post-office operations. transportation, finance, facilities and personnel. The chief postal inspector heads the postal inspection service, which performs the investigative and survey work required by the department.

Early in 1956 the post-office department completed regionalization of administrative responsibility, so that decisions in the field might be made by officials familiar with local conditions; adequate over-all supervision was still maintained by the headquarters staff. By 1956 there were 15 postal regions and 91 district offices.

2. Postal Improvements. — In 1953 the post-office department instituted a program of experimentation with a view toward mechanization of post-office operations wherever feasible and economic. Between 1953 and 1956 a total of 73 major improvements were made in postal methods and techniques, notably a modernization of accounting practices, which were half a century behind the times.

In 19j5 a program of replacement and rehabilitation of obsolete and deteriorated post-office buildings throughout the country was proposed by the postal administration. Dependent upon an increase in postal rates from prevailing 1932 levels, it was planned to spend $133,000,000 a year for five years to carry out the program.

It was intended to implement the program largely through the provisions of the Lease-Purchase act of 1954, enacted by the 83rd congress, and through the post-office department's commercial leasing program. The Lease-Purchase act provided for construction of post-office buildings by private enterprise, and the purchase of such buildings by the post-office department on the instalment plan.

3. National Association of Letter Carriers. — The National Association of Letter Carriers was organized at Milwaukee. Wis., in 1889. It affiliated with the American Federation of Labor on Sept. 20, 1917, and with the government employées council of the federation in 1945. In 19jo it affiliated with the postal telegraph and telephone international. Its membership in 1956 was slightly in excess of 100,000, with 4,200 branches in cities throughout the Cnited States. Qualification for membership in the association is that the applicant must be a city, village or rúral letter carrier on a classified civil service register.

The association maintains its own sick and accident insurance and its own life insurance headquarters in Washington, D.C.

4. Dead-Letter **Office.**—Letters or parcels which cannot be delivered because of defect of address or other cause are sent to the 59 offices of dead letters and 15 offices of dead parcel post. They are carefully examined on both front and back for the name and address of the sender; if these are found, they are returned to the sender. If the sender's address. is lacking, they are kept for a period, after which dead letters are destroyed while dead parcels are sold at auction. During 1955, it was impossible to deliver 20,622,644 letters. of ahich 2,293,412 were returned to the senders. Letters containing valuables enclosed numbered 82.165, of which 71,688 contained money amounting to $231,654. There were also 574,510 unclaimed parcels and articles found loose in the mails; 123,093 aere returned to the senders. The remaining 451,417 parcels were sold at public auction and $269,915 was realized.

5. Relationship With International Postal Service. — In 1844 congress enacted legislation authorizing the postmaster general to enter into formal agreements with other countries for the exchange of mails, and the first agreement was concluded in 1847 uith the Hanseatic republic of Bremen. This was followed in 1848 by an agreement with Great Britain. Another postal union known as the Postal Union of the Americas and Spain was formed by the republics of Sorth, Central and South America, Canada and Spain. The Universal Postal union was organized in 1874, with the U.S. as a charter member. (I. GG.; X.)

II. GREAT BRITAIN

A. HISTORY

The history of postal services goes back to the early days of the great empires of the east, when the permanent maintenance of control over a wide area was seen to depend on the organization and maintenance of rapid and frequent communication. The posts of the Persian empire under the successors of Cyrus are the first great example. The Roman empire brought the official postal service to a high degree of perfection, but with the collapse of the western empire there was a long eclipse of this as of the rest of the machinery of the imperial government.

During the middle ages such posts as existed were maintained by the universities or by the guilds of merchants. With the Renaissance the need for private communication forced itself inevitably upon the notice of the governments of the day. In its gradual growth and expansion the policy followed can be traced to three distinct motives. These are the desire to ensure an official control or censorship, mainly of international correspondence; the search for additional sources of revenue; and the wish to provide an efficient service.

The first motive is prominent in a proclamation of Queen Elizabeth I dated 1591, which prohibits the carriage of letters to and from "the Countreys beyond the seas" except by messengers duly authorized by the master of the posts. This was directed at the private posts maintained by the foreign merchants in London and seems to have been effective at the moment in bringing them to an end. In 1609 James I extended the prohibition to the inland as well as the foreign post, but in this case the motive may have been the protection of the postmaster general's revenue. The importance of state control emerged again during the protectorate, and in Oliver Cromwell's Post Office act of 1657 stress is laid on the importance of a centralized post office as a means not only of promoting trade but of discovering and preventing "many dangerous and wicked designs which have been and are daily contrived against the peace and welfare of this Commonwealth, the intelligence whereof cannot well be communicated but by letter of escript." Postal censorship, long discontinued, was revived for both World Wars I and II.

The growth in knowledge and prosperity which marked the 17th century soon led to deep dissatisfaction with the limited and somewhat inefficient services which prevailed under Elizabeth I and James I, and the reign of Charles I saw the first of the great postal reformers in the person of Thomas Witherings. Witherings began his career as "postmaster of England for foreign parts" and carried out sweeping reforms of the foreign post. In 1635 he nas authorized to bring into operation a reorganization of the inland posts. which he proposed to make self-supporting, instead of being a charge to the crown, by the simple method of making them efficient and cheap. Witherings' scheme consisted in the organization of posts travelling night and day on each of the great post roads and covering a minimum distance of 120 mi. a day, with branch posts working to and from the post towns on the way. A letter could thus be sent to Edinburgh and a reply received in six days—an enormous improvement on anything previously attempted. A regular tarifi of rates was established, based on the "single letter"; *i.e.,* one sheet of paper. This method of charging and the zone system of postage rates remained as the underlying principles of the postal service until the reforms of Rowland Hill.

Witherings' rates on the single letter were as follows: less than 80 mi.. *2d.*; 80 to 140 mi. *4d.*; more than 140 mi., *6d.*; on the borders and in Scotland. 8d.; in Ireland, *9d.*

For letters carried on the branch posts an additional *2d.* was charged. In 16j3 the government decided, for revenue purposes, to let the posts out to farm. The successful tenderer paid £10.000 a year, and the system was continued under the Restoration until 1667. The revenue of the post office, however, was not considered simply as a contribution to the general expenses of government. In 1663 it was settled on the duke of Tork and his male heirs, and somewhat later was charged with a number of pensions. which in 1713 amounted to £22,120, or one-third the total net revenue. The last of these pensions, that payable to the duke of Grafton, was continued until 1856, when it was commuted for £91,000.

1. London Penny Post, 1680.—In 1653 Louis XIV had authorized the establishment of a local post in Paris at a charge of one sou. Profiting no doubt by this example, a London merchant, William Dockwra. brought into existence in 1680 the London penny post. **A** rate of *1d.,* to be prepaid, was charged on all packets up to one pound in weight, the packets being insured up to £10. Several hundred receiving offices were opened, from which an hourly collection was made, the letters being brought into six central offices, where they were sorted, date stamped and sent out for delivery. There were 4 to 8 deliveries a day in the greater part of London and 10 or 12 in the business centres. The area covered extended from Hackney to Lambeth and from Blackwall to Westminster, and there was also a daily delivery, for which an additional 1*d.* was charged, to places 10 or 15 mi. from London.

For some time Dockwra struggled with serious financial difficulties, but no sooner had the penny post begun to show a profit than the duke of York, on whom the post-office revenues were settled, asserted his monopoly. Dockwra was condemned to pay damages and his undertaking was incorporated in the general post office.

2. First Postmaster General.—The act of 1657 was the first comprehensive attempt to regulate the postal service by statute. It established a government monopoly, provided for the post of postmaster general, regulated the treatment of letters brought by private ship and prescribed the rates of postage, both inland and foreign. The act was renewed with practically no alteration immediately after the Restoration. The inland rates were somewhat lower than those charged by Witherings, the maximum rate being 6*d.* for a single letter to or from Ireland.

Another Post Office act was passed in 1711, uniting the post offices of England and Scotland, which had been separated in 1695; regulating the postal service in New York, the West Indies and the other American colonies; prohibiting post-office officials from taking part in politics; and increasing substantially the rates of postage in order to provide for the expenses of the war with France.

The development of the posts since the reforms of Witherings had now raised a difficult administrative problem; viz., that of the crossposts, or letters exchanged between one town and another without passing through London. At this juncture another reformer appeared in the person of Ralph Allen, postmaster of Bath. Allen. who had been in the postal service since his boyhood, was convinced that with proper management the crossposts could be turned into a source of revenue. In 1719 he offered to farm them for £6,000 a year, or 50% more than the net receipts at that time, and in 1721 this offer was accepted for a term of seven years. Allen's farm was successful and the contract was renewed, at a constantly increasing rent, until his death in 1769. The net revenue of the post office increased from £96,000 in 1724 to £165,000 in 1769.

The later years of the 18th century were marked by a great development of the main roads and a consequent improvement in speed of communication. Regular stagecoach services began to be established. The establishment of the mail coach service mas the work of John Palmer of Bath. The coaches were all to leave London at the same time—8 P.M.—and to return together as far as possible. The security of the mails was to be provided for by armed guards.

3. First Mail Coach, 1784.—Palmer succeeded in bringing this project under the personal notice of William Pitt, who saw its merits and ordered its adoption. The first mail coach was established between London and Bath in 1784, and within two years coaches were running to Norwich. Nottingham, Liverpool, Manchester. Leeds, Milford Haven, Holyhead, Exeter and other places. By 1797 there were 42 mail coach routes in operation. Examples of times taken are: London to Holyhead 27 hours, to Edinburgh 43 hours, to Falmouth 29 hours. The development of the post was hampered by the necessity of obtaining revenue to finance the war with France, and the rates of postage were periodically increased until in 1812 they attained the highest point they had ever reached, and at which they remained until the reforms of Rowland Hill.

It is surprising that these rates were retained for 25 years after Waterloo, and when Rowland Hill published his pamphlet on postage in 1836 he had behind him a substantial volume of public discontent. Hill argued that the postal administration was conducted on principles which were in effect an obstacle to the development of postal business. The principal features of the scheme put forward were the aboiition of the method of charging postage on the basis of distance and the number of sheets, and substitution of rates based simply on weight; the prepayment of letters by postage stamps; and the adoption of a uniform minimum rate of 1*d.*

4. **Rowland** Hill's Success, 1840.—It was only after four years of agitation and parliamentary inquiry that penny postage was finally established in 1840. This was the most signal service Great Britain rendered to the cause of postal progress, and from the point of view of developing social relations and business communications it was an unqualified success; it established a standard to which it became the ambition of the rest of the world to attain, This success, however, had to be paid for in another direction. Cheap postage rates were not in themselves the gold mine that certain of their enthusiastic supporters imagined. It is significant to note that the post-office revenue, which in 1839 was more than £1,600,000, dropped to £500,000 in the following year. It was not until 35 years after the introduction of Rowland Hill's reform that the revenue was again as much as it had been in 1839.

For several years after the introduction of penny postage the post office abstained from introducing more reforms and devoted itself to developing its existing services. The effect of the new rate on the volume of correspondence was immediate and continuous. In 1840 the number of letters posted was 169,000,000, or more than double that posted in the previous year. In ten years it had almost quadrupled, and by 1870 had reached the total of nearly 880,000,000.

The initial weight of one-half ounce for a letter adopted by Rowland Hill remained unchanged for more than 30 years; it was raised in 1871 to one ounce, at which it remained until the Jubilee reform of 1897, when the weight carried for 1*d.* was raised to four ounces. In 1897 the postage on all weights above the initial 1*d.* was fixed at ½*d.* per two ounces.

World War I, among its other retrogressive results, brought about the abolition of penny postage 78 years after its first establishment. From 1918, when the basic rate was 1½*d.*, there mere various changes up and down, until it was 2½*d.* for the first two ounces and 1½*d.* for each additional two ounces.

Increases in postal (and telecommunication) charges were introduced from Oct. 1957. The letter postage charges were set at 3*d.* for the first ounce, 1½*d.* for the next, and 1½*d.* for each additional two ounces.

5. Newspapers.—The newspaper post had a varied and anomalous history. In 1840 newspapers were by statute carried free of postage. This, however, was not equivalent to the free postage which has been given on a more or less extended scale in other countries, as from the time of Queen Anne all newspapers had contributed to the revenue by the stamp duty which was levied on every copy. This state of things continued until 1855 when the duty was made optional, the privilege of free postage being continued to such newspapers and even to such periodicals as chose to pay it. Unstamped papers were forwarded by book post (see below). In 1870 the position was altered by act of parliament, which established a rate of ½*d.* for each newspaper irrespective of weight, the privilege being confined to papers published at intervals of not more than seven days and complying with certain specified conditions. The principle of a flat rate irrespective of weight was abandoned in 1915, when the rate was increased. Later alterations brought the rate (from Oct. 1957) to 2½*d.* per copy for the first six ounces and 1½*d.* per copy for each additional six ounces, the maximum being two pounds.

6. Book (Now Printed Paper) Post.—The first special rate of postage introduced after 1840 was the book post, instituted in 1848. This was intended to benefit education and literature and was fixed at 6*d.* a pound. Various reductions were made in the scale until in 1870 it was reduced to ½*d.* per two ounces. From 1915 various changes took place; from Oct. 1957 the rate was 2*d.* for the first two ounces, 2*d.* for the next two and 1*d.* for each additional two ounces. the maximum being two pounds. This post comprises practically all kinds of commercial documents wholly or partly printed, as well as books, magazines, etc.

7. Post Cards.—The next reform was not of British growth. The Austrian post office introduced the inland post card in 1869;

it won immediate success, and was adopted in England in 1870, the rate being fixed at $\frac{1}{2}d$. For many years only official post cards were allowed; the admission of private cards paid at the post-card rate, first allowed in 1894, encouraged that notable development, the picture post card. The rate for post cards was increased in 1918 and again later. From Oct. 1957 it was 23d.

8. Sample Post.—This was established in 1863 to allow a special rate to bona fide trade patterns and samples. The rate fixed at that time mas *3d.* for 4 ounces rising to 1s. 6d. per 24 ounces, this being the maximum weight permitted. After various reductions the rate in 1870 was $\frac{1}{2}d.$ per two ounces. Because of the rule that the sample post should be restricted to bona fide samples, it was always found in practice to be extremely difficult to work, and, at various times, it was abolished, only to be reinstituted at a later date. The service is still not very much used. The maximum weight was eight ounces and the charges from Oct. 1957 were *2d.* for the first two ounces, zd. for the next two and *1d.* for each additional two ounces.

9. Registration.—The system of granting compensation for the loss of a packet in the post was a feature of the original London penny post of 1680. A parliamentary commission in 1838 recommended a uniform system of registration at a charge of *2d.*, liability being accepted up to £5. The reform of postage rates, however, caused the postponement of the scheme and it was not until 1841 that a general registration system came into being, and then only in an attenuated form, a fee of 1s. being charged and no responsibility being accepted in the event of loss. The service was not attractive, and little traffic was obtaiped; but though the fee was reduced, it was not until 1878 that the principle of compensation was adopted. The amount was originally fixed at £2, but was gradually increased. In 1906 the present system was introduced. The minimum fee in the mid-1950s, 1s. od., in the inland service now covers compensation up to £10, and the maximum fee £400. The service is extensively used, nearly 130,000,000 registered letters and parcels being sent annually in the mid-1950s.

10. Business.—The growth of postings is of considerable interest as an indication of the expansion of trade, the spread of education and, of course, of the extension of postal facilities. Table I gives for each decade since the establishment of penny postage the total number of packets of all kinds sent by post and the number per head of the population in Great Britain.

TABLE I.—British Postal Statistics

Year	Number of postal packets of all kinds	Percentage of increase or decrease	Number per head of the population
1839 .	82,000,000	—	3.1
1840 .	169,000,000	+106	6.4
1850 .	327,000,000	+ 93.5	13.2
1860 .	646,000,000	+ 97.6	22.2
1870 .	877,000,000	+ 35.7	28.0
1880 .	1,662,000,000	+ 89.5	47.5
1890 .	2,620,000,000	+ 57.6	69.4
1900 .	3,723,000,000	+ 42.1	89.7
1910 .	5,281,000,000	+ 41.8	116.7
1920 .	5,716,000,000	+ 8.2	127.0
1930 .	6,959,000,000	+ 21.7	152.0
1940 .	6,579,000,000	− 5.5	137.0
1950 .	8,732,000,000	+ 32.7	163.7
1954–55 .	9,500,000,000	+ 8.8	186.3
1955–56 .	9,700,000,000	+ 2.1	190.0

B. RAILWAY MAIL SERVICE

1. Letter Mails.—The first regular railway service to be established was that between Manchester and Liverpool in 1830, and the first Conveyance of Mails act was passed in 1838. Under this act, the provisions of 'which still govern in essentials the relations between the post office and the railways, the postmaster general was given powers to call on the railway companies to convey his mails and guards in all trains. ordinary and special, and to provide if required the use of a whole car for the purpose of sorting letters. The only financial provision in the act was that the railway companies should receive "reasonable remuneration" for their services, any negotiations which could not be settled amicably being referred to arbitration.

Even at this early stage it was seen that the value of the railways lay not only in their superior speed but in the facilities they afforded for doing in a swiftly moving railway car the work of sorting letters which would otherwise fall on a stationary office, and so of securing a considerable advantage in time of delivery. The first travelling post office was established between Birmingham and Liverpool in 1838.

Later in the same year another travelling post office was established between London and Preston, leaving Euston station at 8:30 P.M. At mid-20th century it still left Euston at 8:30 P.M. but terminated at Aberdeen. The speeds on the earlier railways were comparatively slow. The journey from London to Birmingham occupied five and one-half hours, and from London to Manchester or Liverpool nine and one-half. These times were. however, less than half those occupied by the stagecoaches. The last coach was not withdrawn until 1847.

In spite of the great improvements which they offered in the mail service, however, the railways entailed a much heavier cost on the post office than their predecessors, and for several years after their establishment there were difficulties between the companies and the post office on the question of payment.

At the outset mails not carried in a travelling post office were dispatched by train in charge of a post-office guard. The system uorked satisfactorily enough for the small mails of the 1830s; but the great growth in the number of letters which followed the introduction of penny postage soon made this method of transmission inconvenient and unnecessarily costly, and in 1848 statutory powers were obtained under which the railway companies were obliged to convey mails by train in charge of their own guards, nhich remained the normal method of transmission for the great bulk of the mails sent by railway.

Far reaching as are the statutory powers of the postmaster general with regard to the railways, in practice they are never invoked, and the details of the postal service are settled by contracts negotiated with the railway authorities. An important requirement of the post office in the contract is the running of trains at times convenient to the mail service, which cannot be altered without the consent of the postmaster general. Great Britain is covered by an intricate network of mail trains providing complete and direct communication between the different divisions and between all parts of the country, the speed of which is equal to or, in some cases, better than that of the best passenger trains. On the west coast route to Scotland there is a special train devoted entirely to the post office, running nightly in each direction between London and Edinburgh, Glasgow and Aberdeen. This is the trunk main-line mail service of Great Britain, and the staff working in the train varies between 50 and 70 at different times on the run. A similar special train runs in each direction between London and Penzance. In all other cases the mail trains convey passengers as well as mails.

A special feature of the English mail-train service is what is known as the mailbag apparatus, a mechanical contrivance by which mailbags can be dispatched from and received in travelling post offices while the train is travelling at full speed.

2. Inland Air Mails.—The internal air services provided for passengers and freight are utilized for the conveyance of letter mails wherever this method of transport enables a worthwhile improvement in service to be made. No additional postage is payable for this air conveyance.

3. The Parcel Post.—An international parcel post was established at the Postal Union conference in Paris in 1880. The Post Office Parcels act of 1882 was passed, establishing an inland parcel service in Great Britain which came into operation in the following year. The maximum weight of parcels was fixed at seven pounds, with a scale of postage varying from 3d. to 1s., according to weight. No individual contracts were made with the separate railway companies, but the post office paid to the railway clearinghouse 55% of the postage received on all parcels conveyed by railway, the distribution of the sums thus received among the railway companies being undertaken by the clearinghouse. This arrangement enabled the post office to maintain the principle of a flat rate of postage for the whole country.

It soon became evident that for short distances it was possible to convey parcels by road at a lower cost than the payment to the railway companies provided under the act, and very shortly after the establishment of the parcel post parcel coaches were established by the post office. These road services took on a new development with the coming of the internal-combustion engine. The higher speed and greater capacity of the motor van made a large extension of the coach system practicable, and by the outbreak of World War I, parcels were being carried by road during the night between large towns up to a distance of 120 mi.

Following fresh negotiations with the railway companies, it was enacted by the Post Office Parcels act of 1922 that the percentage of the postage payable to the railway companies should be reduced from 55% to 40%, the post office for its part agreeing that the railway companies should be entitled to claim a revision of their remuneration if the number of parcels conveyed otherwise than by railway exceeded 10% of the total number transmitted by post. Under these arrangements many of the road services were terminated as being no longer remunerative. From Jan. 1. 1951, the arrangements between the railways and the post office were based on a contract between the parties which superseded the arrangements laid down in the Post Office Parcels acts.

Since the establishment of the service, the maximum weight has been raised from 7 lb. to 15 lb., and the postage rates have been varied from time to time. The rates from Oct. 1957 were 1*s*. 6*d*., 1*s*. 9*d*., 2s. od., 2*s*. 3*d*., 2s. 6*d*., 2*s*. 9*d*., 3s. od.. 3s. 3*d*. and 3*s*. 6*d*. for parcels not over 2 lb., 3 lb., 4 lb., 5 lb., 6 lb., 7 lb., 8 lb., 11 lb. and 15 lb. respectively.

C. MAIL PACKET SERVICE

The first regular government mail packet service was established by Queen Elizabeth I in 1598 between Holyhead and Dublin. At that period, however, foreign communications were of greater postal importance than those with Ireland, and when James I reaffirmed the post-office monopoly in the case of foreign letters and appointed a postmaster for foreign parts. it clearly became incumbent on the post office to provide a regular means of communication with foreign countries. Witherings. who subsequently reformed the inland post, began his career by establishing efficient and regular communication with France by means of hired boatmen engaged to carry the mail between Dover and Calais.

For the next 50 years the service appears to have been somewhat unsatisfactory and development slow; but in 1686 a regular service was established by government packet between Harwich and the Netherlands, which was followed in 1688 by a service from Falmouth to Corunna. Sp., and in 1703 by a weekly service from Falmouth to Lisbon, Port.

The growth of the British oversea possessions in the 18th century led to further developments. After an unsuccessful attempt at the beginning of the century, regular packets were put on from Falmouth to the West Indies in 1745; packets also ran to North America, and by the end of the 18th century they served a great part of the aorld. The packets themselves were small, being only 70 tons on the shorter services and on the ocean routes 150, vessels of the latter tonnage being, according to a report of 1788, considered fit to go to any part of the world.

The next important event in the history of the packets was the introduction of the steamship. Steamship communication with Ireland was established in 1816, and in 1821 a mail packet of 205 tons burden was put on this service, being followed in the next year by a steamship on the Dover–Calais route. It soon became evident, however, that mails could be carried more advantageously by private companies than by the government, and in 1831 the principle of inviting tenders for the mail service from private companies was introduced.

In the earlier part of this period the government definitely adopted the policy of subsidizing steamship companies in order to establish regular communication on routes where ordinary traffic would not have justified the requisite expenditure, and to ensure the provision of a better type of vessel than would otherwise have been forthcoming. The first contract was made uith Samuel Cunard in 1839 for a subsidy of £55,000 a year and was speedily followed by others. The subsidy policy, however, proved in practice costly, the expenditure having by 1853, when it became the subject of a parliamentary inquiry, reached the considerable sum of £853,000. After that time the principle of the subsidy gradually disappeared; its object had been fulfilled by the establishment of such far-reaching mail services as those of the Peninsular and Oriental company, the Royal Mail Steam Packet company and the Cunard White Star line.

The use of noncontract ships for providing the mail service was, in fact, a return to an earlier epoch in the history of the overseas mail service. The government packets in the 17th and 18th centuries were far from covering the whole field; for example, Africa and Asia were never touched by them, and for correspondence to and from a great part of the world the only means of transport was the private ship. The post office for a long period made only a feeble attempt to secure control of this means of communication. The measures taken were not effective, and as late as 1827 certain coffeehouses, which had customarily kept bags for the acceptance of overseas mail, were still collecting letters in defiance of the law. The general improvement in the postal service, and in particular the effective measures taken to establish regular mail services by private ships whenever such a course was advantageous, gradually abolished the incentive to forward letters by other means than by the post office.

D. AIR MAILS

The history of air mails in Great Britain begins in 1911, when to celebrate the coronation of King George V an air-mail service was run between Hendon and Windsor. Twenty-one trips were performed and a considerable number of picture post cards, etc., carried; but the service was irregular and did not hold out much promise of the development which came a few years later, resulting from the great progress made by aviation during World War I. After the Armistice, an experimental service between Folkestone and Cologne, Ger., set up for the benefit of the army of occupation, was followed in Nov. 1919 by a regular service between London and Paris, on uhich the air fee, originally fixed at the high rate of 2s. 6d. an ounce in addition to postage, was soon reduced to zd. an ounce. Other regular services to European countries followed (including an air parcel service between London and Paris in 1921); air-mail services spread further afield, the England-India service begun in March 1929 being the first stage in extending air-mail services from the United Kingdom to the commonwealth.

During the decade preceding 1939 the United Kingdom post office introduced the so-called "all-up" system, whereby first-class mail was sent by air at normal rates of postage whenever it would thereby secure earlier delivery, in the service to many European countries. An all-up system at a postage rate of $1\frac{1}{2}$*d*. per one-half ounce was also introduced, under the Empire Air Mail scheme, on the British Commonwealth air routes to the Union of South Africa and Australia.

The outbreak of World War II led to the suspension of many air-mail services and the reintroduction of surcharge services on other routes. Aircraft capacity mas at a premium and, to meet the urgent needs of forces personnel in particular, an airgraph service, both from and to the United Kingdom. was introduced in 1941. A lightweight air letter service from forces abroad to the United Kingdom was also introduced in 1941, but did not commence in the outward direction until Dec. 1942. In the airgraph service the messages were written on special forms which were handed in at post offices. The form was photographed on a strip of film 100 ft. long by 16 mm. wide. The film strip, containing 1,700 messages, when enclosed in a cardboard container weighed only $5\frac{1}{2}$ oz., whereas a similar number of letters by ordinary post would have weighed about 50 lb. On receipt at their destination by air, prints prepared from the photographed messages were delivered to the addressees in the ordinary way. More than 350,000,000 airgraph messages were conveyed during the four years in which the service operated.

With the termination of the war. steps were taken to reintroduce air-mail services throughout the world, and it was made possible not only for first-class mail but for second-class mail (at a reduced rate of postage) to be sent from the United Kingdom to practically anywhere. The air letter form was retained as a specially cheap form of air-mail service and this type of communication was internationally recognized by the Universal Postal union in 1952 under the name of "Aerogramme." The all-up service to European destinations was reintroduced and extended, but the high cost of air transport in the postwar period precluded its introduction on the intercontinental routes. Air parcel services were introduced to most destinations.

E. MISCELLANEOUS SERVICES

In addition to the general postal service placed at the disposal of the public, a certain number of special facilities may be obtained by those who wish to have a more rapid or convenient method of delivery. The most important is the express delivery, which was established in 1891. There are several varieties of express delivery, the most useful of which perhaps is that by which a letter or packet may. at any time at which messengers are on duty, be dispatched by special messenger to its destination on payment of a small mileage fee. Living animals are accepted for express delivery if a suitable receptacle or lead is supplied and provided the sender takes precautions to safeguard the postal official from injury. A further service provides for the delivery, immediately on arrival, of letters or parcels received by the ordinary mail. at the request of the sender; and the same facility is given at the request of an addressee who is expecting an important letter.

When a quicker transmission is desired than that afforded by ordinary mail, letters can be accepted at many post offices for conveyance by messenger to the railway station for dispatch by the next available train. A messenger mill meet the train and deliver the packet to the addressee. For certain addresses in Great Britain this arrangement applies to inland air services.

When a regular early delivery of correspondence is desired, any firm or person may rent a private box at the post office, from which he or his messenger may obtain his letters and parcels on application. If, again, his postings are on so considerable a scale that the application of postage stamps becomes inconvenient and expensive, he may on certain conditions arrange to pay the postage in cash; large users of the post may have their correspondence or parcels collected from their premises by the post office. Another method of avoiding the use of postage stamps is the employment of postal franking machines, which are licensed by the post office. These machines impress the correspondence with a red franking stamp which is accepted as the equivalent of a postage stamp. Each machine is provided with a meter, which is set from time to time at the post office, postage being prepaid in cash on the number of impressions which the meter is set to register.

F. THE POST OFFICE AS BANKER

1. Savings Bank. — The British Post Office Savings bank was set up in 1861, as a result of legislation introduced by William Ewart Gladstone. The object was to encourage thrift among the lower-income classes, and limits were therefore set to the amount of money which could be deposited. The maximum amount which may be deposited in one year by any individual is £joo and the maximum balance which may be held is £3,000. Interest is allowed on complete pounds at the rate of $2\frac{1}{2}\%$ and is added to the balance at the end of each calendar year. All accounting is centralized, but a depositor may pay in or withdraw money at any post office in the country at which savings bank business is transacted. There were about 20,000 of these offices in the mid-1950s. A withdrawal on demand up to £10 at a time may be made at any savings bank post office, but if more than one withdrawal exceeding £3 is made within a period of seven days the paying officer retains the book for examination at the chief office. To make larger withdrawals a notice has to be sent to headquarters and an authority to pay is issued to the office named by the depositor. Within certain limits withdrawals may be made by telegram. All deposits are handed over to the national debt commissioners. by whom they are invested for the Post Office Savings Bank fund. The post office draws on the fund to cover any excess of withdrawals over deposits, and the interest earned' *, the investments of the fund is set against the interest due to depositors and management expenses. The Post Office Savings bank has enjoyed increasing popularity through the years. The appeal for savings to help finance World War I gave it an additional impetus, but the accretion of business during World War II passed all records. In 1938 the number of active accounts was about 11,000,000 with a total balance of more than £500,000,000. By the end of 1956 the active accounts numbered more than 22,387,000 and the balance due was more than £1,687,000,000. After 1945 more than 6,500,000 accounts had been set up with initial credits of £370,000,000 in respect of war gratuities and postwar credits for personnel of the fighting and civil defense services but many of these accounts were short-lived.

2. Insurance and Annuity Business. — In 1864 the post office was authorized to set up an insurance and annuity business through the savings bank, but this business has never been of more than moderate dimensions. Insurance business was discontinued on Dec. 31, 1928.

3. Post-Office Stock Register. — A much more successful development was instituted in 1880 when facilities were given to depositors in the savings bank to purchase government stock up to a limit of £300. **A** simple method of purchase was devised at a low rate of commission, and dividends were credited to the purchaser's savings bank account. In 191j the link between the savings bank and the post-office stock system was loosened, and it was no longer necessary to be a savings bank depositor in order to hold stock through the post office, nor did dividends need be paid into a savings bank account. During World War I the machinery proved of great value to the government in making it possible for the small investor to purchase or subscribe to government stock. For many kinds of government stock there was a post-office as well as a Bank of England issue, and subscriptions could be made at most post offices. The most outstanding development of the post-office register occurred during World War II, when a special issue of defense bonds, restricted to the post-office register, was made. The bonds made an appeal to all classes; although initially a maximum limit of £1,000 was set to each holding. the peak holdings of the bonds reached a total of more than £1,000,000,000. The issue open to subscription from May 1, 1956, bore interest at $4\frac{1}{2}\%$ per annum and individual holdings were limited to £1,000. Including other stocks the total of investments on the post-office section of the post-office register at the end of 1956 was £798,740,000 and the number of stock- and bondholders was 2,226,000.

4. Savings Certificates. — A further simple and popular method of investment managed by the post office is the national savings certificate. Originally issued in 1916, it proved attractive to all classes during World War I as a means of helping the war finance. and at the end of 1918 the value of the certificates held had reached £207,000,000. During World War II the sale of certificates was phenomenal, and the value of the certificates held increased from £381,000,000 in 1938 to £1,883,000,000 at the end of 1956. These figures are exclusive of accrued interest. The number of holders was about 20,680,000.

The early certificates were based on a unit of £1, which was the value given to the certificate after it had been held for a number of years. The purchase price of the certificate varied from time to time according to the rate of growth and the number of years before the value reached £1. For the first issue of certificates the purchase price was 15*s*. 6d. and the value of £1 was reached in five years. The purchase price of the 10th issue, on sale from Aug. 1, 1956, was 15*s*. with an increase to £1 after seven years. Interest on the certificates is not paid separately but is included in the value when the certificate is repaid. Certificates are repayable at any time after a few days' notice. The accrued interest is free from income tax. Limits are imposed on the number of certificates which may be held by one individual.

5. Premium Savings Bonds. — Premium savings bonds, issued through the post office by the treasury, were put on sale on Nov. 1, 1956. They differ from other securities offered to the small saver in that instead of earning interest they have, after a qualifying period of six months, chances of winning cash prizes free of U.K. tax. Draws for prizes are held monthly and each unit bond gives the holder one chance in every draw for which it qualifies. A novel feature of the scheme was the method of drawing winning bond

numbers. These were generated electronically and entirely at random by E.R.K.1.E.—Electronic Random Number Indicator Equipment—which was built specially by the post office engineering department.

6. Savings Stamps.—Various aids have been introduced from time to time to encourage the saving of quite small sums (*e.g.*, home safes [until 1942] and slips to which postage stamps could be affixed), but the method of national savings stamps became the main as well as the most popular method. The stamps are issued in denominations of 6d. and 2s. 6d. The stamps can be used for the purchase of savings certificates, government stock and premium savings bonds, or for deposit in the savings bank, but they can also be cashed freely at post offices.

7. Savings Department.— The conduct of the savings bank, savings certificate and government stock and premium savings bond business of the post office is concentrated in the post-office savings department, which is thus responsible for accounts containing about £4,866,000,000 of the public's money. There are few, if any, families in the United Kingdom which do not have a share in these savings in some form or other.

8. Money Orders.—The original establishment of the money order service was a result of the desire of the postmasters general toward the end of the 18th century to prevent the theft of money carried in letters in the post. There was some doubt whether such a service could be established by the post office under its existing powers, so by a curious compromise certain officers of the post office were allowed in 1792 to set up a service on their own account, the cost of advertising it being borne by the postmaster general, who also allowed the relative advices to pass free of postage under the post-office frank. The money order service was taken over by the government in 1838. The rates of commission charged to the public have varied from time to time, and the maximum amount for which a single order may be issued increased until by 1950 the maximum for an inland order was £50. Notwithstanding the competition of the cheaper postal order, the money order still appeals because of the security afforded by the special feature of the service—the advice note which is sent to the office of payment and against which the order is checked before payment.

In 1955–56, 30,103,000 ordinary inland money orders were issued representing £255,260,000. The telegraph money order service came into operation in 1889 and is utilized to a considerable extent; in 1955–56, 1,347,000 inland orders were telegraphed to the total value of £13,909,000.

The overseas money order service came into being in 1856, when arrangements were made for an inward service to Britain from army post offices at Constantinople, Scutari and Balaclava, this plan being extended to Gibraltar and Malta the following year. The first two-way service was with Canada in 1859, and services with other colonies soon followed. In 1868 the first foreign money order service was started with Switzerland. The service was extended gradually to cover most parts of the world in which an inland money order service operated.' A telegraph money order service was started with Germany in 1898 and was subsequently extended to many other countries.

World Wars I and II brought considerable difficulty in maintaining a money order service with foreign countries. At the start of war in 1939 the control of foreign exchange was applied to the overseas money order service, and this control is still operated. The number of overseas orders received in the United Kingdom from overseas countries, including the Irish Republic, in 1955–56, in respect of all the overseas money order services was 1,645,000 representing £8,914,000, and the number of orders sent to overseas countries, including the Irish Republic, for all the money order services was 829,000 representing £7,836,000.

9. Postal Orders.—A reduction in 1871 of the commission charged on money orders under £1 was followed by an increased demand for the low-value orders, and by 1875 the service was being run at a loss. The comparatively high charges which would have been necessary to avoid this loss caused the post office to consider the possibility of introducing a new method of remittance for smaller amounts which would dispense with the advice, an expensive feature of the money order service. As a result the postal order (originally styled postal note) was introduced in 1881. These orders were for fixed denominations up to 21*s.* and from 1951 orders for £2, £3, £4 and £5 were added to the range. Odd amounts (excluding halfpence) can be made up by fixing postage stamps to the orders. They must be made payable to a particular person and preferably at a particular office and can be crossed for payment through a bank. The simplicity, cheapness and convenience of the postal order made it an immediate success. In the first two years the number grew from 4,500,000 to 33,000,000 and in 1955–56 the figure was 569,959,000, representing £204,159,000. Considerable use is made of this form of remittance in connection with football pools and newspaper competitions.

The convenience of the postal order soon led to a proposal to extend its use throughout the empire, and in 1903 all dominions, colonies and dependencies were invited to adhere to a scheme for making postal orders available for remittances to and from the United Kingdom, between one part of the empire and another and within the participating country. Most of the commonwealth, with the notable exceptions of Australia and Canada, operates this scheme, and in 1954–55 about 12,332,000 orders were issued overseas.

G. POST OFFICE AND SOCIAL SERVICES

One of the most striking developments of post-office activities in the 20th century was its assumption of functions which had no connection whatever with its primary purpose but which flowed from its possession of a widespread net ork of local offices having day-to-day financial dealings with the public. This development began many years ago in the use of the post office for the collection of local or national revenue by means of licence duties. For example, dog, gun and game licences, excise licences and motor vehicle licences (renewals) are obtainable from the post office, £11,331,000 being collected by this means in 1955–56.

This, however, was a comparatively small item of business and it was far exceeded by business connected with the social services established from time to time. When the Old Age Pension act of 1908 came into operation, the post office became the paying agent. This arrangement was extended to payments under the Widows', Orphans' and Old Age Contributory Pensions act of 1925 and under the National Insurance act which came into operation in 1948. Similarly, war pensions, separation allowances, national assistance allowances and family allowances are paid by the post office. In 1955–56, 633,666,000 orders for all kinds of pensions, allowances, etc. were paid to the total value of £853,159,000.

A considerable number of stamps are sold for other than postal purposes. Certain inland revenue duties may be paid by postage stamps (*e.g.*, receipt duty), but, in addition, the post office has long assisted the inland revenue authorities by selling such inland revenue and fee stamps as are in general use, as well as entertainment duty stamps. There was also a large sale of stamps for the various state insurance schemes culminating in the National Insurance act, 1946. The value of the insurance stamps sold in 1955–56 was £424,548,000.

Revenue is also collected by the sale of broadcast (sound and television) receiving licences. Records are maintained of the persons who hold such licences and steps taken to ensure that the licences are renewed after their validity has expired.

During 1955–56, 14,311,000 broadcast receiving licences (sound and television) were issued to the value of £25,743,000. The post office also issues amateur transmitting licences and other radio licences.

From April 1, 1956, arrangements between the post office and the treasury similar to those existing before World War II were introduced for a trial period of five years. Under these arrangements the post office provides in its commercial accounts for an annual contribution to the exchequer of £5,000,000 which broadly represents what the post office, but for its exemption, would have been paying in recent years by way of taxation. Any surplus then disclosed by the commercial accounts will be available to the post office as a revenue reserve to be used if necessary to offset any deficiency in other years.

H. BRITISH ARMY POSTAL SERVICE

The British army postal service dates back to the Napoleonic Wars. In 1792 a post-office official went to the Netherlands to organize a private communications service for the British troops there. Similar arrangements were made for the Crimea in 1854, but a military postal service as such first operated in the Egyptian campaign of 1882 when a company of the 24th Middlesex volunteer regiment (post-office rifles) undertook postal duties. Since the beginning of the 20th century at least a nucleus army postal service has existed on an army reserve basis. After 1914 it operated abroad continuously in larger or smaller numbers both in peace and war, and ran services for the air force as well as the army.

Modern British army postal technique began to emerge during the South African War, and it was naturally greatly developed during World War I when large-scale army postal services were needed for the first time. In 1918 the personnel both at home and overseas numbered nearly 6,000, of whom about one-third were women, some being sent to base offices in France for sorting work. Excluding peak traffic at Christmas time the maximum dispatches from home were about 12,000,000 letters and 1,000,000 parcels a week.

World War II with its various phases and events, extensive and rapid movements of large armies, the closing of the Mediterranean, the world-wide dispersal of British forces, etc., presented postal problems of an entirely new and complicated character. However, a far greater range of postal facilities was provided, largely of necessity, than in any previous war: surface letters and parcels, ordinary air letters. lightweight post cards, lightweight air letters, airgraphs and various types of telegrams. The service carries the bulk of official mail; it also provides remittance services and savings facilities and distributes newspapers. The overseas destinations where the army postal service distributed mail were more than 25 in number, and the maximum traffic amounted to about 17,000,000 letters, newspapers and parcels a week, although during Christmas pressure periods it was much greater. The staff abroad and in the United Kingdom numbered more than 7,000, of whom about 2,500 were women of the Auxiliary Territorial service who performed most of the sorting work at the home postal depot.

Liaison and co-operation with British Commonwealth and Allied military postal services necessarily grew to great dimensions by 1944. For the first time, army postal facilities were provided for the army and air force at home. This began soon after the evacuation from Dunkirk and later was greatly used for security purposes for troops who were detailed for the Normandy invasion-in 1944.

Toward the end of the war extensive air-mail services were provided. and in difficult areas such as Burma parachute dropping of mails was practised extensively.

The army postal service serves the army and the royal air force wherever they may be serving overseas. Conditions have varied; for example, in Korea wartime arrangements had to be made and in other areas internal security troubles have given rise to the need for exceptional measures.

I. POSTAL STAFF

In April. 1957, the staff of the British post office—postal, clerical, telegraph, telephone and engineering—numbered 347,000 including about 86,000 women, 85,000 industrial staff and 45,000 part-time staff (counted as halves). Between 3,500 and 4,000 of the United Kingdom staff of the nationalized company, Cable and Wireless Ltd.. were added to the staff in April 1950.

The chief administrative questions arising are recruitment. pay, training, welfare and other conditions of the staff. productivity and staff consultation. The bulk of the staff enjoys the usual civil service conditions of permanence of employment and pensionability. Clerical and professional staff generally belong to grades common to the civil service as a whole. Manipulative staff—postmen, telegraphists, telephonists and postal and telegraph officers—are recruited either by interview and selection or by competition; where recruitment is by selection, preference is given to ex-regular servicemen. The manipulative staff have opportunities of advancement both by competition and by promotion to higher rank, including clerical appointments. Pay and major conditions of service are settled generally by negotiations with the staff associations or, failing agreement, by awards of the civil service arbitration tribunal, subject to the overriding authority of parliament.

The day-to-day staff administration is eased as much as possible by the organization of the post office into seven functional headquarter departments, apart from administrative headquarters, and ten territorial regions, subordinate to which are about 466 head and district post offices and 57 telephone managers' areas, and by the utmost possible decentralization of authority to directors, regional directors, head and district postmasters and telephone managers.

British Postal Trade Unions.—The difficulties which trade unionism has met in outside employment were reflected in the history of the postal staff, and it was not until 1899, after two partial strikes, that the duke of Norfolk consented to receive representations from the Postmen's federation. Thereafter many associations were formed in the post office, indicating the variety of work and the consequent multiplicity of grades. In 1955 there were 27 separate associations officially recognized, with an aggregate membership of 306,911. The largest associations and their membership were in 1955 as shown in Table II.

TABLE 11.—Chief British Postal Trade Unions, 1955

Title	Membership
Union of Post Office Workers	161,481
Post Office Engineering union	61,591
Civil Service Clerical association (post-office section)	24,967
National Federation of Sub-Postmasters	18,806
Association of Post Office Controlling Officers	10,833
National Guild of Telephonists	11,292

In 1920 relations between the administration and the staff entered on a new phase with the establishment of Whitley councils. General questions common to the post office and the rest of the civil service are discussed on the national Whitley council, but the post office has its own headquarters departmental councils (working largely through smaller joint committees) to discuss general matters affecting the staff, and local committees in head post offices, etc., to discuss local matters. The Whitley machinery has on the whole worked smoothly and disagreements are comparatively rare. Whitleyism has in no way superseded the separate unions, which continue to act as independent negotiating bodies on matters such as wages.

In 1947 machinery for joint consultation on productivity was set up on the engineering side to discuss measures to increase output, and in 1949 similar but more elaborate machinery mas established for the nonengineering grades. The Trade Unions act of 1927 forced the post-office unions to sever their connection with the Trades Union congress, but, with the passing of the Trade Disputes and Trade Unions act of 1946, five of the unions mentioned above became affiliated with the T.U.C. The Union of Post Office Workers also became affiliated with the Labour party.

III. INTERNATIONAL POSTAL SERVICE

The importance of the international service is evident from the earliest days of post-office history, but the working of the service is somewhat obscure. In the 16th century a regular service seems to have been provided between London and Calais, which was the port on which foreign communications mainly centred. The outward letters seem to have been carried to their destination by English post-office messengers, while inward letters were brought by foreign messengers as far as Calais.

Witherings reorganized the foreign service, and shortly after his time (1670) a regular postal treaty was concluded between England and France. This was renewed in 1698 after the conclusion of the treaty of Ryswick. The treaty provided that the mail from London for Paris and from Paris for London was to leave twice a week. Between Dover and Calais the English post office provided the mail packets in both directions; the service beyond Calais was provided by France. Letters could be prepaid only to a limited number of destinations—Paris, Rouen or Lyons;

any charges for further transmission were collected from the addressee.

This treaty, soon interrupted by further hostilities, was again renewed in 1713. The new version is interesting as containing the germ of the international system of accounting for transit mails which lasted with but slight alteration until the latter part of the 19th century.

On letters for Italy, which could be franked to Turin, France was to be paid at the rate of 21 sols per single letter; on letters for Spain franked to Bayonne the payment was 19 sols; on letters for Turkey franked to Marseilles, 17 sols. Double letters were charged approximately twice, and letters weighing one ounce four times the single rate The accounting between the two offices was based on the sum of the amounts due on the separate letters, mail by mail. The principles adopted in the 17th century show little change in the 18th, and a treaty concluded with France in 1802 shows comparatively little variation from its predecessors of more than a century before.

As time went on the postal treaties required for the establishment of a gradually expanding foreign service became more and more numerous and complicated. The postage depended on the sums payable to the various post offices concerned in the transit of the letters, and these were often based on their own internal rates and units of weight. The result was an extraordinary variety of rates—often differing materially for the same destination according to the route employed—and a considerable variety in the weight covered by the initial postage rate. Moreover, prepayment was in some cases compulsory, in some cases optional; but compulsory prepayment covered conveyance only up to a certain point, all charges beyond that point being collected from the addressee. The unit of weight was in a large number of cases one-fourth ounce, any letter above that weight being charged pro rata. The lowest postage in force was that to France, which mas 4*d.* per one-fourth ounce. A letter from England to Belgrade, Yugos., via France, weighing one ounce. cost 5*s.;* a half-ounce letter to California via Panamá cost 4s. 8*d.*, in addition to a further charge on delivery. Even to Spain the postage was 2s. zd. per one-half ounce, plus a charge on delivery.

From the point of view of post-office management, the complexity of the service was, with the industrial development of the 19th century and the constant growth of correspondence, reaching a point at mhich the rapid and accurate handling of the mails became practically impossible Almost the only advance made over the procedure in force in the 17th century was that letters were weighed in bulk instead of singly. The example of a simple and uniform tariff had been set by the establishment of penny postage, but the principle which underlay Rowland Hill's scheme for obtaining uniformity (viz., that the cost of conveyance of a letter' represented only a small fraction of the total cost of its treatment) was far from being applicable to the conditions of the international post.

1. Formation of the Universal Postal Union.—The first step in the direction of reform was taken by the United States, which in 1862 suggested a conference for the purpose of considering the improvement and simplification of international postal relations. This met in Paris in 1863 and adopted a code of 31 articles, intended to serve as the basis of international conventions. Further progress was delayed first by the American Civil War and then by the Franco-German War.

In the meantime. however, another great postal reformer, Heinrich von Stephan of the North German Postal confederation, had prepared a project for a universal postal union. based in part on the conclusions of the conference and in part on the experience of Germany, which had several years before formed a postal union including Prussia. Austria and all the other German states, nearly 20 in number. The Swiss government. at the instance of Germany, summoned a conference to meet at Berne to consider the proposal to form a general postal union.

The Congress of Berne in Sept. 1874 was attended by the representatives of 22 states, including the whole of Europe, the United States and Egypt. The result of the congress was the signature of the first International Postal convention, which remained from *1875*, with comparatively little modification, the foundation of the international postal service.

The fundamental principle of the union is contained in a striking article which lays down that for the purposes of postal communication all the signatory countries form a single territory. The practical application of this principle lies in the doctrine of liberty of transit; every member of the union binds itself to transmit the mails entrusted to it by every other member by the best means of communication which it employs for its own mail. Thus each country has in effect the full and unrestricted use of the railway and steamship services of the whole world, and any improvement made by any member of the union is placed at the disposal of any other which desires to utilize it.

The membership of the union was at first somewhat limited, and was mainly European, although from the first the United States, Asiatic Russia and Asiatic Turkey were included. Extensions of membership were, however, rapid. Ten years after its foundation the union included *86* postal administrations; by 1900 there were 113 and at mid-century there was hardly any part of the world remaining outside.

2. The Postal Union Organization.—The organization of the union is simple but effective. Most questions are settled directly between the countries immediately concerned. but for matters in which the whole union is concerned an international bureau is maintained at Berne.

The bureau collects and distributes information of common interest, publishes statistical returns, a monthly journal, lists of steamship and air services, etc., and acts if required as a clearing-house for the settlement of accounts. The cost of the bureau is apportioned in a ratio corresponding to their importance between the various members of the union.

The Universal Postal convention and the subordinate agreements are reviewed periodically, usually at intervals of five years, by a congress to which every member is invited to send delegates. In cases of dispute between postal administrations, the union has adopted the principle of compulsory arbitration. Serious disputes are infrequent, but when they occur the arbitration machinery has invariably been effective.

3. Four Chief Principles.—The first principle was the uniformity of postage rates and of units of weight. The Congress of Berne adopted the rate of 25 gold centimes per 15 grams for letters, but permitted a certain variation within a definite maximum and minimum, and the rate of 7 gold centimes, with a similar variation, per *50* grams of printed papers.

In 1878, however, standard uniform rates in gold centimes were adopted for letters, post cards and printed papers and were retained unaltered until 1920. The only variation allowed was the addition of a surtax in cases where heavy costs for sea transport were incurred. The conditions mhich followed World War I swept away the uniformity which had prevailed for 40 years and brought about a reversion to the original principle of a maximum and a minimum rate which has been maintained ever since. The only change in the units of weight has been the raising of the letter unit from 15 g. to 20 g., or to one ounce for English-speaking countries.

The second basic principle is the classification of postal correspondence into three groups—letters, post cards and other matter (including printed papers, commercial papers and samples). Definite conditions of acceptance, as well as separate rates of postage, were adopted; the delicate distinctions between what can be sent at the cheap rate and what must be charged as a letter, which are often puzzling to the public, depend on international decisions which no individual country is in a position to vary.

The third principle was the adoption of definite payments to be made by the country which dispatches mails by the trains or steamships of another country for the use of those services, with the exception that no payment is made to the country of destination, the flow of correspondence in each direction being assumed to be approximately equal. Here there has been no continuity of practice. Rates for sea services in particular were at the outset extremely high. Over the years the rates for sea and land services have been adjusted from time to time to meet changing circumstances.

The fourth principle was the universal adoption of a system of registration and compensation. International registration differs from internal registration in one important particular, which often puzzles and annoys the sender of a letter. The compensation payable is a fixed amount and is allowed only in the event of the entire loss of the registered packet and not for damage or loss of contents. This principle the union has steadily maintained from its inception.

4. Later Changes. — The original convention applied only to letter mails, but from an early date supplementary agreements were adopted at successive congresses for various extensions of the postal service. In 1878 an agreement for an international money order service was signed by a considerable number of countries; at the same time an insurance service, which provided for payment of compensation for loss or damage of letters containing documents of value (paper money, etc.), was established. This was later extended to cover insured boxes containing valuables such as gold or jewelery. The amount insured varies with the fee paid, and the maximum varies in different countries.

A further considerable advance was made in 1880, when 19 countries concluded a parcel-post agreement. The original agreement was limited to parcels not exceeding three kilograms; it prescribed a simple procedure and fixed rates of payment both for terminal and for transit countries. The scope of the service expanded considerably and provides both for an insurance and a cash-on-delivery service. The agreements above mentioned are not adopted universally throughout the union, but where separate agreements have to be concluded, they generally follow with only slight variations the principles sanctioned by the union.

At the Congress of Paris in 1947 the union accepted a relationship agreement with the United xations under which it became a specialized agency.

5. Commonwealth Preferential Postage. — The idea of adopting preferential postage rates on political grounds began to develop in the era following the establishment of the Universal Postal union, and it was decided by the Postal Congress of Washington in 1897 that the postal union convention should permit the establishment, by agreement, of rates below the standard postage. This decision, coinciding with a growth of the feeling of the unity of the British commonwealth, led to the introduction in 1899, following a special conference, of "imperial penny postage" at a rate of 1*d.* per one-half ounce to Canada, India, South Africa and the crown colonies generally; it was extended to New Zealand in 1901 and Australia in 1905. Certain foreign countries, including the U.S., which were closely linked with the U.K. by tradition or trade were subsequently included in the scheme, but the preferential rate to these countries was withdrawn in 1957 for financial reasons. Throughout the various changes in letter postage brought about by World Wars I and II the principle of maintaining the initial commonwealth letter rate at the same point as the initial inland rate has been uniformly observed.

(R. A. Le.; R. H. Le.)

IV. POSTAL SERVICE OF THE COMMONWEALTH OF NATIONS

In the early days of colonial expansion the postal services established overseas were in theory and to a large extent in practice under the direct control of the postmaster general of Great Britain. Reasons of practical convenience and the development of autonomy in the dominions and colonies gradually led to the establishment of independent postal services.

1. Australia. — Australia's largest business undertaking, the department of the postmaster general, had its beginning in the colony of New South Wales with the establishment of the first post office in Sydney in 1809.

The Australian post office serves the public through 10,000 offices and employs more than 80,000 persons. The postal system covers not only the handling of mails and the transmission of money, but extends to the management of telephone and telegraph systems of the country and to the maintenance of the technical side of the national broadcasting service.

An overland mail service between Sydney and Melbourne commenced in 1838. Sydney and Melbourne were further linked by telegraph in 1858. and telegraphic communication between Australia and other countries was established in 1872. The telephone was introduced only two years after its invention in 1876, and the first telephone exchange (in Melbourne) was opened in 1880.

Australia's first official air-mail service was established in 1921 between Geraldton and Derby in Western Australia, and was extended through to Perth two years later. In the mid-1950s more than 50 internal networks linked all states with subsidiary services to many parts of the interior, covering a route distance of about 39,000 mi. In addition, overseas air-mail services operate several times weekly, bringing Europe and America within a few days' distance by correspondence.

Before federation in 1901, each of the six colonies had maintained its own postal, telegraph and telephone services, but with the passing of the Post and Telegraph act, 1901, by the new federal parliament, the six separate postal services were combined into one federal system. In 1901–02, the first full financial year of operation under the control of the commonwealth, the expenditure of the Australian post office was less than £2,500,000. Expenditure had reached £10,000,000 by 1921–22 and £20,000,000 by 1941–42. Six years later, expenditure had again doubled to reach £40,000,000. In 1948–49 it amounted to £53,400,000.

2. Canada. — Postal service dates from the French regime when in 1705 a courier first carried official and private mails between Quebec, Trois Rivières and Montreal. The post office was established under the British crown by Benjamin Franklin in about 1763 and formed part of the North American system until the American Revolution. In 1851 the separate Canadian provinces assumed control of their postal services, which were merged into a centralized Canada post office at the time of confederation. At mid-20th century Canada operated approximately 12,000 post offices, with revenue reported at $95,957,469 for the year 1948–49 —a 300% increase in 15 years. All domestic mail not exceeding eight ounces in weight is carried by available air service provided air transmission will expedite delivery. Canada's air-mail service connects with the United States and world air networks and operates directly to the United Kingdom, the Netherlands, Mexico, Peru, the West Indies, Australasia, Japan and Hong Kong. Its money order service has an annual turnover exceeding $690,824,786, and its Post Office Savings bank does a considerable business.

3. India and Pakistan. — From time immemorial communication between the different parts of India was maintained by means of couriers both on horse and on foot by the rulers, but this was limited to the carriage of the rulers' mail. After the occupation of India by the British, a somewhat similar postal service was established by Robert Clive in 1766; but this was also mainly intended for official correspondence, and the same principle was followed for many years during the gradual extension of British rule in India.

The post was first made available to the public in 1774 when a regular organization was set up. It was not until 1837 that it was considered to be sufficiently developed to warrant the establishment of a monopoly in favour of the official post.

The Indian post office prior to partition in 1947 was governed by legislation called the Indian Post Office act. The area to be served is immense, and the cost of transport relatively heavy; moreover, the policy of uniform rates irrespective of distance, adopted in England in 1840, was accepted in India as early as 1854, and the aim of the government was to fix the rate as low as possible, the post office never having been expected to make any considerable profit. India became a founder member of the Universal Postal union in 1876.

The number of letters delivered annually is about 1,837,000,000, an average of six letters a head each year. Post-office work has shown a steady and considerable increase, the volume having doubled in a period of about 20 years by mid-20th century when the inland letter postage was 2 annas (2*d.*), the post-card rate $\frac{3}{4}$ anna, the newspaper charge for a weight of ten tolas only $\frac{1}{2}$ anna. A considerable parcel-post service was maintained at comparatively low rates, a parcel of 40 tolas (1 lb.) being conveyed for any distance for the low charge of 6 annas (*6d.*).

A money order service with an annual turnover of nearly Rs. 1,180,000,000 is maintained, and the value payable (cash or delivery) post, which by mid-20th century had been established in India for more than 70 years, was also highly developed, the annual value being more than Rs. 340,000,000.

India is one of the few countries where first-class mail is carried by air at night and carried on the all-up basis without any surcharge. India was the first country in the world to use aerial post (in 1911) and also the first country in the commonwealth to issue a special set of air-mail stamps (in 1929).

In Pskistan, air-mail service between the eastern and western parts of the nation was set up soon after the partition of India in 1947. Air-mail links were also established with the United States and practically all other foreign countries. Pakistan also joined the Universal Postal union.

4. New Zealand. — The New Zealand post office, ministerially controlled by a postmaster general with cabinet rank and the permanent head of which is the director general, not only provides all kinds of postal service but also controls the telegraph, telephone and radio services. In addition it acts as agent for many other departments; *e.g.*, the land and income tax department, the social security department, the public trust office, the State Advances corporation and the registrar of births, deaths and marriages.

The first post office was established at Kororareka (Bay of Islands) in 1840, and the first postage stamps were issued in 1855. The postal department and the telegraph department were amalgamated in 1881. In 1901 New Zealand introduced penny postage not only inland but with all countries of the empire and also with every foreign country which would accept it, submitting to the Postal Union congress of Rome in 1906 a proposition, which was not successful, for the introduction of penny postage on a universal basis. The initial letter postage rate was ad. in 1950.

Scattered throughout the country were 1,933 post, telegraph and telephone offices in 1949. In addition, an extensive rural system of mail delivery was operated. Altogether there were 50,000 rural box holders. Postal traffic is heavy in relation to the population. During the year ended March 31, 1949, 319,229,000 articles of all kinds were posted, an average of 180 a head.

5. Union of South Africa. — The first regular postal service was introduced in South Africa in 1803 when communication was established between Cape Town and the important centres by Hottentot postboys. These foot messengers were replaced by horsed post orderlies, and subsequently the development of the railways made rapid communication possible on an extensive scale. Later the internal air service provided a means of transmission for letters.

The four states of South Africa maintained their separate post offices until the formation of the Union in 1910, when a centralized postal administration was formed. By the mid-1950s there were 3,422 post offices in the Union employing a staff of more than 32,000 persons. The total volume of postal traffic for 1955 amounted to 929,740,000 articles of all kinds.

The inland letter rate in the mid-1950s was, by surface mail, zd. for the first ounce and *1d.* for each additional ounce; by air, *3d.* for the first ounce and *2d.* for each additional ounce. The post-card rate was *1½d.* (surface) or 2d. (air). Parcels were charged for at the following rates: up to eight ounces in weight, *6d.;* and thereafter, 8d. a pound. An interesting feature is the agricultural parcel post for the conveyance of primary products of the soil, horticultural and dairy produce and foodstuffs produced within the Union at a rate of 3d. for one pound. Cash on delivery and insured parcel services also operate.

South Africa is the contracting party for the regular sea conveyance of the mails exchanged with the United Kingdom.

V. POSTAL SERVICE IN OTHER COUNTRIES

1. France. — The creation of a state post in France is generally held to go back to the edict of Luxies issued by Louis XI in 1464, the authenticity of which is, however, disputed by certain historians.

In the course of the centuries, modifications in organization were introduced by different sovereigns. They all aimed at reducing the existing privileges enjoyed by private messengers and at increasing the control of the royal power over the postal service. The culmination of this policy is the edict of the consuls of the 27th *Prairial,* year IX (June 16, 1801), the provisions of which, fixing the basis of the postal monopoly, are still in force.

The system of "farming" the posts which was tried in England for a short period during the 17th century was maintained in France up to the time of the Revolution. In 1792 the system was suppressed and the posts raised to the status of a national agency. In year III (1794–95) this was replaced by an administration-general of posts and stagecoaches, which was transformed in 1804 by Napoleon I into a directorate-general placed under the authority of the minister of finance. Later, by reason of the importance which the postal service had come to assume in the general economy of the country, the control of the postal administration was entrusted, sometimes to an undersecretary of state attached to a minister, sometimes to a minister. The postal administration is now generally placed under the authority of a secretary of state or of a minister.

In the course of the 19th century and the first half of the 20th century, various services were attached to the postal administration — money orders (1817), telegraphs (1878), telephones (1889), postal cheques (1918), etc. Moreover, in view of the number of post offices (20,000), which permits contact with the mass of the population, the postal service has been given the task of carrying out various operations on behalf of other organizations or administrations (National Savings bank, National Bank for Old-Age Pensions, payment of civil and military pensions, investment of state loans, payment of dividend warrants, etc.).

The following figures will give an idea of the importance of the postal traffic. In the mid-1950s the French posts transported about 6,200,000,000 items of ordinary correspondence and 155,000,000 registered and insured items annually. Moreover. 246,500,000 money and postal orders were issued representing 8,500,000,000,000 fr.

The economic and financial conditions resulting from World Wars I and II made it difficult to stabilize postal charges. These charges are fixed generally in relation to cost. However, with a view to aiding the development of commerce and of public information, certain charges are fixed below cost — in particular, those for printed matter and newspapers. Similarly, for easily comprehensible reasons. the charges for the internal service are applied as a whole to items for the territories of the French union.

The parcel-post service, as in all countries, is the responsibility of the postal administration. In France, however, the operation of the service is entrusted to the French National railways (S.N.C.F.). The relations between the postal administration and the railways are laid down in various documents, notably in a convention signed in 1945.

The National Savings bank created in 1881 operates under state guarantee; it is placed under the authority of the minister of posts, telegraphs and telephones, and is represented in its relations with depositors by the postal administration. In the mid-1950s there were 12,800,000 National Savings bank accounts in existence and the amount standing to the credit of depositors amounted to 664,500,000,000 fr.

Finally, the postal cheque service created in 1918 enjoys an increasing popularity with the French public. In the mid-1950s there were 4,000,000 current accounts in operation, and the total amount of the transactions, debit and credit, carried out in the course of a year reached 54,255,000,000,000 fr.

2. Germany. — In 1919 postal and telecommunications matters in Germany became the exclusive affair of the German reich—the head of the *Reichspost* being the *Reichspostminister* responsible to the *Reichstag* The *Reichspostfinanzgesetz* (Imperial Post Office Finance act) of 1924 established the post office on an independent financial basis analogous to that of a commercial company, so that apart from a tax on revenue the treasury had no claims on post-office finances and vice versa. The post-office administration fixed the estimates of expenditure, decided on questions of borrowing for post-office purposes. redemption of debt, investment of postal cheque office balances, rates of pay, classes of business and rate of postage and telegraph and telephone charges.

The *Reichspostnzinister* was assisted by an administrative council, and decisions of the council were implemented by ordinances issued by him. In 1934 the council was replaced by an advisory committee, a change intended only to simplify procedures and reduce administrative costs. At the capitulation in May 1945 the *Reichspostministerium* completely disintegrated and only the *Reichspostdirektion* (regional headquarters) and subordinate offices remained in any more or less organized form. By order of the Allied military government all post-office services in Germany were suspended.

At this time 70% of the post-office buildings had been seriously damaged and 17% totally destroyed, and the staff and transport were dispersed and disorganized. During 1945 a zonal administration mas set up in each of the British and U.S. zones oi occupation, but these mere replaced by a bizonal administration early in 1947. With the creation in Sept. 1949 of a federal republic covering the British, French and U.S. zones, the bizonal administration gave way to a iederal ministry for posts and telecommunications. At the end of 1949 the new iederal ministry employed in all services, including postal, telecommunications, savings bank, *Postcheck,* etc., about 272,000 people serving a population of 41,500,000.

Despite the serious setback during and immediately after World War II, the volume of business in 1949 approached the 1938 figures with an annual postal traffic amounting to 3,400,000,000 letters, 99,000,000 parcels and 656,000,000 papers and periodicals The savings bank, which remained in business throughout the whole of the financial chaos following the capitulation, had 37,000,000 transactions (deposits and withdrawal?) in 1949 with a turnover of 220,000,000 DM., while the *Postcheck* service transacted business to the value of 132,700,000,000 DM The number oi telegrams reached a peak of 4,000,000 a month in May 1948 but settled doun to an average of 1,800,000 per month or 21,000,000 a year—a figure 50% greater than 1938

The number of telephone installations totalled 1,750,000 or 5% less than in 1938, but the traffic at 112,000,000 local calls and 21,000,000 long-distance calls per month exceeded the 1938 traffic by about 10%. The revenue from posts and telecommunications operations for 1949 was of the order of 1,700,000,000 DM

Transmitting stations for radio broadcasting were provided and maintained by the *Deutschepost* until 1948, in which year they were transferred to the several broadcasting corporations then in existence. The number of listeners' licences at the end of 1949 totalled 6,250,000—20% more than in 1938

POST CARDS. The post card originated in Austria where it was introduced on Oct. 1, 1869. Exactly a year later postal cards, with a halfpenny stamp printed in the corner. were officially issued in Great Britain at 6d. a dozen. One side was for the name and address and the other for correspondence and the cards were court size ($3\frac{1}{2}''\times 44''$). The public demand was so great on the first day of sale that police had to regulate the crowds at the general post office. By 1871 the cards were passing through the mails at the rate of 1,500,000 a week In 1894 a card with an adhesive halfpenny stamp was accepted by the post office and in 1899 the size was increased to $5\frac{1}{2}''$ by $3\frac{1}{2}''$ and half the address side was allowed for correspondence, in addition to the reverse side, which might alternatively be used for an advertisement or a picture.

By this time the picture post card was common in Germany and other European countries. Some cards with small pictures had appeared in Great Britain, but immediately the larger card was alloned, German post-card publishers flooded the English market with chromolithographed cards which sold for 1*d.* or less. English photographers, artists and colour printers soon appreciated the possibilities of this new type of stationery and by the turn of the century the collecting of picture post cards was already becoming a craze. It reached its height around 1904 when an average of 16,000,000 cards was handled by the post office per week. In addition to those which passed through the post, many millions mere collected in a "mint" state, and almost every home had its albums. Most countries had one or more periodicals addressed exclusively to the post-card collector, *The Picture Postcard* (1900–04) being the most popular in England. This was the period when the musical play was popular and portraits of stage favourites were the subjects of an enormous variety of bromide or "real photo" cards, which were a speciality of British and French publishers, although views by the various colour processes formed the largest group in all countries.

In the United States and in the British colonies the craze came a little later. It began to wane everywhere soon after and died out with the advent of World War I. The picture post card, however, still forms an important section of the stationery trade. (W. T. B.)

POSTER. A poster is an announcement publicly exhibited which is designed to be understood at a glance. Advertising an event. product or service, the poster must combine immediate visual effectiveness nith concise communication of a message; it must compete for attention in visually confusing surroundings and yet inform the spectator or communicate the advertiser's message to him. The design of posters is a challenge to the artist. and besides their value as commercial objects many posters are of considerable aesthetic interest. Some of the foremost artists of recent years have devoted themselves to the design of posters, and their work has been studied and collected by students of the arts.

History and Development.— A kind of advertising closely related to the poster is the signboard (*q.v.*) or shop sign, hand painted on a wall or on a piece of wood. Signboards of this kind are still used widely. and they have been present in cities and towns through the ages. In their use of a striking symbol rendered in bold shapes and colours, with wording kept to a minimum, these signs are undoubtedly among the ancestors of the modern poster. But in modern times most posters are printed. and identical copies are posted in many different locations joining familiarity with visual impact in the advertising campaign for which the poster is used.

Printing (*q.v.*), as it now exists, dates from the middle of the 15th century. The first posters which have been preserved date from the early years of printing. Composed almost entirely of text, these posters carried notices of royal proclamations, tax assessments, fairs, markets and newly printed books. From a note on the bottom of one such poster (issued by an English printer and bookseller) it is known that these were meant to be left posted in public places, and hence they were an economical means of carrying a message to great numbers of persons.

Illustrations appear on posters from the early period of printmaking. Handbills often illustrated with crude but spirited woodcuts were used as broadsides which recounted notable happenings; these were essentially newssheets in poster form. The widespread use of posters to advertise products for sale (other than books) does not seem to occur before the early years of the 19th century.

Beginnings of the Modern Poster.— In the 19th century the expansion of industry gave new impetus to poster advertising Now wealthy patronage was available, and also a new method of printing had been devised—a method which allowed brilliantly coloured posters to be produced cheaply and easily.

In 1796 Alois Senefelder devised a method of printing from stone, which he called lithography. (*See* LITHOGRAPH) Since lithography allows the image to be drawn directly onto the printing surface, and does not physically alter the drawing in preparing it for printing, artists soon saw in lithography a medium which allowed them to design posters freely and simply. The firm of Rouchon in Paris was one of the pioneers in poster printing. and boldly coloured lithographic posters issued from it as early as 1845. Among the earliest French artists whose work nas utilized for posters are Paul Baudry and Denis Auguste Raffet.

But it was not until 1867 that the first of the great modern poster artists began his career. Jules Chéret left Paris as a young man, in 1856, to study colour lithography in London. When he returned ten years later, he immediately became interested in the problem of designing theatrical posters. In 1867 ChCret's first poster was published, announcing the appearance of Sarah Bernhardt in the play, La *Biche* au *Bois.* ChCret's style immediately attracted great interest; he used clear, rather pastel colours and shimmering. vignetted backgrounds, against which he placed delicate and elegant figures. His lettering was bold and gaily coloured, and the whole effect of his posters is extremely arresting. The visual impact of ChCret's work, coupled with the fact that he was a prolific worker (he designed about 1,000 posters) make his designs a major influence on later 19th-century posters. But there were other developments as well During the last quarter of the 19th century there was an expansion of the realm of the fine arts. Artists no longer felt constrained to work only in painting or sculpture, but turned as well to designing furnishings, books, textiles and other useful things. Posters were not neglected. Painters such as Edouard Manet, Pierre Bonnard, Edouard Vuillard, and Henri de Toulouse-Lautrec all worked in the field, and the last-named is one of the great masters of the medium.

Toulouse-Lautrec was a master of trenchant characterization. and the means he used in his posters were bold and simple. Inspired by the work of Manet and Edgar Degas, as nell as by Japanese colour woodcuts. Toulouse-Lautrec rendered his designs in large. interestingly shaped areas of bold colour and simple values. He used an exceedingly restricted range of colours and textures. carefully combining his shapes with line for maximum visual effectiveness. His line was bold, but sinuous and sensitive, and his backgrounds were the utmost in simplicity—often consisting of the blank paper itself carefully worked into the design of the whole poster. The lettering of Toulouse-Lautrec's posters was kept to a minimum, and the style of letter he used picked up curving rhythms and colours from the illustrations, welding the entire poster into a unified design. He produced his first poster in 1891, after more than ten years' work at painting and drawing. Between 1891 and 1899 he produced about 30 posters—among them several for clients in England and in the United States.

A contemporary of Toulouse-Lautrec whose work is closely related in style is T. A. Steinlen. The two men worked for some of the same clients, and in fact Steinlen's style seems to have been one of the influences upon Toulouse-Lautrec's early posters. The boldness of their work made Toulouse-Lautrec and Steinlen pioneers of a new movement in poster design. and their influence was felt in every European country and in the United States during the 1890s.

The imprint of these French artists can be found in the work of Edward Penfield and Will Bradley in the U.S. The posters of the "Beggarstaff Brothers" (William Nicholson and James Pryde) in England carry boldness and simplicity even further. Another English artist. Aubrey Beardsley, designed a few posters which had an impact comparable to Toulouse-Lautrec's. Beardsley's elegantly curved thin line, equally elegant solid shapes, and his elaborate linear and dotted textures, created a mood of luxurious and almost mysterious sensuousness. Around 1900 many young artists found this attractive. and Beardsley must join Toulouse-Lautrec as one of the main sources in poster and illustrative art for the so-called *art nouveau* (*q.v.*). England and the U.S. had begun to produce illustrated posters in the 1870s, and with the addition of a style of illustration deriving from the popular painting of the time (*i.e* , the adaptation of Sir John E. Millais' "Bubbles" into a soap poster in England), the posters designed in these countries generally followed French developments. Artists in other European countries produced work along similar lines.

20th-Century Posters.—Around 1900 several new movements in art were forming in the Netherlands, in Germany and in Austria. In the field of poster design. France had previously been a leader, but now for the first time its supremacy as a source for innovation was challenged. Developing further some of the ideas first enunciated by John Ruskin and William Morris, these artists shoaed an interest in crafts, techniques and in machine-made forms; this interest motivated them to make use of simple colour schemes based on primary colours, geometrically derived patterns, etc. Their efforts culminated in the work of the Bauhaus at Weimar and Dessau (1919–28) in Germany. The Bauhaus nas an art school. and the nork of both professors and students gave a new direction to design in posters and in every other field. Although its posters were actually of little significance in themselves, and despite the fact that its more radical innovations were subsequently abandoned, the Bauhaus (*q.v.*) remained the major influence through the mid-20th century.

Artists such as Herbert Bayer, Josef Albers. Gyorgy Kepes and later E. McKnight Kauffer, organized lettering and pictorial matter into clearly-defined rectangular and curved areas. Elaboration of colour and of letter forms was kept to a minimum. and some designers even gave up the use of mixed upper- and lower-case letters to avoid distracting variations in size and shape.

With the growth of the advertising industry in the 20th century, the poster assumed greater importance than ever. Cassandre, Carlu and Savignac were typical of the better French poster designers of the generation following World War I: their work combined simplicity and visual force with genuine wit, and the fame of their posters became world-wide. During World Wars I and II, the major powers involved paid tribute to the effectiveness of the poster in according it many tasks: armed forces were recruited, bond issues advertised. participation in the war effort maintained, all by use of large-scale poster campaigns. James Montgomery Flagg and Ben Shahn were typical of the artists who designed posters for the United States. in World Wars I and II, respectively.

Another aidespread use of posters is to advertise the services of transportation companies. A pioneer in this field was the London Transport company in England. which began in 1908 not only to advertise its services but also to commission prominent and promising artists to design posters describing places which could be reached using the facilities of London Transport. Undoubtedly the entire travel-poster industry owes much to the initiative of the directors of London Transport. By the 1930s virtually every major transportation company was publishing and distributing posters. With the increase in the use of posters in the 20th century, it became necessary to institute measures for the control and limitation of public advertising. Laws to control the dimensions and placement of hanging signs were instituted as early as the 18th century both in England and in France. and similar regulations exist in modern times in many countries the world over. In the 20th century city governmental authority has been exercised to limit the placement of posters on walls, and there exist standardizing and limiting measures to govern the use of free-standing billboards. *See* also ADVERTISING.

POSTE RESTANTE, a facility, generally provided at post offices, for the receipt and care of postal packets addressed to be called for. There are usually strict regulations to prevent abuse or fraud. In the United Kingdom it is stipulated that the words "to be called for" or "poste restante" should appear in the address, and it is notified that the facility is intended solely for the accommodation of strangers and travelers, and that even they may not use it for more than three months. Postal packets addressed to initials, or to fictitious names. or to a Christian name without a surname, are not taken in at the poste restante.

Postal packets may not be redirected from one poste restante to another in the same town or from a private address to a poste restante in the same town Redirection from a poste restante is not undertaken for more than 14 days, unless a longer period, not exceeding three months, is specified on the form of application All persons applving at a poste restante are required to furnish sufficient particulars to prevent mistakes and to ensure delivery to the proper person Where a ship is in question the name of the vessel should always be mentioned.

The words "general deliverv" in the US. are synonymous with "poste restante" A general delixerv window is maintained at every post office in the US and is used for handling mail bearing as a part of its address the endorsement "Transient," "To be called toy," "General Delivery" or other words indicating that it is intended for a transient person, such mail to be delivered upon application and identification At those post offices where deliverv carrier service is maintained, residents who use the general delivery window are required to furnish in writing their names and addresses and the reasons for desiring to use the general delivery instead of the carrier service.

POST EXCHANGE: see CANTEEN.

POSTIMPRESSIONISM. The essential difference between Impressionism and Postimpressionism is perhaps best explained by the description of the former as an objective outlook which results in the rendering of the image received on the retina, and of the latter as the mental image expressed in accordance with a subjective outlook. In other words, while Impressionism is based on strict fidelity to natural appearances, the need of Postimpressionism consists, in the main, of absolute attachment to the personal vision, and, in reality, is the expression of the matter received through the glass of Impressionism to be subsequently subjected to an individual thought process.

The statement which emerges from the artist as a result of this process might well be termed Expressionism, mere it not that this name is more exclusively reserved for the excessively brutal German contribution to the movement under consideration. Postimpressionism (a term coined on the occasion of the first exhibition of the work of Cézanne, Van Gogh and Gauguin in London in 1911) provides an alternative which, if less apt, has the merit of being safe.

Postimpressionism was as much a revolt against the naturalism of the Impressionists as Impressionism was a revolt against the tyrannical academic formula. It replaced analysis by synthesis. It despised representation and gave the artist unbridled licence to amplify and distort the forms of nature, acknowledging no law but the artist's sense of fitness in arranging and organizing the contents of his picture so as to express with the greatest possible directness and intensity the material and spiritual significance of his subject — the "treeness" of the tree, as Roger Fry has it, and the "wallness" of the wall.

Delivered from all restraint and rules, the Postimpressionists were able to proceed by leaps and bounds on their excursions into the realms of synthesis and abstraction, to the utter bewilderment of a public which, accustomed to judging art by the degree of its verisimilitude to nature, nas left floundering hopelessly when attempting to fathom the meaning of these startling artistic manifestations.

A quarter of a century was enough to secure for the initiators and leaders of Postimpressionism a position among the beacon lights of European art. Cézanne, Van Gogh and Gauguin are now referred to as the "glorious triumvirate" and the "old masters of Postimpressionism." Their once-despised, numerous and by no means invariably successful paintings are in most of the galleries of modern art, and thousands of pounds are willingly paid for canvases for which the artists during their lifetime would willingly have accepted a few hundred francs.

Cézanne.—Paul Cezanne, who at the beginning of his career threw in his lot with the Impressionists. upon whose technique he formed his own, was among the first to realize the limitations imposed by the Impressionists' scientifically truthful rendering of colour and atmosphere. His dissatisfaction with what he considered the superficiality of Impressionist productions led him to express, more basically and with greater structural firmness, the essential character of the countryside which forever offered him new vistas, new wonders for his interpretation.

His endeavour, in portraiture and still life, as well as in landscape painting, was to accentuate volume and weight — to make the third dimension more clearly and immediately perceptible to the beholder's eye than it is in actual nature, where we are left to guess by experience and by memory of touch. To him is attributable the dictum that all forms in nature can be reduced to the cube, the cylinder and the pyramid.

Van Gogh.—Like Cézanne, Vincent van Gogh derived his technique from the Impressionists; and like Cézanne, he was anything but a facile worker, his heavy hand being but an inadequate instrument for conveying his passionate aesthetic reaction to the thing seen.

Of him it may truly be said that he did not paint, but rather battled with colour and essential line with a frenzy that took no count of finished execution. His pictures are executed in furiously energetic crosshatchings of pure Prussian blue, emerald green, orange and yellow, with a daring justified only by the brilliant harmonies evolved from a palette on which he found no room for neutral tints.

His brushwork can only be likened to vigorous hatchet strokes, corresponding to the elemental force of his emotions. There was something uncanny in his power to perceive and to express the essential nature of any object or scene or person by which his aesthetic impulse was stirred.

Inanimate things became somehow invested with a soul and with a life of their own—a sunflower. a wicker chair, a cypress tree or whatever it happened to be. He was a visionary who found a deep meaning in the humblest objects which his art invested with his own tortured spirit, and which he made eloquent of his own emotions. Van Gogh was the precursor of Expressionism.

Gauguin.—The third member of the great triumvirate, Paul Gauguin. was a close friend of Van Gogh, but of a less impulsive and more reflective turn of mind. Where Van Gogh would shout and even shriek. Gauguin was content to talk, and his words carried more weight, for they were more considered.

If Cézanne devoted his life to the search for volume, and Van Gogh for material and spiritual significance, Gauguin's revolt against Impressionism took the form of a return to decorative pattern, to two-dimensional design as practised by the artists of the far east. He based his effects on abstract form and colour, not on representational truth or on overaccentuation of some particular truth. Ignoring the colour of nature and relying for the expression of his ideas upon his memory more than upon models, Gauguin produced. first in Brittany, then in Tahiti, those splendours of harmonious decoration against which no arguments founded on convention can ever prevail.

It was his belief that, before the spirit of a place could be interpreted, it needed study in all its parts during what he called a "period of incubation." Some proof of the peace Gauguin found can be seen in the restful nature of his paintings.

Matisse.—Of the second generation of Postimpressionists. Henri Matisse went farther even than Gauguin in reconciling western art with the Chinese. He aimed "at convincing us of the reality of his forms by the continuity and flow of his rhythmic line, by the logic of his space relations, and, above all by an entirely new use of colour." His was an art of extreme synthetic simplification, reducing objects almost to symbols, and disdaining any approach to make-believe of reality. It depended entirely on arabesque and was not concerned with the third dimension.

Cubism.—Cézanne had used colour in block form because, by that means. he could best express his feeling for the neight of whatever he depicted, and its relation to other things presented with it, but he kept to the accepted ideas of representation, which were discarded by his Cubist followers, Picasso, Braque, Dérain and Leger, who evolved a new language from Cézanne's suggestion of space. It was a form of art that had nothing whatever to do with realism. and demanded concentration on aesthetic matters to the absolute exclusion of outside practical appearances and accepted canons of judgment. Cubism bears out Ruskin's theory that an artist may deny other truths to the end that one truth may be more apparent.

Like Impressionism, the name "Cubism" was first used in a derogatory sense; it was Matisse who, in 1908, applied it to a painting in which the subject had received treatment of a markedly cubical character. About as far from the Impressionist objective approach as anything could possibly be, Cubism is really a stride — albeit a long stride — beyond the subjective outlook of the Postimpressionists, in that it takes no heed of visual Appearance and renders what are thought to be essential realities in pure abstract form. Pablo Picasso, the most prominent follower of the Cubist gospel. and, indeed. the creator of certain of its elements. was the exponent of scientific Cubism in its purest sense. Another form of Cubism. less pure, is that which is best described as physical, since its fundamentals are culled from visualized realities.

For example, in those of Picasso's works which are based on physical appearances, the objects are presented in a nay at least sufficiently realistic to enable their perception by the ordinary beholder. although he may be at a loss to account for the shapes which they assume. Their recognition, incidentally, at once displaces the work from the category of Cubism in its strict sense. for that entails matters of line and colour wholly unrelated to objects and figures. since the cult does not intend realism to enter into the question. Georges Braque stands, to some extent. as the codifier of Picasso's inventions, acting as an editor of his snipelike movements.

Thus, the products of Picasso are sobered down and reduced to a state of uncompromising logic before being handed on as standardized material. The art of Femand Leger is concentrated upon the mechanical age into which we are advancing. Working in the gay colours of contemporary life, he extracts excellent design from the solid strength of the mechanized world by which he finds himself enveloped.

Albert Gleizes is a devotee of two-dimensional treatment, and his attitude toward a flat surface is that it has no need of the addition of a sculptural third, for the presence of such constitutes a denial of its very nature. This painter, too, does not regard painting as a form of representation, but of presentation of the spirit of the artist. and not of physical matter. Metzinger, Herbin and Lhote are others of the Cubist persuasion, which has demanded. in its time, every conceivable form of liberty. Orphism, Purism, Synchronism. Simultaneism. Integralism, Dadaism and Numeralism all have had their day, and now the parent bids fair to follow them into oblivion. But although Cubism may prove to have been a blind alley, it has been, and still is, an invaluable discipline for artists in general and had its definite use in saving art from the rut of academic pedantry.

Futurism. — Italian Futurism, initiated, heralded and extolled by the eloquent poet Marinetti, and practised by Boccioni, Severini, Carra, Russolo, Balla and other disciples of the founder, was really an offshoot of Cubism, although the connection was not admitted in the Futurist manifestoes. It differs from Cubism insofar as Cubism is concerned with static conditions, while Futurism is essentially dynamic.

This dynamism aims at cinematographic effects, oblivious of the impossibility of creating on a flat surface the illusion of the sequence of movement. Thus, by depicting a horse with 20 legs in various positions to indicate the movement of the gallop, the Futurist endeavours to express the action of the gallop, but does not get beyond the representation of a static horse with 20 legs. Any attempt to change an art of space into an art of time must needs prove abortive.

The dynamic intention of the Futurists also finds expression in "force lines." that is to say in lines, radiating, swirling. wedge-shaped, to indicate either the direction of movement or the manner in which objects would disintegrate in obedience to the force indicated by their form.

Another tenet of Futurism denies the validity of the resemblance of a portrait to the sitter. To the Futurist, a painting of one object covered by another in such a manner that both are visible is a method of indicating his total disbelief in opacity, while a dozen people can be, at the same time and in turn, ten. three, five in number, as well as simultaneously mobile and immobile. Paintings of a box, firmly shut but at the same time disclosing its contents, also are admissible. Pictures must be looked not at but through. and the spectator must feel himself to be in the midst of them. In England, F. T. Marinetti's fiery eloquence enlisted for a time a small following, which included C. R. 1% Nevinson, who adapted with great skill the Futurist formula for a series of remarkable war paintings.

Vorticism.—The chief English contribution to Postimpressionism, however, was the work of the short-lived group of "Vorticists," who, led by Wyndham Lewis, adopted a modified method of Cubism, and included among their number William Roberts, Edward Wadsworth and F. Etchells. In England, as in most countries, these innovators were regarded as incompetent cranks and charlatans, until their employment in connection with the Canadian war memorials and the Imperial War museum brought them official recognition and public fame.

Expressionism. — In Germany the Postimpressionist movement took root and spread with surprising rapidity. Its most abstract form is to be found in the art of the Russian-born W. Kandinsky, who explained his outlook in a book entitled *The Art of Spiritual Harmony*. Max Pechstein, F. Marc, E. Nolde. Oskar Kokoschka and L. Corinth are the most prominent figures among the German Expressionists, among whom must also be counted Marc Chagall, notwithstanding his Russian birth.

Certainly it would seem that the German activities which correspond to those of the Postimpressionist painters in other European countries should be accorded some distinguishing title of their own. The term "Expressionism," therefore, serves the purpose as well as any other, unless one were found which denotes a combination of truth, bestiality, creation and destruction — all expressed in a manner in which a snarling brutality obscures many finer feelings. At the same time it must be admitted that the artist to whom the Expressionists owe so much, the Swiss Ferdinand Hodler, cannot very well be held responsible for the excesses committed by his imitators or contemporaries.

Man and his relation to the world which contains him were subjected by Hodler to every thought process of which his clear brain was capable. and the resulting statements are models of simplicity. precision and originality. Hodler did not attempt to put the unreasoning at ease by being intimate with them, but compelled them, rather, by an almost holy power, to use their own imagination.

Another artist who with Hodler, Cézanne and Van Gogh left his mark upon the evolution of German Expressionism, was the Norwegian Edward Munch, whose achievement in painting leads from the subjective naturalism of the late 19th century to the Postimpressionist tendencies of the present day.

In the United States the new art-gospel of Postimpressionism or Expressionism was popularized mainly by the activity of Jules Pascin (1885–1930), a Bulgarian by birth, who had been working from 1905 onward for *Simplicissimus* and living in France until 1914, when World War I made him seek a new home in the United States.

Pascin was equally distinguished as an illustrator and as a painter, and his work. though always maintaining a very personal note, showed in turn the influence of Daumier, Cézanne, Degas, Renoir and Picasso. He resorted extensively to distortion for the definite purpose of forceful emphasis, and is in this respect related to the German Expressionists.

Effect on **Other** Arts. — Postimpressionism, in its attempts at synthesis, drew on the past to as great an extent as any other movement, but. ignoring the representational tricks discovered by succeeding generations, adopted only the basic, elementary facts of the unsophisticated and consequently more sincere primitive races.

Exploration has brought to light comparatively modern work, in the form of sculpture, pottery and mat designs, by peoples who, throughout the ages, have known no art teaching or influences save those, possibly, of a conquering but equally primitive tribe. From the Congo, Bakota, Benin and other districts of lesser-known Africa, masks and figures have found their way to Europe, there to reveal, to eager searchers for a means of expressing much without complication, wonders of form and rhythm which were bound to receive the investigation of serious artists.

In the same way that Gauguin found stimulation in the vibrant colours of the Polynesian matmakers, so Jacob Epstein and, to a lesser degree, Ossip Tadkine have been helped to fuller expression by deep study of Negro sculpture.

In almost everything — buildings, furniture, dress, design in the home or theatre and especially, perhaps. in that powerful modern factor, advertising — the effect of Postimpressionism and its more successful descendants is very marked, while the benefits accruing to sculpture and the minor arts — woodcuts, engravings, posters, wallpapers and others — have altered the trend of public thought and freed it, to such extent as slow and inartistic officialdom will allow, from the morass of insincerity and vulgarity which had all but swallowed it up.

POSTL, KARL ANTON (1793–1864), Austrian-U.S. novelist whose pseudonym was CHARLES SEALSFIELD. was born in Moravia on March 3, 1793. Ordained a priest, he left his monastic order in Prague and in the 1820s under a pseudonym traveled in the United States. He became a U.S. citizen but settled in Switzerland in 1832, remaining there except for visits to the United States until his death near Solothurn on May 26, 1864.

Postl's books were originally published anonymously and after the publication of his collected works in Stuttgart in 1j volumes (1845–47) under his pseudonym. His identity was not disclosed until after his death. His works were read widely in both English and German editions during the 19th century. Titles in English included The Cabin Book (Eng. trans. 1844) dealing with life in Texas; Frontier Life (1856) and The *United* States as They Are (1828). Postl nas noted for his attempt to characterize broad cultural groups instead of basing his plots on the actions of individual heroes.

POSTLIMINY. Postliminy is a technical term that international lawyers apply to the status of a government in its own territory when this territory has been reacquired from an invading enemy. The territory reacquired may have been the whole territory of the invaded country or merely a part.

Originally the term postliminy was applied to a different situation. A Roman citizen lost all his civil property and matrimonial rights if he became the prisoner of war of an enemy. If he returned he was automatically restored to all his previous rights and obligations and that restoration was called postliminy.

Some few writers still use the term postliminy in the old Roman sense. and a few apply the term to other postwar restoration problems. An example of the latter would be the return of German assets sequestrated in the United States during World War II. (See ALIEN PROPERTY.)

Postliminy in its chief meaning, which applies to returning sovereigns. operates immediately, long before the peace treaty. Normally in the international law of war all final settlements are postponed until peace treaties are made. Under postliminy, however, the returning sovereign may act immediately as if its government had never been absent. Public property seized by the enemy is immediately reacquired. Enemy legislation may be canceled, even with retroactive effect. Property which the enemy has seized and sold may be restored to the owner. Traitors and collaborationists may be punished.

The logical implications of postliminy are so extreme that other rules of international law and morality have to operate against extreme abuses. For instance it would be going too far under postliminy to annul all criminal sentences, to carry actions against collaborationists to the point of imposing standards of martyrdom on the population or to collect debts and taxes already collected by the enemy.

POST-MORTEM EXAMINATION: see AUTOPSY.

POSTOJNA (It. POSTUMIA, Ger. ADELSBERG), a village of southwestern Slovenia. Yugoslavia, 23 mi. S.S.W. of Lubljana. It was transferred to Yugoslavia from Italy in 1947. Pop. (1953) 4,081.

A mile from the town is the entrance to the stalactite cavern of Postumia, largest in Europe. The cavern is divided into several branches. The Piuca river enters the cavern 60 ft. below its mouth In the sala da ballo (ballroom) grotto a great bail is annually held on Whitmonday, when the chamber is brilliantly illuminated. A mile from the entrance the so-called Elysian fields are reached. from which a view of more than 200 yd. in length can be obtained.

The finest of all, however, is the Grotta del Paradiso. These caves are now joined by a tunnel to the Grotta Vera, and with the abyss of the Piuca, which can be traversed in a boat. The stalactite formations assume fantastic shapes. The length of the passages known is nearly 14 mi. These subterranean wonders were known as far back as 1213 (the earliest names found in it date from 1250) and were probably visited by Dante, who certainly knew the lake of Circonio (Cerkniza) in which the Javornik is reflected. But the cavern remained undiscovered in modern times until 1818.

The Magdalene grotto is celebrated for the extraordinary subterranean amphibian, Proteus anguinus, first discovered there. It is about a foot in length. lives on snails and worms and is provided aith both lungs and gills.

POSTON, CHARLES DEBRILL (1825–1902), U.S. public official, author and explorer, who played an important role in the history of Arizona, was born near Elizabethtown, Ky., on April 20, 1825. Poston worked as a clerk of the state supreme court at Nashville, Tenn., before he moved in 1850 to San Francisco, Calif., where he served as clerk in the United States customhouse.

In search of harbours and mineral deposits, Poston led an expedition along the eastern coast of the Gulf of California and in southern Arizona in 1853. He attempted to begin silver-mining operations in Arizona but abandoned the enterprise in 1861 because of the threat of hostile Apache Indians. He thereafter worked in Washington, D.C., to win territorial government for Arizona. which was granted in 1863.

In that year Pres. Abraham Lincoln appointed Poston superintendent of Indian affairs for Arizona, and he later became the first delegate to congress from the Arizona territory. He was defeated for re-election in 1864.

Poston, who studied irrigation in Asia and Egypt and traveled widely in Europe, was appointed register of the U.S. land office at Florence, Ariz., in 1878. He later served in various official capacities in the southwest and promoted irrigation programs. He also contributed articles to a number of publications and wrote books based on his extensive travels, including Europe in the Summer-Time (1868) and Apache Land (1878), a volume of poems.

Poston died at Phoenix, Ariz., on June 24, 1902. His body was moved in 1925 from Phoenix to the top of Poston's butte, near Florence. Ariz., where a rock monument was erected in his memory. Poston, who became interested in sun worshiping in India, had attempted to establish a temple to the sun on the site.

POSTULATE. Though the propositions of a particular mathematical discipline, or branch of mathematics, are generally established by proof, there must be some unproved first principles, if the process of basing one proposition on others from which it is proved is not to be an infinite regress. Similarly, although the terms used are generally introduced by definition, there must be some undefined terms. These unproved first principles are the postulates, and the terms not defined are the primitive *terms*.

For example, in the case of Peano's postulates for arithmetic (so called after Giuseppe Peano, who proposed them as first principles of arithmetic, though the postulates themselves are due rather to C. S. Peirce and Richard Dedekind), the primitive terms are "0," "number" (in the sense of non-negative whole number) and "successor" (in the sense that $x+1$ is the successor of x). And the postulates themselves are: (1) 0 is a number. (2) Every number has a number as its unique successor. (3) Two numbers having the same successor are identical. (4) 0 is not successor of any number. (5) If 0 belongs to a class F, and if whenever a number x belongs to F the successor of x belongs also to F, then all numbers belong to F.

These may be expressed in logistic notation (see LOGIC) by using an individual constant 0, and two functional constants N and S ("$N(x)$" to mean "x is a number," and "$S(x, y)$" to mean "y is successor of x"). However, the implicit assumption that it is only numbers that have successors is best represented by defining $N(x)$ to stand for $(\exists y)S(x, y)$ (and $N(y)$ to stand for $(\exists x)S(y, x)$, etc.), so that the number of primitive terms is reduced to two. The statement of some of the postulates may then be simplified, and the second postulate is also conveniently divided into two parts: (1) $N(0)$. (2_1) $S(x, y) \supset N(y)$. (2_2) $S(x, y) \supset$.

$S(x, z) \supset y = z$. (3) $S(y, x) \supset . S(z, x) \supset y = z$. (4) $\sim S(x, 0)$. (5) $F(0) \supset . F(x)S(x, y) \supset_{xy} F(y) \supset . N(x) \supset_x F(x)$. The postulates have to be added to an underlying logic, which in this case must be a functional calculus of at least second order (see LOGIC) to make definitions possible of addition and multiplication of numbers.

According to the view now usual, the postulates constitute a definition of the particular mathematical discipline; and a change of one of the postulates to something different or contrary would not be wrong, but would merely lead to the definition of a different discipline. This contrasts with an older view according to which the postulates of arithmetic or of Euclidean geometry are a priori truths. The abandonment of the older view was brought about largely by the discovery of non-Euclidean geometry (see GEOMETRY and MATHEMATICS, FOUNDATIONS OF), since Euclid's parallel postulate and its contradictory lead to two geometries which not only are equally sound logically but, in the absence of experimental evidence against the Euclidean postulate, would be equally applicable to physical space.

A set of postulates is called consistent if, in the mathematical discipline which the postulates determine, not both A and $\sim$A are ever theorems. A particular postulate is independent if it is not a theorem of the discipline determined by the remaining postulates.

In general, a mathematical discipline based on a consistent set of postulates can be strengthened (without adding to the list of primitive terms) by adding new, independent postulates in various alternative ways. But if the set of postulates is categorical, there is a sense in which this is not possible. See CATEGORICAL.

(Ao. C.)

POSTUMIA, VIA, an ancient highroad of northern Italy, constructed in 148 B.C. by the consul Spurius Postumius Albinus. It ran from the coast at Genoa through the mountains to Dertona, Placentia (the termination of the Via Aemilia Lepidi) and Cremona, just east of the point where it crossed the Po. From Cremona the road ran eastward to Bedriacum, where one branch ran left to Verona and thence to the Brenner, the other right to Mantua, Altinum and Aquileia. The military occupation of Liguria depended upon this road. and several of the more important towns owed their origin largely to it. Cremona was its central point, the distances being reckoned from it both eastward and westward.

POSY (a shortened form of poesy, Fr. *poésie,* "poetry") a verse of poetry or a motto, either with a moral or religious sentiment or message of love. often inscribed in a ring or sent with a present, such as a bouquet of flowers. This may be the origin of the common use of the word for a nosegay or bouquet. It has been suggested that this use is due to the custom of the symbolic use of flowers. Walter Skeat quotes the title of a tract (Richard Heber's manuscript, 1442), "A new yeare's guifte, or a posie made upon certen flowers." Posy rings, plain or engraved gold rings with a posy inscribed on the inside of the hoops, were very frequently used as betrothal rings from the 16th to the 18th centuries. Common posies were such lines as "In thee my choice/I do rejoice," "As God decreed/so we agreed," and the like.

POTASH, the crude potassium carbonate obtained by lixiviating wood ashes and evaporating the solution to dryness, an operation at one time carried out in iron pots—hence the name from "pot" and "ash." The term "potash" or "caustic potash" is frequently used for potassium hydroxide. In fertilizer terminology, potassium oxide (K_2O) is called potash. See POTASSIUM.

POTASSIUM, a silvery white metal with a brilliant lustre, is one of the most reactive of the metallic elements. This property is illustrated when it is dropped into water; hydrogen is displaced and both the hydrogen and the potassium take fire burning with a violet flame that usually culminates in a slight explosion.

Potassium is not found in a free state in nature, but in combined form is distributed in nearly all soils and terrestrial waters and many rocks. It is one of the elements important for the nutrition of plants, and its compounds are contained in most plant and animal tissues.

Potassium chloride is an important fertilizer. Other potassium compounds have a wide range of industrial and pharmaceutical applications. Metallic potassium has few uses, the most important being the preparation of potassium superoxide (KO_2) for the manufacture of protective breathing equipment. In the rebreather gas mask, the KO_2 reacts with the exhaled air to liberate oxygen and remove carbon dioxide and water.

The symbol of potassium is K (from kalium, a Latinized form of the Arabic word for alkali). Its atomic number is 19, chemical atomic weight 39.100.

Historical Background.—The history of potassium is closely linked to that of sodium. Materials containing their compounds, particularly carbonates and nitrates, were known and used in some of the earliest civilizations. Native sodium carbonate was used by the Egyptians for making glass as early as the 16th century B.C.; records originating in lower Mesopotamia and dating from the 17th century B.C. mention the use of saltpetre for making glazes. However, the ancient technicians and artisans who used these materials, having no knowledge of the chemical and physical methods of analysis and identification, did not distinguish between similar sodium and potassium compounds. The terms used were often general and implied the source rather than the chemical content of the material. Alkali (*q.v.*) originally referred only to the matenal obtained from the ashes of plants, sodium and potassium carbonates. The term soda (*q.v.*), of unknown etymology, was first applied to any alkali and later to the ash of sea plants, while the term potash (pot-ash) was applied to the ash of land vegetations, both of which generally contained a greater proportion of potassium carbonate. The two alkalies, soda and potash, were successively designated as natural and artificial and as mineral and vegetable. In the first decade of the 15th century, potassium salts were being produced in Scotland from the ashes of seaweed. Finally in the 18th century, after it was shown that the "mineral alkali" occurred in the ashes of sea plants and the "vegetable alkali" in a number of minerals, the terms soda and potash were properly applied to specific substances. Since the chemical nature of these common alkalies had not yet been determined. they were believed by some to be elements. A. Lavoisier did not include them in his list of elements, "because," he stated, "these substances are evidently compounds, although however, the nature of the principles which enter into their composition is still unknown." This problem was finally solved in 1897 by the brilliant young English chemist Sir Humphry Davy, who decomposed both the alkalies, obtaining the metals potassium and sodium. It was he who coined the word "potassium"—a Latinized version of "potash."

Since potassium is one of the strongest reducing agents known, it cannot be isolated by chemical reduction without resorting to unusual conditions which favour the necessary equilibrium shift and permit the removal of the product from the system as it is formed. It is therefore not surprising that potassium and the other alkali metals were prepared only after the discovery of current electricity (1800) and the subsequent development of electrolytic methods. Davy prepared potassium by the electrolysis of molten potassium hydroxide using platinum electrodes. He described the experiment:

> A small piece of pure potash . . . was placed upon an insulated disc of platina, connected with the negative side of the battery . . . ; and a platina wire, communicating with the positive side, was brought in contact with the upper surface of the alkali. . . . The potash began to fuse at both its points of electrization. There was a violent effervescence at the upper surface; at the lower or negative surface, there was no liberation of elastic fluid, but small globules having a high metallic lustre . . . appeared, some of which burnt with explosion and bright flame, as soon as they were formed, and others remained, and were merely tarnished, and finally covered with a white film which formed on their surfaces. These globules, numerous experiments soon showed to be the substance I was in search of and a peculiar inflammable principle the basis of potash.

Occurrence and Production.—It is estimated that potassium constitutes about 2.59% of the igneous rocks of the earth's crust, ranking seventh in order of abundance of elements. Its compounds are widely distributed in the primary rocks, the oceans, the soil, plants and animals. Although nearly as abundant as sodium, it is less accessible, and relatively few workable mineral deposits are available; these contain saline residues formed by the evaporation of inland seas which existed in past geological eras. The principal deposit. at Stassfurt, Ger., contains the following minerals: carnallite, $KCl.MgCl_2.6H_2O$; kieserite, $MgSO_4.H_2O$; polyhalite, $K_2SO_4.MgSO_4.2CaSO_4.2H_2O$; as well as kainite, $MgSO_4.KCl.3H_2O$. Important deposits at Wittelsheim in Alsace and in eastern Galicia, Spain, contain sylvinite, KCl.NaCl. One near Kalusz in the Ukrainian S.S.R. contains sylvite, KCl; langbeinite. $K_2SO_4.2MgSO_4$; and kainite. Additional saline deposits are at Carlsbad, N.M., Cardona, Sp., Searles lake in California, the Dead sea in Palestine, Tunis. Lake Elton in the Urals, and Chile. The above minerals are soluble in water and consequently are easily extracted and readily amenable to chemical operations. They represent, however, only a very small fraction of the total quantity of potassium in the earth's crust, the great bulk of which is found in the igneous rocks.

Potassium occurs as an alkali constituent in a number of alumino-silicate minerals, examples of which are: leucite, $KAl(SiO_3)_2$; muscovite mica, $KAl_3Si_3O_{10}(OH)$, ; orthoclase feldspar, $KAlSi_3O_8$; and biotite, $KHMg_2Al_2(SiO_4)_3$. These and other silicate minerals are insoluble in water and, with the exception of leucite. are not processed for their potassium content. In the weathering of igneous rocks, feldspar. for example, is decomposed into clay and soluble potassium salts; it might be expected that the latter would be ultimately carried to the sea by the surface waters. However, the potassium salts are retained by the soil to a large extent, more so than those of sodium, and are utilized by plants. The retention of the potassium ions by the soil may be a result in part of an ion exchange between potassium and the sodium salt of a complex sodium aluminum silicate which belongs to a class of compounds known as zeolites; *e.g.,*

$$2K^+ + Na_2(Al_2H_4Si_3O_{12}) \rightarrow K_2(Al_2H_4Si_3O_{12}) + 2Na^+$$

Soluble potassium salts which are present in all fertile soils are drawn into the roots of plants and accumulate in the plant structure. In the process of plant metabolism part of the inorganic potassium salts are converted into potassium salts of organic acids (*e.g.,* tartrates and oxalates), which, when the plants are burned, are in turn converted to potassium carbonate. All plant structures are therefore potential sources of potassium compounds. The proportion of potassium present in the total plant or animal organism varies widely, but in most vegetation and in higher animals the potassium content is greater than that of sodium. In sea vegetation the balance is more in favour of sodium, but the potassium content is high and in some seaweeds is in excess of that of sodium. Sugar cane and sugar beets contain significant quantities of potassium salts, but the bulk of it (90%) is extracted with the sugar. The residue pulp from the beet or bagasse from the cane therefore contains very little potassium. However, the molasses remaining after the crystallization of the sugar contains 4%–5% of potassium. In some processes the molasses is mixed with the bagasse and burned as a fuel, and the potassium is recovered from the ash. In others the sugar in the molasses is fermented and the potassium salts concentrated in the vinasse which is the residue liquid from the distillation of the alcohol.

The bulk of the potassium salts of industry is obtained from salt deposits and only a very small fraction (approximately 1%) from plant and animal sources. There remains a vast potential source in the silicate minerals such as leucite, wyomingite and glauconite if economic processes of recovery can be' developed.

A number of processes for the preparation of potassium metal by electrolytic reduction and by chemical reduction have been proposed. In 1808 Joseph Gay-Lussac and Louis Thénard obtained the metal by reducing the hydroxide with iron; the materials, including iron wire or turnings. were packed in a gun barrel which was coated with clay and heated to white heat. During the same year F. R. Curaudau prepared potassium by a somewhat similar procedure in which he'reduced potassium carbonate with carbon:

$$K_2CO_3 + 2C \rightarrow 2K + 3CO$$

This reaction was studied by various chemists during the following 50 years, for it was necessary to devise a method for the separation and rapid cooling of the products in order to prevent the formation of the explosive compound $K_6C_6O_6$. These processes were the forerunners of a number of methods in which potassium compounds were reduced by metals such as magnesium and aluminum, or by calcium carbide, hydride or silicide. With the later development of high-vacuum techniques, the use of calcium for reduction of potassium in a vacuum yields the pure metal; the similar use of sodium vapour as the reducing agent has been fairly successful.

Electrolytic methods include the decomposition of the fused hydroxide, the cyanide and a potassium oxysalt dissolved in a fused potassium halide. The Castner cell, developed in 1890 for the manufacture of sodium (*q.v.*), was modified for the more difficult potassium operation, but the results were not entirely satisfactory.

There is very little. if any, industrial demand for potassium metal, and no extensive manufacturing process is known to be in operation. During the first half of the 19th century, metallic potassium was used to produce aluminum by the reduction of the chloride; magnesium, boron and silicon were produced by a similar method. It was shown in 1854 that sodium, which can be produced more cheaply, would serve as well as potassium for the production of magnesium and aluminum, and sodium was subsequently used for these purposes until electrolytic processes were developed. Similarly, sodium replaced potassium in other industrial processes in which the latter was used.

Properties — Naturally occurring potassium consists of three isotopes of mass numbers 39, 40 and 41 with relative abundances 93.1%, 0.0119% and 6.9%, respectively. The least abundant isotope, K^{40}, is radioactive with a half life of 1.2×10^9 years emitting beta particles (electrons):

$$_{19}K^{40} \rightarrow {}_{20}Ca^{40} + e^{--}$$

and, to a lesser extent, gamma radiation by electron capture:

$$_{19}K^{40} + e^{--} \rightarrow {}_{18}Ar^{40} + \gamma$$

Potassium belongs to the group of alkali metals (Group I of the periodic system) and closely resembles the other elements of the group, lithium, sodium, rubidium, cesium and the short-lived radioactive element francium. The atoms of potassium and the other alkali metals each have a single valence electron which is easily removed whereas the remaining electrons are tightly held by the nucleus in completely filled orbitals. Consequently these elements are the most reactive of all the metals and are the strongest reducing agents known. Their valence or oxidation state is uniformly +1 in all their compounds.

When exposed to air, potassium rapidly tarnishes and becomes coated with a film of oxide or hydroxide. At raom temperatures it is soft and pliable and can be cut with a knife, but below 0° C. it is hard and brittle. The vapour of potassium, which is mainly monatomic, contains a small fraction (about 1%) of diatomic molecules which are indicated by a characteristic band spectrum. The solid metal has a body-centred cubic structure with a = 5.25 A. The vapour of potassium is green and it imparts a violet coloration to the flame of a Bunsen burner. The emission spectrum shows a double line (7,699 Å and 7,664 A) near-the infrared and another near the ultraviolet (4,047 Å and 4,044 Å).

Additional physical and atomic properties are listed in Table I.

Many of the physical and chemical properties of potassium may be correlated with its atomic structure. The difference in the atomic radius and the ionic radius is significant; the volume of the atom is nearly four times as great as that of the ion, the valence electron accounting for nearly three-fourths of the total volume. The potassium atom is the largest of the first 36 elements.

TABLE I.--Properties of Potassium

The valence electron is therefore at a relatively great distance from the nucleus and is easily lost to other atoms in chemical reactions. In the solid metal the valence electrons hold the atoms together; but there are not enough of them to form stable electron pairs, so the binding of an atom to its neighbours is relatively weak and the valence electrons can easily pass from one ion to another. Accordingly potassium is soft, has a low melting point and is a good conductor of electricity.

The chemistry of potassium is relatively simple; it has a valence of +1, it does not form complex ions and it is joined to other elements or groups of elements in its compounds by ionic bonds. Potassium is more reactive than sodium and lithium. It inflames spontaneously in moist air, forming a mixture of oxides. Potassium reacts vigorously with water, liberating hydrogen and forming potassium hydroxide. The reaction is:

$$2K + 2H_2O \rightarrow 2KOH + H_2$$

Potassium reacts with nearly all the electronegative elements, including the halogens, sulfur and phosphorus, forming the corresponding halides, the sulfide and phosphide, respectively; with arsenic and antimony forming K_3As and K_3Sb; and with hydrogen to form the hydride. It reacts with organic compounds containing reactive groups (alcohols, halides, etc.); *e.g.*,

$$2K + 2C_2H_5OH \rightarrow 2C_2H_5OK + H_2$$

and vigorously with acids. When heated gently in the presence of dry ammonia gas, potassium reacts to form the amide:

$$2K + 2NH_3 \rightarrow 2KNH_2 + H_2$$

The amide decomposes into the nitride and ammonia when heated strongly:

$$3KNH_2 \rightarrow K3N + 2NH_3$$

Potassium dissolves in liquid ammonia forming a highly conductive blue solution.

The alloying properties of potassium have not been fully investigated. It does not alloy appreciably with lithium nor with gold, iron, zinc or aluminum. but is mutually soluble with sodium. An alloy containing 22.7% of sodium remains liquid at a minimum temperature of −12.5° C. Potassium reacts vigorously with mercury; a number of compounds of the two elements have been identified, among them KHg_2. A compound of cadmium, $Cd_{12}K$, and one with thallium, KTh, have also been reported.

COMPOUNDS

The compounds of potassium are mostly ionic, and their chemical properties in solution are those of the potassium ion and the respective anions. Practically all the potassium compounds are soluble in water, the exceptions being the perchlorate, $KClO_4$ (slightly soluble); the chloroplatinate. K_2PtCl_6; the acid tartrate, $KHC_4H_4O_6$; the fluosilicate, K_2SiF_6; and the cobaltinitrite, $K_3Co(NO_2)_6$. In this and other respects the salts of potassium resemble those of the ammonium ion, NH_4^+.

Oxides.—Potassium forms three oxides and a fourth of less certain existence has been reported. The monoxide. K_2O, may be prepared by heating the metal in a limited supply of air or by heating the nitrate with potassium:

$$2KNO_3 + 10K \rightarrow 6K_2O + N_2$$

It is a white solid, yellow at high temperatures, and combines with water to form potassium hydroxide, KOH. The peroxide. K_2O_2, an orange-coloured solid, is prepared by the reaction of oxygen and the metal, either dry or in liquid ammonia solution. It is not a common substance for it reacts violently with oxygen to form the superoxide. Potassium superoxide. KO,, the commonest of the superoxides, first prepared by Gay-Lussac and Thénard, is made by heating the metal in air at 180°–200° C. or by treating a liquid ammonia solution of the metal with oxygen at −50° C. It is decomposed by water:

$$2KO_2 + 2H_2O \rightarrow 2KOH + H_2O_2 + O_2$$

and oxidizes carbon monoxide to the dioxide below 100° C. At room temperatures it is an orange-yellow solid which turns black when melted. The melting point is 380° C. and the density is 2.15 g. per cubic centimetre. The compound was for many years formulated as K_2O_4, but X-ray studies show the potassium ions and superoxide ions, O_2^-, to be arranged in tetragonal structure. It is paramagnetic with a susceptibility corresponding to one unpaired electron spin; thus the simpler formula, KO,, is indicated. A trioxide. K_2O_3, has been reported, but its behaviour suggests that it may be a mixture of the peroxide and the superoxide, $K_2O_2.2KO_2$.

Potassium hydroxide, or caustic potash, KOH, was formerly prepared by the reaction of an aqueous solution of potassium carbonate with slaked lime (calcium hydroxide):

$$K_2CO_3 + Ca(OH)_2 \rightarrow CaCO_3 + 2KOH$$

The insoluble calcium carbonate was removed by filtration or sedimentation and the hydroxide recovered by evaporation. This was the primitive process whereby the alkali was obtained for soap-making, wood ashes being the source of the carbonate. It was also the standard industrial method until the end of the 19th century, when it was superseded by the electrolytic process. Potassium hydroxide is now manufactured by the electrolysis of an aqueous solution of potassium chloride, whereby chlorine and hydrogen are also produced. The cell used for this electrolysis must be constructed so as to prevent the intermingling of the hydroxide and the chlorine, which react to give the hypochlorite at low temperatures and the chlorate at higher temperatures. The Nelson cell has a graphite anode which is immersed in the salt solution contained in a perforated double-walled steel vessel which serves as a cathode. The vessel is lined with an asbestos diaphragm through which the solution seeps at a rate which prevents the hydroxide, formed at the cathode, from migrating to the anode region. The Castner-Kellner process utilizes a mercury cathode at which the potassium ion is discharged to form an amalgam and the amalgam, in turn, reacts with water to form the hydroxide solution. In either process the chloride and other impurities are removed from the solution containing the hydroxide by crystallization and the hydroxide is recovered by complete evaporation.

Potassium hydroxide is a white solid, stonelike in appearance and brittle with a fibrous crystalline fracture. The density is 2.04 g. per cubic centimetre and it melts at 380° C. It is deliquescent and is sometimes used as a drying agent; if exposed to air, it absorbs water and carbon dioxide. It is very soluble in water; a saturated solution, for example, contains 52.8% of KOH at 20° C. and the solubility increases with the temperature. Solutions of potassium hydroxide are never saturated at the boiling point, which rises steadily with increasing concentration.

Potassium hydroxide is a strong base, being almost totally ionized in dilute solutions. It reacts with the various acids and acid oxides forming the corresponding salts. As it is more expensive than sodium hydroxide, its use, other than for the manufacture of liquid soaps, is somewhat limited.

Potassium hydride, KH, is prepared by the reaction of hydrogen on the heated metal. It is a white, saltlike compound with a density of 1.43 g. per cubic centimetre and possessing a cubic structure of the sodium chloride type. In the electrolysis of the molten hydrides of this type the hydrogen migrates to the anode, indicating that it is the negative ion. The compound is a strong reducing agent, acting violently on water liberating hydrogen:

$$KH + H_2O \rightarrow KOH + Hz$$

It inflames in air.

Potassium carbonate, K_2CO_3, was formerly obtained almost exclusively by lixiviating plant ashes. The first method used to manufacture this salt on an industrial scale was an adaptation of the Le Blanc process, previously developed in France for the production of sodium carbonate. The Solvay process, used to manufacture sodium carbonate, is not applicable to potassium carbonate production because of a difference in the solubility of the two bicarbonates. The crucial reaction in this process takes place because sodium bicarbonate precipitates from a concentrated solution whereas potassium bicarbonate, which is about three times as soluble, does not precipitate under similar conditions.

Potassium carbonate is now made either by the reaction of carbon dioxide on potassium hydroxide,

$$2KOH + CO_2 \rightarrow K_2CO_3 + Hz0$$

or by the Engel-Precht process. In the latter process, carbon dioxide is passed into a concentrated solution of potassium chloride containing a suspension of hydrated magnesium carbonate. A double salt of magnesium carbonate and potassium bicarbonate precipitates:

$$3(MgCO_3.3H_2O) + 2KCl + CO_2 \rightarrow 2(MgCO_3.KHCO_3.4H_2O) + MgCl_2$$

The double salt decomposes when heated:

$$2(MgCO_3.KHCO_3.4H_2O) \rightarrow 2(MgCO_3.3H_2O) + K_2CO_3 + CO_2 + 3H_2O$$

The magnesium carbonate is removed by filtration and the potassium carbonate crystallized by evaporation of the solution.

The density of potassium carbonate is 2.29 g. per cubic centimetre; the melting point, 881° C.; the solubility in 100 g. of water at 0° C., 105.5 g.; and at 100°, 156 g. Anhydrous potassium carbonate is a white, somewhat deliquescent salt. The hydrate, $2K_2CO_3.3H_2O$, crystallizes in monoclinic form from a concentrated solution; below −6° C. the hydrate $K_2CO_3.6H_2O$ crystallizes.

Although stable toward heat, potassium carbonate is decomposed by steam at red heat temperatures:

$$K_2CO_3 + H_2O \rightarrow 2KOH + CO_2$$

When a saturated solution of the carbonate is treated with carbon dioxide, crystals of the less soluble bicarbonate are precipitated:

$$K_2CO_3 + H_2O + CO_2 \rightarrow 2KHCO_3$$

The normal carbonate of a high degree of purity may be obtained by decomposition of the recrystallized bicarbonate at 190° C.:

$$2KHCO_3 \rightarrow K_2CO_3 + Hz0 + CO_2$$

Potassium carbonate is used in the manufacture of hard glass, liquid soaps and numerous inorganic chemicals.

Halogen Compounds.—The halides of potassium and of the other alkali metals are typical salts, predominantly ionic and soluble in water.

A number of their properties are given in Table II.

TABLE 11.—Properties of the Potassium Halides

Property	KF	KCl	KBr	KI
Melting points, °C.	846	768	748	693
Boiling points, °C.	1,498	1,411	1,376	1,330
Densities, g. per c.c.	2 48	1 99	2.75	3.13
Heats of formation, kg. cal. per mole	134.5	104 9	94.2	78.9
Interatomic distances in crystals, Å	2 66	3 14	3 29	3.53

Potassium fluoride, KF, may be prepared by neutralizing potassium carbonate or hydroxide with hydrofluoric acid, and upon evaporation cubic crystals of the salt are obtained. It forms the acid fluoride, KHF_2, when dissolved in hydrofluoric acid solution.

Upon heating the acid salt decomposes:

$$KHF_2 \rightarrow KF + HF$$

The more complex salts KH_2F_3 and KH_3F_4 have been reported. Potassium fluoride, unlike the other potassium halides, forms hydrates, $KF.2H_2O$ and $KF.4H_2O$.

Potassium chloride, KCl, the most abundant of the naturally occurring potassium salts, closely resembles sodium chloride. It is a constituent of a number of minerals found in the Stassfurt and other deposits, some of which are hydrated double salts; *e.g.,* kainite, $MgSO_4.KCl.3H_2O$. Potassium chloride is used for the preparation of many other potassium compounds, including the hydroxide and the carbonate. More than 90% of the potassium chloride produced is used as a fertilizer.

Potassium bromide, KBr, is prepared by the reaction of bromine and potassium hydroxide:

$$3Br_2 + 6KOH \rightarrow 5KBr + KBrO_3 + 3H_2O$$

The bromate decomposes upon heating to form more of the bromide:

$$2KBrO_3 \rightarrow 2KBr + 3O_2$$

Another method of preparation utilizes a solution of ferric and ferrous bromides, a by-product from one of the technical processes for the production of bromine. The iron bromides react with potassium carbonate solution,

$$FeBr_2 + 2FeBr_3 + 4K_2CO_3 \rightarrow 8KBr + Fe_3O_4 + 4CO_2$$

and the ferrosoferric oxide is removed by filtration. Potassium bromide is also obtained from natural brines. It is used in the preparation of photographic emulsions, in process engraving and in medicine as a sedative.

Potassium iodide, KI, is prepared by the reaction of iodine and potassium hydroxide solution:

$$3I_2 + 6KOH \rightarrow 5KI + KIO_3 + 3H_2O$$

Upon evaporation and further heating, usually after the addition of some charcoal, the iodate decomposes, yielding more iodide. The iodate may also be reduced to the iodide in solution by bisulfite ion, stannous ion or a suitable metal such as iron. Iodine dissolves in solutions of potassium iodide by forming the complex tri-iodide, KI_3; higher polyiodide ions containing an odd number of atoms, I_5^-, I_7^- and I_9^-, are formed in very concentrated solutions. Upon evaporation of the KI_3 solution, dark-blue or black crystals of the salt are obtained. Potassium iodide is used in the manufacture of photographic emulsions, in organic chemical syntheses, in animal and poultry feed, in table salt and in some drinking waters. In medicine it is used with iodine for the treatment of hyperthyroidism, and the salt containing radioactive iodine is used in the study and treatment of thyroid cancer. For the oxyhalogen salts see BROMINE; CHLORINE; IODINE.

Sulfur Compounds.—Potassium sulfate, K_2SO_4, a constituent of a number of saline minerals, is a colourless or white compound crystallizing in the rhombic form. Its density is 2.66 g. per cubic centimetre, melting point 1,067° C., refractive index 1.4947 and solubility 24.1 g. per 100 g. of water at 100° C. It is used in fertilizers, as an antiflash agent in smokeless powders and in the manufacture of potassium alums, potassium carbonate and glass.

Potassium bisulfate, $KHSO_4$, is a white, deliquescent substance with a density of 2.4 g. per cubic centimetre and melting point of 210° C. At a high temperature it is converted to the pyrosulfate:

$$2KHSO_4 \rightarrow K_2S_2O_7 + Hz0$$

It is soluble in water, the solution being somewhat acidic because of the ionization of the HSO_4^- ion. Electrolysis of the solution yields the sparingly soluble potassium peroxydisulfate, $K_2S_2O_8$. Potassium bisulfate is used as a flux in the analysis of ores and as a chemical intermediate.

Potassium sulfite, K_2SO_3, is prepared by saturating a solution of potassium hydroxide or carbonate with sulfur dioxide. It exists in the anhydrous form, the monohydrate and the dihydrate, $K_2SO_3.2H_2O$, the latter being the commonest. The solubility of the salt is fairly constant over a wide range of temperature.

Potassium sulfide, K_2S, is a yellow or yellowish-red crystalline substance. It may be prepared by the direct combination of potassium and sulfur or by the reduction of potassium sulfate with carbon or hydrogen. In water solution it is strongly alkaline because of the extensive hydrolysis of the sulfide ion. Upon treatment with sulfur, polysulfides, K_2S_x, with as many as six sulfur atoms are formed. The salt has little use except as a laboratory reagent and a depilatory. See SULFUR.

Potassium nitrate, KNO_3, also called nitre or saltpetre, is a white crystalline salt with a density of 2.11 g. per cubic centimetre, a melting point of 333° C. and a refractive index of 1.5038. It decomposes at 400° C. to potassium nitrite, KNO_2, and oxygen. Since the quantity of the salt obtained from natural deposits is limited, it is prepared by the reaction either of synthetic nitric acid and potassium hydroxide or of naturally occurring potassium chloride and sodium nitrate. It is used in the manufacture of fireworks, gunpowder, fluxes and glass and for curing meats, pickling, tempering steel and impregnating candle wicks. *See* NITRIC ACID AND NITRATES; NITROGEN.

Determination.—Potassium may be identified by its emission spectrum or by the violet colour which its compounds impart to the Bunsen flame; if sodium is present the violet flame is masked and can be observed only through a suitable filter such as cobalt glass. Potassium may be identified and gravimetrically determined in the presence of the alkali metals by precipitation as potassium cobaltinitrite, $K_3Co(NO_2)_6$. Ammonium cobaltinitrite is insoluble and similar in appearance to the potassium salt. It is therefore necessary to eliminate ammonium ion from a sample before testing for potassium. Other gravimetric methods involve the precipitation of potassium perchlorate or of potassium chloride. The flame photometer is also used to quantitatively determine potassium. Another procedure involves the elution of the sample with hydrochloric acid in an ion exchange column. The potassium ion moves through the column at a characteristic rate and the solution carrying it is collected, evaporated and weighed as potassium chloride.

PHARMACOLOGY

The principal salts and preparations of potassium used in medicine are the following:

Potassium acetate has been recommended in cardiac arrhythmias, potassium arsenite solution (Fowler's solution contains 1% of arsenic trioxide) for chronic myelogenous leukemia and psoriasis. Potassium bicarbonate is used as antacid and to alkalize urine. Potassium bitartrate (cream of tartar) has been used as a laxative and dusting powder; large doses can cause renal damage. Potassium bromide is used as a sedative and as an antiepileptic. Potassium chlorate has been used as an astringent in conditions such as stomatitis and Vincent's angina. Potassium dichromate has been used externally as an astringent, antiseptic and caustic; industrial contact may result in ulceration of the hands and destruction of mucous membranes; internally it is a corrosive poison Potassium glycerophosphate has been used as a tonic. Potassium guaiacolsulfonate (thiocol; orthocol) has been recommended as an expectorant. Potassium hydroxide occasionally is used as a caustic; it is extremely corrosive. Potassium permanganate is used as an astringent, antiseptic and oxidizing agent in 1:100 to 1:10,000 solutions; toxic symptoms include emesis, profuse salivation, rapid respiration and albuminuria. Potassium phosphate, monobasic, is used to acidify urine; large doses are cathartic. Potassium sodium tartrate (Rochelle or Seignette salt) is used as a diuretic and as a cathartic. Potassium sulfate is used as a cathartic; it is a powerful irritant, excess doses of which may be fatal. Potassium tartrate (soluble tartar) has been used as a cathartic.

Toxicology.—The symptoms of poisoning by potassium hydroxide or other caustic alkalies are violent pain in the throat, vomiting and collapse. If not immediately fatal, stricture of the esophagus may develop. In emergency treatment the patient is given large amounts of dilute acetic acid (1%), vinegar (1:4), citric acid (1%) or lemon juice, followed by milk or whites of eggs beaten with water. Vomiting should not be induced.

(J. B. Ps.)

POTATO, white potato or Irish potato, cultivated in North America and Europe for its edible tubers, is *Solanum tuberosum*, one of about 100 tuber-bearing species of the section *Tuberarium* in the genus *Solanum*, one of the largest genera of plants. including also the eggplant and many ornamental and narcotic poisonous plants, of the nightshade family (Solanaceae; *q.v.*). Most of the cultivated potatoes of the Andean region of South America are of the species S. *andigenum*. Other tuber-bearing species resemble wild forms; some are cultivated to a small extent but only in the Andean region.

In this article, unless otherwise specified, "potato" refers to *S. tuberosum*.

This article is divided into the following sections:

I. ORIGIN AND EARLY HISTORY

S. tuberosum apparently originated in the Chilean area of South America. S. *andigenum* and a great many other species originated in the Peru-Ecuador-Bolivia area, where the wild species still abound. All species are native to cool climates, and the cultivated forms require relatively cool and moist climates (a mean annual temperature of 40° to 50° F.). *S. tuberosum*, the cultivated potato of North America and Europe, is best adapted to long summer days, characteristic of the high southern latitude of its region of origin. *S. andigenum* is adapted to short days, characteristic of its equatorial origin. Many species were grown by the Indians of South America before discovery by Europeans.

POTATO (**SOLANUM** TUBEROSUM) SHOWING (LEFT) UNDERGROUND STEMS AND TUBERS. (RIGHT) FLOWER AND FRUIT

(A) Single flower. (B) Fruit cut across to show placenta and developing ovules. (C) Longitudinal section through flower. (D) Ripe anther opening and shedding pollen. (E) Longitudinal section through ovary. (F) Fruit

When potatoes (probably not *S. tuberosum)* were first seen by Europeans in the Andean region in 1537, they were erroneously thought to be truffles. In 1577 Sir Francis Drake found *S. tuberosum* being used by the Indians as a staple food in southern Chile. The species was used as food on Spanish ships soon thereafter. There is, however, no clear record as to when and by whom it was first introduced into Europe. No support is known for the claim that it was introduced into Spain in 1553. Evidence suggests that it was introduced there as early as 1565 to 1570, however, and it was known in Italian gardens in the 1580s. R. N. Salaman cites basis for the belief that Sir Walter Raleigh introduced it into Ireland about 1588. The first description of potato was in John

Gerard's *Herball*, published in 1597. Salaman points out that the illustration Gerard used was a woodcut from Jacob Bergzabern's Neuw Kreuterbuch (1588). Potatoes were introduced into Virginia in 1621 from Bermuda, where they had been taken from England. In 1719 migrants from Ireland took potatoes to Londonderry, N.H., where potato growing in the U.S. got its best start.

II. THE POTATO PLANT

1. Plant Characteristics. — S. tuberosum is a herbaceous annual (two to three feet in height) normally propagated by tubers. Seeds do not produce plants true to variety. Aerial stems are erect or procumbent, with or without axillary branches; stems are round or angular, hairy or smooth, green or tinged with purple. The first leaf is usually simple. other leaves having three or four pairs of large, simple, petioled leaflets and smaller leaflets in between. Leaves are arranged spirally on the stem. Fibrous roots arise in groups of three above the nodes on the stem below ground.

The cymose inflorescences occur at about every sixth axil. Flowers open progressively over several days, are without nectar and are rarely visited by insects. The corolla is wheel-shaped, five-lobed and white, yellow, blue, purple or striped; the five erect stamens borne on-the corolla tube converge around the pistil and discharge pollen by terminal pores. The ovary is two-celled with a single style. The fruit is a globular, brownish-green or purple, inedible berry, usually $\frac{1}{2}$ to $\frac{3}{4}$ in. in diameter with many, tiny, smooth, kidney-shaped seeds in the soft flesh.

Lateral stolons extend from axils of the main stem below ground. The ends of the stolons enlarge, forming greatly thickened, succulent, nonwoody, stem structures called tubers. The eyes of the tuber are axils (with the subtended leaf scars of aborted leaves) of this stem, with their terminal and lateral axillary buds. Normally only the terminal bud grows from an eye. but if it is destroyed one or more lateral buds arise. Sprouts normally arise from one or a few eyes at the apical end of the tuber. This apical dominance is destroyed when the tuber is cut into pieces, permitting eyes on each piece to grow. Repeated destruction of sprouts and weakening of the tuber by various means also destroys apical dominance and causes multiple sprouting.

The tuber is covered by a thin, tough, impervious, corky skin. The interior of the tuber contains obscure vascular strands that lie near the surface and lead to the eyes, an outer zone of cells heavily packed with starch and other storage materials and an inner zone having lower content of solids than the outer zone.

2. Varieties. — Several hundred varieties of potatoes are grown in the world. They differ in time of maturity, appearance, skin colour, cooking and marketing qualities, yield and resistance to insects and diseases. A variety that is good in one area may be poor in another. As to maturity, they are classed as first early, second early, midseason and main or late crop. (See Potato Breeding, below.)

III. POTATO CULTURE

1. Seed Potatoes. — For planting purposes potato tubers should be as nearly disease free as feasible because tuber-borne diseases will spread in the field. To minimize disease hazards and ensure varietal purity many countries have established official agencies for inspection of potatoes grown for seed (seed potatoes or seed tubers). The potatoes are certified as being free of certain diseases.

Certified seed is produced in relatively cool districts where diseases are detectable, not being masked by the effects of high temperature. In the U.S. about 25 states produce 45,000,000 to 55,000,000 bu. of certified seed potatoes annually. About half of these are produced in Maine, and Minnesota, North Dakota, Idaho and California produce over 1,000,000 bu. each. In Canada the three maritime provinces produce about 10,000,000 to 11,000,000 bu. annually. Katahdin, Russet Burbank, Red Pontiac, Kennebec, Sebago, Irish Cobbler and White Rose constitute over half the volume of certified seed in the two countries. About 50 other varieties in the U.S. and a dozen others in Canada also are certified.

For planting, tubers must have emerged from dormancy, which in most varieties lasts about two months following harvest. Tubers must have been properly stored and not stored so long as to weaken sprout-producing capacity. Upon harvesting, seed potatoes are stored for two to three weeks at 60° to 70° F. at high humidity to promote development of the corky skin and the healing of wounds, then held at 38" to 40° until three to four weeks before planting time. The temperature is then raised to 50° to stimulate slight sprout development, so that vigorous sprouting can follow promptly after planting.

In some parts of Europe the seed tubers commonly are exposed to light until green sprouts develop before planting, but in the U.S. experimentation showed that there is no advantage to this practice. Cut pieces for planting must contain a bud and should be "blocky" in shape. Tubers or pieces to be planted should weigh at least $1\frac{1}{2}$ oz., preferably 2 oz. Smaller tubers or seed pieces produce less vigorous sprouts and lower yields. Tubers can be cut for seed many weeks before planting if, immediately after cutting, they are held at 60° to 70° F. and high humidity for five or six days to heal the cut surfaces before returning them to cool storage. Such suberization of seed pieces makes them less susceptible to decay than freshly cut seed when planted, and often results in better stands and yields.

2. Soils. — Potatoes are grown profitably on almost all kinds of crop-producing soils except very heavy clays. Deep, friable, rich, moderately acid sandy loams and loams that are high in organic matter are best. Good drainage is essential. Some of the highest yields in the U.S. and some parts of Europe are obtained on loams and mucks, but the highest quality generally is obtained on good mineral soils. The highest yields in England are produced on silt, peat warp and skirty soils. Acid soils of pH 4.8 to 5.3 are desired because scab disease is generally less severe on such soils; yields are low on many alkaline soils.

The soils on which potatoes are grown in different regions are plowed and fitted as they would be for most common farm crops in those regions. They are plowed moderately deeply, eight to ten inches, to cover crop residues and incorporate them into the soil, then disked or harrowed to prepare a medium that is free of clods and trash in which the seed pieces may be planted.

3. Fertilizing. — Fertility of the soil is determined largely by the humus content and by applications of fertilizers. Organic matter or humus is supplied to the soil from crop refuse, rotation with other crops and application of animal manures. In Scotland, England and Ireland, the usual application of animal manure is about 12 tons per acre, supplemented by mineral fertilizers. Seaweed in coastal districts and shoddy or other bulky organic manures in certain other areas in England sometimes replace part of the animal manure. In the United States animal manures are used only on a small portion of the potato acreage, grown by dairy farmers.

Fertilization of the potato crop varies considerably from country to country, state to state and farm to farm with reference to the analysis of the fertilizer and its rate of application. These variations are due to differences in soil type, native fertility of soils, rotations used, soil reaction, rainfall and temperature, varieties used and other factors. Applications of commercial fertilizer in the U.S. and Canada range from none, on some of the rich soils of the west, to a ton or more per acre, depending upon local conditions. The ratios of nitrogen-superphosphate-potash most commonly applied are approximately 1–1–1, 1–2–1, 1–2–2 and 2–3–3. Common analyses of such mixtures in percent are, respectively: 8–8–8, 5–10–5, 5–10–10 and 6–9–9. Fertilizers of higher analyses but similar ratios are used in some districts, especially those requiring large applications. Less fertilizer is used with manure than without manure; often superphosphate only is used with manure. Nitrogen alone may be used on some good mineral soils; superphosphate and potash may be used without nitrogen on some muck soils. Some western soils show no need for added potash.

Responses to Fertilizers. — In western Australia one of the most profitable potato fertilizers proved to be a mixture supplying 200 lb. ammonium sulfate, 800 lb. 22% superphosphate and 100 lb. potassium sulfate per acre. On virgin peat soil 800 lb. superphosphate was found adequate; on old potato soils 400 lb.

gave optimal yields, while on land that had been in pasture 1.600 lb. per acre gave best yields. Potassium is least necessary in that part of Australia.

Nitrogen is of primary importance for high yields of potatoes. Abundant nitrogen produces extensive foliage and prolongs the growing season. With insufficient nitrogen the plants are stunted, leaves are small and light-green colour, the period of growth is reduced and the yields are small. Potato plants producing 400 to 500 bu. per acre contain 120 to 160 lb. of nitrogen per acre. Depending on the native fertility of the soils, soil moisture and other factors, potatoes receive nitrogen applications in commercial fertilizers ranging from none in certain areas in western United States to as much as 160 lb. of nitrogen in some northeastern states.

Response of potatoes to phosphorus applications varies tremendously among potato growing areas. These differences are due largely to the native supply of available phosphorus in some areas in the middle- and far-western United States compared with the eastern and southern areas and also to the large accumulated supplies of phosphorus in some of the eastern soils as a result of annual applications of high quantities of phosphorus. Because of this accumulation from repeated heavy applications more phosphorus is used in some eastern parts of the United States than is necessary for maximum yields.

Potash fertilization for potatoes in the United States varies from none in some of the western areas to as much as 450 lb. K_2O per acre in some portions of the northeast. The chlorine in muriate of potash has a depressing effect on the starch content of tubers and sometimes on the yields when compared with sulfate of potash.

In some of the large potato growing areas of England such as Lincoln and Yorkshire, when the crop follows grain, large quantities of fertilizer are used.. Applications are common of 1,500 lb. per acre of 6–7–10 fertilizer made up of 450 lb. ammonium sulfate, 600 lb. superphosphate and 300 lb. muriate of potash. When potatoes receive applications of animal manures, and in less intensive growing areas where early, second early and main crop potatoes are grown following grain or clover sod, the fertilizer applications are reduced.

Many soils in which potatoes are grown in northeastern United States and along the Atlantic seaboard are deficient in available magnesium for optimum growth of potatoes. These soils are highly acid in reaction. Some of these acid soils, however, do not need magnesium applications, but they respond to additions of calcium in the form of limestone or hydrated lime. Applications of magnesium sulfate are beneficial to the crop in some parts of England. In the United States magnesium in the form of sulfate is sometimes applied as a spray to deficient plants. Soil applications where needed usually are of sulfate of potash-magnesia or of magnesium oxide.

Most soils used in potato production apparently have a sufficient supply of available minor or trace elements and hence do not respond to additions of these elements. On a few soil types, however, and in some limited areas a deficiency occurs and the potato plant responds to applications of one or more minor elements.

Iron deficiency has been experienced in England and has been corrected by spray applications of ferrous sulfate solutions to the foliage.

Manganese deficiency is prevalent in the Fens, Romney Marsh and Yorkshire and occurs occasionally in other parts of Great Britain. Spray applications of 1% manganese sulfate solution at roo gal. per acre supplied the necessary manganese. On neutral sandy swamp soils in western Australia potatoes responded markedly when given five to ten pound-per-acre applications of copper sulfate. The quality of Flava and Ackersegen potatoes was improved by minute applications of boron in Switzerland.

Time and Method of Application.—In most countries of Europe commercial fertilizer is either broadcast after plowing and fitted into the soil before planting or it is distributed in the row just before or after planting. These usually are separate operations as contrasted with the single operation in Canada and the United States of planting and distributing fertilizer in bands on both sides of the seed piece. At the high rates of application used in these countries, this method prevents direct contact of seed piece and fertilizer and therefore avoids burning of the seed or sprout, In some areas of eastern United States, a portion of the fertilizer is applied broadcast before plowing, the remainder being applied in bands through the planter. In some regions of western Europe each of the fertilizers is applied broadcast separately and at different times. The potash is applied in the fall preceding the crop, phosphorus is applied several weeks before planting and nitrogen is broadcast just before or after planting.

4. Rotations and Organic Matter Content of Soils.—It has been shown repeatedly that potatoes grow better in soils relatively high in organic matter. Rotations in which potatoes follow a green-manure crop or one contributing plant residues usually result in increased potato yields. Greatest response to green manures usually is obtained in soils relatively low in organic matter.

Many types of rotations are used in various parts of the world. In some areas in eastern United States potatoes are grown year after year on the same soil. In some parts of Long Island, N.Y., as many as 75 successive crops of potatoes were grown in the same number of years. Rye is usually sown as a cover crop at harvest time and plowed under the following spring. In other eastern areas potatoes are grown in two- or three-year rotations with a small grain, wheat or oats, which has been seeded with one of the clovers, often mammoth red clover. The grain usually is harvested by combine so that nothing but the seed is removed from the field. The clover may be plowed down the following spring as a two-year rotation or allowed to remain the third year and plowed under the next spring. In southern United States soybeans and cowpeas are grown in the potato rotation to supply organic matter to the soil. In western United States potatoes are grown in rotations with alfalfa, sugar beets, sweet clover, small grains or other crops. Many of the rotations containing alfalfa maintain this crop for two to seven years, then potatoes are planted, follo ed by a small grain and then alfalfa again. Dry-land farmers often plant potatoes on summer fallowed land or after some cultivated crop such as beans or corn. Redtop, crimson clover, lespedeza, millet and Sudan grass are often planted in a two-year rotation with potatoes.

As potato growing became more and more a specialized industry, with less being grown by dairymen and general farmers, the rotations became shorter, with potatoes appearing more frequently on the same piece of land.

In England potatoes often follow oats in the rotation. In some areas potatoes follow hay or pasture, especially of wild white clover, and in some sections potatoes follow potatoes. Special crops are also grown for plowing in as green manure, the commonest being rye, Italian ryegrass, rape and vetch.

5. Planting.— In the United States potatoes are planted in nine months of the year. In some of the southern states potatoes are planted in November and December for winter harvest. Later plantings are made in other areas as the season progresses. Most planting is completed by July 1. For the main crop in the northern states, planting should be as early as the soil can be fitted. The critical period in the life of the potato plant occurs when it is developing tubers, and for maximum yields it is necessary that climatic conditions be as favourable as possible during that time. Cool air and soil temperature and ample soil moisture are conducive to maximum growth, setting of tubers and their enlargement.

Virtually all potatoes in the United States are planted with machines. The machine planters are of two general types, the picker and the assisted feed. Two-row planters predominate but there are some one-, three- and four-row planters. The larger planters are adapted only to large, long rowed areas where the land is comparatively level and free of rocks. The rate of planting is determined by the spacing of rows, spacing of seed pieces in the row and size of seed pieces. The rate used is dependent on the natural fertility of the soil, its moisture-holding capacity and the amount of fertilizer that is to be applied. Row spacings in the northern areas of the United States are from 33 to 36 in. In the southern states row spacings often are somewhat greater.

In many parts of Europe planting is done by hand or with machines which require hand labour to place the seed pieces in cups of a chain. The rows are commonly 26 in. apart or less.

As methods of growing improved, space between plants in the row was reduced from about one foot to as close as six to seven inches, especially for producing tubers for seed or to minimize the development of oversize tubers in such varieties as Katahdin and Kennebec which set few tubers per plant. Spacing may be closer where soil and climate favour heavy yields than where medium or light yields generally are obtainable. To plant an acre with two-ounce pieces 8 in. apart in rows 34 in. apart requires 48 bu. of tubers cut into more than 23,000 pieces.

Optimum depth of planting depends on temperature and moisture of the soil, probable weather following planting and mode of conducting field operations later. If planting is shallow, about two inches deep, the soil must be gradually ridged over the row incidental to cultivation. This ensures that the developing tubers are well covered with soil to protect them from light and pests. Early plantings for quick emergence are about two inches deep. Late plantings and plantings for flat culture are about four inches below field level with a two-inch covering of soil. Covering to four inches in depth is completed after the plants have emerged. Shallow planting and quick emergence help avoid losses from rhizoctonia (see Fungus Diseases below). If the soil is hot and dry at shallow depth the pieces should be put deeper, in cooler moist soil.

6. Cultivation. — Potatoes are cultivated mainly to control weeds, but also to break any obstructive crust that may form on the soil surface and to ridge soil over the developing tubers. In some districts the first cultivation consists merely of harrowing the entire soil surface as shallowly as possible just before the plants emerge. In other districts a shallow weeder or cultivator is used. All cultivation must be shallow to avoid injuring the potato roots; working too close to the plants may injure tubers near the surface. Compaction of the soil with heavy machinery and unnecessarily frequent workings are to be avoided. Cultivation should be discontinued at full bloom of the plants or when they nearly meet between the rows. Some cultivation is necessary later to control late-appearing weeds and to move soil over the row to ensure against exposure of shallow-lying tubers.

In some districts weeds are largely controlled by spraying the soil surface with a herbicide before the plants emerge.

7. Effect of Climate on Yield. — The potato tuber is a storage organ, an enlarged stem, and starch is the main material stored. Conditions which favour the formation and storage of starch are necessary for maximum tuber growth. Sugars are formed in the leaves as a product of photosynthesis and starch is synthesized from the simple sugars. The same materials are also used to provide energy for plant growth. Therefore, to have growth and enlargement of the tubers there must be an excess of carbohydrates above that used for vegetative growth.

Rate of photosynthesis is affected by light intensity, temperature, carbon dioxide supply, chlorophyll content of the leaves and stem, and the accumulation of sugars in the tops of the plants. Maximum yield occurs when foliage growth is extensive and rapid early in the season and later declines or ceases; at this time weather conditions should favour photosynthesis, and later the plant should die slowly.

Length of Day. — Long, warm days are most suitable for the growth of tops in the potato. Shorter days are more beneficial for tuber formation. Therefore, conditions most suitable for maximum tuber yields are long days which favour large top growth followed by short days to stimulate tuber formation.

Temperature. — By influencing the rate of photosynthesis and rate of respiration, temperature affects tuber formation and yields of potatoes. Optimum temperatures for tuber formation are from about 59° to 64° F. Usually no tubers are formed above 84° F. In many sections of the U.S. where temperatures during the growing season are above the optimum of 59°–64° there is a negative correlation between temperature and yield. In England and most of Ireland the average growing season temperature is near the optimum. In Scotland it is somewhat lower than the optimum. In some midwestern areas in the United States and in some parts of Australia yields are relatively low, primarily because of the prevailing high temperatures.

There is an interaction between the effect of temperature and day length or photoperiod. By reducing the photoperiod to $10\frac{1}{2}$ hr. tuber formation has occurred at 90° F.

Sunlight. — Little is known regarding the definite effects of sunlight on the growth of potatoes, although it must influence rate of photosynthesis. It is known that shaded plants produce tubers much lower in specific gravity and dry matter than those in normal sunlight.

Rainfall. — In many areas there is a direct correlation between rainfall and yield of potatoes. This is true where rainfall is low and growth of foliage and tubers suffers from lack of moisture. On the other hand, in areas or seasons where rainfall is excessive—interfering with cultivation, waterlogging the soil, etc.—an increase in rainfall may be associated with reduction in yield.

8. Irrigation. — Since rainfall is so important in potato production and since many areas receive insufficient amounts for best growth, irrigation is utilized to supplement this rainfall. In some areas in western United States it is infeasible to try to grow potatoes without irrigation. In these areas furrow irrigation is practised. Furrows are usually made between each row or every other row. On flat areas of heavy soil the furrows should be deep and narrow so that the water will be applied to the soil below the tubers and will not wet the tops of the ridges before it has reached the opposite ends of the rows. Small furrows should be used on steep slopes or in soil that washes badly. Length of the furrows should be determined by the rate at which the soil absorbs water. From three to ten applications are necessary during each growing season. Frequent light applications of water of two to four acre-inches give better results than less frequent heavy applications. All the soil except the tops of the ridges should be kept moist for best growth. In some years it is necessary to irrigate before or immediately after planting to ensure early emergence of the plants. Irrigating in the fall or in early spring before planting is better than irrigating immediately after planting. Some areas in the west also are irrigated by raising and lowering the water table by controlling the water level in ditches spaced 60 to 80 ft. apart. In eastern United States rainfall is often supplemented with irrigation, chiefly the portable pipe sprinkler type. Wells and streams supply the water in these areas.

IV. POTATO DISEASES

Potato diseases are classed according to causal agents into virus, bacterial, fungus, insect, nematode and nonparasitic or physiological diseases.

1. Virus Diseases. — Viruses are often considered to be nonliving chemical entities which are capable of causing disease and capable of reproduction only within the host. They are transmitted from plant to plant by insects and sometimes by other agencies. In almost all cases the disease is perpetuated by tuber propagation. Among the widespread virus diseases of the potato ranking high in importance are mild mosaic or crinkle mosaic, latent mosaic, rugose mosaic, leaf roll, spindle tuber, yellow dwarf and purple top.

Mild Mosaic (Potato Virus A). — This is called crinkle in England. Symptoms are a mottling of leaves with different shades of green, sometimes accompanied by more or less rugosity of the leaf surface. Symptoms are favoured by cool weather and masked at high temperatures. The virus is transmitted by various species of aphids. American varieties which are field resistant are Irish Cobbler, Chippewa, Katahdin and Sebago. These do not become diseased by natural means but can show symptoms if grafted onto diseased plants. Varieties which are very susceptible are Green Mountain, Bliss Triumph and Warba.

Latent *Mosaic* (Potato Virus *X*). — All of the older American varieties and some of those of Europe may be 100% infected but show no visible symptoms. Some of the European varieties, when inoculated, show a severe necrosis of the top with the ultimate death of the plant. These varieties will remain free from the virus except for the individual necrotic plants. Most of the ne er American varieties, free from the virus originally, are infected in varying degrees. If infected with a severe strain of the virus the affected plants show rather severe mottling. The milder strains produce no visible symptoms. The presence of a milder strain usually protects the plant from attack by the severe strains. Spread of the virus is brought about by mechanical means such as the cutting knife or the rubbing together of sprouts or of leaves, etc. Apparently no insect is involved. The severe strains are known to reduce yields and it is possible that the milder ones do also to a lesser extent.

Rugose Mosaic (Potato Virus *Y*).—When this virus is introduced into a healthy plant, the first symptoms are usually necrotic spots on some of the leaves. Later the spotting becomes more extensive, showing as streaks on the back of the veins, on the petioles and on the main stem. The lower leaves become yellow, often with characteristic dark-green circles on them, and drop off completely or remain hanging by a thread. When grown from diseased tubers, the necrotic symptoms are much reduced, the principal symptoms being dwarfing of the plant. rugosity of the leaves, mottling and slight streaking on the veins. Yield is markedly reduced. There are some varieties which carry this virus with little or no symptoms. Spread is by aphids.

Control of Mosaic Viruses.—Certified seed or other seed of low virus content should be planted each year. Plants containing the X virus (latent mosaic virus) but showing no symptoms produce lower yields than virus-free clones of the same variety. In some countries potato stocks free from latent-mosaic and other viruses are selected and maintained.

Leaf Roll.—This is one of the most important and widespread of the potato virus diseases. Current season infection appears first on the upper leaves. The severity of symptoms depends on time of infection; late season infection may result in no symptoms. Secondary symptoms, the result of infection from an infected seed piece, appear first on the lowest leaves when the plants are small. They progress upward on the younger leaves until the entire top is affected. The margins of the leaflets roll or curl upward, the tissues become rigid and leathery and the plant has an abnormally erect habit. Internodes, petioles and stolons are dwarfed, growth is retarded, and the number and size of tubers are reduced. The foliage turns light green and may show a reddish tinge at the margin of the leaf. Tubers of some varieties show net necrosis from current season infection. This shows up as small brown strands at the stem end of the interior of the tuber and extends toward the apical end. Leaf roll is perpetuated by planting tubers from infected plants. It is carried from plant to plant by aphids, the species *Myzus* persicae being most efficient. Use of certified seed, isolation of seed fields, control of aphids and early harvesting of the seed help in control. Development of leaf-roll resistant varieties is in progress in the United States and Europe.

Spindle Tuber.—This disease is widespread in the North American continent but was not reported elsewhere. Tubers from infected plants are often elongated, cylindrical and may be pointed. Plants have an erect habit and the leaves are smaller and more glabrous than normal. Margins of leaflets are fluted. The angle of attachment of the leaves to the stems is more acute than normal. Diameters of stems and petioles are reduced.

Symptoms are more severe in plants grown in wet, hot soil. Infected tubers carry this disease from season to season. It is transmitted by aphids, grasshoppers, flea beetles and tarnished plant bugs, as well as by cutting knives, picker planters and other mechanical means. Use of certified seed is the most practicable method of control.

Yellow Dwarf.—The foliage is yellowish green and the tops are dwarfed or develop into a rosette. Plants may die before or after emergence or may continue a dwarfed growth until normal maturity. Tubers usually are small and misshapen, with small necrotic areas scattered throughout the flesh. Growth cracks often occur. This disease is transmitted by the clover leafhopper. Some varieties such as Warba. Sebago and Russet Burbank appear to have some resistance to this disease. Absence of other host plants such as oxeye daisy in nearby fields helps to control this disease. There appears to be little transmission from diseased potato plants.

Purple Top.—Terminal growth of shoots is retarded and young leaflets roll upward and become rigid in infected plants. These leaflets become pale yellow or purple in colour depending on the variety. Axillary buds start and may become tuberous. Phloem necrosis may occur throughout the tops, roots and tubers. Tubers from affectedplants may be spongy and may produce weak plants or none at all. Few of the tubers produce typically diseased plants. The aster-yellows virus causes this disease and is transmitted by leafhoppers. There is little transmission from potato to potato. Weeds are the source of the virus. No satisfactory control for this disease was developed by the early 1960s.

Other Virus Diseases.—Virus diseases of less importance are calico, witches'-broom, spotted wilt and veinal yellows.

2. Fungus Diseases.—Late blight.—This most serious and widespread of all potato diseases was first recorded in Europe and the United States about 1830. It increased in severity and in 1845–46 almost completely destroyed the crop in Ireland, resulting in the Irish famine. It is most prevalent in the cool, humid regions of the temperate zone. The causal organism is Phytophfhora *infestans,* a parasitic fungus. The first signs of this disease are brownish to black lesions on any portion of the plant tops, principally on the leaves. On the underside of the leaf a white mildew appears on the margin of the lesions. The disease, is favoured by cool, moist conditions and its progress restricted by dry. hot weather.

Tubers may be subjected to infection while in the ground, during harvest and in storage. A brown to purple discoloration of the skin first appears followed by a brownish dry rot which extends under the surface. Infected tubers are the principal source for overwintering of this disease.

Large numbers of microscopic pear-shaped spores are produced on the tiny white threads of this fungus. They are easily detached and carried to other plants by air currents. There, in the presence of water, they germinate by the production of six to ten free-swimming zoospores from each spore. After a few minutes of activity the zoospores come to rest and germinate by the production of a germ tube which enters the leaf. Spores are formed at a relative humidity of 91% to 100% and most abundantly at temperatures of 65° to 70° F. Zoospores form most rapidly at 54° F. and germinate most rapidly at 65° to 70° F. Cool, moist periods thus result in most rapid formation of spores and germination of the zoospores. After infection has occurred, slightly higher temperatures favour rapid growth of the fungus.

Many varieties which are resistant to late blight have been developed by breeding and selection; wild species, such as *Solanum* demissum, have been used for this purpose. The resistant American varieties Placid, Essex, Kennebec and Cherokee are among these. Many physiological races of P. *infestans* have been found. The resistant varieties produced to date are, however, all susceptible to one or more of these races and should be protected with a fungicide when the disease is severe.

Bordeaux mixture has been used for control of late blight in many countries since 1885. This fungicide is effective when the foliage is thoroughly covered by spraying. New growth should be protected by spraying before infection occurs and older growth, from which weathering has removed the fungicide, must receive additional applications. Insoluble copper applications as sprays or dusts also offer adequate protection in many areas. Organic fungicides such as zineb (Dithane Z78 and Parzate) and nabam plus zinc sulfate are also successful in controlling late blight in many areas.

In the Netherlands, England and certain areas in the United States, forecasting late blight epidemics on the basis of current and forecasted weather proved successful in suggesting more timely fungicidal applications. To prevent contamination of tubers during harvest when the disease spores are present, growers often kill the green potato vines before harvest. This is done with sulfuric acid in England and with sodium arsenite, dinitro sprays or with flame throwers and mechanical beaters in the United States.

Tuber refuse, such as culls, from the storehouse should be destroyed by burying, burning or treating with growth inhibitors so that it cannot become a source of infection for the next crop.

Early Blight.—This disease, caused by Alternaria *solani,* appears first as dark-brown to black spots on the leaves. Concentric ridges often form in the dead areas resulting in a characteristic target-board effect. The spots are three or four millimetres in diameter and oval or angular in shape. When the spots are numerous the leaves die. Usually lower leaves are affected first, drying up as the disease progresses toward the top. Slightly sunken, circular or irregular lesions appear on the surface of infected tubers.

Early blight is more difficult to control with Bordeaux mixture than is late blight. Spray applications of the carbamates, nabam plus zinc sulfate and zineb (Dithane Z78 and Parzate) are effective in the control of this disease.

Potato Scab.—Caused by *Streptomyces* scabies, this disease has been known for more than 100 years in Europe and the United States and occurs all over the world. It attacks the surface of tubers and damages their appearance. Sometimes it penetrates two to five millimétres, and is described as pitted scab. It is more prevalent in soils pH 5.2 to 6.5 and relatively scarce in soils below pH 5.0. The organism may live indefinitely in the soil. It is favoured by high temperatures and low moisture in the soil. The young tuber is most susceptible, infection occurring through lenticels, stomata, wounds and through the cuticle.

Varieties differ in their susceptibility to scab. Russet skinned varieties such as Russet Burbank, Russet Rural and Russet Sebago are more resistant than the smooth-skinned Burbank, Rural and Sebago. Other American varieties resistant to scab are Menominee, Ontario, Seneca, Cayuga, Yampa and Cherokee. Resistant European varieties are Jubel, Arnica, Hindenburg and Ostragis.

Seed treatment has been practised for many years to kill the organism on the surface of tubers. Soaks or dips in mercuric chloride, hot or cold formaldehyde and organic mercury dips such as Semesan Bel have been successful. In some soils the presence of mercury increases the severity of the disease. The organism is so widely prevalent in American soils that tuber treatment is of doubtful value. Maintaining soils at about pH 5.0 or lower by avoiding use of lime, adding sulfur or acid-forming fertilizers and the turning under of green-manure crops are useful. Probably the best control is by use of resistant varieties.

Powdery Scab.—This disease, caused by *Spongospora subterranea*, is relatively unimportant in the United States. It is widespread in Europe and parts of Asia, South America, Africa, Australia and New Zealand. It appears as small pustules on the surface of tubers which contain dusty spore masses. These sometimes enlarge to form cankers. In storage, dry rot often follows.

No satisfactory control measures were developed by the early 1960s. Seed treatments used for common scab are sometimes practised. In some countries a search for resistant varieties continues.

Black Wart.—This disease is caused by Synchytrium *endobioticum* and occurs in most countries of western Europe. It occurs in the United States to a slight extent in Pennsylvania, West Virginia and Maryland. It has been restricted to that area in the United States by quarantine measures and planting of immune varieties. This disease may appear as abnormal growth or warts on all underground parts of the plant except the roots. The resting spores may remain viable in soil for many years. Many varieties are immune to this disease. In parts of Europe varieties have been screened for resistance for many years, and only new varieties that are immune may be introduced.

The United States prohibits the entry of potatoes from all countries except Canada and some parts of Mexico, for the purpose of preventing the establishment of black wart and other serious diseases. Those areas in the United States where this disease exists are required to use immune varieties, and export from such areas is not allowed. This disease has been kept under control in Europe by the use of immune varieties.

Verticillium Wilt.—Caused by Verticillium *albo-atrum,* this disease often is confused with other diseases in which wilt occurs. The lower leaves often turn yellow as a first sign. The internodes are short, resulting in a rosette of the top, and upper leaves fold inward toward the midrib. Wilting usually occurs. The vascular system of the lower stem discolours and browning occurs in the stem ends of some of the affected tubers. It results in early dying of tops and reduces yields. This disease is borne in the tuber from one generation and location to another and survives in soil and diseased plants. It may be spread from plant to plant during the growing season by root contact. Disease-free seed is difficult to obtain by roguing.

The disease is rapidly increasing in severity in some parts of the United States and is important in some areas of eastern Canada and eastern and northwestern United States. Rotation and use of resistant varieties are recommended for control.

Fusarium Wilts.—Wilts are caused by Fusarium *oxysporum* and F. solani var. *eumartii*. The disease caused by the first is almost identical as to symptoms with that caused by Verticillium. The wilt caused by F. solani var. eumartii shows also a bronzing and withering of upper leaves, black internal lesions at the nodes of stems and in the interior of tubers and a tuber rot, usually starting at the stem end. Although infection may take place either from the soil or from the seed, soil infection appears generally more important. Discoloration of the vascular tissues in underground stems and in tubers occurs in all the wilt diseases. Rotation and use of certified seed are suggested control measures.

Fusarium Tuber Rots.—Several species of Fusarium cause tuber rots. The rots are soft and wet or dry and powdery, depending more upon the conditions of the environment than the species of fungus. The fungi are soil-inhabiting and the spores are introduced into the storages in the soil adhering to the harvested tubers. The fungi enter the tubers through small wounds made in handling or through cuts made in preparing seed for planting. The best control for these rots is to avoid injuries to the tubers. Healing of wounds may be hastened by maintaining a high humidity and a temperature of 65° to 70° F. for several days after harvest. Treating potatoes with a chemical to destroy the spores before cutting seed is sometimes practised.

Rhizoctonia (Black Scurf).—This disease caused by *Pellicularia filamentosa* (formerly Rhizoctonia solani) is world-wide in distribution and is most conspicuous on the surface of tubers as brown to black spots (sclerotia) resembling areas of dirt. Rarely does this disease penetrate the tuber. The tips of potato sprouts are very susceptible to infection by this organism, and in some instances they are killed before appearance aboveground. Often this results in poor stands in potato fields. Lesions or stem cankers occur on the stems of infected plants. When these are extensive, they interfere with the normal downward flow of carbohydrates to the tubers, there is accumulation in the tops, resulting in stunting, rosetting and formation of aerial tubers in the leaf axils.

This fungus lives in the soil and on the surface of tubers from season to season. Seed treatment with chemicals used for common scab control has been used for control of the disease but is no longer recommended generally. Value of seed treatment is limited because of the disease which remains in the soil. Shallow planting of seed tubers reduces sprout injury and stem cankers, resulting in better stands of plants. The seed pieces gradually are covered deeper by cultivation after the sprouts have emerged.

Other Fungus Diseases.—These include leak, pinkrot, gray mold, skin spot, silver scurf, black dot, Phoma, charcoal rot, powdery mildew, rust, Sclerotinia, southern blight and violet root rot.

3. Bacterial Diseases.—Black Leg.—Caused by *Erwinia* atroseptica, it affects growing plants and tubers in storage, and is called black leg because the base of the stem becomes shriveled and blackened. Plants become rigid and upright and sometimes show a yellowing, particularly of the lower leaves. Growth is retarded. If the young tubers become infected through the stem end, soft rot of the pith occurs. Large plants sometimes show a black soft rot of the aboveground portions of the stem.

The organisms live in the soil, in decaying plants and sometimes in the tubers. Infection usually occurs through wounds in the tuber or through lenticels. The fly and larva of the seed-corn magot, and possibly other flies, are active in spreading this disease. Heat damage, sunscald and freezing injury make the tubers more susceptible to infection. Commercial washing of potatoes often favours soft rot development in subsequent transit.

Preventing bruising of potatoes, protecting tubers from the sun, chlorinating the wash water and drying potatoes after washing help to control storage decay. Healing of wounds by holding potatoes several days at high humidities and 65° to 70° F. also reduces decay loss. Avoiding exposure of cut seed potatoes to light or to insect infestation is recommended. Control of black leg on the plants may be effected by destroying potato refuse piles.

Brown Rot (Southern Bacterial Wilt).—Caused by *Pseudomonas* solanacearum, this is common in tropical countries and in southeastern U.S. Leaves wilt, turn a bronze colour, shrivel and die. Cut stems and tubers exude whitish bacterial masses from the vascular system. Bacterial masses also may exude from the eyes of tubers. Decay of the tuber continues after harvest and the symptoms may simulate those of ring rot. The disease is favoured by high soil moisture and soil temperature.

Since the disease may be spread by infected tubers, seed should not be used from affected areas. Use of certified seed is recommended. In some sandy soils it is possible to control this disease partially by adding sulfur to obtain a pH of 4.0 for several months, followed by lime to attain a pH of 5.0 before planting. Use of partially resistant varieties such as Sebago, Katahdin and Chippewa also is suggested.

Ring Rot.—This rot is a result of infection with *Corynebacterium* sepedonicum. Known in Europe for many years, it was first reported in the U.S. in 1932. The symptoms are similar to those of brown rot. First symptoms are a pale yellow chlorosis between the veins of the leaves. Margins of the leaves die, and the plant is stunted and withers. There is little discoloration of stem tissues. If the underground stem is cut, a milky exudate can be squeezed out. A light yellow vascular discoloration shows up first in the tuber. The affected tissue has a soft cheesy consistency. The tissue of the vascular ring may turn brown and break down, forming cavities which may extend to the pith and cortex and show up as lesions on the surface of the tuber. This disease organism lives primarily in tubers from season to season but also carries over on cutting knives. crates, sacks, storage bins and harvesting and grading machinery. It enters tubers through wounds. It probably is spread in the field by irrigation water and is spread from plant to plant through adjoining root systems. Tubers may carry the organism internally and yet produce infected plants and tubers that show no symptoms if growth has occurred at continuously cool temperatures.

In the United States use of certified seed should help in the control since no visibly infected plants or tubers are permitted in certified seed. Any ring-rot infection should be followed by disinfection of storage house, planters, diggers. cultivation machinery. crates, bags and sorting equipment. Formaldehyde or copper sulfate may be used for disinfection. Disinfection of the cutting knife with boiling water or mercuric chloride also is desirable. Resistant varieties such as Teton may be used.

4. Insect Pests.—The potato is attacked by more than 100 kinds of insects; the following, however, probably cause the most widespread damage: aphids, flea beetles, leafhoppers, wireworms, Colorado potato beetles, potato tuberworms, nematodes and psyllids.

Aphid.—The green peach aphid, Myzus persicae, and potato aphid, Macrosiphum *solanifolii,* are common on potatoes. Both the adults and their young suck the sap from potato foliage, causing the leaves to curl downward. They usually feed on the lower sides of leaves and move very slowly and only short distances unless carried by the wind. They transmit the virus diseases of mild mosaic, rugose mosaic, spindle tuber, leaf roll and unmottled curly dwarf from plant to plant.

The adult potato aphid is about $\frac{1}{8}$ in. long and may be green or pink; the adult green peach aphid is much smaller and is greenish or yellowish green. Most aphids are wingless.

Sprays of wettable powder, or emulsifiable concentrate of parathion or parathion dusts are recommended for control of aphids. They should be applied at a rate of seven ounces of parathion per acre, and the insecticide must reach the undersides of the leaves. It must not be applied within five days of harvest.

Flea Beetle.—The potato flea beetle, *Epitrix cucumeris,* chews small holes in the leaves, giving them a shot-hole appearance. Badly eaten leaves wither and die, thereby resulting in reduced yields of tubers. Flea beetles carry unmottled curly dwarf and spindle tuber diseases from one plant to another. The larvae also scar the surface of potato tubers, sometimes boring into them. Adult flea beetles usually are shiny black and $\frac{1}{16}$ to $\frac{1}{8}$ in. long. They hibernate as adults in soil, grass or weeds. They have from one to four generations a year. Control measures for adult flea beetles are the same as those for Colorado potato beetles (see below). Larvae are controlled by applying two pounds per acre of dieldrin or two to three pounds per acre of aldrin or heptachlor to the soil surface and working it in before planting.

Leafhopper.—This pest, Empoasca fabae, is a pale green, wedge-shaped insect about $\frac{1}{8}$ in. long which feeds mostly on the undersides of leaves. The adults and nymphs suck the sap from leaves and stems, weakening the plants. They also introduce a toxic secretion into the plant which results in hopperburn. The tips and margins of the leaves curl upward. turn yellow and become brown and brittle. Entire fields may be destroyed as if by hot, dry weather. The adults overwinter under leaves, weeds and trash and have two to four generations a year.

Methods of control are applications of DDT, the same as for control of the Colorado potato beetle.

Wireworms.—Two species, wheat wireworm, Agriotes mancus, and eastern field wireworm, *Limonius agonus,* are major pests of potatoes. Larvae of wireworms feed on potato seed pieces and also chew deep holes in the developing tubers, often making them unmarketable. Adults of wireworms are slender, hard-shelled snap or click beetles $\frac{1}{4}$ to $\frac{1}{2}$ in. long. The larvae are yellowish to orange, from $\frac{1}{2}$ to 1 in. long and have jointed bodies. They do most damage on light sandy loam soils and prefer areas where it is cool and moist. They live for several years, feeding in the upper layers in spring and summer and going deeper in the soil during winter.

The wheat wireworm thrives especially in fields planted to sod or hay crops, and clean cultivation gradually reduces its numbers. The eastern field wireworm, on the other hand, thrives in clean cultivated areas. Earlier methods of control were by proper rotations and clean cultivation. Later, however, it proved more efficient to control it with soil applications of insecticides. Four to ten pounds of chlordane or three pounds of dieldrin or of heptachlor per acre sprayed on plowed land and then worked into the top four to six inches of soil just before planting give good control of this pest.

Colorado Potato Beetle.—This insect, Leptinotarsa *decemlineata,* is one of the most widespread pests in the United States and Canada but is becoming of lesser importance as the result of good control measures. It is much feared in western European countries and quarantined areas have been established against it. Adults and larvae, but largely the latter, feed on the leaves and if not controlled may consume all of the leaves, with only the stems remaining. They also are known to spread brown rot, spindle tuber and ring rot.

The adults are hard-shelled beetles about $\frac{3}{8}$ in. long and $\frac{1}{4}$ in. wide with black and yellow stripes extending lengthwise on their wing covers. Orange-yellow eggs are laid on end in masses on the undersides of leaves. The larvae or slugs are dark red with black spots and become orange coloured with age. The adults spend the winter in the ground. There are from one to three generations a year.

Sprays of 50% wettable powder DDT at 2 lb. per acre or 2¼ to 3 pt. of 25% DDT emulsion per acre usually prove effective in control. Five percent DDT dust at 20 to 35 lb. per acre also is recommended. In some areas this pest has developed a resistance to DDT. The recommended control under such conditions is spray applications of $\frac{1}{4}$ to $\frac{1}{2}$ lb. per acre of dieldrin or $\frac{1}{4}$ to $\frac{3}{4}$ lb. per acre of heptachlor.

Potato Tuberworm (Gnorimoschema *operculella).*—This attacks foliage and tubers both before they are dug and in storage. It has been found in more than one-half of the states of the U.S. The adult is a gray moth about $\frac{1}{4}$ in. long with dark-brown wing markings. The larvae tunnel in the midrib of the leaf and in the stem. They also burrow just under the skin or tunnel into the flesh of tubers.

Several control measures are recommended. Spray or dust applications of DDT similar to that for control of colorado potato beetles and leafhoppers will destroy larvae on the foliage. The walls of storage houses also should be sprayed with DDT. Since the moths lay eggs on exposed tubers the rows should be well hilled and tubers should be picked up promptly after digging.

Potato *Psyllid*.—This insect, Paratrioza cockerelli, is destructive in certain areas in western United States. The nymphs suck juices from the leaves and inject a substance into plants that causes a curling and yellowing of the leaves known as psyllid yellows. The first symptoms are curling of the basal portion of terminal leaflets and a change in colour from green to light green or yellow. Curling continues and the leaves become leathery reddish-purple, and the plant is stunted. The set of tubers is increased but growth is retarded and tubers remain small. Sometimes aerial tubers appear in the axils of leaves.

Starting when plants are six inches high, three to four applications of DDT given at 10- to 14-day intervals proves effective as a control. As a spray 2 lb. of 50% wettable powder DDT per acre or 20 to 35 lb. of 5% DDT dust is recommended.

Nematodes.—The nematodes (very small roundworms which live in soil or water) of known importance as pathogens on potato are the root knot nematode, golden nematode, tuber rot nematode and meadow nematode. They may cause serious damage to roots and tubers. Chemical fumigation of the soil seems to be the most feasible control.

5. Nonparasitic Diseases (Physiological Diseases).—Low Temperature Injuries.—Freezing or frost injury may occur by low temperatures just before or during harvest and also later in insufficiently protected storages or during transit. If very low temperatures are prolonged the tubers become soft and watery and subject to bacterial action. At temperatures between 28° and 30° F. injury may appear as ring necrosis, net necrosis or blotch necrosis. Ring necrosis consists of brown or black discoloration in the vascular ring, most often appearing at the stem end of the tuber. Net necrosis consists of darkening of scattered strands of phloem which are toward the interior of the tuber within the vascular ring. Blotch necrosis consists of irregular dark, fairly large areas usually near the exterior of the tuber. Prolonged exposure to temperatures as high as 35° F. may result in injury similar to the above or in mahogany browning.

High Temperature Injuries.—Greening and scalding of tubers may occur when they are exposed to the rays of the sun. Severity of injury depends on light intensity, temperature and exposure time. Chlorophyll accompanied by an alkaloid, solanine, will appear as a green area on the surface of tubers exposed to light. This results in a bitter taste of the tuber. If the temperature and the light intensity are high, scalding of the tuber exterior may occur after several hours exposure. Breakdown on drying out of the affected area may follow and bacterial soft rot often is initiated.

High soil temperatures sometimes result in tubers with internal necrosis, brownish dead areas scattered throughout the interior of the tuber.

Blackheart.—This results when cells in or near the centre of a tuber cannot secure an adequate supply of oxygen. The cells degenerate, stimulating a process which results first in a reddish-brown discoloration which gradually blackens. This condition sometimes develops in overheated cars in transit or overheated storages. Poorly ventilated storage bins also may initiate the occurrence of this defect. At high temperatures, air cannot penetrate the compact tissue of the tuber rapidly enough to supply oxygen at the rate it is needed for the higher rate of respiration which accompanies the high temperature. As a result the tissues break down and turn dark.

Hollow Heart.—This name is given to the defect in which the tissue of the interior of the tuber splits or dies, forming a cavity or space. It occurs most commonly in large tubers; its cause and prevention are not well known.

V. POTATO BREEDING

The potatoes that were brought to Europe from Peru and Chile in the latter half of the 16th century bad very irregularly-shaped tubers, disfigured by outgrowths and extremely deep eyes. These varieties were the rule until the earlier part of the 19th century. In the hands of plant breeders the shape, colour and quality were much improved. Most of the improvements were made after 1845, when potato diseases focused attention on the crop. In that year potato blight reached Europe and became so destructive in Ireland as to cause a famine and much loss of life. This gave an impetus to the search for varieties resistant to disease. Perhaps the first and most important new seedling in Great Britain was the variety Victoria, raised and introduced by William Paterson of Dundee. It was the parent of many other great potatoes later produced, including Champion, Up-to-Date, Great Scot and Ninetyfold. Simultaneously and for the same reasons there was great activity in the production of new varieties in the United States. C. E. Goodrich of Utica, N.Y., conceived the idea that the disastrous epidemics of late blight during the years 1843–47 were the result of a reduction in the vigour of the plants. Though he did not succeed in the control of late blight, he laid the foundation of potato breeding in the United States by furnishing material to be used by other breeders. The ancestry of 170 varieties can be traced back to Goodrich's Garnet Chili, a seedling of the imported Rough Purple Chili. They include several well known varieties of commerce such as Burbank, Early Ohio, Green Mountain and Triumph. The Magnum Bonum, a popular potato of England and north European countries, was bred from Early Rose by J. Clark of Christchurch, Eng. Clark also grew Abundance, Epicure and Ninetyfold, varieties still of some importance.

The second wave of potato blight came in 1870 and caused much destruction in the existing varieties. Breeders concentrated on securing more resistant forms. Nicol of Arbroath then introduced the Champion, a high yielding resistant variety, which soon was largely grown throughout Scotland and Ireland and in time in most potato districts of the world.

Archibald Findlay of Scotland was successful in developing many varieties, including Up-to-Date and British Queen. The Up-to-Date, especially, made both Scotland and Ireland famous for potatoes, and this variety was exported to all parts of the world. From 1907 to 1928 Donald McKelvie was active as a potato breeder; his Arran Chief, Arran Banner, Arran Comrade and Arran Consul became popular in many places. German breeders raised Richter's Imperator, the President and Paulsen's Juli, all of such merit as to justify wide cultivation. The work of C. G. Pringle of Charlotte, Vt., is said to represent the first systematic effort to obtain seed by controlled hybridization. His varietal contributions were the Alpha, Adirondack, Rubicund, Ruby and Snowflake.

Early in the 20th century a number of varieties immune to wart were bred in Europe.

When potato breeding was actively undertaken by the U.S. department of agriculture in 1910 under the direction of William Stuart, the only disease resistance sought was that against the late-blight fungus. It was not until some years later that it became evident that the virus diseases were a greater menace to potato production than late blight. It was soon realized that the widespread occurrence of potato virus diseases such as the various types of mosaic, leaf roll, spindle tuber, curly dwarf, yellow dwarf and streak could be controlled only by the breeding mode of attack. The first step in this direction was toward the development of varieties resistant to one of the commonest of these diseases, mild mosaic. Seedlings that showed some resistance to virus infection were selected by Charles F. Clark, who became associated with Stuart in this work. Clark crossed the resistant seedlings with one another and with other seedlings and varieties. As a result a number of new varieties with a high degree of resistance to mild mosaic, with desirable tuber characters, good habit of vine growth and relatively high yield were distributed to growers. Katahdin, Chippewa and Houma were the first of these.

While this work was being carried on by the department of agriculture a few of the state experiment stations, especially at Minnesota and Cornell universities, had undertaken potato breeding work. It was soon realized that problems and objectives in this field cut across state lines and involved large regions of the entire country. It was therefore decided in 1928 to organize the work as a national project with all interested state experiment stations and the United States department of agriculture co-operating. Material was sent also to any foreign country requesting it. Under the direction of F. J. Stevenson, who took charge of the project in 1930, a number of varieties were developed and introduced. The expansion in the organization greatly increased the number of problems attacked. The so-called economic characters such as yield, time of maturity, depth of eye, shape of tuber and culinary quality were given primary consideration, but intensive work was done also on resistance to various diseases and insect pests. Resistance was obtained to the virus diseases such as mild mosaic, latent mosaic. veinbanding, leaf roll and yellow dwarf. Immunity from late blight was found in many hybrid seedlings of the wild species, *Solanum demissum*, crossed with cultivated varieties of *S. tuberosum*. Resistance to this disease was found also in some of the cultivated varieties themselves and in a number of progenies obtained from Germany. The latter may be related to *S. demissum*. Seedling varieties highly resistant to common scab under a wide range of environmental conditions were produced. Varieties tolerant to Fusarium wilt also were produced. Many of the new productions were resistant, if not immune, to potato wart. Resistance to brown rot and ring rot were found to be inherent in a number of varieties and progenies. Wide differences were found between varieties and seedlings in their reaction to injury by the insect pests, leafhoppers, flea beetles and psyllids.

The principal commercial varieties in the United States were for many years those originated in the middle and late 19th century. These arose as mutations or sports, as chance seedlings, or as a result of crossbreeding. Some of these are still grown in large acreages. Early varieties are Irish Cobbler, Triumph and Early Ohio, and some of the late varieties are Green Mountain, White Rural. Russet Rural, Russet Burbank and White Rose. After 1930 a number of new varieties were originated and distributed to growers under the National Potato Breeding program and independently by some state agricultural experiment stations. Among these are early varieties such as Mesaba, Warba, Red Warba, Chippewa, Pawnee, Kasota, Cherokee, Progress, LaSoda, Early Gem and White Cloud. Late varieties are Katahdin, Sebago, Houma, Mohawk, Pontiac, Red Pontiac, Sequoia, Menominee, Erie, Kennebec, Ontario. Teton and Canoga.

D. Reddick of Cornell university (Ithaca, N.Y.) bred and introduced a number of late-blight resistant varieties, some of which are Empire, Chenango, Essex, Placid, Cortland, Madison, Snowdrift, Virgil and Harford.

In England the leading main crop variety is Majestic, followed by King Edward VII, Arran Peak, Gladstone, Arran Banner and Redskin. Kerr's Pink is by far the most popular variety for table stock in Scotland; others are Redskin and Golden Wonder. In Northern Ireland, Arran Victory is most popular, others being Kerr's Pink, Arran Banner, Arran Peak, Arran Consul and Gladstone. Most popular early varieties in England are Great Scot, Dunbar Rover, Epicure, Arran Pilot, Home Guard, Duke of York, Eclipse and Sharpe's Express. British Queen is most extensively grown in Scotland and Northern Ireland.

VI. COMPOSITION, NUTRITIVE VALUE, COOKERY

1. Chemical Composition of the Potato.—While there are differences in chemical composition among varieties, a much greater variability occurs within any one variety as a result of conditions under which potatoes are grown. Every factor which affects growth of the potato also influences its chemical composition. Therefore, only approximations to average composition of tubers can be given. The following may be taken only as an example: dry matter 18% to 28%; starch 12% to 20%; total carbohydrate 15% to 23%; protein 1 3% to 2.7%; ash 0.64% to 1.3%; fat. trace to 0.5% and crude fibre 0.33% to 1.0%. The following amino acids are found in the potato: lysine, tyrosine, cystine, histidine, arginine, tryptophane, proline, alanine, valine, leucine, phenylalanine and glutamic acid. The following minerals and trace elements are reported in the ash of potatoes: phosphorus, calcium, magnesium, sodium, potassium, iron, sulfur, chlorine, zinc, bromine, copper, boron, silicon, manganese, iodine, lithium, arsenic, cobalt, nickel and aluminum. The total carbohydrates are made up largely of starch, reducing sugars and sucrose. The following organic acids also are found: oxalic, citric, succinic, malic and tartaric. A number of enzymes, several pectins and solanine also are reported. Most of these constituents undoubtedly have an effect on mealiness, colour, flavour and nutritive value of the potato.

2. Nutritive Value of the Potato.—Potatoes are a good source of energy as measured by calories provided and also of vitamin C and several of the necessary minerals. From 100 g. of potatoes with 25% loss in peeling the following food value will be obtained after they are boiled but nothing added to them: 12 g. starch, 0.23 g total nitrogen, 0.04 g. fat, 300 mg. potassium, 35 mg. phosphorus, 9 mg. calcium, 0.65 mg. iron, .0075 mg. vitamin A, .055 mg. vitamin B_1, .008 mg. riboflavin, .3 mg. nicotinic acid and 15 mg. vitamin C or ascorbic acid. Fifty-two calories would be supplied by this portion of boiled potato.

3. Cooking Quality.—Cooking quality is comprised of (1) consistency, texture or degree of mealiness, (2) colour of flesh after cooking and (3) taste or flavour. In the United States and England and several other European countries most consumers desire a mealy potato when it is boiled, steamed or baked. In many other countries a firm or soggy texture is desired. All prefer a white or golden yellow colour of flesh after boiling. A light, golden brown colour of French fries and chips is preferred. A mild flavoured potato probably is preferred by most consumers. High dry matter potatoes are best for baking, French fries, potato chips and dehydrating. Low specific gravity tubers are better for canning since they are not likely to fall apart during processing.

Factors which affect mealiness of potatoes include variety, soil moisture, soil type, amount and analyses of fertilizers applied, date of planting, date of harvest. mulching, temperature during the growing season, especially during the last few weeks, spray program for control of insects and diseases and method of vine killing. In the United States millions of bushels of potatoes are purchased on the basis of specific gravity for potato-chip processing. The potato hydrometer is used for this purpose. Experiments show that it is feasible to separate potatoes by salt solutions into groups that will be mealy when cooked and other groups which will not slough or fall apart when boiled. After-cooking darkening of potatoes is influenced by such factors as variety, growing season temperature, amount of sunshine, fertilizers and maturity of the tubers.

4. Potato Processing.—Millions of bushels of potatoes are processed annually in Europe into starch, alcohol, potato meal, flour, dextrose and other products. Few are processed into potato chips, dehydrated mashed potatoes. French fries and canned potatoes. In the United States. on the other hand, comparatively little potato flour and very little potato starch are made and in normal times practically no alcohol, dextrose, meal, etc. About 40,000,000 bu. are utilized annually for making potato chips, frozen French fries, canned and dehydrated potatoes. For potato chips alone more than 30,000,000 bu. are used annually.

VII. WORLD PRODUCTION AND TRADE

In volume of fresh product, the potato ranks first among the world's most important food crops. It is grown in almost every country in the world. It is of greatest economic importance, however, in countries of the north temperate zone where it is relatively cool during the growing season. It is well adapted to the countries of northern Europe, and production and yields are considerably higher in several of these countries than in the United States and Canada. Over 90% of the potato crop of the world is grown in Europe. Yields in northern European countries are also higher than those of warmer climates in the southern part of the continent.

Potatoes enter extensively into international trade. In the 1950s the Netherlands, Germany, Denmark, Ireland and Italy exported more potatoes than they imported. England and Wales produced large quantities but not sufficient to supply the wants of their population. Much of this demand was supplied by shipments from Scotland and Ireland, where growing conditions are excellent, and an excess is produced. Some countries both export and import, the exports sometimes consisting of seed potatoes and the imports of early crop potatoes grown in an area where they are marketed before the home crop is ready. Such is the usual situation between the United States and Canada, although some main crop table stock also is sent to the United States from Canada.

Large quantities of potatoes in Germany. the Netherlands, Ireland and other northern countries of Europe are grown specifically for manufacture of alcohol, starch, potato meal or flour and for livestock feeding. Only the excess crop and culls are used for such purposes in the United States and Canada. European countries also consume for human food much larger quantities of potatoes than the United States and Canada.

POTATO LIFTER: see HARVESTING MACHINERY.

POTATO RACE, a contest in which the winner is the first who collects in a basket or other receptacle a number of potatoes, usually eight. placed two yards apart along a straight line, and then crosses a line five or ten yards farther on.

POTATO SPIRIT. The replacement of grain by potatoes as the source of supply of alcohol for commercial use has, since the middle of the 19th century, developed into an important industry, particularly in Germany, where it is a prominent feature in the organization of the agriculture of the country. In great measure it is carried on by the mutual co-operation of the farmers who supply the potatoes to joint-owned distilleries for conversion into alcohol, receiving later the spent wash and residues which, containing nitrogen. phosphorus and potash, are of considerable value as a cattle food. Extensive breeding of cattle is thus facilitated, resulting in a heavy production of manure useful in the cultivation of the potatoes. The initial operations in the production of alcohol from potatoes are the mashing and the saccharification of the starch by means of malted barley or acids. The details of the process show considerable variation. In one method extensively adopted, the potatoes, after being cooked by steam heating and reduced to a homogeneous pulp in a mill, are mixed with malt and water. After the mass has been maintained at a temperature of about 60° C. for three to four hours, yeast is added and fermentation takes place. Distillation is accomplished by steam heating with mechanical agitation. In another method the potatoes after being reduced to a pulp in a rasping machine are partially drained of their natural water. Boiling uater and malt are added, the mass being allowed to stand for three to four hours. The clear liquid and subsequent washings are fermented with yeast and the spirit distilled off in the usual manner; this method has considerable advantages over that first described, the distillation from the liquid being cleaner and the residual paste being excellent as a cattle food. The spirit obtained by pot-still distillation is liable to act in a deleterious manner upon the animal economy. It has a strong flavour of fusel oil, since amyl and isobutyl alcohols are present in considerable proportions. These may be almost completely removed by distillation in a patent still. It has been claimed that 28.6 gal. of absolute alcohol can be obtained from a ton of potatoes.

(F. G. H. T.; R. SU.)

POTATO WAR, the name given by the Prussians to the War of the Bavarian Succession in 1778–79 (Kartoffelkrieg). The Prussians and a Saxon contingent, commanded by Frederick the Great and his brother Prince Henry, were opposed to two Austrian armies under Ernst von Loudon and Franz Moritz, Count Lacy. The operations consisted almost entirely of manoeuvres which had for their object the obtaining or the denial to the enemy of food supplies. The war thus acquired the name of *Kartoffelkrieg.* Its duration was from July 3. 1778, to the assembly of the congress of Teschen on March 10, 1779, and its total cost £4,350,000 and 20,000 men to all parties. The war may be studied from a military point as an extreme example of what Karl von Clausewitz calls "war with a restricted aim."

POTAWATOMI, a tribe of North American Indians, Algonkian in language and culture, whose name connotes "firemakers" (with flints or a one-stringed bow). Their traditions unite them to prehistoric Ojibwa and Ottawa of the eastern woodlands, an affiliation which is also affirmed by 17th century Jesuit accounts, and by internal evidence of culture and language. All sources indicate that separation of these tribes occurred in the late 17th century. Like other Algonkins. Potawatomi migrated west from the Atlantic seaboard, in part under Iroquois pressure. Potawatomi were observed in 1670 on islands around Green Bay, Wis., from which they spread south into territories of Michigan, Wisconsin, Illinois and Indiana.

The tribe joined France against the Iroquois and it joined Pontiac in his uprising; it joined England in the American Revolution and opposed England in 1812. Crowded by settlers. the Potawatomi moved west beyond the Mississippi; some in Indiana fled the U.S. military into Canada. In 1846, most Potawatomi were removed by U.S. soldiers to a reservation in Kansas, where they became known as the Prairie Band. Apparently during the westerly trek such new lifeways as communal buffalo hunts (replacing the chase of woodlands big game and fish), associated camp organization and the intertribal Plains sign language were borrowed from alien prairie tribes.

In 1861 most members of the Kansas band decided to take their lands in severalty and sell them for cash, and after disputes with the others, moved in 1868 to Oklahoma's Indian territory. Henceforth they were called Citizen Potawatomi. Despite the parting and the Citizens' assimilation to the dominant white life, the two groups maintained contact with each other, with the small impoverished Forest (or, "Stray") Potawatomi band that had fled to Wisconsin, and with the yet smaller Huron Potawatomi band that fled to Michigan in the 1830s. Separation favoured differences among the bands in social existence and speech.

The Prairie Band cherished its reservation as a home for the dying culture, blending aboriginal crafts and values with others from colonial and contemporary America. During the 1930s there was some cultural resurgence, but in the second half of the 20th century acculturation was proceeding at a rapid pace. (R. LA.)

POTCHEFSTROOM, a town in Transvaal, Union of South Africa, at 26° 30' S., 27° 40' E., altitude 4,436 ft., 88 mi. S.W. of Johannesburg by rail. Pop. (1951) 32,058, of whom 16,708 were white, 13,415 natives (Bantu), 476 Asian and 1,459 coloured. The town is built on the banks of the Mooi river, 15 mi. above its junction with the Vaal. Gold occurs in the neighbourhood.

Potchefstroom was founded in Nov. 1838 by Hendrik Potgieter, and is the oldest town in and first capital of the Transvaal. In 1862 it was the scene of civil war betueen rival Boer factions. In 1880–81 the garrison camped outside the town was besieged by Boers under Commandant P. A. Cronje. The British troops, 250 in number, were confined to a fort 25 yd. square and lost more than one-third of their strength in killed and wounded before they surrendered on March 21, the action having begun on Dec. 18, 1880. Charges of treachery were brought against Cronje for failing to notify the besieged that an armistice had been agreed to by the Boer leaders. Of this armistice Col. R. W. C. Winsloe, who was in command of the British, became aware before the surrender took place. On the suggestion of Commandant Gen. P. J. Joubert the capitulation was considered as cancelled, and a detachment of British troops reoccupied the town until the conclusion of peace. In the Anglo-Boer War of 1899–1902 Potchefstroom was occupied by the British without opposition. Potchefstroom was developed as an educational centre. It has several high schools, a training college, a university college. a constituent of the University of South Africa, and an agricultural school. The latter is situated on the government experimental farm.

POTEEN, called also potheen, potsheen and potyeen, the term usually applied in Ireland to any potable spirit illicitly distilled in a pot still—poit'in, pota or pot. Illicit distillation was extensively practised in the 19th century, particularly in the inaccessible districts of the island, but it has been largely suppressed. The character of the substances used in preparing the wash, which is fermented preparatory to distillation (see RUM; WHISKY; etc.), varies greatly. While malf and barley chiefly are used, the spirit is often obtained by fermentation of molasses or other saccharine matter. Method of fermentation, type of still employed, rate of distillation and proportion of distillate to wash, depending as they do upon the circumstances and wish of the distiller, are also lacking in uniformity. This absence of standardization in materials and methods results in great variation in composition of the spirits. Generally they may be stated to fall into two classes, approximating to whisky when malt and barley are used. and to rum when the wash is of a more saccharine nature. The proportion of secondary ingredients almost invariably is high, however, even when compared with pot-still spirits made by reputable firms. Allen, in a series of analyses presented to the Select Committee on British and Foreign Spirits, recorded 128.8 gr. of amyl alcohol in poteen as compared with an average of 56 gr. in eight samples of Irish whisky. (F. G. H. T.)

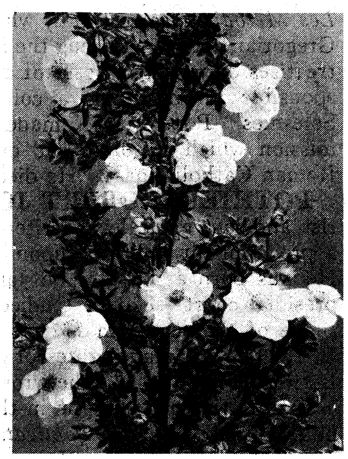
POTEMKIN, GRIGORY ALEKSANDROVICH, PRINCE (1739–1791), Russian statesman, was born at Chizheva near Smolensk. He was educated at the Moscow university and in 1755 entered the "Reiter" of the horse guards. His participation in the coup d'état of July 8, 1762, attracted the attention of the new empress, Catherine II, who made him a Kammerjunker and gave him a small estate. He distinguished himself in the Turkish war of 1769, and in 1771 he became Catherine's prime favourite. Catherine bestowed on him the highest honours, among others the post of commander in chief and governor general of "New Russia" (Ukraine). In 1775 he was superseded in the empress's graces by Zavadovsky; but the relations between Catherine and her former lover continued to be most friendly, and his influence with her was never seriously disturbed by any of her subsequent favourites.

Potemkin's correspondence with the empress was uninterrupted. He was deeply interested in the question of the southern boundaries of Russia and consequently in the fate of the Turkish empire. In 1776 he sketched the plan for the conquest of the Crimea which was subsequently realized; and he was busy with the so-called Greek project, which aimed at restoring the Byzantine empire under one of Catherine's grandsons. In many of the Balkan states he had well-informed agents. After he became field marshal, in 1784, he introduced many reforms into the'army and built a fleet in the Black sea, which, though constructed of very bad materials, did excellent service in Catherine's second Turkish war (1787–92). His colonizing system was exposed to very severe criticism, yet it is impossible not to admire the results of his stupendous activity. The arsenal of Kherson, begun in 1778, the harbour of Sevastopol and the new fleet of 15 liners and 25 smaller vessels, were monuments of his genius. But there was exaggeration in all he attempted. He spared neither men, money nor himself in attempting to carry out his gigantic scheme for the colonization of the south Russian steppes; but he never calculated the cost, and more than three-quarters of the design had to be abandoned when but half finished.

Catherine's famous expedition to the south in 1787 was a triumph for Potemkin, for he concealed all the weak points of his administration. On this occasion he received the title of prince of Tauris. The same year the second Turkish war began, and the founder of New Russia acted as commander in chief. But the army was ill equipped and unprepared. and Potemkin, in a hysterical fit of depression, would have resigned but for the steady encouragement of the empress. Only after Suvarov had valiantly defended Kinburn did he take heart again and besiege and capture Ochakov and Bender. In 1790 he conducted the military operations on the Dniester and held his court at Jassy with more than Asiatic pomp. In 1791 he returned to St. Petersburg, where, along with his friend Bezborodko (*q.v.*), he made vain efforts to overthrow the new favourite, Zubov. The empress grew impatient and compelled him (1791) to return to Jassy to conduct the peace negotiations as chief Russian plenipotentiary. On Oct. 5, while on his way to Nikolayev, he died in the open steppe, 40 mi. from Jassy. Potemkin was indubitably the most extraordinary of all the Catherinian favourites. He was an able administrator, licentious, extravagant, but loyal, generous and magnanimous. Nearly all the anecdotes related of him by Helbig, in the biography contributed by him to the journal *Minerva* (1797–1800) and freely utilized by later biographers, are absolutely worthless.

See V. A. Bilbasov, *Geschichte Katharinas II* (Berlin, 1891–93); C. de Larivière, *Catherine la Grande d'après sa correspondance* (Paris, 1895); anonymous, La *Cour de Catherine II: Ses collaborateurs* (St. Petersburg, 1899); A. V. Lopukhin, *Sketch of the Congress of Jassy, 1791* (Rus; *St.* Petersburg, 1893); *The Papers of Prince Potemkin, 1744–1793* (Rus.; *St.* Petersburg, 1893–95). (R. N. B.)

POTENTILLA, a large genus of plants of the rose family (Rosaceae, *q.v.*), comprising more than 300 species, mostly herbs, widespread in north temperate and arctic regions, many being cultivated as border and rock garden plants. Various species bear brilliantly coloured flowers and graceful foliage. A soil of a good loamy staple, enriched with rotten dung, is most suitable. Potentillas may be increased, though not freely, by parting them into as many pieces as there are crowns, the side growths being those which can usually be thus separated. This may be done in autumn or spring, and the plants will generally bloom the following season. The species and some of the varieties reproduce true from seed, and are readily increased by that means.



J. HORACE MCFARLAND CO

PURDOM BUSH CINQUEFOIL (POTENTILLA PURDOMI)

Nine wild species occur in the British Isles and more than 50 in North America, many being called cinquefoil or five-finger.

POTENTIOMETER: see INSTRUMENTS, ELECTRICAL MEASURING.

POTENZA (anc. POTENTIA), a town and episcopal see of Basilicata, Italy, capital of the province of Potenza, 103 mi. by rail S.E. of Naples. Pop. (1951) 22,371. Situated 2,700 ft. above sea level on an isolated hill above the Basento (anc. Casuentus), it is exposed to winds and has a far more northerly climate than its position (40° 40' N.) implies, and is one of the coldest towns in Italy.

The ancient Potentia lay about 470 ft. lower, by the river, at the intersection of the road leading west to the Via Popillia and northeast to the Via Appia, with the Via Herculia.

Potentia must be distinguished from Potentia in Picenum, on the Adriatic coast. In 1694 there was a severe earthquake; the more terrible earthquake which on Dec. 16 and 17, 1857, passed through southern Italy, and in Basilicata (Lucania) alone killed 32,475 persons, laid the greater part of Potenza in ruins. It was also damaged by the earthquake of 1910. In 1860 it was the first town to rise against the Neapolitan government.

POTGIETER, EVERHARDES JOHANNES (1808–1875), Dutch prose writer and poet, was born at Zwolle, in Overyssel, on June 17, 1808. He started life in a merchant's office at Antwerp. In 1831 he made a journey to Sweden and then settled in Amsterdam. With Heije, the popular poet of Holland in those days. and Bakhuizen van den Brink, the historian, Potgieter founded De *Muzen* ("The Muses," 1834–36), a literary review, which was, however, soon superseded by De *Gids* ("The Guide"), a monthly, which became the leading magazine of Holland. In it he wrote, mostly under the initials of "W D ——g," a great number of articles and poems. The first collected edition of his poems (1832–68) appeared in two volumes (Haarlem, 1868–75), preceded by some of his contributions to De *Gids,* in t o volumes also

(Haarlem, 1864), and followed by three volumes of his *Studien en Schetsen* ("Studies and Sketches," Haarlem, 1879). Potgieter's favourite master among the Dutch classics was Hooft, whose peculiarities in style and language he admired and imitated. In Holland Potgieter's influence has been very marked and beneficial; but his own style, that of ultrapurist, was at times somewhat forced, stilted and not always easily understood.

The best edition of Potgieter's works is that by his friend and executor J. C. Zimmermann, 19 vol. (1885–90).

POTHIER, DOM JOSEPH (1835–1923), French musical scholar, was born at Bouzemont, near St. Dié, Dec. 7, 1835. He became a Benedictine in 1859 and, after holding various positions of authority in two French abbeys, was named abbot of a third, St. Wandrille, in 1898. In 1901, when members of religious orders were compelled by law to leave France, the monastery was temporarily located in Belgium. Shortly after he entered the Benedictine order at Solesmes, Dom Pothier was encouraged by Dom Guéranger, who had started a movement to revive the ancient plain song, to study early church music. In 1880 Dom Pothier published *Les Mélodies grégoriennes,* which became the standard work on Gregorian chants. During the next 25 years he wrote seven other treatises on various phases of ancient religious music and was responsible for beginning a collection of musical manuscripts at Solesmes. Pope Pius X made him chairman (1904) of a commission which re-edited and published the musical parts of the Roman Catholic mass. He died at Conques, Belg., Dec. 8, 1923.

POTHIER, ROBERT JOSEPH (1699–1772), French jurist and last great legal writer before the Revolution, exercised a predominant influence upon the draftsmen of the *Code Civil.* He was born at Orléans on Jan. 9, 1699, son of a judge of the presidial court. Having studied law, he was himself appointed a judge of that court in 1720, a post which he held for 52 years. In 1749 he was made professor of law in the university of Orléans. Between 1748 and 1752 he wrote *Pandectae Justinianae in novum ordinem digestae,* a classic in the study of Roman law. In 1761 he published *Traité des obligations* and followed it with a series of great treatises upon the various categories of contracts and many other branches of civil law. He died in Orlkans on March 2, 1772. His writings rationalized the various *coûtumes* of France into clear and logical legal principles which Napoleon's codifiers often adopted word for word. Even after the code his work was resorted to as authority where the code was silent or ambiguous.

BIBLIOGRAPHY.—Editions of Pothier's collected works by Siffrein (1820–24), by A. M. Dupin (1824–25) and by J. J. Bugnet (1861–62). *See* also A. M. Dupin, *Dissertation sur la vie et les ouvrages de Pothier* (1827); A. F. M. Frémont, *Vie de* R. *J. Pothier* (1859). (L. N. B.)

POTI, a seaport of the U.S.S.R., in the Georgian S.S.R., in 42° 10' N., 40° 38' E., on the Rion river, on the Black sea coast.

There are berths for eight or ten large steamers and an elevator for loading manganese, the chief export from the Kvirili valley. The town is linked by rail with Baku. Pop. (1957 est.) 43,000.

The ancient Phasis, a commercial colony of the Greek city of Miletus, stood on this site. In 1578 Sultan Murad III, of Turkey, built a fortress there, which was destroyed during a war with Persia. In 1640 the Imeretians attacked the town. Poti was a great slave market. It was captured by the Russians in 1812 and in 1829 recaptured and annexed.

POTLATCH, an Indian term, denotes the lavish feasts especially characteristic of the Tlingit, Kwakiutl and other tribes of the northwest coast of America. The potlatch was given by one chief or clan to another on ceremonial occasions and was marked by great profusion of food and gifts, often accompanied by destruction of property by the hosts, as in the breaking of highly prized copper plaques and the burning of blankets and furs. The potlatch reflected a very high value placed on wealth as a status symbol. It was a matter of honour to accept any invitation to a potlatch and to give a grander feast in return. Refusal involved loss of prestige and rank. *See* INDIANS, NORTHWEST COAST.

POTOCRI, IGNACY (1741–1809), Polish statesman and writer, son of Eustachy Potocki, general of artillery of the army of Lithuania, was born at Podhajce. He was educated first at Warsaw beneath the eye of the pedagogic reformer Stanislaw Konarski (1700–73), and subsequently in Italy, where he proposed to take orders. On returning home, however, he abandoned this idea, and as a member of the newly instituted commission of education rendered invaluable services to his country for the next 16 years. He earnestly desired reform of the constitution also and was thus attracted to the party of Czartoryski. Elected deputy to every diet after 1778, he was a conspicuous member of the patriotic opposition. In matters of importance nothing was done without his advice. His influence was at its height during the "four years' " *sejm* (1788–92). He advocated reform of the constitution, defended eloquently the right of the towns to the franchise and urged an alliance with Prussia. Thus he was one of the creators of the constitution of May 3, 1791, although his aristocratic antecedents prevented him from going the lengths of the more radical reformers. On the formation of the confederation of Targowica, Potocki emigrated to Dresden, but on the outbreak of the revolution of 1794 he returned to Poland, was appointed a member of the national government and entrusted with the conduct of foreign affairs. At the fall of Warsaw he surrendered to Suvorov and was sent to Russia, where he remained until 1796. When he returned to Poland he retired to the village of Klimuntowo, where for the next 13 years he devoted himself to literature. At the end of the war of 1809 he was commissioned to go to Vienna to present to Napoleon the petitions of the Galicians for the incorporation of their province with the grand duchy of Warsaw. He died at Vienna the same year.

POTOCKI, STANISLAW FELIX (1752–1805), Polish politician, son of Franciszek Salezy Potocki, palatine of Kiev, was born in 1752. Through family influence, he became grand standard bearer of the crown at the age of 22. In 1782 he was made palatine of Russia, in 1784 a lieutenant general and in 1789 purchased the rank of a general of artillery, Liberal, enlightened, a generous master and a professed patriot, he had awakened great hopes; but he identified the public welfare with the welfare of the individual magnates, and, when elected to the four-years' diet, schemed to divide Poland into an oligarchy of autonomous grandees exercising the supreme po er in rotation (in fact, a perpetual interregnum). The election of Stanislaw Malachowski (*q.v.*) and Kazimierz Sapieha as marshals of the diet still further alienated him from the Liberals, and he retired to Vienna where he continued to carry on an active propaganda against the new ideas. He protested against the constitution of May 3, 1791, and, after attempting fruitlessly to induce the emperor Leopold to intervene, proceeded with his friends in March 1792 to St. Petersburg, and subsequently with the connivance of the empress Catherine formed the confederation of Targowica (May 14, 1792), of which he was the marshal, or rather the dictator, directing its operations from his castle at Tulczyn. When the May constitution was overthrown, Potocki (March 1793) went on a diplomatic mission to St. Petersburg; but, finding himself duped, he settled down at Tulczyn.

POTOMAC, a river in the east central United States, rises in the Appalachian mountains of West Virginia and flows southeastward into Chesapeake bay, draining an area of approximately 14,500 sq.mi. Its two headwaters; the north and the south branch, join about 15 mi. below Cumberland, Md. From there to the bay it is 287 mi. long, 117 of which are tidal. At Harpers Ferry it receives the Shenandoah river from the Appalachian valley to the south and after traversing the easternmost mountain chains through a series of spectacular watergaps it is joined by the Monocacy river in the Piedmont region and by the Anacostia or east branch at Washington, D.C. Together with its north branch, it forms the boundary between Maryland and West Virginia from its source to Harpers Ferry, and from there to its mouth it is the boundary between Maryland and Virginia. The District of Columbia lies on its left bank at the head of tidewater. Navigability of the tidal portion is assured by channels dredged to a depth of 18 and 21 ft, at Washington and of 24 ft. through all the shoals. Washington and Alexandria (Va.) possess minor port facilities; the lower Anacostia is navigable to Bladensburg, Md., for small craft. For a stretch of about 12 mi. upstream from Washington the Potomac descends from the Piedmont to the coastal plain in a series of rapids and falls, of which Great Falls contains a cataract about 35 ft. high. The Chesapeake and Ohio canal. paralleling the Potomac, was completed in 1850 from Georgetown to Cumberland; traffic ceased at the beginning of the 20th century but the canal remains a scenic and recreational asset.

POTOROO: *see* RAT KANGAROO.

POTOSÍ, a department of Bolivia, bounded north by Oruro and Cochabamba, east by Chuquisaca and Tarija, west by Chile and south by Argentina. Pop. (1950) 534,399. Area 45,644 sq.mi. Situated in the southwest of the country, it ranks second in population and fourth in territorial area among Bolivia's departments. Potosi (*q.v.*) is capital of the department and of the province of Cercado. Indians, mestizos and people of European descent make up the population.

The department is noted for its great mineral wealth and its high physical altitude. The surface is extremely rugged, being traversed by the eastern branch of the Andes, and the climate is rigorous. Elevations range from about 6,000 ft. to more than 20,000 ft. above sea level. The capital city stands at an altitude of over 13,700 ft., and the temperature there seldom exceeds 59" F. Livestock grazing and agriculture are carried on, chiefly at lower elevations owing to the harsh natural environment of the Altiplano. Vegetation is scarce and there is little water for irrigation. The region is drained mainly by the affluents of the Pilcomayo. The department is also deficient in fuels, a significant obstacle to industrial development.

The Spanish mining industry in Bolivia began in 1540 with the operation of the silver mines of Porco (now the province of Quijarro) by Gonzalo Pizarro and Diego Centeno. The discovery in 1545 of Cerro Potosi, a conical mountain rising 15,680 ft. above sea level, establishzd Potosi as the foremost silver producing region in the world. It is estimated that the region subsequently produced $1,000,000,000 worth of silver. The Cerro is composed of one of the richest ore bodies yet discovered, an ore containing tin, bismuth and tungsten in addition to silver.

Potosi declined in importance as a mining area as a result of the diminution of the more readily available ores and to progress in technology which made feasible the use of lower quality ores in more accessible locations. The exploitation of Bolivia's tin ores which began shortly before the turn of the 20th century, restored mining activity in the department. The construction of a railway from Antofagasta to the centre of the plateau in 1892 made it possible to ship out ores of lesser value than those of silver; newly discovered uses for tin created an expanding market for that metal. Lead, zinc, antimony, copper, bismuth, sulfur. gold, silver and wolfram, are also worked in the region. Among the 13 provinces of the department, those notable for minerals comprise Sud Chichas (regarded as the richest), Cercado, Chayanta, Bustillo, Charcas, Linares, Alonso de Ibañez. Nor and Sud Lipez and Nor Chicas. Extensive deposits of solid salt, the Salar de Uyuni (3,500 sq.mi.) and Copaisa, Chiguana and Empexa, south of Lake Poopó, are also exploited.

Air, railroad and highway facilities are available within the department. A branch line of the Antofagasta-La Paz railway extends to the city of Potosi from the junction at Rio Mulato. This line (15,705 ft. above sea level at Condor) is one of the highest railways in the world. (J. L. TR.)

POTOSÍ, a city in Bolivia, capital of the department of Potosi, is located on a cold and barren plateau 275 mi. S. of La Paz. Pop. (1950) 45,758. One of the highest cities of the world (altitude over 13.700 ft.), it stands in the shadow of the fabulous Cerro Potosi and its 5.000 mines. The temperature seldom exceeds 59° F. Legend attributes the name to "potojchi," Quechua word meaning "thunder," on account of rumblings inside the mountain. The city came into existence after the discovery of silver in the *cerro* by the Indian Gualpa, whose master Juan de Villaroel registered the first claim April 21, 1545. Charles V conferred upon it the title Villa Imperial (1547). Philip II chartered the university (1571) and the mint (1572). So great was the wealth of the mines that "as rich as Potosi" became a current expression. About 200 merchants supplied the city with luxuries from all parts of the world. It was a turbulent city full of factions, such as the Vicunas and Vascongados, who waged full-fledged civil war, 1623–26. Population fluctuated with the mineral production. Of the estimated 160.000 residents in 1650 only 8,000 remained when Simón Bolivar liberated the area in the final battle of the Wars for Independence, Oct. 5, 1825. Rich tin deposits replaced the diminishing silver lode and 20th century Potosi became the leading industrial city of Bolivia. Iron, steel, shoes, soft drinks, beer, furniture, electric products and mosaics supplemented mining (tin, lead, copper, silver) and refining industries.

Although flood and earthquake have taken their toll, Potosi retains its colonial charm. The city is laid out in squares with narrow, sometimes winding streets originating in the central plaza, around which are grouped the government house, city hall, national college, mint. treasury and cathedral, dating back to colonial times. It is on a highway* and the Sucre-Potosi railway connects with the Antofagasta-Bolivia line.

See Lewis Hanke, *The Imperial City of Potosi* (1956). (G. B. Co)

POTOTAN, a municipality (with administrative centre and 64 *barrios* or districts) of the province of Iloilo, island of Panay, Philippines, on the Jaluar river, and located along the railway, about 17 mi. N.E. of Iloilo, the provincial capital. Pop. (1959 est.) 42,530. The chief agricultural products are sugar, maize (corn), palay (rice), tobacco and abacá (Manila hemp). Cattle, carabao and horses are bred for local use and for export. Panay-Bisayan is the vernacular. Of the inhabitants aged 6 to 19 inclusive, 41.7% in 1939 attended school, while 51.8% 10 years old and over was literate.

POTSDAM, a town in Germany in the district of the same name and formerly one of the residences of the German emperor, on the Havel river, 16 mi. S.W. of Berlin, on the main line of railway to Magdeburg. Pop. (1950) 118,180. It is connected with the capital by two local lines and by a steamboat service through the chain of lakes formed by the river. Potsdam, originally Poztupimi, a Slavonic fishing village, is first mentioned in 993. A town in the 14th century, it was unimportant until the great elector built a palace there between 1660 and 1682, and even at the close of his reign it contained only 3,000 inhabitants. The elector Frederick William I greatly enlarged Potsdam, and his stiff military tastes are reflected in the monotonous uniformity of the streets. Frederick the Great continued his father's work. and was the real creator of the splendour of the town.

The palace, a large quadrangular building of the 17th century, is chiefly interesting for the numerous relics it contains of Frederick the Great. It also contains reminiscences of Voltaire, who resided there for several years. The principal churches are the Nikolaikirche; the Church of the Holy Ghost, built in 1728; and the Friedenskirche, or Church of Peace, erected in 1845–50, to which is attached a mausoleum. Among other conspicuous buildings are the military establishments, the town hall and the Brandenburg gate. Potsdam has manufactures of chemicals, furniture, chocolate. soap, tobacco and surgical and musical instruments. Market gardening affords occupation to many of the inhabitants, and the cultivation of winter violets is a specialty. The Havel is well stocked with fish. To the south of the town lies the observatory.

POTT, PERCIVALL (1714–1788), English surgeon, the first surgeon of his day in England, excelling even his pupil John Hunter, was born in London on Jan. 6, 1714. He became assistant surgeon at St. Bartholomew's in 1744 and was full surgeon, 1749–87. Pott introduced various important innovations in procedure, doing much to abolish the extensive use of excharotics (corrosive agents) and the actual cautery that was prevalent when he began his career. A particular form of fracture of the ankle which he sustained through a fall from his horse in 1756 is still described as Pott's fracture. His book *Some Few Remarks Upon Fractures and Dislocations* had a far-reaching influence in Great Britain and France. Pott's disease is an osteitis of the vertebrae of which he gave an excellent clinical description in his *Remarks on That kind of Palsy of the Lower Limbs Which Is frequently*

Found to Accompany a *Curvature* of the Spine (1779). Pott died in London on Dec. 22, 1788.

See Fielding Hudson Garrison, *Introduction to the History,* of *Medicine,* p *344* (1929).

POTTER, ALONZO (1800–1865), U.S. Protestant Episcopal bishop and educator, was born at Beekman (now La Grange). N.Y.. July 6, 1800. He graduated in 1818 at Union college. where he became tutor and then professor of mathematics after a brief period spent in studying theology at Philadelphia. He was a rector of St. Paul's. Boston. from 1826 to 1831, when he returned to Union as professor of philosophy and political economy, becoming vice-president of the college in 1838. He was consecrated bishop of Pennsylvania on Sept. 23. 1845.

Potter died on board ship in San Francisco harbour on July 4, 1865.

By his publication with G. B Emerson of The School and the *Schoolmaster* (1842) and by his lectures Potter did much to extend and better public school education. He was particularly interested in work for young men and in temperance reform, As a legislator in the church he was wise and progressive. He established the Philadelphia Divinity school (1863) and laboured for the hospital of the Protestant Episcopal Church in Philadelphia

See M. A De Wolfe Howe, *Memoirs of the Life and Services of the Rt. Rev. Alonzo Potter, D D. (1870).*

POTTER, HENRY CODMAN (1834–1908), U.S. Protestant Episcopal bishop, the son of Bishop Alonzo Patter, was born in Schenectady, N Y., on May 25, 1834. In Oct. 1883 he was consecrated assistant to his uncle Horatio Potter, bishop of New Tork, whom he succeeded in 1887. He died in Cooperstown, S.Y.. July 21, 1908. During his administration the cornerstone of the cathedral of St. John the Divine was laid (Dec. 27, 1892). As rector of Grace church he worked to make it an "institutional church" with clubs for working men and girls, day nurseries and kindergartens.

Potter won fame on the centennial of Washington's inauguration by his address on the dangers and corruptions of the spoils system

See Harriette *A* Keyser, *Bishop Potter, the People's Friend* (1910), and the official biography by George Hodges (1915).

POTTER, PAUL (PAULUS) (1625–1654), Dutch painter and etcher. celebrated chiefly as an animal painter. son of the painter Pieter Potter, was born at Enkhuizen in 1625. He entered the Guild of St. Luke at Delft in 1646. In 1649 he moved to The Hague, where in the following year he married Adriana, daughter of the architect Claes van Balkeneynde. In 1652 he settled in Amsterdam, where he died on Jan. 15, 1654. Potter probably received his early training from his father, but his style shows little dependence upon that of earlier masters. Animals appear prominently in all of Potter's characteristic works, sometimes singly (the "Grey Horse," dated 1653, Hamburg), more usually in small groups silhouetted against the sky. or in greater numbers with peasant figures and rustic buildings in an extensive landscape. So lifelike is his portrayal of cows, horses and other domestic animals that many critics tend to regard this as his only talent, and to treat him as one of the minor Dutch masters—charming, but limited in range. This is an undervaluation of Potter's genius. His range of subject matter is limited by his own choice, but within that range he displays powers far above many contemporaries who are usually judged to be more eminent. No Dutch painter of his time was more sensitive to the passing moods of nature, or to the countryside's timeless harmony of beast, landscape and weather, and none gives the impression of having observed the landscape of his country with deeper love or understanding. In addition, Potter possessed a remarkably developed feeling for design, expressed in the grouping of his forms and in his use of eloquent silhouette, dark on light or light on dark. All of these qualities can be admired in the superb "Early Morning" (1647. Salzburg museum). which is possibly his most perfect masterpiece. This is a fine, open composition, painted with a small, but firm and lively touch; the light of early morning—and of early spring—is deliciously rendered. and there is a keen understanding of both animal and human behaviour. Like most of his really successful pictures it is on a small scale, and painted on panel.

In so tragically short a career there was naturally little development in style between the earlier and the later works, but 1647 seems to mark a peak in his achievement, for many of the finest paintings bear this date. Characteristic works are: "Cattle in a Stormy Landscape" (1647; National gallery, London) ; "Horses Tethered at a Cottage Door" (1647 or 1649; Louvre. Paris); "Peasant With Cattle" (1648; Cassel) and "Cattle Reflected in Rater" (1648; Mauritshuis. The Hague). Among works which depart from his normal scale or style, the huge "Young Bull" (1647; The Hague), which is on the scale of life, is his most celebrated though surely not his finest work, while "Orpheus Charming the Beasts" (1650; Rijksmuseum. Amsterdam). is an untypical excursion into a poetic world reminiscent of Roland Savery. Potter's etchings of animals show all the skill and sympathy of his paintings.

See T van Westrheene, *Paulus Potter, Sa vie et ses oeuvres* (1867); *C.* H. de Groot, *Catalogue* of . . . Dutch *Painfers,* etc, vol. iv (1912).

(R. E. W. J)

POTTERIES, THE, a name applied to a district of north Staffordshire. the principal seat of the china and earthen are industry in England. It lies in the upper part of the Trent basin. For a distance of 9 mi. from southeast to northwest and about 3 mi. from northeast to southwest, the district resembles one great town, but the chief centres are Burslem. Hanley. Longton, Stoke-on-Trent. Fenton and Tunstall (except Fenton, the "Five Towns" of Arnold Bennett's novels). These towns were amalgamated in 1910 as one municipal borough under the name of Stoke-on-Trent (*q v.*), which was made a city in 1925. Newcastle-under-Lyme, though not sharing in the staple industry, may also be reckoned in the district. In 1769 Josiah Wedgwood founded potteries at Etruria, by the Trent and Mersey canal; they are now at Barlaston. Wedgwood and Minton are the two most famous family names connected with the china industry of the district. Coal, from the north Staffordshire coal field, and coarse clay are the only local natural products used in the industry, the finer clay and other ingredients being brought from elsewhere.

POTTER'S CLAY: see KAOLIN.

POTTERY AND PORCELAIN. The word "pottery" (Fr. *poterie*) in its widest sense includes all objects fashioned from clay and then hardened by fire: the word "porcelain" should only be applied to certain well marked varieties of pottery. Pottery is dependent on two important natural properties of that great and wide-spread group of rocky or earthy substances known as clays viz., the property of plasticity and the property of being converted when fired into one of the most indestructible of ordinary things "Ceramics" or "keramics" (Gr. *keramos,* earthenware) is a general term for the study of the art of pottery. It is adopted for this purpose both in French (*ceramique*) and in German (*Keramik*).

INTRODUCTION

The primitive races took such clay as they found on the surface of the ground, or by some river-bed, and, spreading it out on a stone slab, picking out the rocky fragments, then beating it with the hands, with stones or boards, or even treading it with their feet, proceeded to fashion it into such shapes as need or fancy dictated. Fired in an open fire, such pottery may be buff, drab, brown or red—and those from imperfect firing become smoked, gray or black. For ages tools and methods remained of the simplest—the fingers for shaping or building up vessels, a piece of mat or basket-work for giving initial support to a larger vase—until some original genius of the tribe found that by starting to build up his pot on the flattened side of a boulder he could turn his support so as to bring every part in succession under his hand, and thus the potter's wheel was invented.

At first this simple hand-made pottery was hardened by drying in the sun, but the increasing use of fire soon brought out the fact that a baked clay vessel became as hard as stone. Different districts produced different colours of clay, and thus colour decoration arose. On this substructure all the pottery of the last 4,000 years has been built, for behind all Egyptian, Greek or

Chinese pottery we find the same primitive foundations.

In subsequent articles on this subject we find that the Egyptians evolved schemes of glowing colour—brilliant glazes fired on objects, shaped in sand held together with a little clay, or actually carved from rocks or stone; the Greeks produced their marvels of plastic form, and then turned the plastic clay into imitations of metal forms; the Romans spread some knowledge of the craft over all the empire, but with its fall pottery was forgotten along with its greater achievement. Egypt and the Near East continued the splendours of their glorious past, and glazed and painted pottery was still made by traditional methods. Many interesting kinds of decorated pottery were made at Old Cairo, Alexandria, Damascus, in Syria, Anatolia and elsewhere (on which the later Moslem potters founded their glorious works).

Meantime, in the farther East, the Chinese—the greatest race of potters the world has ever seen—were quietly gathering strength, until from their glazed, hard-fired pottery there emerged the marvellous, white translucent porcelain, one of the wonders of the mediaeval world.

With the dawn of the 15th century, the state of affairs was practically this: In European countries proper, we find rudely fashioned and decorated wares in which we can trace the slow development of a native craft from the superposition of Roman methods on the primitive work of the peoples. The vessels were mostly intended for use and not for show; were clumsily fashioned of any local clay, and if glazed at all then only with coarse lead-glazes, coloured yellow or green; in no case above the level of workmanship of the travelling brick- or tile-maker. The finest expression of this native style is to be found in the Gothic tile pavements of France, Germany and England.

As early as the 12th century the superior artistic pottery of the Moslem nations had already attracted the notice of Europeans as an article of luxury for the weaithy; and we may well believe the traditional accounts that Saracen potters were brought into Italy, France and Burgundy to introduce the practice of their art, while Italian potters certainly penetrated into the workshops of eastern Spain and elsewhere and gathered new ideas.

During the 15th and 16th centuries, Chinese porcelain also began to find its way into Europe, and by the whiteness of its substance and its marvellous translucence excited the attention of the Italian majolists and alchemists. The first European imitation of this famous oriental porcelain of which we have indubitable record was made at Florence (1575–85) by alchemists or potters working under the patronage, and, it is said, with the active collaboration of Francesco de' Medici. This Florentine porcelain was the first of those distinctively European wares, made in avowed imitation of the Chinese, which form a connecting link between pottery and glass, for they may be considered either as pottery rendered translucent or as glass rendered opaque by shaping and firing a mixture containing a large percentage of glass with a very little clay.

During the 18th century not only was there a very large trade in imported Chinese and Japanese porcelain, but there was a great development cf porcelain manufacture in Europe,

The 19th century witnessed a great and steady growth in the output of porcelain and pottery of all kinds in Europe and the United States. Mechanical methods were largely called in to supplement or replace what had hitherto remained almost pure handicraft. The English methods of preparing and mixing the materials of the body and glaze, and the English device of replacing painted decoration by machine printing, to a large extent carried the day, with a great gain to the mechanical aspects of the work and in many cases with an entire extinction of its artistic spirit.

The 20th century opened with a wider outlook among the potters of Europe and America. In every country men were striving once again to bring back to their world-old craft something of artistic taste and skill.

TECHNIQUE

All pottery, whether of ancient or modern times, is made by the simplest method. The clay, dug from the earth's surface. is prepared by beating and kneading with the hands, feet or simple mallets of stone or wood. Care is taken that all stones and hard particles are picked out. In ancient pottery, the clay, well tempered with water, was almost invariably used without any additional material. From this pure clay, vessels were shaped by scooping out or cutting a solid lump or ball, by building up piece by piece or by squeezing cakes of clay on to some natural object or prepared mould or form. The potter's wheel, though very ancient, was a comparatively late invention, arrived at independently by many races of men. In its simplest form it was a heavy disk pivoted in a central point to be set going by the hand, as the workman squatted on the ground. About the Christian era, and in Egypt apparently, a much larger disk, which the potter could rotate with his foot, was introduced; this gave the potter an opportunity to use both hands in the manipulation of the clay. In the 17th century the wheel was spun by means of a cord working over a pulley, and in the 19th century the steam driven wheel was introduced.

The rotating process completed, the piece is removed from the wheel and set, aside to dry. When it is about leather-hard, it may be recentred carefully on the wheel (the old practice), or placed in a horizontal lathe (16th century) and turned down to the exact shape and polished to an even, smooth surface. Many Greek vases have obviously been "thrown" in separate sections. So too with the Chinese; many of their forms have been made in two or three portions, subsequently joined together and finished on the outside as one piece. *(See* TERRA-COTTA.)

Firing.—The type of kiln used by the potters of ancient Egypt or Greece have not entirely vanished from present day use; it is only in the civilized countries of the modern world that they have been replaced by improved and perfected devices. The potters of certain sections of the Near East and of Japan remain content with the crudest and most primitive types of kilns. With the organization of the pottery as a factory industry in the 18th century, improved kilns were introduced, and the type of kiln now used in civilized countries is a verticle furnace from 10 to 22 ft. in diameter and of similar height, capable, therefore, of cantaining at one firing a quantity of pottery that would have formed the output of a mediaeval potter for a year. Gas-fired kilns and ovens are now being used or experimented with in every country, and their perfection, which cannot be far distant, will improve the most vital of the potters' processes both in certainty and economy.

Glazes.—We can only consider as glazes those definite superficial layers of molten material which have been fired on the clay substance. Glazes are as varied as the various kinds of pottery, and it must never be forgotten that each kind of pottery is at its best with its appropriate glaze. The most important types of glaze are (1) alkaline glazes, *e.g.,* Egyptian, Syrian, Persian, etc., the oldest and most uncertain; (2) lead glazes, the most widespread in its use and the best for all ordinary purposes; (3) felspathic glazes, the glazes of hard-fired porcelains, generally unsuited to any other material; (4) salt-glaze, produced by vapours of common salt, the special glaze of sione-wares.

Colours.—The primitive potters of ancient and modern times have all striven to decorate their wares with colour. The simplest, and therefore the earliest, colour decoration was carried out in natural earths and clays. The clays are so varied in composition that they fire to every shade of colour from white to grey, cream, buff, red, brown or even to a bronze which is almost black. One clay daubed or painted upon another formed the primitive palette of the potter, especially before the invention of glaze. When glaze was used these natural clays were changed in tint, and native earths, other than clays, containing iron, manganese and cobalt, were gradually discovered and used. It is also surprising to note that some of the very earliest glazes were coloured glasses containing copper or iron (the green, turquoise and yellow glazes of the ancient Egyptians and Assyrians). Marvellous work was wrought in these few materials, but the era of the finest pottery-colour dawns with the Persian, Syrian and Egyptian work that preceded the Crusades. By this time the art of glazing pottery with a clear soda-lime glaze had been thoroughly learnt. Vases, tiles, etc., shaped in good plastic clay, were covered with a white, highly siliceous coating fit to receive glazes of this type, and giving the best possible ground for the painted colours then known. The colours already spoken of were either clay colours or what are known as "under glaze" colours, because they were painted on the pottery before the glaze was fired.

The earliest glazes of the Egyptians appear not to have been white, but were coloured throughout their substance, and this use of coloured glazes as apart from painted colour was developed along with the painted decoration by the later Egyptian, Syrian and Persian potters. Green, yellow and brown glazes were almost the only artistic productions of the mediaeval European potters' kilns, and their use everywhere preceded the introduction of painted pottery.

With the exceedingly refractory felspathic glazes of Chinese porcelain very few underglaze colours could be used; and the prevalence of blue and white among the early specimens of Chinese porcelains is due to the fact that cobalt was almost the only substance known to the potters of the Ming dynasty which would endure the high temperature needed to melt their glazes. Consequently the Chinese were driven to invent the method of painting in coloured fusible glasses on the already fired glaze. They adopted for this purpose the coloured enamels used on metal; hence the common term "enamel decoration," which is so generally applied to painting in those colours which are attached to the already fired glaze by refiring at a lower temperature. With the introduction of this many-coloured Chinese porcelain into Europe the same practice was eagerly followed by our European potters, and a new palette of colours and fresh styles of decoration soon arose amongst us.

It must be pointed out that the colour possibilities in any method of pottery decoration are largely dependent on the temperature at which the colour needs to be fired. The clay colours are naturally more limited in range than the under-glaze colours, and these in their turn than the on-glaze colours.

Metals. — The noble metals, such as gold, platinum and silver, have been largely used since the early years of the 18th century as adjuncts to pottery decoration, especially on the fine white earthenwares and porcelains of the last two centuries. At first the gold was applied with a kind of japanner's size and was not fired to the glaze, but for the last 150 years or so the metals have generally been fired to the surface of the glaze like enamel colours, by mixing the metal with a small proportion of flux or fusible ground glass. There can scarcely be a doubt that the ancient lustres of Persia, Syria and Spain were believed to be a form of gilding, though their decorative effect was much more beautiful than gilding has ever been. The early Chinese and Japanese gilding appears, like the European, to have been "sized" or water-gilt, not fired; and it seems probable that the use of "fired" gold was taught to the Oriental by the European in the 18th century. To-day "liquid" gold is exported to China and Japan from Europe for the use of the potter. (For Egyptian pottery, *see* EGYPT: *History: Ancient Civilization and Culture;* for primitive far eastern and near eastern pottery, *see* section *Near and Far East* of this article. *See* also BABYLONIA AND ASSYRIA. and POTTERY, PRIMITIVE.) (X.)

GREEK POTTERY

The pottery of ancient Greece, prehistoric and historical, is distinguished from all other fictile wares of the same ages by its free development of naturalistic painted decoration. The ceramic painter's art was so far separated from the potter's in the classical period, that each could put his signature to his own portion of the work, and there can be little doubt that the best Minoan pottery was equally the joint product of the two craftsmen. This uniformity in Prehellenic and Hellenic ceramics can hardly be fortuitous. Though Late Minoan (Mycenaean) vase-painting contains no visible element of design that was adopted by the Geometric artists, the technique of potter and painter passed intact across the apparent gap in culture that separates the Aegean ages of Bronze and Iron, and the subsequent revival of naturalistic ornament in the Archaic Greek period shows that something more than mere mechanical skill had been inherited.

Prehistoric Origins. — The technique in which the masterpieces of classical vase-painting were executed was first perfected in Minoan Crete, but its invention was not Cretan. Painted pottery was made in prehistoric Mesopotamia and Egypt long before its appearance in Aegean lands. Pre-Sumerian ware bears decoration fired on pale clay in a dark medium of ferruginous earth fused with an alkaline flux, and one variety of Egyptian predynastic pottery has dull white pigment similarly fired on a dark ferruginous wash. Both processes were applied in Early Minoan pottery; the latter was brilliantly exploited in the polychrome Middle Minoan style (Kamares ware), but the former finally prevailed, because of its greater freedom, in the Late Minoan age. *(See* CRETE: *Archaeology.)* At the close of the M.M. period, when Cretan arts were transplanted to the Greek mainland, the colonial (Mycenaean) fabric of Minoan pottery displaced the inferior and largely handmade native wares, Helladic, Cycladic and Thessalian, which formerly marked the various cultural regions. *(See* GREEK ARCHAEOLOGY.) By the end of the Mycenaean age the pottery of the whole Aegean area was uniform, except on its northern and eastern borders, where Danubian and Anatolian influences were preponderant. This latest Mycenaean ware preserves the forms and fabric of the best Minoan models, but its ornament is atrophied. Shells, octopods and seaweed have degenerated into rows of wavy lines, lily and papyrus flowers appear as groups of parallel curves or chevrons, and the rich designs of linked and running spirals give way to bands of single coils. But the clay is finely worked, the pots accurately turned, the firing hard and even, the glaze dense and lustrous. Two Mycenaean fabrics can certainly be distinguished. The more numerous class has a warm yellow clay surface and its black glaze fires red. The smaller group is made of exceedingly smooth pale greenish clay, and painted with brown-fired glaze, which tends, to flake away from the close texture of the surface. The latter belongs to the Argolid, and was made from the same white clay that produced the later Protocorinthian and Corinthian wares.

The Geometric Style. — The next historical phase in Greece was the transition from bronze to iron, about 1000 B.C., a cultural change that involved the violent downfall of the Mycenaean polity. Arts were generally submerged, but the pottery can be identified. It is called Submycenaean or Protogeometric, as its elements appear to attach themselves to the old Minoan or the new Hellenic system. The technique is still Minoan and is often brilliant, but many of the pot-shapes are modified and the decorative patterns assume a new character. The surviving Mycenaean motives are resolved into their simplest linear elements, and these tend to combine again in rigid geometric schemes. Another tendency was to abandon painted patterns and cover the whole pot with black glaze. In this potent fallow the new principles of Hellenic art were laid, and the so-called Geometric style sprang rapid and luxuriant. In its mature phase a Geometric vase is covered with narrow horizontal bands of minute and crowded ornament, rows of repeated figures, triangles, lozenges, circles, continuous or panelled bands of zig-zags, chequers and, chiefly characteristic, the maeander. This last motive, always drawn in double outline filled with hatching, is probably the key to the origin of the style. It appears at the same period in Italy, in the pottery and bronze work of the Villanova culture, and since there is no evidence of intercourse between the two countries at this date, must have been introduced into both from a common northern source. Its first occurrence in Greece is in isolated bands or panels reserved on necks or bodies of black-glazed pots, a rudimentary form of decoration which was as universal as the former Mycenaean style. Subsequent developments were local, and many styles have been identified in mainland Greece, the Aegean islands and the coast of Asia Minor. The most elaborate is that of Athens, called Dipylon ware after the cemetery at the city-gate, where the largest vases have been found. These are huge sepulchral jars which sometimes bear among the geometric patterns broader bands or longer panels filled with pictures of funerals, a corpse surrounded by mourners, and processions of chariots, human and animal figures being drawn schematically in black silhouette. These subjects are the first expression of Hellenic delight in representation, which quickly dominated decorative art and ultimately destroyed it. The live subject, human and animal, was also utilized in the Geometric style as a decorative unit, in bands of soldiers carrying shields and spears, of grazing horses, deer and goats, running dogs and birds. The birds belong, like the maeander, to primary sources of the style, but the grazing and running quadrupeds are a later feature, and are probably the first signs of oriental influence.

Oriental Influences.—The political changes that destroyed the Mycenaean power had also interrupted Aegean relations with Asia and Egypt, but when contact was restored, about the 10th century, the new Greek world became doubly linked with the ancient foreign civilizations, by its colonies on the coast of Asia Minor as well as by its own and Phoenician commerce. The effects of oriental contact are visible in all Greek arts after the 9th century. The actual commodities that served Greek vase-painters for models have not been identified, and if, as is possible, they were textiles, cannot have survived. They seem to have been brightly coloured, for touches of red and white paint enliven the black figures in all the orientalizing styles. But accurate drawing and incised contours suggest metal prototypes, and some bronze and silver bowls and cups engraved in the same manner have been found in Greece and Italy. (See BRONZE.) Oriental motives in the late Geometric style, besides the bands of animals, are cable-pattern (guilloche), palmettes in bands or panels, and base-rays. The latter are derived from the petals of a flower-calix; originally Egyptian, they are a common feature of Asiatic pottery, and particularly of late Hittite vases. These novelties broke up the conventional Geometric art, and the succeeding local wares bear very little resemblance to one another.

Protocorinthian, etc.—The principal early orientalizing styles are Protocorinthian, Protoattic, Island (Melian), and Ionian (Rhodian). They belong broadly to the 7th century. The true Protocorinthian fabric was located in the Argolid, where a very precise and simple geometric style had been established. Precision is the distinguishing feature of Protocorinthian ware, and is accentuated by the miniature forms of nearly all existing vases. They are made of the smooth pale yellow clay which distinguishes the local Mycenaean fabric, and which invites fine craftsmanship by its plasticity. Conical cups (skyphoi) and pointed oval scent-bottles (lekythoi) are typical forms. Their earliest subgeometric ornament of simple linear patterns was soon displaced by bands of animals, particularly running dogs, palmettes and lotus, cables and rays, all of which were in turn subordinated to a main frieze containing human or monstrous figures, sphinxes, chimaeras, centaurs and the like. The background in the figure-friezes is filled with detached ornaments, in this style typically the dot-rosette, a device which belongs properly to metal reliefs, where it is simply executed with a round-nosed punch. The influence of metal-work is also visible in the sharpness of this style and in its use of engraving to define outlines and inner markings of the silhouettes. The colour is enriched with patches of dull red and white. as if inlaid on the black-glaze figures, for details such as manes, throats and bellies of animals, armour, clothes and hair of men. Masterpieces of the Protocorinthian style are the Chigi vase in the Villa Gierlia at Rome, a large jug with an amazingly elaborate battle-piece and hunting-scenes in three friezes, and two small scent-bottles, with fancifully modelled tops and hardly less elaborate hunts and battles on their bodies, in Berlin and London (the Macmillan lekythos). A purely decorative Protocorinthian scheme consists of scales or tongues closely incised on a black-glazed surface and painted alternately white and red, together with thin bands and dot-rosettes in the same bright colours. Large and small vases are entirely or partially covered with these ornaments. This fabric was largely exported, particularly to Italy, where it was more or less successfully imitated by Greek and Etruscan potters. Another Protocorinthian group consists of little vases moulded in natural forms, squatting men, busts and heads, animals, birds and shells. They were largely copied from Egyptian faience figures. and in their turn influenced the Egyptian vase-shapes. Large quantities of these Egyptian blue-glazed wares were exported from the Greek settlement of Naucratis, and some were evidently made there, or in some Greek colony in Asia, for the style of many pieces is more Greek than Egyptian, and one found in Rhodes bears a Greek inscription. The same shapes, particularly heads in helmets, were made in ordinary Greek pottery in Rhodes, and other plastically decorated fabrics from the same island are made of black ware like the Etruscan bucchero nero. Large storage-jars, with plastic patterns worked in relief or impressed in friezes with engraved cylinders, are also represented on Ionian sites. Protoattic pottery exhibits the same developments as Protocorinthian, but in a very different style. Vases and their painted decoration are large and vigorous, their fabric rather coarse, in red clay. Various stages of development are called by names of places where typical examples have been found, Phaleron and Vourva. They illustrate the intrusion and refinement of the Oriental repertory, from the animal-frieze with its close array of filling-ornaments to the isolation of human subjects in a clear field. The Island style is as bold as the Attic; it affects heavy spiral ornaments, gay colours, and ambitious narrative-subjects. Crete was a main channel of the new influence, but its pottery is not yet adequately represented. A typical Island form is a large high-necked bowl with a tall conical foot. Some examples, usually attributed to Melos, are painted over a white slip.

Ionian.—In this technical peculiarity they resemble the fabrics of Ionia, where the white slip was universal. This is a pipe-clay wash laid on the rough body of the vase to make a ground for painting. It is rare in Geometric fabrics, and seems to have come in with Oriental decoration; it was probably an anciept Anatolian invention, for it occurs in Hittite, Syrian, and Cypriote wares, and its immediate source may have been Lydia. The many fabrics of early Ionian style are generally represented by Rhodian vases. These are mostly jugs with rays or lotus-wreaths on foot and shoulder, and animal-friezes on the body, done on the white ground in large black-glaze figures with dull red patches. Among the filling-ornaments are looped semicircles (roundels) attached to the borders of the frieze. Human subjects are rare, the most prominent animal-figures are sphinxes, and the characteristic motive is a band of grazing goats. Large plates are a frequent shape, painted with lotus designs, or with concentric panel-friezes containing heads of goats and birds. A very similar fabric, mostly found in the Ionian city of Naucratis in Egypt, has been called Milesian, but may have been made locally. Clazomenae is chiefly represented by large painted sarcophagi. The red and white ornament on black, which was used in Protocorinthian ware, appears also on Rhodian vases, though not quite in the same forms. Red and white bands stand alone, or separate the floral and animal friezes, and the same colours are used for drawing lotus wreaths, or for filling tongues or lotus and palmette-petals, or even animals outlined by incision on the black ground. A fabric resembling the Ionian, but apparently belonging to mainland Greece, is the so-called Cyrenaic, which, since the discovery of a complete stylistic series in Spartan temple-deposits, has been known rather as Laconian. The excavation of Cyrene should decide the question of its origin. It is a white-slipped ware with bold decorative painting, large black and white chequers and step-patterns and solid rays in its subgeometric form, pomegranates and lotus-buds formally disposed between animal-friezes in its orientalizing phase. Its early shapes are somewhat fantastic; a typical drinking-cup (*lakaina*) has a low convex body, from which two long loop-handles spring, and a tall concave lip or neck. A mature work is the famous *kylix* in the Bibliothèque Nationale of Paris, with a picture of King Arcesilas of Cyrene supervising in oriental state the lading of a ship. It is this scene that caused the fabric first to be attributed to Cyrene.

The Black-figure Style.—Towards the end of the 7th century the local fabrics, which had diverged so widely in their orientalizing phases, tended to come together again, perhaps under Athenian influence, in the Black-figure style. The expansive interest in human form and human life enlarged the fields in which these subjects were accommodated; animal and floral friezes were reduced in width and relegated to the less conspicuous positions on the pots. In the mature style of the 6th century ornamental animals hardly occur at all, and floral patterns are only used for borders or bands and panels in which narrative-pictures are displayed. But the new pictorial style retained the technique of the old ornament. The figures are drawn in black silhouette on the clay ground, and inner details are indicated by incision and by colour. The same dull red and white pigments were laid on the black glaze or on the clay in place of it. Both were decoratively applied without consideration of reality to produce a colour-pattern, but white was specially used for faces and limbs of women. White slip disappears as a mark of locality, but occurs on special occasions in several fabrics. The normal surface has the same colour as the body of .the clay, light yellow in Corinthian, light red in Attic and most other wares. The natural colour of Attic clay was enriched with red ochre (*miltos*) and this substance had shch industrial importance that its supply was strictly controlled by the Athenian Government. Corinthian ware in its latest development tried to imitate the Attic colour with a red wash. The history of Greek pottery in the 6th century is the continuous progress of the Athenian fabric towards its ultimate monopoly. At the beginning of the century there were numerous other black-figure wares, Protocorinthian and Corinthian, Laconian (or Cyrenaic), Boeotian, Chalcidian, and Ionian, but hardly any of these survived beyond its elementary stages. The passing of Protocorinthian into Corinthian was accompanied by such a fundamental change of content that the process is obscured, and it is sometimes supposed that the Corinthian potteries displaced those of some neighbouring city, perhaps Sicyon, which had produced the Protocorinthian ware. But though the output was increased and the style changed, the fabric remained constant, and most of the old forms continue to appear with the new decoration. The change took place at the end of the 7th century, and was evidently due to new Oriental models, perhaps textiles instead of metal work. Globular and baggy oval bottles (*aryballoi* and *alabastra*) came into fashion, with large figures, often monstrous or grotesque, painted in a loose style which is the antithesis of Protocorinthian precision. Backgrounds that had been sparsely studded with neat dot-rosettes are now filled up with irregular patches. This is the common ware that was distributed east and west by Corinthian trade. Besides it is a pictorial style which omits the filling-ornament. There is a splendid series of large Corinthian bowls (krateres) bearing scenes from life and legend, with single subsidiary bands of animals or horsemen. In their free use of colour, their technique of outline-drawing, and their deep designs of overlapping figures, these vase-pictures probably give a better idea of monumental painting than any other surviving documents. Chalcidian pottery stands very close to metal work in its angular vase-shapes and sharp figures. The evidence by which the various fabrics are assigned to their localities lies in the forms of the letters in which the names of gods and heroes are inscribed beside their figures. Ionian black-figure designs are lively in colour and in action; the Clazomenian fabric, like the Laconian, retains its subgeometric subsidiary bands. Ionian wares were largely imitated in Etruria, and some of them may have been made there by immigrant craftsmen. Such are the Caeretan *Hydriai,* a brilliantly decorated series of water-jars found at Cervetri (Caere). Their free floral patterns connect them with the Fikellura vases (so-called after a Rhodian site), an odd old-fashioned group that keeps the white slip technique and is shy of narrative-pictures. One of the last Ionian inventions, the *eye-kylix* (a cup mainly decorated with two large pairs of eyes), was adopted by Attic potters. A related Attic series (*Kleinmeister* kylikes) has miniature figures, often single, in an upper band, and below these, or sometimes alone, a line of minute writing, a drinking posy, a love-name or an artist's signature.

Signatures. — The practice of signing vases began in the 7th century; a Protocorinthian lekythos and a (perhaps Argive) krater with the names of their potters, Pyrrhos and Aristonothos, are the earliest examples. Timonidas, Chares and Milonidas are the only known Corinthian painters; there are four or five Boeotians, and the rest are Attic. Names are always accompanied by the words made (ἐποίησε) or painted (ἔγραψε), sometimes by both. The former is taken to be the potter's signature, but the term is not explicit, and may apply to the owner of the factory, to the manipulator of the clay, or to the maker and decorator. But double signatures indicate that the functions of potter and painter were generally separate: "Ergotimos made me, Klitias painted me" on the François vase; and one man occasionally claims both honours: "Exekias painted and made me." More than roo Attic masters are known by name. Many were manifestly foreign, and some were slaves from the unpromising regions of Thrace and Scythia. One of the great black-figure potters bears an Egyptian name, Amasis; his work reveals Ionian affinities and shows that the Athenian monopoly was partly achieved by attracting foreign craftsmen to the city. Mature Attic pottery incorporates the best qualities of the fabrics which it superseded, technical excellence accomplished draughtsmanship and a large repertory of pot-shapes and decorative schemes.

Vase Shapes. — In archaeological usage the numerous shapes are denoted by 'ancient names which do not always rest on ancient authority, but they are accepted as a convenient means of classification. Important forms are two-handled storage-jars (amphora, *pelike*, stamnos), mixing-bowls (krater, in variety), water-pots (*hydria, kalpis*), jugs (*oinochoe,* olpe, *prochoos*), drinking-cups (*kylix,* kantharos, kotyle, *phiale,* skyphos), and oil-bottles (alabastron, *aryballos,* askos, lekythos). All were, copied from metal models. Greek pottery was never a free art; its forms and decoration were inspired, controlled, and finally destroyed by progress in the arts of painting and metallurgy. After the middle of the 6th century, when technical perfection had been achieved, Attic decorators set themselves to perfect their draughtsmanship and power of expression, and the interest of painted pottery after that time is largely as a document in the history of drawing. The finest early black-figure work is the François vase in Florence, a monumental krater signed by Klitias and Ergotimos. It is covered with bands of lively narrative, the Calydonian boar-hunt, the funeral games of Patroclos, the marriage of Peleus and Thetis, the death of Troilos, and the battle of Pygmies and cranes. Among many later masterpieces is an *amphora* in the Vatican made and painted by Exekias, with a single panel-picture on each side. One picture shows Achilles and Aias playing draughts. The group is a stock subject reproduced by several painters, an excerpt, doubtless, from a monumental picture of the siege of Troy. The intentness of the poses and the elaboration of incised detail represent the last possible achievement of this style.

The Red-figure Style. — The innovation was made before the end of the 6th century, about 520 B.C. Some masters, notably Andocides and Pamphaios, produced vases in both styles, and even combined the two on one vase. In the new process the background was blacked and the figures reserved on the red clay; inner markings, details of limbs and features were drawn in thin lines of black glaze, hair and clothing were occasionally done with a diluted brown or yellow wash of the same medium. The glaze has not been successfully reproduced by modern experiment, but analysis shows that it was composed of ferruginous earth with an alkaline flux. It was applied to the pot after the clay was dried, and before firing. The design was lightly sketched with a point, then drawn in outline and detail, apparently with a pen. The background was blacked in, and certain contours of the figures accentuated with relief lines of thick glaze. Touches of colour, red and gold, were very rarely added, and pot and glaze were fired together in a single operation. The new drawing had unlimited freedom and made rapid progress in truth and expression, but its decorative qualities were slight. The formality of archaic art and the restraint of early classical drawing preserved the decorative value of the figures to some extent, but after the middle of the 5th century, when the problems of representation had been solved, this character was lost, and facile drawing admitted weak design.

Attic Masters; Love-names. — Epiktetos, Euphronios, Euthymides, Brygos, Hieron, Douris, are a few names of the great archaic-masters; Sotades, Polygnotos, Meidias, of the free style. Some of these signed as potters, some as painters, and there are anonymous painters, no less capable and far more numerous, whose style can be recognized in their work. Recent research has gone far towards identifying all the hands in Attic red-figure drawing. Where the artist is not known by name, he is called after the potter for whom he worked (the Brygos painter, Meidias painter), after one of his vases or the collection in which it is preserved (the Villa Giulia painter, the painter of the Bowdoin Box) or a notable subject (the Pan painter), or after other persons named on his vases (the Panaitios painter). These, the so-called love-names, refer to popular idols of their day. When known to history they are youths of noble family, and the form of inscription *Panaitios* is handsome (Παναίτιος καλός) indicates that their fame rested on their good looks. The duration of this popularity was therefore not very long, and the use of historical names, Glaukon, Leagros, Miltiades, is valuable evidence for the dates of the vases. The character of red-figure subjects changes with the style. Archaic artists favoured heroic deeds and genial life, exploits of Herakles and Theseus, battles with Amazons and Centaurs, athletic contests and drinking-bouts. The early free style suited contemplative subjects, boys leaving home for the wars, religious and musical ceremonies. In the late free or florid style the scene is largely filled with idle women clad in voluptuous robes and trifling with winged love-gods.

Late Attic and Italian Fabrics.—In the early 4th century an attempt was made to revive this dull field again with colours, white generally for flesh of one or two figures in a group, blue, green, red and gold for drapery and jewels. Gold was often laid on details modelled in relief. These vases have been largely found in North Africa and South Russia, and take their name from the Crimean town of Kertch. They represent the last phase of pictorial painted pottery in Greece. The art survived, however, and even flourished for at least another hundred years in South Italy, where it was first established at the end of the 5th century. Another Attic fabric, the white-slipped ware which was regularly used for funeral lekythoi and occasionally for kylikes and other shapes in black-figure and outline-drawing, also came to a natural end in the 4th century, but was not involved in the same artistic decadence, since its decoration had proceeded on the broader lines of painting. These little vases, oil-bottles made for offerings to the dead, generally bear pictures of the tomb with boys and maidens bringing gifts. Clothes and mourning-sashes are painted in bright colours, and free brush-work dominates the designs. But painted patterns did not entirely disappear with pictorial subjects.

Hellenistic Relief-wares.—There was always a large class of black-glazed vases which had no other painting, but were sometimes fluted or impressed with slight ornaments in close imitation of metal. These were further adorned in the 4th and 3rd centuries with wreaths and necklaces drawn or engraved, or modelled and painted white or gilt, and occasionally with moulded figures like bronze plaques in relief. This style seems to have been universal in Hellenistic Greece, and was also produced extensively in Apulia and Campania (Gnathia and Capua wares). Another Hellenistic fabric, usually black-glazed, has purely plastic decoration, being exactly copied or even cast from contemporary bronze and silver vessels ornamented with reliefs. One group of bowls is called, for no good reason, Megarian or Homeric; it may be the Samian ware mentioned by Pliny, and is certainly the prototype of the Roman pottery wrongly called by that name. Bowls have decorative foliate patterns, or bear mythological and heroic scenes, often accompanied by written descriptions or verses quoted from the plays or poems which they illustrate. Another type, called Calene *phiale,* and mostly made in Italy, is a shallow bowl with a central medallion or interior border-frieze in relief. Two examples in the British Museum, with a frieze of chariots, are replicas of a silver bowl in the same collection. (See SILVERSMITHS' AND GOLDSMITHS' WORK.) Some Hellenistic wares preserved the old tradition of black painted ornament on a light clay ground or slip. Their designs are mostly wreaths and garlands, and their fabrics seem to be located in the East, particularly at Alexandria in Egypt (Hadra vases). Alexandria and Tarsus were the first centre5 of manufacture of Greek pottery glazed in modern fashion. Blue and green faience mas the speciality of Egyptian potteries. It had been imitated by the archaic Greeks and appears with Greek designs again in the Hellenistic age. But the new glaze is quite different, and was probably an Asiatic invention. It is a thick vitreous substance made with a metallic flux, in colours ranging from brown through yellow and green to blue, and was usually laid over lamps and similar small vessels moulded in relief or entirely modelled in natural forms. But at this point Greek plastic pottery finally merges with Italian. The art of the Mediterranean world in the 2nd century B.C. was Hellenistic, industry was cosmopolitan, and it is not always possible to know in which country the fabrics were located.

ANCIENT ITALIAN POTTERY

North and south Italy were separate cultural provinces in prehistoric times. The south, with Sicily, produced some elaborately painted pottery, which may be related to the Neolithic wares of mainland Greece, and some incised with rectilinear patterns like those on the earliest fabrics of Troy and Crete. But there is no evidence of contact between the Aegean and Italian areas before the Late Mycenaean age (c. 1300 B.C.), and the mutual resemblances in the pottery are equally referable to the universal similarity of primitive abstract decoration. In any case this south Italian art lived and died in isolation. Contemporary pottery of the north and central regions was of much coarser type, seldom decorated at all and never painted. But the Bronze age (Terremare) fabrics, though inferior in quality, had a plastic character that influenced the southern shapes and developed through the Villanova style into classical Etruscan ware. It was probably not fortuitous that the Hellenistic relief styles were largely established in Italy, and that the pottery of the Roman empire bore plastic decoration.

Prehistoric Origins.—The decorative elements in Terremare pottery are knobs and ribs on the bodies and fantastic modelling of handles, which often end in horns and crescents. The same elements, which had Danubian affinities, persisted in early Iron age (Villamova) fabrics, and the Geometric style in which the other Villanova ornament was designed also reflects the influence of central European art. The similarity of this Villanova Geometric to the contemporary Dipylon Geometric style of Greece has sometimes been referred to Greek influence in Italy, but there is no other trace of contact at this time (c. goo B.C.), and it is probable that the same style penetrated both peninsulas from the north. In each case the new designs found an effective medium ready for their expression. Greek Geometric pottery was painted in the old Minoan technique, the Italian patterns were engraved or stamped or modelled in soft clay. The characteristic maeander, which the Greeks painted in a hatched band, appears in Italy in a band of parallel incisions. The Italian style, like the technique, is far more primitive than the Hellenic. Villanova pottery is not wheel-made; its clay is coarse, red or brown in body with a darker surface which at its best is polished black. This type of pottery is known in Italian archaeology as impasto. The surface colouring was probably done by fumigation. The fabric is thick and clumsy and the shapes are composed of the simple globular and conical forms that belong to elementary metalwork. A typical cinerary urn has a tall biconical body with a single horizontal handle on its wide middle. Its mouth is often covered with a shallow one-handled bowl. The natural development of such pottery was towards closer imitation of metal in refinement of fabric and accuracy of form, but the process was disturbed by the intrusion of foreign influences from Greece and Asia. This contact, which began in the 8th century, coincided with the first settlements of Greeks in Italy and with the rise of Etruscan civilization.

Etruscan **Bucchero.**—The native Etruscan pottery is called in Italian bucchero nero, or simply bucchero. The clay is fine and coloured black throughout its substance, probably by chemical reduction in the kiln or by previous staining. The fabric is generally heavy, since most of the vases were made in moulds and the wheel was rarely used. There are, however, some very fine, thin pieces. Besides the simple developments from Villanova forms, among which the arched band-handle is conspicuous, are copies of Greek and oriental models, *oinochoai, kantharoi, kylikes,* enriched with various kinds of moulded ornament, engraved, impressed or modelled. The three processes were often applied to one pot. Linear designs were drawn freehand with a graver or a wheel; they consist of animal and human subjects, floral ornaments, palmette and lotus and simple geometric figures, zig-zags, hatched triangles, linked arcs and spiral coils. Common patterns are fan-shaped groups of dots or dashes impressed with toothed wheels. Small decorative units like rosettes and stars were applied with separate stamps, and continuous patterns such as cables *(guilloche)* were done with engraved wheels. Elaborate friezes in relief were similarly executed with cylinders like Babylonian seal-stones engraved with real and monstrous animals and scenes of hunts, races, banquets and funerals. They were applied to all kinds of vases, but are particularly common on the body of the characteristic Etruscan *kylix* or *calix,* a cylindrical cup on a heavy stem which was a Phoenician form, and perhaps originally Hittite. Some ivory examples carved with similar reliefs were among the foreign articles in the Barberini tomb at Praeneste. Many of these cups are supported by three or four modelled struts, in addition to or instead of the central stem, set between the edges of base and body. They are in the form of human figures or flat strips decorated in relief or openwork. Plastic ornament was also applied to these and other vessels in large reliefs, usually of single animal figures on the bodies, rows of masks on rims, and heads standing free on handles. Bodies were also ribbed and fluted and moulded with gadroons, tongues and petals.

Greek Influences. — Though the foreign influence in this modification of Etruscan pottery may have been Asiatic and derived through Phoenician channels, Greek models introduced the innovation of painted patterns in ferruginous glaze. Greek artistic influence was doubly strong in Italy because the workmen were imported together with their works, 'either as colonists in the Greek settlements of the south or as adventurers in Etruscan cities. There was, for instance, a considerable manufacture of Protocorinthian ware at Cumae (Naples), founded from Chalcis about 750 B.C., and the local Greek fabric can only be distinguished from imported originals by a slight difference in the clay. But some other pieces found at Cumae reveal their provincial origin in coarser forms and decoration, and still more debased versions found on Etruscan sites are evidently the work of Italian potters. The Greeks rediscovered Italy at the end of their Geometric period and the first Etruscan ware painted in the Greek method bears simple rectilinear patterns, not often closely copied from Greek designs, in dull black glaze on light clay. At the same time, and perhaps earlier, there was painted decoration in Etruscan and Latin pottery done in dull white on the dark *impasto* and *bucchero* surfaces. A fabric of red *bucchero* connected with Falerii frequently bears white linear patterns. Greek and oriental subjects, bands of animals and lotus, were also painted in the same medium, and black *bucchero* was perhaps more often finished with polychrome ornament than the present condition of the vases indicates, for these colours were badly fixed and are very fugitive. Protocorinthian and Corinthian pottery were more skilfully copied and to such an extent that the Italian versions of these styles are now as plentiful as Greek originals, particularly jugs with subgeometric patterns, *lekythoi* and *alabastra* with polychrome imbricated decoration and those with bands of running dogs. In the black-figure period (6th century) Greek influence was so intense that it is not possible to decide whether some groups, Caeretan *hydriai* and Pontic *amphorae* were made in Italy, Ionia or Greece. But ordinary Italian products are easily detected by their inferior style and fabric. As Greek art progressed, Etruscan fell behind, and there can be no confusion between the two fabrics in the red-figure style, though most of the existing Attic vases have been found in Etruria. For this reason they were thought on first discovery to be Etruscan, and the false name still lingers in popular usage. It has also been supposed that Attic vases were made chiefly for the Etruscan market, but the fact is that their better preservation in Italy is due to the Etruscan practice of burying them as funeral furniture in chamber tombs.

South Italian Red-figure. — Between the later Attic originals and their Etruscan imitations stand the great series of red-figure vases made in the Greek cities of south Italy, which are derivative rather than imitative, and contain many Italian elements. They had a vigorous life for a hundred years after the disappearance of the true Greek industry. Painted pottery had been made by the natives of south Italy since the 8th or 7th century, at first without any traces of Hellenic influence, in fantastic shapes, large *askoi* and strongly curved and carinated cups with horned handles, elaborately ornamented with geometric patterns (Peucetian ware), and in the 5th century with Greek floral motives in place of the rectilinear designs (Messapian). Some of their peculiar shapes were ultimately incorporated in the red-figure fabrics, but the new style at first was wholly Greek, and its earliest examples are not easily distinguished from Attic vases; they may, indeed, be the work of Athenian artists living in Italy. But in the 4th century definite local styles were formed, differing from Attic in certain vase-shapes, colours of clay and paint, types of subjects and styles of drawing. The recognized south Italian fabrics are Lucanian, Campanian and Apulian, with a special group attributed to Paestum. They differ from one another in some technical and stylistic details, but all are marked by dull brownish clays, extravagant shapes and florid ornament. The simplest style is Lucanian, which probably represents an early phase of the industry. Mature Campanian and Apulian are gaily and profusely ornamented, but the effort is generally limited to one face of the pot, the reverse side being filled with dull conventional figures. Some large vases bear mythological scenes, but ordinary pieces have commonplace subjects of youths and maidens lounging in exaggerated elegance and a close atmosphere of ribbons, flowers, pet animals and domestic furniture. The filling of the backgrounds approaches that of the Greek orientalizing styles. Border patterns, palmettes, waves and foliate wreaths are bold and large. Subsidiary colours, white, yellow, red, were freely applied in dots, lines and washes. Men's costume often reflects Italian fashions, particularly on Campanian vases, a very short tunic with broad belt, and feathered helmets and triangular breastplates for soldiers, presumably the Samnite armour. Dress, pose and gesture of the figures have a histrionic extravagance which seems actually to have been taken from the stage. An important class of subjects consists of theatrical scenes, particularly from the tragedies of Euripides. Burlesques of tragic and heroic legends are also depicted. These were the local *phlyakes,* the kind of farce that the Tarentines were attending in the theatre when they saw the Roman fleet entering their harbour, in 302 B.C. The stage and scenery are often illustrated in these pictures. Only three artists are known in the Italian schools, and two of them, Assteas and Python, belong to the Paestum group. Both painted theatrical scenes. A *krater* by Python shows Alcmena on the funeral pyre, Antenor and Amphitryon setting light to it, and in the upper background, by a characteristic and perhaps theatrical convention of perspective, half-figures of rain-nymphs pouring water out of pitchers on the fire at the behest of Zeus. The most imposing Apulian vases are great sepulchral *amphorae, hydriai* and *krateres.* They bear pictures of elaborate funeral monuments, done in white paint, gabled tombstones or shrines with reliefs or statues of the dead, to whom mourners (in red-figure) bring gifts. Another florid south Italian class of pottery has free plastic ornament; large globular *askoi,* a native shape, have gorgon-masks and fronts of harses on their bodies, large statuettes of women, cupids and winged goddesses standing on rims and handles, all brightly painted in blue and red.

Hellenistic Relief-wares. — These Graeco-Italian fabrics were succeeded, in the 3rd century, by Hellenistic pottery imitating metal, black glazed ware painted with white, yellow and red necklaces and garlands or moulded in relief, The first class takes the name from Gnathia (Egnazia) in Apulia, where much of it has been found. There was certainly an Italian fabric in this style, for several pieces bear Latin legends, mostly dedications to deities such as *Aecetiai pocolom (Aequitiae poculum,* the cup of Justice) painted with the foliate decoration. Some of the contemporary relief wares were also made in Italy. Moulded signatures on several bowls fix their place of origin at Cales in Campania and their maker's nationality as Roman: L. *Canoleios* L. *F. fecit Calenos.* A similar fabric assigned to Bolsena in Etruria is unglazed, and may have been gilt or silvered.

Roman Pottery. — It was also in Etruria, at Arezzo (Arretium), that the first Italian fabric was established of the fine red pottery, variously called Arretine or Samian or *terra sigillata,* which became the standard ware throughout the Roman world for several centuries. *Terra sigillata* is the modern archaeological name for the whole class. Samian is a misnomer; it may perhaps be applied to some Greek fabrics, but means nothing definite. Pliny says that the reputation formerly held by Samian table pottery had passed in his day to Arretium and other places in Italy, Spain and Asia Minor. There is no trace of a Spanish fabric in the existing material, but examples of Asiatic origin have been found at Laodicea, Pergamon, Myrina and elsewhere. It is a purely Hellenistic type of pottery, whether made in Italy or Greece.

Arretine.—Arretine is the name of the Italian fabric, which was not made solely at Arezzo. Provincial Roman varieties, mostly Gaulish, are named from their places of manufacture, La Graufesenque, Lezoux, etc. All this pottery is made of bright red clay and, when ornamented, moulded with reliefs (*sigilla*). Some early (2nd century B.C.) products of Arezzo are black glazed, but they hardly enter into the series. The vases are generally small, for table use, and very rarely have handles; they are mostly bowls, cups and saucers of shallow cylindrical and globular forms. Their lustre was produced with a thin alkaline glaze, which gives an extraordinary depth and richness to the colour of the clay. The earliest decoration was copied from the embossed silverware which was originally a speciality of Alexandria and Antioch. (*See* SILVERSMITHS' AND GOLDSMITHS' WORK.) The bodies are completely covered with floral and foliate designs, masks and decorative furniture, human and animal figures, allegorical and mythological scenes, processions, sacrifices, battles, hunts, dances, feasts and similar episodes of social life The vases, or their decorated bodies, were cast complete in clay moulds, which were prepared mechanically by means of separate stamps, for the component elements of the design. The final artistic effect was therefore dependent on the potters' manipulative skill. The potters' signatures were stamped into the moulds, sometimes appearing in relief on small tablets among the ornamental figures, sometimes in sunk spaces, rectangular, round or fancifully shaped as footprints, wreaths or stars on rims or bases, inside or outside the vessels. Plain wares are ordinarily stamped inside the base. The names of Arretine potters begin about 100 B.C. They represent owners of factories, whose names are sometimes given in the formal Roman manner, sometimes greatly abbreviated and in monogram, and the actual potters, slaves, who often have foreign names. The master potter Marcus Perennius signed M. *Perenni,* M. *Peren, M. Pere, M. Per,* and *M. Pe.* Seventeen slave names occur on his vases, sometimes in conjunction with the master's, sometimes alone. Bargates and Tigranes are the best known; the latter signed *Tigran, Tigra and Tigr.* Aulus Titius signed *A. Titi. Figvl(ina) Arret(ina).* The factory of Rasinius was directed by Lucius of that family in the Augustan period and by Gaius Rasinius Pisanus in the Flavian, by which time the Arretine potteries were turning out replicas of Gaulish work. The large numbers of names and the many varieties of vase shapes and types of ornament that were produced during the long life of this pottery, have been very accurately recorded, and the pottery has become a valuable archaeological index for determining the dates of other Roman objects, buildings and sites, with which it is found in excavation.

Gaulish Terra **Sigillata.**—The Italian fabric came to an end about A.D. 100, being displaced in Italy and the provinces by *terra sigillata* made in France Italy still produced its own coarse pottery for ordinary domestic use, unglazed and undecorated vessels, which formed the bulk of ancient pottery at all periods. The new Gaulish ware was precisely the same as Arretine in fabric, and at least as good in technical quality; its colour is even superior, a darker and brighter red, and its paste is usually harder than the Arretine. But the decoration is inferior, the ornament is in very low relief, and designs and figures are generally small and mean. It is found all over the Roman world, but most abundantly in central France. Finds of moulds and kilns have fixed the localities of the two principal fabrics at La Graufesenque (Aveyron) and Lezoux (Puy-de-Dame), in the ancient Rutenian and Arvernian territories. The Gaulish fabrics began before the middle of the 1st century A.D. and ended about the middle of the 3rd, but ornamented vases were probably not cast from moulds after the middle of the 2nd century. The names are often Gaulish, and even Roman names are spelt in Gaulish fashion, *Tornos* for *Turnus.* It is a strange fact that native elements do not appear in the designs. The forms were at first identical with Arretine or derivative, and there was the same distinction of shapes for ornamented and plain wares. The commonest type of ornamented vase was a carinated bowl with a band of design on each plane *(Form* 29). It was succeeded in popularity about A.D. 150 by a bowl cylindrical in form, which in its turn gave place to a type of hemispherical shape *(Form* 37). The commonest plain red vessels are very wide and shallow cylindrical and conical bowls or flat saucers. The earliest ornament consists of purely decorative motives, wreaths and scrolls, with a few animals incorporated in the foliate designs. These bands are continuous, but the figure-subjects, which began about A.D. 75, are broken up in panels, medallions and arcades, and a free style of figure composition was not reached until the 2nd century. It is characteristic of Lezoux bowls. The figures are minute and were generally taken from well-known Hellenistic sculptural types. There are a few mythological groups. A purely Roman subject, the gladiatorial duel, is very frequent. In the free style hunters chasing animals are popular subjects.

Barbotine **and** Lead-glaze. — A technical innovation of the and century was relief applied in *barbotine,* slip clay laid on by piping. It seems to have been a German invention, since it appears first on native Rhenish pottery of the 1st century. Its early use in *terra sigillata* was for small foliate patterns on the rims of flat bowls and dishes, but in the 3rd century it began to replace moulded work on bowls of the standard Roman shape. Another Teutonic element in the Roman fabrics of this date is a globular jar with narrow neck (*olla*), which could not be cast entire. Its ornament was therefore made in separate plaques or medallions and affixed to the pot; scrolls in *barbotine* form a setting for these reliefs, which are largely topical in subject, portraits of emperors, gladiatorial contests and theatrical scenes, often accompanied by explanatory inscriptions. These were made in Provence and also at Lezoux, where they were the last products of the Roman industry. The Gaulish output was not large in Roman times and its forms were trifling, small vases and lamps and toys ornamented with reliefs or modelled in the shapes of animals and common objects. But in the Eastern empire the process was generally used for Byzantine pottery. It was adopted by the conquering nations after the fall of Rome, and became the medium of ceramic decoration in mediaeval Europe. (E. J. F.)

EUROPEAN POTTERY

TO END OF 18TH CENTURY

Byzantine. — The Eastern Empire with its capital at Constantinople was the channel through which, after the downfall of Roman civilisation in the West, the art and culture of the East was communicated to Europe, and the artistic ancestry of later European pottery is to be sought, in part, in this quarter. Evidence is scanty, however, as to the nature of Byzantine pottery, owing to the cessation of the pre-Christian custom of burying earthenware and other vessels in the tombs of the dead. What little we know is derived from finds of potsherds in excavations at Constantinople and a few sites in Greece, Cyprus, the Crimea and elsewhere. These are of two main types, both of red-bodied earthenware with a surface coating of transparent lead glaze. The decoration in one type is in relief, produced with impressions of a wooden stamp; in the other it is of the kind known as *sgraffito,* engraved with a pointed tool through a coating of white slip. The fragments are mostly those of bowls and deep dishes; the ornamental motives include human figures, animals and birds of symbolic import, simple leaf designs, interlacements, monograms and the Greek cross. The glaze is generally yellow; a bright copper-green is also found.

Hispano-Moresque Ware.—The chronology of the Byzantine wares discussed above is difficult to establish, but it is probable that they date from the two or three centuries immediately preceding the Turkish conquest of Constantinople in 1456. Pottery of artistic quality was known long before this date in Spain, fragments with painted decoration akin to that of the contemporary wares of Mesopotamia and Egypt having been found on the site of Medina az-Zahra, the palace of the Caliphs near Cordova, destroyed in the 11th century. References are found in writers of the 12th century and later to the "golden pottery" of Calatayud (in Aragon) and of the Kingdom of Granada; this phrase undoubtedly means the tin-enamelled earthenwares painted in metallic lustre colours, derived from silver and copper, which are the most famous of the Hispano-Moresque wares, although no surviving specimens are known which can be referred to a date earlier than the 14th century. To this period belong the celebrated vase in the Alhambra, with its decoration of confronted gazelles, arabesques and inscriptions, in golden lustre with touches of blue, and the similar vases scattered in various museums. A bowl of similar style, at Berlin, which is marked with the name of Malaga, suggests that that city rather than Granada was the place of origin of this Andalusian class of lustred pottery. In later times the manufacture passed to the kingdom of VALENCIA, whence in the 15th century such wares were shipped to places so far distant as Leeuwarden, London, the Crimea and Cairo. The chief Valencian pottery centre in the 14th century was Paterna, where quantities of enamelled ware have been found with human figures, animals and foliage designs of pronouncedly Gothic character painted in manganese-purple and green. In the neighbouring town of Manises, on the domain of the Buyl family, lustred pottery was made which the writings of Eximenes show to have been already famous for its beauty in 1383. In the earlier Manises wares we find designs of strongly Oriental character, comprising the Islamic "tree of life," palm-motives and Arabic inscriptions (generally the word *alafia,* "blessing," repeated in formalized characters). Early in the 15th century we find bold heraldic animals in blue against lustred spirals, and from about 1450, especially in wares made with heraldic designs for export to Italy, beautiful diapers of vine-leaves and small flowers. In the 16th century renaissance foliage makes its appearance, and in the decadent 17th century wares a crowded ornament of birds and leaves in a fiery copper lustre. Fine blue-and-white wares were made at Teruel (Aragon). At Seville and Toledo especially were produced polychrome-enamelled tiles, at first cut so as to form geometrical and other designs in enamel pigments, which are kept within the outlines, first by painting these in manganese mixed with a greasy medium (de cuerda seca), and afterwards (from about 1510) by moulding the outlines in slight relief (de cuenca). Earthenware dishes with bold animal designs executed by the cuerda seca technique were made at Toledo. Mention must be made also of the great amphora-shaped wine-jars, well-heads and fonts with stamped or incised ornament, sometimes covered with a green enamel, which were made at Triana (Seville) and elsewhere in southern Spain in the 14th and 15th centuries.

Italian **Maiolica.**—The Italian wares of the early Renaissance period represent the highest achievement of the potter's art in Europe. They are mostly of the type known as maiolica, that is, earthenware coated with an opaque tin glaze or enamel as a recipient for painted decoration. The name was first used in Italy in the 15th century of the lustred Valencian wares imported in Majorcan trading ships and mistakenly supposed to have been made in Majorca; it was afterwards extended to Italian limitations of them and finally to unlustred earthenware with a tin enamel. Such wares have been found at Orvieto, Faenza, Siena and elsewhere, dating from the 14th and 15th centuries, with designs of animals, birds, foliage and heraldry of Gothic style in manganese-purple and green, recalling those of the Spanish wares of Paterna.

DERUTA MAIOLICA DISH

By the end of the 15th century the palette was extended to five principal colours or more, but the designs retained their purely decorative character. After 1500 a change to pictorialism came about, with a further range of colouring, dishes and vases being at last treated merely as recipients for subject-paintings (*istoriati*); later in the century the arabesques of Raphael and his school based on ancient Roman wall-paintings began to influence maiolica design, and in the 17th century decoration of this type found a rival in monochrome blue painting in emulation of Chinese porcelain and the Dutch wares of the time, heralding the downfall of the art of maiolica in competition with English earthenware in the 18th century. A great part of the output of the maiolica-potters, in the form of large dishes, wall-panels and vases, was intended from the outset for decoration only; dishes with appropriate designs were a favourite form of gift as love-tokens or to celebrate betrothals and weddings. The "useful" wares include plates, jugs and large pitchers, and expecially drug-pots for the equipment of feudal or monastic pharmacies, either with a handle and short spout or of the waisted cylindrical shape known as albarello. Pavement-tiles were also an important part of the output of certain workshops. From about 1500 onwards the influence of contemporary graphic art becomes increasingly apparent in the decoration of maiolica. Woodcuts in devotional and other books and the engravings on copper of German as well as Italian masters provided the painters with motifs.

Early in the 15th century, under the lordship of the Manfredi, Faenza became an important centre of the craft; the city soon rose to such predominance that its name was adopted in French and other languages for enamelled earthenware in general. Floor-tiles, dated 1487, of great beauty, powerful design and colouring in the church of San Petronio, Bologna, are shown by inscriptions on them to have been made at Faenza in the workshop of the Betini family. The leading Faventine workshop from about 1500 was the Casa Pirota; the dishes and drug-vases there made display a great wealth and variety of ornament based on early Renaissance motives — cupids, masks, dolphins, cornucopias and the like, generally in reserve on a blue ground. One class of wares is painted in dark blue and white on an enamel stained lavender-blue. A great master of the craft, identified by the signature on the back of a dish painted with Christ amongst the Doctors as Ieronimo da Forli, is believed to have lived at Faenza; he adapted compositions of Diirer and others in paintings displaying all the resources of the art in unexcelled beauty of harmonious colour ("The Resurrection," Victoria and Albert Museum, London; "Martyrdom of St. Sebastian," Florence; "Death of the Virgin," British Museum).

CAFFAGGIOLO MAIOLICA JUG

It seems that maiolica was not made at Florence, but potteries existed in its neighbourhood at Montelupo and Caffaggiolo. To the former perhaps belong the noble 15th century wares, especially two-handled nearly globular drug-pots, painted in a thick blackish blue and purple with animals, birds and human figures amongst foliage which from its type has won for these wares the appellation "oak-leaf jars"; in the 17th century this place produced dishes with crude figures of musketeers. A pottery attached to a castle of the Medici, Caffaggiolo, was the source of some of the most sumptuous maiolica ever made, great dishes, bowls and pitchers with the arms of the Medici and of the two popes of that family, triumphs in the manner of Mantegna, and subjects after Florentine artists. Hardly less splendid are the wares of Siena, particularly of one Maestro Benedetto; they excel in vigorous ornamental designs of early Renaissance character, in a palette dominated by a rich orange-yellow. Conspicuous among them are the drug-vases with an oval panel on one side formed by a ribboned wreath of fruit and foliage and traversed by a wide band bearing the name of the intended contents. The typical Sienese painting is seen also in the heraldic and grotesque designs of the pavement-tiles of the Petrucci Palace, Siena, now scattered in various museums. The Sienese wares were imitated at Deruta, near Perugia, which was, however, better known for its lustred wares (the earliest with a date, a relief of St. Sebastian in the Victoria and Albert Museum, is of 1501); these are painted in blue outline and shading, filled in with a pale lemon- or straw-yellow lustre. They take the form especially of two-handled vases and goblets and heavy wide-rimmed dishes, often painted with a lady's bust accompanied by a moralising adage or with figures influenced by Perugino.

ANTWERP MAIOLICA DISH

A large share of the production of maiolica in the 16th century belongs to the duchy of Urbino. Castel Durante (now called Urbania) made wares predominantly decorated with fancifully-conceived arrangements of weapons, musical instruments and the like combined in trophies with grotesque masks, dolphins and cornucopias. One Zoua (*i.e.,* Giovanni) Maria employed such themes as borders to enclose figure-subjects of exquisite delicacy. Castel Durante was also the birth-place of Nicola Pelliparío, the greatest of maiolica-painters, who migrated to Urbino and there adopted the name Fontana; he brought narrative (istoriato) painting to an unsurpassed pitch of perfection in several services of plates with. mythological and other subjects, particularly one with the arms and devices of Isabella d'Este and another now in the Museo Civico, Venice. He freely adapted motives from engravings, including the woodcuts of an edition of Ovid's Metamorphoses published at Venice in 1497. Nicola's style was followed, in progressive deterioration, by his grandson, Orazio Fontana, and others of his family, and by Francesco Xanto and Alfonso Patanazzi, all of whom owned or painted at potteries at Urbino itself. In these, about 1550, a new and pleasing style of ornament was adopted, of airy and fanciful arabesques in the manner of Raphael scattered over a creamy white ground; about the same time also Urbino began to produce imposing snake-handled urns, fountains, wine-cisterns, salt-cellars and inkstands (the latter often in the form of a group of figures) in shapes largely borrowed from bronze or silver. Pictorial wares similar to those of Urbino were made about 1560 in the workshop of the Lanfranchi family at Pesaro. The maiolica of Gubbio, made by Maestro Giorgio Andreoli and his successors, is famous for its lustre painting, in golden yellow and especially in a rich ruby colour; at first this artist followed the style of the Deruta lustred wares, but about 1518 he began to produce designs of his own, including grotesques and trophies like those of Castel Durante, figures of *putti* within symmetrical border-ornament, and pictorial subjects based on engravings, chiefly after Raphael. Besides making pottery for his own decoration, he added lustre enrichments to already-painted wares sent from Urbino, Castel Durante and Faenza for the purpose.

There were several maiolica factories at Venice. In some of these pictorial wares were made like those of Urbino, but generally of indifferent quality. One Maestro Lodovico produced about 1530–50 a distinctive class of wares strongly influenced by the Near Eastern pottery and Chinese porcelain then beginning to be imported by Venetian traders; they are painted solely or chiefly in blue on an enamel stained to a pale greyish-blue. The 17th century Venetian maiolica displays a fondness for architectural subjects and occasionally ornament in high relief imitating contemporary *repoussé* silver.

The potteries of the Ligurian coast between Genoa and Savona came into prominence in the 17th century with their blue-and-white maiolica sometimes directly copied from Chinese porcelain; at the same time close imitations of Turkish earthenware were being made at Candiana near Padua. From about 1670 onwards the potteries of Castelli, in the Abruzzi, and its neighbourhood produced wares with polychrome painting in subdued colouring of figure-subjects and landscapes.

Italy is remarkable not only for its maiolica but also for a distinctive kind of lead-glazed earthenware with decoration incised through a coating of white slip (*sgraffito*). The glaze is generally of a deep buff tone, giving a dark brown colour to the red body where revealed by the engraving of the decoration, which is often heightened by touches of green and purple laid on with a brush before the application of the glaze. The technique, derived through the Byzantine dominions from the Islamic East, attained artistic importance in Italy towards the end of the 15th century. Recent investigations have shown that although it was practised at several other places north of the Apennines, the wares in which it is displayed at its best were made under the patronage of the Bentivoglio family at Bologna. Sgraffito ware was made at Bologna until the 17th century.

French Faience. — pottery found in excavations at various places in Provence, and at Agen, and tiles from the church of Brioude, prove that tin-enamelled earthenware, with painting in manganese-purple and green, was made in Southern France as early as the late 14th century. Maiolica of a more developed type was made in the 16th century at Lyons by Italian potters from Florence and Faenza; to them are attributed certain wares with pictorial subjects in the Urbino style and French inscriptions, and tiles from the church of Brou. About 1540–60 Masseot Abaquesne was making maiolica and tiles painted with purely French renaissance designs at Rouen. Some rare examples with heraldic decoration are believed to be the work of Antoine Sigalon of Nimes.

In 1578 a pottery for this kind of earthenware (called in French faience) was set up at Nevers by three brothers named Conrade, from Albissola near Genoa, and continued in the hands of their descendants. In the 17th century, under Chinese influences, polychrome gave way to blue-and-white painting, with manganese for the outlines, though classical themes continued for a time in favour. Soon after, subjects adapted from late Ming Chinese porcelain became the fashion.

A privilege for making faience at Rouen was accorded in 1644 to Nicolas Poirel, who was succeeded by Edme Poterat and his son, and in the reign of Louis XIV. the city became a thriving centre of the faience industry, noteworthy for the large dimensions of many of its wares — dishes, wall-cisterns, and life-size busts on pedestals. A distinctive style of decoration was introduced characterised by wide borders and radial arrangements of palmettes, scrolls and festoons somewhat resembling lace; in the motives of this graceful lambrequin decoration Chinese elements are blended with those of the classical baroque. The painting is carried out in blue, either alone or combined with red or ochre-yellow. About 1730, in the pottery of Guillibaud and others, a change came about in favour of a more varied polychrome palette; motives borrowed from the Far East assert themselves, together with the asymmetrical scrollwork, shells and cornucopias of the rococo, and towards the end of the century the enamel-painted flowers of contemporary porcelain were imitated. The faience industry at Rouen as elsewhere was killed by competition with imported English wares.

At Moustiers in Provence faience began to be made shortly before 1700 by members of the Clérissy family. Among their early productions are dishes of exceptionally large diameter with hunting-subjects after engravings by Tempesta and wares, especially oblong trays, with airy baroque designs in the manner of Bérain; these were at first in blue, afterwards polychrome. In 1738 Joseph Olerys, a Moustiers potter who had spent some years at Alcora in Spain, introduced a new floral style in colours with sprays resembling potato-blossoms, and grotesque figures borrowed from the engravings of Callot. About 1677 one of the Clérissys of Moustiers moved to Marseilles and there made faience, similar to that of his native town, in the suburb of St. Jean-du-Désert. Several factories were at work at Marseilles during the 18th century; chief among them were those of Veuve Perrin, Joseph Robert and Honré Savy.

In Lorraine flourishing faience-factories were carried on at Strasbourg and Niderviller, both conspicuous for the fine quality of their overglaze enamel painting. The Strasbourg pottery, in the hands of the Hannong family, came to an end in 1774 after some half century of existence. Its earliest wares were blue-and-white in the manner of Rouen. Its later table wares in good rococo shapes based on silversmith's work show quasi-naturalistic flower-painting skilfully rendered in fresh colours dominated by a strong crimson, which exercised a great influence on the work of other French faience factories. That founded by Baron Beyerlé in 1754 at Niderviller and transferred in 1774 to the Comte de Custine made similar enamel-painted faience, including admirable figures, mostly of children or peasants, from models by the sculptors Cyfflé and Lemire.

Faience of artistic quality was made at many other French towns in the 18th century. Sceaux near Paris produced both porcelain and enamel-painted faience hardly inferior to porcelain. Aprey is known for gaily-coloured wares of a more homely kind. In Paris, at Lille and Rennes the formal style of Rouen was followed. St. Omer and St. Amand-les-Eaux in French Flanders, and Montpellier in Languedoc also had faience-factories.

Faience of Northern Europe, Spain and Portugal. — Early in the 16th century an Italian potter from Castel Durante, Guido di Savino, was settled at Antwerp, and from this time may be dated the beginning of maiolica-production in the Netherlands. The Antwerp wares, which included pavement-tiles, show the influence of the Faenza potteries in simple floral and linear motives, but soon took on the distinctive characteristics of Netherlandish renaissance design. About 1560–70 maiolica-potters from Antwerp carried their arl as Protestant refugees to Holland and England. Rotterdam and Haarlem became centres of production of earthenware and wall-tiles with animal, flower and fruit motives in strong colouring, and large tilework pictures with figure-subjects. Towards 1650 Delft came to the fore and for more than a century continued with its numerous potteries, known by their signs (the Peacock, the Star, etc.), as a thriving centre of industry exporting its wares all over the civilized world. Aelbrecht de Keizer is the earliest Delft potter whose productions are known, if the initials AK on certain blue-and-white pieces are rightly identified as his; the designs on these are borrowed from the contemporary Chinese porcelain then being imported in quantities by the Dutch East India Company. About 1600 we find plates and panels charmingly painted in blue with Dutch or Italian landscapes, by Frederick van Fritjtom. Samuel van Eenhoorn developed the Chinese fashion in a broad highly decorative manner of his own. To Adrianus Koek are owing the imposing blue-and-white hyacinth-vases made to the order of Queen Mary for the adornment of Hampton Court Palace; their ornament is borrowed from the French baroque designer, Daniel Marot. Other potters adopted Biblical subjects or scenes from Dutch life of the time (often in series continued through a set of plates or dishes) for the decoration of their wares. About 1700 close imitations of Chinese porcelain of the reign of K'ang Hsi, both blue-and-white and five-colour, were made, especially by Lambertus van Eenhoorn and Louwijs Fictoor, whose monograms are indistinguishable; notable amongst them are chimney-piece sets of large covered jars and vases, often reeded (so-called cachemire ornament). The wares produced became ever more varied, including statuettes and even model violins. Before 1700 muffle pigments and gilding were introduced by Rochus Hoppesteyn, in vases with classical figure-subjects, and by Adriaen Pijnacker, in imitations of Japanese polychrome porcelain dominated by a vivid red. Coloured enamel grounds were also occasionally used, notably a fine black in imitation of lacquer. As the 18th century advanced the wares became more commercial in character; the Delft potteries declined, only ten surviving till 1794. Somewhat rustic wares in the Delft style continued to be made till recent times at Makkum and elsewhere in Friesland.

BRISTOL DELFT DISH, TULIP DESIGN

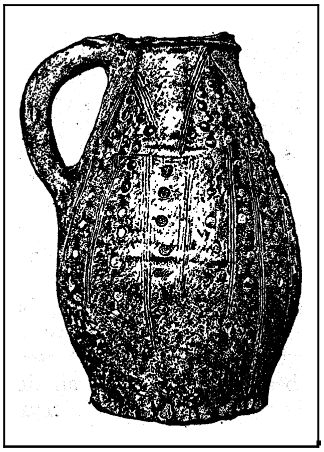
In Spain the adoption of the renaissance and Italian influences resulted during the 16th century in the production of enamelled earthenware entirely different in character from Hispano-Moresque ware. The settlement of an Italian tile-painter, Nicoloso Pisano, in Seville about 1503 brought about a widespread employment of maiolica tile-pictures for wall-decoration. At the same time Talavera and the neighbouring Puente del Arzobispo became the leading centre of pottery production. They produced, alongside wares in which Netherlandish renaissance ornament can be recognised, others of a strongly native character painted with animated hunting and battle scenes or with large busts or animals amongst loose foliated scrolls, in blue alone or in a limited range of colours dominated by a strong copper-green. From Talavera, potters went out to Mexico and there founded a vigorous industry. The foundation of a faience factory by the Count of Aranda in 1727 at Alcora led to the decline of Talavera. The faience mostly painted in blue and purple made in the 17th century at Lisbon, in which freely-handled Chinese themes are blended with renaissance motives has decorative value.

It is recorded that about 1567 Jasper Andries and Jacob Sanson fled from Antwerp to England to escape religious persecution and set up potteries at Norwich, whence in 1570 they moved to London. Their productions have not been identified, but it is likely that they resembled the maiolica at that time made in the Netherlands, and it is possible that certain jugs with mottled blue, purple and orange colouring over a tin enamel, generally found with silver mounts, were made by them. The earliest piece of maiolica of certain English origin is dated 1601; we may note here that at a later stage such wares were known as "delft," after the chief Dutch centre of production from about 1650 onwards. After 1625 dated pieces made at Lambeth and elsewhere near London become plentiful, chiefly dishes and small mugs with decoration painted either in blue in crude imitation of contemporary Chinese porcelain or with coloured designs of fruit and flowers or arabesques in imitation of Dutch and Italian wares. Wine-bottles painted with the name of the intended contents were also made in quantity. Towards 16jo figure-subjects, mostly scriptural (especially the Fall) become plentiful. Imitations of the "Persian" blue ware of Nevers were also made. From London the maiolica industry was carried to Brislington, near Bristol, where in 1682 we find working one Edward Ward, who in 1683 established a pottery at Temple Back, Bristol. He was succeeded at Brislington in 1697 by Thomas Frank. Other leading Bristol potters of the 18th century were Richard Frank, and Joseph Flower. John Bowen and Michael Edkins were painters employed by several of the potters. The earliest recorded date on Brislington-Bristol ware is 1652. The early designs include tulip and other flower designs in the Dutch manner, Chinese subjects and portraits of sovereigns or celebrities of the day. After 1700 Chinese motives take the lead, but adapted in a free and original manner. Landscapes of a lccal character with figures, in blue, were also in favour. The third great centre of delft production in England was Liverpool, which in the 18th century exported such wares in quantity to America. Shaw, Pennington and Barnes were the leading potters. Their wares show less individuality than those of Bristol. Notable among them are the punch-bowls made for skippers with polychrome paintings of their vessels; a speciality of Liverpool were the delft tiles with transfer prints in black or red executed by Sadler and Green. Delft was also made at Wincanton, Dublin and Glasgow.

Tin-enamelled earthenware was made by German potters from 1620 onwards. They learnt the art of maiolica in Venice, amongst them Augustin Hirsvogel of Nuremberg; he is believed to have been the maker of the owl shaped jugs made apparently for presentation purposes. The earliest known date on German maiolica is 1526. These early wares were painted in blue, with imitations of Venetian designs, or with figure-subjects derived from contemporary German engravings. Maiolica-painting was applied to the decoration of tilework stoves in the Tyrol, in Austria and especially at Winterthur in Switzerland, where from 1590 to 1740, approximately, a flourishing maiolica industry was carried on by the Pfau family and others. About 1618 the majolica technique was introduced by Lorenz Speckner in the potteries of Kreussen, in Bavaria (of special note are his drug-pots boldly painted with spirals in blue), and about the same time blue-and-white wares, especially narrow-necked pear-shaped jugs, showing Chinese influences, were made at Hamburg. The settlement of two Dutch potters at Hanau in 1661, and the establishment of a factory at Frankfort-on-the-Main in 1666 mark the beginning of a second phase, under Dutch influences, in which the Chinese fashions of the day determined the styles of decoration. Frankfort is notable for large dishes and jars with bold adaptations of late Ming motives in a remarkably clean vivid blue. Faience-factories at Nuremberg, Bayreuth, Ansbach, Dresden, Berlin, Potsdam and elsewhere are witnesses to the spread of these wares in cheap imitation of blue-and-white and five-colour porcelain. Potsdam was the first place to attempt to simulate Chinese "powdered blue" on faience. Tankards with baroque panelled designs or somewhat crude polychrome renderings of Chinese landscapes were made extensively at Erfurt and minor factories in Thuringia. In the 17th century glass-enamellers such as Johann Schaper and Abraham Helmhack of Nuremberg took to decorating in their own homes (as *"Hausmaler"*) faience obtained "in the white" from the factories. Their paintings of landscape or scriptural and other figure-subjects in black monochrome (*schwarzlot*) or bright polychrome are often of extraordinary fineness of execution. From their work arose the adoption of overglaze enamel-painting in the potteries themselves. This prepared the way for the third phase, the spread of French influences from Strasbourg and Marseilles, seen in coloured naturalistic floral decoration and French rococo forms for the wares. Disseminators of this technique were Johann Eberhardt, Ludwig Ehrenreich and Johann Tannich; the latter, trained under Hannong at Strasbourg, worked afterwards in several factories, notably at Kiel and Mosbach. From Germany the manufacture of faience spread to Scandinavia; flourishing factories at Copenhagen, Sleswick, Rorstrand near Stockholm and Herreboe in Norway produced chiefly blue-and-white wares showing Dutch and Chinese influences; large tea-trays, sometimes used as table-tops, and punch-bowls in the form of a bishop's mitre are conspicuous amongst their output. At the Marieberg factory, Stockholm, founded in 1758, the enamel-painted faience of Strasbourg was successfully imitated. Hollitsch in Hungary also produced enamel-painted faience of good quality closely resembling that of Strasbourg.

Mediaeval Pottery of North-west Europe.—The mediaeval pottery of western Europe is unpretentious and often crude in technique, but shows at the same time great virility and dignity of form. Glaze had passed entirely out of use in the Dark Ages. On later wares, when present, it is a soft galena glaze, sometimes stained brown with iron or green with copper. Decoration is effected by scratching with a point, or by impression with cut stamps or the application of reliefs such as overlapping scales or strips of clay pressed on with the potter's thumb, or rough floral and heraldic ornaments shaped in moulds; painting with red, brown and white clay pigments is the exception, but clays of various colour are often combined in relief decorations. Vessels such as aquamaniles, in rude human or animal form, and jugs modelled into human features, are not unusual. These characteristics are common to France, Germany and England.

In France the revival of glaze began in the 13th century, when Savignies, in the neighbourhood of Beauvais, began to become an important centre of production, of which in the 15th and 16th centuries the bluish-glazed wares with applied heraldic and floral ornament enjoyed some esteem; from the 14th century La-Chapelle-des-Pots near Saintes, was another important centre. Fine earthenware with inscriptions in Gothic characters and floral designs, made after the Italian manner by the *sgraffito* technique and including Italian shapes such as the *albarello* jar, appear towards 1500, and shortly after polychrome lead-glazed wares began to be made. Ornamental earthenware finials for gables were produced, especially in Normandy, from late mediaeval times onward.



BY COURTESY OF THE YORKSHIRE MUSEUM
MEDIAEVAL ENGLISH JUG

Remains of mediaeval potter's kilns have been found in England at Nottinghani, Lincoln and Cheam, and community of characteristics amongst vessels dug up at Oxford indicate local production; the same is true of York, and simple pottery must have been made at many other places. The earliest remaining wares, certain tall slender jugs of light buff earthenware, with a double swell in their profile, are attributed to the 13th century. In the 14th century forms tend to become more squat, glaze and applied or incised decorations appear. Greater refinement of shape is seen in green-glazed jugs of the 15th century, and under the Tudors elaborate moulded heraldic reliefs are found. In Germany the hard-fired semi-vitrified ware known as stoneware was first made, from the 14th century onwards. The earliest specimens are slender jugs, strongly wheel-marked, in a creamy-white body, made at Siegburg near Bonn. Drinking-vessels of great elaboration, often double-walled, the outer wall being pierced with Gothic tracery, were made of a hard brown ware in the 15th century at Dreihausen, Hesse. Floor-tiles form a great part of the output of mediaeval kilns, and were made wherever great churches were being built. Those of France and England have glazed bichromatic inlaid decoration, the German tiles, mostly unglazed, showing stamped or moulded designs. Tilework was used in Germany for architectural details also, and especially for stoves.

French and German Lead-glazed **Earthenware.**—With the arrival of the renaissance in France pottery rose in that country to a higher level of general esteem, and two highly specialized experimental developments took place. One of these passed without lasting influence on ceramic history, that of the famous so-called Henri II. ware; the place of its production was for long a mystery but it is now known to have been made at St. Porchaire in Poitou, approximately from 1525 to 1560. It is of a fine whitish clay, with a cream-coloured glaze, and decorated with designs built up from impressions of metal stamps like those of a bookbinder and inlaid in the manner of *niello* with darker clays; in the later examples touches of blue, green and purple pigment are added. The early forms are imitations of metalwork; later, salt-cellars, standing cups and ewers were built up like architecture in miniature with applied reliefs and statuettes and inlays imitating tile pavements. Devices of François I. and Henri II. and the crescents of Diane de Poitiers appear on many of the pieces.

Of greater significance was the work of Bernard Palissy (*q.v.*). After years of experiment he made coloured lead glazes, blue, green, purple and brown, of an excellence never attained before. His earlier wares were decorated with casts from the smaller fauna and flora of the district of Saintes. Later he adopted reliefs of figure subjects or formal designs. He was succeeded by two sons and by several potters who early in the 17th century made wares in his manner, including statuettes after bronze originals, at Avon and Fontainebleau, and at Manerbe (Calvados). Earthenware with a rich dark brown lead glaze. in forms copied from metalwork, was made towards 1600 at Avignon.

Contemporaneously with Palissy various potters in south Germany were making polychrome earthenware of a similar type, but combining a white tin enamel with coloured lead glazes. This technique was employed specially in the production of stove-tiles, which from about 1550 onwards were commonly decorated with figure-subjects of biblical or allegorical reference, reflecting the all-pervading religious pre-occupations of the time, rendered in relief under a renaissance arched recess. Potters known as Hafner, who worked in this manner, were settled at Nuremberg (Paul Preuning and others) and also at Salzburg and elsewhere in Austria. Besides stoves they made jugs with applied reliefs (sometimes including figures in the round in a recessed niche) and bright-coloured glazes. An analogous ware, made from about 1550 at Neisse in Silesia, is characterised by designs rendered by means of deeply-incised outlines separating the coloured glazes and enamels. In the 17th century the wares of the Hafner in Central Europe fell to the level of peasant pottery, which, however. has often great aesthetic value.

German and Flemish Stoneware — Artistic stoneware began to be made at Cologne about 1540. It is characterised by the ferruginous brown stain of its salt glaze. Its commonest form is that of a round-bellied jug with a bearded man's mask applied on the front of the narrow neck, a form which under the name *Bartmann* or "greybeard" became common in most stoneware potteries. Small applied medallions resembling the Roman coins frequently dug up in the city and its neighbourhood, and coiled branches with small oak leaves and acorns, are also frequent motives of decoration. About 1 j66 one of the Cologne workshops was removed to Frecher, where the manufacture especially of greybeards for Rhenish wine, exported in quantity to England and elsewhere, lasted into the 18th century. At Siegburg the mediaeval white stoneware took on a renaissance dress about 1550; the place was famous for its tall slightly-tapering tankards (*Schnellen*) with heraldic and figure reliefs in three adjacent vertical panels, the finest being the work of the Kniitgen family. Raeren, near Aix-la-Chapelle, was also a centre of the industry; its wares are deep brown-glazed, and (at a later stage) grey ware with cobalt-blue colouring in places. The characteristic productions are jugs, often of large dimensions, with elaborate mouldings and reliefs which generally take the form of a frieze, either continuous or broken into arcading, round the belly and sometimes also the neck. Jan Emens and Baldem Mennicken were the most gifted of the Raereṇ potters. Soon after 1600 the potteries of Siegburg (sacked by the Swedes in 1632) and Raeren declined, and many of the potters migrated .to the Westerwald district near Coblentz, where at Grenzhausen and Höhr the industry lasted till it was superseded by earthenware of the English type late in the 18th century. The Westerwald stoneware is grey in body, and its relief decorations, in which figure subjects tended to give place to formal floral motives, are picked out with colouring in cobalt blue and occasionally also in manganese purple. Stoneware, mostly inferior imitations of the Rhenish, was made in the 17th and 18th centuries at Bouffoualx and elsewhere in the south Netherlands. Kreussen in Bavaria produced in the 17th century a chocolate-brown stoneware with reliefs (of the Apostles, Electors of the Empire, etc.) painted in the vivid colours of the contemporary enamelled glass. Altenburg in Saxony and Bunzlau in Silesia also made relief-decorated stoneware.

BY COURTESY OF THE DIRECTOR OF THE VICTORIA AND ALBERT MUSEUM
JUG, OF COLOGNE STONEWARE

English Stoneware and Lead-glazed Earthenware. — The importation of German stoneware in the 17th century led to various attempts to imitate it in England. The most conspicuous was that of John Dwight, an Oxford scientist, who set up a pottery at Fulham about 1670 in which he made not only bottles and mugs in stoneware of various colours but also statuettes, modelled by an unknown artist (perhaps the sculptor, Grinling Gibbons), in white or dark brown clay with a thin coating of salt-glaze; these famous works, including busts of Prince Rupert and others and figures of classical deities, are amongst the most remarkable achievements in the history of plastic art. Stoneware of good quality, with a lustrous brown glaze, decorated with stamped, incised and moulded designs, often dated, was made at Nottingham from about 1695 onwards by John Morley and others of that family. Similar ware was made later at Chesterfield and Swinton. Another experimenter in stoneware was Francis Place, who worked about 1685 at York. Dwight had competitors also in the brothers Elers, two Dutch silversmiths who made teapots in a fine red-bodied ware, imitating Chinese boccaro ware, at Bradwell Wood near Newcastle-under-Lyme; their work was of great importance in its revolutionary effect on the output of the North Staffordshire potteries.

Mediaeval traditions in the production of coarse red earthenware with decoration in white "slip" (that is, clay diluted to a creamy consistency) were followed throughout the 17th and 18th centuries in many small potteries throughout England. Wrotham in Kent produced "tygs" (drinking-vessels with several handles) and posset-pots with neatly applied pads of clay stamped with initials or floral devices, animals and birds. At Bethersden near Ashford the inlay technique of the mediaeval tiles was adopted for pottery. By working with a comb the different coloured clays in a semi-liquid state on the surface of the wares, marbled and feather patterns of real distinction were often produced. No attempt at lightness and refinement of shape was made in the district until the advent of the brothers Elers, which stimulated the local potters to improve their technique. Soon after 1700, in response to the demand newly created by the introduction of tea-drinking, John Astbury was making tea-services, with small stamped reliefs in white on a red ground, and similar wares in a harder fired drab stoneware, from which about 1720, by the introduction of ground flints into the body, the Staffordshire white salt-glaze ware was evolved. A further advance came with the introduction of the process of casting the wares in plaster moulds with relief designs. About 1750 "marbled" wares were made by mixing clays of different colours, also "tortoiseshell" ware with mottled glazes, and tea-services in the form of cauliflowers and pineapples coloured after nature; such wares were produced especially by Thomas Whieldon, who in 1753 took into partnership a young potter destined later to revolutionise the industry. This was Josiah Wedgwood (*q.v.*). His new productions were "black basaltes" ware, an improvement on the black unglazed stoneware of the district, and jasper ware, a fine stoneware stained with blue, green, lilac and other colours and generally decorated with applied cameo reliefs in white. For shapes and decoration he drew upon the recently-published repertories of Greek vases, conforming entirely to the neo-classical taste of the period. He engaged John Flaxman and other sculptors to provide him with designs. An important part of his output were small medallions with portraits or other reliefs, made for mounting in furniture or as jewellery. For decorating his Queen's ware he introduced transfer printing, sending it at first to Liverpool to be printed by Sadler and Green. Wedgwood had many competitors who produced imitations of most of his wares; in Staffordshire, Adams, Neale, Turner and Palmer were the most important. Cream-coloured ware of good quality was made from about 1770 onwards at Leeds and elsewhere in Yorkshire; pierced decoration is its most characteristic feature. Earthenware figures emulating those of the porcelain factories were made at Burslem from about 1765 onwards by Ralph Wood, his son Ralph, and his grandson Enoch, and by many other Staffordshire potters. The earliest, painted in coloured glazes in the manner of Palissy ware, are mostly from models by a French artist, John Voyez, who generally copied the figures of Cyfflé of Niderviller; they have considerable artistic merit Lead-glazed earthenware of good quality was also made in the late 18th century at Liverpool, Bristol, Swansea, Newcastle-on-Tyne and Sunderland. A variety made in many places is the so-called silver lustre ware, coated with platinum, in imitation of silver plate. After 1800 the English earthenwares were rapidly degraded. (B. RA.)

EUROPEAN PORCELAIN TO END OF 18TH CENTURY

From the time of its first appearance in Europe, at the latest in the 15th century, Chinese porcelain was regarded by potters as in the highest degree worthy of imitation. Admiration for its whiteness led to the use of a white enamel or slip-covering on the earthenwares of Italy and other countries, whilst its translucency and vitrified texture misled the potters into supposing that a substance of the nature of common glass entered into its composition. Attempts to imitate it in this way were made in small manufactories at several places—as at the glass-making centre of Venice and elsewhere in Italy, more particularly at Florence, where a factory was started under the patronage of Francesco de' Medici, not later than 1581. Medici porcelain was decorated, as a rule in a soft blue only, with motives drawn from Italian maiolica in combination with Chinese elements imitated from wares of the type made for export to Persia. The manufacture is supposed to have been continued at Pisa; later and not dissimilar porcelain is to be attributed to Candiana near Padua. No settled manufacture was, however, in existence before the latter part of the 17th century. Edme Poterat of Rouen and his son Louis were granted a privilege in 1673, whilst another factory founded in 1677 at St. Cloud near Paris had by the end of the century grown to considerable size. These artificial porcelains, fired at a low temperature and made translucent with the aid of a previously fired glassy mixture or frit, were of the type now known as soft-paste (*pâte tendre*). They remained the characteristic porcelains of France for nearly a hundred years, and somewhat similar compositions were widely used in England, Italy and Spain during the 18th century.

Meanwhile in Germany the insight of Tschirnhausen and Bottger (see below) had perceived that porcelain of Chinese type could be made only with potters' materials, and by experiments with the fusing of clays were discovered, first, a hard red stoneware. and in 1709 true, that is. hard-paste, porcelain, which is essentially a high-fired mixture of the fusible and non-fusible silicates of alumina, called by the Chinese *petuntse* and *kaolin*, and in English china-stone and china-clay. From the manufacture founded at Meissen upon Böttger's discovery sprang others making hard-paste at Vienna and other places in Germany, at Venice, St. Petersburg and elsewhere Hard-paste began to be made at Sèvres in 1769 but did not entirely displace the *pâte tendre* until the beginning of the 19th century. In England hard-paste was independently rediscovered before 1768, but it was used in a single manufacture only and was superseded towards the end of the 18th century by a universally-adopied hybrid composition in which china-clay was partially replaced by the ashes of calcined bones, an ingredient which had for some time previously been used in a characteristic type of English soft-paste.

STAFFORDSHIRE SLIP WARE: DECORATION MADE WITH WHITE CLAY DILUTED TO CREAMY CONSISTENCY

France.—The rare porcelain attributed to the Poterats of Rouen resembles in decoration the blue-painted faience of the same city, and similar painting in Louis *Quatorze* style is characteristic also of much of the St. Cloud porcelain. Jugs, cups and saucers, pomade-pots and other small objects, as well as flower-pots of considerable size, were the chief productions of St. Cloud: they were as a rule tastefully and substantially potted with a fine feeling for the qualities of a rather yellowish but pleasant-toned material. Plum-sprays amongst other motives in relief were sometimes copied from *blanc* de *Chine*, for which this French porcelain has often been mistaken. Fluting and scale-pattern were also favourite decorations Painting in turquoise-blue, red yellow and green was inspired by Japanese Kakiemon porcelain. Boldly modelled figures inclining to the grotesque were done. St. Cloud (which was founded by Pierre Chicaneau in 1677) came to an end in 1768. Very similar porcelain, as a rule indistinguishable from the St Cloud, was made in Paris at a factory in the Rue de la Ville-l'Evêque and at Lille.

Porcelain of distinctive character was made at Chantilly, where a factory was founded in 1725 by Louis-Henri of Bourbon, duc de Condé Here for the first twenty years or so the material was singular in being covered with a glaze made opaque with oxide of tin At its best Chantilly is of a beautiful creamy white colour. "Kakiemon" patterns were freely copied in designs of great charm. The Meissen styles of flower painting (*q.v.*) and the formal "Indian" and naturalistic "German" flowers were adapted in the French taste, as were some of the figure-models of the same factory. In the later Chantilly, coloured grounds were imitated from Skvres and the tin-glaze was given up; slight decoration in underglaze blue was favoured for cheaper wares. The factory ceased to make soft-paste about the end of the century.

The factory at Mennecy-Villeroy, near Paris, was a continuation of one in the Rue de Charonne in Paris, founded in 1735 by François Barbin, who removed his establishment to Mennecy in 1748 to place it under the patronage of Louis François de Neufville, duc de Villeroy. The earliest of Barbin's productions were in Rouen-St. Cloud style, but later a great variety of small objects was made and enamelled in colours of a singular freshness, amongst which a purplish rose-pink is prominent. At its best, Mennecy porcelain is of unsurpassed quality, mellow in tone and texture and of a warm white colour. Some charming figures were'made. The factory was removed in 1773 to Bourg-la-Reine and ceased to make porcelain about 1790.

The beauty of material characteristic of the French soft-pastes was achieved in the highest degree in the productions of the royal factory at Vincennes, which was removed to Sèvres, between Paris and Versailles, in 1756. This factory was established in 1738, under the patronage of Orry de Fulvy, by two workmen named Dubois, who, however, failed to produce porcelain. A workman named Gravant eventually succeeded, in 1745, and a company was formed with a subvention from Louis XV., who finally in 1759 took over the factory, which enjoyed certain exclusive privileges (such as the use of gilding) amounting to a monopoly. The Royal proprietorship ended, with the Revolution, in 1793, but the establishment has continued under State control to the present day. The Vincennes productions at first consisted chiefly of porcelain flowers in imitation of those of Meissen, intended for mounting in ormolu. Meissen styles of painting were copied in this early period, though the forms, largely in rococo style, were designed by the court-goldsmith Duplessis. Jean-Jacques Bachelier supervised the painting and gilding, whilst the chemist Hellot was in charge of the technical side. Painting in panels reserved on a coloured or diapered ground enriched with gilding, soon became the characteristic Sèvres decoration, and the succession of the ground colours is the chief feature in the chronology of the great period of 40 years from 1749 onwards. The dark gros *bleu*, probably 'imitating Chinese powdered-blue, was introduced in 1749 and abandoned in favour of the brighter bleu de roi about 1756. Turquoise-blue (bleu *céleste*), yellow (jaune jonquille) and green grounds made their appearance in 1752, 1753 and 1756 The rose Pompadour (miscalled in England rose du Barry), invented by Chrouet, appeared in 1757 and went out of fashion in seven years. The favourite painting in monochrome (*en*-camaieu) was at first generally in crimson, later in blue. Particulars of many of the painters and the marks used by them may be found in several books of reference. Late in the period, about 1780, an enameller named Cotteau invented the so-called jewelled decoration in which drops of coloured enamel were fused over gilding. Glazed and coloured figures were made in the early years of the factory in rivalry with Meissen, but about 1751 Bachelier introduced biscuit or unglazed porcelain as a medium for novel work for which the painter Boucher made designs to be executed by Blondeau and others. The sculptors Falconet and la Rue in the earlier period, and Pajou and Boizot in the later, created many models for execution in Skvres biscuit. The influence of Boucher is apparent throughout in the painting and modelling, whilst the so-called *Louis* Seize neo-classical style began to replace the rococo soon after the transfer to Sèvres in 1756. For technical skill and perfection, and for delicacy and taste (if not for more vital qualities) Skvres porcelain is unsurpassed. Soft-paste at all times has the merit of absorbing enamel-colours into its easily-fusible glaze, and this is nowhere more evident than on Sèvres china.

Though soft-paste was the medium of the finest Skvres productions, hard-paste was made occasionally (from kaolin found after long search at St. Yrieix near Limoges) as early as 1769 and finally superseded the other altogether in 1804, when the newly appointed director Brongniart gave up the manufacture of the more costly material with a view to repairing the financial distress of the factory, caused by the Revolution. Hard-paste became the medium of a style marked by a severe and even pompous classicism, shared also by a number of other factories which had sprung up in the latter part of the 18th century in Paris and the neighbourhood, largely under the patronage of members of the Royal family. Rue Thiroux, La Courtille, Rue de Bondy ("Manufacture d'Angoulême") and Rue Popincourt (Nast's factory) were the chief. Other French factories making hard-paste and equally concerned to imitate Skvres, were at Lille, Étiolles, La Seynie, Boissette, Limoges and Valenciennes.

Hard-paste of distinctive character was made at the faience factories of Strasbourg and Niderviller and of Joseph Robert at Marseilles. The first-named was closed at the instance of Vincennes in 1753 and Paul Hannong, its proprietor, crossed the frontier to found the Frankenthal factory.

Some soft-paste of fine quality was made also at Sceaux, Orleans, Arras and St. Amand-les-Eaux, whilst at Tournai (which was part of France in the 18th century) soft-paste was used for wares inspired as much by Meissen as by Skvres.

Germany. — The discovery of hard-paste by Johann Friedrich Bottger was the result of experiments into the vitrification by heat of clays and rocks, conducted by him in association with Ehrenfried Walther Tschirnhausen, with whom he had been concerned in the establishment of a faience factory at Dresden. Like almost all scientists of the time, Bottger believed in the possibility of transmuting base metals into gold, and he was kept, virtually a prisoner, in the service of Augustus the Strong, King of Saxony, who hoped to benefit by the exclusive property of his alchemist's secrets. The first important product of Bottger's labours was a hard red stoneware, comparable with the so-called buccaro of Yi-hsing in China. First produced in 1708, it was quickly developed into a medium capable, by cutting and polishing, of expressing much of the baroque taste of the time. Silvering and gilding and a black glaze, invented by Bottger, were sometimes added to it. Imitations were made at Plaue-an-der-Havel, and at Bayreuth. The first glazed white porcelain was produced by Bottger alone in 1709; its regular manufacture did not begin until four years later. The earliest specimens inclined to a smoky tone, and the decoration (for which Irminger, a goldsmith, was responsible) of applied acanthus leaves, masks and rich mouldings, was similar to that of the red ware.

In 1710 the manufacture was removed to the Albrechtsberg at Meissen, but the making of the white porcelain was not fully mastered until 171j. Though without adequate financial support, Bottger succeeded in the four years before his death in 1719 in perfecting his material and in inventing a wide range of enamel colours, including a rare pale-violet lustre-colour almost peculiar to the factory and much used in the subsequent period.

In 1720 the painter Johann Gregor Heroldt was appointed director, and in the next 20 years introduced many new decorations—*chinoiseries* in gold and colours, landscape- and figure-subjects, as well as adaptations of Japanese and Chinese flowers (*indianische* Blumen) and other designs. Purple and red monochromes were used in a novel style. About 1740 Heroldt introduced the naturalistic deutsche *Blumen.* Though underglaze blue was never thoroughly mastered, many new colours were compounded for use as grounds, often richly gilt in baroque style, with panelled decoration. Almost every ground colour used elsewhere later on was employed at Meissen under Heroldt.

The appointment as modeller of Johann Joachim Kaendler in 1731 marked the beginning of a period of great development in the plastic decoration. The king had constantly pressed for colossal figures in porcelain which Kaendler's predecessor, Gottlob Kirchner, had failed to produce to his satisfaction. Kaendler succeeded with these so far as the natural unfitness of the medium would allow; and then proceeded to create a succession of new forms for table-ware — plates, tureens, sweetmeat-stands, candelabra, etc.—with modelled ornament, as well as a range of highly individual small figures. It was the court custom to group wax or sugar models on the dinner-tables, and Kaendler, helped by Friedrich Elias Meyer, Johann Friedrich Eberlein and Peter Reinicke, created many porcelain figures for use in the same way. Some subjects were novel in being drawn from contemporary life, embodying a satirical or witty commentary. Kaendler was the first to understand the potentialities of glaze and colour in the make-up of the porcelain figure, which in his hands was never merely monumental sculpture reduced in scale. French rococo was not without influence on Kaendler's style after about 1740, but he remained essentially a baroque sculptor, and continued to work for the factory until his death in 1775.

Meissen remained the premier porcelain factory in **Europe** until the Seven Years' War, which broke out in 1756, when Frederick the Great virtually sacked the place. Technically excellent work was done under the direction of Count Marcolini (1774–1813), but the former position was never regained. Skvres fashions were copied, and an artist actually from Skvres, Michel-Victor Acier, made many characteristic models in the sentimental style, whilst an academic sculptor, Christoph Jiichtzer, made biscuit figures in the classical manner.

Following the fashion set in Saxony, many other German princes sought to establish or patronise china-factories, and by 1760 no fewer than eight had come into existence in this way. Broadly, Meissen styles prevailed until about 1760, when Skvres fashions and the neo-classical began to predominate. The dependence upon Meissen and Skvres, however, was very much less than a superficial view would indicate.

In 1718 a runaway Meissen workman, Christoph Konrad Hunger, enabled Claude du Paquier to start a factory at Vienna, which was in 1744 sold to the state. Much of du Paquier's china was decorated by independent enamellers (*Hausmaler*); the factory's own styles were remarkable for the frequent use of a black (Schwarzlot) and other monochromes in rich baroque designs. Mayerhofer became director in 1751. Vienna figures of the period about 1760 have a very distinct and airy charm. In 1784 a prosperous period began under the directorship of Konrad von Sorgenthal. A modeller Anton Grassi (who had previously made some lively enamelled figures) began to use biscuit with success, whilst in the last decade of the century was made the porcelain with elaborate miniature pictures in the style of oil paintings, with rich gilding and coloured grounds which was formerly considered the best, and still is the most famous, Vienna work.

At Berlin, a wool manufacturer Wilhelm Kaspar Wegely made porcelain of fine quality, including figures, from 1752 to 1757. A few years later, a financier named Gotzkowsky started a factory which in 1763 was taken over by Frederick the Great. Berlin table-wares tend to favour simple colouring with a special fondness for pink diaper (Mosaik) borders. Some good figures were made by Friedrich Elias Meyer (brought from Meissen in the Seven Years' War), his brother, Christoph, and others.

With the help of one Löwenfinck from Meissen, porcelain was made at a faience-factory at Höchst as early as 1746, under the patronage of the Elector of Mainz, but not in any quantity until 1760. Very lively figures in Meissen rococo styles preceded those made by Johann Peter Melchior (appointed 1767), upon which the factory's fame chiefly rests. Melchior's very personal style shares the same inspiration as the contemporary Sèvres models: he showed an equal mastery in the treatment of the nude, in figures of children, and in portrait busts and plaques. All have the smooth, not glossy surface and soft colouring that are characteristic of Hochst.

The factory at Fiirstenberg in Brunswick was established in 1753 by Duke Charles I, with the help of Johann Benckgraff of Hochst. A feature of the early porcelain was the use of elaborate moulded patterns designed to disguise the imperfections of the material. In the last twenty years of the 18th century biscuit was used for a series of portrait medallions in white on blue.

The Bavarian state factory, founded in 1747 at Neudeck, and transferred in 1761 to Nymphenburg, is chiefly famous for its figures, for which Franz Anton Bustelli (*fl.* 1754–63) made models which are perhaps the finest plastic expression of rococo. The same qualities, however, distinguish the delicately painted table-wares and vases of the factory. Bustelli was followed by Aulicztk, who in turn gave place in 1797 to the Höchst and Frankenthal modeller J. P. Melchior.

The Frankenthal factory was founded by Paul Hannong of Strasbourg in 1755 under the patronage of the Elector Palatine. The early figures modelled by J. W. Lanz, their subjects chiefly drawn from contemporary life, are amongst the best produced in Germany, whilst the classical models of Konrad Link (made 1762–66) share the largeness of style of the best later work of Kaendler. Other able modellers were J. G. Luck, and Karl Gottlieb Luck, and in 1779 J. P. Melchior came to Frankenthal from Hochst.

Though the porcelain of Ludwigsburg is seldom free from imperfections and generally grey in tone, it was the medium of some excellent figures, for which amongst others the sculptor J. C. W. Beyer (1764–67) made some models combining rococo character with the classical style. The factory was founded in 1756 and taken over in 1758 by Charles Eugene, Duke of Württemberg.

Amongst the minor German factories founded in 1756 by the Prince-Bishop of Fulda has a deserved reputation for high quality both in the modelling of figures and the painting of table-wares. Another factory, started in 1758 at Ansbach and transferred four years later to Bruckberg, closely followed Meissen models. Others of some importance were at Ottwtiler in Nassau-Saarbrucken (founded 1763), Cassel in Hesse (founded 1766), Pfalz-Zweibrucken (founded 1767), Baden-Baden and Kelsterbach. In the forest region of Thuringia, many private factories sprang up soon after 1760 making cheap useful wares, as well as imitations (often definitely fraudulent) of the better Meissen china. Very good porcelain, however, was made at Kloster-Veilsdorf, Gotha, Ilmenau and Volkstedt. The rather crude figures of Limbach sometimes have an attractive simplicity. Porcelain was also made at Gera, Gross-Breitenbach and Rauenstein.

In the earlier days of Meissen and Vienna no serious attempt was made to prevent undecorated porcelain from reaching the hands of independent enamellers, though eventually the Meissen factory adopted the plan of cancelling its mark (by a cut in the paste) on all defective pieces sold in the white. Amongst many excellent *Hausmaler* may be mentioned J. Aufenwerth of Augsburg and J. F. Metsch of Bayreuth; Preussler, Ignaz Bottengruber and his pupils H. G. von Bressler and C. F. von Wolfsburg, all of Breslau, who specialized in monochrome painting, chiefly in red and in black, in which last also Jacob Helchis decorated Vienna porcelain in a distinctive manner. The wandering arcanist C. K. Hunger of Meissen, Vienna and Venice, practised a style of painting in thick gold, and about the middle of the century, F. Mayer of Pressnitz worked in several styles, and Canon Busch of Hildesheim made original engravings on porcelain with a diamond-point and coloured them with black.

Switzerland. — In Switzerland, porcelain was made at a factory at Schoren near Zurich, founded in 1763. Though smoky in tone and painted in subdued colours, Zürich china has a very distinct charm and delicacy. Another Swiss factory at Nyon made hard porcelain in French style in the late 18th century.

Belgium and Holland. — Hard-paste factories of no great importance were in existence in the 18th century at Weesp (afterwards transferred to Oude Loosdrecht and Oude Amstel) and The Hague, where, however, Tournai and other porcelain was sometimes decorated and marked. Paris styles were followed at Etterbeek near Brussels.

Denmark and Sweden — At Copenhagen as at Marieberg (Stockholm) soft-paste was made at first. At the former from about 1760 Louis Fournier from Vincennes made wares in French style until hard-paste began to be made about 1772: in this last a series of Norwegian peasant-figures is noteworthy. At Marieberg, Pierre Berthevin from Mennecy made soft-paste from 1766 to 1769, and a hybrid porcelain was used for the next twenty years.

Russia. — Hard porcelain in German style was made in Russia as early as 1745, but was scarcely an established manufacture until the time of Catherine II. (1762–96). Amongst the little that is distinctive in the Imperial porcelain from the St. Petersburg factory a series of figures of Russian folk-types may be mentioned. Other factories included one conducted by an Englishman, Gardner, at Verbilki and Tver near Moscow.

Italy. — Venice shares with Meissen and Vienna the distinction of a porcelain factory established in the first quarter of the 18th century,' in the period of the baroque style. Two brothers, Francesco and Giuseppe Vezzi, founded their factory in 1720 with the aid of the Meissen and Vienna workman Hunger. It ceased to exist soon after the death of the first-named in 1740. The Vezzi porcelain resembles Meissen in its technique of painting, in which iron-red plays a prominent part, but a certain Italian fantasy and irresponsibility distinguishes it. Another Venetian factory seems to have been in operation from 1758 to 1763 under one Hewilcke of Dresden, but little is known of it, and that founded by Geminiano Cozzi in 1765 made most of the porcelain for which Venice is celebrated. Meissen was again much imitated, but the fantastic Italian rococo and a freshness of colour mark much of the Cozzi china, which was a kind of soft-paste. The existing Doccia factory was founded about 1735 by the Marchese Carlo Ginori, with the help of a chemist from Vienna, Karl Wendelin Anreiter. Its earliest work included some distinctive baroque decoration, and later on in the 18th century some highly dramatic groups were made. Factories at Nove, Vinovo near Turin, and Treviso produced more or less original work, whilst at Capo-di-Monte near Naples, a celebrated factory was in operation from 1743 until 1759, when its patron Charles, king of Naples, succeeded to the Spanish throne and the establishment was transferred to Buen Retiro. Typical Capo-di-Monte china is a glassy soft-paste, extravagantly decorated with reliefs, often of figure-subjects; it was much imitated at the Naples factory which was in a sense its successor (1771–1821), and at Doccia and elsewhere in the 19th century.

Spain and Portugal. — The Madrid or Buen Retiro porcelain (1759–1808) was of various quality but included some of the most beautifully modelled and coloured figures ever made in Europe. For these the modeller Giuseppe Gricci was probably responsible. Amongst many styles of painting on vases and table-wares there is much that is of a minute but significant delicacy. The manufacture was revived at La Moncloa from 1817 to 1849. Porcelain was also made at the count of Aranda's faience-factory at Alcora from 1774, and at Vista Alegre in Portugal from 1790.

England. — No certain English porcelain is known of earlier date than the so-called "goat and bee" jugs, made of a soft paste resembling milk-white glass and incised with the name of the Chelsea factory, the date 1745 and a triangle. This "triangle-period" of the Chelsea factory is believed to have ended about 1750, when Nicholas Sprimont apparently displaced Charles Gouyn as manager. Chelsea china of the next eight years is the finest ever made in England. Of a smooth soft-paste capable of giving the most delicate quality to enamel-painting, Chelsea is more often original than any other English porcelain, though its styles were largely inspired by Meissen. The figures in particular are unsurpassed for beauty of modelling. The mark of an anchor, at first in relief, later painted in red, belongs to this period, 1750–58, which ended with the death of the proprietor, Sir Everard Fawkener. In the subsequent period, when Sprimont was proprietor as well as manager, the rococo style (at the time outmoded at Sèvres) survived for ten years in extravagant forms of great interest. Coloured grounds, including a dark "mazarine" blue and a rich broken crimson were inspired by Sèvres, as were figure-subjects, *chinoiseries,* and other styles of painting. Profuse gilding of fine quality, richly brocaded costumes and *bocages* or backgrounds of flowers and foliage were characteristic of the boldly modelled figures, some of which were at one time erroneously attributed to the sculptor Roubiliac. The beautiful Chelsea toys—scent-bottles, seals, bonbonnières and the like—were made from about 1750 onwards and even continued to be done at the factory after its sale in 1770 to William Duesbury, the proprietor of the Derby factory. This had been in existence since 1750 and had made figures and other porcelain in Chelsea styles, but of comparatively little merit. The productions of the period 1770–1784 (when the Chelsea works were closed) are often known as Chelsea-Derby china. The pseudo-classical vases and the figures (including some in biscuit) in the fashionable sentimental Sèvres styles are of less importance than the table-wares which are the chief title to fame of the Derby factory. Later porcelain in the same excellent tradition was painted by artists whose names are known, such as Zachariah Boreman and William Billingsley. Derby declined after the succession to the management of Robert Bloor in 1811, and came to an end in 1848.

The Bow factory was perhaps in existence in 1744, but its productions before 1750 have not been certainly identified. From 1749 (when a distinctive bone-ash paste was adopted) to about 1760 its productions were largely inspired by, and often close copies of Meissen, but rank next to Chelsea for delicacy of modelling, and have the attraction of a beautiful ivory-toned material and clean strong colouring. Later Bow, which was marked with an anchor and a dagger, shows a distinct falling off in these respects. Lowestoft was an offshoot of Bow and largely imitated the productions of other factories, as well as Chinese models, in soft-paste. At Longton Hall in Staffordshire from about 1750 to 1760 William Littler made excellent figures and other wares of a soft porcelain in which are apparent some of the attractive qualities of the more rustic Staffordshire earthenware. A rich blue enamel used as a ground, and a fondness for dishes and vessels in the form of folded leaves were characteristic of Longton Hall. At Lowdin's factory at Bristol, transferred to Worcester in 1752, soapstone (steatite) was used in the paste, and Chinese, Japanese and Meissen motives were employed with an attractive simplicity. Amongst the best Worcester china, made between 1755 and 1765, may be singled out the beautiful armorial mugs. Transfer-printing was adopted very largely as a mode of decoration at Worcester. About 1768, painters from Chelsea were engaged, and a showy style with rich gilding and coloured grounds, including a distinctive "scale-blue," became the fashion of the day. The painting of highly-coloured "exotic birds" was inspired by Chelsea. The later "Flight" and "Flight and Barr" periods of Worcester (which succeeded the so-called Dr. Wall period, 1751–83) show a marked decline in taste. Some Liverpool factories and that at Caughley (the "Salopian" factory), making porcelain from about 1760 to 1772 respectively, may be regarded as offshoots of Worcester. At Plymouth, William Cookworthy had discovered the secret of hard-paste before 1768 (when he took out a patent), and made figures and useful ware employing Chinese, rococo and classical motives. His factory was transferred to Bristol in 1770, and sold in 1773 to Richard Champion, who made much handsome table-ware as well as figures in the classical style. The Plymouth and Bristol china often fails in effect on account of its comparatively hard glaze, into which the colours have not fused. Champion sold his patent in 1782 to a Staffordshire syndicate who continued to make hard-paste in "cottage style" at the New Hall factory until about 1810. Meanwhile a hybrid porcelain made of hard-paste materials in combination with bone-ash had been introduced before the end of the century by Spode and others. The history of this china, like that of a beautiful but unpractical soft-paste made by William Billingsley, at first at Pinxton (1796) and afterwards at Nantgarw and Swansea (1814–17), belongs to the 19th century.

NINETEENTH CENTURY EUROPEAN POTTERY AND PORCELAIN

The period of the Napoleonic Wars marks a definite break with the older traditions of craftsmanship: European civilization emerged impoverished and found the Industrial Revolution complete. In the more pretentious wares, the Empire style was a pompous and frigid continuation of the neo-classical, and the "revived rococo" of 1820–50 was one of the first of the series of revivals that make up the greater part of the "styles" of the century. Some of the older factories, such as Meissen and Vienna, were even content to reproduce their former inventions, whilst the Great Exhibition of 1851 saw a general attempt to outdo in "exquisiteness" the most costly Sèvres productions of the 18th century. At Sèvres itself work of a high order of technical accomplishment was done under the management of Brongniart, who remained director until his death in 1847. In England the porcelain made by the Spodes and their successors Copeland's, of Stoke-on-Trent, by Minton's of the same place, and at Coalport and Swinton (Rockingham factory) was often very creditable technically but artistically of little account.

Amongst the cheaper types of pottery, the cream-coloured earthenware of Staffordshire commanded at the beginning of the century a world-market which it retained for a long time despite Continental rivals perforce driven to make the so-called *faience anglaise.* In France the English method of transfer-printed decoration was also adopted, notably at Creil and Montereau, and the development of the deposits of kaolin in the neighbourhood of Limoges led to a rapid growth of the pottery industry in that part of the country. In Italy, some distinguished and fanciful painting was done on cream-ware by the firm of Giustiniani of Naples.

After the Great Exhibition, manufacturers began to be aware of "Art," and pottery inspired by Renaissance models—by maiolica, "Palissy ware" and Limoges enamels—made its appearance. The Paris Exhibition of 1867 introduced a fashion for Japanese naturalism and asymmetry, and some European porcelain was even made (as at Worcester) in imitation of the degraded "export Satsuma" of the period. The collecting of Turkish and Syrian pottery (called at the time "Rhodian" and "Persian") brought a vogue for designs in the same style, from which issued the work of William de Morgan who at a later stage began to make ruby-lustred wares inspired by Italian maiolica; he was also in a sense the representative in pottery of the Morris movement towards handicraft as against industrial machine-work. In France Théodore Deck made similar essays towards the rich colour of the "Damascus" wares; and indeed the most noteworthy pottery of the last forty years of the century was the work of individual artists striving to emulate the great achievements of past times. In particular, Chinese single-coloured and *flambé* glazes inspired the high-fired stonewares and porcelain of Chaplet, Lachenal, Delaherche and Dalpayrat in France, and of Mr. Bernard Moore in England. Mr. William Burton developed some distinctive single-coloured glazes and lustre-pigments for Pilkingtons of Manchester, and similar lustred effects were also obtained by Zéolnay of Pecs (Fiinfkirchen) in Hungary, and by the Massiers of Golfe Juan in France. The so-called Arts and Crafts movement in England, by drawing attention to the virtues of peasant art, brought a sentimental fashion for simpler lead-glazed decorative wares; at Florence the Montelupo style was revived, whilst more or less exact copies of Hispano-Moresque and later Italian maiolica were made by Cantagalli and also by various other potters.

At the older porcelain factories in the latter part of the century some innovations of importance included the crystalline glazes and subdued green, grey, mauve and blue underglaze colours introduced at the Royal Copenhagen factory, and used for delicately painted vases and figures of Danish peasants and animals, modelled by some able sculptors. Similar work was and is being done by Bing and Grondahl of the same city, by Heubach of Lichte in Thuringia, and by the Meissen and Rorstrand (Stockholm) factories. A mode of impasto decoration, known as *pâte sur pâte,* in which successive layers of white or coloured slip were applied to a dark ground, was skilfully practised at Skvres by several artists, notably by Taxile Doat, and was brought to England by M. L. Solon, who worked for Minton's of Stoke-on-Trent. This was perhaps the foremost English factory, where Léon Arnoux was director, and the well-known sculptor, A. Carrier-Belleuse (afterwards at Sèvres) a principal modeller. At Wedgwood's another French artist, Emile Lessore (who had also been at Minton's), developed a delicate and individual manner of painting on cream-coloured earthenware.

Salt-glazed stoneware was revived in national styles by Villeroy and Boch of Mettlach, and by Doulton's of Lambeth, one of whose modellers, R. W. Martin, with his brothers Edwin and Walter, employed the material for grotesque figures and vases which have the merit of attractive colour in their sombre browns and greens, and show, moreover, a true feeling for pottery technique. Equally attractive work in stoneware was done by the French sculptor, Jean Carriks, and by E. Bigot of Paris. In Germany, Max Lauger of Karlsruhe developed an interesting style of decoration modelled in slip under coloured glazes. At the national factories of Berlin and Sèvres, highly accomplished work was done in many styles, with the support of up-to-date scientific knowledge, and the Paris Exhibition of 1900 marked the culmination of what may be called the eclectic period of European ceramic art. (W. B. Ho.)

MODERN CONTINENTAL

At the end of the 19th century the movement in the domain of the applied arts, with which the names of Ruskin, William Morris, Walter Crane and their fellow-artists are connected, wrought a great change. At first this tendency scrupulously supported the preservation of the methods of handicraft, and strongly opposed manufactured articles. But the same principles with which it originated, and which were indeed identical with those out of which the applied arts had developed in all previous periods, gained ground in the meantime, and the possibility of having artistic articles for practical use came once more within the purview of increasingly larger groups. Gradually also there came into being a desire to bring them within the reach of the many by changing the expensive handmade articles for manufactured goods, but such production was to be led by artists. But in proportion as these ideas became more general, a reaction set in against their excessive rationalistic elements. Consequently, after the beginning of the 20th century taste inclined towards the ornamental, the lively, the richly coloured, though the basic principle that the shape and appearance of the object should be determined by the requirements of material, technique and purpose was not neglected.

Artists, sensitive to shape and colour, could be satisfied with the ceramic production, for working the soft clay on a potter's wheel allows scope for the most individual expression. So far as the continent of Europe was concerned, there were two centres whence the above described development sprang: France and Denmark, or, more strictly speaking Copenhagen. An important development in Holland has exerted little influence outside its own boundaries, and similarly in Germany, while both have undoubtedly profited from French and Danish artists.

MODERN CERAMIC TECHNIQUES

By ceramics is meant all production of which the final result is baked clay in different grades of hardness and purity.

Porcelain.—The composition of European hard porcelain has remained about the same since the 18th century. The ingredients consist of the plastic material, kaolin. and the non-plastic quartz and felspar, which, in the process of working, is used as a diluting element, and in firing, as a cement. The kaolin is principally found in Germany, but always mixed with another soil. It has to be purified by washing. The quartz and felspar must be cleaned. The fragments of iron, in particular, have to be removed, as they are dangerous to the product. By mixing these ingredients the plastic material is obtained. This is made homogeneous by a mechanical method, and it frequently lies unmoved for some months in a special cellar in order to be moulded once again. Then the shaping can begin. It is not usual to shape this fine material by hand, but moulds are used which have been made of plaster after the models fashioned out by artists. The plastic material is pressed into these moulds or poured out in them as a pulp. In the latter case the plaster absorbs so much liquid that a sheath is formed alongside the inside of the mould, out of which the superfluous pulp can be poured. Shaping is followed by drying. After that there is the controlling and the removing of the casting seam and other unevenness. If the object consists of more than one part these are joined together. They are then put in the kiln in sagars or clay boxes so that the heat is more evenly distributed over the piece, and heated to about 950 degrees. The porcelain has then become hard and water-tight but dull. This is therefore followed by glazing. The objects are dipped into a liquid consisting of the same ingredients as the material, but in which felspar and quartz predominate. The objects which have been glazed in this way must then be fired in a heat of 1,370°–1,458°, again in sagars. This heating lasts from 20 to 30 hours, and is followed by a gradual cooling which takes three days. A full kiln never produces everything perfect, the many dangers in the firing—for example all objects shrink about one-sixth of their volume—result in articles being spoiled by exploding, warping, etc.

The porcelain is then ready to be painted with dyes, with which a very lightly fusible glass-powder has been mixed. In order to make these melt together with the glazing and become durable the painted objects are heated in an enamelling-furnace to a heat of 700°–800°. This heat must be reached quickly and the cooling takes place equally rapidly in order to keep the colours bright. The old porcelain bakers painted on the so-called biscuit-ware, *i.e.,* after the first baking and before the glazing, but they could only make use of very few colours at this stage—really only cobalt blue, as most other colours could not endure the heat of the second firing. Modem ceramic technique, however, has considerably extended this process of painting before the glazing. Since Copenhagen's success with it, it has been more generally used and imitated. In these cases the paint is put on the material in a different way, viz., as a liquid with a brush or squirt and then engraved in order to increase the plastic impression of depths. After that the objects are glazed. In a high temperature the colours under the glazing mix with the material, except in the case of cobalt blue, which mixes with the glaze. This process has the technical advantage of making the colours durable, but on the other hand it has a disadvantage in the artistic sense, in that the covering colour reduces the lustre of the porcelain itself by breaking the rays of light which cause the minute crystals in the porcelain to glitter. This is not the case with painting after glazing. Another way of ornamenting, which, however, has the same artistic disadvantage, is to coat with coloured glaze, which is applied in one colour. By adding metals the glazing can be made what is known as "streaming"; or, by choosing a glazing compound, the coefficient of expansion of which is smaller than that of the material, irregular fissures or artificial crackles can be obtained with the cooling.

Grès.—Grès has many qualities in common with porcelain, but it is grey or ash-coloured and not translucent. The material needs less working in order to purify it. As this clay is already fairly hard after being dried in the open air the first firing can be omitted and the ornamenting begun at once. After being painted the objects can be put in the furnace without sagars and may be baked at a temperature of 1,190°. Throwing salt in the furnace causes an evaporation which brings a glaze on the objects. The colour is then ash-like, or, with a higher temperature, red-brown. The modem ceramist, however, prefers a superior kind of grks, which is more carefully washrd, has the colour of ivory, and to which kaolin can be added (French grks kaoliné). The painting takes place as with the ordinary grès before the glazing, after which it is baked and is coated with lead glazing. The grks can also be coated with an engobe-like pulp glaze.

Earthenware. — In England, at the end of the 18th century, this imitation and rival of porcelain was invented. In the course of the 19th century it obtained a prominent place in ceramic production, especially for domestic use. It consists of a plastic clay, freed as much as possible from iron and white-burning, but with which some quartz and felspar are mixed. Sometimes some kaolin also is added. The washing must be done very carefully. The exact shape is obtained by the moulding of the liquefied clay. Both during the first and second firing the objects are placed in sagars. Between the two firings the painting and the glazing take place. The ornamenting can also be done by coating the whole object with a pulp glaze.

Maiolica.—This is the name of a kind of porous pottery which after the drying and firing is coated with a tin glazing, either by immersion or squirting. On this non-transparent coating decoration is painted with dyes consisting of metallic oxides—a work that requires great skill, as retouching is impossible. During the process of baking the colours mix with the glaze. The effect is sometimes improved by coating the colours with a second glaze, this time a transparent lead glaze. So-called lustres can also be obtained by means of metallic reductions.

Pottery. — Pottery is the earliest ceramic production of mankind. For this a slightly calcareous potter's clay is used, which when baked becomes a red or yellow shard that still has to be glazed to render it water-tight. Decoration can be done in different ways—for instance by putting on ornaments of clay in a different colour (barbotine *décor*), or by painting them. The whole object can also be coated with another kind of clay and the décor in the original reproduced by scratching away the outer coating. It can also be engraved (*graffite décor*). In all these cases a transparent lead glaze is applied. By a combination of the different techniques all kinds of variety are possible and usual.

Historical Survey. — Interest in this fine old handicraft was revived in the period beginning with the Great Exhibition in London in 1851. Museums of industrial art were opened, and applied-art schools followed the lead, by the imitation of old models. Imitation led to a revival and improvement of old techniques and this was fostered by chemical science which in these years grew more and more important. People grew tired of imitation, however, and inspiration was sought elsewhere. It was found in the closer acquaintance with Japanese ceramic art at the Paris exhibition in 1867 and more especially in that of 1878. This inspiration took effect in two directions. First, it showed the possibility of another attitude towards nature and the reproduction of nature, and so pointed out a new way to porcelain; a new way to which Denmark was to lead a few years later. Secondly, it demonstrated the splendid ceramic qualities of the old Japanese grès. From this originated the new ceramic art of the French. This is the starting point of the history of modem ceramics.

FRANCE

The revival of French ceramic art was initiated by Ernest Chaplet, who was born at Skvres in 1835 and whose work became world famous 20 years before Jean Carriks, the sculptor, became a ceramist, under the influence of the exhibition of 1878. Chaplet entered the Skvres factory in 1848, and at the exhibition of 1855 he produced work of his own. Afterwards he worked at Laurin's at Bourg la Reine, where he reapplied the old barbotine technique. For it he used very white earth mixed with colour-oxides, which he painted on ordinary potter's earth. The success he had with this at the exhibition of 1878 did not last. In 1875 he became manager of the ceramic factory of Haviland in Paris, which factory he took over in 1885, and in 1887 he went to Choisy-le-Roi, where he lived and worked until his death in 1909. His great merit is the application of "flammés"—colour glazes without real figure ornamentation that cover his grks and sometimes his porcelain, copper-red, white, violet and blue in all varieties and combinations. First Japanese grks, and later the monochromatic Chinese porcelains inspired him, but his own work retains an independent quality. His trade mark is the rosary (*chapelet*). By the time that Chaplet reached the high-water mark of his fame Carriks had already achieved success. Jean Carriks was born in 1855. As a sculptor, with strong leanings to the decorative, he sought for picturesque effects. Deeply influenced by the charm of the Japanese work exhibited in 1878, he decided to devote himself to ceramic art, and to use grks as his material. Far from Paris, in St. Amand-en-Puisaye and Montriveau, in the neighbourhood of Nevers, where he found his material, he began to experiment in a furnace of his own, and in the exhibition of 1889 he showed the results which won universal admiration. The Japanese influence is strong, especially in his vases and bowls that are ornamented with streaming glazes. But his work has a character of its own, and he avoids what he considers the too great brightness of the Japanese glazes, and so obtains a better harmony between the colours of the glazes and the clay.

Besides numerous vases and bowls, simple and with no ornamentation other than the glaze, Carriks created a great number of plastic works such as masks, heads, figures of animals, etc., which please not only by their construction, their exquisite colour and beautiful surface, but also by their subtle characterization. His last work was a monumental hall which the Princess de Scey-Montbeliard had made in her hotel in the Avenue St. Martin. But he did not live to see it completed. He was ill when the work began, and on July 1, 1894, he died. His friend, the architect G. Hoentschel, who made china after the same method as Carriès, gave a large collection of the latter's work to Paris (Musée du Petit Palais). Another disciple was Paul Jeanneny (1861–1920), who took over Carriks' atelier in St. Amand. Neither he nor Hoentschel has done any plastic work. Jeanneny's work is even more closely connected with Japanese ceramics than is the work of the others.

In the meantime Chaplet had started a school, and the most prominent of the artists, who with their master formed the group of "L'Art du Feu," was Auguste Delaherche, who, when Chaplet went to live at Choisy-le-Roi, took over his furnace at Vaugirard in 1887. At first he worked with streaming glazes, and sometimes combined these with designs in relief. But gradually he simplified his methods. In the museum at Skvres there is an early dish of his with a motif of oak leaves; but his later work is remarkable only for the dull glow of his warm-coloured émails, strong and deep, dark and velvety. Other disciples of Chaplet are: Adrien Dalpayrat, born at Limoges, who collaborated first with Voisin-Delacroix and later with Mlle. Lesbros. His work can be recognized by the deeply coloured blue, blood-red or yellow opaque glazing, reminiscent of oil painting. Technically his workshop was very highly developed; sometimes he made vases several yards high in blue and red spotted grks.

Edmond Lachenal was much more under Japanese influence. For ornamentation, especially in his dull green glazed pots, he used naturalistic branches and flowers or blossoms, brought out in relief, and tinged with white or rose red. By giving his works an acid bath he succeeded in making the surface peculiarly velvety

—*émail velouté*. Albert Dammouse considered the material more, and his work at the Sbvres factory has a character entirely its own. For the decorating of his rather simple forms he used plant motifs, and often those of mosses and seaweeds. In so-called *pâte-décor,* the glaze and the pâte material are applied side by side or one over the other, as in enamel painting. Dammouse avoided bright colours and tried to get dark, deep harmonic tinges. In connection with this the Englishman Taxile Doat might also be mentioned. He worked at the Sèvres factory and produced *pâte-décor* Especially remarkable are his grbs articles on the surface of which have been affixed small porcelain insets with heads of animals. Alexandre Bigot, who has carried out designs for Henri van der Velden, and J. C. and M. Cazin (father and son), attained fame with their richly coloured running-glazes. They are inferior, however, to some of the younger artists, who in closer association with Chaplet and Delaherche, raised, with the help of the latter, French grbs to a height not reached by the older artists. First among these are Emile Lenoble and Emile Decoeur. Lenoble, Chaplet's son-in-law, not only took over Chaplet's furnaces, but also inherited his preference for grbs. But his work is quite different. Except in some of his Japanese-like products with a half coating of brown-black glaze, he specialized in engobes, in which he knew how to produce simple but very strong straight-lined ornaments by erasing. The colours of his engobes are of a blackish brown, grey, deep blue, green, orange-red, and white, and always of a quiet tone that harmonizes with the simplicity of the grey clay material. Decoeur is finer and more complicated with his dim, delicate glazes, occasionally bright, but generally dull, in which colour is more important than with Lenoble. Other ornament is lacking in his work or is reduced to a minimum, such as a few simple lines, a small cufic motif in relief, or a margin of leaves reminiscent of Chinese celadons. His bowls and pots are covered with a soft brown-yellow, a delicate green or blue glaze, usually rather thick and applied in a somewhat streaming manner. For softness of surface, his work equals the very best old Chinese and Japanese wares. Raoul Lachenal, the son of Edmond Lachenal, follows after Decoeur, and sometimes his work is equally good. Henri Simmen does the same, but he often imitates Japanese examples too servilely. Jean Mayodon decorates his work with figures like those on antique and Persian examples; *e.g.,* slender, leaping deer. René Buthaud has another technique—his decoration is of large flat human figures and a strong relief produced by deep incisions.

Of the artists who work in earthenware André Methey must be particularly mentioned. He is the greatest lover of colour and the greatest decorator, an artist who seeks inspiration not in Chinese or Japanese work, but in the rich ceramic production of ancient Persia whose metallic lustres he tries to equal. He is at his best when he builds up his décors from rhythmical repetition of very simple motifs taken from nature. Etienne Avenard follows his example. Félix Massoul uses in his work much heavier colours, his décor is more geometric and not so delicate as Methey's. Finally, the very simple but always fine forms and décors of Jean Besnard are not without merit.

While French ceramic artists were following new paths and bringing French work into world-wide prominence the development of the porcelain factory at Shes — the former glory of France—was negligible save in one respect, that of technique. At the Great Exhibition of 1851, Sbvres created a very bad impression. In 1852 Regnault was made director. An improvement resulted, but only in so far as the art director Dieterlé (till 1856) and after him Nicolle tried to make very clever imitations of the 18th century examples, instead of the dull repetition of the old traditions. Under L. Robert who was in charge from 1872 the old post of "directeur des travaux d'art" was reinstituted, and Carrier-Belleuse was appointed to it; new men were engaged, amongst others the young Rodin from 1880–82. But, in spite of these efforts and the experiments of the able and resourceful T. Deck a new ceramic art was not born. After Deck's death in 1891 the factory was reorganized, and in 1896, in anticipation of the Paris Exhibition of 1900, an extensive working scheme was drawn up as the basis for more modern and artistic development.

By a decree of Oct. 1, 1926, greater independence was granted to this factory.

Outside the Sèvres factory the only names worthy of note are those of Taxile Doat who has already been mentioned, and Camille Naudot, who about 1900 did some fine work in porcelain tendre. Haviland, in Limoges, worked at painting-before-glazing and also tried to produce artistic earthenware, but without producing anything special. A group of artists in Glatigny, near Versailles, who called themselves after this place, produced porcelains with streaming glazes reminiscent of grbs. Their example was followed by Pillivuyt in Paris. The first to attempt to make artistic stoneware of this kind in France was G. de Feure. In general, however, few good things have been produced. There were several tea and dinner sets at the exhibition of 1925, designed by decorative artists, but they seldom had a cachet of their own. Good work was done by Robert Bonfils, Maurice Dufresne, Suzanne Lalique and, probably the best of all, Marcel Goupy.

GERMANY

In connection with the revival of the German ceramic industry in the 20th century two names may be mentioned here, Th. Schmuz-Baudisz and Max Lauger. Both were attracted to the ceramic industry by knowledge of the so-called peasant pottery. and both learned the industry in its simplest forms from potters in Bavaria or the Black Forest. In this way it was impressed on them that the first thing a ceramist should know is that the shape and decoration of any object must depend very largely on the nature and composition of the material and on the technique of firing.

Max Lauger, who worked at Karlsruhe, decorated his vases and jugs, which were simple in shape and of a deep and even colour, with motifs from nature applied in clay of a different colour. His work resembles the *barbotine décor.* Working for a factory in Kandern he also designed, with the technical expert C. Mayer, architectonically applied earthenware, a great number of tiles, tile-tableaux, and mural coverings. Later, he worked in maiolica for the Majolica Manufaktur at Karlsruhe, and produced articles decorated in strong colours. These have greatly influenced younger artists, such as Ludwig Koenig and Georg Schrimpf, who, however, are inclined to an affected naïveté. Th. Schmuz-Baudisz was a painter at Munich, who after 1896 devoted himself to ceramics. He began to shape his objects himself and decorated them with motifs of flora and fauna which he cut out in the engobes that covered his pots. His decorations are much more strongly stylized than those of Lauger. In 1902 he became director of the Staatliche Porzellan Manufaktur at Berlin. The work of Elisabeth Schmidt-Pecht must also be mentioned; it is simple in decoration and form. In the meantime the porcelain factories took some interest in modern work. The Berlin factory, although strongly dependent on the taste of the court, had already, under Dr. Seger, about 1884, made experiments with copper-oxide glazes, and had even obtained good results in red and blue on the so-called flammés and running-glazes. The plastic articles, however, remained of little importance in spite of some successful products by Franz Metzner. But when Schmuz-Baudisz, who had started making domestic porcelain with simple decorations at the factory of Swaine and Company in Huttensteinach, moved to the factory at Berlin, the example of Copenhagen was soon followed and painting-before-glazing was applied. Of the artists, Adolf Flad and Max Durschke must be mentioned. Schmuz-Baudisz, who set himself the task of designing landscapes in coiour on large porcelain tiles, attempted a difficult technique which was not always justifiable from an artistic point of view. For many years the plastic work at Berlin could not free itself from the influence of the court. Since that time, however. Hermann Hubatsch has made clever statuettes, and in animal pieces Anton Pachegger (1917) and Edmund Otto have done sensitive work But a great deal has not been accomplished, and in this respect Berlin is just as unimportant as Meissen for the same period. in that, although technically very clever, it produced nothing really important until 1918.

In 1918 Max Adolf Pfeiffer was made director; he brought new life into the factory and made a great improvement especially in plastic work, to which some of the younger artists, for instance E. P. Borner, Max Esser and Paul Scheurich have contributed. More important than Meissen and Berlin in modern ceramics has been Nymphenburg in Bavaria. In 1888 Albert Bauml became director, and he soon attached some young artists to his establishment who, so far as plastic work is concerned, have obtained astonishing results. Jozef \F'ackerle was especially prominent here. He made beautiful types of peasant pottery, and also humorous groups from 18th century life. He fully mastered the possibilities of porcelain, and made some clever models in maiolica. For some years Wackerle worked at Berlin. Theodor Karner has done animal pieces which are in the first rank; of his disciples W. Neuhäuser must be mentioned.

Among other important factories may be mentioned the Schwarzburger Werkstätten für Porzellankunst at Unterweissbach, later combined with those at Volkstedt, of which M. A. Pfeiffer was director. He knew how to escape the influence of Copenhagen and sought to produce original work. Jozef Wackerle first worked here and also Ernst Barlach, who with his figures of Russian peasants introduced an entirely new style. Moritz Pfeiffer's table decoration "Hunting scene" also deserves mention. Besides these, good plastic models have been made by Hugo Meisch and by Arthur Storch, while Hans Poelzig has succeeded in making porcelain subservient to modern interior decoration.

Andreas at Leipzig has attempted to make expressionist porcelain pieces, but so far the fine qualities of porcelain have not been adapted to this method of expression. Maiolica offers a better field, and is better adapted to painting. The somewhat affectedly naïve products of L. Koenig and G. Schrimpf have already been mentioned. They work at the Majolica Manufaktur at Rarlsruhe, where other younger artists are also engaged. Another and smaller workshop is that of the women ceramists J. Biehler and M Goossen at Nymphenburg. They have made good reliefs and also free pieces. Two other Munich workers deserve mention, Georg Kemper, who produces miniature pieces, sensitive in form and colour, of *putti* and such like; while Konigsbauer attempts a close resemblance to mediaeval forms with his double-surfaced sided jugs of which the outer one is open-worked. Something like this is also found in the maiolica work of Otto Müller who was inspired by Chinese examples, and in the pottery of Kurt Feuerriegel who is more inspired by 16th century models, though both of them, especially the former, produce work with a character of their own. The same can be said of Auguste Papendieck who works independently in the neighbourhood of Bremen, and who, in her monochrome, slightly glazed vases, aims at great simpiicity and pure technique.

Finally some important progressive features can be seen in the development of stoneware. The domestic pottery of the firm of Villeroy and Boch, who have factories in various places, is frequently meritorious work. In particular their Dresden factory has obtained good results. J. Kühne and Jean Beck design forms and décors The Wachtersbacher Steingutfabrik at Schlierbach has had as art directors Chr. Neureuthet and, after his death, Ed. Schweitzer. Good plastics have been made by Ernst Riegel.

AUSTRIA

During the 19th century there was no artistic ceramic work to speak of in Austria. The revival dates from the first years of the 20th century. Following an exhibition of simple and brightly coloured ceramics at the Viennese Secession in 1902, Bertold Loffler began his attempts to create something new with ordinary red clay, and was joined soon after by Michael Powolny, the most important person in Austrian ceramics. They established a workshop, the Wiener Keramik, where Powolny's pieces of ordinary clay, fired and brightly glazed, were produced. In 1907 there followed the collaboration with the Wiener Werkstatte, where Josef Hoffmann sought and found new possibilities for the entire industrial art. On the ceramic side he was helped by Kolo Moser (d. 1918). The Werkbund exhibition of 1912 showed not only the *putti* and other figures wreathed and surrounded by flowers, but also the ceramics in black and white under-glaze which has become a special Viennese type and has been imitated endlessly. In the same year the Wiener Keramik collaborated with the Gmundener Keramische Werkstatte, where, under the directorship of Franz and Emile Schleisz, peasant pottery developed into an artistic product. An important side of this industry was practised by Powolny, who made work for interior decoration and tiles for stoves at Gmunden. One of the most prolific designers is Otto Prutscher. Meanwhile, Powolny has a number of disciples at the Wiener Kunstgewerbeschule, who work at the Wiener Werkstatte or in small studios of their own. The Wiener Porzellan Manufaktur has come under the influence of the revival in earthenware. Multi-coloured décors by Franz Zulow cover its products. In general, however, lively and dainty as the whole of Austrian ceramic production may be, it is always in danger of becoming affected.

HOLLAND

In the 19th century the famous ceramic traditions of the early maiolica and Delft ware, with its cream pâte, had completely disappeared. That which had taste imported from elsewhere flourished. In the last quarter of the century there was a revival. J. Thooft in 1876 bought the last remaining Delft factory, De Porceleyne Fles, and. together with Ad. Lecomte, he applied himself to the revival of Dutch artistic pottery. Unfortunately at first this usually consisted of an imitation of old Delft ware,—blue and, later on, coloured; but shortly after, in 1884 at The Hague, the German ceramist W. Von Gudenberg together with the decorative artist Th. Colenbrander, began to make more original work in the Rozenburg factory. Colenbrander's designs were novel and distinguished, his décors sometimes under Japanese influence, but usually completely his own, were in rich colours and usually had phantasies of plant motifs. There are amongst these bright and slightly too brilliantly glazed pieces of faience hints of futuristic compositions, but they are purer from a decorative point of view. Production of this kind at the Rozenburg factory lasted only until 1889 when Colenbrander left it. It was not revived until 1916, when the vogue was for rather heavy, darkly painted faience. A peculiar product was a kind of very thin pseudo-porcelain, in pale colours, shaped and painted in Jugend style. Japanese influence can be recognized in the ornament. The material, as thin as paper, has not been generally used. Meanwhile the De Porceleyne Fles found two clever artists in L. Senf and E. L. F. Bodart who made various experiments, including dark brown earthenware with running glazes and graffite ornaments, and glass-covered faience with painting inspired by Persian colour and décor. Gold and silver lustre ware has also been successful.

A third tendency became apparent, the influence of the English movement in industrial art inspired by Morris and Crane. On the one hand this was seen in the workshops when first at Amstelhoek and later at Distel an attempt was made to produce beautiful domestic ware with simple materials and old ceramic techniques. On the other hand an independent potter, W. C. Brouwer, turned original shapes on a potter's wheel, which, coated with self-made glazes, were simple but elegant objects. Very little plastic work was done, but the sculptor J. Mendes Da Costa made very delicate and typical small groups of Jewish women and animals in lead-glazed grès.

An important figure in the 20th century was C. J. Lanooy, who, as an independent ceramist, imitated the grès flambés of the French, and produced very original and most beautifully coloured pieces. His glazes in which metallic oxides play an important part, are frequently very fortunate discoveries. B. Kienhuys, for a long time a teacher at Hagen, Westphalia, and later at the industrial school at Amsterdam, has a fine feeling for harmonious colouring, and his pots and vases certainly have good and original shapes. Th. Nieuwenhuys and C. Lion Cachet, who as decorative artists occupied themselves with many forms of art, designed faience for the Distel which is deserving of attention. About 1912 Colenbrander, for a short time, made faience covered with dull glazes on which his peculiar décors, principally in blue and brown, were painted. Again, about 1925, in his old age, he designed underglaze décors on the faience of the Arnhem factory Ram. At the same time the factory of Eskaf produced beautiful domestic ware with white streaming glazes, sometimes decorated in black in a plastic manner, and also miniature plastics, both by H. Krop. At the factory of Z. Holland at Gouda, domestic ware of good shape ana colour was made by C. De Lorm. Brouwer still continues his work and also frequently designs ware for interior decoration. Besides those of Senf and Bodart and their disciples the De Porceleyne Fles produces very good tiles, usually in monochrome, but also in fine colours. Generally speaking, Dutch faience—no porcelain or grès is produced—has a distinct character of its own.

(H. E. VAN GE.)

SCANDINAVIA

Interest in ceramics in Scandinavia was renewed with unusual vigour about the end of the 19th century. This movement, particularly in Denmark, may be attributed to Philip Schou, for some time the manager of the Royal Porcelain works. The white underglaze porcelain, introduced at the end of the 19th century by Arnold Krog, by virtue of its plastic qualities and the depth and perspective it can give to a picture, demands decorations taken from nature and everyday life. The decorations and the more severe ornamental lines which in other ceramic art attain such beauty of perfection, are out of place here; but a sentiment from the air, from the water, from bird, animal or plant life, is reproduced by this underglaze porcelain as by nothing else. This school, which is thus of a national character, is bound up with a great development in sculpture, especially of animals portrayed as they are in life, and of figures, which also reproduce Danish atmospheres, whether taken from life or literature, as for example, Hans Andersen's fairy tales. Another type, the fluted porcelain, which in English-speaking countries is called "the blue Danish pattern," is akin to the underglaze porcelain. The pattern originally came from China, but in course of time has become entirely Danish and has undergone an interesting development. All the models, even the plainest, are the work of the best and most artistic designers and thus the whole set is stamped with a refinement which makes it probably the most popular dinner-service in the world at the present moment.

It is interesting to note that the first great novelty which appeared after underglaze porcelain had made its mark was its direct antithesis—the overglaze. It is interesting also to see how three different artists solved the problem of creating modern overglaze porcelain and its sculpture. Henning, imaginative, artistically great, with a cosmopolitan stimulus, conjures up romance by blending the cultures of East and West in beautiful, rather voluptuous figures; whereas Carl Martin Hansen takes his themes from the almost forgotten national dresses of men, women and children in the various parts of his native country; and A. Malinowski seeks the ideal of his art in white porcelain, only very discreetly and very slightly decorated with a little sepia and gold.

Biscuit, a peculiar material, was at one time, particularly towards the close of the 18th century, admired over the whole world. And then the taste for it died away, probably because the ceramic importance of the material was not sufficiently appreciated. Compare old Sèvres with modern Sèvres, old Wedgwood with modern Wedgwood, and the difference will be seen—and this difference is not due solely to age, for all porcelain changes slightly with age; it is presumably due to the failure to recognize the importance of the question of material. Even when biscuit was introduced in the reproduction of the works of Thorvaldsen, this recognition was lacking, and it was only after more than zo years of research and experiment that the Royal Porcelain works in Denmark discovered a faintly cream-coloured biscuit—amber against the light—which artists, particularly Malinowski, have endeavoured to mould to their work.

Only three principal colours can be used on underglaze porcelain, blue, green and a reddish tone, and painters have therefore had recourse to overglaze technique where every colour is available, especially gold. However, after numerous experiments with white and grey porcelain, and with stoneware, etc., our artists have found in greyish crackled porcelain a background for painting that inspires them to break new ground. In this porcelain the artist works with vigour, and his decorations possess at the same time a sweetness, a charm, a freshness and a freedom made possible by the employment of this new material, and it is an interesting fact that to attain their effects the artists are not content with crackled porcelain; they want the crackled large or small, square or round, according to the motifs they have created; and the potter knows how to satisfy these demands. A closer collaboration between technique and art scarcely exists.

Of late years unusual interest has been taken in celadon, that remarkable old Chinese porcelain which was discovered through iron having become mixed in the glaze, the effect being that the glaze became green when the porcelain was baked in a certain way. The material is not easy to work with; it requires its own artistic treatment, its own particular shapes, a very special glazing and a special glaze. The material gives opportunity for line effects, architectural effects and reliefs. Often it assumes a jade-like character and is in the closest harmony with the old Chinese culture.

Almost simultaneously with the renaissance of overglaze technique, work was started upon stoneware, a ceramic material that is between porcelain and faience. Porcelain is a siliceous, translucent material; stoneware is a siliceous, opaque material; faience is a porous material. It is interesting to see the strange and unexpected effects which appear gradually as one studies the material more and more. There are the coloured glazes, the fine surface aptly termed *peau de vierge* in France; Jais Nielsen's strong, turquoise-blue glazes, which make one think of the ceramic wonders of Persia and Samarcand, and Kyhn's splendid animals.

From the beginning of the 20th century the Copenhagen Faience works has endeavoured to create a modern style of faience of high artistic merit. It must be remembered that present-day faience is generally different from faiences which delighted the world in mediaeval times. The fine collections of Italian and French and Moorish faience all have tin glazes. These tin glazes are less used in modem faience; for technical reasons potters have turned to a lead glaze or a hydric borate glaze, and attention has principally been devoted to finding an artistic expression for a product of this kind. Here, too, the work is under the glaze where, in contrast to porcelain, one can employ the whole of the colour scale. The designs produced under the leadership of Joachim are gay and lively, rich and glowing, and characteristically Danish. The ground colour resembles that of English faience; but it will not be denied that the artistic treatment of faience in this modem material is much more difficult than tin faience and porcelain, because the glaze is a clearer and lighter glass than the glaze upon porcelain and tin faience, and it has required great trouble to obtain the proper harmony between body, colour and glaze. Joachim has attained great heights with this remarkable faience. The simplicity of decoration and colour, and the definite glaze shades are a constant source of pleasure.

There is in Denmark another very important pottery, Bing and Gröndahl's Porcelain works, which were established in 1853. The same desire which seized Philip Schou to ennoble the material on the basis of Danish artistic culture also animated Harald Bing, who was manager at that time. He engaged the artist, Peitro Krohn, whose finest work is, perhaps, the beautiful heron set, in which he has created something extremely decorative by means of a combination of underglaze and gold. In 1900, at the exhibition in Paris, it entered upon entirely new paths. Later on Bing and Grondahl attached such artists to their establishment as Kai Nielsen, whose Venus seems to be a symbol of complete harmony between art and material. In 1925, at the exhibition at Paris, Jean Gauguin exhibited a number of works in stoneware with chamotte, in which he proved himself a very gifted artist. By various chemical means, he created peculiar and beautiful works which, in stoneware, may to some extent correspond to biscuit in porcelain. Jean Gauguin's latest works, in faience with tin glaze, demonstrate the fresh and bold imagination of the artist in a sculptural sense.

A beautiful and peculiar art which has arisen in Denmark is the manufacture of earthenware, particularly at Kähler's works at Nastved, where two generations have succeeded in showing novel and interesting results in refined glazed earthenware. The material itself is ordinary clay from the fields near the factory. The work lies in the baking, the painting and the glaze, in which much is done with lustres—the red copper lustres ranking higher, in some ways, than both Clément Massier's from Golfe de Juan and the Hungarian lustres from Fiinfkirchen. The factory has extended the colour range of these lustre glazes and has some grey lustres which, in the hands of the painter Tirslund, have attained the finest effects.

On the island of Bornholm there is a small factory, Hjort's pottery. It is, perhaps, not very well known outside of Denmark, but Hjort's stoneware is of excellent quality, even though the output is limited. He turns out small vases and figures with coloured glazes, 6th a charm characteristic of his own touch. His glazes excel by their great thickness. And finally, we must not neglect to name the artist, Hansen-Jacobsen, who has dreamed of creating ceramic wonders and so often realized his dreams.

Sweden has worked on different lines. Whereas Denmark has, perhaps, devoted herself principally to the free ceramic art, Sweden has had a background for her ceramic development that might well be envied by other countries. Sweden has always possessed a great folk-art which has produced distinguished work, especially in her textile wares, her wood-carving and her iron, and this art has influenced the great factories, such as Gustafsberg, Rorstrand and Gafle, in their production of characteristic dinner-sets which are in the closest possible harmony with Swedish home-life. There is no doubt that this art is very desirable and peculiar to Sweden, and that the highest ceramic ideal lies in raising the artistic level of such dinner-sets, where the scope of the artist is so much more limited than in free art.

Norway, in the two factories, Porsgrund and Egernsund, the one porcelain and the other faience, has repeatedly been on the verge of creating something national and unique, but has unfortunately abandoned it uncompleted.

The factory, "Arabia," in Finland, has attempted to achieve the same end, but stern necessity has doubtless confined its production within the boundaries set by the economic life of the country. (F. DA.)

ENGLAND

English cream-coloured earthenware still retains much of the market it gained by its excellent quality in the latter part of the 18th century, and modern taste has reverted to slight graceful patterns not at all unlike those on Wedgwood's early "Queen's ware." Some noteworthy private decorators have contributed to this. Alfred and Louise Powell have painted some interesting designs on Wedgwood pottery, and latterly on wares of their own making. Dora Billington's fancifully decorated table-wares should also be mentioned here, amongst the work of a small group of people whose efforts, though slight in themselves, are significant as determining the styles eventually adopted by the manufacturers. Standing apart from all other "useful wares" are the charming and original things designed by John and Truda Adams and made by Carter, Stabler and Adams of Poole: a novel and pleasant half-glossy surface and distinctive clean colour are amongst their good qualities.

The decorative styles first inspired, late in the 19th century, by the Chinese *flambé* and other glazes have been continued by (amongst others) W. Moorcroft of Stoke-on-Trent, Doulton's of Burslem, W. Howson Taylor (Ruskin Pottery, Smethwick), Bernard Moore and Pilkington's of Manchester. The last-named have continued their work in lustre-painting, and in 1928 introduced some very pleasant grey glazes, with effective slight designs in black by Gwladys Rodgers. The later work of the Martin brothers in salt-glazed stoneware showed a praiseworthy advance in simplicity. Doulton's Lambeth stoneware with coloured glazes has been used for statuary by Gilbert Bayes in a manner practised also with success by Mr. and Mrs. Harold Stabler. Perhaps the best and certainly the most promising work in glazed pottery-sculpture has been done by John Skeaping. Interesting figures on a smaller scale, inspired by 18th century china, have been made by Charles Vyse and Gwendolen Parnell.

Amongst the studio-potters, W. Staite Murray's genius has produced much work superficially resembling the early Chinese but highly personal in its low-toned glazes and austerely beautiful forms and decorations. Of equal importance is the fine work in stoneware of Bernard Leach, also inspired by Far Eastern models. The art of Reginald Wells is less simple and direct, stressing colour rather than form, but capable of charming effects. Amongst the other artist-potters, Frances Richards has produced some interesting glazes on stoneware and three other women, Nora Braden, K. Pleydell-Bouverie and Sylvia Fox-Strangways, deserve mention for original work. Mr. Leach and his pupil, Michael Cardew, have revived with success the interesting English slip-ware technique, but high-fired stoneware is likely to be the most fruitful medium in this branch of the potter's art. (W. B. Ho.)

Other Countries. — There has been no important development in ceramics in countries other than those dealt with above. Neither Spain nor Italy has produced more than imitations of the old Spanish-Mauresque and Italian styles; Czechoslovakia and Switzerland are endeavouring to produce a distinctive native pottery, but with no very remarkable results.

NEAR AND FAR EAST

CHINA

The supreme excellence of Chinese pottery in mediaeval and later times gives an unusual zest to the enquiry into the first phases of Chinese ceramic history; and we welcome the new light recently shed on them by Prof. J. G. Andersson's discoveries in Honan and Kansu which reveal the existence of two distinct kinds of pottery in pre-dynastic times. The Andersson finds have been provisionally divided into six periods; and the earliest and, oddly enough, the most artistic of his pottery can hardly be later in time than 3000 B.C. It consists both of funerary wares and pottery for general use, made by hand (helped perhaps by a slow wheel) of

EARLY CHINESE POTTERY; (A) NEOLITHIC POTTERY FROM KANSU. (B) NEOLITHIC MAT-MARKED POTTERY FROM HONAN, (C) PAINTED POTTERY OF THE 4TH CENTURY B.C.

finely levigated, thin and strongly baked buff and red clays, shaped in pleasing, and often quite imposing, forms and decorated with elegant painted designs in red, black, purple and white clays which have been submitted to the fire of the kiln. This painted ware, which is superior in technique to any of the pre-Han pottery of dynastic times so far known, has interesting, if superficial, resemblances to the painted pottery found at Anau, Susa and other western Asiatic sites of late neolithic date.

Alongside this painted ware Andersson found another type of pottery, a coarser, grey earthenware made without the wheel and often impressed on the exterior with markings which suggest that

2. Bowl painted with a view of Chelsea church and water front. Chelsea. Gold anchor mark, about 1760
3. Mask jug painted with figures in a landscape and armorial bearings. Worcester, about 1765
4. Vase in the neoclassical style painted with scenes representing Damon and Musidora, probably by James Banford. Derby, about 1785
5. Teapot and cover painted in colours and gilded. Plymouth or Bristol, about 1770
6. Hexagonal vase decorated in panels, the figures by John Donaldson. Worcester, about 1770
7. Statuette of George III after a portrait by Johann Zoffany. Chelsea-Derby, about 1770
8. Shepherd and shepherdess in biscuit porcelain. Derby, about 1790
9. Figure emblematic of Water from a set of the Elements. Bristol, about 1775

the wet clay had been wrapped in matting or some coarse textile. This mat-marked pottery evidently had a long life, for it was still made in Chou and Han times.

The next important discovery belongs to the Yin dynasty (1765–1122 B.C.). On the site of the Yin tombs near An-yang in Honan were found pieces of a white pottery and of carved ivory and bone. The pottery, doubtless made of kaolinic earth, has been carved like the ivory and bone with the conventional designs and angular fret patterns which are usually associated with pre-Han bronzes. Complete vessels of this kind of carved white ware must have had a striking appearance, if indeed the fragments ever formed part of pottery vessels and were not, as has been suggested, moulds for the use of the bronze maker.

HAN WELL JAR

From the George Eumorfopoulos collection

All the rest of the pre-Han pottery which is known is funeral ware of a rough and not very interesting type, generally following the forms of the more precious bronze vessels for which it was doubtless a substitute. It is frequently mat-marked, and much of it is roughly coloured with unfired pigments.

The Han Dynasty (206 B.C.–A.D. 220).—The Han pottery, though the knowledge of it is still confined to the funeral wares recovered from tombs, shows a considerable advance in ceramic technique. Many of the Han vessels, such as the wine vases, are of elegant form, and they are ornamented with artistic designs in a variety of ways, by painting with unfired pigments, by stamping, by the application of reliefs which have been separately formed in moulds, and by incising.

Glaze is now used, apparently for the first time, a transparent lead glaze of yellowish tone which is coloured green with copper oxide and variegated by the use of liquid clays or slips of different colours. The underlying body of the glazed ware is usually red and this showing through the transparent glaze gives a brown or reddish brown surface when the glaze has not been coloured green by the use of copper.

Probably this lead glaze was introduced from western Asia, where it was in use in late Roman times; for the Chinese were in touch with the Roman empire in the Han dynasty.

Many of the pottery objects recovered from Han tombs are of deep archaeological interest, for they include, besides the household and ritual vessels, models of the buildings, implements, livestock and even human beings which had belonged to the household of the deceased. Further, it is noteworthy that the potters who supplied this funeral furniture evinced much artistic skill in the way in which they conventionalized their models. Thus the granary tower and the wellhead are transformed into picturesque objects, and even the model of the kitchen stove is not devoid of ornamental qualities.

PROTOPORCELAIN VASE (3RD OR 4TH CENTURY)

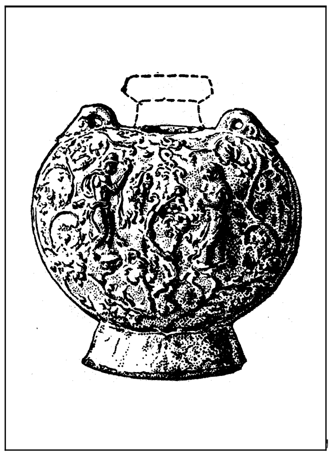
Han to T'ang (A.D. 220–618).—To the interval between Han and T'ang belongs a considerable group of figures and other beings. Animals are in many ways the most attractive of all the Chinese grave goods. Some of them are little later in date than the Han dynasty; but they evidently range over a long period, for whole sets of figurines of this class in the Toronto museum are known to have been found in tombs of the Liang dynasty (A.D. 502–557).

There are, besides, wine jars, vases, incense burners and toilet boxes of the 3rd and 4th centuries which are finely painted in unfired pigments with a style and execution not unworthy of the paintings on silk. The Han lead glaze continued in use, and it is by no means easy to differentiate the glazed pottery of the Han and of the immediately succeeding periods. There are, however, certain flask-shaped bottles with green and brown lead glaze over well-moulded reliefs which, though certainly post-Han, are probably earlier than the T'ang dynasty. Some of them are remarkable for their western types of ornament, such as dancing and piping figures, which would be at home in a Herculaneum frieze, surrounded by vine scrolls. Similar designs are seen on late Hellenistic pottery; and this doubtless was the source from which the Chinese potters drew their inspiration.

There is yet another kind of glazed ware which belongs to this interval, and which is apparently of purely Chinese origin. It is a kaolinic stoneware of hard gray body with a high-fired glaze of greenish brown tint. Specimens of this ware analyzed by H. W. Nichols of Chicago were pronounced to be a kind of proto-porcelain. In other words they are believed to contain the elements of porcelain, though in an unperfected state. M. Nakao held that the glaze of this ware is a wood-ash glaze evolved from the accidental gloss which often forms on pottery fired to a high temperature in a wood-fed furnace, as in the case of the early Korean pottery. It is practically certain that this kaolinic pottery with its glaze of feldspar and wood ashes forms a stage in the evolution of true porcelain which the Chinese had discovered by the T'ang dynasty. Indeed it is highly probable that porcelain was evolved from this material at some period in the interval between Han and T'ang. The colour of the glaze was probably caused by iron impurities in the clay, and this glaze is the oeginning of the celadon green glazes which owe their colour to iron.

The T'ang Dynasty (618–907).—In the great T'ang dynasty the Chinese empire reached its widest expansion, and China was without doubt the greatest and most civilized power in the world. It was an age of splendour for all the arts?and the potter's art was in no way behind the rest. Oddly enough, Chinese ceramic literature has little to tell of the T'ang potters. But Chinese ceramic literature is a comparatively modern growth and the secrets of T'ang pottery, laid bare only in modern times, were known in Europe almost as early as in China.

It was in fact largely as a result of the excavations made by European railway engineers that the contents of many T'ang tombs came to light, and what is known of T'ang pottery, as in the case of the earlier wares, is practically limited to the sepulchral wares. Saturally these do not show the T'ang potters in the most favourable light, but they characterize the great progress which had been made in ceramic technique and demonstrate the artistic capabilities of T'ang craftsmen. They make it clear, too, that western influences were active in China in this enlightened age, for traces of late Hellenistic, Sassanian and Persian art are frequently found in the forms and designs of the pottery of this period.



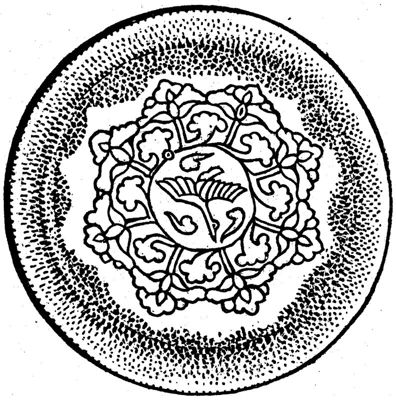
FROM THE GEORGE EUMORFOPOULOS COLLECTION

FLASK OF BUFF STONEWARE WITH BROWN GLAZE: T'ANG PERIOD OR EARLIER

On the T'ang funeral pottery the figures of human beings, birds and animals are modelled in a lively and spirited fashion, especially those of horses and camels: dancing girls and musicians. They are usually of a white or pinkish white clay, soft where lightly fired, but some occasionally are baked to considerable hardness. Some of them are unglazed and tricked out with red, black and blue pigments. Others are covered with a thin, transparent, lead glaze of faint yellowish tint, while on the more elaborate this glaze is coloured with washes, streaks or mottling of green, amber yellow or blue. The flesh parts of the glazed figures are commonly left without glaze, and in this case they are painted with the pigments mentioned above. Besides the figures, vases, ewers, bowls, cups and dishes of various kinds are found in the tombs; and among them are amphora-shaped jars of strikingly Hellenistic form and ewers of Sassanian type with a bird's head below the lip, a form common again in Persian pottery of a slightly later date.

The glazes used on the figures appear also on these vessels, sometimes in monochrome, more often in mottled colours, but they rarely cover the whole exterior of the vessel, stopping as a rule in a wavy line short of the base. The base of the T'ang vase is usually flat and shaved at the edge.

The decoration of T'ang pottery is chiefly effected by moulding in relief, by applying reliefs which have been stamped out separately, by carving the surface or by incising it with a pointed instrument.



FROM THE GEORGE EUMORFOPOULOS COLLECTION
DISH OF THE T'ANG DYNASTY

Painting with a brush was also used not only for the application of pigments on unglazed wares, but in rare instances for decorating in black under a green glaze.

The T'ang pottery so far discussed shows a considerable advance on its predecessors in the use of coloured lead glazes; but it is also apparent that great strides were now made with the harder, feldspathic glazes which were fired at a much higher temperature. The important excavations on the 9th century site of Samarra on the Tigris (see F. Sarre, Die Keramik *von Samarra,* 1925, and also below under Persian pottery) revealed quite a number of fragments of porcellanous stoneware and even true porcelain of Chinese make. From them we gather that these advanced ceramic products were not only made, but had actually become articles of overseas trade in the T'ang dynasty. They include a semi-porcelain with closely crackled. yellowish white glaze or with green and mottled glazes, or again with the sea-green glaze which we distinguish by the name of celadon; besides pure porcelain with white or ivory glaze. Other high-fired T'ang glazes are a chocolate brown, verging on black, a watery green and a brown splashed with frothy grey.

FROM THE GEORGE EUMORFOPOULOS COLLECTION
LEFT, PORCELAIN EWER WITH WHITE GLAZE, T'ANG PERIOD: RIGHT. WHITE PORCELAIN BOTTLE WITH UNGLAZED BASE, T'ANG PERIOD

But the progress of the T'ang potter is not to be measured by improved technique alone. The beauty of the vase-forms which he threw on the wheel places him in the front rank of potters, and his incised and moulded ornaments prove him to have been a true ceramic artist.

In the half century which intervened between the T'ang and Sung dynasties ceramic history records the manufacture of two interesting wares, both of which are still a puzzle to the student. One is the celebrated Ch'ai ware which was reputed to have been "thin as paper, resonant as a musical stone and blue as the sky seen between the clouds after rain." This was an imperial ware made for a few years only in the neighbourbood of K'ai-fêng Fu in Honan; and apparently no complete specimen of it remained above ground even in the 16th century. The traditional description of it suggests a kind of porcelain, and modern opinion holds that it probably belonged to the ying *ch'ing* class of ware which will be described presently. But this is only a theory and, it must be added, a theory which is by no means universally accepted.

The other is the *pi sê* (secret colour) ware made at Yiieh Chou, the modern Shao-hsing Fu in Chekiang, for the princely house of Chien. It is generally agreed that this was a porcelain or semi-porcelain with grey green glaze of the celadon type.

***The Sung Dynasty* (960–1279).**—The Sung dynasty was another Augustan age of Chinese art, and ceramic writers in after years described the Sung porcelains in reverential terms as the classic wares of China. Collectors treasured them with loving care, so that not a few have survived above the ground and we are not dependent entirely on excavated funeral goods for our estimate of the Sung potter's skill. Something too is recorded of the history of the more noted Sung factories, and slender as is the information given it has enabled the modern student to attempt a reasoned, though not yet assured, classification of the principal types, namely the Ju, Kuan, Ko, Ting, Lung-ch'iian, Chün, Chien and Tz'ŭ Chou, with a few subsidiary wares in addition.

The Imperial Ju ware was made at Ju Chou, near K'ai-fêng Fu in Honan, for a brief period at the beginning of the 12th century; but we gather that it belongs to a type of ware which was made at several potteries, *e.g.,* in the districts of T'ang Têng and Yao on the north of the Yellow river—besides at Ju Chou itself. The Ju Chou ware, however, excelled the rest and doubtless the imperial works were manned by picked Ju Chou potters. The Chinese descriptions of the Imperial Ju ware, which was already extremely scarce in the 16th century, leave us in some doubt as to its exact nature, but the most plausible theory is that it was of the ying ch'ing type. The term ying ch'ing, which means misty blue or green (the colour word ch'ing connoting both blue and green), is applied by the Chinese to-day to a soft-looking, bubbly porcelain glaze, white in colour but with a faint tinge of blue or greenish blue which sometimes develops a definite blue tint.

This tinge of colour has been traced to the presence of a minute quantity of iron in the ware. The *ying ch'ing* porcelain is a relatively low-fired ware and the body has a somewhat granular texture. It varies much in quality, from a coarse material with impure, pearly grey glaze to an exquisite eggshell porcelain thin and translucent and of a deliciously soft and melting quality. The best specimens are skilfully potted and of elegant shape, and the decoration, if any, is carved in low relief, incised with a fine point or pressed out in moulds. It is surmised that some of the finer ying *ch'ing* porcelain may have been made at the Imperial Ju Chou factory, while the rest comes from the numerous private factories working with more or less skill on the same lines. It must however be understood that the identification of this ware with the famous Ju porcelain is not yet proved.

Another type which is still problematical is the Kuan. The name itself leaves room for various interpretations, and the description of it in Chinese works, like most Chinese descriptions, is full of ambiguities. Kuan means imperial, and Kuan ware may be nothing more than imperial ware of whatever kind. But Chinese writers evidently intended the Kuan wares of the Sung dynasty to be distinctive types. They describe first of all a Kuan ware made in the neighbourhood of the capital, K'ai-fêng Fu, for a short time before 1127, when the Sung court was driven south of the Yangtze by the Kin Tartars. The identification of this northern Kuan is extremely uncertain, though there are reasons for thinking that it had the opalescent, blue-grey type of glaze which was developed to its full on the Chün Chou ware (see p. 364). The southern Kuan, made after 1127 in the precincts of the imperial palace at Hang-chou, whither the Sung court had been transferred, so closely resembled the Ko ware that many Chinese writers do not attempt to discriminate between the Ko and Kuan.

FROM THE GEORGE EUMORFOPOULOS COLLECTION

TZ'U CHOU VASE, YUAN DYNASTY
A band of lotus scroll with one of foliage below ornaments this buff grey vase which has a black finish

The Ko ware is described in some detail in Chinese books. It got its name from the elder of two potter brothers Chang who lived in the Lung-ch'üan district in Chekiang in the Southern Sung period, being in fact the ware of the "elder brother" (ko). It is evident, however, that the term Ko ware was not confined to any individual's work, but passed into general use as a generic term for a group of wares made over a long period at various places. Like the Hang Chou Kuan, the Sung Ko ware was made of a dark-coloured clay (we are told by one writer that this clay was actually brought from Hang Chou to the Lung-ch'üan district), and for this reason it has a dark brown edge on the unglazed foot-rim and a brown mouth-rim where the glaze is thin enough to allow the body material to show through it. The glaze itself was crackled, sometimes in a wide network of cracks, sometimes in a close pattern of small crackle which was likened to fish roe. The crackle was further emphasized by staining it with red or black. The colours of the Ko glaze are described as *fên* ch'ing, *hui sê,* mi sê, which may be rendered grey green, ash colour and millet colour or yellowish, and less intelligibly as tan *pai,* which was probably something of the ying *ch'ing* colour.

Well accredited specimens in Western collections have a blackish body material which gives the traditional "brown mouth and iron foot," a thick opaque glaze, lustrous and fat, with crackle stained red or black, and of bluish grey, greenish grey or buff grey colours, which tally well with the Chinese descriptions. We read of Ko ware made in the Yuan and even the early Ming periods; and in later times the term Ko glaze was current for all the grey and buff crackled glazes which figure so largely in the Chinese potter's output.

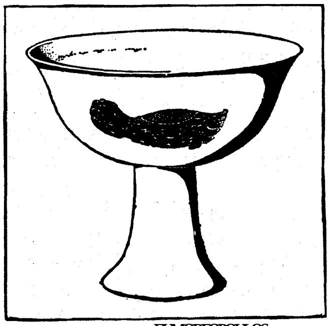
The crackle affected by the Chinese potter from the Sung dynasty onwards was deliberately sought by definite processes and was eventually got under perfect control, so that large or small crackle could be produced at will. It is unlikely that the earlier processes were very reliable, such as the plunging of the ware while still warm into cold water; but the Chinese eventually discovered that the mixing of a certain kind of stone (apparently pegmatite) with the glaze disturbed the relationship of body and glaze sufficiently to ensure crackle, and they learnt to prepare a crackle glaze which was applied in single, double or treble doses according to the size of the crackle desired

Lung-ch'üan Celadon.—The Lung-ch'üan district in Chekiang, the home of the original Ko ware, had long been noted for a beautiful ware which is familiar to us under the name of celadon.

It is a porcelain or semi-porcelain of greyish white body with a thick translucent glaze varying from greyish and bluish green to sea-green and grass-green

The most precious of the Lung-ch'üan celadons has a delicate bluish grey or greenish grey glaze over a finely potted porcelain body which is almost white. Such was the ware reputed to have been made by the younger Chang at the village of Liu-t'ien in the Southern Sung period; and collectors distinguish it by the Japanese name *kinuta,* after a famous vase in shape of a mallet (kinuta), which is preserved in a Japanese temple. Nothing could be more subtly beautiful than this soft, misty bluish grey porcelain.

It is not known how far back the industry of Lung-ch'üan dates; but the fragments of celadon found on the 9th century site of Samarra, in Mesopotamia, may well have been made there. On the other hand, we are told that the kilns were transferred to the neighbouring Ch'u-chou at the beginning of the Ming period and that they flourished there till the end of that dynasty. The output must have been large, and it formed from the earliest time an important item of Chinese export trade. Fragments of celadon are found in the ruins of ancient cities all over the Near East, and we know from actual records that celadon was imported into Egypt and carried thence along the Mediterranean coasts as far as Morocco. Fragments too have been found on the coastal sites of East Africa as far south as Zanzibar. India and the East Indies had their share of the trade, and a few pieces of celadon found their way even to western Europe in the middle ages. This justly celebrated ware, the export celadon, was a stoutly built greyish porcelain with a beautiful sea-green glaze of considerable thickness but transparent enough to allow the carved, moulded or incised designs to show through clearly.

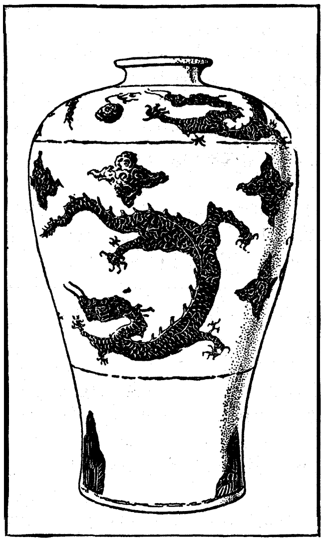


FROM THE GEORGE EUMORFOPOULOS COLLECTION

HSÜAN TÊ PORCELAIN STEM-CUP
One of the three crimson red fishes painted on the outside is shown

Besides the carved and incised designs which are of great beauty, reliefs moulded or applied were effectively used. Sometimes these reliefs—floral medallions, fishes and even figure subjects—were left uncovered by the glaze, and in this case they invariably took on a red or reddish brown colour as a result of exposure to the fire in the kiln.

This browning, caused by the presence of iron in the clay, is in all parts of the ware which were unprotected by the glaze, such as the base-rims and the large unglazed ring which is often seen on the bottoms of dishes. It was thought at one time that the presence of this ring was a sign of Ming origin, but it is very doubtful if this rule holds good; and the distinction between Ming, Yuan and Sung celadons, no easy matter, must depend on an appreciation of style and finish. Much help in this delicate task of connoisseurship can be obtained from a study of the other Sung wares, especially the Ting porcelain (see below) with its carved and engraved floral designs which closely resemble those used on the celadons. In the hands of the Sung artists these designs had a freshness and spontaneity which is dulled by repetition on the Ming wares. A special type of celadon is variegated by patches of reddish brown derived from iron. This is known as "spotted celadon," the tobi *seiji* of the Japanese.



BY COURTESY OF THE BRITISH MUSEUM

PORCELAIN VASE WITH DRAGONS

Other Celadons.—Though the industry in Chekiang is said to have died out in the 17th century, it was not to be expected that such a beautiful glaze as the sea-green celadon would be allowed to disappear. It was, in fact, made with slight variations in many other pottery centres. At Ching-tê Chên it was used over the white porcelain body for which that place is noted, and the Ching-tê Chên celadons have the ordinary white glaze, and sometimes a reign mark in blue, on their bases. A celadon glaze was used on the Kwangtung stoneware; and there are many specimens with glaze of celadon type but so different in body from the typical Chekiang ware that one must perforce look to some other centre for their origin. Consulting Chinese books provides little help in this quest. It is true that they speak of a certain T'ung ware, made near K'ai-fêng Fu in Honan, as if it were of the celadon class. But the identification of the T'ung is quite conjectural. In the absence of definite indications, the term "northern celadon" has been adopted for one large and important group. It comprises bowls, small dishes, vases, incense burners, etc., with a dry buff-gray stoneware body and an olive-green celadon glaze. The decoration is carved, incised or moulded, often with much skill and taste; and it closely resembles that of the ying ch'ing, or Ju type of porcelain, a fact which suggests a Honan origin for the ware.

This northern origin, however, is not accepted by all authorities. Nakao. for instance, held that it is only a variety of the Chekiang celadons, in spite of the very obvious difference between it and the usual Lung-ch'iian types, and he is probably right in supposing that the art of celadon manufacture was introduced into southern Korea from Chekiang, the most accessible Chinese ceramic centre. And it must be admitted that the resemblance between the so-called northern celadon and the Korean is remarkably close.

A stoneware of celadon type but with a pale and watery glaze was made at Sawankhalok in Siam as early as the 14th century; and in more recent times good celadon wares, scarcely distinguishable from the Lung-ch'uan, have been made in several parts of Japan. It may be added that the imported celadon wares were freely imitated in Persia and Egypt, but these imitations, made with the soft near eastern pottery, are easily recognizable for what they are.

Ting Ware.—Another of the classic Sung types is the ivory-white porcelain made at Ting Chou in southern Chihli. It is a singularly pure and beautiful ware with a flour-white body, slightly translucent, and a glaze of cream or ivory tint, which, however, tends to run in tears or drops on the outside of the bowls and dishes. A peculiarity of the ware, which it shares with the *ying* ch'ing, or Ju type, is that the mouth rims of bowls and dishes are often unglazed while the base is covered with glaze, thus reversing the usual conditions. The rough rims of such vessels are generally concealed by a band of silver or copper. The Ting ware was exquisitely decorated with carved or incised designs, largely floral, and in some cases, eipecially in the later periods, the more mechanical method of pressing out the designs in moulds was used with good efiect.

Besides the fine ivory-white Ting ware there are several varieties. One is known as t'u (earthy) Ting because it has a more opaque and earthy-looking body. This kind has a soft, cream-white glaze which is usually covered with faint crackle. Chinese writers also speak of Ting wares with black, red and brown or purple glazes.

The two first are probably glazes of the Honan temmoku type; but the purple Ting has so far eluded recognition. There is also mention of a painted Ting ware, which must have resembled the painted stoneware of Tz'ŭ Chou.

The beauty of the white Ting porcelain encouraged, while its simplicity abetted, numerous imitations, some of which are admitted by Chinese writers to be practically indistinguishable from the original. There was, for instance, the southern Ting, made by Ting Chou potters who moved south with the Sung court in 1127 and who seem to have settled in the neighbourhood of Ching-tê Chên. Then there were the famous imitations made by P'êng Chun-pao at Ho Chou in Shansi; and the Ssŭ Chou and Su Chou nares of Anhwei which were bought for Ting ware in the Sung dynasty "by persons who liked a bargain." There are the white wares of Hsuan Chou, and those made at the "white earth village" near Hsiao Hsien in northern Kiangsu. There were the cream-white wares made at Tz'ŭ Chou which were regarded as equal to Ting, and another of a singularly pleasing stoneware with gray or light buff body covered with a wash of white slip and a beautiful waxen white glaze closely crackled and recalling the finer t'u Ting wares. Much of this ware has been excavated on the site of the submerged town of Kiiluhsien (destroyed by flood in 1108), and many of the specimens have been made additionally attractive by pinkish gray stains acquired during burial.

The Ting Chou factories themselves, though their fame died down after the Sung period, continued in operation, and Ting ware is mentioned in court records as late as the middle of the 16th century. About this time too a celebrated potter at Ching-tê Chên, Chou Tan-ch'iian, made himself a name by his wonderful imitations of Sung Ting vessels, and apparently he had many followers who kept up the traditions of his work at Ching-tê Chên long after his death.

Chün Ware.—Yet another celebrated ware was the Chun, which was made at Chün Chou in the K'ai-fêng Fu district of Honan. It was in fact, like the white Ting and the green celadon, one of the key wares of the Sung dynasty. According to Nakao it is the type of ware which would naturally result from the firing of a kaolinic body and feldspathic glaze coloured by copper in the oxidizing flame of the typical round kiln of northern China.

The finer Chün wares have a gray porcellanous body and a thick opalescent glaze full of bubbles and minute pinholes (caused by the bursting of bubbles), and displaying a wonderful variety of colours which are the result in part of the protean changes of copper oxide in an oxidizing flame, in part of a trace of iron which is present in the body material, and in part of the play of light in a highly opalescent glaze. Copper under the conditions prevailing in the Chün Chou kilns was capable of producing a range of colour from blue to blood red, and the Chün glazes display endless combinations of these colours suffusing a basically gray glaze. Thus there are in the extremes an even lavender gray and an almost uniform purplish red, and between these a variety of splashed, streaked and mottled effects of blue, gray, purple and crushed strawberry red. Again the interior of shallow dishes is often frosted over with an opaque, greenish gray; and the Chün glaze is apt to break into irregular V-shaped lines known as earth-worm marks, which the Chinese connoisseurs regard as a sign of genuine Sung make. The Chün ware is strong and heavy, and the finer specimens consist mainly of flowerpots and shallow bowls which could serve as stands for the flowerpots or alternatively as bulb bowls. This class of Chun ware has a wash of brown glaze on the base and a ring of "spur" marks formed by the pointed stilts on which the vessel rested in the kiln. It is moreover usually incised with a series number which ranges from one to ten and apparently in'dicates the size, No. 1 being the largest. An "outsize" is indicated by addition of the character ta which means large.

It is known that the Chün factories continued active through the Sung and Yüan dynasties and as late as the 16th century. In fact it is not established when their activity ended. Consequently there is much difficulty in distinguishing the, Sung and later Chün wares; and the tendency is to call the finer specimens Sung and the coarser Yuan, too little regard being paid to the fact that much of the ware must be as late as Ming. All that can be said for certain is that the heyday of the Chün factories was in the Sung and that their reputation faded after the Yuan dynasty.

There is a peculiarly beautiful group of wares which belong to the Chün class, and, if fineness is a criterion, also to the Sung period. They have the gray porcellanous body of the numbered Chün wares, and an opalescent glaze which is, however, thinner and smoother than the usual Chun glaze. Its colour is lavender gray, but it is richly suffused, or splashed, with a lovely plum purple and this purple sometimes dominates the whole surface. The glaze flows more or less evenly down to the edge of the base rims, and it usually reappears on a small patch on the base. Sometimes the purple splashes on this ware are symmetrically disposed and even deliberately designed to suggest the forms of fishes, birds, animals or fruits, showing clearly that these patches, though doubtless at first accidental, were later brought under control. To what factory does this group belong? Is it merely a variety of the Chun Chou ware or is it something else? One of the descriptions given of the Northern Kuan ware suggests that it may belong to that obscure category; and some collectors distinguish it as Chün ware of Kuan type.

It is evident that many kilns were at work on the Chun type of ware, and probably in other districts besides Chun Chou, but we have little or no information on this point. We do, however, know that the Chun wares had many imitators. Good copies were made at Ching-tê Chên, probably as early as the Ming dynasty, certainly in the Yung Chêng period of the Ch'ing dynasty (1723–35); but there is little difficulty in distinguishing these later copies which have a white porcelain body and sometimes even a reign-mark. Other imitations made elsewhere can also be detected by variations of the body material and peculiarities of the glaze. Such are the Fatshan Chün ware made at the famous stoneware factories at Shekwan near Fatshan, in Kwangtung (*q.v.*), in Ming and later times; and the Yi-hsing Chüns which were made at Yi-hsing near the Great Lake in Kiangsu, the home of the red stoneware tea-pots. The Yi-hsing imitations have a buff or red stoneware body and a thick opalescent glaze of lavender turquoise colour with or without obviously artificial splashes of purple and crimson. While easily distinguished from the real Chün wares, they are often mistaken for another type which remains to be considered. This is the "soft Chün" (also called *ma chün* by Chinese traders), an attractive ware with light buff body and a beautiful, opaque turquoise or lavender blue glaze closely crackled and suffused here and there with purple or crimson splashes. Where it was made and when are by no means certain; but the shapes of the ware suggest in some cases the Sung and in others the Ming period, and the glaze is of the northern type. A degenerate descendant of this soft Chun is still made at Yü Chou which is the modern name of Chun Chou, and probably this was the original home of the ware.

Chien Wares.—Another large and widely distributed group of stoneware is commonly called, for want of a better general term, by the Japanese name *temmoku*. This name was first given to the black tea bowls for which Chien-an and afterwards Chien-yang, in Fukien, were noted in the Sung dynasty and even earlier. They are made of a blackish stoneware with a thick treacly glaze of purplish black shot with brown lines like hare's fur or mottled with brown like the breast feathers of a partridge. Their glaze stops in a thick irregular welt short of the base outside and forms in a deep pool on the bottom inside. The "hare's-fur or partridge" cups were commonly preferred for use in the tea-testing competitions, as their thick structure made the cup cool to handle and their dark glaze showed up the least trace of the green tea dust. In Japan they have always been fashionable in the tea ceremonies. The Chien glaze owes its colour to iron, which under varying conditions produces a reddish brown as well as a black colour. Indeed the brown and black seem to be always struggling for the mastery in the Chien glaze. Sometimes the brown completely dominates the black: sometimes it only emerges in streaks and spots, and sometimes again these spots are crystalline and have a silvery sheen.

The black ferruginous glaze is by no means confined to the Fukien factories. It was, and still is, made in many parts of China, chiefly in the north; and one of the northern wares which has this black and brown glaze over a whitish stoneware body is known to collectors as Honan *temmoku*. The northern black glazes are often of a peculiarly rich and luscious quality, and sometimes they are boldly flecked with lustrous brown and even painted with sketchy designs of flowers and birds in the same brown. On rare specimens the glaze is strewn more or less regularly with silvery crystais, the "oil spots" so greatly prized by the Japanese; while on others it comes out a uniform reddish brown, the *kaki temmoku* of the Japanese. Another ware which is commonly grouped with the *temmoku* is that believed to have been found on the site of the old Sung potteries at Yung-ho Chên near Ch'i-an Fu, in Kiangsi. In this case the body is a buff stoneware and the glaze is a rather thin blackish brown which flows evenly to the base and is often mottled with golden brown in tortoise-shell fashion or streaked and dappled with frothy grey. A further feature is painted ornament—prunus blossoms and sprays, birds, butterflies, inscribed medallions and symmetrical designs—in dull golden brown in the black or dappled glaze.

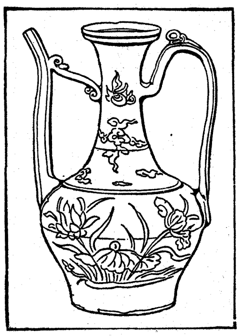
Tz'u Chou.—The last important group of Sung wares takes its name from the great pottery centre Tz'ŭ Chou, once in Honan and now in the south-west corner of Chihli. The Tz'ii Chou ware is a grey or buff-grey stoneware, which is usually coated with white slip and covered with creamy glaze. The plain cream white Tz'ii Chou stoneware has been mentioned among the Ting types, but the ware is more usually decorated with painted or incised designs.

The painted designs, floral or otherwise, are laid on with a bold brush in black or brown slip, sometimes supplemented by an ochreous red under the cream glaze. Painting in enamels—green, yellow and red—over the glaze was also used, occasionally in the Sung period and frequently in later times. The incised, or *graffiato*, Tz'ii Chou ware has many varieties. Simple incised designs are comparatively scarce, the more usual practice being to coat the vessel with white or brown slip which was then scraped away so as to leave the design slightly relieved in white or brown against a buff-grey body. A coating of transparent cream glaze over this produced cream white design on a mouse grey ground, if the slip was uhite. Where brown was used the slip usually contained the glazing material and the design appeared in brown or black glaze against an unglazed ground. Both of these *grafiato* types have great decorative value. The black and brown painted Tz'ŭ Chou is the commonest type and its merits vary with the quality of the drawing.

The Tz'ŭ Chou potteries have a history which can be traced from the 6th century to the present day. and there will always be room for debate as to the age of particular specimens. Further, most of the Tz'ŭ Chou types were made at other potteries scattered over northern China, and doubtless much that we call Tz'ŭ Chou really belongs to other potteries which worked on similar lines. This will explain variations in the body material of wares of the Tz'ŭ Chou type, and why a red body, quite unlike the original buff grey, is found on some of the most beautiful members of the group, such as the vases with black painted and *graffiato* designs under transparent green glaze or with black painted designs under a lovely peacock blue.

The potters who made these choice objects must have been among the foremost of their craft, but, though they used the Tz'ii Chou methods, their wares differ fundamentally from what we know as Tz'ŭ Chou.

Chinese ceramic records name several other Sung potteries in various parts of China, but they are hardly more than names to us and we know little or nothing of their productions. Practically all the Sung wares which we know, however, are comprised in the types already described. The forms, except where they were moulded after those of old bronzes, are simple and elegant, such as come naturally from the hands of a gifted "thrower" on the potter's wheel. The character of the classic Sung wares may be summed up in two words, simplicity and refinement.



FROM THE GEORGE EUMORFOPOULOS COLLECTION
MING EWER (1368-1644); INCISED DECORATION AND TURQUOISE GLAZE

For the purpose of this brief sketch the Yuan dynasty (1279–1368) may be regarded as a continuation of the Sung. The Mongol conquerors had nothing to bring into the stock in trade of the Chinese potter except a taste for certain Western forms and designs acquired in the other extreme of their transcontinental empire. Further we are told that they were hard task-masters and that the ceramic industry, in common with many others, especially the more artistic crafts, lost ground under their unsympathetic rule.

The Ming Dynasty (1368–1644).—In 1368 tbe Yuan was replaced by the native dynasty of the Ming, which ruled China till 1644; and, when the country had recovered from the interdynastic struggles, the ceramic art took a new lease of life, though under somewhat changed conditions. The Sung monochrome wares, the celadons, Chun wares, etc., went out of favour and the old factories sank into obscurity, while the fame and importance of the great porcelain town of Ching-tê Chbn, near the Po-yang lake in Kiangsi, overshadowed all the rest. The first Ming emperors had their capital in Nanking and the proximity of Ching-tê Chên to the seat of government doubtless helped its development. At any rate from this time onwards the fine white porcelain of Ching-tê Chên was in general demand and the imperial factory there was rebuilt and reorganized to keep the court supplied with it; and Chinese ceramic writers thenceforward speak of Ching-tê Chên and little else.

The neighbourhood of Ching-tb Chên had long been noted for its excellent ceramic wares. It was ordered to supply goods to the court as early as the 6th century, and it received its present name in the Ching Tê period of the Sung dynasty (1004–07). All that the industry required in the way of material was lavishly supplied by the neighbouring hills, kaolin (china clay) for the body of the porcelain and *petuntse* (china stone) to mix with it and to form the glaze, wood ashes to soften the glaze, and cobaltiferous ore of manganese to make the blue for the underglaze painting and the blue glazes. The staple product of Ching-tê Chên is the fine white porcelain which has made China a household word throughout the world; and as this ware lent itself peculiarly well to painted decoration, the vogue for painted porcelain rapidly replaced the old Sung taste for monochromes. They fall into three chief groups, namely blue and white, enamelled wares and three-colour glazed wares, all of which are essentially pictorial in their decoration.

Blue **and** White.—The beautiful cobalt blue is one of the few ceramic colours which will stand the high temperature required to melt the porcelain glaze, and which consequently can be used under the glaze. Thus the blue colour, painted on the body of the ware and covered with a transparent sheet of glaze, gives a perfectly protected picture which will last as long as the porcelain itself. The idea of painting porcelain in this fashion was not new in the Ming dynasty. It was known to the Sung potters, but it was only in the Ming dynasty that blue and white became fashionable. Kor is the idea necessarily of Chinese origin, for blue painting was certainly known to the Near-Eastern potters as early as the 9th century, and we have as yet no indication of its use in China at so early a date. In the Ming dynasty, however, the Ching-tê Chên potters made it specially their own, and their blue and white was not only supplied in large quantities to the imperial court but was exported all over the eastern hemisphere.

During certain reigns—Hsiian Tê (1426–35), Chbng Tê (1506–21) and Chia Ching (1522–66)—the native supplies of cobalt blue were supplemented by a superior blue imported from the Near East and known as Mohammedan blue. This imported material was scarce and costly and was at first reserved for the imperial factory, and even so it was usually diluted with the common native cobalt. Later on supplies of it found their way into the hands of the private manufacturers. According to Chinese accounts it varied much in tone, but the kind best known to us is the Mohammedan blue of the Chia Ching period which is a dark violet blue of great strength ard intensity. In general the Ming blue is painted in one of two ways, either in finely pencilled line drawing or in strongly outlined designs filled in with flat washes. The better class of Ming porcelain, made 'for imperial and native use, was potted thin and finely shaped; and this is now rare and only to be acquired from Chinese collections. But there is a commonzr class which was more strongly and roughly fashioned to meet the exigencies of the export trade, and this has been found in considerable quantities in India, the East Indies, Persia, Egypt and even in Europe. But all the Ming blue and white, whether made for home or foreign consumption, is distinguished by a freshness and freedom of design which make the commonest specimen a desirable possession.

TURKISH POTTERY JUG

Another colour used, like the cobalt blue, under the glaze, is a red derived from copper. It was a difficult colour to control but it was used with success in several Ming reigns, notably the Hsüan Te (see page 363) and Ch'êng Hua, both as monochrome and in designs painted in the same way as the blue and white.

Ming Enamelled Wares.—Pictorial designs having become fashionable, means were found to paint them on the glaze as well as under it. The chief advantage in on-glaze painting lies in the wider range of colours available. The over-glaze colours, commonly distinguished as enamels, are made of coloured glass ground to powder and liquefied so as to be usable on a brush. They are "fixed" in a small stove, or muffle, at a low temperature which is sufficient to melt the enamel powder and make it adhere to the glaze without actually melting the latter.

The colours used are leaf green and turquoise green derived from copper, a brownish yellow derived from iron, and aubergine purple derived from manganese, besides which a dry black pigment was obtained from manganese and a thin tomato red (halfway between a pigment and an enamel) from iron. The Ming red is apt to become iridescent and lustrous; both it and the black are used for painting outlines, and the latter was sometimes washed on and covered with transparent green to form a composite black. Gilding was also used. With this palette the Ming potters produced richly coloured porcelain, decorated with pictorial designs and formal brocade patterns. In some cases the enamels were combined with underglaze blue and this colour scheme, though known in the I jth century, was so popular in the Wan Li period (1573–1619) that it has come to be known as the wan *li wu ts'ai* or Wan Li polychrome. Another type, known as the "red and green family," is characterized by the absence of blue and the predominance of red and green, and again there are effective combinations of two colours such as red and yellow, blue and yellow, blue and green, red and green, red and gold and more rarely green and gold.

Besides being painted on the glaze the enamel colours were sometimes painted on the biscuit, *i.e.,* the fired but unglazed porcelain body; but this technique was commoner in the succeeding dynasty and will be discussed later.

"Three-colour" Ming Wares.—There are few kinds of ceramic ware, Chinese or otherwise, that make such a brave show as the Ming three-colour (*san ts'ai*) porcelain. Though nominally combinations of three, the glazes which make up the colour scheme of this group are dark violet blue, turquoise, aubergine purple, yellow and a neutral white; and they are used in washes over designs set in single-colour ground which is usually dark blue or turquoise. To prevent the colours from overrunning each other the designs are outlined by incised lines or by threads of clay, or they are carved in open work. The glazes themselves, though harder than the enamels discussed in the last section, do not require the full heat of the porcelain kiln to melt them, and consequently the ware has to be "biscuited" (subjected to a preliminary firing) and then, when the glazes have been applied, fired again in the cooler parts of the kiln.

They are, in fact, what the French call them, glazes *du demi-grand feu.*

The decoration of the three-colour ware is bold; it includes large floral subjects, lotus and cranes, peonies and peacocks, and a few set figure subjects such as the Eight Immortals paying court to the God of Longevity, Wang Chih watching the game of chess, etc. The details are often built up in slight relief, certain parts such as faces and hands of human figures being left unglazed. The glazes are thick and inclined to be opaque. Much of the three-colour ware dates from the 15th century. In the 16th century the glazes tend to become sleeker, smoother and more transparent, and incised decoration is used.

The three-colour decoration was not confined to porcelain. Excellent specimens of it are seen on both stoneware and earthenware bodies. Indeed some of the most beautiful three-colour vases have a buff stoneware body and bold floral designs in minutely crackled glazes which include a peacock blue of peculiarly attractive tone. Where this group of fine pottery was made is not known; but it is found in widely separated parts of China and may have been made in several factories.

Other **Ming** Wares.—Though monochrome porcelains no longer held the premier position, they were still made in considerable quantity and some of them received special notice from Chinese writers. The sacrificial red (chi hung) of the Hsiian Te and Ch'êng Hua periods, a brilliant underglaze red derived from copper, was most noted; and next came the chi *ch'ing,* an intense blue glaze of the Hsiian Te period; and a lovely blue glaze of slightly mottled texture is found on some of the Chia Ching porcelains. There were, besides, celadon green, lustrous black and brown glazes; and all the demi-grand feu glazes of the three-colour porcelains were used individually as monochromes, the turquoise blue being especially effective.

LAMP FROM THE MOSQUE OF OMAR

Beautiful, too, are the pure **white porcelains (white was the colour required in certain forms** of ritual and also by the court during periods of mourning) ; and special mention is made of the exquisite white "egg-shell" bowls of the reign of Yung Lo (1403–24) and of the white altar cups of the Hsiian Te and Chia Ching periods. If any decoration was added to these white wares it was faintly carved, incised or traced in white slip under the glaze, a subtle form of ornament known as an hua or secret decoration. Another and more conspicuous form of slip decoration is traced in white on blue or green glazes in a manner resembling the modem *pâte sur pâte.* Reliefs in white biscuit and remarkably fine open work distinguish some of the later Ming porcelains, the open work being of such superhuman delicacy that it was called *kuei kung* or devil's work. A quantity of stoneware and earthenware was made all over China in the Ming period. The best known are the tile work and architectural pottery which are often finely modelled: they are usually glazed with green, yellow, aubergine purple, turquoise or blue. On parts of the famous Nanking pagoda, built in the beginning of the 15th century, white porcelain was also employed for the same purpose. Many vases and vessels of everyday use were also made as by-products of the tile works which existed in all large centres of population to supply local needs; but it is hard to distinguish the common pottery of the Ming from that of the earlier and later periods, except where there is a close analogy with some known type of Ming porcelain to help us.

In the early years of the 16th century direct contact was established between Europe and China; and Chinese porcelain, together with silk and tea, soon became an important item of European trade. From this time onwards we note the influence of European taste affecting the Chinese porcelain to a steadily increasing extent.

The **Ch'ing** Dynasty **(1644–1911).**—The Ch'ing dynasty of the Manchus replaced the Ming in 1644; but it was not till about 1680 that its rule was firmly established over a pacified country. A succession of three able and enlightened emperors—R'ang Hsi (1662–1722), Yung Chêng (1723–35) and Ch'ien Lung (1736–95)—gave China a long period of good rule and the ideal conditions for the development of the arts, which indeed enjoyed at this time an unusual amount of imperial patronage. The imperial porcelain factory at Ching-tê Chên was managed by a series of exceptionally capable directors. Ts'ang Ying-hsüan, appointed in 1682, remained in charge till the end of the K'ang Hsi period. Nien Hsi-yao was appointed by the Emperor Yung Chêng and in 1728 he was given as an assistant the celebrated T'ang Ying, who succeeded him in 1736 and held the post with great distinction till 1749. T'ang Ying left behind him several treatises on the manufacture under his control, and in addition to these we have the letters of the Jesuit father d'Entrecolles which were written from Ching-tê Chên in 1712 and 1722, giving us an intimate picture of the life and industry of the great porcelain centre with its 3,000 furnaces.

The period from 1680 to 1749 must be regarded as the most fertile in the annals of Chinese ceramics. The porcelains of this time are distinguished by fine finish and perfect command of material and technique. They do not, however, differ basically from those of the Ming potters, who had little to learn in the essentials of their craft; and on the whole they suffer by comparison with the Ming in the matter of originality and freshness. The Ch'ing wares indeed are often a trifle stale and mechanical. Still they have enjoyed a long period of popularity in Europe, and their relative weakness has only recently become apparent; for we have only recently made acquaintance with the better types of Ming porcelain.

Ch'ing Blue and White.—Old Nanking is a household phrase in Europe for Chinese blue and white. None the less it is a misnomer, for while much of that ware was transhipped from Nanking, none of it was actually made there. Old Nanking is in fact the blue and white porcelain. of Ching-tê Chên and chiefly that made in the K'ang Hsi period and imported into Europe by the Dutch and other East India merchants. It was justly famous, for never was more care expended on the preparation of the ware and the refining of the blue. The best K'ang Hsi blue is pure sapphire, without the tinge of violet or grey so often observable in the Ming blue; and it is usually laid on in graded washes which give it its splendid, vibrating depths. As to the painted designs they are mainly Ming themes, when they are not of the formal arabesque type; but some of them are of outstanding beauty, such as the design of ascending and descending branches of flowering prunus reserved in white in a ground of marbled blue which is netted over with lines suggesting cracked ice.

The prunus blossom falling on the breaking ice is a symbol of returning spring; and this motive is a favourite one for the decoration of the jars in which gifts of fragrant tea and sweetmeats were sent at the new year—a festival which falls in China three to seven weeks later than in our calendar. The vogue of blue and white seems to have died down at the end of the K'ang Hsi period, for after that time the ware in general sank into mediocrity, though exceptions must be made of two types. One is the close imitations of Ming blue and white made in the Yung Chêng period; and the other is the so-called "soft paste" blue and white, a ware prepared with "soapy rock" (hua shih), a kind of pegmatite, and exquisitely painted with the finest brushwork and the purest blue under a soft-looking crackled glaze. Another name given to this porcelain is "steatitic," in the belief that the hua shih was soap-stone or steatite. It was an expensive ware and chiefly used for small objects such as snuff bottles and the furniture of the writing table, in which the Chinese literati take special delight.

Famille **Verte.**—This is the name given to the K'ang Hsi porcelain decorated in transparent enamels. These enamels are in the main the same as those used in the Ming period, but there are a few differences. The iron red is a coral rather than a tomato red, the yellow is clearer than the brownish Ming yellow, there are additional shades of green, and the Ming turquoise green is replaced by a beautiful violet blue enamel.

The enamels are either painted over the glaze or are washed over black-outlined designs painted direct on the unglazed porcelain or biscuit. The latter process was not unknown in the Ming period, but most of the existing specimens, though often miscalled Ming, belong to the Ch'ing dynasty. Some of the finest Ch'ing porcelains are enamelled on the biscuit, such as the sumptuous vases with grounds of green-black (*famille noire*), figures and groups.

Not unlike the porcelain enamelled on the biscuit is that decorated with washes of coloured glazes, chiefly green, yellow and aubergine. This is the Ch'ing version of the Ming three-colour ware; but the Ch'ing glazes are sleek and transparent. Sometimes they are laid on in patches making a motley decoration which is known in the trade as "egg and spinach" glaze.

Ch'ing Monochromes.—The Ch'ing monochromes comprise the Ming types, close imitations of the old Sung glazes and many novelties.

Among the best known is the *lang yao* red, which follows the Ming chi hung but has a character of its own, varying from bright cherry red and deep ox-blood (sung de boeuf) colour to a dappled glaze of crushed strawberry tint. This red is called after a potter family of the name of Lang; and, though imitated in subsequent reigns, it was never so well controlled or so fine in colour as on the K'ang Hsi porcelain. Another success of the K'ang Hsi period was the "peach bloom" glaze, pinkish red in colour but flecked with russet spots and broken by passages of green. Between the peach red and *lang* yao are many shades of maroon and liver colour. Other K'ang Hsi glazes are the mirror-black, the powder-blue and the pale lavender or clair de *lune;* and Chinese writers mention turquoise, eel-skin yellow and snake-skin green as specialties of the period.

We need not dwell on the many other monochromes—whites, celadons, lustrous browns, aubergine purples, violet blues and so forth; but there is a group of composite glazes which requires notice.

They are formed by washes of enamel over a stone-coloured crackled glaze; and they include "apple-green," camellia leaf green, sage green and mustard yellow. Coral red was also used in monochrome, but this and many enamels of the famille rose types belong chiefly to the Ch'ien Lung period, as also do the splashed or *flambé* reds which came at first by accident but which T'ang Ying succeeded in getting under perfect control.

Famille Rose.—In the third decade of the 18th century a revolution took place in the enamelled porcelains. A new palette of colours was introduced, opaque enamels among which rose pinks (derived from gold) are most conspicuous. The Chinese called these new colours *juan* ts'ai (soft colours) or yang ts'ai (foreign colours), and we have adopted for them the French name famille rose. The famille rose displaced the famille verte, and it brought with it a new and more effeminate type of decoration with delicate designs executed with a miniature-like refinement. The colours are seen at their best on the Yung Chêng porcelain with a few sprays of flowers thrown artistically across the white surface. The more elaborate ruby-back dishes and table services with crowded figure-subjects and complicated borders are less satisfactory; but these were painted in the Canton enamelling establishments and were destined for the European trade. At Canton, too, were decorated large quantities of Ching-tê Chên porcelain with coats of arms and other European designs directly ordered by the foreign merchants.

The famille verte enamels, though eclipsed by the *famille* rose, were not entirely suppressed; and they emerged again in a mixed palette of transparent and opaque colours. These mixed enamels were effectively used by a school of painters who worked in the style of one Ku Yüeh-hsüan, a maker and decorator of glass in the early years of Ch'ien Lung's reign. Good specimens are rare, for they are prized by Chinese collectors. Other specialities of the Ch'ien Lung period are "lace-work" porcelain with designs deeply incised and forming semi-transparencies; and "rice-grain" porcelain in which the designs are actually cut out of the side of the vessel though allowed to fill up with glaze. A third type, known as *graviata,* has a covering of opaque *famille rose* enamel which is diapered with incised scroll-work.

The monochromes of the Yung Chêng and Ch'ien Lung periods include those of the K'ang Hsi with numerous additions, some of which have already been mentioned. Great ingenuity was exercised by the Ch'ien Lung potters in the imitation of natural substances in glaze; the effects of tea dust, iron-rust and bronze are cleverly produced, and enamelled metal, shells, birds' eggs, grained wood, jade, ivory, etc., are copied so closely as to deceive the eye But tbese *tours de* force are symptoms of an art which had passed its maturity; and after the 18th century the porcelain has little interest, being mainly of an imitative kind. Exceptions may be made of the Peking medallion bowls, the finer snuff bottles of the Tao Kuang period (1820–50) and some of the imperial porcelains which maintained a high standard of technique. The devastation of Ching-tê Chên during the T'ai-p'ing rebellion in 1853 was a crowning disaster to the ceramic industry of China.

Provincial Porcelains and Pottery.—The bulk of the Ch'ing dynasty porcelains which have reached Europe is of Ching-tê Chên make; but there were many provincial factories which supplied local needs and which also catered for the sea-borne trade to India and the East Indies. These provincial wares are generally of a coarse type; but a shining exception is the white porcelain made at Tê-hua in the province of Fukien. This is the blanc de Chine of the old French catalogues, which was freely exported from Amoy in the 17th and 18th centuries, and which served as a model for most of the early European porcelains. It is a beautiful, translucent ware with a soft-looking, melting glaze of milk or cream white, sometimes warmed with a pinkish tinge; and it was chiefly used for ornamental objects such as vases, libation cups, incense burners, figures and groups, less often for table wares. It is decorated, if at all, with slight, applied reliefs, moulded or incised designs, rarely with painted enamels. The Tê-hua factories are known to have existed in the last half of the Ming dynasty, and they are still active to-day; and as the character of the ware has changed very little, the dating of specimens will always be difficult.

Immense quantities of earthenware and stoneware have been and are still made in every part of China. We know little of the individual potteries, but there are two centres which must be mentioned. Yi-hsing, on the west side of the Great Lake in Kiangsu, has been noted since the 16th century for a fine stoneware, chiefly red but also buff, grey and of other colours formed by clever blending of the local clays. The red tea ware of Yi-hsing came to Europe with China tea as early as the 17th century. It was classed at that time with the American buccaro ware; and it was copied closely by Dutch, English and German potters, notably by Bottger at Dresden and by Dwight and Elers in England. The Yi-hsing tea-pots were cleverly fashioned, often in fanciful shapes, and decorated with reliefs, moulded and incised designs and in some cases with glazes and even enamels.

The second centre lies in the province of Kwangtung, the principal potteries being at Shekwan near Fatshan, a few miles west of Canton. The Shekwan ware is a stoneware verging on porcelain; and the standard type has a thick flocculent glaze of brown mottled with blue and grey and sometimes with vivid red. Glazes of the Sung Chün type and celadon green, as already mentioned, besides *flambé* red were also used; and some of the Shekwan stoneware dates back to the Ming period, though the bulk of it is of comparatively recent date.

The reader is reminded that true Chinese decoration is never meaningless. Its meaning may be directly expressed in semi-religious emblems such as the Eight Buddhist Symbols, the attributes of the Eight Immortals, the Eight Precious Things, etc.; or indirectly by motives which suggest good wishes, such as the peach, crane, tortoise and pine (long life), the bat (happiness), the pomegranate (fertility). Again combinations of flowers, animals, etc., can be read rebus-fashion into auspicious phrases; for the Chinese language abounds in homophones and the Chinese delight in puns. They also delight in themes of religious and historical import; and the understanding of their decorative designs involves a deep study of their religion, history and folk-lore.

Numerous marks and seals are used on Chinese pottery and porcelain; but for these again the reader must consult special books. The most important and the most frequent of the marks are the reign-names (*nien* hao) of the emperors; but there are also potters' names, phrases of good omen, symbols and the names of halls and workshops, which it would be futile to enumerate without giving the actual marks and their readings.

KOREA

The geographical position of Korea makes it a natural link between China and Japan. In close contact with China the Koreans were absorbing Chinese influences from the Han dynasty onwards; and Chinese graves of the Han period excavated in Korea prove by their contents that the Koreans must have been familiar with the arts of their great western neighbour. But in actual fact the early Korean pottery, though doubtless its essentials were learnt rrom the Chinese, developed on lines of its own. It is a hard, slate-grey ware, unglazed except for an accidental smear of glossy brown which probably came from the wood ashes in the kiln, and ornamented with large perforations, rather crude reliefs and simple incised patterns. This is the ruling type found in the tombs of the Silla period, which is generally regarded as extending from the 1st to the 10th century, though the Silla state did not actually become paramount till the 7th century. Naturally the Silla pottery varies considerably in such a great space of time, and some of it is potted thin, fired hard and of a neat and almost ornamental appearance.

The Korai Period **(918–1392).**—But the heyday of Korean ceramics belongs to the succeeding Koryu or Korai period, when the Korean potters suddenly developed a skill which was the admiration of the Chinese themselves. There can be little doubt that this sudden change was wrought either by Chinese refugees or by Koreans who had gone to China to study. For the home of the new industry was in southern Korea, in the Zenra district; and, as Dr. Nakao has pointed out, this district is connected by the most convenient sea route with the coast of Chekiang. the home of the Chinese celadon in the imitation of which the Koreans specialized. The characteristic Korean ware of the Korai period is a porcellanous stoneware with a celadon glaze which at its best resembles blue green ice, but which varies in tone to olive green and brown. A Chinese writer, Hsü Ching, who visited Korea in 1125 compared this ware in one passage with the secret-colour (pi *sê*) ware of Yüeh Chou and the contemporary Ju Chou porcelain, and in another passage with the celadon of Lung-ch'iian. The same writer adds that in form and style it resembled Ting Chou porcelain, a statement of which we quickly realize the truth in comparing the etched, engraved and moulded designs in the Korean bowls with those of the ivory white Ting ware. Incidentally it may be mentioned here that a white porcelain of Ting type and a bluish white porcelain of *ying ch'ing* type have both been found in Korai tombs; but whether they were, all or some, made in Korea itself or imported from China are questions not yet decided. The finest Korai ware is undoubtedly the blue green celadon made in the best period which may be placed between 1050 and 1170; and it is either plain or delicately decorated with etched or carved designs. Sometimes the glaze is more grass green like the typical Lung-ch'iian celadon or olive green like the so-called northern celadon (see above).

Indeed there are specimens which could hardly be distinguished from this latter ware, were it not for the typical Korean finish of the base which is shallow and covered with glaze and almost always scarred with the marks of the spurs or sand on which the piece was supported in the kiln. This rough finish of the base and a tendency to lose shape in the firing are two defects which are apt to mar even the best Korean ware.

It was probably in the last half of the 12th century that a typically Korean method of decorating the celadon ware was first used, namely inlaying the incised designs with black and white clays. Discreetly used this decoration produced a very charming effect; but it was overdone and soon became hackneyed. The easy but mechanical method of stamping the designs instead of drawing them with the stylus was adopted, and a stiff and crowded ornamentation resulted. To this inferior class belongs the so-called "Mishima" ware with its radiating cord patterns which recalled to the Japanese the lines of their Mishima almanac.

Other less usual kinds of decoration on the Korai ware are painting in underglaze red, painting in bold, but often rather crude, designs in brown (rarely in white) in the style of the Chinese Tz'ŭ Chou pottery, and blending variously coloured clays so as to make a marbled body. Black- and brown-glazed wares of the "Honan *temmoku*" class are also found in Korea, but, as with the ivory white and *ying ch'ing* types, their native origin remains to be proved. By the end of the 13th century the Korai pottery had become definitely decadent: the beautiful celadon glaze had turned brown and cement-coloured, and the inlaid and brown-painted wares were coarse and clumsy.

The Korai dynasty was followed by the Yi which lasted from 1392 to 1910. The capital was removed from Song-do to Seoul and the name of the kingdom was changed to Chosen. But the country was impoverished by many calamities and the final blow to its prosperity came with the invasion of the Japanese under Hideyoshi at the end of the 16th century. From this time Korea was virtually closed to the outside world and became a veritable hermit kingdom. We know little of the early Yi pottery except so far as it is reflected in Japanese imitations. From these we would infer that it included a rough kind of red or grey pottery with translucent glaze varying from brown to light grey tinged with pink; coarse *mishima*, and brown-painted wares which the Japanese call *e-gorai* (painted Korean); a creamy buff ware with closely crackled glaze; and grey ware with opaque milk white glaze of thin paint-like appearance which the Japanese call *koma-gai.* For the rest, specimens of the 17th to 19th century wares in our collections comprise porcellanous stoneware with crackled grey or buff glaze, plain or painted with sketchy designs in dull underglaze blue; and white porcelain painted in underglaze blue and red, with occasional relief decoration and open work.

JAPAN

Japan, like every other country, has its primitive pottery, a rough hand-made material sometimes mat-marked like the primitive Chinese. A more advanced type is found in the dolmen burials which date from the 3rd century B.C. to the 7th A.D. The dolmen-builders were invaders from the mainland, doubtless from Korea, and the dolmen pottery closely resembles the Korean wares of the Silla period. The development of the potter's art in Japan was slow—perhaps it was retarded by the preference for other materials, such as lacquer, for the articles of every day use—and it seems at first only to have moved forward under the stimulus of foreign influences. The first foreign influence was Korean. The next was Chinese, and this must have been felt as early as the 8th century, for the treasure of the Emperor Shomu, preserved at Nara, includes a few specimens of motley glazed pottery of T'ang type. In the 13th century Kato Shirazaemon is said to have gone to China to study the work of the Sung potters, and to have set up kilns in Seto on his return. Reputed specimens of his work are tea jars and tea bowls with thick treacly glazes of black, amber brown, chocolate and yellowish grey colour. This type of pottery took a firm hold in Japan and variations of the Seto glazes were subsequently made in many factories throughout the country. A second and more potent wave of Korean influence flooded Japan after Hideyoshi's campaigns in the 16th century, from which he brought back a large number of Korean captives. It happened too that about the same time the famous aesthete Senno Rikiu organized the tea ceremony, which has played ever since an important part in Japanese social life. The masters of the tea ceremony decided that pottery was the most fitting material for the tea vessels; and the Japanese potters soon learnt from the Koreans how to meet the demand satisfactorily. Hence the numerous imitations of Korean Yi dynasty wares to which allusion was made in the last section. Indeed many of the best known Japanese potteries, such as those of Karatsu, Satsuma, Shigaraki, Takatori and Hagi, owe most of their importance, and also very often their origin, to Korean teachers. From the 16th century onward Japanese pottery developed rapidly and many new and original types were invented, of which the *raku* ware is one of the most important

Though the credit for the invention of *raku* ware is given to a Korean family settled in the Kioto district, the ware itself is essentially Japanese. It is a soft, hand-made earthenware, requiring only a slight firing, and covered with a peculiarly waxen, treacly and semi-opaque glaze of various colours of which the black and salmon are the earliest and the yellow, green, cream white and mixed colours later.

Another successful Japanese creation is the antithesis of the *raku* ware. It is a hard reddish brown stoneware unglazed as a rule, except for an accidental smear, and evidently well suited for figure modelling. Its habitat is the province of Bizen, where the industry can be traced back to the 14th century. A fine, hard, buff pottery with closely crackled cream glaze is another Japanese specialty. It is a development of the Korean *koma gai,* or white ware; and it reached its finest expression in Satsuma. Here and at numerous factories in Kyoto it was used as the vehicle for enamelled decoration.

The art of enamelling on porcelain was learnt from China, the story being that Sakaida Kakiemon, an Arita potter, was instructed in it by a Chinese ship's master about the middle of the 17th century. One of the most-celebrated Japanese potters, whose art-name is Ninsei, adapted its use to the cream glazed pottery and developed a special style of enamelling in purely Japanese taste. Ogata Kenzan, another of the great Japanese ceramic artists, at the end of the 17th century found a way of using enamelled decoration on the soft *raku* glazes. From this time onwards Chinese influence was discounted in the pottery which displays much originality and a true national style.

Japanese Porcelain.—Meanwhile the manufacture of porcelain had started in Japan. Needless to say the technique was learnt from the Chinese, a potter named Gorodayu go Shonzui visiting Ching-tê Chên itself to study in the 15th century. Shonzui's difficulty on his return to Japan was to find suitable raw material and he was forced to work with imported Chinese clays. Not till the beginning of the 17th century did the discovery of the important deposits of porcelain stone on Izumi Yama, in the Arita district of Hizen, permit the establishment of the Japanese porcelain industry on a firm basis. The Arita district was the chief centre of the manufacture; and it was here, at the seaport Imari, that the Dutch traders obtained the "Old Imari" porcelain with which they flooded Europe. Here too Kakiemon practised his new-found art of enamelling, in a style which is for ever associated with his name. The Kakiemon enamels were soft orange red, grass green and lilac blue, supplemented by pale primrose yellow, turquoise green, gilding and occasionally by underglaze blue; and his decorations are slight and in the best Japanese taste. A few blossoms, a floral medallion, a flowering prunus tree, a banded hedge with birds, quails and millet, a tiger and bamboos, a dragon and sometimes children are motives of the nicely balanced Kakiemon designs which have been imitated wherever porcelain has been made.

The "Old Imari" of the Dutch importers included another highly specialized but less artistic kind of porcelain. It was painted with masses of heavy impure blue supplemented by red and gold and to a less extent by enamel colours. The designs are irregular and confused, asymmetrical panels enclosed by mixed brocade patterns. Over-loaded, but not without decorative value, they appealed strongly to the Dutch taste.

Many factories were started in the Arita district, those of the princely houses of Hirado and Nabeshima being the most noted; and the industry soon spread to other provinces. It was early established in the Kutani district of the province of Kaga and at a little later period at Seto in Owari, Mino, Kioto and many other places. The Kaga potteries in the 19th century popularized a special kind of decoration in red and gold; but on the whole Japanese painted porcelain follows closely on Chinese lines, and the highest ambition seems to have been to make wares which could be mistaken for Ming porcelain. The Koto factory on the shore of Lake Biwa was noted for its enamelled porcelain in the middle of the 19th century; and good imitations of Chinese celadon were made in the Arita district at an early date and at Sanda and Kioto since the end of the 18th century. In the early 19th century remarkably fine porcelain of "egg-shell" thinness was made at Mikawachi, in Seto, Shiba and Mino.

Since the reopening of Japan to the foreigner in 1868 vast quantities of pottery and porcelain have been made for the Western market. These wares, usually overloaded with ornament, do not represent true Japanese taste, which requires that a piece of pottery be made strictly to serve its useful purpose and decorated soberly in a style appropriate to its form and use.

It is not practicable within the compass of this article to describe the work of individual potters, and the mere mention of famous names, such as Banko, Hozan, Dohachi, Eisen, Rokubei and Zengoro Hozen, cannot serve any useful purpose. The potteries are very numerous, being for the most part small family concerns; and as each had its individual mark or seal and a proper pride in using it, the list of Japanese potter's marks is a formidable one, for which the reader must consult works cited below.

PERSIA AND THE NEAR EAST

The ceramic history of the Near East between late Roman and Islamic times is still obscure. Little Sassanian pottery of any importance has been identified, and the excavations at Constantinople which should tell the Byzantine side of the story have hardly begun. But the continuity of ceramic tradition in these regions is not for a moment in doubt. The most familiar of all the Persian glazes is the blue-green which appears on late Babylonian, Parthian and late Roman wares; while in Egypt there is no real break in the sequence of potters from early dynastic times to the present day, though the chain of evidence is very weak in the period immediately preceding the coming of Islam.

The "Gabri" Types.—What is reputed to be the earliest type of mediaeval Persian pottery has been called "Gabri" because it was believed to have been made by the pre-Islamic, fire-worshipping (Gabri) peoples. It is an earthenware with a reddish body which is usually concealed by a coating of white slip (liquid clay) and covered with a transparent lead glaze. The commonest form of decoration was effected by cutting or scratching a design through the slip coating so as to expose the red ware below; and by varying the naturally yellowish colour of the glaze by washes of green and purplish brown, derived respectively from copper and manganese. This technique is probably of Byzantine derivation, but it has been used since in every civilized country and at all periods. The Gabri ware, though often crude and bucolic, is attractive for its bold designs and warm colouring, and in the best specimens the rendering of animal forms among floral scrolls and of ornamental inscriptions is highly artistic.

In point of date some of it may go back to the early days of Islam (7th century), but the bulk of it may safely be placed between the 10th and 13th centuries. In Egypt the same technique was largely used on the armorial pottery of the 15th century. Gabri ware has been excavated chiefly in northern Persia, at Zendjan, Rhages and Hamadan; and a kindred ware reputed to come from Amul, south of the Caspian, is distinguished by the additional colours, yellow and ochreous red. A rare type reputed also to be of Amul make has painted designs in white on a background of black slip. A red ware with painting in coloured slips, as well as with incised ornament, has been found in some quantity as far east as Samarkand.

Samarra.—A shining exception to the usual haphazard excavation is the work done by Profs. Sarre and Herzfeld in the ruins of Samarra on the Tigris, a site which was occupied for about 50 years in the 9th century. The finds made here are of the utmost historic importance, and they include a variety of interesting pottery types. One is a thin reddish buff earthenware decorated in low relief with formal designs under a green lead glaze and strongly reminiscent of the lead glazed wares of the late Roman period. Another and more characteristic type is a close-grained, buff pottery with an opaque greyish white glaze which is sometimes painted with a dark cobalt blue, sometimes with lustre pigments of golden brown, green or blood red tones. The blue-painted ware is varied at times with patches of green and manganese brown. The same Samarra body is found with monochrome white, green and yellow glazes, and also with glazes splashed and mottled with green and yellow in the style of the Chinese T'ang wares with or without incised designs. Indeed it is clear that the Samarra potters deliberately set themselves to copy Chinese wares, fragments of which in company with white and celadon porcelain have been found on the site. But the most important of the Samarra fragments are those decorated with lustre.

Lustre painting is perhaps the chief contribution of the Near East to ceramic decoration. When and where it was first used are still debated questions, but one fact at any rate is established by the Samarra finds, namely that the process was fully developed in the 9th century. The lustre is applied in the form of a metallic salt (derived from copper or silver) which is painted on the glazed ware and developed at a low temperature in a special kind of kiln. This process deposits a film of metal on the surface of the ware, in colour golden brown, greenish or red, and when the film is thin enough to allow the light to penetrate it, it glows with beautiful rainbow reflections. The blue-painted and the lustred pottery of the Samarra type have been found at Susa certainly, and, according to report, at Rhages also; and examples of the lustred types have all been found in the waste heaps at Fostat in Egypt.

Rakka Ware.—Extensive pottery remains. including a number of kiln wasters, have been dug up at Rakka, in Syria, a place situated on the Euphrates about 100 m. E. of Aleppo. Rakka is a very ancient site and one which had considerable importance between the 8th and the 14th centuries. It includes ruins of several cities, one of which was the residence for a time of the Caliph Harun Al-Rashid. The pottery found at Rakka is of a type which became general in the Near East after the 10th or 11th century. It has a sandy, white or buff white body, loosely constructed and friable, and it is covered with a clear silicious glaze which became opaque when tinted with certain colours. A bowl of Rakka ware figured in Chatfield Pier's book is said to have a dated inscription of the year 831: it is painted in black under a pale blue glaze. Other Rakka wares are decorated with a characteristic brownish lustre; and some of these may date back to the 10th or 11th century. Others again have designs in bold relief which is lustred, or covered with opaque turquoise or translucent bluish green glaze. But the most characteristic type is painted in black under a pale blue glaze or in blue and black under a clear glaze.

Sometimes the glaze is coloured a fine purplish brown with manganese. The blue and black painted ware is common to Syria and Egypt, whence its name Syro-Egyptian, and the bulk of it was made between the 13th and the 15th centuries.

Kiln sites have also been found at Rakka with remains of another kind of ware which appears to belong to the 11th or 12th century. It is white with engraved designs under a clear glaze which is sometimes coloured with dabs of blue. Probably other colours also were used, for specimens of this type reported to come from Rhages have the same features with the addition of green, yellow and manganese purple.

Rhages Ware.—To return to Persia, the ruins of Rhages have long been a happy hunting ground for pottery seekers, and they have produced wares of great variety and of many periods. There is little doubt that Rhages was an important centre of the ceramic industry, though very few waste pieces have been found to indicate the presence of kilns. The city, once the capital of the Djebal, was laid waste by the Mongols in 1220, and, though not completely abandoned till the 17th century, it never recovered from this disaster. The classic period of Persian pottery is from the 12th to the 14th century; and among the fragments found at Rhages are some of the most beautiful Persian wares. They are mostly made of the sandy white material; and the glaze is usually opaque and of a creamy tone, and much of it is finely painted with golden brown lustre with or without touches of blue. Another beautiful type, specially associated with the name of Rhages, is painted in enamel colours heightened by leaf gilding on a cream white or turquoise blue glaze. The Rhages enamels include blue, turquoise, manganese purple, red, green, mixed colours and white, and, with the exception of the blue, they generally have a mat appearance which gives a subdued splendour to the colour scheme. The designs on this Rhages enamelled ware are pencilled with miniature-like fineness recalling to a great extent the beautiful workmanship in the manuscript illuminations of the early 13th century. Indeed it has been thought that the court miniaturists may have assisted at the work In some cases, especially with the more formal designs, parts of the pattern are built up in relief and these incrustations are jewelled with enamels and gilding.

Again the red, white and gold are effectively used in tracing formal designs on a fine dark blue glaze or on an opaque turquoise glaze which frequently covers moulded reliefs. Enamel colours too are sometimes used on the unglazed water jugs of porous buff earthenware, which are found all over the Near East and which are often decorated with artistic relief ornament.

The ruins of Sultanabad, in Kazvin, have also given us much fine pottery of the classic period, wares painted in lustre with or without blue, decorated in strong relief under blue, turquoise or green glazes, and painted in blue and brown under a clear glaze. The most characteristic Sultanabad type is a variety of the last mentioned, with animals, birds or human figures set in a background of close foliage, outlined in black and washed in with blue. The central motives are frequently speckled with black dots, and parts of the ornament are slightly raised.

The beauty of these specimens is further enhanced by the warm grey tone of the glazed ware in the remaining spaces. Chinese influence is frequently observable in the drawing of the figures, and pure Chinese motives such as the dragon and phoenix also appear. These features indicate a date in the second half of the 13th century after the Mongol conquest. Excavations at Khar have produced pottery of the best Rhages types, and it is probable that many other sites could be found equally productive, for there is no doubt that pottery centres were widely distributed throughout Persia and that Rhages and Sultanabad are only two of many.

Persian **Tiles.**—One of the most attractive forms of Persian pottery, the beautiful lustred wall tiles, have been found at Rhages Veramin, Koum, Natinz. Meshed and Kashan, and it is reasonable to suppose that such things were manufactured on the spot. But the wall tiles illustrate almost every phase of Persian ceramic art. Some of the earliest have ornamental inscriptions in strong relief and a coating of monochrome glaze, light blue or green. Next came the splendid lustred tiles, cut into star shapes and decorated with a complete design on each, chiefly consisting of ornamental foliage which sometimes encloses animals, birds and even human figures. An inscribed border usually completes the tile, and many of the inscriptions have the added interest of dates in the 13th and 14th centuries. The designs are sometimes painted direct in the lustre pigment, sometimes reserved in a lustred ground: details are etched with a needle point and parts of the design, especially the borders, are often touched with blue and occasionally with turquoise. It was soon discovered by the craftsmen that a slight relief gives additional play to the lustre, and reliefs were freely used, especially on the larger mihrab tiles. In place of lustre we also find traceries of red, white and gold on dark blue or turquoise glaze as on the Rhages wares. Another characteristic Persian mural decoration is in a mosaic composed of glazed pottery, sawn in intricate patterns and embedded in mortar. There are fine examples of this work on buildings of the 14th century. Later the same general effect was produced by the easier method of painting the design in coloured glazes leaving the outlines dry to represent mortar.

Before leaving the classic period of Persian pottery mention should be made of the fairy-like effects obtained in the sides of bowls and vases by open work designs into which the glaze has been allowed to run, forming transparencies. This beautiful decoration is seen on white wares which may be as old as the 11th century and on the pottery found at Rhages, Sultanabad and Fostat. It reappears at a later date on the so-called Gombroon ware.

Later Persian Wares.—In the post-classical period, from the 15th century onwards, the fashions in Persian pottery underwent considerable change. Few of the older styles survived, and those which did are barely recognizable. The body of the ware is the same sandy white material; but it is more highly vitrified and quite often it is translucent in the thinner parts, a condition only occasionally noticeable in the early wares. It is in fact a kind of soft porcelain. Chinese influence is very strong in the decoration. Celadon greens and other colours are copied as monochromes or painted with traceries of white slip: the painted designs in blue and black, or in blue alone, under a clear glaze, so closely follow the Ming blue and white that they are often mistaken for it. The Persian potters even marked their wares with imitations of Chinese seals. Survivals of the old Persian types include decoration scratched through a black slip under a pale blue glaze, painting in black under a blue glaze, and lustre ware, but in every case the character of the designs has changed. As to the lustre ware it would perhaps be more correct to describe it as a revival, for we have no examples made during the century which preceded the reign of Shah Abbas (1587–1629). On the revived ware the lustre is greenish or reddish brown in colour and its reflections are generally coppery, but sometimes of a beautiful ruby tint. It is applied over a white, or a vivid blue, glaze, rarely over yellow; and the designs are freely drawn trees and plants, among which the cypress occurs frequently, animals and birds and formal patterns, arabesque scrolls, leaf medallions and cable borders. The old device of reserving the design in a ground of lustre does not seem to have been used. Though this ware is generally known as Shah Abbas lustre, the only published specimen with a date was made in the year 1651 (or 1673 according to the reading), and a jug in the British Museum has a metal mount of about 1700. The ware in fact seems to be a 17th century revival but there is no evidence that it continued beyond that period.

The effective use of pierced ornament filled with transparent glaze on the earlier wares has already been noted. After a long interval it reappears on the white translucent ware of the later periods. The incised patterns are of a simple kind and they are supplemented as a rule with a few sprays or arabesques in blue and black. This singularly light and elegant pottery has been called Gombroon ware, because it was believed to have been shipped from the poft of Gombroon; but it was probably made in many places, and the material differs in no respect from the contemporary ware made all over Persia. The few known dated examples are of a rather coarse type and belong to the early years of the 19th century; but the ware was largely made in the 18th and some of it may date back to the 17th century.

The late Persian types are no easier to localize than the earlier. Chardin, who travelled in Persia in the 17th century, tells us that faience in Chinese style was produced all over the country, but that the best came from Shiraz, Meshed, Yezd, Zorende and Kerman. There is an interesting product of Yezd in the British Museum, a kettle-shaped ewer of fine white ware well painted in blue in Chinese style and inscribed "The Work of Mahmûd Mi'mar of Yezd. The decorator of it the poor Zari. 1025" (=A.D. 1616). Hannover describes a pottery decorated in blue, green and a red similar to that used on the Turkish wares (see below), which he believed to be of Kerman make. Kubatcha in the Caucasus is also credited with the manufacture of a ware painted in similar colours or in a greyish blue under a glaze which tends to crackle. A typical specimen of this ware is a dish with a female bust surrounded by floral ornament, while others have rather coarsely painted designs in the style of Chinese blue and white; but all that can be said with certainty is that pottery of this kind has been found in the neighbourhood of Kubatcha. With even less reason a considerable group of post-classical pottery with black designs under a transparent blue glaze, which is inclined to crackle, have been assigned to Kubatcha; but there is little doubt that this type was made in various parts of Persia and certainly at Damascus. Specimens exist with dates around the year 1500.

The later tile work tends to be pictorial, with hawking figures on horseback and the like in slight relief in a ground of landscape and flowers. One of the best examples of the 17th century tile work is in the Victoria and Albert Museum, a large panel made up of many plaques and representing a princess and court ladies in a garden of flowers and cypress trees.

In the middle of the 18th century overglaze enamel painting in the colours of the Chinese *famille* rose came into use on tiles and on ordinary pottery. But the late 18th century and the 19th century Persian wares are in the main coarse versions of older types.

Mention has already been made of the early lustred pottery, the *graffiato* wares, and the blue and black painted wares of Syrian type found in Egypt, and of the continuity of the potters' art there from early dynastic times to the present day. Most of the early Persian and Syrian types were made in Egypt in the neighbourhood of Cairo; and the finds at Fostat are specially rich in lustre wares of all kinds, in pottery painted in black and blue under a clear glaze, and in monochromes which imitate Chinese porcelain.

Turkish and Damascus Wares.—Little is known of the potteries of Asia Minor in the middle ages, but in the 16th century under Ottoman rule they became famous for a pottery which is unsurpassed for its bold designs and powerful colouring. It is directly descended from Persian wares, but it has decided characteristics of its own which reflect the taste and temperament of the Ottoman peoples. It has the standard Near Eastern body of sandy whitish material, but in all the better specimens this body is dressed with a slip of fine white clay. On this the decoration is painted in black outlines which are filled in with brilliant blue, turquoise, green, and either manganese purple or thick red, under a clear glassy glaze. The colours are laid on with a full brush, and the Turkish designs have a distinctive character. They consist chiefly of sprays of certain flowers such as the narcissus, tulip, carnation, rose, fritillary, etc., naturalistically treated, or of arabesques of feathery leaves; and the dishes have borders of spiral clouds.

The transition from the old Persian types to the full-blown Turkish ware is abrupt; but a link may be found in the pottery of Damascus.

Outside this important city, kiln sites have been found with remains of a pottery of the 14th century Syro-Egyptian type, painted in blue and black under a clear glaze; and there is a vase with lustred decoration on a blue glaze, bearing legend "painted by Yussuf of Damascus" which implies a knowledge of the lustre technique among the Damascenes. Pottery painted in black under a blue glaze has been found in some quantity near Damascus and tiles of the same kind of ware adorn buildings in the city. Some of these have delicate Persian scroll-work suggesting a date not later than the 15th century, while other specimens have the large feathery leaf designs which appear on the Turkish wares. Finally Damascus has been credited with the manufacture of the most refined of the wares of Turkish type, distinguished from the rest by soft colours which include a dull lilac in place of the thick Turkish red, a delicate turquoise blue and sage green, and also by a certain Persian flavour in its arabesque ornaments. It must be admitted, however, that the claims of Damascus to a monopoly of this ware are more than doubtful.

The most outstanding feature of the pure Turkish pottery is a brilliant red colour, made with Armenian bole, which is laid on in palpable relief. Its manufacture must have been widely spread over the Turkish dominions, for the ware is found effectively decorating the walls of mosques and public buildings from Adrianople to Cairo. Important centres of the manufacture were at Constantinople, Nicaea, Broussa and possibly in the island of Rhodes, though the old tradition that the ware came exclusively from Rhodes has been proved erroneous. The dating of the Turkish ware is established by the tiles on various buildings of which the history has been preserved, by a few specimens with European metal mounts and by still rarer pieces with dated inscriptions. From these sources we learn that the best period was in the 16th century, and that the quality of the ware had deteriorated by the last part of the 17th century, when the designs had become coarse and hackneyed and the ware itself dirty and yellowish. A beautiful mosque lamp of the finest Turkish ware in "Damascus" style in the British Museum bears the date 1549. A ware of such individuality could not fail to affect the pottery of other regions, and its influence can be traced on the Persian pottery of the 17th century, and particularly on the kind which is called Kubatcha.

Kutahia in Anatolia was till quite recent times a busy ceramic centre. From the 17th century onwards a pottery of Turkish type was made here, but painted with small patterns—palmettes, scrolls and flowers, scale and leaf diapers, etc.—in lively colours including blue, turquoise, green, yellow and the Turkish red. It is a crisp ware, thinly potted and sometimes engraved with criss-cross patterns in the paste. Dated specimens of the years 1719 and 1787 are known. A much more artistic ware painted in shades of blue has also been attributed to Kutahia; but this attribution rests on the reading of an inscription of a ewer in the Godman collection (Cat. Pl. LV., No. 35) which is given as follows: "This mass cruet commemorates the servant of God, Abraham of Kutahia, Anno Armen: 959" (=A.D. 1510). The date is interesting, but if the reading is correct it still leaves open the question whether the ewer was made at Kutahia or elsewhere.

UNITED STATES

It is difficult to write an accurate comprehensive story of pottery and porcelain in the United States. There are several reasons. First, local history is inadequate. In some parts of the country where the potters did not belong to the group considered socially important, it is almost impossible to trace accurately their activities because they were seldom mentioned in newspapers or records. In other sections, the potters were among the leaders so that complete records are available. As a result, it is sometimes incorrectly supposed that certain parts of the country had practically no pioneer potters. The second reason is that until the 20th century, ceramic history centred attention on foreign developments. The third reason is that nowhere is terminology clear-cut, due to the fact that pottery began before there were printed records and has continued to spread and develop in many directions ever since so that each new development has been a gradual merging of one phase of expression into another. Such changes often took place simultaneously even in different parts of the same country. Twentieth century commercial practice added to the confusion of terms. Often manufacturers gave to their ware trade names which erroneously suggested classification within groups popularly considered valuable. Because of looseness in terminology, it was usually impossible to determine unquestionably where one classification ended and another began, or to list characteristics which could remain unchallenged as distinguishing qualities of a given group.

Historically, development of pottery and porcelain in the United States was practically a duplication of the progress of ceramic history of the world except that, due to an accumulated ceramic knowledge and new scientific and industrial processes, ceramic development in the United States took place within about 300 years, while the world development had been going on for many centuries. The history of American pottery and porcelain can be divided into three distinct periods. The first comprised pioneer pottery made by individual potters for utilitarian purposes. By gradual change, ceramics became an important industry supplying quantities of inexpensive ware made by mass production methods, and about the middle of the 19th century the decoration and making of pottery and porcelain began as an art,

Pioneer Pottery.—Pioneer pottery resulted from the use of natural local materials made simply and directly into articles needed in the everyday life of the group wherein the potter lived. As a result, the ware had a ruggedness, directness and simplicity which are usually lost as soon as civilization reaches the point where needs are less demanding.

Potteries were operated by three and four generations of the same family. The principles and problems of the potter's life were similar to those of a carpenter or blacksmith—only materials and equipment were different. Often the potter mas part farmer or tradesman. Usually, the red firing clay was baked at a comparatively low temperature so that the ware was porous and easily broken. Glazes were lead or a mixture of lead, flint and clay. Workshops were fitted with a wheel and a kiln. Near by was a clay pit with a paddle turned by a mule or horse for mixing. In most cases, ware was thrown on the wheel but occasionally it was pressed into or over moulds of fired clay or wood. Often pieces were decorated with quaint designs, mottoes or patriotic inscriptions. The drawing was childlike, the craftsmanship varied.

Decoration was done in various ways. In one method, slip (liquid clay) of a different colour was painted on by means of a brush or slip cup. This was called "slip painting." Sometimes a piece was partially or completely covered by slip and later, when the piece was "leather-hard," the design was scratched through the slip. This method was known as "sgraffito." At other times a design was cut or scratched into the clay without the coating of slip. Such objects as churns, crocks, pitchers, plates and toys were made. The colours mere terra-cotta, white, dark brown and yellow, with touches of green and blue. Often the ware was distributed by boat, especially throughout the Ohio and Mississippi valleys as far south as New Orleans. At other times it was sold in local stores or peddled from door to door. Some pieces are valuable historically because important events were recorded and dated. Examples of this ware can be found both in museums and in private collections. One of the best displays is in the Pennsylvania museum in Philadelphia.

The term "pioneer" potter refers more to a point of view or a stage of development than to chronology During the colonization period, pottery enterprises spread. In each case, the simplest use of local clays made into utensils was the most logical beginning.

By the early 17th century, many pioneer potteries were established, though the exact date and location of the first potter is not known. In 1641, John Pride was working in Salem, Massachusetts. There are indications that potteries were in Jamestown, Virginia, at the time of Captain John Smith and it is known that as early as 1650 several potteries had been established in Virginia. It appears that in 1684, a pottery was functioning in Burlington, New Jersey. Dr. Daniel Coxe of London, once governor of New Jersey, caused the pottery to be built. In eastern Pennsylvania, Germans settled as early as 1735, then spread southward and westward. Beginning about 1750, over 11j potteries were recorded in eastern Pennsylvania alone, making colourful slip-painted and sgraffito ware according to the German tradition. All were small. The Bell pottery of Waynesboro boasted six wheels. It was considered large. Peter Craven, the first of the Jugtown potters in North Carolina, is said to have come from Staffordshire, England, about 1750. From that time to the present date Jugtown potters have supplied the needs of that community. The ware is shaped on the wheel and glazed with simple glazes. The first pottery known west of the Alleghenies was built at Morgantown, West Virginia, by Foulke, about 1784, and continued until 1890 William McFarland went from Kentucky to Losantiville, later called Cincinnati, and many others followed to various parts of Ohio, Indiana, Illinois, Minnesota, Missouri and farther west. The Moravians were established in North Carolina about 1840. They were the same race and religion as the German settlers of Pennsylvania. Their ware was similar. One potter was named Brother Aust. He must have been successful because the authorities of the colonies complained that people came from a radius of 50 to 60mi. to buy. He was ordered to discontinue sales to outsiders "on account of the crowd it draws."

Refinement of Ware.—As communities became more estabfished and there were time and money for more than bare essentials, pottery began to leave the pioneer stage. This took place as a gradual natural growth, affected tremendously by the development of the machine age and greater use of available scientific knowledge. These changes brought about increased refinement of clays, more expert workmanship, higher fire--effecting harder bodies and glazes—mould production, improved machinery and new decorative processes. Thus, generally speaking, one may say that pottery began with pioneer ware—soft, crude and red—and progressed by successive steps through Rockingham ware to a gray stoneware often glazed with salt, and on to white china and porcelain.

During the early part of the 18th century potteries sprang up in many places and great development followed. Two families, headed by John Remmey and William and Peter Crolius, established themselves at "Pot Baker's Hill" or "Potters' Hill," New York city, in 1745. The two families worked and lived as neighbours for several generations. Both families included members influential in public life. Connecticut, the birthplace of the beanpot, led in quantity production of poftery and earthenware from 1771 to 1850. In 1793, Captain John Norton, who had learned his trade in Litchfield, Connecticut, founded a pottery in Bennington, Vermont. It functioned over a century. The ware of this period was glazed in several ways; one was by throwing salt into the fire so it would volatilize and coat the piece with sodium silicate, thus making what is known as "salt glaze ware." In a second method, a stoneware clay was coated with Albany slip, a low-burning red clay. By firing the coated piece to a high temperature, the slip melted into a beautiful brown glaze.

Beginning of White Ware.—Next came interest in a whiter ware. During the last part of the 17th century and throughout the 18th, England, France and Germany were striving to produce ware equal to porcelains from China. In the Bodleian Library at Oxford an old record indicates that "white Chiney Ware" was made at the pottery established by Dr. Daniel Coxe near Burlington, New Jersey. It may have been the first white ware made in the United States. In 1745, William Cookworthy (*q.v.*), an important potter of England, wrote referring to a "china earth" discovered in Virginia. He said, "I have lately with me the person who hath discovered the china earth. He had samples of the china ware of their making with him, which were, I think, equal to the Asiatic. 'Twas found in the back of Virginia. He has gone for a cargo of it, having bought the whole country from the Indians." Some authorities believe the samples referred to were made in the United States; others think they were made in England from clay imported into England from the United States. In a patent taken out in 1774 by Edward Heylyn and Thomas Frye of the Bow Pottery in England for the making of "china ware" it was stated that the material was "an earth, the product of the Chirokee nation in America, called by the natives 'Unaker'." Samples found at the Wedgewood factory and tested by William Burton proved that "Unaker" was a china clay.

During the 18th century, after Philadelphia had become the social capital of the United States, there was a demand for better ceramic wares to supply the needs of a well-to-do class. With this background, more refined ware began to succeed. In 1765, Josiah Wedgewood was worried because potteries were being established in the American colonies. Referring to the colonial market, he wrote, "We cannot make anything too rich and costly."

For about 100 years, potters tried to make chinaware before they were able to record commercial success. During that time, numerous fortunes were lost. Many of these efforts took place in or near Philadelphia. Alexander Trotter was mentioned in 1808 as a leading manufacturer of Queensware (earthenware). Another Philadelphia potter was Abraham Miller, member of a family of potters, an expert modeller, member of the State senate, and a leading member of the Franklin Institute. In 1824, he exhibited a silver lustre pitcher and a specimen of porcelain. In 1842, he showed decorated plates, vases and ornamental flower pots. By the time he died in 1858, excellent American porcelain was being made, equal in quality to the best produced in England. Around 1850, American potters began to succeed in producing a vitrified earthenware and parian—a hard, unglazed white ware, which required fewer skilled workmen and presented no problems with glaze and colour. Later, a modified parian appeared as a very thinly cast glazed ware. It was called Belleek. Although small amounts of high grade white ware had been made, it was not until about 1825 that porcelain was manufactured in any quantity. About 1820, William E. Tucker, a member of a Quaker family of educators in Philadelphia, undertook to decorate imported white ware by the overglazed process. Soon he became interested in making his own ware for decorating. The beginnings were crude, but several medals were earned. In 182 j, he succeeded in making hard-paste porcelain. Eventually, there were financial struggles and changes in partnerships until, in 1832, Joseph Hemphill joined the firm, bringing financial backing and a great capacity for business. Soon Tucker died and Hemphill imported capable workmen from Europe. As a result, the firm experienced a period of producing excellent ware of expert workmanship and a better quality of design.

Moulds for Quantity **Production.**—In 1859, the demand for cheaper domestic ware had grown sufficiently to enable potters to establish themselves on a sounder financial basis. Mould making was being carried on as a trade by men who made and sold moulds, though exclusive rights were not yet practised. Small potteries often purchased their moulds from a mould maker or a defunct potter. Probably no one person contributed as much practical information toward this change in production as William Bloor. In Trenton, New Jersey, from 1854 to 1859, he was associated with James Taylor and Henry Speeler who established the first pottery factory in Trenton in 1852. In 1856, a medal was awarded the firm by the Franklin Institute of Philadelphia. In 1859, he went to East Liverpool from whence he had come in 1854. There, in 1860, he manufactured on a commercial scale the first white ware to be made in East Liverpool, Ohio, now one of the great pottery centres of the world. The ware was translucent and well vitrified. Most of it was made in moulds and skilfully decorated with designs painted by expert workmen. This success had a great influence on the production of moderately priced white ware. In 1865 he returned to Trenton, which at that time was America's pottery centre and helped establish the firm which later became the Eutreria pottery where a high quality Belleek china and fine ivory porcelain were made.

In 1870, he went back to East Liverpool where he supplied the potteries with materials from mines he had discovered and owned in New England, Maryland and Missouri. Later, he helped establish the Dresden pottery of which firm he was a member when he died in 1877. In the *Journal of the American Ceramic Society* it is stated of Bloor: "Giving information freely to competitors in Trenton and East Liverpool, the transition from yellow ware to white ware was quickly made under Bloor's tutelage. Americans were ready and able to purchase white ware made on Bloor's formulas and by Bloor's methods. Thus the white dinnerware industry of Trenton and East Liverpool was started by Mr. Bloor."

One pioneer in the manufacture of pottery in Trenton, New Jersey, told how he had travelled over the States of New York, Pennsylvania, Delaware and Ohio, searching for the best place to manufacture pottery. He had chosen Trenton because it was between the two great markets—New York and Philadelphia—and because the section was healthy, abounding with fine clay and convenient for the collection of other materials by canal or river.

Referring to development during a few years following 1861, he wrote: "If the business increases at the same ratio, Trenton is destined to be the Staffordshire of America and in 50 years hence but little ware will need to be imported." In 1890, Mrs. Benjamin Harrison wished to buy domestic tableware for the White House but could find nothing suitable. It was not until 1918 that Lenox, Incorporated, Trenton, New Jersey, supplied the White House with the first American-made table service.

Imported Workmen. — Far-sighted manufacturers often brought skilled workmen from France, England and Germany to improve the quality of their ware. About 1835, Joseph Hemphill of Philadelphia imported experts from Sevres who produced pieces more or less copies of Sevres ware. In 1843, Julius Norton, the third generation of potters at Bennington, Vermont, brought over John Harrison, modeller from Copeland; he brought many of the latest moulds and designs being used in England. About the middle of the 19th century, Charles Cartlidge and Company of Green Point, New York, brought Josiah Jones from the Staffordshire pottery in England. He was a designer, modeller and ceramist. Soon after his arrival he imported Elijah Tatler, a decorator of great ability. In 1853, the firm sent ware to the International exhibit in New York. It included tea and dinner sets in bone china, as well as earthenware and statuettes, modelled by Jones. There are good specimens of these in the Metropolitan museum and the Pennsylvania museum.

Handicaps. — From the beginning, unfamiliarity with new materials was a definite handicap to the potter. One who had been a master workman in the old country might find himself bankrupt in the new country before he became accustomed to materials. Since there was little scientific ceramic knowledge he had to discover correct materials and proportions by the trial and error method before his funds were depleted. While the problems of new materials were being overcome, and better ware was being developed, a more sophisticated social life was evolving so that the potter had to deal with a public prejudice against American-made ware. Sometimes the cause of the prejudice was due to the fact that American-made ware was more crude, but often people considered it elegant to use imported ware. The European manufacturers encouraged that feeling. At times there was sabotage among the American workmen, sympathetic with the mother country. At other times the markets were temporarily flooded with ware to be sold at a price the local manufacturer could not meet, so that the potter had to go out of business or move to a section where there was less competition.

Toward the end of the 19th century, there were other handicaps. Both in Europe and the United States, emphasis had been placed upon improved techniques for mass production at the expense of sound design. As a result, many pieces were created primarily as demonstration of technical skill with little thought of good design. Eventually there was a reaction, especially in Europe where simpler and better design began to replace the extravagantly ornate. The designers in the United States still clung to the type of design traditional with the designers, who were usually old countrymen. Conservatism and prejudice against ware made in the United States lasted well into the 20th century.

Ceramics Becomes Scientific. — Up to the end of the 19th century, ceramic information had been guarded and handed on from generation to generation. New discoveries were kept secret and experimentation was carried on by rule of thumb. While working on the minerals from 1884 to 1894, Edward Orton, Jr., discovered a dearth of literature concerning the science of ceramics. Being a public spirited. practical man, he succeeded in getting sufficient support for a law authorizing the establishment of a ceramic department at Ohio State university in Columbus in 1894. It was the first school in the United States for the scientific study of ceramic engineering. Not long after that the New York State College of Ceramics was established at Alfred, New York, with Charles F. Binns as its director. Dr. Binns had had life-long acquaintance with ceramics since his father was a factory superintendent in England and he himself was for some time superintendent in the Royal Porcelain Works at Worcester, England. Soon other States had established similar departments. At these schools scientific methods were developed for compounding efficient bodies and glazes and for solving problems encountered by the potters. The ceramists turned more and more to the fields of chemistry, physics, geology, mineralogy, microscopy and other sciences to discover what those fields might contribute.

Under the leadership of Edward Orton, Jr., the American Ceramic Society was founded in 1898 to co-ordinate ceramic interests and further progress. Its work was carried on by meetings, by collecting, publishing, and distributing available ceramic information and by encouraging research. Thus ceramic knowledge became accumulative so that early in the 20th century a person successfully completing a four-year ceramic course had the opportunity of a better understanding of the science of ceramics than a master under the old system could have had after working a lifetime.

As trained ceramists were gradually absorbed into the potteries, they greatly influenced production — making better-wearing bodies and glazes and developing cheaper factory methods. However, because emphasis was put on science and technique, at the expense of good design in form, colour and decoration, the country was soon producing ware which was of the best technically but the designs were often copies of European patterns or a conglomeration of patterns produced under a variety of conditions. As a result, the ever-developing taste of the American public continued to be prejudiced in favour of imported ware, but this time for a different reason. It was no longer the quality of the ware or workmanship which was responsible for the prejudice but instead lack of beauty and distinction and the absence of that intangible quality which comes from the hand of a skilled creator but is lost by one who copies — regardless of how accurately the work is done.

Pottery and Porcelain as an **Art.**—About the middle of the 19th century, European women were interested in doing over-glaze decorating. The idea spread to America where it became fashionable for women to go to Europe to study the subject. In 1879. the Cincinnati Pottery Club was formed by a group of women for the purpose of encouraging sound pottery production. They did under- and over-glaze decoration and made porcelain. Much credit is due this pioneer work. In 1891 the National Ceramic Association was founded. Ten thousand women were actively engaged in the United States working at ceramics. Five thousand earned a living doing over-glaze painting. The association was organized in Chicago where there were 1,000 pottery decorators. The object was to advance the art and secure the finest possible exhibition for the World's Fair. In 1892 Mrs. S. S. Frackelton of Milwaukee, Wisconsin, organized the "National League of Mineral Painters." Its aim was to bring into closer relationship the over-glaze painters in order to define lines of study and to aid in the development of a national school of ceramic art. At one time the membership became as high as 500 women. They exhibited in many places and took part in international expositions, often winning recognition for exceptional achievement. Later, Mrs. Frackelton did excellent work with salt glaze in an effort to use a humble material as a medium for artistic expression. She received honours at home and abroad. Many of the decorators became interested in creating the forms they were to decorate. Some of those creating the forms continued to expand until a business or profession was established. As a result of the activity of the Cincinnati Pottery Club, the Rookwood pottery developed. The Pewabic pottery was established by Mrs. Stratton in Detroit. Mr. and Mrs. A. Robineau in Syracuse, New York, turned to porcelain, carved decoration, crystalline and other glazes. Also, they were in charge of a ceramic department at the University of Syracuse. Charles F. Binns in his work at the New York State College of Ceramics lent valuable support to the expression of ceramics as an art. Besides helping to organize the science of ceramics, he made excellent stone ware of the quality of the Chinese. He knew factory methods and mas an expert craftsman who often explored the historical background of ceramics. Because of his broad interests and high standards, he was an inspiring teacher in the field of ceramic art. Many excellent ceramic artists were trained by him and valuable research was done under his direction.

It was only natural that the increased interest in the art expression of ceramics should result in new scientific developments among the artists and improved design for individual and manufactured ware. To study and further these ends, a section of the American Ceramic Society was organized which was known as the Art Division of the American Ceramic Society. Work of the division is carried on through regular meetings, exhibitions and research reports and other articles published in the *Journal of the American Ceramic Society*. The most important regular exhibition is organized annually at the Syracuse Museum of Fine Art as a Robineau Memorial Ceramic Exhibition. It was started in 1932 by Ann Wetherill Olmstead, director of the museum. Because of Miss Olmstead's work, American potters were invited to send an exhibition to museums in the Scandinavian countries, to England. and to many important museums and galleries of the United States. As a result of various efforts the quality and appearance of work done by studio potters improved greatly during the first half of the 20th century and the design of ware for reproduction methods is given increasing attention.

After about 150 years of technical, financial and artistic struggle, it is encouraging to find that in 1940, the best of the United States pottery and porcelain is as good in quality and design as any made. Ceramic artists in many parts of the country work as designers, studio potters and teachers; the number increases steadily and standards constantly improve as the general public learns to understand the beauty of fine ceramics.

Many States have tax-supported ceramic schools. Art schools advocating better designs for industrial use encourage the ceramic department to study mass production possibilities and methods along with the craft of the potter. Pottery work is taken more and more seriously in public schools. The national, State and local governments are sponsoring the making of pottery as an art expression. A U.S. ceramic experiment station is in the Tennessee Valley.

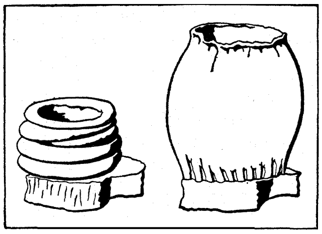
POTTERY, PRIMITIVE. Receptacles of some kind are essential to man, however primitive, and are made of basketry, skins, gourds and other suitable natural objects. But over all these pottery has an advantage. for it can be brought into contact with fire and not be destroyed, and it is therefore valuable for cooking purposes.

Pottery-making is not universal, however; partly because its construction is not easily carried on under certain cultural conditions, *e.g.,* a nomadic life; partly because it depends upon suitable materials being available, though sometimes potters obtain their clay from other districts. It is absent from large regions of America, and in certain islands of the west Pacific has become a lost art. The knowledge of pottery-making was, at one time, believed to mark a stage in the cultural development of mankind, but its presence among such peoples as the Andamanese, Eskimo, Bushmen and Hottentots: and its absence among the advanced Polynesians, make this questionable.

The manufacture of pottery falls into five stages: preparing the *body* or raw material; shaping the pot; drying and firing it; decorating it; and varnishing or in some other way rendering it non-porous. This last is often lacking in the pot-making of primitive peoples, but the other four processes are found in the manufacture of the simplest wares.

As regards the raw material, it seems that the clay is frequently dug and seasoned for a while before using. Clays vary very greatly. Those which are highly plastic and hold the water, though convenient for working. are liable through excessive shrinkage to crack in the drying or firing of the pot and must therefore be ***opened*** by mixing them with non-plastic materials. Sand is often used to this end, or carbonaceous materials such as chopped grass, cinders, dried cow or donkey dung; frequently old potsherds are ground up for this purpose. In mixing the *body,* the proportion of clap, *opener* and water necessarily varies greatly and is judged empirically by the potter.

Shaping. — The body having been prepared, the next stage is the shaping. There are three main ways of doing this: by hand, with the aid of a few simple implements; by moulding; and by throwing on the potter's wheel. Of these, the first is by far the most common. There are two hand techniques — modelled and coiled. The simplest way in which a pot is modelled is that used by the women of the Baronga in South Africa. Having kneaded the body into a very soft ball, the woman "makes a hole in it, which she enlarges by degrees, hollowing it out and gradually giving it the shape she wishes. . . . It is astonishing to see the beautiful symmetry of these utensils." (H. Junod, *The Life of a South African Tribe.)* If the pot is to be a big one, the initial lump of clay may not be enough and more is added to build up the walls of the vessel. Frequently the pot is modelled in parts, which are then welded together.



FROM DALE & SMITH, "THE ILA SPEAKING PEOPLE OF NORTHERN RHODESIA" (MACMILLAN)

FIG. 1.—STAGES IN PRIMITIVE POTTERY PRODUCTION

Left, rings of clay piled up. Right, walls completed by scraping the clay upwards

In the coiling technique, the raw material is rolled out into a slender rope which is coiled upon itself (fig. 1).

The coils are carefully worked together with the fingers and the unevennesses smoothed away, so that, when the pot is finished, no trace of them is visible except occasionally in faint ridges on the inner surface. The modelled and coiled techniques may be combined; the base of the pot is modelled from a lump and the coils built up on this.

Certain tribes used baskets for moulds. These were subsequently burned in the firing. A similar method is used by shaping the belly of the pot over a ring of vegetable fibre, then adding the neck and base. In these examples a mould is destroyed with every pot made. More advanced is the method by which one mould is made to serve several times. Among the Hausas of Nigeria, a pot is inverted and over this a sheet of clay is spread so as to form a bell-like dome. This is then removed from the mould and the shoulders and neck modelled by hand (fig. 2). A moulded pot may be made in two or more sections, then joined.

Shaping a pot by means of throwing on the wheel is little known among primitive peoples, because primitive potters can make by hand pots which rival those thrown and because it takes years to learn to throw expertly.

Drying and Firing.—When a pot is finally shaped, it is necessary to render the clay hard by firing it. The material of which a vessel is composed contains a certain amount of free water which can be removed by leaving it to dry or be sun-baked for a time; but it also contains a quantity of combined water which is only liberated at a temperature of from 350°–400° C. If only sun-baked, the vessel when filled with water would absorb this and after a short while collapse into a shapeless mass. But when the combined water has been liberated the clay is completely decomposed; it is impossible for it to become malleable again and it will hold water safely. Except, therefore, for certain pots which are destined only to contain grain and other dry goods, all vessels must be fired.

After being shaped the pot is set aside to dry for some hours, usually where there is a free current of air. Except in a few cases, ware is fired but once. Usually the firing is done in the open. The pyre is carefully built and the pots stacked so that the heat may circulate freely. A genuine kiln has only been recorded from the region of the Lower Congo. It seems to be a beehive shaped structure. The more common primitive practice is to bake the ware in a hole in the ground. The "oven" is fairly elaborate, for charcoal is used and openings are therefore cut through the soil to the chamber that bellows may be employed to sustain the

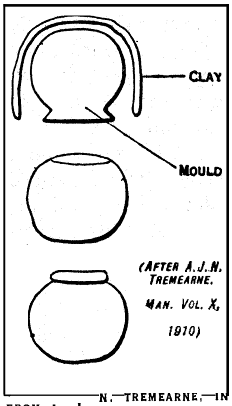
7. Set of service ware in "Manhattan" shape by Viktor Schreckengost, American Limoges China company

necessary heat. The time taken for firing varies greatly, from about half-an-hour to two days. Pots which have been fired for only a short time are less durable than others. There is great diversity of shapes and an amazing similarity in wares widely separated from each other in time and space. Some elaborate forms have a utilitarian purpose, others a religious significance, while others appear to be the outcome of the artist's desire to create something beautiful. In many cases, the pots are modelled in imitation of natural or manufactured objects, which before the introduction of ceramics served the people as vessels.



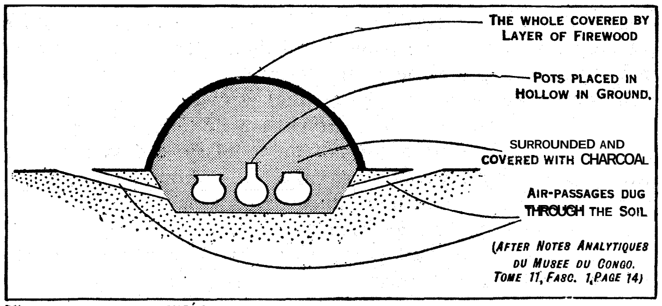
FROM A. J. N. TREMEARNE, IN "MAN"

FIG. 2.— POTTERY-MAKING

1. Clay spread over inverted pot, 2. Clay removed from mould and shaped, 3. New pot with roll of clay for mouth modelling

Decoration and **Colour.**—In most primitive pottery decoration is done by means of incised lines, made with a pointed stick, thumbnail or coil of rope. Sometimes wooden stamps are used or the "beater" with the aid of which the pot is modelled is carved or wrapped about with string and the designs may be but the marks thus left on the surface. Where pots are moulded over baskets, the clay will be decorated by the impress of these. The most usual designs are bands of chevrons or other rectilinear skeuomorphs, though animal and plant, and occasionally human motifs, do occur. To increase the effect,the incisions are often filled with powdered lime or some other substance which shows up against the dark background of the vessel. Less common are ornaments applied to the surface such as knobs, scrolls and figurines. Raised designs are also produced by pressing out the wall of the pot from within. Another method, of restricted distribution, is that of scraping away the surface so as to leave the figures in relief.

The colour of a vessel is to a great extent dependent upon the composition of the body and the method of firing. Of materials present in bodies, iron is usually the only colouring element. This, on being subjected to heat under oxidizing conditions, is changed into a red iron oxide and gives a shade varying from yellow to an orange or red; under reducing conditions producing a colour which ranges from light bluish gray to a deep, sometimes metallic, black. Usually among primitive peoples no effort is



BY COURTESY OF THE MUSÉE DU CONGO

FIG. 3.— DIAGRAM SHOWING PROCESS OF BAKING POTTERY

made to produce certain shades by regulating the conditions of the firing. A dark colour is often the result of a pot's being smoked; this may be an unintentional incident of the firing. but among the Ashanti it is brought about by setting the vessel, while still red-hot from the furnace, on a heap of dry tinder. This it ignites. Water is then poured on and the pile is left smoking. The smoke permeates the heated clay and deposits on and sometimes through it a mixture of finely divided tar and carbon, rendering it non-porous. Decoration by means of slip is occasionally found, but true painted pottery is extremely rare among primitive peoples.

Varnishing. — Fired pots are nearly always porous. They are therefore frequently varnished and this varnish is often decorative as well as useful. Many different methods are employed to treat the suriace with a resin, gum, fat or gelatinous substance. Similar in artistic effect to varnishing but without so great utilitarian value is the practice of polishing or burnishing the ware, but this is only possible where the clay is of a fine body. Though vessels are the most common pottery products of primitive peoples, other things are sometimes made, such as tobacco pipes, drums, toys and figurines.

Sociological and Religious Aspect. — Little attention has as yet been paid by ethnologists to the religious and sociological aspects of pot-making. Generally the craft is confined to one sex, usually the iemale, except where the potter's wheel is used, which is always operated by men. In so far as domestic utensils are naturally matters which concern women it is not strange that they should be the potters, but this does not explain why, in many cases, men are definitely prohibited from potting nor why their very presence during the manufacture is inimical to it. Thus among the Sema Nagas of Assam a man may not even speak to a woman thus engaged nor approach her work. The making of ceramics is often the prerogative of certain families or a certain district and any infringement of this may easily cause trouble. Even where this is not so, certain villages become famous for their wares. Theories oi origins are necessarily speculative, but in evolving them it must not be iorgotten that clay shaped and burnt does not produce a pot. The body must be properly prepared, the vessel properly dried and fired under suitable conditions. The accidental discovery of pottery, thereiore, is not so easy as has sometimes been implied.

POTTHAST, AUGUST (1824–1898), German historian, was born at Hoxter on Aug. 13, 1824, and was educated at Paderborn, Münster and Berlin. He assisted G. H. Pertz, the editor of the *Monumenta Germaniae historica*, and edited the *Regesta pontificum romanorum, 1198–1304* (1874–75). From 1874 to 1894 he was librarian of the German Reichstag. Potthast piled the monumental and indispensable *Bibliotheca historica medii aevi* (1862; new enlarged ed., 1896), a guide to the sources of European history in the middle ages. The work, in the form of an index, gives particulars of practically all the historical writers of Europe and their work between 375 and 1500. Potthast died on Feb. 13, 1898.

POTTO, the name of the West African slow lemurs, *Perodicticus* and *Arctocebus,* popularly miscalled sloths. The aborted condition of the index finger is their most distinctive feature. The ordinary potto (*P. potto*) is about the size of a squirrel, with large staring eyes and a stump of a tail; its colour is rufous brown. It occurs from Ghana to the mountains of Kenya. The awantibo (*Arctocebus calabarensis*), nearly allied, of Old Calabar, has no tail. See PRIMATES.

POTTSTOWN, a borough of Montgomery county, Pa., U.S., on the Schuylkill river, about 38 mi. N.W. of Philadelphia, is the trading centre for a prosperous farm, dairy and industrial region. Hill school, a college preparatory school for boys, is located there. The borough has a council-manager form of government, in effect since 1945. Steel fabricators and the manufacture of tires, tubes and related products, are the largest industries. Other manufactures include universal joints and axles, pipe fittings, gray iron castings, boilers, dresses and shirts, dairy and bakery products, paper boxes, and clay and concrete pipes.

In the immediate area of Pottstown iron was manufactured by 1717. The first cold-blast iron furnace in America was erected by Thomas Potts and Thomas Rutter in 1720, and the Coventry forge produced the first commercial steel in Pennsylvania in 1732. The prosperity of Pottstown was based mainly on the production of iron and steel until about 1918, when fabrication replaced the reduction of ores.

John Potts, ironmaster and merchant, laid out the town in 1752 under the name of Pottsgrove. Arthur St. Clair was a resident of Pottsgrove when he was elected president of the Continental congress. In 1815 the town was incorporated as the borough of Pottstown. For comparative population figures see table in PENNSYLVANIA: *Population.* (L. A. GR.)

POTTSVILLE, a city of Pennsylvania. U.S., on the Schuylkill river, 93 mi. N.W. of Philadelphia; the seat of Schuylkill county. It is a picturesque town at the gap of the Schuylkill river through Sharp mountain and has many narrow and extremely steep streets. The shopping centre is extensive and attractive, serving a retail-trade area with a population of more than 100,000. Pottsville is located on the southern edge of the Pennsylvania anthracite coal region, and after the opening of the Schuylkill canal in 1824 the prosperity of the city was closely related to anthracite prosperity. The steady decline of the anthracite industry in the mid-20th century brought problems of chronic unemployment and of loss in population. (For comparative population figures *see* table in PENNSYLVANIA: *Population.*) The Greater Pottsville Industrial Development corporation experienced some success in bringing new industries to the area. Besides extensive mining industries and railroad shops, manufactures produce aluminum extrusions, plastics. dresses and shirts. an assortment of steel products, shoes, beer, concrete products and paper boxes.

Permanent settlers came to the site of Pottsville about 1795 and soon established a furnace for the production of raw iron. John Potts acquired and expanded the local iron furnace and set the stage for an important iron and steel industry that lasted until the 1920s. He laid out the town of Pottsville in 1816. It was incorporated as a borough in 1828, became the county seat in 1851 and was chartered as a third-class city in 1911. In the 1860s and 1870s Pottsville was a rallying point of the Molly Maguires (*q.v.*). (L. A. GR.)

POUGHKEEPSIE, a city of New York, U.S , on the east bank of the Hudson river, midway between New York city and Albany, the seat of Dutchess county, a rich dairy-farming area The city is the shopping centre of the mid-Hudson valley and contains many diversified industries. Among the largest are an electronic business machines company, a dairy machinery company and a printing and lithographing company. Other manufactures include clothing. cigars, chemicals, cough drops and ball-bearings. Among the nationalities represented in the city are Italians, Poles, Irish, Germans and Dutch.

Vassar, a private college of liberal arts for women (founded 1861), has a cosmopolitan student body and a distinguished faculty. Its founder, Matthew Vassar, conceived the idea "to build and endow a college for young women which shall be to them what Yale and Harvard are to young men." The college was incorporated as Vassar Female college, but under the influence of the intrepid feminist Sarah J. Hale, editor of *Godey's Ladies Book,* "Female" was deleted in 1867. From 1925 Vassar has conducted a Summer Institute of Family and Community Living for parents and their children, social workers and teachers. Also in Poughkeepsie is the Dutchess Community college, a junior college affiliated with State University of New York, opened in 1958. Extensive medical facilities are offered at Vassar and St. Francis hospitals and at the Hudson River State hospital for mental illness.

The Hudson river near Poughkeepsie for many years was the scene of the annual Poughkeepsie regatta of the Intercollegiate Rowing association, one of the most famous rowing events in the world Established in 1895, it was held annually until 1949 except for 1898 when it was at Saratoga lake and for 1917–19, 1933 and 1942–46, when no competition was held. In 1950 the regatta was moved from Poughkeepsie to Marietta, O., and later to Onondaga lake. Syracuse. N Y. (*see* ROWING)

The name Poughkeepsie was derived from Indian words meaning "the reed-covered lodge by the little water place." The town was settled by the Dutch in 1687 and served as the capital of New York state temporarily in 1778. A thriving river port in the early 19th century, from which ships carried grain to New York, it suffered a decline after the completion of the Erie canal and turned to industry and commerce. Poughkeepsie was incorporated as a city in 1854 and in 1952 adopted the council-manager form of government. For comparative population figures *see* table in NEW YORK: *Population.* (E. M. A.; X.)

POULENC, FRANCIS (1899–), French composer, was born in Paris on Jan. 7, 1899. His first important work, the *Rapsodie Nègre,* played in Paris in 1917, excited much interest as the work of so young a composer. It was followed by *Le bestzaire* and *Cocardes* (1919) and *Quatre poèmes de Max Jacob* (1921) for solo voice and chamber orchestra. In 1920–21 he wrote the comic opera. *Le gendarme incompris,* for one violin, one violoncello, one double-bass, one clarinet, one trombone and triangle. His works include a ballet, *Les Biches* (1924); a cantata, *Figure humaine* (1943); and the comic opera, *Les Mamelles de Tirésias* (1944).

POULTRY AND GAME PREPARATION. The term poultry includes fowls, ducks (domestic), turkeys, guinea fowl and geese; the word game is usually applied to wild duck. partridges, grouse, pheasants, quails, deer (venison) and other edible wild birds and beasts. Rabbits, hare and pigeons are usually classed with game.

Poultry and game may be cooked in a variety of ways: roasted; boiled; grilled; stewed in various forms; boned and made into galantines; baked in pies, puddings, *vol-au-vents,* pasties, etc.; combined with cereals, jellies and special sauces, or pounded and used for spreading on pastry or bread and butter. *See* also MEAT COOKERY; PASTRY. HOME MADE.

Preparation of Game and Poultry. — Poultry and feathered game should be plucked and then singed to remove any stray hairs or feathers. It is easier to pluck poultry when warm. The neck is cut off at the shoulder, leaving the skin. There are two ways to draw poultry. The English loosen the skin around the vent with the point of a knife, lay the bird on a board, back uppermost, make a small incision in the skin of the neck lengthwise, insert the fingers through the opening and draw out the entrails. being careful to avoid breaking the gall. Americans cut a slit from the vent of about two inches and draw out the entrails from there. The gizzard, from which the inner bag has been removed. heart and liver are saved for giblet gravy or used in the stuffing. The bird is then washed thoroughly inside and out with cold water. Chop off the ends of the claws and fold back the pinions in the form of a triangle; turn the bird over and bend back the legs toward the neck. Either pin in place nith a skewer (if a small bird) or use a trussing needle and stitch through the bird under the knee bones, at the same time securing the flap and pinions. Birds which need larding should then be covered with bacon fat.

Roasting. — Birds which require stuffing should be filled with a suitable forcemeat (chopped meat, spiced and seasoned) which ought, if possible, to include the pounded liver of the bird. Turkeys and large fowls (capons) are frequently stuffed with veal and ham forcemeat flavoured with lemon peel and nutmeg or with chestnuts; geese and ducks with sage and onions chopped finely and mixed with other forcemeat ingredients, and ducks are occasionally stuffed with prunes and apples. Roast wild duck, widgeon, teal and most small game birds are generally served without stuffing,though pheasants may be stuffed with chestnuts. To keep game birds moist while cooking, a small piece of butter or rump steak is often placed inside the bird. Small birds should be protected with a buttered paper or larding. To roast very small birds, *e.g.,* larks, place them on a skewer.

The best way to roast a haunch of venison is to wrap it in buttered paper and seal this over with a flour and water paste. Ordinary dripping is used for basting poultry and venison, but butter is preferable for basting game birds. About 10–20 minutes before poultry and game have finished cooking remove buttered paper or larding and dredge with flour.

A good gravy with roast poultry or game is essential. Stuffed birds need a thickened gravy. Bread, cranberry, mushroom or chestnut sauce may be served with turkey, and sausage or bacon is a common addition. Roast fowl, pheasant, partridge and grouse are all usually accompanied by rashers of bacon and bread sauce. Water cress is used as a garnish. Fried bread crumbs are served with partridge, pheasant and grouse. Red currant jelly should always accompany roast venison and hare. Apple sauce is substituted for bread sauce in serving roast goose.

Poultry is boned and stuffed to form a galantine. Remove the head and feet; then draw the bird. Divide the skin down the back with a sharp knife and turn down the flesh from the ribs, breast and side bones, leaving these as bare as possible. Pull legs and wings carefully out at the sockets, cutting the sinews through with a knife, and turn these inside out with the rest of the outside skin. Free the skeleton and turn the skin outward again. Stuff the bird to restore its original shape.

Other Methods of Cooking. — All poultry may be boiled in the same way as butcher's meat, *i.e.,* in a well-flavoured stock (*see* FOOD PREPARATION) and served with different sauces; *e.g.*, boiled chicken and egg sauce. Generally, game is not boiled. Both game and poultry are used for making entrées and these may take the form of elaborate stews (brown stews flavoured with special condiments. such as mushrooms, truffles. orange peel, vegetables, etc.); salmi of game; timbales (molds of cold poultry and game); creams (purées with cream and egg liaison); fricassees; *blanquettes;* spatchcock of game (split bird grilled and served with melted butter to moisten); jellies (cold game and poultry purées formed into shapes and masked with aspic or white sauce, or both mixed togetherj; minced game and poultry formed into *rissoles* or croquettes and dipped in batter, rolled in pastry or dipped in egg and bread crumbs and fried in deep fat.

In the making of soups, game and poultry are also used as foundations, and any game or poultry may be used for making raised pies, ordinary pies, pasties and vol-au-vents. Where sufficient giblets are available these may also be used for pie making. To prepare giblets. first scald them and remove any outer skins, such as tough skin adhering to gizzards, etc., take out crop and remove gall. Cut into convenient pieces and partially stew before adding to the pie.

Rabbits and Hares.—For roasting, rabbits and hares are first cleaned and then filled with stuffing; after which they are se n up. Extend the forelegs straight along the sides and skewer through the body. Bring the hind legs forward and bend back the head onto the shoulders and fix into place by passing a skewer through the mouth into the body. For stewing, brown the meat in the same way as for meat. Rabbits may also be curried. For jugged hare! skin and clean the hare. joint it and remove the liver; place in an earthenware pot and add a bunch of sweet herbs, onion stuck with cloves. blade of mace, piece of lemon rind, celery seed or stalk of fresh celery. carrot and a few button mushrooms. Cover with stock. Cook slowly until the flesh is tender. Strain off the gravy and thicken with flour. pounded liver and some of the blood of the hare. Stir in one tablespoon of red currant jelly, one tablespoon of Worcester sauce and a dessertspoon of mushroom catchup. A wineglass of port wine is frequently added to this dish. Serve with fried or poached forcemeat balls and red currant jelly.

POULTRY AND POULTRY FARMING. In practically all countries poultry farming for the purpose of producing meat and eggs for table use is carried on to some extent. In fact, few other agricultural enterprises are so widespread, and in the United States: Canada, England, Ireland, Denmark! Australia, China and some other countries, the poultry industry is one of the leading branches of agriculture. Within each country the egg and chicken business is by far the most important branch of the poultry industry.

In the United States turkey production is a relatively important enterprise although in most countries it is carried on to a limited extent only. The raising of ducks for eggs is an industry of moderate importance in England, the Netherlands and Belgium and for meat production primarily in the United States. Geese are raised exclusively for meat, goose production being of limited importance in practically all countries except Germany and in one or two other European countries. The raising of guinea fowl for meat production is of relatively little importance in any country.

In all countries most flock owners of chickens are primarily interested in egg production because more income is obtained from egg production than from chicken-meat production. In certain sections of some countries, especially France, England and the United States, however, producers receive practically all of their poultry receipts from market poultry.

Domestic breeds of chickens are descended from the jungle fowl (*q.v.*) of India. The numerous modern breeds of chickens known throughout the world may be conveniently classified into the following five classes, on the basis of their origin: English, Asiatic, American. Mediterranean and Continental European. The breeds belonging to the Mediterranean class are for the most part somewhat smaller in body size and more active than the breeds belonging to the other classes. Also, Mediterranean breeds lay white-shelled eggs, become broody, that is. inclined to try to incubate their eggs, relatively seldom, and have white ear lobes whereas most of the breeds belonging to other classes lay brown-shelled eggs. are likely to become broody, and have red ear lobes. The Mediterranean breeds are not as well suited for meat production as most of the other breeds. The Asiatic and some of the Continental European breeds have feathered shanks whereas other breeds have nonfeathered shanks.

Principal Breeds and Varieties.—Although there are more than 100 breeds and varieties of chickens, the number kept primarily for meat or egg production or both is very limited. several breeds and numerous varieties having been developed because of some unique structural character, such as an odd shape of comb or the presence of a crest on the top of the head, or because of the beauty of the plumage pattern. All birds belonging to the same breed have the same shape. Varieties within a breed differ with respect to colour of plumage. There are numerous Bantam breeds, kept by some poultrymen as novelties. Only the more popular breeds and varieties of outstanding economic importance can be discussed here.

Australorp.—This breed originated in Australia and was developed primarily as an egg producer, although its medium size makes it a good meat bird. The comb is single, the skin white and the plumage black. It is kept to some extent in the United States but is more popular in Australia.

Cornish.—A breed of poultry developed in England and imported into the U.S. in 1887. It gained considerable popularity partly because of its excellent meat properties and its yellow skin. It has close feathering and a compact. heavily meated body, the breast being very deep and broad. The Cornish lays a brown-shelled egg and is a broody fowl. It has a pea comb. In spite of its excellent meat properties. the Cornish has never demonstrated that it is a very great layer. There are three varieties. the dark, the white and the white-laced red. White Cornish males are frequently mated nith White Plymouth Rock and other females for the production of broiler chicks They will carry some of the good meat characteristics of the Cornish and increased vigour resulting from the crossing.

Dorktng—The Dorking is an English breed. Dorkings have long, broad. deep and low-set bodies and five toes, most other breeds having four toes. The Silver Gray Dorking has a single comb and white skin, is an excellent meat bird and is used to a considerable extent in England for crossing with some of the game breeds.

Leghorn.—Of the 12 different varieties of Leghorns, only the Single-Comb W'hite is kept extensively in any country. The Leghorns belong to the Mediterranean class. White Leghorns have been bred to a high level of egg production in England, Canada, Australia and the United States and for years have occupied a very prominent place on commercial poultry plants devoted to market egg production. Its white-shelled egg and yellow skin enhance its popularity, although Leghorns do not make as good table birds as most of the larger sized breeds. For market egg production, exclusively. and for economy of production the Single-Comb White Leghorn is pre-eminent.

New Hampshire.—The New Hampshire is an American breed, with single comb and yellow skin, and used in the United States and Canada as an egg and meat producer. In both sexes the plumage over most of the body is chestnut red, and there is some black in wing and tail feathers; in the male the hackle and saddle feathers are reddish bay.

Orpington.—This is a single-combed English breed of which there are four varieties: Buff. Black, White and Blue. The Buff and White varieties have enjoyed more popularity in England than the other varieties. The Orpington is an egg producer of moderate ability as compared with the Leghorn and the more popular American breeds. The white skin is largely responsible for the raising of the Buff variety in the middlewestern section of the United States, where a dressed carcass with a light-coloured finish is sometimes desired.

Plymouth Rock.—Among seven different varieties of this American breed. only the Barred and the White varieties have assumed a place of economic importance. The comb is single and the skin is yellow. In the Barred variety the black and white bars should be of equal width in males, and the white bars should be one-half as wide as the black bars in females. The Plymouth Rock is a bird of good size, with good fleshing properties, and when properly bred lays well.

White Plymouth Rocks have become popular for broiler production because of the white plumage. The females are frequently mated with Delaware or White Cornish males for the production of crossbred broilers with white or nearly white plumage. Crossing stimulates growth rate and increases vigour.

Rhode Island Red.—The Rhode Island Red is another American breed, the Single-Comb variety being much more popular in England, Canada and the United States than the Rose-Comb variety. The skin is yellow. The plumage should be rich dark red over all parts of the body, there being black in the tail and parts of the wing feathers. The Single-Comb Rhode Island Red has been bred extensively for egg production and in the United States especially, some strains lay as well as some of the best strains of Single-Comb White Leghorns.

Sussex.—This English breed contains the Light, Speckled and Red varieties, the Light variety being by far the most popular in England although but few of any Sussex varieties are kept in other countries. The comb is single and the skin is white. In plumage colouration the Light Sussex is similar to the Light Brahma. Sussex fowl have long been noted for the excellence of their flesh and are kept extensively in England for the production of roasters. After about 1925, English poultry breeders made considerable improvement in the laying qualities of the Light Sussex.

Wyandotte.—Among several varieties of this American breed, the White Wyandotte is the only variety bred extensively in England, the United States or other countries. Wyandottes have rose combs and yellow skins. Like several other American varieties, they are a good general-purpose fowl, suitable for both meat and egg production. In England, egg production has been developed to a higher level among White Wyandottes than in other countries. In the United States White Wyandotte has largely been supplanted in popularity by the other previously mentioned American varieties.

Other Breeds and Varieties.--Of hundreds of other breeds and varieties of chickens kept in various countries, only a few can be mentioned. The Ancona is a Mediterranean breed with mottled plumage. The Dark Cornish is of English origin and has a very broad, compact body, ideal as a roaster type but a poor layer; it is sometimes used for crossing with other breeds. The Faverolle is a French breed with feathered shanks; in England the Salmon Faverolle is crossed extensively with the Light Sussex for roaster production. Old English and Modern Game breeds make excellent roasters but are poor layers and are kept largely by fanciers. The Jersey White Giant is the largest of the American breeds, developed primarily as a meat breed and is not noted for egg production. The Light Brahma has always been the most popular representative of the Asiatic breeds but is kept to a limited extent only. The Black Minorca is the largest of the Mediterranean breeds but has never been kept to any great extent in any country. The Black Sumatra is a native of Sumatra and is a fancier's breed exclusively.

Breeding for Meat and Egg Production.—Success in raising chickens for meat and egg production is largely a matter of good stock plus good management. Good stock can be secured only from carefully selected, well bred parents that are properly mated.

Meat Production Standards.—For profitable meat production, chickens must grow at a rapid rate and make good gains in body weight for the feed they consume. Usually the fewer pounds of feed consumed per pound of gain in body weight, the greater the profit in meat production. The characteristics which birds raised for meat production should possess include: (1) good health and vigour; (2) fast wing feathering at hatching time and fast tail feathering at ten days of age; (3) well feathered over the back by eight weeks of age; (4) rapid growth to marketing time; (5) well-proportioned body, with good length and width and fair depth in proportion to shank length, body depth being uniform from front to rear; (6) good fleshing on breast and thighs. The selection of breeding stock on the basis of these six characteristics implies that the poultry breeder must carry on a definite selection program from hatching time to the time of mating.

Commercial poultrymen interested in poultry meat production exclusively frequently resort to crossbreeding with beneficial results, since crossbreeding tends to stimulate growth during the first 10 or 12 weeks, and mortality is usually less than among purebred chickens. However, the actual results secured from crossbreeding depend largely on the breeding quality of the parental breeds crossed. In England, and to a lesser extent in some other English-speaking countries, new breeds have been developed by crossbreeding for the purpose of enabling the sexes to be separated at hatching time according to differences in the colour of the down. This makes it possible for meat producers to purchase male chicks only and market egg producers to purchase female chicks only.

Egg Production Standards.—In addition to the six characteristics for meat production given previously, a pullet, or young hen, to lay well, should possess the following four outstanding characteristics: (7) early sexual maturity; White Leghorns should commence to lay at about 150 days of age and Light Sussex, New Hampshires, Plymouth Rocks, Rhode Island Reds and other general-purpose birds at about 170 days of age; (8) pullets of all varieties should lay at a rate of at least 50% production, or a minimum of 15 eggs per month; (9) there should be little or no broodiness; White Leghorns usually do not exhibit much broodiness, but general-purpose varieties must be bred for nonbroodiness or there will be numerous interruptions in laying; (10) pullets of all varieties should continue to lay for a period of approximately ten months from the time they start to lay.

In order to develop a strain of birds noted for a high level of egg production, the poultry breeder must adopt a rigid program of selecting his breeding stock from year to year. The program of selections should be based on minimum standards for early sexual maturity, rate of laying, nonbroodiness and persistence of production. Selecting birds with good pedigrees for future breeding purposes is an additional help in developing a good laying strain. The best help of all in selecting females for breeding purposes is to select them from among the families of full sisters that are outstanding in laying performance. Males for future breeding purposes should also be selected from the outstanding families but too close inbreeding should be avoided.

Additional Standards of a Good Strain.—In addition to the ten desirable characteristics previously mentioned, a good strain of chickens should also possess the following essential characteristics: (11) good egg size, eggs attaining approximately standard weight (2 oz. each) within about 60 days from the time a pullet commences laying; (12) eggs of good interior quality; (13) hatchability of at least 75% of all eggs incubated; (14) low mortality among growing chickens and laying stock; the strain should possess the ability to resist disease to a marked degree; (15) long productive life.

Renewing the Flock.—Whether chickens are raised for meat production or pullets are kept for egg production, the entire flock or part of it has to be renewed every year. Commercial producers of broilers and fryers renew their flocks several times a year, depending upon the number of lots produced annually. Market egg producers should plan each year to replace about two-thirds of the layers with a fresh lot of pullets because birds usually lay about 20% fewer eggs in their second than in their first laying year.

In practically all English-speaking countries it is possible for the great majority of poultry producers to secure from hatcheries the chicks necessary to renew their flocks. Hatching chicks in incubators rather than under broody hens makes it possible to secure larger numbers earlier in the season, which is a distinct advantage. The egg capacity of incubators used by a commercial hatchery operator may run up to several thousand eggs, these incubators being heated for the most part by gas, coal, oil or electricity.

Hatchery operators may be divided roughly into two groups: (1) those who produce their hatching eggs with their own breeding flocks; and (2) those who secure their hatching eggs from flocks owned by others. The hatchery operator who produces his own hatching eggs naturally has complete control over his flock and is thus in a position to do a great deal toward improving the quality of chicks hatched for customers. The most progressive hatchery operators who secure their hatching eggs from various flock owners adopt a system of close supervision concerning the management of the flocks and see to it that the females are carefully selected and are mated to males with as good breeding as possible.

Since many of the chickens raised in different countries each year are secured as chicks from hatcheries, it is quite apparent that they occupy a very important place in the poultry industry. The quality of chicks produced by hatcheries determines very largely the results secured by those who purchase the chicks for meat or egg production.

Rearing Chickens.—If a few chickens only are to be raised, they may be brooded with hens, but if a few hundred or more are to be raised, they should be brooded artificially. Moreover, brooding chicks artificially makes it possible to raise a larger number at one time than with natural brooding so that a larger number of pullets of the same age may be placed in the laying house in the fall of the year.

There are several different types of brooders for artificial brooding, varying according to size, design and the kind of fuel used to supply heat. Brooders differ in size from those accommodating about 50 chicks to those accommodating several thousand chicks.

Most makes of brooders are portable and can be moved from place to place. Many of the portable brooders are equipped with canopies or hovers for conserving the heat to a limited area near its source. There are colony brooders for lots of about 60 to a few hundred chickens, continuous brooders for brooding chickens by the thousands, and battery brooders for brooding in strict confinement. The kind of fuel used to supply heat in colony brooders may be kerosene, coal, wood, oil, gas or electricity. Continuous brooders are heated by burning coal, gas or oil. Battery brooders are usually heated electrically.

When only a few chickens are to be raised, some kind of lamp brooder is often justified, because the initial expense is relatively low. On the other hand, if a few hundred or more chickens are to be raised, one of the other types of brooders would undoubtedly be justified.

Most poultrymen use electric, oil-burning or coal-burning portable brooders. Best results are usually secured when not more than 250 chickens are brooded together.

For the first few days, the temperature under the hover of the brooder should be about 95° F. at about two inches above the floor. The temperature should be lowered about 5° each week depending upon the time of the year and the outside temperature. The temperature of the brooder house should be about 70° F. The most critical period in brooding is the first two weeks; thus the most careful attention should be given the brooder during this time. Drafts in the brooder house should be avoided and the litter should be kept dry to prevent the spread of disease. When the chickens are well feathered, they require little heat. Plenty of waterers and hopper feed space should be provided, larger sized waterers and dry mash hoppers being provided as the chickens grow.

A 10 ft. × 12 ft. or a 12 ft. × 12 ft. colony brooder house is large enough for brooding 250 chickens up to about eight weeks, when the sexes should be separated. The pullets may be moved to range shelters to be reared on range, and the cockerels may be kept until they attain broiler, fryer or roaster stage.

Feeding Chickens.—Chicks should be given a finely ground starting mash feed containing 20% to 22% protein as soon as possible after hatching and placing in the brooder house. When the chicks are about eight weeks old the protein may be reduced to about 16% by changing the composition of the mash or by feeding some whole grain with the starting mash. A hundred chicks will eat 10 to 20 pounds of feed the first week and 10 to 20 additional pounds each week during the next eight or nine weeks, depending on the breed of chicks being raised, the energy content of the ration and the rate of growth desired.

Chicks deprived of sufficient sunshine or vitamin D will develop rickets, characterized by poor growth, ruffled feathers, a wobbly gait, sitting down much of the time, crooked breast bone and bones of low ash content. An improper balance of calcium and phosphorus in the ration and a deficiency of manganese may result in perosis—enlarged hock joints and crooked legs. A deficiency of riboflavin will result in a curled toe paralysis and a deficiency of pantothenic acid in chick dermatitis.

Chickens are generally changed from the growing ration to a laying ration when 16 to 20 weeks old. This may be a 16% protein all mash ration; a 20% protein mash to be fed with a limited amount of grain; or a mash concentrate (24% to 32% protein) fed free choice with grain. The mash feed is kept before layers at all times. The grain is usually a mixture of two or more of the following; corn, wheat. oats and sorghum grains. Oyster shell or limestone grit should be kept available at all times. A hundred laying hens will eat about 17 to 30 lb. of feed daily, depending on size of birds, rate of production and weather conditions. A hundred layers of small egg type birds in the same rate of lay as 100 heavy meat type chickens will eat 4 to 5 lb. less feed daily.

The ration fed will influence the number of eggs laid and their quality and hatchability. A deficiency of vitamin D or calcium will result in thin egg shells. The consumption of grass will result in darker yolks and succulent feed in thinner whites. A deficiency of riboflavin, vitamin B_{12} and vitamin D will result in eggs of poor hatchability.

A few chickens may be maintained largely on table scraps, milk, corn, grass and bugs and worms from range. Larger numbers of chickens and those kept in confinement will need to be fed a complete ration. It is usually advisable to start chicks on a commercial chick starter. Later a commercial concentrate may be purchased for feeding with home grown grains. It is difficult for the poultryman to buy, accurately weigh and properly mix the small amounts of vitamins, trace minerals, antibiotics, amino acids, coccidiostats and other drugs used in modern mash feeds. *(See* also FEEDS, ANIMAL.)

Housing the Laying Stock.—The purpose of housing is to give the layers protection and keep them comfortable so that they will be efficient egg producers. In extremely hot weather the layers are very likely to suffer considerably if they cannot secure relief in a cool house. The chicken has no sweat glands to assist in keeping the body cool. In extremely cold weather, chickens not only suffer from the cold in a poorly built house but use too much of the energy contained in their feed to conserve body heat instead of producing eggs. The primary objective in housing laying stock, therefore, is to protect the birds against excessively high and low temperatures and especially against sudden changes in temperature. In addition, the proper housing of the layers makes it possible to manage them more efficiently. The size of the house needed varies according to the size of the flock. For flocks of 15, 25 and 50 birds, houses should have about 70, 100 and 180 sq.ft. floor space, respectively. A flock of 125 birds should have about 400 sq.ft. floor space. A flock of several hundred birds may be housed in a pen.

It costs less, on the average, to build a square house than a long narrow one, which is likely to be drafty. Houses for small flocks should be at least 10 ft. deep, and houses for large flocks should be 30 to 40 ft. deep. Large flocks may be kept in houses that are two, three or four stories high. A multistoried house reduces the labour required to manage a large flock, as compared with a single-storied house. A multistoried house simplifies ventilating problems to some extent and makes it possible to maintain more uniform temperatures in summer and winter.

A concrete floor is more durable and much more sanitary than a board floor. Insulating the walls and roof. especially the latter, helps greatly to keep the house cool in summer and warm in winter. The proper ventilation of the house is necessary in order to remove excessive moisture and provide fresh air but, at the same time, drafts should be avoided. Sunlight in the laying house is desirable not only because it brightens up the house but also because it tends to keep the house dry and is a good germicide, being effective in destroying disease organisms.

Moreover, sunlight is a good source of vitamin D. A good absorbent litter helps to keep the floor dry. How frequently the litter should be removed depends largely on the number of birds in the house, weather conditions and the extent to which the house is properly ventilated.

Diseases and Parasites of Poultry. — Chickens and other species of poultry are subject to both external and internal parasite infestation. Lice, the most troublesome external parasites, may be controlled by dusting with sodium fluoride or DDT or by a liquid fumigant, nicotine sulfate or lindane sprayed on the perches. The red or roost mites live in cracks and crevices on the perches and in the nests. They may be destroyed by spraying the nests and perches with Carbolineum or oil.

The chief internal parasites affecting poultry are various species of round worms and flat segmented tapeworms. Birds become infested by picking up the embryonated worm eggs from infected soil and litter. Resistance to worm infestation increases with age. The best preventives are feeding a well-balanced ration and keeping the chicks away from infected range, soil and mature birds during the first few weeks after hatching.

Protozoa *(Eimeria)* cause an intestinal disease in growing chickens — coccidiosis — characterized by bloody droppings. The trouble may be prevented by feeding a coccidiostat at a low level in the starting and growing mash. In case of an outbreak of the disease, it may be corrected by feeding one of the sulfa drugs at the recommended level or placing it in the drinking water

There are a few molds that may cause a diseased condition in poultry. Apergillosis affects the lungs and air sacs; thrush the mouth and gullet; and favus the face. comb and skin of the bird. The latter may be spread to man through skin abrasions.

The principal bacterial diseases affecting poultry are pullorum disease, fowl typhoid, cholera and tuberculosis. Pullorum disease may be transmitted to chicks through the egg. A blood agglutination test is used to detect carriers of pullorum in the breeding flock. Incubator fumigation may be used to prevent the spread in the machines. The disease causes high mortality during the first two weeks after hatching and is characterized by a diarrhea or spots in the lungs. In case of an outbreak, it may be checked by feeding a sulfa drug or a nitrofuran in the mash or incorporating the drug in the drinking water. Fowl typhoid and cholera cause disease among older birds. The troubles may be checked by the same drugs used to check an outbreak of pullorum. Fowl tuberculosis affects birds more than a year old. The birds become thin and die. Hard gritty lesions may be found on the liver, spleen and intestines. Fowl tuberculosis may spread to swine and possibly other farm animals. The best control procedure is to dispose of the flock, clean up the premises and restock with chicks.

Virus diseases are the principal causes of mortality and poor production in laying flocks. The principal ones are leucosis, fowl pox, Newcastle disease and infectious bronchitis. All except leucosis may be prevented by preventive vaccination by means of a dust, spray, addition to the drinking water, or individual inoculations. Leucosis may affect almost any tissues of the body and generally birds between 6 and 18 months of age. Symptoms include paralysis, blindness, bone and muscle tumors, emaciation, big livers and visceral tumors. Birds may be selected on a family basis for resistance to leucosis.

Marketing Eggs. — Nearly all eggs at the time they are laid are of high quality. They represent the kind of eggs that most consumers would like to purchase the year round. The proper steps to preserve fresh-laid egg quality are far more important than most producers realize. The proper preparation of eggs for market and marketing them to best advantage are just as important, in many respects, as producing them efficiently.

Since the germ of a fertile egg begins to develop at about 82° F., eggs for market should be kept at a temperature lower than this, a temperature of 55° F. being desirable. All producers of market eggs should keep the males away from the females except during the breeding season.

Unless eggs are gathered frequently and cooled promptly in warm weather, they commence to deteriorate. The higher the temperature and the drier the air of the room in which eggs are held, the more rapid the deterioration. Some of the most striking changes that take place in eggs subjected to high temperatures and dry atmosphere are: (1) water evaporates through the porous shell; (2) the thick white tends to break down into thin white; (3) the yolk membrane becomes weaker; and (4) the yolk becomes more flaccid.

The excessive heating of eggs, whether from being exposed to the sun's rays or held for a long time in a warm room, results in a complete breakdown of the thick white, giving the entire white a watery appearance.

Clean litter and clean nests, one for every five hens, are essential for the production of clean eggs. The eggs should be gathered in wire baskets three or four times daily in warm weather and stored in a room in which the temperature is about 55° F. and the relative humidity about 75%.

Flock owners nho have only a few layers often sell all of their surplus eggs direct to consumers. This is especially true of flock owners in villages or those living in areas adjacent to towns and cities. In the case of farm and commercial flock owners the eggs may pass through any one of several different marketing channels before reaching the consumer. Selling market eggs on a graded basis is in the best interests of producers, dealers and consumers. Eggs are graded according to size, shell cleanliness, size of air cell and the quality of the yolk and white.

The method of packing eggs in different countries varies. In several European countries, for instance, long wooden boxes are used for packing eggs in straw whereas in Canada and the United States different kinds of containers are used, including cartons holding ½ doz. or 1 doz., and fibre or cardboard boxes holding 15 or 30 doz. From the surplus producing areas in a country, eggs are shipped in refrigerated cars or trucks to wholesalers who sell them to retailers.

Co-operative egg marketing methods have been developed extensively in various English-speaking countries, especially the United States and Australia as well as in such countries as Ireland and Denmark.

Prior to World War II some countries, including China, Denmark, Australia, New Zealand, South Africa and Ireland, exported considerable quantities of eggs annually to Great Britain, which is primarily an importing country. (See also EGG.)

Marketing Chickens. — Chickens are sold alive at various ages, ranging from those about six weeks old, weighing about one pound each, to those that are several years old. They are all called chickens when one wishes to distinguish them from turkeys, guineas, ducks and geese. From the market standpoint, however, the term chicken is usually used to distinguish growing birds, except stags and capons, from cocks and hens, the latter usually being referred to as fowl. Stags are older chickens; they have more prominent spurs, and the flesh is not so tender. Capons are male birds that were castrated while young, the flesh being relatively tender even when the birds are almost fully grown.

While the marketing of live chickens is an important industry in many countries, the proportion of dressed poultry marketed by live-poultry buyers increased considerably after about 1930. In all countries the great bulk of market poultry is sold to consumers either in the dressed, drawn or cut-up form. A dressed bird is one that has been killed and plucked. A drawn bird is a dressed bird from which the head, feet and entrails have been removed. A cut-up chicken is a drawn bird that has been cut up into parts suitable for frying.

Feed should be withheld from birds for about ten hours before they are killed and plucked. The different methods of plucking chickens include dry plucking, hard-scald plucking, semiscald plucking, wax plucking and machine plucking. Dry plucking must be done the moment tha bird is killed, while the body is still warm. The hard-scald method involves immersing the bird for a few seconds, except the head and feet, in water kept at a temperature of 180° to 190° F. If the water is too hot or the birds remain in the water too long, the skin will have a scalded appearance. For semiscalding, the temperature of the water should he approximately 127° F. for broilers, 128" F. for fowl, and the birds should be kept in the water for 30 to 35 sec. Wax plucking is a somewhat involved process in which a special kind of melted wax is used

to facilitate the removal of feathers, pinfeathers and hair. Plucking machines are used extensively in the United States and England. Some of the machines are equipped with a revolving disk or cylinder for dry plucking and others are equipped with a revolving cylinder to which rubber fingers are attached for plucking by the semiscald method.

After the birds have been plucked, the heads, feet and vents are cleaned thoroughly in order to give the dressed carcasses an attractive appearance. After the birds are dressed, they should be cooled thoroughly by immersing them in cold water for about an hour, or they may be held for about a day in a room for dry cooling at a temperature of 32° to 34° F. If the dressed birds are to be packed in boxes or other containers for shipment to market, the heads are wrapped in parchment or kraft paper waxed on one side.

In some countries, especially the United States, dressed birds are drawn in poultry-packing plants and after being inspected and cleaned are prepared so that they are ready to be placed in the consumer's oven for roasting; or they may be packaged and frozen at 0° F. or lower.

The practice of selling fresh-killed chickens cut in pieces suitable for frying has gained considerable impetus in the United States and Canada. Buying cut-up chicken is popular with many housewives, because practically no labour is necessary in preparing the poultry for the frying pan.

Raising Ducks for Meat and Eggs.—Duck raising is practised on a limited scale in practically all countries. for the most part as a small farm enterprise; but in such countries as England and the Netherlands they are kept extensively for egg production, and in the United States a considerable number of commercial plants have been developed for meat production exclusively. The Runner duck, formerly called the Indian Runner, and the Khaki-Campbell are especially adapted for egg production, whereas the larger sized Pekin breed is a meat producer of exceptional merit. Some strains of Runners and Khaki-Campbells will lay better than many strains of chickens. Pekin ducks grown commercially for meat are marketed from about 8 to 12 weeks of age. when they weigh from about 43 to 7 lb. each. In England the Aylesbury is the kind kept for meat production. The Muscovy duck, of South American origin, is kept on farms for meat production to some extent because it does not quack.

Turkey Raising.—Turkeys are raised mainly for meat production. The trend in turkey breeding has been toward fewer breeds in recent years. White varieties are becoming more popular than coloured ones because they are preferred by consumers. They do not show the dark pin feathers found in the Bronze and other coloured varieties. Hotels, restaurants and institutions prefer large birds, 1j to 30 lb. when ready for the oven. Most families prefer a smaller, 5 to 15 lb. turkey when ready for the oven.

The incubation period for turkey eggs is 28 days. Turkey poults are generally started on a 26% to 28% protein all mash ration. They may be moved to range when eight to ten weeks old or reared in confinement. Small breeds of turkeys are generally ready for market when about five months old and the large breeds when about six or seven months old. Some large breeds of turkeys are sold when partially grown as turkey broilers weighing 6 to 10 lb. and when 10 to 16 weeks of age.

The principal turkey diseases are pullorum, blackhead and sinusitis. Pullorum may be controlled by the same procedures used for chickens (*see* above). Blackhead is a protozoan disease that may affect turkeys of all ages. Mature chickens and turkeys may be carriers. A histostat may be fed as a preventive or treatment for blackhead Sinusitis may be checked by isolation of sick birds and injection of an antibiotic into the swollen sinus.

Goose Raising.—Goose raising is a farm enterprise of limited proportions in practically all countries, although in Germany, Austria, parts of France and certain sections of other countries, goose raising on a commercial basis is carried on extensively. The Toulouse, predominantly gray in colour, and the Embden, a white breed, are the two outstanding meat-producing breeds. In some commercial plants, market geese are fattened by a special process, the forced-feeding of noodles sometimes being practised, resulting in a considerable enlargement of the livers.

Some goose raisers make a practice of plucking feathers from the live birds, usually just before the birds molt, up to one pound of feathers being obtained from a bird.

Guinea Raising.—Guineas are raised as a sideline on a few farms in various countries. In some cities there is a relatively good market for them, and they are often used as a substitute for game birds, such as quail. grouse, pheasant and partridge.

Pigeon Production.—Pigeons are kept for squab production, messengers and exhibition. The Homer is the most popular breed for squab production. A pair of pigeons will raise six pairs of squabs annually. The incubation period for most pigeons is 17 days. Pigeons are generally fed cereal grains and legume seeds. Squabs are generally marketed when three to four weeks old.

See also GAME BIRDS.

POULTRY FEEDS: *see* FEEDS, ANIMAL.

POUND, SIR (ALFRED) DUDLEY (PICKMAN ROGERS) (1877–1943), British naval officer, first sea lord and admiral of the fleet during World War II, was born on Aug. 29, 1877, on the Isle of Wight, the son of an English father and an American mother. He entered the navy in 1891. As a lieutenant he specialized as a torpedo officer, and in 1913 was appointed as an instructor at the new naval staff college. Having been promoted captain in 1914, he served as assistant to Admiral Lord Fisher. At the battle of Jutland he commanded H.M.S. "Colossus." During the last years of the war he reorganized the operations division at the admiralty into the plans division, of which he was director from 1922 to 1925. He then served two years in the Mediterranean under Admiral Sir Roger Keyes, returning to the admiralty as assistant chief of naval staff with the rank of rear admiral (1927–29). From 1929 to 1931 he commanded a battle cruiser squadron and from 1932 to 1935 was second sea lord. He was commander in chief of the Mediterranean fleet (1936–39) at the time of the Spanish civil war. In May 1939 he was recalled to become first sea lord and chief of naval staff, which office he held until three weeks before his death on Oct. 21, 1943. In July 1939 he was promoted admiral of the fleet.

As first sea lord Pound shared the responsibility with the first lord. Winston Churchill, of mobilizing the fleet and conducting the naval war at a critical period. Unlike the air ministry and the war office. the admiralty was an operational centre, so that Pound was personally involved in such events as the hunt for the "Graf Spee," the Norwegian campaign, the fall of France and the early U-boat campaign. The most successful collaboration between the planning staff at the admiralty and the commander in chief at sea was the sinking of the "Bismarck." Pound combined exceptional administrative ability and capacity for work with an imperturbable temperament. (C. C. L.)

POUND, EZRA LOOMIS (1885–), U.S. poet, critic and one of the most influential single agents in the development of 20th century English writing, was born in Hailey, Ida . Oct. 30, 1885. His family traditions were those of the northnestern frontier, where a man thrived by discerning the most direct procedure and pursuing it boldly. By the time he had settled in Europe (1907) after an education in romance philology at the University of Pennsylvania and Hamilton college, he had developed his unique conviction that poetry is a craft demanding active intelligence, and begun his lifelong labour of educating and assisting his contemporaries. As foreign editor of Poetry (Chicago) he brought to its pages Robert Frost, W. B. Yeats and the first published work of T. S. Eliot. He forced Wyndham Lewis's *Tarr* and James Joyce's *Portrait of the Artist as a Young Man* (1916) and *L'lysses* (1922) into print, founded the Imagist movement and in 1922, by a brilliant feat of editing, extracted Eliot's *Waste Land* from a sprawling manuscript twice its published length.

His major poems are *Homage to Sextus Propertius* (1917), *Hugh Selwyn Mauberley* (1920), and *The Cantos*, a long work in progress, dating from the early 1920s, that undertakes to assemble. sharpen and order the traditions and signposts of fructive intellectual history. His translations include the Anglo-Saxon *Seafarer* (1912), the Chinese *Cathay* (1915) and *Classic Anthology* (1954), and the Confucian books (1947–50). His *Letters* were published in 1950, and a selection of his *Literary Essays* in 1954.

From 1946 to 1958 he was confined in St. Elizabeth's hospital in Washington after being ruled mentally unfit to answer indictments for treason growing out of broadcasts he gave on the Italian radio, 1940–45. Following his release from St. Elizabeth's, Pound returned to Italy.

POUND, ROSCOE (1870–), U.S. jurist and educator, a leading exponent of the reform of judicial administration, was born in Lincoln. Neb., Oct. 27. 1870. He studied at the University of Nebraska (A.B. 1888. A.M. 1889, Ph.D. 1897), attended Harvard law school (1889–90), and practised law in Nebraska from 1890 until 1907. After teaching at the Nebraska, Northwestern and The University of Chicago law schools (1899–1910), he taught at Harvard law school (1910–47), where he served as dean (1916–36). After his retirement in 1947 he was active in numerous legal, editorial and educational positions.

Pound's activities in bar association work led to close co-operation between law teachers and the organized bar. Many fields of the law, including jurisprudence. Roman law, equity and criminal law, were enriched by his writings and teaching. He directed the Cleveland Survey of Criminal Justice in 1922 and was a leader in the cause of efficient court administration.

Pound wrote nearly 1,000 pieces. including 250 books and major papers, and 250 opinions as commissioner of appeals of the supreme court of Nebraska! 1901–03. He also did research and riting early in his career on botanical geography. Among his books are *The Spirit of the Common Law* (1921); *Criminal Justice in America* (1930); *Organization of Courts* (1940); *The Task of the Law* (1944); *New Paths of fhe Law* (1950); and *The Lawyer from Antiquity to Modern Times* (1953).

POUND (1) An enclosure in which cattle or other animals are retained until redeemed by the owners, or when taken in distraint until replevied, such retention being in the nature of a pledge or security to compel satisfaction for debt or damage done. Animals may be seized or impounded when *(a)* distrained for rent; (b) damage *feasant, i.e.*, doing harm on the land of the person seizing; *(c)* straying; (d) taken under legal process. The pound-keeper is obliged to receive everything offered to his custody and is not answerable if the thing offered be illegally impounded. Where cattle are impounded the impounder must supply sufficient food and water (Cruelty to Animals Acts, 1849 and 1854); any person, moreover, is authorized to enter a place where animals are impounded without food and water more than 12 hours and supply them; and the cost of such food is to be paid by the owner of the animal before it is removed. Pounds are almost obsolete. *(See* DISTRESS.)

POUND (2)—(a) a measure of weight; (b) an English money of account. (See POUND STERLING.)

(a) The English standard unit of weight is the *avoirdupois* pound of 7,000 grains. The earliest weight in the English system was the Saxon pound, subsequently known as the tower pound, from the old mint pound kept in the Tower of London. The tower pound weighed 5,400 grains and this weight of silver was coined into 240 pence or 20 shillings, hence pound in sense (b) (a pound weight of silver). The pound troy, probably introduced from France. was in use as early as 1415 and was adopted as the legal standard for gold and silver in 1527. The act which abolished the tower pound (18 Hen. VIII: the "pounde Troye which exceedeth the pounde Tower in weight iii quarters of the oz.") substituted a pound of 5,760 grains, at which the pound troy still remains. There was in use together with the pound troy, the merchant's pound, weighing 6,750 grains, which was established about 1270 for all commodities except gold, silver and medicines, but it was generally superseded by the pound avoirdupois about 1330. There was also in use for a short time another merchant's pound, introduced from France and Germany; this pound weighed 7,200 grains. The pound avoirdupois has remained in use continuously since the 14th century, although it may have varied slightiy at different periods—the Elizabethan standard was probably 7,200 grains. The standard pound troy, placed together with the standard yard in the custody of the clerk of the house of commons by a resolution of the house of June 2, 1758, was destroyed at the burning of the houses of parliament in 1834. In 1838 a commission was appointed to consider the restoration of the standards, and in consequence of their report in 1841 the pound avoirdupois of 7.000 grains was substituted for the pound troy as the standard. A new standard pound avoirdupois was made under the direction of a committee appointed in 1834 (which reported in 1854), by comparison with authenticated copies of the original standard (see *Phil. Trans.* 1856). This standard pound was legalized by an act of 1855 (18 & 19 Vict. c. 72). The standard avoirdupois pound is made of platinum, in the form of a cylinder nearly 1.35 in. high and 1.15 in. in diameter, and is marked "P.S. 1844. 1 lb.," P.S. meaning parliamentary standard. It is preserved at the standards office, in the custody of the board of trade.

Whereas the British standard pound was determined by independent legislative action, the U.S. avoirdupois pound was derived from the international kilogram. By a law of 1866 and an executive order of 1893, the U.S. pound was established on the basis of 2.204621 pounds per kilogram.

See the *Reports of the Standards Commission* (6 parts, 1868–73).

POUND STERLING. From about the year 775 silver coins known as "sterlings" or pennies were issued in the Saxon kingdoms, 240 of them being minted from the pound of silver then in use for weighing the precious metals, which was probably about equal to the later troy pound. Hence large payments came to be reckoned in "pounds of sterlings," a phrase later shortened to "pounds sterling." After the Norman conquest the pound was divided for accounting purposes into 20 shillings and in mediaeval Latin documents the words *Libra, solidus* and *denarius* were used to denote the pound, shilling and penny, which gave rise to the use of the symbols *£., s., d. (see* SHILLING; STERLING). Silver pennies were the only coins used until the 13th century, and the pound as the unit of account was based upon a silver standard until the 18th century, when the growth of trade brought large quantities of gold into the country and permitted a gradual change from the silver to the gold standard. In 1717 gold of 22 carats was rated in money at £3 17*s.* 10½*d.* per oz. troy.

The addition of paper money to the circulation added great flexibility to the quantity of money. The heavy issues of paper to finance the Napoleonic wars caused the abandonment of the gold standard in 1797 and the pound remained inconvertible until 1819 when the gold standard was restored without any change in the standard weight. During the 19th century, London was the world's leading financial centre and as such set the rules of the game associated with the classical gold standard. It was maintained without a break until 1914 when wartime dislocations and inflation brought about its suspension. The British government regulated the value of sterling at the pegged rate of 4.76 dollars to the pound.

In 1919, after World War I, there was a heavy fall in the value of sterling, but in 1925 the convertibility of sterling into gold was restored for the second time at Sir Isaac Newton's old 1717 rate.

The new gold standard, which was aptly characterized as an orchestra with three conductors—London, Paris and New York—was much more fragile than the old. Indeed, Lord Keynes argued at the time that the restoration of the prewar dollar par of exchange would subject the external and hence the internal economic position to intolerable strains. Events soon confirmed his forebodings. The great depression starting in 1929 led to an unprecedented contraction of employment and foreign trade and to an acute stringency of credit. The City, which had endeavoured to cling to its customary international financial role by borrowing short in order to continue lending long, was exposed to a huge drain of short-term capital in the summer of 1931 after the crisis of confidence set off by the failure of the Austrian Creditanstalt, which spread rapidly to the German and other banking systems. Traditional methods such as raising the bank rate and borrowing from foreign central banks having proved ineffectual, the government released the Bank of England from its gold standard obligations Sept. 19, 1931, and sterling became a fluctuating currency.

Beginning in 1932 the pound's external value was regulated by the exchange equalization account, which bought and sold sterling for gold and foreign exchange with the announced objective of limiting short-run fluctuations without necessarily preventing longer run adjustments. At the same time new issues of external loans were severely restricted. In fact, the pound-dollar relationship was quite stable within a narrow range around the old par between 1934 and 1938, when the fear of European war precipitated a heavy outflow of gold and liquid funds to New York city. Nevertheless, the account was a successful instrument of exchange policy during the chequered period in which the United States and the franc countries also abandoned the gold standard; not the least of its achievements was the approximate doubling of the official gold and dollar reserves, which enabled Britain to tide over the critical interval between the outbreak of World War II and the adoption of Lend-Lease in 1941.

When World War II began in Sept. 1939, the British government immediately imposed rigid controls over all foreign exchange transactions and pegged the dollar rate at 4.03, which was maintained for ten years. The International Monetary fund, established on the basis of the Bretton Woods agreement of 1944 envisaged the institution of a stable and orderly postwar international currency pattern. and the U.S. loan of 1945 was designed to facilitate the difficult transition to normalcy. But Britain's international economic position, and with it the value of the pound, remained precarious, as was demonstrated by the disastrous and short-lived convertibility experiment of the summer of 1947 and the devaluation of Sept. 1949, when the exchange rate was drastically cut to $2.80 U.S. The interpretation of the long-run effects of the 1949 devaluation was rendered particularly obscure and controversial because of the accompanying discrimination against dollar area imports and because of the impact of the Korean war and the sharp increase in world commodity prices.

The terms of trade, which worsened markedly in 1950–51, virtually regained their predevaluation level in 1954, but retail prices were more than 30% higher. Despite all the stresses of World Wars I and II and their aftermaths and despite its softness in relation to the dollar, the pound, the international currency of the sterling area, remained one of the two leading world currencies. *See* also EXCHANGE, FOREIGN; GOLD STANDARD; INTERNATIONAL PAYMENTS; MONEY. (S. AR.)

POUSSIN, GASPARD: *see* DUGHET, GASPARD.

POUSSIN, NICOLAS (1593/94–1665), the greatest and most characteristic French painter of the 17th century, the leading exponent of pictorial classicism of that period and one of the greatest masters of all time, was born near Les Andelys, Normandy. At about the age of 17 he moved to Paris, where he stayed for the next 12 years, working under various Mannerist artists and studying in the royal collections of painting. sculpture and engraving. At the court of the queen mother he met his first important patron, the Italian poet G. Marino, who commissioned a series of drawings illustrating Ovid's *Metamorphoses.* They are at once crude and Mannerist in style and not very promising.

In 1624 Poussin reached Rome. where Marino introduced him to Marcello Sacchetti, through whom he met Francesco Cardinal Barberini. His style during this period is not easy to define as he was experimenting in various directions at once; but one important influence was that of the Bolognese classical artist, Domenichino. The culminating work of this phase was a large altarpiece for St. Peter's representing the "Martyrdom of St. Erasmus" (1629; Vatican gallery). However, it was a comparative failure and Poussin never again tried to compete with the Italian masters of the baroque on their own ground. Thereafter he painted only for private patrons and confined his work to a format rarely more than five feet in length. From 1629 to about 1633 Poussin took his themes from classical mythology and from Torquato Tasso, and his style became romantic and poetical under the influence of the Venetians, especially Titian; examples are "The Arcadian Shepherds" (1629; Chatsworth, Derbyshire), "Rinaldo and Armida" (c. 1629; Dulwich) and "Cephalus and Aurora" (c. 1630; National gallery, London).

In the mid-1630s he began deliberately to turn toward Raphael and antiquity for his inspiration and to evolve the purely classical idiom which he retained to the end of his life. He also included religious themes once more. beginning with stories which offered a good pageant (*e.g.*, "The Worship of the Golden Calf," *c.* 1636; National gallery), but going on to choose incidents of deeper moral significance in which human reactions to a given situation constitute the main interest. The most important work which exemplifies this phase is the series of "Seven Sacraments" painted for Cassiano del Pozzo, secretary to Francesco Barberini, of which five are now in the duke of Rutland's collection; in connection with another, "The Gathering of Manna" (1639; Louvre, Paris), Poussin wrote that it should be possible to "read" the emotions of all the various figures in the composition.

In 1640 Poussin was summoned to Paris by the king and Cardinal Richelieu, and among his commissions was the decoration of the long gallery of the Louvre. However, disillusionment set in, the local artists intrigued against him and he returned to Rome in 1642. The most valuable result of his visit to his native country had been the friendships which he formed with his French patrons, notably Fréart de Chantelou, whose interest in Stoic and Epicurean philosophy appealed strongly to Poussin. Both his religious and secular paintings of the 1640s and 1650s are concerned with moments of crisis or difficult moral choice, and Poussin's heroes are always those who reject vice and the pleasures of the senses in favour of virtue and the dictates of reason; *e.g.,* Coriolanus, Scipio, Phocion. Diogenes. His style was consciously calculated to express such a mood of austere rectitude. Thus in the "Testament of Eudamidas" (1644–48; Copenhagen) there are only five figures, all painted in dull or harsh colours against the severest possible background. Even in his landscapes, a form which Poussin first took up about 1645 and which he used for the stories of Diogenes and Phocion, the disorder of nature is reduced to the order of geometry, and trees and shrubs are made to approach the condition of architecture. The second series of "Seven Sacraments," executed for Chantelou (1644–48; earl of Ellesmere's collection), has a solemnity which is relatively lacking in the more picturesque first series. In each case the composition is conceived very carefully, not only on the surface but also in depth, recalling the methods of Raphael and reflecting Poussin's own practice at this time of supplementing his preparatory drawings with a three-dimensional model made of wax figures set in a boxlike stage.

Poussin believed in reason as the guiding principle of artistic creation and he was an artist who, in Sir Joshua Reynolds' phrase, was "naturalized in antiquity," yet his figures are never merely cold or lifeless. Though in pose they may resemble figures used by Raphael or in ancient Roman sculpture, they have a strange and unmistakable vitality of their own. Even in his late period, when all movement, including gesture and facial expression, had been reduced to a minimum, his forms are instinct with life. The devotion he has inspired in so many later French artists, among them David and Ingres, Cézanne and Picasso, bears eloquent testimony to this. Poussin died in Rome on Nov. 19, 1665.

POVERTY. Poverty may be defined as an insufficiency of the material necessities of life. This is not a very exact definition because the necessities of one society may be luxuries in another and completely unknown in a third. The idea of insufficiency is likewise difficult to fix with precision. Some writers distinguish between poverty as the normal condition of the poorest stratum of a population and indigence or misery as the economic helplessness of people who have no regular source of income.

Another way of looking at the matter is to distinguish the three types of poverty which are discussed below:

Collective poverty is a more or less permanent insufficiency of the material means of life for an entire population, because of limited economic resources. Entire regions such as India and north Africa, as well as the lower income groups in the prosperous countries of the west, fall into this category.

Cyclical poverty is the widespread but temporary deprivation which occurs because of a failure of crops in an agricultural economy or a breakdown of trade in a commercial economy or overproduction in an industrial economy. In former times, cyclical poverty implied the periodic recurrence of famine. In modern times the commonest symptom is mass unemployment.

Individual poverty is a condition of want which results from individual misfortune or incapacity. In every society the widows and orphans, the victims of accident and failure, the residents of idle villages and the workers of bankrupt enterprises, the criminals and the outcasts, the lame, the halt, the blind, the mentally abnormal and the mentally deficient, the drunks and drug addicts, the sick and the aged have special problems of support. In industrially advanced countries it has become customary for the state to provide varying degrees of relief for each of these situations, but these measures are often not sufficient to support a normal style of life. Some mention should also be made of ideal poverty, which is a condition of want, or at least of frugality. maintained as an end in itself. Thus Christianity and Buddhism both give. a large place to the conception of poverty as a virtue, and both provide for vows of poverty to be taken by those entering the religious life under certain conditions. There is also a long tradition of poverty as a secular virtue, going back at least as far as Lycurgus' constitution for ancient Sparta.

The range of possible definitions of what constitutes a condition of want is bounded by literal starvation at one end. This phenomenon was common throughout the world in earlier times. It still occurs with appalling frequency in underdeveloped regions and in the wake of war. At the other extreme. poverty may be merely a family's failure to achieve the average level of living of a particular society at a particular time. Since the level of living of technically advanced countries rises steadily, there are many inconsistencies of time and place. The 20th-century English pauper eats more and better food than the propertied yeoman of two centuries ago. An unemployed worker in the United States may enjoy more comforts than a fully employed Chinese.

Regardless of the limits set to the phenomenon of poverty. there are two important things which may be said about it.

First, the penalties of poverty are always severe. Compared with their contemporaries, the poor will always be found to have more illness! shorter lives, more physical and mental defects, more frequent personal crises, less education, less opportunity for advancement, less security and less leisure. It is debatable whether these disadvantages are offset by intangible benefits such as freedom from anxiety.

Second, it appears plainly that the economic progress of the past few centuries has tended to mitigate poverty everywhere by abolishing famine and raising the minimum level of living which society will tolerate. Indeed, poverty seems to be disappearing altogether in the most prosperous regions of the world. Although many doubts have been expressed as to the ultimate value of this economic progress, it is absurd to deny its existence. There is hardly any useful commodity whose per capita consumption has not increased in a spectacular way in the last century. In the more industrialized countries of the world, attention has shifted almost completely from the age-old problem of finding enough food for the population to the new problem of furnishing every family with automobiles and refrigerators. Even in the most backward and overcrowded agricultural regions, the increase of productivity and the improvement of transportation have made it technically possible to protect everyone from hunger.

Despite these favourable omens, the majority of the world's families in mid-20th century were still desperately poor compared with the average family of North America or western Europe. The first result of a secure food supply is a violent increase in population. Such an increase reached its peak in Europe about 1800. A similar wave of population growth was still gathering momentum in Asia and Africa in the second half of the 20th century. Consequently, there is sometimes a decline rather than an advance of living standards in the presence of increasing social wealth. This is what seems to have happened in Europe in the early part of the 19th century. It was still occurring in various parts of the world in the second half of the 20th century. Although the semi-starvation which was normal throughout past history was by then comparatively rare, it was estimated that half of the human race still subsisted predominantly on coarse grains, and that at least seven-tenths did not have a nutritionally adequate diet. The average daily ration of a Chinese could be obtained by an American automobile worker in exchange for about four minutes of work.

Collective Poverty. — There are two situations which may account for collective poverty — a scarcity of resources or an unequal distribution of resources.

The relative abundance of economic products depends upon the level of technical development in an area and the density of its population. A primitive economic system, without much use of nonhuman energy, may nevertheless be able to provide a fairly high level of living if the density of population is low and there is an abundance of arable land and other natural resources. This was still the case, for example, in the 20th century in many of the Pacific islands. With a moderately advanced technology, differences of population density become critical. Although the French controlled much the same technology as the English in the 18th century, the much greater population density of France produced living conditions which struck Arthur Young and other English observers as degraded. Similarly, despite the steady advancement of Indian agriculture and industry in the past three centuries, the acceleration of population growth over the same period—presumably due to the reduction of famine — seemed to have lowered the level of living appreciably. The existing evidence suggests that the average Hindu of 1950 did not consume as much as his forbears under the Great Mogul. Much the same might be said of China, the other great poverty area in modern Asia.

In the ancient world, where the growth of population was almost universally restricted, the level of living appears to have been distinctly higher than in medieval or early modern Europe.

In advanced economies, the relationship between density of population and level of living disappears, because the availability of land no longer sets the limits for total production. In the United States after World War II the net value added by agriculture never rose above 10% of the national income, although the value of agricultural production was more than 20 times as great as it had been before the Civil War. During the same century, the proportion of the labour force engaged in agriculture declined from two-thirds to less than one-sixth.

In 1948, North America, with about 7% of the world's population, had approximately 43% of the world's income, while Asia, with more than 55% of the world's population, had about 16% of the world's income.

Per capita income in the United States in 1950 was $1,593, while in the same year it was $50 or less in India, the colonial areas of Middle America, China and central Africa. These areas combined had about half of the world's population. There was an equally impressive gap between the industrialized countries of western Europe, with per capita incomes ranging from $400 to $1,000, and the countries industrialized more recently. The estimate for the Soviet Union in 1938 was $181. It was only $143 for Japan.

The meaning of Chinese or Indian poverty in actual experience is that the mass of population in these countries must spend most of their earnings for food. Even so, they are unable to buy a balanced diet. In order to obtain the minimum number of calories required for survival, most of their food intake must be in the form of cereals or rice. Regardless of the type of agriculture, the calorie output per man-hour of labour is greater in the production of grains than in the production of other foodstuffs.

Even in the most prosperous countries there are regions and classes which do not share in the general prosperity. In the United States, where per capita consumption far exceeded the rest of the world in 1950, there were nevertheless 1,900,000 families with incomes under $1,000 in that year and another 5,500,000 whose incomes did not exceed $2,000.

The available evidence indicates that economic progress is normally accompanied by equalization of income, so that the most unequal distributions are found in the poorest countries and the least unequal distributions are found in the richest countries regardless of their differing social and fiscal arrangements.

It is not only because of the widespread prevalence of misery that the contrast between rich and poor is more striking in undeveloped areas. The actual inequality appears to be greater. Jean Fourastié proposed a theoretical explanation in his *Machinisme et bien-être;* namely, that when a dense population is dependent upon limited agricultural resources, all of the marginal land which provides the cultivator's bare subsistence tends to be taken up, and the rent of the better land, from which a surplus can be gotten, tends to be very high. Because of the close and probably inherent relationship between economic progress and equalization of income, the remedy for collective poverty is always essentially the same. In every case, some way must be found of raising the total income of the poverty-stricken population. In other words, per capita consumption of goods and services must be raised. This in turn can only be accomplished by an increase of output per man-hour worked, since in the long run a population cannot consume more than it produces.

The consequences of collective poverty are most strikingly evident in an examination of population statistics. The life expectation at birth around 1950 was over 65 for the most prosperous group of countries, such as the United States and New Zealand. It stood between 50 and 60 for countries of intermediate prosperity, such as France and Austria; between 40 and 50 for moderately poor countries, such as Greece and Japan; and was estimated to be around 30 for India and China. Infant mortality showed an even wider range, from more than 200 deaths per 1,000 live births in the first year of life in the least favoured areas to about 25 in the richest areas.

The relationship between collective poverty and the birth rate is much more complex and cannot be fully treated here. As noted above, the first technical advances in a formerly undeveloped area are likely to be followed by sharp increases of population. The two reasons for this are the decline of infant mortality and the elimination of famine. This is what happened to the European population in the 17th century and it produced a tenfold increase in about ten generations.

Subsequently, with increasing industrial advancement, more and more of the population is drawn into nonagricultural employments and into the cities, whose habits of life tend toward smaller families. Eventually, as happened in France around 1900 and in the United States about 1930, the birth rate may fall below the level which is necessarv for the long-run maintenance of a stable population. However, with continued prosperity and the decentralization of the urban population, there is a tendency for a new cycle of population growth on a more moderate scale to appear. There is no assurance, of course, that economic progress will not be interrupted at some point in this sequence. It can be argued that the commercial development of India and Indonesia by European colonists was initially responsible for the inflation of population by improving the material conditions of life, but that as the colonial system became stabilized, the further progress which would have checked the growth of population was prevented.

The problem of productivity in overcrowded areas received a good deal of attention after World War II, in connection with the U.S. Point Four program and the efforts of the United Nations in former colonial areas. Increasing the productivity of an "underdeveloped" country is always difficult but probably never impossible. Several conditions must be met. First, capital must be provided from an outside source. Underdeveloped areas produce barely enough to keep their populations alive and are unable to provide new capital equipment out of surplus production. Second, improvements to be undertaken must be adapted to the economic circumstances of the area. In a sparsely populated region with no scarcity of land, such as the irrigable deserts of the near east, the principal need is for hydroelectric or atomic energy to stimulate manufacturing. In moderately settled areas, with primitive agricultural techniques. the most promising solution to collective poverty seems to be the improvement of agricultural productivity, since there is no other way of releasing materials and manpower for industrial production. In an area of dense agricultural population with traditions of intensive cultivation, the improvement of transportation may claim first attention.

Technical innovations cannot be successfully made without taking account of the total pattern into which the new elements must be fitted. The meanings attached to a tractor or a lathe are not the same in all cultural settings. The attitudes which contribute to industrial efficiency in Detroit cannot readily be mobilized in Rangoon. On the other hand, the fundamental motives for technological improvement exist almost everywhere—as demands for higher living standards.

In general, the penetration of western technology into the remote corners of the world did seem to be ameliorating the poverty of underdeveloped areas, although slowly and unsteadily. The 20th century especially saw a remarkable expansion in the supply of mechanical energy, which increased fourfold from 1900 to 1950. Most of the underprivileged Europeans at mid-century were far better fed, clothed and housed than the average of their preindustrial ancestors, and there was every reason to think that this improvement would be continuous if not interrupted by the atomic destruction of civilization. For most of the world's people, however, the economy of abundance could still not be assured, and could not be until the rising trend of production clearly outstripped the rising trend of reproduction.

Cyclical Poverty.—In the preindustrial world, economic crises were accompanied by high prices. Prices rose periodically because of scarcities of food, which brought widespread misery. Since the Industrial Revolution, the typical crisis has been caused by overproduction and accompanied by low prices. The sign of crisis and the characteristic type of cyclical poverty in economically advanced countries is mass unemployment.

There are some exceptions to the foregoing generalization, of course. Crises of overproduction were not entirely unknown in the commercial towns of an earlier era. Food scarcities occurred in the 20th century as a result of war or enemy occupation. The Netherlands, for example, suffered an authentic famine in the winter of 1944–45.

Famine was extremely common in the preindustrial world. Fourastié estimated that for the average peasant family in France, the minimum ration of $2\frac{1}{2}$ lb. of bread or 3,000 cal. a day was not attained in one out of four years in the 18th century. The last major famine in western Europe due entirely to natural causes was that of 1709, but hunger has been widespread at many times and places since then. Even in the United States, which has not known a general famine, there has never been a year in which some areas, such as the mountain counties of Kentucky, did not exhibit widespread hunger.

The business cycle in the modem sense, with accompanying mass unemployment, developed gradually in the 19th century. While the severity of successive crises varied, their coverage widened consistently as national economies became more dependent upon each other. There was also an irregular tendency for crises to last longer and longer. The great depression, which began about 1930, lasted for the better part of a decade in most of the countries involved.

In 1935 the number of unemployed in the United States approached 20,000,000, and about one-third of the population was receiving public relief or assistance. The impact of the crisis was equally severe in western and central Europe where it was further complicated by the political unrest which eventually led to World War II. Unemployment decreased very gradually from the high point of the early 1930s, and it was not until after the outbreak of war in 1939 that the surplus manpower was absorbed. Although the business cycle has been closely studied and the entire pattern of events is well understood, economists are not unanimous as to the causes. The remedies are of two kinds. First. through control of production or through the manipulation of market mechanisms, the state may intervene to interrupt the deflationary spiral of falling prices and decreasing employment before it acquires momentum. Second, the victims of unemployment may be protected by governmental subsidies in cash or kind or by employment on public works. As a matter of fact, all of these devices were finally adopted by the governments of all of the countries involved in the great depression, although with many variations of detail. In Britain the principal reliance was upon direct assistance, commonly known as the "dole." In the United States, after some experimentation. the federal government established the huge public enterprise known as the Works Progress administration. During the same decade, a great deal of experimentation was carried on with devices for controlling the cycle itself. In England, France, Italy and the Scandinavian countries, government participation in heavy industry was increased. In the United States, Canada, Germany and some other countries, the central supply of bank credit began to be vigilantly supervised and controlled.

Whether these devices have effectively terminated the business cycle must for some time remain uncertain. Conditions in the decade after World War II did not permit a clear-cut test. A high rate of productive activity throughout the world was associated with heavy military expenditures, the repair of war damage and a number of unusual circumstances which facilitated economic co-operation among the nations.

Even in the absence of widespread mass unemployment, unemployment continued to present serious local problems here and there in the world, being sporadically severe in some sections of every economy. The alleviation of unemployment by insurance benefits or other forms of relief had become a standard practice in civilized countries. Such aid is only sufficient to cushion the unemployed against homelessness and starvation. It cannot prevent other kinds of family hardship, including the loss of savings, the thwarting of plans and the experience of insecurity.

Individual Poverty. — The term "individual poverty" may be used to denote the inability or failure of a family to obtain the necessary income for the minimum customary level of living at a given time and place. There is, of course, a numerical correlation between the incidence of individual poverty and of collective or cyclical poverty. In a poor country or in a bad year, the risks of indigence for marginal wage earners will be very much greater than in prosperous countries and good years. Nevertheless, the phenomenon of individual poverty is quite distinct. It occurs whenever regular earnings are interrupted in such a way that the individual or family can no longer purchase food, clothing, housing and fuel, or when the earnings of a handicapped or underprivileged worker are so low in proportion to his obligations that he cannot sustain himself without outside aid.

The earliest students of this subject took some comfort to their conscience by blaming the undeserving poor for their own plight. Thus, in his *Inquiries Concerning the Poor,* the Rev. John McFarlan of Edinburgh wrote in 1782 that "in tracing the causes of poverty, I have endeavoured to show that the greatest number of those who are now objects of charity are either such as have reduced themselves to this situation by sloth and vice, or such as, by a very moderate degree of industry and frugality, might have prevented indigence." Somewhat later it became a scholarly game to estimate the exact proportions of blameless and blameworthy paupers.. Late in the 19th century, Amos G. Warner concluded that 25% of the poor in the United States owed their condition to laxness, shiftlessness and insobriety, while the remaining three-quarters were victims of misfortune. British studies of the same period estimated about half of the poor to be innocent and the other half to be responsible for their own misfortunes. The first scientifically respectable study of the causes of individual poverty was made by the tireless Charles Booth, who analyzed 4,076 cases of indigence in London. For 62%, the principal cause of poverty was ill-paid or irregular employment; 23% of his sample had been reduced to misery by large families or illness. The remaining 15% were said to be drunken, thriftless or lazy. In subsequent British investigations by B. Seebohm Rowntree and by Sir Arthur Lyon Bou-ley and A. R. Burnett-Hurst, the attempt to find a single cause of poverty was abandoned. Among low-paid factory workers, illness or temporary unemployment were likely to bring bitter hardship for those families with many children. The same contingencies threatened only moderate hardship for single wage earners or small families. The death of the principal wage earner usually meant the impoverishment of a family with small children.

Poverty could also be explained by the varying number of dependents whom the worker had to support during his lifetime taken in relation to his varying earning power from youth to old age. Rowntree, whose three social surveys of the English to n of York (in 1900, 1936 and 1950) were the most detailed empirical investigations made in this field, described a career pattern for the industrial worker. It is characterized by two periods of sufficiency above the poverty line, in youth and in middle age, when the worker enjoys full earnings but has no dependent children; and by three episodes of poverty, as a dependent child, as an overburdened young father and as a dependent old man. Something like this individual career pattern can probably be traced in every social stratum, although it is a little difficult to establish with precision in the highly dynamic economies of the 20th century where the conditions of the worker's childhood are not likely to remain stable until his old age.

A good deal is known about the style of life of families living at a level below their previous minimum. Available cash tends to be used for the purchase of food, and there is a continuous depletion of savings, family capital and credit. Carle C. Zimmerman studied the living conditions in a Cuban sugar-growing area of families who had incomes of less than one dollar per day. Practically all of their resources were devoted to food. In less favourable climates, the problem of finding housing at the level of living where all income is needed for food is likely to provoke community action before absolute indigence is achieved. The history of such measures may be very briefly summarized:

In the preindustrial era the care of paupers was everywhere a local responsibility, and everywhere reluctantly discharged. The role of the central government, as illustrated in the famous poor law of Elizabeth I (1601) and the edicts of Colbert concerning the treatment of vagabonds, was limited to seeing that local responsibilities were carried out more or less. Less extreme cases were generally handled by private action and some elements of aid to the poor fell into the traditional domain of the church. In the industrial era, with the coming of large-scale urbanization, this traditional local responsibility collapsed. For a while nothing took its place except sporadic repression by the police. As Anatole France remarked, "The law, in its majestic equality, forbade the rich and poor alike to sleep under bridges." Beginning with the social insurance program in Germany between 1878 and 1891, the next 75 years saw the enactment at uneven rates and in various fashions of a more or less complete program of welfare measures in every industrialized country, designed to provide minimum subsistence to the victims of each category of poverty. In the United States the enactment of such measures was one of the central themes of the New Deal. It included unemployment insurance, pensions for the aged, aid to widows and dependent children and special provisions for the blind and the handicapped. The main outlines of this system were embodied in the Social Security act of 1935 and its 1939 amendments. In Britain earlier legislation along these lines was supplemented by the enactment, in the National Insurance act of 1946 and the accompanying Health Service act, of most of the features of the "cradle to grave" protection proposed by the 1942 Beveridge report.

Individual poverty in the prosperous countries may be said to be well on the way to solution. The abolition of beggary, of spectacular misery and even of the traditional roles of the widow and the orphan is a cultural revolution whose exact implications are difficult to grasp.

However, many residual problems remain. Pensions and welfare payments tend to be meagre when first established and to become more so with time as they lag behind changes in the price level. In the United States especially, the high cost of medical services creates a special category of hardship. The piecemeal nature of most welfare programs and the prevailing prejudice that public welfare benefits should be kept at a low level means in practice that if starvation has been abolished, misery has been stabilized.

POWDER METALLURGY, the fabrication of useful items from a metal powder or a mixture of powders, thus differing from most metallurgical techniques, which initially involve the solidification of a molten metal. Fabrication by powder metallurgy techniques is usually employed for one of two reasons: W

1. Such techniques may be the only known means of producing certain metals, alloys or mixtures of two or more metals having desirable physical or mechanical properties. This is the case in producing metals having very high melting points, such as tungsten; in making alloys of two metals or materials that cannot normally be mixed together, such as copper and graphite; and, finally, in producing porous parts which can allow a liquid or gas to permeate their pores.

2. Powder metallurgy may be the cheapest method of manufacture, as is often the case where a large number of identical small parts, such as gears for calculating machines, are required. Powder-metallurgy techniques can be used to form such parts directly to shape, with little or no finishing or machining required. Also, scrap losses are minimized, and raw-material inventory for production consists of only a few grades of metal powder. These three factors contribute to the economic advantages of powder-metallurgy techniques.

BONDING OF METAL POWDER

In order to bond powder particles into a mass which is solid enough to withstand the stresses encountered in service, the powder must be heated, or sintered. This may require from a few minutes to two or three hours for completion. There are t o distinctly different types of sintering encountered in powder metallurgy. One is described as sintering with no liquid present: the sintering temperature is such that there is no molten metal present during the major portion of the sintering period. One of the constituents of the powder being sintered may melt initially when the powder is first heated, but if this molten metal alloys with the solid particles present and thus disappears during the course of sintering, the process is considered to take place with essentially no liquid present.

A second type of sintering takes place with molten metal present during the entire sintering period. In the first case, the solid particles of metal in the powder being sintered must be allowed to bond themselves together through the rather slow motion of individual atoms of the metal within the solid. In the second case, the molten metal wets the remaining solid particles and rapidly flows around them and into the spaces between them if enough of the liquid metal is present. When the powder is cooled from the sintering temperature, the molten metal solidifies and bonds the solid particles together.

Sintering with no liquid present is analogous to the coalescence of small drops of water to form a single large drop. A finely divided material, either solid or liquid, will tend to reduce its exposed surface area as much as possible. In the case of a metal, the strength of the particles resists this tendency unless the temperature is high enough to allow the atoms of the metal to move about to some extent within the particles. The lowest temperature at which this motion takes place is called the **recrystallization** temperature of the metal.

Table I gives the recrystallization temperatures and the melting points of some metals commonly used in the powder-metallurgy industry. Sintering of these metals must take place above the recrystallization temperature but below the melting point if the part being sintered is to retain its shape.

Table I.—*Recrystallization Temperatures and Melting Points*

Metal	Recrystallization Temperature, °C	Melting Point, °C
Tin	20	232
Aluminum	150	660
Silver	200	961
Copper	200	1,083
Beryllium	—	1,280
Iron	450	1,535
Zirconium	750	1,750
Titanium	600	1,820
Molybdenum	900	2,635
Tantalum	1,050	2,996
Tungsten	1,200	3,410

The time required for sintering to take place with no liquid metal present depends on the condition of the powder, the size of the particles and the sintering temperature. The closer the packing of the powder particles, the smaller the particle size and the higher the temperature, the shorter the time required for sintering. To keep the sintering time within reasonable limits, the powder is generally compacted under high pressures to bring the particles as close together as possible. The average particle size ranges from about 0.004 to 0.00001 in. in diameter, and the powder contains both large and small particles in order to have as many points of contact between particles as possible. The temperature of sintering is kept as high as possible above the recrystallization temperature as is consistent with retaining the desired shape of the part being made.

During sintering with a liquid metal present, the proportion of liquid to solid metal must not get too high, or the part will lose its shape, or distort badly. The amount of molten metal present should not exceed about 30% of the total volume of liquid and solid together. The time required for sintering in this instance generally depends on the condition and size of the solid particles and upon the temperature, just as in sintering with no liquid metal present. However, the greater the amount of liquid metal present during sintering, the shorter will be the sintering time.

One other variety of sintering is actually intermediate between the two types described above. If a metal powder is partially sintered with no liquid metal present, it will contain interconnected holes or pores between the solid metal particles. If the partially sintered metal is placed in contact with a molten metal that will wet the sintered powder but not alloy with it, then the molten metal will infiltrate the sintered powder and, if enough liquid is present, fill up the pores.

In all sintering processes the dimensions of the mass of powder being sintered changes during sintering. This change is almost invariably a shrinkage except in the case of certain copper-tin powder mixtures. The amount of the shrinkage depends on the composition of the powder, the amount of compression to which the powder has been subjected before sintering and the time and temperature of sintering. Shrinkages vary from 1% or 2% up to about 25%. This shrinkage must be allowed for in the design of parts which are to be made directly to shape.

MANUFACTURE OF METAL POWDERS

In general, metal in powdered form is a premium product, since energy must be expended to obtain a metal in a finely divided condition. Also, powders for powder metallurgy must often meet certain specifications as to particle size, shape and other properties. To meet these, careful precautions may have to be taken during manufacture of the powder. There are two classes of methods used to manufacture metal powders: mechanical and chemical.

Mechanical methods are applied to either solid or liquid metals. The most widely used method for solids is milling by power-driven hammers (hammer milling) or balls in a rotating container (ball milling). If the metal is brittle, it will easily break into many small, equiaxed particles. Milling times may run from one or two hours to 100 hours or more, with the longer times resulting in very finely divided powder. This type of particle can be used in powder-metallurgy products. If the metal is ductile, however, and can be readily deformed, it will form small, flat flakes when pounded. This type of particle is not well adapted to fabrication of items by powder-metallurgy techniques but finds use as pigment for inks and paints. Solid metals can also be cut or machined to produce fine chips. Liquid metals can be subjected to various processes that break up the metal into droplets, atomizations, which are allowed to solidify in air or water. In most of these methods a stream of liquid metal is broken up by an air blast or a stream of water and the air or water also cools, or freezes, the metal droplets. Another method consists of having a stream of molten metal fall onto a rotating wheel which is simultaneously cooled by air or water. These processes are applicable to any metal or alloy that can conveniently be melted. Metals with melting points up to and including that of iron or steel can be produced in powder form by these techniques.

One advantage of mechanical methods of powder production is that alloy powders containing two or more constituents can be produced. Such alloys as brass (copper-zinc), bronze (copper-tin) and steel (iron-carbon) can be produced in powder form in this way. This is not generally true of the chemical methods of powder production. The greatest disadvantage of milling methods is that these are restricted to brittle metals or alloys, and most useful metals, like copper and iron, as well as their alloys, are ductile. This problem can sometimes be avoided by intentionally embrittling a normally ductile material, pulverizing this while it is in the brittle condition and then treating the powder to restore its ductility if ductility of the powder is required. Certain magnetic iron-nickel alloy powders are made in this fashion.

Chemical methods of producing metal powders are adaptable to a large number of metals. In reduction. the most widely used method, a compound of the metal (generally an oxide, although sulfides and chlorides are also employed) is reduced by a chemical agent, either a gas, liquid or solid. which breaks down the compound into particles of the desired metal and some by-product which must be removed or separated from the metal itself. If the original metal compound is a solid, the size of the particles of the resultant metal depend largely on the condition of the solid compound; a finely divided compound will yield small metal particles. Most solid metal compounds, like oxides, are brittle and can be milled to a fine particle size, so with these the reduction method can produce a finely divided metal powder.

Where the by-product of the reduction of a metal compound and a chemical agent is a gas, its removal is simple and requires only some form of vacuum pump or a continuous flow of an inert or reducing gas to sweep the by-product away. An example is the reduction of copper oxide with hydrogen gas at 350° C. (662° F.) to form copper metal and steam. The steam is easily removed by continually passing fresh hydrogen over the solid copper oxide. The by-product may, however, be a solid or a liquid which solidifies on cooling from the reduction temperature, as in the case of the reduction of titanium tetrachloride with magnesium at 900° C. (1,652" F.). The by-product formed along with the titanium metal is molten magnesium chloride, which solidifies around and between the titanium particles. The magnesium chloride must be dissolved away from the titanium with dilute acid or removed by melting and distillation in a vacuum.

Another widely used chemical method is the electrolysis of a liquid solution which contains the desired metal. Many metal compounds may be dissolved in water at room temperature or in a molten metal compound at elevated temperatures. An electric current is passed through the solution, and the metal is deposited on the cathode. This process is similar to electroplating, but the conditions of current and temperature are adjusted to produce a porous, flaky or brittle deposit of metal. This coating is scraped off or broken up to obtain the powder. If the powder is required to be ductile, it is generally heated in an inert or other protective atmosphere to soften the metal. Nickel, copper and iron powders are often made by this process from aqueous solutions. Titanium and zirconium powders are made by electrolysis of fused chlorides.

A few miscellaneous chemical methods are used to produce minor amounts of metal powders. Some metals. like copper, are readily obtained as water solutions of their compounds. If clean scrap iron or steel is placed in these solutions, copper metal will be precipitated while iron dissolves in the solution. Since copper is more valuable than steel, this process is economically sound for copper production. Iron and nickel form gaseous compounds with carbon monoxide at elevated temperatures and pressure. These compounds are called carbonyls, and they may be broken down into metal particles and carbon monoxide again at low pressures. This technique allows the formation of spherical particles of iron or nickel, which are useful in certain specialized applications in the electronics industry. Stainless steel which has been slowly cooled from a high temperature is attacked rapidly at local areas throughout the material by dilute acidic copper solutions in water. This local attack causes the stainless steel to literally fall apart into individual particles, which can be quite small if the material has been properly treated. This last case is an exception to the general rule that alloy powders cannot be made by chemical methods.

TABLE 11.—Metal Powder Manufacturing Processes

Metal	Processes
Tin	Atomization
Aluminum	Atomization
Silver	Atomization, electrolysis, precipitation
Copper	Reduction, atomization, precipitation, electrolysis
Brass	Atomization
Bronze	Atomization
Beryllium	Reduction, electrolysis
Iron	Reduction, electrolysis
Steel	Atomization
Titanium	Reduction
Molybdenum	Reduction
Tantalum	Electrolysis
Tungsten	Reduction

Table II is a list of some metals used in powder metallurgy, along with the processes mhich can be used to produce each.

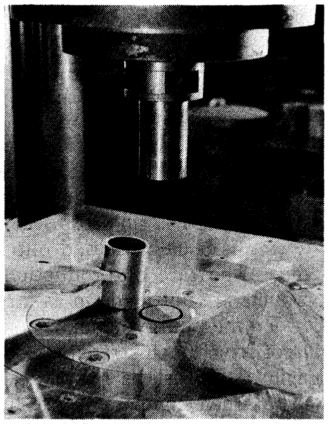
PROCESSES AND PRODUCTS

The processes used in powder metallurgy can be divided into three general classes, depending on the types of metal used in each those involving metals of relatively low melting point which are ductile. such as silver. copper and iron; those processes involving the so-called refractory metals of high melting point which are usually brittle, such as tungsten, molybdenum and titanium; and the processes for the production of materials known as cemented carbide, which contain tungsten carbide.

Ductile Metals.— Parts made from ductile metal powders generally are produced directly to the shape in which they will be utilized. Most of these parts mhich are produced by ponder metallurgy consist of an alloy of two or more metals, such as copper and tin, or a mixture of two or more metals that do not alloy and that cannot normally be mixed together, such as copper and tungsten. If an alloy part is the final product, it is often made by starting with the separate constituents and allowing alloying to take place during the sintering operation, rather than starting with alloy powder. This practice is usually carried out with parts made from copper alloys, while iron-alloy parts are more often made by starting with alloy powder.

The production starts with the mixing or blending together of the required constituent powders along with a solid lubricant, which is very similar to a soap, such as zinc stearate; this lubricant allows the powder particles to flow easily and also is necessary to reduce friction when the powder mixture is pressed to shape. The powder at this point has a density of about 50% to 60% of the density of a similar mass of solid, nonporous metal of the same composition.

A pressing, or briquetting, operation forms the metal powder to the desired Shape at room temperature. A die of strong, hard material, generally a high-quality steel, and a punch, or plunger, are used. This method of forming parts has several limitations that must be borne in mind in the design of parts to be made from ductile metals by powder metallurgy. The die must have straight sides and cannot be undercut, since metal powder, even though it is blended with a lubricant, will not flow readily into an undercut portion of the die cavity that is not directly subjected to pressure from the punch. In addition, the powder tends to adhere to the inside walls of the die cavity. This effect is called die-wall friction and acts to decrease the pressure which is available to compact the powder. Despite lubricants blended in with the powder, die-wall friction prohibits the compaction of parts whose height is more than about three times their width, so that tall, narrow shapes are not easily made by pressing. Die-wall friction also causes wear of the die; the lifetime of a die is of the order of 150,000 pressings even when the surface of the die cavity is made as hard and wear resistant as possible.



BY COURTESY OF AMPLEX DIVISION, CHRYSLER CORP

BRIQUETTING PRESS SHOWING (LEFT) PART EJECTED FROM THE DIE AND (RIGHT) METAL POWDER FROM WHICH PARTS ARE MADE

The pressures used to compact ductile metal powders range from about 10 to 50 tons per square inch, depending on the shape of the part and the type of metal used. After pressing, the part is removed from the die, and the pressure used must have been sufficient to give the compacted powder enough strength to withstand this removal and subsequent handling. If only a few parts are being made on an experimental basis, simple hand-operated hydraulic presses are used. If many thousands of parts are to be made, automatic presses, either mechanical or hydraulic, are necessary; the former have maximum capacities of about 100 tons total force and can produce parts at rates up to 100 per minute, while the hydraulic presses are capable of exerting up to 5.000 tons total force at a rate of one to five pressings per minute. The tonnage capacities of such presses limit the size of parts that can be made to about two inches square in mechanical presses or about eight inches square in hydraulic presses. One type of automatic mechanical press known as the rotary press compacts several small batches of powder simultaneously and is capable of a maximum output rate of several thousand parts per minute. Automatic presses measure the correct amount of powder into the die cavity, compact the powder, eject this compacted powder and then repeat their cycle. Either the total amount of compaction of the powder or the total force exerted on the powder may be controlled, depending on the type of press. Some presses have a double action that exerts pressure on the powder in the die from both top and bottom to obtain more uniform compaction.

During pressing, the metal powder is compacted by a ratio of almost 2 to 1, so that the compacted powder is about 60% to 80% as dense as a similar mass of solid metal. Only ductile metals can be subjected to a compaction of this magnitude. Brittle powders usually have a high strength that prevents such a considerable compression at practically attainable pressures, and even if they could be compressed by the application of a high enough pressure, the particles of a brittle material would fracture and not interlock or flow around each other as do the particles of a ductile metal powder. This last feature is particularly important, since it means that the interlocked particles of a compacted ductile metal powder will have appreciable strength after pressing. The powder after pressing is called a green compact and should have a strength of at least a few hundred pounds per square inch to allow normal handling. The exterior surface of the green compact after it has been ejected from the die will have almost exactly the same shape and size as the cavity of the die in which it was formed. To develop strength to withstand the stresses encountered in service, however, it must be sintered to bond the individual particles together.

Sintering of green compacts of ductile metal powders generally takes place with no liquid phase present, since this method of sintering results in the least distortion of the shape of the green compacts. Many iron-powder parts, however, are sintered in contact with molten brass or copper, so that the liquid metal infiltrates the partially sintered iron structure. The furnaces used for sintering ductile metals show as much variation in size and type as do presses for compaction Sintering furnaces have one characteristic in common: they must protect the heated metal powder being sintered from contact with the air if a clean. oxide-free part is desired. Gaseous furnace atmospheres commonly used for this purpose are carbon monoxide-carbon dioxide mixtures with varying amounts of nitrogen, pure hydrogen, and hydrogen-nitrogen mixtures. The carbon monoxide-carbon dioxide mixtures are made from the partial combustion of coke or illuminating gas; hydrogen is made by electrolyzing water into its constituents and is readily available commercially; and hydrogen-nitrogen mixtures are obtained by the dissociation of ammonia gas. The sintering atmosphere is usually enclosed in a muffle which is heated externally by burners or electric-resistance elements. Electric heating is more generally used because it is clean and easy to control. The temperatures used to sinter ductile metal compacts range from about 900° C. (1,625° F.) to about 1,300" C. (2,372° F.).

The smaller furnaces used for sintering may be only a few feet long and of the pusher type in which an operator places green compacts in trays and pushes these slowly through the furnace from one end to the other. This type will sinter only a few hundred parts per hour. Large furnaces are employed where many parts must be sintered, and may be of the pusher type with automatic and mechanized operation. the roller-hearth type with rollers along the bottom of the muffle over which trays of parts are passed, or the belt-conveyer type which has an endless heat-resistant alloy belt passing continually through the furnace. This latter type of furnace can sinter thousands of parts per hour. (See FURNACE, METALLURGICAL.)

The strength and toughness of a sintered compact of a ductile metal powder will be somewhat less than those of a cast material of the same composition due to porosity inherent in the powder-metallurgy part. Infiltration of a partially sintered part, however, increases its strength. Also, parts made from some types of steel powder can be heat-treated after sintering to develop higher strengths than would be obtained from as-sintered material. In general the good compressive strength and the lower tensile strength and toughness of pressed and sintered parts must be considered for projected applications.

Ductile metal compacts experience a shrinkage of about 1% to 5% in their dimensions during sintering. When this is properly allowed for in the design of dies, sintered parts can be produced which will have their dimensions equal to any specified size within a tolerance of from 0.3% to 1%. Many parts produced to such tolerances can be used as is, with no further treatment necessary. This dimensional tolerance may not meet all design requirements, however, so that some postsintering operation is necessary. The most common procedure is to make parts slightly oversized as regards the exterior dimensions and then compress the part slightly in a split or sectional die to bring it to the correct size. This is known as coining, and no metal is removed from the part in this operation. Interior dimensions, some exterior contours, and such features as an internally threaded hole which cannot be pressed to shape require machining operations on the sintered part. Sintered parts may also receive treatments other than coining or machining. Parts designed for use as bearings are usually impregnated with lubricating oil or a solid antifriction material by means of a vacuum treatment. The oil in the pores of the bearing serves as a reservoir for lubrication during the lifetime of the bearing. Steel parts which require high strength may be reheated and quenched in oil or water to develop this strength. Parts may also be electroplated to provide a more corrosion-resistant or attractive surface.

A few types of powder-metallurgy products made from ductile metals do not follow the exact cycle of pressing and sintering which has been described. Metal-powder filters are one example of such parts. These filters are made from powder particles of equiaxed or spherical shape and uniform size so that the openings between the particles will all be of the same size. The powder is not pressed. since pressing would distort the particles. Instead the powder is poured into suitable forms of graphite or ceramic and heated while still confined in these forms. The sintering of the particles is allowed to take place to develop reasonable strength in the filter. but not to the extent where the pores between the particles are closed up due to shrinkage.

SURFACE OF POROUS BRONZE BEARING MADE FROM METAL POWDER; POLISHED. NOT ETCHED. DARK AREAS REPRESENT VOIDS IN THE METAL BEARING. MAGNIFIED 250 TIMES

Alloy powders, such as bronze or stainless steel for corrosion-resistant purposes, are generally used in the manufacture of metal-powder filters.

The pressing operation may also be replaced by other compacting procedures. Ductile metal powder can be fed between a pair of rotating rolls which compact the powder into a wide, continuous sheet. Or metal powder can be extruded through a shaped. wear-resistant alloy nozzle called an extrusion die. This process is much like that of pressing paste through a tube, except that higher pressures are required. Extrusion is particularly successful in fabricating parts from aluminum powders. *(See* also DIE CASTING.)

TARLE 111.—Items Made From Ductile Metal Powders

Description	Composition	Uses
Small structural parts, such as gear cams, retainers .	Iron, brass, bronze, ion infiltrated with copper, aluminum	Machine parts where strength is not extremely important
Small structural parts . .	Steel	High strength machine parts
Porous bearings . . .	Bronze, copper-graphite, lead-bronze	Bearings or bushings (often impregnated with lubricating oil)
Electric conductors . .	Copper-tungsten, silver-molybdenum, copper-graphite	Switch contacts current collectors in 'rotating machinery
Friction linings . . .	Copper-graphite silica-lead	High-friction material for heavy-duty clutches and brakes
Filters	Bronze iron stainless steel,' nickel'alloys	Rigid filters, corrosion-resistant filters
Heavymetal. . . .	Tungsten-nickel	High-density material for weights and radiation shielding

Table III is a list of some of the items made from ductile metal powders. Some of these have unique compositions or physical properties that can be attained only through use of powder-metallurgy techniques. Others could also be made by more conventional processes but are sometimes more economically produced by powder metallurgy when a large number of parts, of the order of *10,000* or more, is required.

Refractory **Metals.**—The refractory metals can be considered as those with melting points above about *1,600"* C. (2,912° F.), with the exception of beryllium, which melts at 1.280° C. *(2,336"* F.). These metals, unlike metals of lower melting points, are generally obtainable from their compounds only as powders. They are usually utilized in the pure form .or with only small amounts of other elements as alloying additions. A few parts are made directly to shape by the pressing and sintering of powders of the refractory metals, just as in the case of ductile metal ponders. This is particularly true with beryllium and titanium. Chiefly. honever, powder metallurgy is used to produce a bar or ingot of the refractory metal, which is then further processed by mechanical working to make wire, rod, tubing or sheet.

Since most refractory metals form powder particles which are either too brittle or too hard to be compacted like the ductile metals, they can be compacted at room temperature only with a binder to hold the particles together. Examples are niobium, tantalum, molybdenum and tungsten. Production starts with the blending of the metal powder with from ½% to *2%* of a binder, such as paraffin wax, dissolved in a volatile solvent. The solvent is evaporated by gentle heating to leave a coating of binder on each powder particle. The powder is then compressed at pressures of up to *50* tons per square inch, in a die with a rectangular cavity about *1* in. in cross section by *12* or *18* in. in length. The pressing is usually carried out in hydraulic presses controlled by hand. The rate of production is low, but the refractory-metal products are not made in as large quantities as are parts made by ponder metallurgy from the ductile metals. The binders used do not have much strength so that the compacted powder is quite fragile and must be handled carefully to prevent breakage.

The green compact is presintered in a protective atmosphere at about *1,000"* C. (1,832° *F.)* to volatilize the binder and to give the compact enough strength to withstand further sintering. The second sintering must be carried out at high temperatures that would be difficult to obtain in conventional furnaces *(see* Table I). Heating of the ingots to accomplish sintering is carried out by passing a heavy electric current through the metal. Heat is generated directly within the ingot because of the resistance it offers to the current flow. *(See* FURNACE, ELECTRIC.) The amount of the current is carefully controlled to bring the temperature of the ingot close to its melting point in order to carry out sintering in the shortest possible time. Distortion of the ingots is pronounced under these conditions but is not important, since the ingot is mechanically worked by hot forging or other processes after sintering.

The atmosphere used for sintering of the refractory metals must not only prevent oxidation of the metal but also must not react detrimentally with the metal itself. For molybdenum and tungsten purified hydrogen gas makes a satisfactory atmosphere. Since niobium and tantalum are embrittled by heating in a hydrogen atmosphere, they are sintered in vacuum.

Molybdenum and tungsten ingots are brittle, although strong, after sintering, in contrast to niobium and tantalum. Some amount of ductility can be produced in the former by proper mechanical aorking of the ingots; this working also closes up the pores remaining in the ingot after sintering, to make a completely dense material. The sintered ingots must first be forged hot, then forged or rolled at successively lower and lower temperatures until deformation, such as cold-rolling into sheet or drawing into wire, is possible at room temperature.

To make ingots or certain shapes of refractory metals from powders, the processes of pressing and sintering can also be combined into a single operation known as hot-pressing. This is actually compaction of the metal above its recrystallization temperature. Extrusion is a more satisfactory process to achieve compaction than is pressing in a die because of the problem of finding a die material that can withstand the high temperature encountered in hot-pressing. In extrusion, on the other hand, the process is so rapid that the extrusion die does not become too hot during the process except at the surface immediately in contact with the hot metal powder. Hot extrusion has been applied chiefly to beryllium. zirconium and titanium. Since these metals would oxidize if exposed to air when hot, the powders are placed in a thin-walled steel container which is evacuated by means of vacuum pumps. The container and powder are then heated, and the hot assembly is extruded in presses of up to *1,000* tons capacity. The steel container is removed after extrusion by machining. The result of extrusion is a rod or tube with a diameter of up to two or three inches, which is almost completely dense. A rod can be further mechanically worked by rolling or other processes. while tubes are used for applications requiring piping which has to nithstand corrosive or other conditions for which these metals are suited. In this connection, it should be noted that beryllium and zirconium are both particularly useful in the production of nuclear energy, since these metals have a very low neutron absorption. and parts made from them can be used in the interior construction of nuclear reactors.

Hot-pressing with a die is most feasible with refractory metal powders if the powder is placed in the die and heated by passing a current through the powder itself. If the rate of heating of the powder is high enough, the die will not become hot throughout but only at the surface in contact with the ponder. This technique requires that the powder be insulated electrically from the die wall by some type of high-resistance lining so that the die will not short-circuit the heating current around the powder.

Ingots of the refractory metals can also be made from relatively coarse powders of these metals by the process of arc melting. In this process, the powder is fed through a vertical hollow tube into an electric arc which is struck between the powder and a water-cooled ingot mold. The heat of the arc actually sinters the powder as it approaches the end of the tube so that the arc is burning from the relatively rigid sintered powder at the bottom of the tube The heat of the arc melts the ponder. but not the water-cooled mold. so that molten metal drips into the mold to form a small pool of molten metal just beneath the arc. Arc melting is carried out in a vacuum to prevent oxidation of the metal and also to eliminate impurities in the metal nhich can be removed as gas or vapour.

TABLE IV.—*Refractory Metals*

Metal	Use
Beryllium . . .	Construction of nuclear reactors, windows for X-my tubes
Zirconium	Construction of nuclear reactors, corrosion-resistant parts
Titanium	Lightweight aircraft parts, corrosion-resistant parts
Molybdenum . . .	Vacuum-tube components, electrical resistors, electrical contacts
Tantalum	Highly corrosion-reiistant parts, vacuum-tube components, electrical capacitors
Tungsten	Vacuum-tube filaments and parts, electrical contacts, glass-to-metal seals

Completely dense ingots weighing over 100 lb. can be produced by arc melting; these are generally brittle as made and must be hot-forged and mechanically worked like a pressed and sintered ingot. Arc melting has been successfully applied to all refractory metals.

Some of the refractory metals, notably titanium, molybdenum and tungsten, are used as alloying elements in the manufacture of certain grades of steel. The metals are alloyed with molten iron in about a 50–50 proportion to form a brittle material which is then crushed to a coarse powder for addition to molten steel.

Table IV lists some of the uses of relatively pure refractory metals made by powder metallurgy.

Cemented Carbides.— The so-called cemented-carbide materials made by powder metallurgy contain, as their principal constituent, powder of the compound of tungsten and carbon known as tungsten carbide. This compound is formed by heating tungsten powder and carbon powder together to 1,500° C. (2.732" F.) in a hydrogen atmosphere for from one to two hours. The powders are held in graphite crucibles and heated in furnaces like those described below which are used for the sintering of the cemented-carbide material. Other refractory metals, notably titanium and tantalum, also form similar compounds, and these are often used along with tungsten carbide powder. The carbides have extremely high melting points and are very hard. The principal use of cemented carbides is as metal-cutting tools and as parts which must resist wear or abrasion.

The melting point of carbides is so high that pure tungsten carbide powder cannot be satisfactorily sintered. The carbide particles must be bonded or cemented together with another metal, and cobalt is generally used for this purpose in amounts ranging from 3% to 25%. The manufacture of cemented-carbide materials starts with the blending of carbide powders and cobalt powder. The blended powders are mixed with a binder, as in the case of the refractory metals. and pressed to shape in a die and punch set. A presintering treatment at about 900° C. (1,652° F.) evaporates the binder and results in a material which has about the strength and consistency of chalk. The material in this condition can now be shaped by machining or grinding to provide the shape necessary in the finished part. The machining operation must be carried out at this point in the manufacture because the final product is so hard as to defy most cutting or grinding operations except those using the hardest of abrasives.

After shaping the presintered compact to size, this is sintered at a temperature of from 1,450" C. to 1,550° C. (2,642° F. to 2.822° F.). During this sintering process the cobalt melts so that molten cobalt metal completely surrounds the carbide particles. Shrinkages of up to 25% in the dimensions of the compact take place during sintering. and this shrinkage must be carefully allowed for in the shaping of the presintered compact.

The furnaces used for sintering cemented carbides are fairly small. Many utilize a ceramic muffle tube and an electric-resistance heater made either from one of the refractory metals, such as molybdenum, or from graphite. Some furnaces consist of a graphite muffle tube surrounded by a water-cooled coil of copper tubing. with a high-frequency electric current passing through the tubing (3,000–100,000 cycles per second). This arrangement is known as an induction-heating furnace. since the high-frequency current in the coil induces an electric current in the graphite tube within the coil. The induced current. in turn, heats up the graphite to a high temperature. In both types of furnace, purified hydrogen gas is generally used as the furnace atmosphere to protect the carbide and the cobalt metals from oxidation and also to protect the heater of an electric-resistance furnace or the graphite of an induction-heating furnace. To accomplish this, the entire furnace, heater and muffle alike, is surrounded by an enclosure which contains the furnace atmosphere. Electric-resistance furnaces used for sintering cemented carbides are of the pusher type. while induction-heating furnaces are usually batch type which must be loaded with presintered compacts: heated to the sintering temperature, cooled, emptied of their charge and then reloaded. The heating and cooling rates of an induction-heating furnace are high enough so that this procedure is feasible. (See also FURNACE, ELECTRIC.)

The sintered carbide material may be utilized as is or subjected to further operations. In the manufacture of cutting tools for high-speed metal-cutting machines, such as lathes, milling machines or drill presses. the cemented carbide is needed only for the tip of the cutting tool. A steel shank. which is a rod or rectangular piece of tough steel, is used to hold a small piece of the sintered carbide material. This piece may typically be only a fraction of an inch in thickness and half an inch square. Smal! pieces of cemented carbide of this type are fastened to the steel shank by brazing or soldering with copper or silver alloys. This technique can be used to fasten cemented-carbide tips to lathe cutting tools, drills, saw blades and almost any other type of cutting tool. The advantage of cemented carbide over tool steel as a cutting tool stems from its ability to cut while red hot.

If the cemented carbide is to be used as a wear-resistant material, it may be inserted in a hole made in a heavier piece of steel. The dimensions of the carbide and the hole should be such that carbide can be pressed into the hole under pressure. Another method of getting a good fit is to cool the carbide to below room temperature, while the steel is heated to cause expansion. If the dimensions of the carbide and the hole are correct, the chilled carbide can easily be inserted in the hole in the warm steel, and when the whole assembly reaches room temperature, the steel will have contracted around the cemented carbide to grip it tightly.

A few types of small cemented-carbide parts are made by hot-pressing in dies, as in the case of refractory metals. This process offers some advantage in rapidly producing parts of somewhat lower quality than those made by pressing and sintering.

Carbide powders can also be used to provide hard, wear-resistant coatings on large areas of a softer metal without going through the pressing and sintering cycle. For this purpose, carbide powder and cobalt powder are forced into a hollow nickel or iron tube about one-quarter inch or larger in diameter. Twelve-inch lengths of this carbide-filled tubing can be used as arc-welding electrodes to provide a hard facing of carbide particles bonded with a cobalt-nickel-iron alloy on any electrically conducting surface. The process consists of striking an electric arc between the electrode and the surface to be plated, just as in arc welding. The heavy electric current in the arc (50–200 amp.) causes melting of the end of the tube, the cobalt and the surface layer of the work being plated. Tungsten carbide and molten metal drop from the end of the electrode to the surface of the work and solidify there to produce a material much like a cemented carbide,. In this fashion, a tough base metal may be coated with an extremely wear-resistant coating about one-sixteenth to one-eighth inch thick.

In another version of this process, a hot mixture of tungsten carbide and cobalt powders is projected forcibly onto a base-metal surface by a gas explosion to produce very thin wear-resistant coatings on the base metal.

Since the end of World War II, much effort has been devoted to the development of heat-resistant materials which can operate under stress at high temperatures, as, for example, in gas turbines or jet engines. These materials have been made experimentally from powdered compounds of refractory metals with carbon, boron and silicon. These elements form carbides, borides and silicides, respectively, with most of the refractory metals. Powder particles of these compounds can be bonded together with a metal, as in the manufacture of cemented carbides. The major shortcoming of such materials is their poor resistance to mechanical shock. The same may be said of metal-ceramic combinations made from ceramic powders which are bonded with a metal. But ceramic parts of silicon carbide and aluminum oxide are produced by pressing and sintering on an industrial scale for unique application.

Schwartz, "Cemented or Sintered Carbides," *Metals Handbook,* American Society for Metals (1948). (J. WU.)

POWDER RIVER, the name of two streams in the western part of the U.S., one heading in Wyoming and the other in Oregon.

Powder river in Wyoming drains the east and south slopes of the Bighorn mountains through Crazy Woman and Clear creeks and a flat central plains area through its north, middle, and south fork tributaries. Near Kaycee, Wyo., the river flows east 18 mi. and then bends abruptly north to the Wyoming-Montana border, where it curves eastward and then northward to join the Yellowstone near Terry, Mont. Little Powder river, an east side tributary, heads in Wyoming near Gillette and flows due north to the main stem near Broadus, Mont.

Powder river in northeastern Oregon is bordered on the west by the Blue mountains, on the north by the Wallowa mountains and on the south by sagebrush-covered hills. The river flows generally southeast and empties into Snake river near Robinette, Ore. (G. V. SK.)

POWELL, CECIL FRANK (1903–), British physicist, who was awarded the 1950 Nobel prize for physics "for his development of the photographic method in the study of nuclear processes and for his discoveries concerning mesons," was born at Tonbridge, Kent, Dec. 5, 1903. After studying natural science at Sidney Sussex college, Cambridge, he worked for two years as a research student in the Cavendish laboratory. In 1928 he was appointed research assistant to A. M. Tyndall, director of the Wills Physical laboratory at the University of Bristol; there he remained as lecturer, reader and, after 1948, as Melville Wills professor of physics. His experiments led to many fundamental discoveries. The most important of these was the development of a photographic method of observing the tracks of elementary particles. The method was subsequently applied to the study of the particles occurring in the primary cosmic rays which come from outer space. This was done by exposing plates coated with a special emulsion on high mountains and in special balloons made of a thin plastic material. One consequence of this work was the discovery in 1947 of new forms of matter, the heavy mesons. Powell was elected a fellow of the Royal society in 1949. In collaboration with G. P. S. Occhialini he wrote *Nuclear Physics in Photographs* (1937) and many papers on the development of the photographic method in nuclear physics. (W. J. BP.)

POWELL, JOHN WESLEY (1834–1902), U.S. ethnologist and geologist, the founder of the United States Bureau of American Ethnology, is remembered both for his pioneer classification of American Indian languages and for his surveys of the Rocky mountain region. He was born in Mount Morris, N.Y., on March 24, 1834, and educated at Wheaton (Ill.) and Oberlin (O.) colleges. After serving in the Union army throughout the Civil War, he began his professional career in geology with his appointment, in 1865, as professor of geology and curator of the museum at Illinois Wesleyan university, Bloomington, and afterward at Illinois Normal college, Normal. In 1867 Powell began a series of expeditions to the Rocky mountains and the canyons of the Green and Colorado rivers during which, in 1869, he made a daring boat trip of three months through the Grand Canyon. For the Smithsonian institution, in which he founded and directed the Bureau of American Ethnology, he also made ethnological studies that resulted in the first definitive analysis of North American Indian languages. His able work led to the establishment of the United States geographical and geological survey of the Rocky mountain region, with which he was occupied from 1870 to 1875. This survey was incorporated with the United States geological and geographical survey in 1879, the year in which Powell became director of the Bureau of American Ethnology. In 1881 he was appointed director also of the geological survey, a post he occupied until 1894. He died in Haven, Me., on Sept. 23, 1902.

Powell's works in linguistics included *introduction to the Study of American Indian Languages* (1880); and the classic "Linguistic Families of North America," Bureau of American Ethnology, *Seventh Annual Report* for 1885–86 (1891). His main publications in geology were *Exploration of the Colorado River of the West and Its Tributaries* (1875); *Report of the Geology of the Eastern Portion of the Uinta Mountains* (1876); *Report on the Lands of the Arid Regions of the United States* (1878); and *Canyons of the Colorado* (1895).

See also W. C. Darrah, *Powell of the Colorado* (1951); Wallace Stegner, *Beyond the Hundredth Meridian: John Wesley Powell and the Second Opening of the West* (1954).

POWELL, VAVASOR (1617–1670), Welsh Nonconformist, was born in Radnorshire and educated at Jesus college, Oxford. About 1639 he became an itinerant preacher, and for preaching in various parts of Wales he was twice arrested in 1640. During the Civil War he preached in and around London. In 1646 he returned to Wales, and with a salary granted by parliament resumed his itinerant preaching. In 1650 parliament appointed a commission "for the better propagation and preaching of the gospel in Wales," and Powell acted as one of its principal advisers. In 1653 he returned to London and, having denounced Cromwell for accepting the office of lord protector, he was imprisoned. At the Restoration in 1660 he was arrested for preaching, and after a short period of freedom he was again seized, and remained in prison for seven years. He was set free in 1667, but in 1668 he was again a prisoner, and he died in custody on Oct. 27, 1670.

See *The Life and Death of Mr. Vavasor Powell,* ed. by E. Bagshaw the younger (1671), which contains his autobiography; D. Davies, *Vavasor Powell* (1896).

POWER. The word "power," as used by the engineer, indicates energy under human control and available for doing mechanical work. The principal sources of power are the muscular energy of men and animals; the kinetic energy of the winds and of streams; the potential energy of water at high levels, of the tides and of waves; the heat of the earth and of the sun; and heat derived from the combustion of fuels. Of these sources of power the winds. waves and solar heat suffer the disadvantage of being essentially intermittent and therefore requiring some method of storage of power if the demand for power is continuous. From the point of view of the size and cost of the power plant. when large amounts of power are required, windmills. wave motors and solar engines are not adaptable to large-scale power generation; tidal power, while it may be developed in certain'places for large power. usually entails excessive first cost; volcanic power or natural steam is used in Italy and Iceland; hydraulic turbines and heat engines alone permit the construction of compact plants of. practically unlimited capacity and of moderate first cost. The commonly accepted unit of power is the horsepower, which was defined by James Watt (1736–1819) in 1783 as the equivalent of 33.000 foot-pounds (f.p.) of work per minute. This is about ten times as much work as can be done per minute by a labourer working eight hours per day.

The use of domesticated animals was the first enlargement of the power of man and the beginning of his civilization. The use of the wind for sailing vessels was an early development, but its use in operating windmills dates from about the 12th century. Water wheels were known in Greek times and are described by Vitruvius. but their capacity was very small. To the end of the 18th century the largest water wheels for industrial use did not exceed 10 h.p. The earliest operative heat engine was the cannon, used first at the end of the 13th century. The social consequences of its invention were momentous; it had a great part in the destruction of the feudal system. It represented a greater concentration of power than had been possible previously. Its indirect influence in stimulating the development of the art of cutting metals is of prime importance in the history of the heat engine.

The special incentive which gave birth to the steam engine was the desire to remove water from mines (particularly the tin mines of Cornwall). In 1698 Capt. Thomas Savery's engine was patented and a number of his engines were built. They were found to be extravagant in their use of coal. Four years later the first steam engine using a cylinder and piston was devised by Thomas Newcomen.

It was while repairing a model of this engine that James Watt made the improvements that resulted in the modern steam engine. In 1782 Watt patented a double-acting rotative engine which, for the first time, made steam power available for driving all kinds of mechanism. The result of this invention was the factory system and the Industrial Revolution. It became possible also to apply steam power to navigation and to railroads.

The next important advance in power generation mas the invention by Benôit Fourneyron of the hydraulic (reaction) turbine in 1827, for utilizing the energy of water available under high heads. Impulse water turbines of the Pelton type! adapted to use the highest heads. were developed in California about 1860. Hydraulic turbines reached a high degree of perfection, giving efficiencies in excess of 90%.

The thermal efficiency of a heat engine is a function of the maximum and minimum temperatures of the working substance and also of the cycle of operations. The cycle of maximum efficiency for given temperature limits is the Carnot cycle. Combustion, which is the source of heat in heat engines, may occur either outside the engine (external combustioni or inside the engine (internal combustion). In external-combustion engines the working substance is distinct from the products of combustion, and heat travels to it by conduction through containing walls, such as boiler heating-surface, The maximum temperature of the working substance is then limited by the strength of the containing walls at high temperature. \\-ith internal combustion the products of combustion are used as the working substance, and there is no maximum temperature limit, since the containing walls. piston and valves can be water-cooled. The theoretical thermal efficiency of the steam turbine is about 36%, of the diesel engine about 50% The brake thermal efficiencies actually realized are considerably loner. The internal-combustion engine is compact, of light weight, instantly available for use, has low labour cost and no stand-by losses. Its principal disadvantage is that it uses a fuel more costly than coal except in diesel engines utilizing the cheapest grades of oil.

The first practical internal-combustion engine was that of E. Lenoir (1860). Two years later Beau de Rochas showed that for good efficiency it is necessary to compress the explosive mixture before igniting it. and in 1876 this idea was effectively realized in a successful explosion engine by N. 4. Otto. The Otto cycle is the standard cycle in automobile. airplane and many stationary and marine engines. The fuel used by Lenoir and Otto was coal gas, but in 1883 Gottlieb Daimler substituted volatile liquid hydrocarbon fuel (gasoline or petrol) and thereby made the engine available for automotive purposes. The use of less volatile hydrocarbon fuels (kerosene, fuel oil, etc.) was first successfully developed by Hornsby in the Hornsby-Xckroyd engine of 1893. A year later Rudolf Diesel built his first engine, in which the air is brought up to the temperature of ignition of the fuel by the work of compression alone and fuel is injected in a finely atomized state after the compression is completed. It is possible to burn in it any fuel that can be atomized by high-pressure air injection. by spraying under very high pressure through small openings, or by other means. It ofiers the combination of the cheapest fuel and the highest efficiency of utilization. The diesel engine was slow in development at first because of many practical difficulties. especially from heat stresses. It came into wide use, however, in ships, railway locomotives and motorbuses.

The principal uses for power up to about 1890 were for driving shafting, pumps. compressors and hoists, for locomotives and for marine propulsion. With the improvements that had recently been made in the use of electricity the power station appeared. Electricity is a means for transmission of power and the only means which is economical for long distances and for complicated systems. The earlier power-transmission systems by rope drives. compressed air and water under pressure were too costly and cumbersome to survive.

The history of the development of power shows a constant striving for greater economy. greater compactness of the units and greater capacity of each unit.

POWER ALCOHOL: *see* ALCOHOL.

POWER AMPLIFIER. In radio work the ratio of the alternating-current power produced in the output circuit to the alternating-current power supplied to the input circuit is known as the power amplification. A power amplifier is an amplifier which is capable of producing relatively large power in an output circuit.

See AMPLIFICATION.

POWER OF ATTORNEY or LETTER OF ATTORNEY is a written authority, usually, though not necessarily, under hand and seal, empowering the person named therein to do some act or acts on behalf of the principal, which otherwise could only be done by the principal himself. It is either general or special. A general power of attorney authorizes the agent to act for his principal in all matters, or in all matters of a particular nature. or generally in respect of a particular business. A special power of attorney authorizes the agent to represent his principal only in regard to some particular specified act.

A power of attorney expires with death of the principal, and is revocable at his n-ill, even by a verbal notice. unless it has been given for a valuable consideration to secure some interest of the donee. The law relating to powers of attorney is a branch of the law of agency.

Powers of attorney are used freely in the United States. where their form and usage follow that of England. *See* AGENCY.

POWERS, HIRAM (1805–1873), perhaps the most famous U.S. sculptor of the middle of the 19th century. was horn in Woodstock. Vt., on June 29. 1805. He discovered his talent for modeling while working in a waxworks museum in Cincinnati, O., about

1829. In *1835* he set out for Italy to become a sculptor, stopping in Washington to model a portrait of Andrew Jackson (now in the Metropolitan Museum of Art, New York city), which is probably the best portrait he ever made.

He arrived in Italy in *1837* and settled in Florence, where he remained for the rest of his life. Powers' most famous work was the "Greek Slave" (Corcoran gallery, Washington, D.C.), a female nude, which caused a sensation when it was exhibited at the Crystal Palace exposition in London in *1851.* High prices were paid for his work. He produced many portrait busts of the prominent American visitors to his studio, where he charmed them with his lively conversation.

Powers died in Florence on June *27, 1873,* just when his sculpture and that of his contemporaries was beginning to be supplanted by the work of a later generation.

POWER TRANSMISSION. The appliances for the utilization of natural sources of energy may be classified into three groups: (1) Prime movers, by means of which the natural form of energy is transformed into mechanical energy. To this group belong all such devices as water, gas and steam turbines, steam engines, internal-combustion engines, etc. (2) Machinery of any kind which is driven by energy made available by the prime mover. To this group belong all machine tools, textile machinery, pumping machinery, cranes—in fact every kind of machine which requires any considerable quantity of energy to drive it. *(3)* The appliances by means of which the energy made available by the prime mover is transmitted to the machine designed to utilize it.

In many cases the prime mover is combined with the machine in such a way that the transmitting mechanism is not distinctly differentiated from either the prime mover or the machine, as in the case of the locomotive. In other cases the energy made available by the prime mover is distributed to a number of separate machines at a distance from the prime mover, as in the multiple pulley-and-belt drives used in early factories. In this case the transmitting mechanism has a distinct individuality.

Finally, prime movers may be located in places where the natural source of energy is abundant (near waterfalls or in the neighbourhood of coal fields), and the energy made available is transmitted in bulk to factories, etc.. at relatively great distances. In this case the method and mechanism of distribution become of paramount importance, since the distance between the prime mover and the places where the energy is to be utilized is limited only by the efficiency of the mechanism of distribution.

This article deals with power transmission by mechanical and hydraulic means. For a discussion of the generation, transmission and distribution of electricity, *see* ELECTRIC POWER. (X.)

MECHANICAL POWER TRANSMISSION

Mechanical power transmission refers to the transfer of power through and among machines by means of mechanical devices, such as shafts, gears, belts and clutches. Other methods of power transmission, *e.g.,* electrical, are generally used to convey power over long distances. Power can also be transmitted by means of vibrating media, such as sound and electromagnetic waves—as, for instance, in the tremendous force that is effected by an explosive charge. Any moving mass possesses energy and, therefore, power. A flowing river or a blowing wind each possesses power which is available anywhere along its path of travel.

POWER AND ITS MEASUREMENT

Power.—Power is the time rate of doing work. When a body weighing 5 lb. is raised vertically a distance of *4* ft., *20* ft. lb. of work are performed. In general, work is done whenever a force is moved through a distance; work is the product of force times displacement. Either the force or the displacement must be effective; *i.e.,* either the displacement must be the component parallel to the force direction or the force must be the component parallel to the displacement path.

In fig. *1,* for example, the applied force makes an angle of 30° with the direction of motion of the box along the floor. Thus the component parallel to the floor—the effective force—is *100* × cos 30°, or *86.6* lb. The work, then. is *86.6* × 5. or *433* foot-pounds (f.p.). The downward component, *100* × sin 30°, or 50 lb.. per-

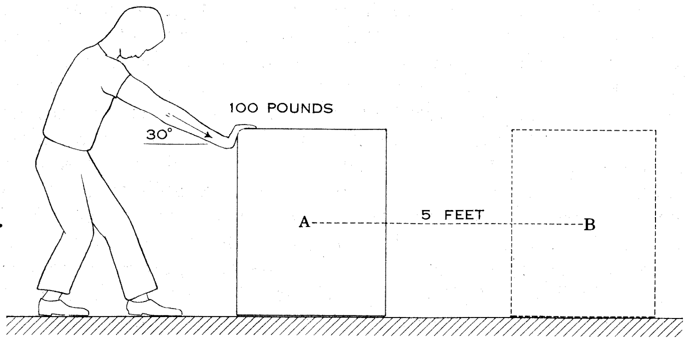

FIG. 1.—WORK SHOWN AS A RESULT OF FORCE (THRUST OF 100 LB. AT AN ANGLE OF 30°) AND DISTANCE (OBJECT MOVED 5 FT.. A TO B)

forms no work because the box does not move in the vertical direction.

The factor of time is not considered in this example. On a slick floor the box might have moved 5 ft. in *3* seconds. while on a rough floor the time might have been *30* seconds. The difference is due to the frictional force between floor and box. What the frictional force does is also work, but the energy is wasted in heating the floor or the box, or both. Less of the total work is left in the second case, and so the box moves (accelerates) slower. The point is that the same amount of work is expended in each case but over a different period of time. In the first case, work is performed at *43313* or *144.3* foot-pound-seconds (f.p.s.), and in the second case at *433130* or *14.43* f.p.s. These figures are a measure of power—the time rate of doing work *(see* POWER; HORSEPOWER).

Mathematically, the time rate of work is expressed as dW/dt—the first derivative of work, W, with respect to time, t. This is the power at any given instant; the average power during some particular time interval is the total work divided by the time consumed: $P_{avg} = W/\Delta t$.

Work performed by a force F on a body which is thereby displaced a distance ds in the direction of the force is Fds; the power P is Fds/dt. Since ds/dt, the time rate of displacement, is velocity, power equals force times velocity, or $P = Fv$. Thus, force multiplied by effective velocity is an expression of power.

A torque or moment M_t applied to a body will cause it to rotate. That is, the body will undergo an angular displacement $d\theta$ during the time dt. The power involved here is: $\mathbf{P} = dW/dt = M_t d\theta/dt = M_t \omega$, where ω is the angular velocity. Power is thus the result of force translation along a straight line, torque rotation about a plane, or some combination of the two.

These fundamental definitions can be used to derive the power involved in any particular case. When the force, or torque, and velocity are constant, power is computed, using the finite expressions. When either or both vary, the infinitesimal expressions are applied and integrated. Such cases can become quite complicated, mathematically.

Power Measurement.—Power-delivering machines must be evaluated, because the amount of power being delivered is most important. In numerous cases, power output can be measured at different places. For instance, in the case of an automobile, power can be measured at the output end of the engine or at the wheels. Thus it is possible to measure and identify power in many ways, such as indicated horsepower, brake horsepower, shaft horsepower and friction horsepower *(see* HORSEPOWER).

In steam, gasoline and diesel engines, the working substance, resulting from the fuel combustion outside or inside the cylinder, exerts a varying force on a moving piston. In a reciprocating compressor and pump, power supplied to the shaft is transmitted to the piston and, in turn, to the working substance. In either case the piston force is variable. This variation must somehow be measured if the power delivered to or by the piston is to be determined. **A** special device called an indicator is used, and indicated horsepower (i.h.p.) is thus measured.

Of the many types of indicators, probably the most common is the piston type, often called a steam-engine indicator (it was originally designed to measure the power of steam engines). In a device of this type. the piston within the body of the indicator is actuated by the varying pressure within the engine cylinder to which it is connected. Motion of the indicator piston is, in turn, resisted by a calibrated spring and thus moves in direct proportion to the pressure and the spring force. A string fastened to the drum at one end and to the engine crosshead at the other rotates the drum to correspond to the engine-piston motion, giving a record of pressure versus piston displacement on a sheet wrapped around the drum. The area within the indicator diagram, being force times displacement, represents the net work performed by or on the engine piston during each cycle. It is therefore a measure of the engine's power. Actually, power is determined by first computing the mean effective pressure (m.e p.)—the diagram area divided by the diagram length. The calculation yields the equivalent constant pressure which defines the same amount of work. When the m.e.p. is multiplied by the piston area, the total force is found. This force multiplied by the stroke L and the number of cycles per minute n, and divided by the horsepower factor, yields the indicated horsepower:

$$\text{i.h.p.} = \frac{(\text{m.e.p.})ALn}{33{,}000} \text{ per piston face}$$

The result, of course, must be multiplied by the number of cylinders (or faces when each side of each piston develops power) present in the engine. Other indicators differ in the type of pressure-sensing unit or recording device; electrical, optical and diaphragm principles have been used.

Power may also be measured at the output end of an engine. A dynamometer such as the Prony brake, is used for this purpose. The Prony brake is an energy-dissipating device in which friction generates heat. Some dynamometers use fluid friction in place of solid friction; e g., hydraulic and air dynamometers. In other types, poner is converted to electrical energy and dissipated in resistors as heat. Still another type is the torque transmission dynamometer, which measures the power actually being delivered. The power passes through the dynamometer without waste and is delivered by it to the work shaft. It is the angular twist occurring in the dynamometer shaft nhich is measured; this twist is directly proportional to the torque and so can be used to obtain the shaft horsepower (s h.p.). Another transmission dynamometer uses electric strain gauges to sense the twist in the shaft, the strain gauge output being calibrated to yield the torque. which then can be converted into shaft horsepower (see DYNAMOMETER).

Whenever one body slides or rolls over another, friction develops. Friction consumes power, and the poner thus lost is called friction horsepower. Friction horseponer is not easy to measure. It can be determined, however, by measuring the power input at zero load; the entire input must be friction power, since external mork is not being done. Friction horsepower can also be found by the method of difference: both input and output power, *e.g.*, indicated and brake horseponer, are measured; the difference between the two is loss and so represents friction horsepower.

Any power wasted in friction becomes unavailable to do the machine's work, and thus the machine becomes less efficient. Mechanical efficiency, therefore, can be stated as the ratio of input to output horsepower. It is a measure of an engine's capacity to keep the externally usable power at a maximum; alternatively, it is also a measure of the ability of a machine to use the power supplied it to do useful work.

POWER PRODUCTION

Prime Movers.—Prime movers are power-generating devices, the output of which is used to operate machines. It is immaterial how the power is developed within the prime mover. In some, the energy is created chemically, as the burning gases in the internal-combustion engine; others convert one form of energy into another by physical means. For instance, steam is expanded to yield shaft power in the reciprocating steam engine; *i.e.*, heat is transformed into mechanical power.

The terms prime mover, power source and power plant are often used interchangeably. but differences may exist. A prime mover provides the immediate energy needed to run the machine: the tiny motor powering an electric shaver is a prime mover. A power plant generates power within itself: the automobile engine is a power plant, but it also acts as a prime mover, turning the rear wheels of the car.

Fundamentally, the sun is the source of all power; the equivalent of the energy obtained from 2×10^{14} tons of coal reaches the earth as solar energy each year. If man knew how, he could produce 1 h.p. from the solar energy striking each square yard. Some of this energy is naturally consumed for man's welfare: evaporation and climatic differences, which bring about rain and winds, supply water, water power and wind power; vegetation feeds both man and animal and so generates muscular power; and the vegetation of past ages is available as coal and petroleum.

For practical purposes, discussion must be limited to power sources found on earth in sufficient quantity for man's use. These are muscle, water and wind power, wood, coal. petroleum and natural gas. The direct use of solar energy constitutes another, although as yet minor, source (see SOLAR ENERGY, UTILIZATION OF). Atomic power is a source man has learned to harness only recently, and nuclear reactors are now used as the heat source in steam-power plants and marine propulsion. The only major difference between the ordinary and the nuclear steam-power plant is the replacement of the boiler by the reactor (see ATOMIC ENERGY; NUCLEAR ENGINEERING).

A typical list of prime movers might include: (1) muscles; (2) windmills; (3) sails; (4) water wheels; (5) reciprocating steam engines; (6) spark-ignition engines; (7) diesel engines; (8) hydraulic turbines; (9) steam turbines; (10) gas turbines; (11) jet and rocket engines; (12) electric motors; and (13) springs. The first four are industrially no longer important in much of the world, although they were in the past; however, in technically undeveloped nations they still provide the major portion of the power consumed.

MECHANICAL TRANSMISSION ELEMENTS

Devices which transmit the power output of prime movers to the place of use are transmission elements. Power involves time, force or torque, and velocity. The same power can result from a large force at low velocity or from a small force at high velocity. In one place on a machine one combination may be required; at an adjoining place, the other combination. If both locations are to be supplied by the same prime mover, many transmission elements may have to be interposed. Therefore, the elements may be numerous and complex.

Mechanical transmission elements include such devices as shafts, gears, belt drives, chain drives, couplings, clutches, brakes, power screws, cams, linkages, flywheels and bearings.

Shafts.—The various designs of shafts may be classified for convenience into two groups: transmission and machine shafts. Transmission shafts are those used outside the machine to bring power to it. These may be relatively long and supported at several places. Line shafts and countershafts, so common in older manufacturing plants, were of this type, distributing the power from a single prime mover to machines throughout the plant. In modern plants the single prime mover has been replaced by individual prime movers, one in each machine. Therefore any shafting needed becomes an integral part of the machine and so falls into the second group, machine shafts.

Basically there is no difference between machine and transmission shafts. Both transmit power, and they differ only in length and the number of stations at which power is withdrawn. The diameter depends upon the torque being transmitted and may be just as large on a short shaft as on a long one. In addition to the torque, shafts are subjected to bending forces (transverse to the shaft), if only due to their weight. Thus, flexure, as well as torsion stresses, is alnays present.

Since shafts are often critical members, they must be properly designed. The amount of twist, as well as the stress, must remain within safe limits. Generally, shafts are made of plain carbon and alloy steels. When greater strength is required, particularly at higher speeds, nickel, nickel-chromium and chrome-vanadium alloy steels are used. Shafts are hot-rolled to standard sizes. and for use under severe fatigue conditions. they are turned and ground or polished to eliminate all surface defects. In addition, they often are given special heat-treatments.

Most shafts are solid and of circular cross section, although they may be hollow, *e.g.*, to carry lubricants on an inner, concentric shaft, and occasionally a power shaft may have a cross section other than circular (see SHAFT. DRIVING).

Keyways and keys are an integral part of power shafting. Sometimes a shaft alone is used betn-een the prime mover and load; more often. however, shafts have many other power-transmission elements attached to them. The elements must be fixed rigidly to the shaft. and to assure this, fasteners, such as keys, pins, cotters and splines. are used. These devices are interposed between the shaft and transmission elements to prevent relative motion between them. This often involves keyways along the shaft, as well as fasteners (*see* KEYS AND KEYWAYS).

Gears.—When teeth are placed around the surface of a cylinder, cone or hyperboloid. the member becomes a gear, another power-transmission element. Gears can transfer power from one shaft to another. and the shafts may be intersecting. as well as parallel. The transmission is positive because gears provide meshing surfaces which do not depend upon friction as the driving medium. Power must be transferred at a constant velocity ratio, quietly and with a low friction loss. Such requirements are not easily satisfied. Thus, gear teeth must be of proper profile, dimension. tolerance and finish. Gears having standard profiles but differing in other details are needed to connect the many shaft directions and satisfy other conditions arising in power transmission. The following types have been developed: spur, bevel, hypoid, helical, herringbone and norm. Detailed descriptions and applications may be found in the article GEARS.

Belt Drives.—Belts are convenient power connectors when shafts are some distance apart and when an absolutely constant velocity ratio is not essential. Belts usually are used to connect shafts that are parallel, but the flexibility of belts permit other arrangements. Belt-connected shafts can be made to turn in opposite directions by crossing the belt.

Leather is the most common flat belt material) but rubber, balata and textiles are also used. The leather is tanned. mineral tanning being preferred for applications where water, steam and oil are present. and layers of the leather then are cemented to form multiple-ply belts. Belt lengths must be fastened together to form the closed loop needed for a drive. The most efficient joint is the cemented lap joint. A simple type is the rawhide-lacing method; wire hooks and steel loops are also used.

A necessary part of the belt drive is the pulley over which the belt rides. Iron, steel, wood, compressed fibre. and plastic laminates are all used to make pulleys. Split as well as solid pulleys are common, the split type being easy to fasten to a long shaft because the halves can be placed over the shait and clamped to it. When it is required to stop and start the driven shaft while the driving shaft continues its rotation. a tight-loose pulley combination is useful; the belt is shifted from one pulley to the other by means of a lever arrangement.

The V-belt, having a reinforced trapezoidal section: can transmit more power because of the gripping action between the belt sides and the V-grooved sheave. Most V-belts have a rubber-fabric outer cover surrounding a central portion of cotton- or wire-reinforced rubber. V-belts are made endless and in a sufficient nurnber of standard sizes to meet most needs. Stretch in these drives is best taken up by means of idler pulleys or pivoted motor bases.

A more recent belting development is the toothed belt. which has teeth on its inner surface to engage corresponding spaces on axially grooved pulleys. This arrangement approximates the positive gear drive. and it can be used when a flexible drive capable of synchronizing the shafts is needed. (See also PULLEY AND BELT.)

Chain **Drive.**—When positive power transmission between shafts too far apart for gear connection is desired, chain drives become useful. The greater elasticity of chain drives also provides better shock absorption. In addition! wear is reduced because of the larger contact area.

A chain is a combination of close-tolerance links, pins and rollers. Standard chains are made in two forms: roller chain and silent chain. and they are manufactured in many sizes. Three principal dimensions define the chain: the pitch (length between rollers). the inside width of the chain and the outside diameter of the roller. A special link. easy to assemble and disassemble, is used to fasten the chain ends. Chains ride on sprockets or toothed wheels, the teeth being shaped to mesh precisely with the chain links.

A less refined but equally practical chain drive can be obtained by running a common link chain over a sprocket designed in the form of a pulley with its rim shaped to interlock with the links. This type of drive is especially useful when heavy loads must be lifted without danger of slippage, as in the anchor windlass and in the differential chain hoist used in maintenance shops. (See CHAIN.)

Couplings.—Couplings are used to join shafts. In general, a coupling is considered a permanent connector, although it can be disconnected for repairs. Both rigid and flexible couplings are made: the latter allow for slight shaft misalignments. Couplings are made in many different styles, the most important of which are discussed in the article COUPLING.

Clutches.—The clutch is a device designed to connect and disconnect a power source and a load. Mechanical-contact clutches are of the positive friction type. Positive clutches contain protruding jaws which engage when the two halves are brought together. The jaws are either square (in which case rotation in either direction may be handled) or spiral (in which case only unidirectional rotation is possible).

The positive clutch is simple, slip-free and light. It does not develop appreciable heat and so can be engaged and disengaged frequently. On the other hand, the sudden engagement and release subjects not only the clutch but also the attached machinery to much shock and wear.

The friction clutch contains two friction surfaces. one on the driving element, the other on the driven element. and some form of linkage to engage and disengage the friction surfaces. Probably the chief advantage of the friction clutch is its ability to slip slightly when first engaged, thus cushioning shocks and reducing wear and stresses. The most common types are discussed in the article CLUTCH.

Brakes.—The mechanical brake, like the clutch, contains two friction surfaces and a mechanism which brings them into contact. The brake absorbs kinetic energy by generating and dissipating heat. Block, band, disk and shoe brakes are common. (See BRAKE.)

Power Screws.—Threaded rods (screws) are often used to transmit power. Lathes, presses, jacks and materials-testing machines are typical of devices employing power-transmission screws. Screw drives are not very efficient, but for slow. powerful motion, they are convenient. The lathe tool-carriage screw (see LATHE) is illustrative of an important trait of the power screw: its ability to convert a rotational force (torque) into a powerful linear (translational) force.

Cams and Linkages.—A cam transmits power by means of a follower in direct contact with it. The contact is either sliding or rolling. The cam itself can take many forms and can impart an infinite variety of reciprocating or oscillating motions to the follower. Because it can be designed to provide nearly any complex motion. it finds much use in automation devices, computers and servomechanisms. (See CALI.)

Like cams, linkages primarily transmit motion. although in some applications they may push or pull a load and in transmitting power become machines. For instance, the power generated at the piston of an internal-combustion engine is transmitted to the crankshaft by means of the connecting rod. The combination is one of the two basic link mechanisms: the slider crank and the four-bar chain. Important linkages of one type or the other are devices like the Scotch yoke, the Whitworth quick-return mechanism, the Geneva wheel, escapements, toggle joints, Hooke's coupling and the straight-line mechanisms. (See LINKAGES.)

Flywheels, Bearings. — These two devices only assist in power transmission; they do not in themselves actually transmit power. Flywheels are attached to a shaft and. because of the large mass involved, absorb and release energy to maintain a more uniform rotation. For example, during the power stroke of a punch press the kinetic energy of the flywheel provides some of the power suddenly needed. Therefore, shaft rotation is reduced but not stopped, as it might be without the flywheel.

Bearings permit motion of one part relative to another with a minimum of friction or power loss, while simultaneously supporting the load on the moving element. Thus, again, bearings are necessary machine elements in a power-transmission system but do not themselves transmit useful power. (See BEARINGS.)

(J. P. V.)

HYDRAULIC POWER TRANSMISSION

A variety of machines use some liquid for developing a push or pull, for moving some object or for controlling some action. Oil, water or some other liquid can be used, but oil is the most common. For practical purposes, it does not change its volume when the pressure is increased. Thus, if oil fills a hydraulic system completely (leaving no air or gas pockets), the motion of a piston can be controlled conveniently and within close limits by the oil flow. Oil lubricates the sliding parts and also prevents rust.

Many complicated hydraulic systems have been developed; however, most of these are essentially combinations of certain simple hydraulic circuits. A study of these simple systems is helpful in understanding the more complicated systems.

Hydraulic Press. — The simple system in fig. 2 illustrates the action of many devices, including the hydraulic press. The two cylinders are connected by a pipe. There is a close-fitting piston in each cylinder, and liquid in the pipe and cylinders. Assuming no leakage past the piston, the pressure of the fluid is the same in all parts — a statement of Pascal's law (see MECHANICS, FLUID). Essentially the same fluid pressure acts on the face of each piston. Thus a small force F_1 on piston A (small area) can balance a large force F_2 on piston B (large area). In principle, the hydraulic press is analogous to the mechanical lever.

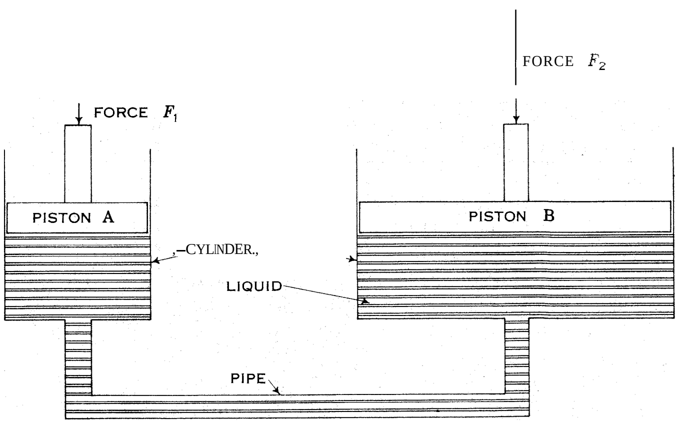

FIG. 2.— HYDRAULIC PRESS

Hydraulic System.—Fig. 3 is an example of a hydraulic system. Oil from a reservoir flows through a pipe into the pump, which increases the pressure of the oil. The oil then flows through a pipe into the control valve, which regulates the flow to the cylinder. A relief valve, pre-set at some safe maximum pressure, is provided for the protection of the system; if the oil pressure should rise above the safe maximum, the relief valve will open and relieve the pressure. Oil entering the cylinder acts on the piston, and this action develops a force on the piston rod which can be used to operate some device. Oil from the cylinder returns to the reservoir. A filter in the circuit removes dirt and foreign matter from the oil.

As an illustration, assume that the oil pressure produced by the pump is 1,000 lb. per square inch (p.s.i.) and that the piston area

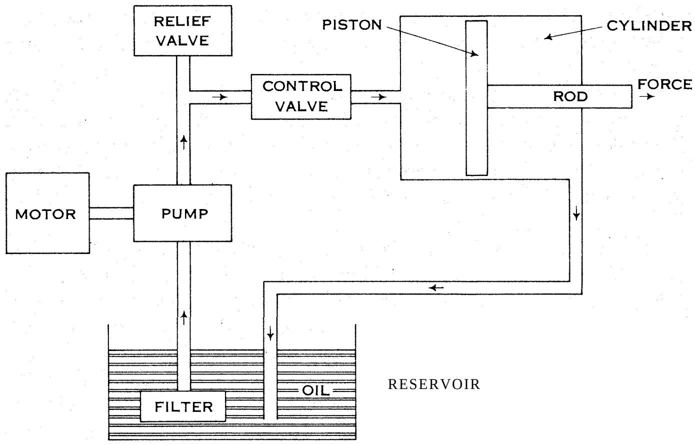

FIG 3 — COMPONENTS OF A HYDRAULIC SYSTEM

over which the oil pressure acts is 3 sq.in. The force on the piston then is $3 \times 1{,}000$, or 3,000 lb. Thus, a relatively small pressure, acting on a small cylinder, produces a relatively large force to act on some load.

Fig. 3 also illustrates the principle of the hydraulic amplifier. Assuming that the pump produces a pressure of 1.000 p.s.i in the system. as above, and that a force of 8 oz. is required to move the control valve through its entire range, from fully closed to fully opened, the 8-oz. force can be used to vary the output force on the piston through a range of 0–3,000 lb.

General Features of Hydraulic Systems. — There are three basic parts in the typical hydraulic system: (1) an oil pump; (2) a cylinder or chamber having an actuating piston driven by the liquid; and (3) valves and piping to control the flow of the liquid. The actuating piston can be given any motion desired for control and power. Straight-line reciprocating motion is common. and rotary motion of the driven unit can be accomplished with different hydraulic motors. With these basic features in mind, it is possible to develop different combinations of the simple system.

Hydraulic Pumps and Motors. — In the electric generator, mechanical energy is converted into electrical energy. In the fluid pump, mechanical energy is converted into fluid energy. Therefore, the electric generator and the pump are analogous. Likewise, both the electric motor and the hydraulic motor produce mechanical work, the former from electrical energy, the latter from mechanical energy. The fluid motor may be of either the reciprocating or the rotary type.

Hydraulic machines are of two principal kinds: the dynamic or velocity machine and the positive-displacement or static-pressure machine. In the dynamic or velocity type the action between some mechanical part and a fluid involves significant changes in fluid velocity. The electric fan and the automobile torque convertor are examples of the dynamic type.

In the positive-displacement or static-pressure machine the characteristic action is a volumetric change or a displacement action. The hand bicycle pump is an example of the displacement type of hydraulic machine. A positive-displacement machine may have either a fixed or a variable displacement. For example, the internal-combustion engine involves a crank, connecting rod, and piston; the piston displaces a certain fixed volume in the cylinder with each revolution of the crank. If the stroke could be varied, then the displacement could be varied.

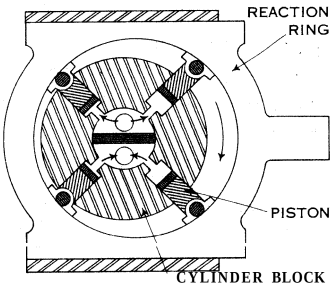
The basic hydraulic machine is the common plunger pump. It consists of a cylinder fitted with a reciprocating piston, and valves for directing the liquid to and from the cylinder. When acting as a pump, the piston does work on the liquid; the pressure is increased. When functioning as a motor, the liquid does work on the piston.

In a rotary hydraulic pump, work is done by a rotating member on the fluid; the pressure at the outlet is higher than the pressure at the inlet. In a rotary hydraulic motor, fluid pressure at the inlet is higher than fluid pressure at the outlet; the difference in fluid pressure is absorbed by the rotating member to turn the out- shaft. Rotary machines are usually classified into three main types, according t the design of the rotating element: , vane or piston.

The hydraulic gear pump or motor has a pair of meshing gears in a casing. As the gears rotate, liquid passing through the inlet is trapped between their teeth and the casing and is carried around to the outlet. During each revolution of the gears a certain volume of liquid is transferred from inlet to outlet, so this is a fixed-displacement machine.

The hydraulic vane pump or motor has a rotating member fitted with sliding vanes and set off-centre in a casing. The entering liquid is trapped between the vanes (which ride on the inside of the case) and is carried to the discharge. Both the gear machine and the vane machine are described further in the article PUMP.

Fig. 4 shows the design principles of a hydraulic radial-piston pump or motor. The stationary reaction ring and the rotating cylinder block have centres which do not coincide. As the cylinder block rotates, the pistons in the cylinder block execute a reciprocating motion in a radial direction. By means of a valve arrangement, the liquid moves in and out of the machine at the centre of the cylinder block. The displacement of this machine can be varied by altering the distance between the centres of the cylinder block and the reaction ring.

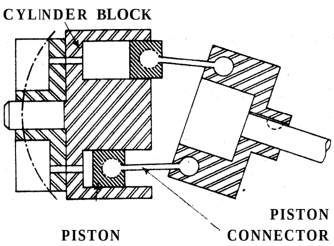


AFTER E F WRIGHT, "PUMPS,' "MECHANICIL ENGINEERS, HANDBOOK"; REPRODUCED BY PER. MISSION OF MCGRAW-HILL BOOK COMPANY, INC.

FIG. 4.— HYDRAULIC RADIAL-PISTON PUMP OR MOTOR

Various arrangements of axial-piston machines have been devised. Fig. 5 illustrates the features of one arrangement of a hydraulic axial-piston pump or motor. The pistons move back and forth in the cylinder block in a direction parallel to the axis of rotation of the cylinder block; this explains the term "axial-piston." The liquid enters and leaves the piston chambers, or bores, at the left end of the cylinder block, which is suitably arranged with a valve plate. The axis of the rotating shaft (either driver or driven) is set at an angle with respect to the axis of rotation of the cylinder block. As the shaft rotates, the piston connector actuates the piston; in one revolutibn of the shaft, each piston has reciprocated back and forth. This machine can be arranged for a variable displacement by varying the angle.

Standard gear pumps and motors are available for pressures of 2,000 p.s.i. or more, and gear motors are rated to deliver up to 20 h.p. Vane pumps and motors are made for the same pressures, and vane motors will deliver up to 125 h.p. Rotary piston pumps and motors are built for pressures of 5,000 p.s.i. or more, and the motors have outputs of as much as 150 h.p.



AFTER E F WRIGHT. "PUMPS," "MECHANICAL ENGINEERS HANDBOOK REPRODUCED BY PER. MISSION OF MCGRAW HILL BOOK COMPANY, INC.

FIG. 5.— HYDRAULICAXIAL-PISTON PUMP OR MOTOR

Valves.—In hydraulic systems one of the most common types of valve is the piston or spool valve (fig. 6). As shown in the figure, fluid enters port A, passes through the valve body and leaves at port B. By sliding the valve stem, the ports A and B could be blocked by a spool. Various arrangements of ports and spools can be used to get different types of flow control.

Accumulators.—Some hydraulic systems include an accumulator, which is a device for storing fluid energy. An air accumulator is a closed chamber, partly filled with air, into which the pump supplying hydraulic power to a machine delivers liquid while the machine is not working at full capacity. Such an air cushion is used on many reciprocating water pumps. The main purpose of the accumulator is to allow hydraulic machines, such as lifts and

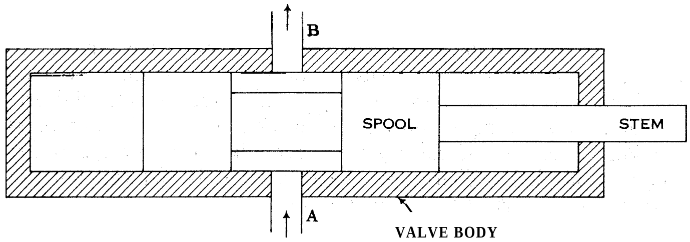


FIG. 6.— PISTON OR SPOOL VALVE

presses, to work for a short time at a greater rate than the pump can supply energy. The accumulator acts as a pressure regulator; it serves to damp out pressure surges and shocks in the system.

Hydraulic **Transmissions.**—Various methods can be used to connect two rotating shafts. In many cases purely mechanical connectors are suitable: gears, chain drives, clutches. In other applications, however, service requirements are best met with some form of hydraulic connector or transmission. In practice two types of hydraulic transmissions are commonly found: (1) the static or displacement transmission; and (2) the hydraulic, hydrodynamic or dynamic coupling.

Displacement Transmission.—The hydraulic displacement transmission is a combination of a rotary pump and a rotary motor connected by piping. The pump may be some distance from the motor, or the two may be mounted in a single housing.

This type of transmission has several advantages For example, the output shaft can be maintained at a constant speed despite a varying input-shaft speed. The direction and speed of the output shaft can be controlled remotely and accurately, and a fixed power output can be maintained over a range of speeds. Automatic overload protection can be maintained, and power consumption can be kept low.

There are four major combinations of pump and motor in a displacement-type transmission.

In the first, a variable-displacement rotary pump is connected to a fixed-displacement hydraulic motor. For a constant work load, a variation in the output-shaft speed will result in an almost constant output torque and variable power. Constant-torque hydraulic transmissions are used on machine tools and conveyors.

A second arrangement couples a fixed-displacement rotary pump with a fixed-displacement rotary motor; there is a flow-control valve in the connecting line to vary the rate of oil flow to the motor. If the load on the output shaft is constant, the output torque will be constant and the power will vary proportionally with the speed.

In a third arrangement, a fixed-displacement pump is connected to a variable-displacement motor. There are various applications, as in machine-tool spindle drives, in which it is desired to maintain constant output power as the output speed is varied. This condition can be realized by varying the hydraulic motor displacement; in this case the output torque decreases as the speed increases.

Finally a variable-displacement pump may be connected to a variable-displacement motor. This combination gives different variations in output-shaft speed, torque and power.

Hydraulic Coupling.—A hydraulic coupling is a combination of a centrifugal pump and a hydraulic turbine. It is sometimes called a hydraulic flywheel, primarily because it reduces torsional vibrations. The action of a hydraulic coupling can best be illustrated by two ordinary electric fans set facing each other. One fan is started by switching on the electric current; its blades rotate, the air flow turning the blades of the other fan. In the hydraulic coupling, the rotating input or primary shaft drives a centrifugal-pump runner or impeller. This usually has straight radial vanes or blades; in construction it resembles a grapefruit half, with the fruit removed. As the pump runner builds up speed, kinetic energy is added to the fluid, which flows outward along the vanes, crosses a gap and enters the turbine runner. Usually the turbine runner is similar in construction to the pump impeller, with straight radial blades. After sufficient energy has been developed, the liquid turns the turbine runner, which is connected to output or secondary shaft. There is no mechanical connection between the input and output shafts; the linkage between them is solely through the medium of the moving fluid.

Since there are no torque-reacting members in the hydraulic coupling other than the pump impeller and the turbine runner, the output torque always equals the input torque for steady operating conditions. The speed of the input shaft always exceeds that of the output shaft. At the start of operation, the input shaft rotates while the output shaft remains stationary; the "slippage" is 100% ; at normal speeds and loads: the slip may be low as 1%–4%. The efficiency of the coupling is defined as the ratio of the power output to the power input. At ,normal speeds and loads, the efficiency of a hydraulic coupling is high; it may be 95%–99%. Torsional vibrations or shocks on either shaft of the hydraulic coupling are damped by the fluid: The load on the output shaft may be stalled without stalling the driver or input shaft. Hydraulic couplings have been built with capacities ranging from 1 to 36,000 h.p. In some automotive transmissions, a hydraulic coupling-is added, along with the gearbox, in the power drive between the engine and the rear wheels. The hydraulic coupling is not a substitute for the gearbox: the gearbox is used to change the torque, whereas the hydraulic coupling does not change the torque. The hydraulic coupling merely serves to cushion shocks.

A variant of the hydraulic coupling is the electromagnetic clutch, which contains a fluid suspension of paramagnetic particles (*e.g.,* a compound of iron). When an external magnetic field is applied, the fluid suspension becomes almost solidified and capable of transmitting torque. (R. C. Br.)

POWHATAN. This group of Algonkin Indian tribes in the tidewater portion of Virginia and southern Maryland had been melded into a confederacy by the conquests of an able chief known by the same name, shortly before the settlement of Jamestown in 1607. His daughter Pocahontas (*q.v.*) married John Rolfe. After Powhatan's death the Indians massacred 347 British settlers in 1622. Fourteen years of relentless warfare followed until the Indians submitted, only to rise again in 1641 and slay 500 whites. The war that followed broke them, and though in 1669, 2.100 remained of the original 8,000, they dwindled to about 700. mixed with Negroes and whites, and were known as Chickahominy, Pamunkey and by other tribal names. (A. L. K.; X.)

POWIS, EARLS AND MARQUESSES OF. Before the Norman Conquest the Welsh principality of Powis, comprising the county of Montgomery and parts of the counties of Brecknock, Radnor, Shropshire, Merioneth and Denbigh, was subject to the princes of North Wales. Early in the 12th century it was divided into upper and lower Powis. In 1283 Owen ap Griffith, prince of upper Powis, is said to have formally resigned his princely title (*nomen et circulum principatus*) and his lands to the English king Edward I at Shrewsbury, and received the lands again as an English barony. This barony of Powis passed through female inheritance to the family of Cherleton and in 1421 to that of Grey. It fell into abeyance in 1551.

In 1587 Sir Edward Herbert (d. 1595), a younger son of William Herbert, earl of Pembroke, purchased some of the lands of the barony, including Red castle, afterward Powis castle, near Welshpool, and in 1629 his son William (c. 1573–1656) was created Baron Powis. William's grandson. William, the 3rd baron (*c.* 1626–1696), was created earl of Powis in 1674 and Viscount Montgomery and marquess of Powis in 1687. As one of the leading members of the Roman Catholic aristocracy in England, Powis was accused of complicity in some of the alleged popish plots and was imprisoned in the Tower of London from 1678 to 1685. Me followed James II into exile and was created duke of Powis by the dethroned king. William. 2nd marquess, who had a somewhat chequered career as a Jacobite, died in October 1745, and when his son William, the 3rd marquess, died in 1748 the titles became extinct.

In 1748 Henry Arthur Herbert (c. 1703–72), who had been made Baron Herbert of Cherbury in 1743, was created Baron Powis and earl of Powis. The titles became extinct a second time when his son George Edward died in January 1801. George's sister and heiress, Henrietta Antonia (1758–1830), married Edward Clive (1754–1839), son and heir of the great Lord Clive. In 1804, he was created Baron Powis and earl of Powis.

P'O-YANG, a lake in northern Kiangsi province, China, is a rapidly silting up flood reservoir for the Yangtze river at the northern end of the basin, the drainage of which coincides with the area of Kiangsi province in central China. The lake covers an area of 1,073 sq mi. and is 70 ft. deep at high water. but shrinks greatly during the dry winters. Through its flood plain flows its chief river, the Kan Chiang. from the south. the Lo-an Shui and Hsin Chiang from the east, and the Hsiu Shui from the northwest. River steamboats navigate between the lower reaches of these and the narrow northern P'o-yang arm to reach the Yangtze at Hu-k'ou. (H. J. Ws.)

POYNMGS, SIR EDWARD (1459–1521), lord deputy of Ireland. was the only son of Robert Poynings. second son of the 5th Baron Poynings. His mother was a daughter of Sir William Paston. and some of her correspondence is to be found in the *Paston Letters.* Robert Poynings was implicated in Jack Cade's rebellion, and Edward was himself concerned in a Kentish rising against Richard III. which compelled him to escape to the continent. He attached himself to Henry, earl of Richmond, afterward King Henry VII, with whom he returned to England in 1485. Poynings was employed by Henry VII in the wars on the continent, and in 1493 he was made governor of Calais. In the following year he went to Ireland as lord deputy under the viceroyalty of Prince Henry, afterward King Henry VIII. Poynings immediately set about anglicizing the government of Ireland, which he thoroughly accomplished, after inflicting punishment on the powerful Irish clans who supported the imposture of Perkin Warbeck. He then summoned the celebrated parliament of Drogheda, which met in December 1494, and enacted the "Statutes of Drogheda." famous in Irish history as "Poynings's law," subordinating the Irish legislature to that of England, till its repeal in 1782. After defeating Perkin Warbeck at Waterford and driving him out of Ireland, Poynings returned to England in 1496, and was appointed warden of the Cinque Ports. He was employed both in military commands and in diplomatic missions by Henry VII. and later by Henry VIII. his achievement being the negotiation of the "Holy League" in 1513.

Gilbert, *History of the Viceroys of Ireland* (1865) ; J. A. Froudc, *The English in Ireland,* 3 vols. (1872–74) ; Wilhelm Busch, *England Under the Tudors,* ed. by James Gairdner (189;).

POYNTER, SIR EDWARD JOHN, 1st Bart. (1836–1919), English painter. son of Ambrose Poynter, architect, was born in Paris on March 20. 1836. He pursued his art studies in England and in Paris (under Gleyre. 1856–59), and exhibited his first picture at the Royal Academy in 1861. He became a member of the Royal Academy in 1876.

In .the decorative arts he practised freely as a designer in fresco, mosaic. stained glass. pottery, tilework and the like.

Poynter proved himself a vigorous and successful administrator, in 1894 becoming director of the National gallery. Under his rule the National Gallery of British Art. at Millbank. presented by the late Sir Henry Tate. became a department of the National gallery. He edited the great *Illustrated Catalogue* of *the National Gallery* (1889–1900). in which every picture in the collection was reproduced. On the death of Sir John Millais in 1896, Poynter was elected president of the Royal Academy and was knighted. He was made a baronet in 1902. Poynter died in London on July 26, 1919.

POYNTING, JOHN HENRY (1852–1914), British physicist and experimenter in gravitation, was born at Monton, near Manchester, on Sept. 9, 1852. He studied at Owens college, Manchester, and at Trinity college, Cambridge. He was bracketed third wrangler in 1876. Poynting went as demonstrator in physics to Owens college, but returned to Cambridge in 1878 on his election as fellow of Trinity college. In 1880 he was appointed professor of physics at the Mason college, which afterward became the University of Birmingham. He retained this post until his death at Birmingham on March 30, 1914.

Poynting carried out experiments over a period of 12 years to determine the gravitational constant and the mean density of the earth. He used a balance method and during the course of his experiments added considerable knowledge to the technique of accurate weighing. (*See* GRAVITATION: Poynting's Experiment.) Poynting's best-known work is that in the papers "On the Transfer of Energy in the Electromagnetic Field" (Phil. Trans. *A.*, 1884) and "On the connection between Electric Currents and the Electric and Magnetic Induction in the Surrounding Field" (*Phil.* Trans *A.*, 1888). In the first paper Poynting showed that the flow of energy at a point could be expressed by a simple formula in terms of the electric and magnetic forces at that point. This is known as Poynting's theorem and the vector is also called by his name. Poynting also wrote papers on radiation and the pressure of light and several books.

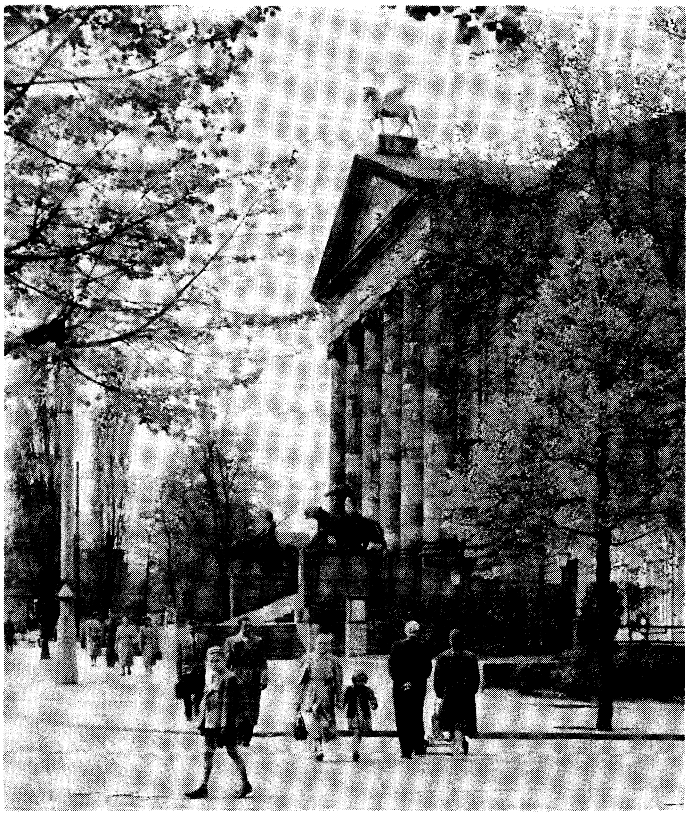
POZAREVAC or PASSAROWITZ, the capital of the Pozarevac department of Serbia, Yugoslavia. Population (1961) 24,290. It lies 8 mi. from its harbour, Dubravitsa, on the Danube. The town has no special industry, but being a road centre, is the principal market of a large and fruitful plain. At Lubichevo, 2 mi. W., is a state model farm, a stud farm, and a nursery for mulberries. Lignite is worked at Kostolats, 7 mi. N. by E., and the hills in this district show many traces of Roman mines. Roman coins, sarcophagi and inscriptions are also found. The famous Treaty of Passarowitz between Austria and Turkey was signed there in 1718. The town was taken by the Serbs under Kara George in 1804, and in 1815 Prince Milosh of Serbia again defeated the Turks there. Germans occupied it in April 1941.

POZNAN, one of the oldest cities of Poland, the chief town of Poznan province (*wojewodztwo*) and the see of a Roman Catholic archbishopric, is situated on a uide plain on the Warta, a tributary of the Oder, 174 mi. W. of Warsaw and 146 mi. E. of Berlin. Area 84.6 sq.mi. Pop. (1950) 320,670; (1960) 407,800.

The oldest part of the city lies in the fork formed by the two arms of the Warta (here flowing northward) and the Cybina, its right bank tributary. It became known as the Cathedral Island or Ostrow *Tumski.* There, in 968, the first Roman Catholic cathedral of Poland was erected in Romanesque style. It was rebuilt in Gothic style in the 14th and 15th century and again in the 18th century. Badly damaged during the 1945 fighting, it was rebuilt in Gothic style. The Golden chapel (1837), a Raczynski foundation, escaped destruction; it contains the tombs of the first two kings of Poland, Mieczyslaw or Mieszko I and Boleslau I the Brave. The smaller Gothic St. Mary's church (1434) and the baroque archbishop's palace (1732) stand nearby.

In the 13th century a new town (now known as the Old Town or *Stare Miasto*) began to grow on the left bank of the Warta Its centre was occupied by the Old Market place with a town hall built about 1300 in Gothic style; after the great fire of 1536 it was rebuilt in 1556–60 in Renaissance style; destroyed in 1945 it was restored to its former magnificence to become a museum.

Toward the end of the 18th century the city grew farther westward. New streets were constructed around a wide rectangular square (1803) named Freedom square in 1919. The most remarkable building facing the square is the neo-classic Raczynski library (1829); this, too, was destroyed in 1945 and rebuilt in 1956. In 1905–10 William II, the German emperor, built in the



PHOTOGRAPH, EASTFOTO

POZNAN OPERA HOUSE

western part of the city a neo-Romanesque castle, which after Poland's restoration housed some faculties of the university and became the new city hall after 1945. The city walls, built by the Germans in the mid-19th century, were dismantled in 1902 and replaced by a green belt, but the citadel on the north side remained. The town area was increased by including the suburbs of Srodka (east), Wilda (south), Jezyce and Lazarz (west) and Gorczyn (southwest). In 1921 the administrative area covered 25.5 sq.mi. and the population was 169.422, including 9,392 Germans and 2,088 Jens. Between World Wars I and II Poznan grew considerably in size and its population increased by more than 100.000.

Poznan has a university founded in 1919, a college of engineering, a medical academy, a higher school of agriculture and five other institutions of higher education. It is the seat of an association of sciences founded in 1857. It has an astronomic observatory, five museums, an opera house and five theatres.

Poznan is an important communications centre lying on the Berlin-Warsaw main railway line. It is also linked by rail with Danzig, Szczecin, Prague and Lodz, and by air with Warsaw.

The city's industries, originally connected with agriculture, were considerably developed after 1918, when the Hipolit Cegielski plant, founded in the mid-19th century, was enlarged to build heavy machinery. A tire and chemical factory were also established. In 1921 the Poznan fair was inaugurated and from 1925 it acquired an international importance.

History.—Poznan was founded as a fortified place with a castle in the 10th century. It became the see of the first Polish bishop (968) and the first (together with Gniezno) capital of Poland. In 1253 Poznan was granted municipal autonomy and in 1394 King Wladyslaw II Jagiello gave the city staple right (see STAPLE) for all wares passing from Poland into Germany and from Germany into Poland. The German settlers, who began to arrive about 1250, were gradually assimilated. From the mid-15th century to the beginning of the 17th century the city prospered and became a centre of the Polish Renaissance and Reformation movement. The Lubranski academy, the first humanist institution of higher education in Poland, was founded there (1519).

The Swedish wars of the mid-17th century and the Great Northern war at the beginning of the 18th century ruined the city. Its revival at the end of the 18th century was interrupted by its annexation to Prussia in 1793. From 1807 to 1815 Poznan was part of the duchy of Warsaw, afterward reverting to Prussia.

Under the German regime, especially during 1830–48, the city was a centre of Polish cultural and social progress and political conspiracy. After the unsuccessful rising of 1848, measures of repression against Polish organizations followed, but a resolutely anti-Polish and anti-Roman Catholic policy on a large scale was originated by Otto von Bismarck, and was carried out after 1871. Poznan then became the bulwark of the Poles in their successful struggle against germanization. In 1886 the Commission on Colonization was established in the city to buy up Polish land for German colonists. The Poles countered by co-operative credit organizations in which both peasants of the countryside and the middle class of the town took a prominent share. Aleksander Jackowski (1816–1905) and Father Piotr Wawrzyniak (1849–1910) were the main organizers of this economic resistance movement; soon the Poles succeeded in buying more land than they lost.

In 1894 the creation of a subsidized *Deutscher Ostnzurkenverein* (nicknamed H.K.T. by the Poles from the initials of its three founders) for the promotion of German advance in the east, the great increase of the funds at the disposal of the Commission on Colonization, the financing of a campaign against the Polish middle class—all proved insufficient: and Bernard von Bülow, the German chancellor, brought, in 1904 and 1908, new legislative means to bear. but they were largely rendered futile by the disciplined organization of the entire Polish element, as well as by its continuous growth. Poznan and its countryside shared in the material progress of Germany after 1871. Between that year and 1910 the city's population increased from 56,000 to 156,000.

On Dec. 27, 1918, the city rose against the Germans, shaking off a 103-year occupation. In Sept. 1939 the Germans returned to Poznan for more than five years. In Jan.–Feb. 1945 the city became a battlefield for the retreating Germans and the victorious Soviet forces. By the 1950s the city's rebuilding was completed. Although remaining the chief town of the province, Poznan, in 1956, became an independent administrative unit. The famous strike at the Cegielski plant on June 28, 1956, was the beginning of a national process of liberalization.

POZNANIA (Polish, POZNANSKIE), a Polish province (*wojewodztwo*), bounded north by the province of Koszalin, northeast by the province of Bydgoszcz, east by the province of Lodz, south by the provinces of Opole and Wroclaw. and west by the provinces of Zielona Gora and Szczecin. Area 10,596 sq.mi. Pop. (1960) 1,993,600.

The province is part of the central Polish plain and consists of a low plateau intersected by the Warta river, the right bank tributary of the Oder. The surface is dotted with small lakes and ponds, and there are many broad fens and swamps. The soil is light and sandy, but much of the land reclaimed in the marshy districts is very fertile. The greater part of the province is under tillage and only about 17% is occupied by forests. The principal crops are rye. wheat. oats. barley. potatoes, sugar beet. hops and tobacco. There are also excellent pastures supporting large numbers of cattle and sheep. Pigs are raised on a large scale. The mineral resources of the province are small, but there are important machine-building. chemical. cement. glass and textile industries at Poznan. Kalisz. Gniezno and Ostrow. as well as purely agricultural industries such as distilling. brewing, sugar and tobacco. Besides Poznan, the chief town. there are the following medium-sized towns in the province (pop. 1960): Kalisz (70,000), Gniezno (44,000), Ostrow (42,000), Pila (34,000) and Leszno (29,000).

History.—Poznania is the cradle of the Polish state. From very early times it has been known as *Wielkopolska,* or Great Poland, as opposed to *Malopolska,* or Little Poland, to the southeast. From 1138 to 1314 Wielkopolska was one of the autonomous Polish principalities within a form of a federal Polish state. After the re-uniting of the kingdom of Poland under Wladyslaw I Lokietek. Poznania shared the fate of the united country.

At the first partition of Poland, in 1772, the districts to the north of the Notec river fell to the share of Prussia. The rest of the province followed in 1793. In 1807, after the peace of Tilsit, the province was incorporated with the duchy of Warsaw, but in 1815 it reverted to Prussia as the grand duchy of Poznan. During the first decades after the Congress of Vienna, the Prussian regime was, on the whole, conciliatory and Prince Antoni Radziwill, a Polish nobleman, was appointed lieutenant governor of the province; there was a provincial assembly and local representative bodies. At the end of 1830, however, a new policy was inaugurated with the presidency of E. H. von Flotwell: the experiment of settling subsidized German colonists on Polish soil (started by Frederick the Great after the partition of Poland) was resumed, and the Polish language deprived of its position of equality with German in the government offices, the law courts and the schools.

In 1848 Poznania revolted against Prussian rule, but this armed rising was suppressed and a policy of stricter germanization was applied. In the period of *Kulturkampf,* from 1872–74, German became the language for all teaching. Polish was not allowed except for religious instruction and in the two first classes of the primary schools. In 1900 Polish was completely eliminated by the decision that even the catechism must be taught in German. This measure provoked, in 1901, the incident of Wrzesnia (the protest of Polish mothers who took the part of their children when the latter were beaten by the schoolmasters for refusing to say the Lord's Prayer in German) and, in 1903, the famous children's strike, which lasted for more than a year.

The sharpest battle that the Poles had to sustain in defense of their nationality was the struggle for the soil. It was marked by three laws: the Colonization lam (April 26, 1886); the law forbidding building (Aug. 20, 1904); and the Law of Expropriation (March 20, 1908). In enforcing these laws Germany spent 1,300,000,000 gold marks (mainly in Poznania, but also in Pomorze and Upper Silesia) between 1886 and 1914. Bismarck established the form of this policy, and Bernhard von Bülow continued it. But the Poles would not give in. The report of the Commission on Colonization (Ansiedelungskomnzission). prepared in 1906. on the 20th anniversary of its foundation, stated: "Incontestably the Poles have increased their material force. Their national consciousness has become stronger."

In 1910 the *Provinz Posen,* as it was called, covered an area of 11,193 sq.mi. and had a population of 2,099,831 of which, according to the German census, only 61% were Poles. These "61%," however, shortly after the armistice of Nov. 11, 1918, rose on Dec. 27 and shook off German domination.

The treaty of Versailles did not restore Poznania to Poland according to its historic frontiers. but left certain border districts in Germany. This newly defined Poznania had an area of 10.242 sq.mi. with a population of 1,967,865 (1921 census), including 327.846 Germans. Ten years later the total population was 2,106,500. including 173,500 Germans. A change in the administrative division of Poland took place on April 1, 1938. Certain northern districts of Poznania (for instance. Bydgoszcz) were given to Pomorze, while certain others, belonging previously to the province of Lodz (Kalisz. Kolo), were added to Poznania. As a result, its area was increased to 10,899 sq.mi. and its population (1931 census) to 2,339,600.

During World War II Germany annexed the whole of western Poland. Poznania was called *Gau Wartheland* and even Lodz (renamed Litzmannstadt) was added to it. After the war. when the formerly German lands east of the Oder-Seisse frontier were included in Poland. the province of Poznania was temporarily extended westward up to the Oder. but on July 6, 1950, when a new province of Zielona Gora was created in the west. Poznania returned. with a few exceptions. to its 1938 boundaries.

POZOBLANCO, a town of southern Spain in the province of Córdova. near the headwaters of the Guadamatillas and of other small subtributaries of the Guadiana. Pop. (1950) 14,773 (mun.). Its fairs are famed for their livestock and agricultural products. There are zinc and argentiferous lead mines nearby, and manufactures of cloth and leather in the town.

POZZO, ANDREA (1642–1709), Italian painter and architect, who was noted for his use of perspective. was born at Trento on Nov. 30, 1642. At the age of 24 he entered the Society of Jesus as a lay brother, and most of his work was done in painting frescoes and altarpieces for his order. After Pozzo won recognition by his painting in the dome of the Jesuit church in Turin, he was called to Rome to decorate the Church of St. Ignatius, where he did what many consider his most notable work. Pozzo died on Aug. 31, 1709.

POZZO DI BORGO, CARLO ANDREA, COUNT (1764–1842), Russian diplomatist, was born at Alata, near Ajaccio, of a noble Corsican family, on March 8, 1764, about four years before the cession of the island to France. He was educated at Pisa, and in early life was closely associated with Napoleon and Joseph Bonaparte, the two families being at that time closely allied in politics. Pozzo mas one of the two delegates sent to the National Assembly in Paris to demand the political incorporation of Corsica in France, and was subsequently a Corsican deputy to the Legislative Assembly, where he sat on the benches of the right until the events of Aug. 1792. On his return to Corsica he was warmly received by Paoli, but found himself in opposition to the Bonaparte brothers, who were now veering to the Jacobin party. Under the new constitution Pozzo was elected *procureur-général-syndic,* that is, chief of the civil government. while Paoli commanded the army. With Paoli he refused to obey a summons to the bar of the Convention, and the definite breach with the Bonaparte family, who actively supported the revolutionary authorities, dates from this time. Eventually Paoli and Pozzo accepted'foreign help, and from 1794 to 1796, during the English protectorate of Corsica, Pozzo was president of the council of state under Sir Gilbert Elliot. When Napoleon sent troops to occupy the island he was excepted from the general amnesty, and took refuge in Rome, but the French authorities demanded his expulsion and gave orders for his arrest in northern Italy. After a short stay in London he accompanied in 1798 Elliot (now become Lord Minto) on an embassy to Vienna, where he lived for six years.

In 1804, through the influence of Prince Adam Czartoryski, he entered the Russian diplomatic service. In 1805 he was Russian commissioner with the Anglo-Neapolitan, and in 1806 with the Prussian army. He was entrusted with an important mission to Constantinople in 1807, but the conclusion of the alliance between Alexander I and Napoleon at Tilsit in July interrupted his career. He returned to Vienna. but on the demand of Kapoleon for his extradition Metternich desired him to leave the capital. He then retired to London again and remained in England until 1812, when he was recalled by Alexander. He diligently sought to sow dissension in the Bonaparte household, and in a mission to Sweden he secured the co-operation of Bernadotte against Napoleon. On the entry of the allies into Paris he became commissary general to the provisional government.

At the Bourbon restoration Pozzo di Borgo became Russian ambassador at the Tuileries, and sought to secure a marriage between the duke of Berry and the Russian grandduchess Anna. Alexander's sister. He was present at the congress of Vienna, and during the Hundred Days he joined Louis XVIII in Belgium, where he was instructed to discuss the situation with Wellington. The tsar dreamed of allowing an appeal to the people of France on the subject of the government of France in accordance with his vague liberalizing tendencies, but Pozzo's suggestions in this direction were met by violent opposition, the duke refusing to make any concessions to what he regarded as rebellion: in St. Petersburg, on the other hand. Pozzo's attachment to the Bourbon dynasty was considered excessive. During the early years of his residence in Paris Pozzo laboured tirelessly to lessen the burdens laid on France by the allies and to shorten the period of foreign occupation. That his French sympathies were recognized in Paris is shown by the strange suggestion that he should enter the French ministry with the portfolio of foreign affairs.

Pozzo's influence at the Tuileries declined with the accession of Charles X. whose reactionary tendencies had always been distasteful to him; but at the revolution of 1830. when the tsar Nicholas was reluctant to acknowledge Louis Philippe, he did good service in preventing difficulties with Russia. In 1832 he visited St. Petersburg: the next year he was in London renewing his relations with Wellington, and early in 1835 he was suddenly transferred to the London embassy in succession to Prince Lieven. Although he did not lose in official standing, Pozzo was aware that this change was due to suspicions long harboured in various quarters in St. Petersburg that his diplomacy was too favourable to French interests. In London his health suffered, and he retired in 1839 to Paris, where he died on Feb. 15, 1842.

See Ouvaroff, *Stein et Pozzo* (St. Petersburg, 1846) ; *Correspondance diplomatique du comte Pozzo di Borgo et du comte de Nesselrode,* ed. by Charles Pozzo di Borgo, 2 vol. (Paris, 1890–97); Vicomte A. Maggiolo, *Corse, France et Russie. Pozzo di Borgo, 1764–1842* (Paris, 1890); J. B. H. R. Capefigure, *Les Diplomates européens,* 4 vol. (1843–47).

POZZUOLI (anc. PUTEOLI, *q.v.*), a seaport and episcopal see of Campania. It., in the province of Naples, $7\frac{1}{2}$ mi. W. of it by rail. Pop. (1957 est.) 46,434 (commune). It is on the base of a hill projecting into the Bay of Pozzuoli, separated from the main portion of the Gulf of Naples by the promontory of Posilipo. The volcanic pozzuolana earth (also found near Rome), used now as in Roman times for making cement and concrete, derives its name from the place. In the middle ages Pozzuoli was frequently sacked and also damaged by the natural convulsions of 1198 and 1538. It has large ironworks and melting furnaces.

PRABHU, the small writer caste of western India, corresponding to the Kayasth of Bengal. It stands high socially and professionally.

PRACHINBURI, is a sparsely settled province (changwat) of Thailand. Area 4,554 sq.mi. Pop. (1960) 325,089. It is located east of the Chao Phraya river delta between the hills of northeast and southeast Thailand and provides a historic corridor to Cambodia through which rival armies moved to attack each other. Most of the area is in pasture and forests. The cultivated land and population settlements, including the provincial capital, are concentrated in the northnestern part where there is heavier rainfall, better soils and irrigation facilities. The chief products are hardwood, charcoal, rice, sugar cane, horns and hides. Prachinburi, the provincial capital and river port, is 76 rail mi. from Bangkok on the trunk railroad which connects with Phnom Penh, the capital of Cambodia. As an old walled city, it was an outpost to guard the kingdom from approaching Cambodian armies or to serve as a supply depot for Thai armies moving eastward to attack Cambodia. (T. F. B.)

PRACTICE AND PROCEDURE. The practice and procedure in the English and United States courts stems from a common source, the common-law and equity procedures as developed in England from the 14th to the 18th centuries. While later innovations had considerable similarities, yet certain diversities developed in the two countries. The fact. plus the variations among the American states themselves, makes desirable the separate treatment of the subject for England and for the United States.

ENGLAND

The practice and procedure of the high court of justice in England is regulated by the Judicature act. 192j (which repealed and consolidated nearly all the former Judicature acts). and the various rules of court made pursuant to various acts passed in and since 1883. Lest the Judicature acts and rules as so framed should not provide for every contingency, it was expressly provided by rule in 1883 that "where no other provision is made by the Judicature Act or Rules the procedure and practice existing in 1883 should remain in force." The object of the Judicature acts and the rules made thereunder was to improve a system of practice and procedure which had grown up through the centuries. Although those concerned to defend the ancient order were wont to say that it made for precision, particularly in the matter of pleadings, there can be no doubt that its advantages were, or became. hidden under its chief defects—prolixity and technicality.

The following is an attempt to state, in outline, the practice and procedure in the high court in England. In the performance of his task the writer has kept one fact constantly in mind; namely, that if the reason for a particular rule or canon of procedure is appreciated. the rule will be better understood. The rules of procedure did not spring into being in a single day; they are the result of years of experience. And it will always be found that whether it be sound or not there is a reason for every rule, howsoever technical it may appear to be.

Various Forms of "Proceeding." — In the high court of justice, civil actions are begun by obtaining from the officers of the court a document known as a writ of summons. In this document are stated the names of the parties and the nature of the claim made (nhich in the case of liquidated sums of money must be precise and particular). It is sealed and issued to the party suing it out, and served on the opposing party, not by an officer of the court but by an agent of the plaintiff. The tenor of the writ is to require the defendant to appear and answer the claim, and to indicate the consequences.

Many proceedings in the high court are initiated by forms of summons different from the writ of summons. Of those issued in the high court three classes merit mention:

1. For determining interlocutory matters of practice and procedure arising in "a pending cause or matter." These are now limited as far as possible to a general summons for directions introduced in 1883 so as to discourage frequent and expensive applications to the masters or judges of the high court on questions of detail. These summonses are sealed and issued on application at the offices of the high court. The matters raised are dealt with by a master with an appeal to a judge in chambers summarily. In matters of practice and procedure there is no appeal from a judge at chambers without leave from him or from the court of appeal.

2. For determining certain classes of questions with more dispatch and less cost than is entailed by action or petition. This kind of summons is known as an "originating summons," because under it proceedings may be originated without nrit for certain kinds of relief specified in the rules (see *The* Annual Practice, 1956, p. 1041). The originating summons may be used in all divisions of the high court, but is chiefly employed in the chancery division, where it to a great extent supersedes actions for the administration of trusts or of the estates of deceased persons, and for the foreclosure of mortgages. A similar but not identical procedure was created with reference to questions of title, etc., to real property. In the queen's bench and probate divisions the originating summons is used for determining summarily questions as to property between husband and wife, or the right to custody of children, and many other matters (O. 54, rr. 4B–4F), but there is nothing to prevent a summons of this kind issuing in the queen's bench for the determination of some such question as the construction of a bill of lading. The proceedings on an originating summons are conducted summarily at chambers without pleadings, and the evidence is usually written. In the chancery division when the questions raised are important the summons is often adjourned into court. An appeal lies to the court of appeal from decisions on originating summonses. The forms of summonses and the procedure thereon in civil cases in the high court are regulated by the Rules of the Supreme Court.

3. Certain proceedings on the crown side of the queen's bench' division are begun by summons (*e.g.,* applications for bail); and in vacation writs of habeas corpus. mandamus, prohibition and certiorari are asked for by summons as the full court is not in session. (See Croun Office rules. 1906.)

Mandamus has always been regarded as an exceptional remedy to supplement the deficiencies of the common lam, or defects of justice. The writ is used to compel inferior courts to hear and determine according to lam cases nithin their jurisdiction; *e.g.,* where a county court or justices in petty or quarter sessions refuse to assume a jurisdiction which they possess to deal with a matter brought before them. It has been employed to compel municipal bodies to discharge their duties as to providing proper sewerage for their districts. etc. The courts do not prescribe the specific manner in nhich the duty is to be discharged, but 'do not stay their hands until substantial compliance is established.

At common law mandamus lies only for the performance of acts of a public or official character. The enforcement of merely psivate obligations. such as those arising from contracts, is not uithin its scope. But now a mandamus may be granted by an interlocutory order of the high court in all cases in which it shall appear to the court just or convenient that such an order should be made. (O. 53.) The remedy which is thus created is an attempt to engraft upon the old common-law remedy by damages a right in the nature of specific performance of the duty in question. It is not limited to cases in which the prerogative writ would be granted; but mandamus is not granted when the result desired can be obtained by some remedy equally convenient, beneficial and effective, or a particular and different remedy is provided by statute. An action for mandamus does not lie against judicial officers such as justices. The mandamus issued in the action is no longer a writ of mandamus, but a judgment or order having effect equivalent to the writ formerly used. (See INJUNCTION.)

Action at Law. — The term "action" in English law means at the high court of justice "a civil proceeding commenced by writ of summons or in such other manner as may be prescribed by rules of court" (*e.g*, by originating summons). The proceeding thus commenced ends by judgment and execution. The stages in an English action are the writ, by which the persons against whom relief is claimed are summoned before the court; the pleadings and interlocutory steps, by which the issues between the parties are adjusted; the trial, at nhich the issues of fact and law involved are brought before the tribunal; the judgment, by which the relief sought is granted or refused; and execution, by which the law gives to the successful party the fruits of the judgment.

The procedure varies according as the action is in the high court. a county court or one of the other local courts of record which still survive; but there is no substantial difference in the incidents of trial, judgment and execution in any of these courts.

Action Against the Crown. — Until 1947 the crown was not liable in tort. and for a breach by the state of a contract between the state and a subject, the remedy of the subject was not by action against the agents of the state who acted for the state in the making or breach of the contract. but against the crown itself by the petition of right, which was granted only on the fiat of the attorney general. By virtue of the Crown Proceedings act, 1947, however, any claim which might formerly have been enforced by petition of right may be enforced in accordance (broadly speaking) with the ordinary rules of procedure. The act further provided (by s. 2) that (subject to certain exceptions) the crown shall be liable (1) for tort committed by its servants or agents, (2) for breach of the duty which a master is liable, at common law, to his servant or agent and (3) for breach of any duty attaching at common law to the ownership, occupation, possession or control of property. It is important to notice. however, that the servant or agent here referred to must be in the paid service of the crown. This very general liability of the crown is cut down in two certain important respects. Thus no proceedings in tort lie against the crown for anything done or omitted by an officer of the post office in relation to a postal packet. The crown, however. may in certain circumstances be liable to some extent for the loss of a registered inland postal packet. Again. the act makes special provision as to the liability of the crown (in tort) for anything done or omitted by a member of the armed forces. Broadly speaking, neither the crown nor the soldier is liable for anything done by the soldier when on duty, or when on any land, premises or vehicle used for the purposes of the armed forces.

But notwithstanding all that is to be found in this act, the old maxim of the constitution—"the sovereign can do no wrong"——still prevails, for it was provided by s. 40 (1) that nothing in the act was to apply to proceedings brought against or to authorize proceedings to be brought against the sovereign in his private capacity.

The Writ of Summons. — This is the universal means of commencing an action in the high court. It is addressed to the defendant, and may be either generally or specially endorsed with a statement of the nature of the claim made. The latter form of endorsement is allowed in certain cases (see section Specially

Endorsed Writ and Summary Judgment below). The writ may be issued out of the central office or out of a district registry, and the plaintiff may name on his writ the division of the high court in which he proposes to have the case tried. There are special rules governing the issue of urits in probate and admiralty actions. The writ remains in force for 12 months, but may be renewed for good cause after the expiration of that time. Service must be personal, unless where substituted service is allowed. and in special cases, such as actions to recover land and admiralty actions. Service out of the jurisdiction of a writ or notice of a writ is allowed only by leave of a judge. Notice of the issue of a writ and not the writ itself is served on a defendant who is neither a British subject nor in the British commonwealth. The law is contained in the Rules of the Supreme Court, especially Orders ii–xi and xiv.

Appearance. — Every writ has upon it a memorandum pointing out to the defendant that he must, in due course, enter an appearance, otherwise judgment may be signed against him in default. Appearance is entered by the defendant delivering to the proper officer a memorandum stating the name of his solicitor or that he will defend in person (O. 12, r. 8). If a defendant is appearing in person (*i.e.,* without a solicitor) he may enter an appearance by posting the appearance to the proper officer (O. 12, r. 8a). He must give notice of appearance to the plaintiff or his solicitor. He must give his address for service which, if he has entered appearance in London, must be within three miles of the royal courts of justice, and if in a district registry, the address must be within the district. In the vast majority of cases the defendant leaves it to his solicitor to enter appearance for him. He may enter a conditional appearance if he disputes the jurisdiction of the court. or desires to allege some informality or irregularity in the service of the writ (O. 12, r. 30).

If the defendant does not enter an appearance and the writ has been specially endorsed (*see* below), the plaintiff may sign judgment in default for his debt and costs (O. 13, r. 3). But this rule does not apply where the defendant is an infant or a lunatic—the court, in the exercise of its parental jurisdiction, prohibiting such litigants from compromising without leave. Where, however, a defendant does not appear to a writ in which the plaintiff claims damages or other relief O. 13, rr. 5–7 (as amended in 1957) make special provision to enable the plaintiff to obtain speedy judgment. As to actions on bonds, *see* 0. 53G, r. 14. Judgment for the possession of land may be obtained as a result of default in appearance. These rules as to default, however, are subject to this—that any judgment by default may be set aside on such terms as to costs or otherwise as to the court shall seem just (O. 13, r. 10). As a general rule, however, if the judgment has been regularly signed, it will be set aside only on very stringent terms, and the defendant must show that he has a meritorious defense.

Specially Endorsed Writ and Summary **Judgment.**—Appearance having been entered, the next step is taken by the plaintiff. In any action in the chancery of queen's bench division other than one which includes (1) a claim for libel, slander, malicious prosecution, false imprisonment, seduction or breach of promise of marriage or (2) a claim based on fraud, the writ may be specially endorsed with or accompanied by a statement of claim (0. 6, r. 1). Failure to use the special endorsement may have effect to diminish the costs of a successful plaintiff in certain cases but not, for example, in a case involving a claim for damages for personal injuries. If the writ has been specially endorsed, the plaintiff may (unless the crown be defendant) issue a summons for summary judgment before a master (O. 14, r. 1). A summons for judgment must be supported by an affidavit; the plaintiff must depose that in his belief there is no defense save (in a proper case) as to the amount of damages. If the defendant does not appear, or if he appears and shows no cause to the contrary, judgment will be given forthwith by the master in chambers. Where, however, the defendant appears in answer to the summons and shows by affidavit or otherwise that he has a defense, going to the whole cause of action, leave to defend will be given, and the master will then give directions as to the further conduct of the suit. Sometimes it will appear that the defendant has no answer to part of the claim. In that case the master generally orders payment to the plaintiff's solicitors in a certain time, or judgment in default, and gives directions as to the balance. In rare cases the master will order money sought to be brought into court as a condition of leave to defend. But a plaintiff ought not to proceed for summary judgment unless he has substantial grounds for believing there is no defense to the action. Should it turn out that there is a defense of which he must, or ought to, have known, he runs the risk of having to pay the costs.

Having given leave to defend, or to enter judgment subject to suspension of execution pending trial of a counterclaim, the master must give directions for the further conduct of the proceedings pursuant to 0. 30, rr. 2 to 7. If the issue is clear and simple he has power to send it for trial into the short cause list. In that case it is set down for trial without pleadings, and it comes on for trial before a judge alone in a very short space of time. Where, however, service issues are raised necessitating an order for discovery and pleadings, directions are given providing for those matters and settling the place of trial—whether in London or at assizes. If the amount is below a certain figure, the case is generally remitted for trial in the county court, the costs being left to the county court judge. If it involves a technical or scientific inquiry, or the examination of accounts, the master may send it to an official referee. Finally, if the parties agree, he may order it to be tried before a master, who fixes a time and day and hears the whole case with witnesses. His decision on a reference of this kind is subject to an appeal to a divisional court.

From the decision of a master on a summons for judgment, an appeal lies to the judge in chambers, who may reverse or vary the master's order. It not infrequently happens that the party who is unsuccessful before the master carries in fresh evidence before the judge in chambers. From the judge an appeal lies (with leave) to the court of appeal. subject to this, that where the judge has given unconditional leave to defend, there is no further appeal of any kind.

Application for Trial Without Pleadings. — If (in certain cases, *see* below) the writ is specially endorsed the plaintiff may (instead of the notice, if any, to the defendant that if he enters an appearance he must also deliver a defense) including a notice to the defendant that if he enters an appearance, the plaintiff intends to apply for trial without further pleadings. This rule does not apply (broadly speaking) to actions for negligence, nuisance or for damages in respect of the death of any person. The application must be supported by an affidavit (O. 14B, r. 1).

Summons for Directions. — In all other cases commenced by writ and subject to an exception to be presently mentioned, the plaintiff in every action must take out a summons for directions (0. 30, r. 1). This he does seven days after the pleadings have been closed. This rule, however, does not apply to (among others) admiralty actions, or to an action where the writ is specially endorsed, or to an action for infringement of a patent. The powers conferred upon "the court or a judge" (which phrase includes a master) to give directions are very wide. It is impossible to set them all out in this place. They derive (in the main) from rules of court as revised in 1954, and the extent of the master's pou-ers is made known to the parties by the form of the summons (form 3A in appendix K to the R.S.C.) in which all the matters with which the master can deal are set out—the idea being that those that are not required to be inserted in the order shall be struck out by the master. Such directions may be given as to the future course of the action as appear best adapted to secure its just, expeditious and economical disposal. If any particular matter cannot be disposed of on the first hearing of the summons, it can be adjourned (0. 30, r. 2). On the hearing the master must consider, if necessary of his own motion (1) the amendment of pleadings; (2) the admission in evidence of statements in documents although the makers of those statements are not called as uitnesses; (3) the mode in which evidence may be given at the trial and the limitation of evidence in certain cases (0. 30, r. 3). The master must also endeavor to cause the parties to make reasonable admissions with a view to saving costs; (ibid., r. 4) and may record any agreement to limit the right of appeal (ibid., r. 5). He may order documents to be produced to him without being produced to the other side and cause any refusal to produce such a document to be recorded. but subject to this — that no document which is privileged from disclosure need be produced save with the consent of the party concerned (ibid., r. 6). When giving directions the master deals with discovery and inspection of documents, interrogatories, letters and the place and mode of trial. If a plaintiff fails to take out a summons for directions, the defendant may apply for the' action to be dismissed for want of prosecution (O. 30, r. 7 [8]).

Parties. —.All persons may be joined in one action as plaintiffs in whom any right to relief arising out of the same transaction is alleged to exist, whether jointly or severally, or in the alternative where, if such persons brought suit separately, a common question of law or fact would arise (O. 16, r. 1). Should it appear, however, that any such joinder may embarrass or delay the trial, separate trials may be ordered (*ibid.*). Again. if an action is by accident brought by the wrong plaintiff a new plaintiff may be substituted or added (O. 16. r. 2).

As regards defendant. all persons may be joined as such against whom the right to any relief is alleged to exist. whether jointly or severally or in the alternative (O. 16, r. 4). If numerous persons having the same interest in the cause or matter desire to assert or defend their rights, the court may authorize one or more of them to represent all (O. 16, r. 9). As a corollary to the above rules it is important to notice that the court has ample power to strike out parties improperly joined. and to add others who should be before the court in order that the matters in dispute may be effectually determined (O. 16, r. 11). As regards lunatics and infants the rules are strict to prevent anything in the nature of a settlement or compromise of an action save with the consent of the court or a judge. Money recovered by infant or lunatic may be; kept in court or otherwise protected for the benefit of the party concerned.

Third-Party Procedure. — It is obvious that where A has a claim against B, B may have a claim against C which arises, or which he desires to assert, only because A has brought an action against him. It would be unfortunate and would involve unnecessary expense to all parties if B were bound to refrain from suing C until A had sued him. A remedy for this is provided by what is known as third-party procedure (O. 16A. r. 48), under which, where a defendant claims contribution or indemnity against a person not a party to the action, he may, by leave, issue a third-party notice.

To that notice (which corresponds to a writ) the third party must appear, otherwise judgment may go against him by default (O. 16A, r. 1). If he does appear, suitable directions may be given so that all the questions between all the parties may be tried in the same action (O. 16A, rr. 4, 5). The third party may bring a fourth party from whom he seeks indemnity subject to the same rules as prevail in relation to third parties (O. 16A, r. 11).

Change of Parties. — An action does not abate because of the marriage, death or bankruptcy, etc., of any party thereto, if the cause of action survives (O. 17, r. 1). and nhere any marriage, etc., takes place, or there is any devolution of estate by operation of law, the court may order that the husband, personal representative, trustee or other successor to interest of any party shall be made a party and served with notice of the proceedings (O. 17, r. 2 Similarly, any person. who by reason of a marriage, death, bankruptcy or assignment after action brought acquires an interest in the dispute may apply to be made a party (O. 17, r. 4).

Several causes of action may be joined in the same action; but the court may order that there shall be separate trials if the various causes of action which appear upon the record cannot be conveniently tried together (O. 18, r. 1). This rule is subject to one notable exception; namely, that no other cause of action can be joined with an action for the recovery of land, except by leave of the court (O. 18, r. 2). Application for leave is made ex parte to a master before the writ is served.

The Pleadings. — Normally, in an action tried in the queen's bench division, "pleadings" are delivered. They consist of a statement of claim. the defense (and counterclaim, if any) and reply and, in rare cases, a rejoinder. No pleading subsequent to defense can, however, be delivered without leave.

A pleading is the term applied in English law to the preparation of the statement of the facts on which either party to a civil action founds his claim to a decision in his favour on the questions involved in the proceeding; and also to the document in which these statements are embodied. The term "pleadings" is used for the collected whole of the statements of both parties; the term "pleading" for each separate part of the pleadings.

The object of the pleadings is to secure that both parties shall know what are the real issues between them. A plaintiff must (in certain cases) deliver a statement of claim; a defendant must put in a defense and he may also plead a setoff or counterclaim. The plaintiff must (in certain cases) reply to the defense, and must put in a defense to the counterclaim. The rules of pleading are so framed as to restrict the length of pleadings as much as possible. So "every pleading shall contain, and contain only, a statement in a summary form of the material facts on which the party pleading relies for his claim or defence. as the case may be, but not the evidence by which they are to be proved." The pleader must confine himself to material facts — but an allegation may be material though it is not necessary. He must confine himself, too, to facts material at that stage of the action.

With a view to avoiding prolixity, the rules provide that a contract which is to be implied from a series of letters or conversations, or from various circumstances, may be referred to as a fact without setting out all the letters. etc., in detail. But reference to those letters, etc., and the substance of material conversation must be given. Matters of law need not be pleaded to. But even though it may necessitate a long and elaborate statement, all material facts must be set out in a pleading. If material, dates. names and items are not given, the pleader may be ordered to give particulars. A pleading may contain alternative and inconsistent allegations.

As indicated. particulars may be ordered if a pleading is not sufficiently explicit. With regard to the defense. it is seldom enough merely to traverse (*i.e.,* deny or refuse to admit) the matters in the statement of claim. For example, if the plaintiff sets up a contract which was in fact made, it would be idle for the defendant merely to deny the existence of a contract. He should. in a proper case. confess (*i.e.,* admit) the contract and avoid the effect of that confession by (1) setting up the statute of fraud or limitations or by setting up (2) that the contract has been duly performed or rescinded; or (3) that it was illegal; or (4) that some condition precedent to his liability has not been performed. In an action of debt a mere denial of the debt is expressly declared by the rules to be inadmissible; and in an action for liquidated sums the defense must deny the order or contract, the delivery or the amount claimed. Again, in an action for money had and received, the defense must deny the receipt of the money, or the existence of those facts which are alleged to make such receipt by the defendant a receipt to the use of the plaintiff. If the defendant desires to deny the right of a plaintiff to sue in a representative capacity, he must do so specifically (O. 21, r. j). While the defendant should make every denial which is really necessary, he should avoid denying matters which are really immaterial. If he does so, the court has power to make him pay any extra costs occasioned thereby (O. 21, r. 9).

A defendant may set off, or set up by way of counterclaim, any right or claim, against the plaintiff, and this has the same effect as a cross action (O. 19, r. 3; O. 21, r. 15). (But as to setoff or counterclaim against the crown, see **O.** 19, r. 3A.) Further as to counterclaim, it may be made not only against the plaintiff but against other parties to the action, and against a person who is not a party (O. 21, r. 11). But whereas a counterclaim against a plaintiff and a person already a party is merely delivered, a counterclaim involving a third party must be served on him like a writ. Such third party must appear as if he were a defendant to an action, and, having done so, may deliver a defense without any leave from the court (O. 21, r. 14). If there is a counterclaim on the record, and the original action is stayed, discontinued or dismissed, the counterclaim can nevertheless be proceeded with (O. 21, r. 16). As to defenses generally, a plea "in abatement" (*e.g.,* that a third person should have been added as plaintiff) is not allowed. Finally in an action for the recovery of land against a defendant who is in possession by himself or his tenant the defendant (unless he has some equitable defense) need only plead that he is in possession. This puts everything in issue and enables him to raise any defense—even the statute of limitations (O. 21, r. 21). The reason assigned for this (by Lord Justice William Brett, later Viscount Esher) is that the plaintiff in an action for recovery of land must recover on the strength of his own title and not through any defect in the defendant's title. "Possession is nine points of the law."

Payment Into Court.—There is no part of the procedure in civil actions more important to the litigant than that which enables a defendant to pay money into court. By a judicious payment into court a defendant may bring proceedings to an end, and so avoid the costs of what may be an expensive action. Further, if he pays in enough or more than enough to satisfy the plaintiff's claim, the plaintiff will have to bear all costs incurred subsequent to the date of payment-in.

The rules provide that in any action for debt or damages (not, *e.g.,* in an action for an account) or in an admiralty action, the defendant, at any time after appearance, may, upon notice to the plaintiff, pay into court a sum of money in satisfaction of the claim, or, where several causes of action are joined in one action, in satisfaction of one or more causes of action; and that if the defendant pleads tender, he must bring the amount tendered into court. In his notice (which must be in writing) the defendant must specify the cause of action to which the payment is related, and state whether he admits or denies liability (O. 22, r. 1). Within 14 days of a notice of payment-in, the plaintiff may, by notice, accept the payment in satisfaction. and then becomes entitled to receive payment out of court, which must be made to him or his solicitor. Thereupon the action is stayed as to the cause of action in respect of which the payment is made (ibid., rr. 2 [1] [2]). If the plaintiff accepts the amount paid in, or accepts a sum paid in respect of one cause of action, and gives notice that he abandons his other causes of action, he may tax his costs incurred down to the date of payment-in and sign judgment for those costs (ibid., r. 2 [3]). But this rule (O. 22, r. 2) does not apply to admiralty actions, or in cases where there is a plea of tender.

A special privilege is conferred on the plaintiff in an action for defamation. Having taken money out in satisfaction. he may apply for leave to make a statement in open court on terms approved by a judge (O. 22, r. 2 [4]).

One of two or more defendants sued in the same action may pay into court, but in that case, although the action is stayed as regards that defendant. the money cannot be paid out except in pursuance of an order of the court disposing of the whole action (O. 22, r. 4).

Except in certain actions for libel (see below), the fact of payment-in must not be mentioned in the pleadings or to the judge or jury until after the trial. The judge may then take the fact into account when deciding upon costs (ibid., r. 6).

This rule applies in an ordinary action for libel; but in an action for libel brought against a newspaper, the defendant may plead absence of malice, publication without gross negligence, apology and payment into court, by virture of the Libel acts, 1843 and 1845 (ibid., r. 6). In such a case, the payment into court is mentioned in the pleadings.

There is one case in which the defendant ought certainly, in his own interest, to pay money into court. This is where, in answer to a claim for a liquidated sum, he has made a tender before action. Tender of what is due is a complete defense to an action; but where there is a plea of tender upon the record, it will not avail the defendant unless he has brought the amount tendered into court. And this is good sense, because the defendant's attitude must be that he always was and still is ready and willing to pay his debt. But where money has been paid into court with a plea of tender, the plaintiff cannot terminate the action by taking that money out of court; for he will thereby admit the defense and the costs of the whole action will be the defendant's.

But it is not always necessary for a defendant to admit liability for the sum paid in. In any action of debt he may pay in without admitting liability (except when he pleads tender). This is a mere offer to secure peace, which may appear with any other defense; *e.g.,* a denial of the contract or a plea of performance.

To the general rule that it rests with plaintiff to say whether he will or will not accept money paid into court, there is an exception in any case where the plaintiff is an infant or a person of unsound mind. Acceptance of a sum paid in involves (or may involve) a compromise of the action. and the court, exercising a parental jurisdiction in such matters, will refuse to allow a compromise which may not be fair to the plaintiff. And so the court has power, not only to refuse to allow a compromise, but it may provide, by order. for the money being retained in court and invested or otherwise disposed of for the benefit of the infant (until he attains the age of 21) or lunatic as the case may be. (See generally O. 22, r. 14 [2].)

Reply and Subsequent Pleadings.—The defense having been delivered, the plaintiff may find it necessary to deliver a reply. But now a mere joinder of issue is unnecessary and (O. 27, r. 13) no reply or subsequent pleading (*e.g.,* rejoinder, surrejoinder, etc.) can be delivered without order except in certain admiralty cases (O. 23). But a reply must be delivered in certain actions for defamation (see O. 19, r. 22). A defendant must not suggest a new cause of action in his reply, for that would be what the old pleaders called a "departure." And the reason is plain. To a new cause of action the defendant must be enabled to put in a defense in accordance with the rules. A new cause of action must therefore appear in an amended statement of claim.

Cases may occur in which, although the plaintiff had a good cause of action when he issued his writ. something happened afterward to satisfy his claim or discharge the cause of action. For example, he may accept payment of the debt sued for, or a sum of money by way of compromise of a claim for damages. Such acceptance or compromise would constitute a defense. If it takes place before the expiration of the time limited for defense, the defendant may raise it in his defense, signifying that it arose since action brought (O. 24, r. 1). And even if it arises after that time, the defendant may raise it by leave (O. 24, r. 2). The plaintiff may thereupon "confess" such defense and tax his costs up to the time when it was delivered (O. 24, r. 3) unless the court shall otherwise order. A similar rule obtains with reference to a reply which sets up new matter in defense to a setoff or counterclaim. A counterclaim may be founded on facts which have arisen since action brought, but it must be phrased as so arising.

Discontinuance.—In certain circumstances an action may be discontinued, or a defense withdrawn. Thus at any time before receipt of defense, or after receipt thereof before taking any proceeding other than interlocutory (*e.g.,* a summons for particulars), the plaintiff may, without leave, by notice in writing discontinue the whole action, or withdraw any part of it as against all or any of the defendants, subject to the payment of costs (O. 26, r. 1).

Proceedings in Lieu of Demurrer.—In former days it was competent for a defendant to "demur" to the statement of claim on the ground that it disclosed no cause of action. The result was that many a claim was defeated and costs were often incurred merely because the plaintiff had not put his case in proper form. Demurrer was later abolished (O. 25, r. 1) but any party may raise a point of law by his pleading, and the point so raised shall be disposed of at or after the trial subject to this, that if the parties consent or the court so orders the point may be set down for hearing and disposed of before the trial (O. 25, r. 2). If the decision substantially disposes of the whole action, the action may be dismissed (O. 25, r. 3). This course may be conveniently adopted where it is obvious that a serious question arises as to whether the statement of claim as drafted discloses any cause of action, or the defense any answer in law to the claim.

Striking Out Pleadings.— The court may order a pleading to be struck out on the ground that it discloses no reasonable cause of action or answer (O. 25, r. 4). In any such case, or if the action or defense be shown by the pleadings to be frivolous or vexatious: it may be stayed or dismissed, or judgment may be entered for the defendant accordingly as may be just (ibid.). To succeed in such an application, an objecting party must be able to point to some defect in the pleading itself. The rule is acted upon only in plain and obvious cases. So if. in an action on a contract, it be clear that there is no contract between the plaintiff and the defendant; or no contract valid in law; or that the matter is already decided; or where the statement of claim on the face of it shows that there is a good defense: it will be struck out.

But the court will generally give a party leave to amend a pleading before striking it out. Apart from the rule above mentioned (and O. 19, r. 25, which enables anything scandalous or vexatious, or which tends to delay. etc.. the trial of an action, to be struck out) the court has inherent jurisdiction to stay all proceedings before it which are obviously frivolous or vexatious or an abuse of its process. An application to strike out on these grounds should be supported by an affidavit. Discontinuance by the plaintiff does not affect a counterclaim, but a counterclaim cannot be set up after discontinuance.

A defendant may by leave, and only by leave, and upon terms, withdraw the whole or part of his defense or counterclaim. If the defense is withdrawn, the plaintiff can sign judgment in default of defense. An application so to withdraw may be made at any time. A cause entered for trial may be withdrawn by either plaintiff or defendant upon producing a consent in writing to the proper officer (0. 26, r. 2). The plaintiff must pay the defendant's costs if he discontinue an action (0. 26. r. 3); and if he bring another action for the same or substantially the same cause. it may be stayed if the costs of the former action are not paid (O. 26, r. 4).

Default of Pleading.— The rules of pleading are enforced by this— that if a party does not plead as and when required. he may, if he is a plaintiff, have his action dismissed, if he is a defendant, have judgment signed against him. Thus if a plaintiff being bound to deliver a statement of claim does not do so within the time allowed, the defendant may apply to have the action dismissed for want of prosecution. and on the hearing of the application the court may either dismiss the action or make such order as shall be thought just (O. 27, r. 1). Where the plaintiff delivers his statement of claim after the application has been made, the court will generally make no order save that he pay the costs. The plaintiff need not deliver a statement of claim save under an order for directions. for which he must himself apply. If he does not so apply within 14 days of the defendant's appearance the defendant may have the action dismissed (0. 30, r. 8). A plaintiff may be in default in delivering a reply .and defense to a counterclaim. If so, the defendant's only remedy is to move for judgment under O. 27, r. 11, even when the counterclaim is for a liquidated demand and even if some other person has been made a defendant to the counterclaim.

A defendant may make default either in not entering an appearance or in not putting in his defense. If he has not appeared, and, the writ not being especially endorsed, he has had a statement of claim filed against him in default, he must appear and deliver his defense within ten days of the tiling of the statement of claim. Otherwise he may have judgment signed against him with costs (O. 21, rr. 2–9). In such a case, however, if the plaintiff could have signed judgment merely in default of appearance, he can only have such costs as he would have had in that case. In other words, he will not be allowed the costs of the statement of claim. If a defendant has appeared to the writ other considerations arise. If the writ was specially endorsed he must deliver a defense within ten days 'unless the plaintiff has proceeded for summary judgment (0. 21, r. 6), and in other cases if a separate statement of claim has been delivered he must deliver his defense within the time limited by the summons for directions (0. 21. r. 8).

The procedure to be adopted if the defendant has not put in a defense depends upon the nature of the action. (See generally O. 27, rr. 4–6, as amended by R.S.C. No. 1, 1957.)

Close of Pleadings.— There comes a time in every action when the pleadings are deemed to be closed. Where no reply or subsequent pleading is ordered then within four days of the delivery of the last pleading, or where a reply has been ordered within a certain time, at the end of that period the pleadings are to be deemed closed and all statements therein put in issue (0. 27, r. 13). This, however, does not apply to a reply to a counterclaim which is really a defense. Unless the plaintiff obtains leave to reply to a counterclaim, the statements of fact which it contains shall be deemed to be admitted after the expiration of ten days, unless a reply has been ordered, in which case, if the order is not complied with, the facts will be deemed to be admitted.

Amendment.— In former times the ends of justice were often defeated. and the litigant was put to an enormous amount of unnecessary expense, because the powers of the court to allow amendment of pleadings were greatly restricted. Now. however, the court or a judge may at any time, and on such terms as to costs or otherwise as may be thought right, amend any deficit in any proceedings, and all necessary amendments shall be made for the purpose of determining the real question or issue raised by or depending on the proceedings (0. 28, r. 12).

Amendment of Pleadings.— The court or a judge may at any stage of the proceedings allow either party to alter or amend his endorsement or pleadings in such manner and on such terms as may be just, and all such amendments shall be made as may be necessary for the purpose of determining the real question in controversy between the parties (0. 28, r. 1). Under this rule amendment will always be allowed, if it can be made without injustice to the other side. While a new cause of action may be introduced into the statement of claim by amendment, if the plaintiff at the same time seeks to stand on his original claim, leaving his writ unamended, this is practically a discontinuance, for the new claim is wholly unsupported by the writ. Such an amendment will only be allowed on the terms that the plaintiff pays all costs down to the time of the amendment, and that all proceedings are stayed until those costs are paid.

A common informer is but seldom allowed to amend his statement of claim in an action for penalties. Amendment is often allowed on an application to strike out a pleading as embarrassing or because it discloses no cause of action. Although, when a statement of claim is delivered the plaintiff may therein alter, modify or extend his claim without any amendment of the writ, he cannot add a claim on a wholly new and different cause of action except by leave; and if leave is given the writ should be amended. The writ or the statement of claim must be amended in one case; *i.e.*, where the plaintiff recovers by verdict of a jury more than the amount he has actually claimed. Otherwise he cannot recover the amount of the verdict. Amendment may be allowed at any time but it should obviously be made at the earliest possible moment. A defendant may have no answer to the claim as amended. A plaintiff may find it necessary to confess an amended defense and stop his action; or, where the amendment involves a payment of money into court, he may be content with the amount paid in.

A plaintiff may, in certain cases. and within a certain time, amend his statement of claim. whether endorsed on the writ or not, without leave (0. 28, r. 2). But he cannot, in the exercise of this privilege: add a cause of action which has accrued to him since the writ—although he can do that by leave. Nor can he add new parties. If he has delivered particulars with the statement of claim he can amend them under this rule; but particulars delivered otherwise can be amended only by leave. Under this rule a special endorsement can be amended provided the claim is one which can be specially endorsed. A similar rule (0. 28, r. 3) applies to a counterclaim. But it is important to notice that any amendment so made without leave may be disallowed—or allowed only upon terms—on the application of the other side if the justice of the case so requires (0. 28. r. 4).

It has been stated that amendment to statement of claim or counterclaim without leave can be made only within a certain time. All other amendments to claim or defense, or to any other pleading, can be made only by the leave of the court or a judge and upon such terms as to costs as may be just (0. 28, r. 6). If an order giving leave to amend is made and the amendment is not made within the time limited or within 14 days of the date of the order, the order is void, unless the time is extended by the court or a judge (0. 28, r. 7). Moreover, the amended pleading must be delivered to the opposite party within the time allowing the same (0. 28, r. 10).

Actions By or Against Firms.—If a firm desires to bring an action; or anyone desires to bring an action against a firm, in the firm name. special considerations arise. Broadly speaking, a firm consisting of more than one person carrying on a business within the jurisdiction may sue or be sued in the firm name. but subject to this—that the names of the partners must, if required, be revealed to the other side. Where, however, a man carries on business in a name other than his own, he can sue only in his own name, but he may be sued in the name of his firm. He must, however, reveal his true name if required. Service of process on a firm may be effected either upon any one of the partners, or upon the manager at the place of business of the firm. The person served must be told, at the time, whether he is served as a partner or as manager. A firm cannot enter an appearance as such, it must appear by one of the partners personally; but an alleged partner may appear with a denial that he is a partner. The property of the firm within the jurisdiction can be seized in execution of a judgment against the firm, and so can the property of individual partners. This is but a summary of 0. 48A, which provides a complete code of rules on the subject. It must be carefully studied by anyone who is concerned in an action by or against a firm.

Discovery.—The pleadings having been closed, the parties in most cases proceed to have discovery, either of facts or documents or both. The English common-law courts were originally unable to compel a litigant before a trial to disclose the facts and documents on which he relied. In equity, however. a different rule prevailed, there being an absolute right to discovery of all material facts on which a case was founded. Now the practice is regulated by the Rules of the Supreme Court. 1883, Order 31. Discovery is of two kinds; namely. by interrogatories and by affidavit of documents, provision being also made for the production and inspection of documents. Where a party to a suit can make an affidavit stating that in his belief certain specified documents are or have been in the possession of some other party, the court may make an order that such party state on affidavit whether he has or ever had any of those documents in his possession, or if he has parted with them or what has become of them. A further application may then be made by notice to the party who has admitted possession of the documents for production and inspection. Copies also may be taken of the more important documents. There is also discovery of facts obtained by means of interrogatories; *i.e.*, written questions addressed on behalf of one party. before trial. to the other party. who is bound to answer them in writing upon oath. In order to prevent needless expense the party seeking discovery used to have to secure the cost of it by paying into court a sum of money, but this rule was later abolished. Objection may be taken to discovery either of a fact or a document on the ground of privilege or that the matters sought to be discovered are criminatory.

Thus all documents and communications passing between a litigant and his legal advisers are absolutely privileged and need not be disclosed. Again, where an admission of a fact or the production of a document might involve the admission of a criminal offense, the litigant may refuse to give discovery. Where the opposite party is not satisfied with an affidavit of documents, or the answer to an interrogatory, he may in certain cases apply for a further and better affidavit or answer, and in some cases the master to whom the application is made will himself examine a document in order to see whether it shall be disclosed or not. The advantage of discovery lies in this—that it forces a litigant to reveal his case on oath. It is one thing to make a statement or deny a fact in a pleading. That merely has effect to put the matter in issue. It is a much more serious matter to have to swear to a fact in an affidavit, because, in the case of the answer to an interrogatory, it may be put in evidence by the opposite party at the trial. As to discovery against the crown, see O. 31, r. 5B; and as to discovery in action for libel and slander special attention should be paid to O. 31, r. 12, and to a note on p. 517 of the *Annual* Practice, 1956.

Evidence on Commission.—Cases often arise in which it is impossible because of illness or absence to secure the attendance of a witness at the trial. In such circumstances the court has power (conferred by O. 37, r. 5 et seq.) to direct that the evidence be taken anywhere before an officer of the court or any other person. It must be shown, however, that the witness will be unable to attend. either because of illness or because he is out of the jurisdiction, and cannot be compelled to attend by subpoena. Even a plaintiff may be allowed to give evidence on commission: but this is a privilege seldom granted. The evidence of the witness is written down and signed by him and can be put in at the trial. In certain foreign countries, where evidence cannot be taken on commission, it is secured by letters of request, which are sent through the foreign office.

Admission.—Although the pleadings show that everything is in issue in an action, it is competent for either party to give notice that he admits the truth of the whole or part of his opponent's case (0. 32, r. 1). This secures the costs of proving those facts, and, if the whole cause of action is admitted, enables the party to whom the admission is made to apply for judgment (0. 32, r. 6). Apart from this. either party may give notice to the other to admit facts and if he refuses to do so unreasonably he may have to pay the costs of the necessary proof of those facts (ibid., [4]). Similarly notice may be given to admit documents; indeed the costs of proving any document may be disallowed if the notice is not given (O. 32, r. 3).

Special Case.—The parties to any cause or matter may concur in stating the questions of law arising therein in the form of a special case for the opinion of the court (0. 34, r. 1), and the court may order a question of law to be decided either by special case or otherwise before any question of fact is tried (0. 34, r. 2).

Transfer and Consolidation of Action.—Action may be transferred from one division of the high court to another by an order of the court or a judge of the division in which the case is proccding (0. 49, r. 1). Causes pending in the same division may be consolidated with each other (O. 49. r. 8).

Application and Proceedings at *Chambers*.—All applications at chambers (*i.e.*, before a master or a judge) are made by summons unless they are made ex parte; that is to say, by one side only. Applications at chambers generally are regulated by O. 54, while 0. 55 prescribes the rules observed in chambers in the chancery division.

Proceedings in District Registries.—To meet the convenience of suitors who do not live in or near London, district registries have been established in various parts of the country. Proceedings can be taken in a district registry only in an action in which the writ has been issued out of that registry. Broadly speaking. the powers of a district registrar are similar to those of a master of the supreme court.

In certain cases. however, where an action has been commenced in a registry the defendant can as of right have it moved to London, and the court has power in all cases to move an action from a registry to London or vice versa. (See generally 0. 35.) Proceedings by poor persons under the Matrimonial Causes acts in district registries are provided for by 0. 35A.

Trial.—The places and mode of trial are fixed by the order made on a summons for directions. Where a case is to be tried in London. it is assigned to one of three lists—the jury list, the London nonjury list and the short nonjury list (0. 36, r. 1A and 29 [1]). The master, when making the order, tries to form an opinion as to the time which the hearing will last. As a rule a case sent to the short nonjurp list will not require more than two hours. The plaintiff must give notice of trial (0. 36, r. 11j, and if he fails to do so, within the time prescribed by the rules, the defendant may do so, or else apply to have the action dismissed for want of prosecution (O. 36, r. 12). Trial follows upon the completion of the steps necessary to bring the parties before the court and to adjust the issues upon which the court is to adjudicate, which may be summed up in the term pleading. In England the trial is usually in open court, and it is rare to try cases at chambers or to attempt to exclude the public from the hearing. In practice, hearing at chambers is ordered only where to try in open court would be to defeat the ends of justice. An action by or against the crown cannot be tried out of London without the consent of the crown (O. 36, r. 1B). In the high court of justice in England several modes of trial are now used:

1. Trial by judge with a jury used in the queen's bench division and in probate and matrimonial cases. There is a right to have a jury as a matter of course in actions of defamation, false imprisonment, malicious prosecution, seduction or breach of promise of marriage and in cases where a charge of fraud is made.

2. Trial by a judge without a jury is invariable in the chancery division and is common in other divisions. Cases in the chancery division are not tried with a jury unless a special order is made (O. 36, r. 3); and the high court in cases in which trial without jury could be ordered without consent still retains the power of so trying them, and has also acquired power to direct trial without a jury of any issue requiring prolonged examination of documents or accounts or scientific or local investigation.

3. Trial with assessors, usually in admiralty cases (the assessors being nautical). but rare in other divisions.

4. Trial by an official referee in certain cases involving much detail (R.S.C., O. 36). Formerly there was no appeal from the decision of an official referee, save on a question of law, but now, by virtue of O. 36A, r. 8, 1957, there may, in cases involving a charge of fraud, be an appeal on a question of fact.

5. Where the parties consent, trial may be had of any case in the queen's bench division before a master in chamhers.

The parties may be represented in the high court by counsel or may conduct their case in person. The trial is carried on by stating to the court the pleadings if any and by opening the plaintiff's case. This is followed by the evidence of the witnesses, who are sworn and examined and cross-examined. On the completion of the plaintiff's case and evidence, the defendant's case is stated and evidence adduced in support of it. The plaintiff or his counsel has, as a rule, the reply or last word unless the defendant has called no evidence. If when the trial is called the plaintiff appears and the defendant does not. the plaintiff may prove his case (O. 36, r. 31). If the plaintiff does not appear, the defendant may have judgment dismissing the action, and may prove his counterclaim if he has one (O. 36, r. 32). But any judgment by default may be set aside on terms.

At the conclusion the judge sums up the law and facts of the case to the jury and their verdict is returned, or if there is no jury the judge gives judgment stating his conclusion on the law and the facts involved. He then directs that judgment shall be entered as he thinks right (O. 36, r. 39), and a memorandum is endorsed on the judgment pointing out that if it is not obeyed, the defendant will be liable to process of execution (O. 41, r. 5).

Juries.—In England the trial jury (also called petty jury or traverse jury) consists of 12 jurors, except in the county court where the number is 8. Women are now summoned as jurors, but a husband and wife cannot be summoned on the same occasion. A woman may, however, claim exemption on the ground that by reason of pregnancy or some other feminine condition or ailment she is or will be unfit to serve. Either party to the suit may apply to the court for an order that the jury shall consist wholly of men or wholly of women. In civil but not in criminal cases the trial may by consent be by fewer than 12 jurors, and the verdict may by consent be that of the majority.

The jurors are selected from the inhabitants of the county, borough. or other area for which the court to which they are summoned is commissioned to act.

Exemptions from juries include members of the legislature and judges, ministers of various denominations, practising barristers and solicitors, registered medical practitioners and dentists and officers and soldiers of the regular army. Persons over 60 are exempt but not disqualified. Lists of the jurors are prepared by the overseers in rural parishes and by the town clerks in boroughs, and are submitted to justices for revision. When jurors are required for a civil or criminal trial they are summoned by the sheriff or, if he cannot act, by the coroner.

For the purpose of civil trials in the superior courts there is only one list of jurors, special juries having been abolished.

The jurors are the judges of fact upon the evidence laid before them. Their province is strictly limited to questions of fact, and within that province they are still further restricted to matters proved by evidence in the course of the trial and in theory must not act upon their own personal knowledge and observation except so far as it proceeds from what is called a "view" of the subject matter of the litigation.

While the jury is in legal theory absolute as to matters of fact, it is in practice largely controlled by the judges. Not only does the judge at the trial decide as to the relevancy of the evidence tendered to the issues to be proved, and as to the admissibility of questions put to a witness, but he also advises the jury as to the logical bearing of the evidence admitted upon the matters to be found by the jury. The rules as to admissibility of evidence, largely based upon scholastic logic! sometimes difficult to apply, and almost unknown in continental jurisprudence. coupled with the right of an English judge to sum up the evidence (denied to French judges) and to express his own opinion as to its value (denied to U.S. judges), fetter to some extent the independence or limit the chances of error of the jury.

The appellate court will not upset a verdict when there is substantial and conflicting evidence before the jury. In such cases it is for the jury to say which side is to be believed, and the court will not interfere with the verdict. To upset a verdict on the ground that there is no evidence to go to the jury implies that the judge at the trial ought to have withdrawn the case from the jury. Under modern procedure, in order to avoid the risk of a new trial, it is not uncommon to take the verdict of a jury on the hypothesis that there was evidence for their consideration, and to leave the unsuccessful party to apply for judgment notwithstanding the verdict. The question whether there was any evidence proper to be submitted to the jury arises oftenest in cases involving an imputation of negligence; *e.g.,* in an action of damages against a railway company for injuries sustained in a collision.

This statement indicates existing practice but scarcely determines what relation between the facts proved and the conclusion to be established is necessary to make the facts evidence from which a jury may infer the conclusion. The true explanation is to be found in the principle of relevancy. Any fact which is relevant to the issue constitutes evidence to go before the jury, and roughly speaking, if there is a connection, as cause and effect, between any fact and the fact to be proved, the former is relevant. As regards damages the court has always had wide powers, as damages are often a question of law. But when the amount of the damages awarded by a jury is challenged as excessive or inadequate, the appellate court, if it considers the amount unreasonably large or unreasonably small, must order a new trial unless both parties consent to a reduction or increase of the damages to a figure fixed by the court; see *Watt* v. *Watt* (1905), App. Cas. 11j.

Judgment and Execution.—Execution is allowed as a matter of course after judgment except where it has for some reason been stayed; *e.g.,* where an appeal is pending. (See generally R.S.C., O. 42.) A judgment for the recovery of money or costs is enforced. as a rule: by writ of *fieri facias* addressed to the sheriff. and directing him to cause to be made (*fieri facias*) of the goods and chattels of the debtor a levy of a sum sufficient to satisfy the judgment and costs, which carry interest at 4% per annum. The seizure effected by the sheriff or his officer, under this writ. of the property of the debtor. is what is popularly known as "the putting in" of an execution. The seizure should be carried out with all possible dispatch. The sheriff or his officer must not break open the debtor's house in effecting a seizure, for "a man's house is his castle"; but this principle applies only to a dwelling house, and a barn or outhouse unconnected with the dwelling house may be broken into. The sheriff on receipt of the writ endorses it on the day, hour, month and year when he received it; and the writ binds the debtor's goods as at the date of its delivery, except as regards goods sold before seizure in market overt, or purchased for value, without notice before actual seizure (Sale of Goods act, 1893, s. 26, which supersedes s. 16 of the Statute of Frauds and s. 1 of the Mercantile Law Amendment act. 1856).

This rule is limited to goods, and does not apply to the money or bank notes of the debtor which are not bound by the writ till seized under it (Johnson v. Pickering, Oct. 14, 1907, C.A.). The mere seizure of the goods, however, although, subject to such exceptions as those just stated, it binds the interest of the debtor, and gives the sheriff such an interest in the goods as will enable him to sue for the recovery of their possession, does not pass the property in the goods to the sheriff. The goods are in the custody of the law. But the property remains in the debtor who may get rid of the execution on payment of the claim and fees of the sheriff. The wearing apparel, bedding, tools, etc., of the debtor to the value of £5 are protected. Competing claims as to the ownership of the goods seized are brought before the courts by the procedure of "interpleader." In the queen's bench division, the sheriff issues a summons before a master in chambers calling upon the execution creditors and claimant to appear and state their respective cases. If the claim is not admitted by the execution creditor, an issue is directed to try the merits and either party may ask the master to try the issue himself. This he generally does at the earliest possible opportunity, for the sheriff being in possession, costs are mounting up. Otherwise the "issue" is reported for trial to the high court or county court, the claimant being directed to bring the amount of the sheriff's valuation into court. That money being in coyrt, the sheriff withdraws. After seizure the sheriff must retain possession, and, in default of payment by the execution debtor, proceed to sell. Where the judgment debt, including legal expenses, exceeds £20, the sale must be by public auction, unless the court otherwise orders, and must be publicly advertised. The proceeds of sale, after deduction of the sheriff's fees and expenses, become the property of the execution creditor to the extent of his claim.

Under the law of bankruptcy, the sheriff, in case of sale under a judgment for a sum exceeding £20, is required to hold the proceeds for 14 days in case notice of bankruptcy proceedings should be served upon him. (See BANKRUPTCY.) Imprisonment for debt in execution of civil judgment was abolished except in cases of default in the nature of contempt, unsatisfied by judgments for penalties, defaults by persons in a fiduciary character and defaults by judgment debtors.

Writ of *Elegit*.—The writ of elegit is a process enabling the creditor to satisfy his judgment debt out of the lands of the debtor. It derives its name from the election of the creditor in favour of this mode of recovery. It is founded on the Statute of Westminster (1285, 13 Ed. I. c. 18), under which the sheriff was required to deliver to the creditor all the chattels (except oxen and beasts of the plow) and *half* the lands of the debtor until the debt was satisfied. By the Judgments act, 1838, the remedy was extended to all the debtor's lands, and by the Bankruptcy act, 1883 (now replaced by the Bankruptcy act, 1914), the writ no longer extends to the debtor's goods. The writ is enforceable against legal interests whether in possession or remainder but not against equitable interests in land. When the debtor's interest is equitable recourse is had to equitable execution by the appointment of a receiver or to bankruptcy proceedings. (See R.S.C., O. 43.)

Writs of Possession and Delivery.—Judgments for the recovery or for the delivery of the possession of land are enforceable by writ of possession. The recovery of specific chattels is obtained by writ of delivery (R.S.C., O. 47, 48).

Writ of *Sequestration*.—Where a judgment directing the payment of money into court, or the performance by the defendant of any act within a limited time, has not been complied with, or where a corporation has wilfully disobeyed a judgment, a writ of sequestration is issued, to not less than four sequestrators, ordering them to enter upon the real estate of the party in default, and to "sequester" the rents and profits until the judgment has been obeyed (R.S.C., O. 43, r. 6).

Equitable Execution.—Where a judgment creditor is othenvise unable to reach the property of his debtor he may obtain equitable execution, usually by the appointment of a receiver, who collects the rents and profits of the debtor's land for the benefit of the creditor (R.S.C., O. 1, rr. 15A–22). But receivers may be appointed of interests in personal property belonging to the debtor by virtue of the Judicature act, 1873, s. 25 (8). The plaintiff may apply ex parte for leave to issue a summons for the appointment of a receiver and for an injunction to restrain the defendant from parting with his property pending the hearing of the summons. Such an application may be heard by a master.

Attachment.—A judgment creditor may "attach" debts due by third parties to his debtor by what are known as garnishee proceedings. A garnishee order nisi may be made by a master of the queen's bench on the application of the judgment creditor. It must be supported by an affidavit in which the judgment creditor or his solicitor swears positively that there is a debt owing by the garnishee to the judgment debtor. Money on current or deposit account at a hank, may be attached, but subject, in the case of money on deposit. to a new rule (0.4'5. r. 10) made in 1957. Stock and shares belonging to a judgment debtor may be charged by a charging order, so as, in the first instance, to prevent transler of the stock or payment of the dividends. and ultimately to enable the judgment creditor to realize his charge.

A writ of attachment of the person of a defaulting debtor or party may be obtained in a variety of cases akin to contempt (*e.g.*, against a person failing to comply with an order to answer interrogatories, or against a solicitor not entering an appearance in an action, in breach of his written undertaking to do so), and in the cases where imprisonment for debt is still preserved by the Debtors act, 1869 (R.S.C.O. xliv). Contempt of court in its ordinary forms is also punishable by summary committal (see CONTEMPT [LEGAL]).

Another form of execution analogous to the attachment of a debt is a charging order. This directs that any stock, funds or shares of a public company in England, standing in the name of a debtor in his own right or in the name of any person in his trust for him, shall stand charged with the payment of the judgment debt and interest. The charge cannot be enforced for six calendar months after the order (O. 46, r. 1).

Interpleader.—This in English law is the form of action by which a person, who is sued at law by two or more parties claiming adversely to each other for the recovery of money or goods wherein he has no interest, obtains relief by procuring the rival claimants to try their rights between or among themselves only. Originally the only relief available to the possessor against such adverse claims was by means of a bill of interpleader in equity. The Interpleader act, 1831, enabled the defendant in such cases, on application to the court, to have the original action stayed and converted into a trial between the two claimants. The Common Law Procedure act of 1860 further extended the power of the common-law courts in interpleader; and the Judicature act, 1875 (repealed and re-enacted by the Judicature act! 1925), provides that the practice and procedure under these two statutes should apply to all divisions of the high court of justice. The Judicature act also extended the remedy of interpleader to a debtor or other person liable in respect of a debt alleged to be assigned, when the assignment was disputed. In 1883 the acts of 1831 and 1860 were embodied in the form of rules by the Rules of the Supreme Court (1883), O. 47, by reference to which all questions of interpleader in the high court of justice are now determined. Interpleader is the equivalent of multiplepoinding in Scots law.

Costs.—When giving judgment in England, the judge usually deals with the costs of the action, as to which he has an absolute discretion, although it must, of course, be exercised judicially. The term "costs" denotes the expenses incurred (1) in employing a lawyer in his professional capacity for purposes other than litigation; (2) in instituting and carrying on litigation whether with or without the aid of a lawyer.

The retainer of a solicitor implies a contract to pay to him his proper charges and disbursements with respect. to the work done by him as a solicitor. In cases of conveyancing his remuneration is for the most part regulated by scales according to value on the value of the property dealt with (Solicitors' Remuneration order, 1882), and clients are free to make written-agreements for the conduct of any class of nonlitigious business, fixing the costs by a percentage on the value of the amount involved. So far as litigious business is concerned, the arrangement known as "no cure no pay" is objected to by the courts and the profession as leading to speculative actions, and stipulations as to a share of the proceeds of a successful action are champertous and illegal. An English solicitor's bill drawn in the old form is a voluminous itemized narrative of every act done by him in the cause or matter with a charge set against each entry and often against each letter written. Before the solicitor can recover from his client the amount of his charges. he must deliver a signed bill of costs and wait a month before suing.

The high court has a threefold jurisdiction to deal with solicitors' costs: (1) by virtue of its jurisdiction over them as its officers: (2) statutory, under the Solicitors act, 1843, and other legislation: (3) ordinary, to ascertain the reasonableness of charges made the subject of a claim.

The client can. as a matter of course, get an order for taxation within a month of the delivery of the solicitor's bill, and either client or solicitor can get such an order as of course within 12 months of delivery. After expiry of that time the court may order taxation if the special circumstances call for it, and even so late as up to 12 months after actual payment.

Costs as between solicitor and client are taxed in the same office as litigious costs, and objections to the decisions of the taxing officer, if properly made, can be taken for review to a judge of the high court and to the court of appeal.

The expenses of litigation fall in the first instance on the person who undertakes the proceedings or retains and employs the lawyer. It is in accordance with the ordinary ideas of justice that the expenses of the successful party to litigation should be defrayed by the unsuccessful party, a notion expressed in the phrase "costs follow the event." But there are many special circumstances which interfere to modify the application of this rule. The action, though successful, may be in its nature frivolous or vexatious, or it may have been brought in a higher court where a lower court would have been competent to deal with it. On the other hand the defendant, although he has escaped a judgment against him, may by his conduct have rendered the action necessary or otherwise justifiable. In such cases the rule that costs should follow the event would be felt to work an injustice, and exceptions to its operation have therefore been devised. In the law of England the provisions as to litigious costs, though now simpler than of old, are still elaborate and complicated, and the costs themselves are on a higher scale than is known in most other countries.

Except as regards appeals to the house of lords and suits in equity, the right to recover costs from the opposite party in litigation has always depended on statute law or on rules made under statutory authority. "Costs are the creature of statute." The house of lords has declared its competence to grant costs on appeals independently of statute.

In the judicial committee of the privy council the power to award. in its discretion, costs on appeals from the colonies or other matters referred to it is given by s. 1; of the Judicial Committee act, 1833; and the costs are taxed by the registrar of the council.

The general rule now in force in the supreme court of judicature is as follows: "Subject to the provisions of the Judicature Acts and the rules of the court made thereunder, . . . the costs of and incident to all proceedings in the Supreme Court, including the administration of estates and trusts, shall be in the discretion of the court or judge. . . . Provided (1) that nothing herein contained shall deprive an executor, administrator, trustee or mortgagee who has not unreasonably instituted, carried on or resisted any proceedings of any right to costs out of a particular estate or fund to which he would be entitled under the rules hitherto . . . acted upon in the chancery division . . ."

The rule above stated applies to civil proceedings on the crown side of the queen's bench division, including mandamus, prohibition quo warranto and certiorari (R. v. *Woodhouse*, 1906, 2 K.B. 502, 540); and to proceedings on the revenue side of that division (0. 68, r. 1); but it does not apply to criminal proceedings in the high court, which are regulated by the crown office rules of 1906, or by statutes dealing with particular breaches of the law, and as to procedure in taxing costs by O. 65, r. 27, of the Rules of the Supreme Court.

The rule is also subject to specific provision empowering the courts to limit the costs to be adjudged against the unsuccessful party in proceedings in the high court, which could and should have been instituted in a county court (*e.g.*, actions of contract under £100 or actions of tort in which less than £10 is recovered), unless the plaintiff, claiming a liquidated sum, has taken proceedings under O. 14 in the high court, in which case he *may* get high court costs if he recovers more than £20.

Costs of interlocutory proceedings in the course of a litigation are sometimes said to be "costs in the cause"; that is, they abide the results of the principal issue. A party succeeding in interlocutory proceedings, and paying the costs therein made "costs in the cause," would recover the amount of such costs if he had a judgment for costs on the result of the whole trial, but not otherwise. But it is usual now not to tax the costs of interlocutory proceedings till after final judgment.

When an order to pay the costs of litigation is made the costs are taxed in the central office of the high court, unless the court when making the order fixes the amount to be paid (R.S.C., O. 65, r. 23).

The taxation is effected, under an elaborate set of regulations, by reference to the prescribed scales, and on what is known as the lower scale, unless the court has specially ordered taxation on the higher scale (R.S.C.. 0. 65, rr. 8, 9, appendix N).

In the taxation of litigious costs two methods are still adopted, known as "between party and party" and "between solicitor and client." Unless a special order is made the first of the two methods is adopted. Formerly "party and party" costs were found to be a very imperfect indemnity to the successful litigant, because many items which his solicitor would be entitled to charge against him for the purposes of the litigation were not recoverable from his unsuccessful opponent. The high court can, in exercise of the equitable jurisdiction derived from the court of chancery, make orders on the losing party to pay the costs of the winner as between solicitor and client. These orders are not often made except in the chancery division. But even where party and party costs only are ordered to be paid under the present practice (dating from 1902), the taxing office allows against the unsuccessful party all costs, charges and expenses necessary or proper for the attainment of justice or defending the rights of the successful party, but not costs incurred through overcaution. negligence or by paying special fees to counsel or special fees to nitnesses or other persons. or by any other unusual expenses (R.S.C., O. 65, rr. 27, 29). This practice tends to give an approximate indemnity, while preventing oppression of the losing party by making him pay for lavish expenditure by his opponent. (As to costs in cases where one of the parties has legal aid, *see*, generally, *The Annual* Practice, 1957, pp. 1482–83 and 3747–52.)

Cost of Litigation.— Complaint is often made of the cost of litigation. It is important to notice, however, that the losing party to a suit who is condemned in costs need pay only the amount allowed on taxation Counsel may have 1,000 guineas on his brief; but the taxing master may afterward determine that "the other side" shall pay only one-tenth of that fee. What he pays his own solicitor is the litigant's onn concern, but. subject to this, a client can always ask to have his solicitor's bill taxed. An examination of a number of bills of costs which one or other of the parties to a suit has been ordered to pay (subject to taxation) shows that the larger items are counsel's fees, fees to expert witnesses, expenses of witnesses and (in some cases) the cost of copying documents. So far as the solicitor is concerned these are all out-of-pocket items. The solicitor's own charges may, of course, be considerable if the preparation of the case has involved a large number of interviews and the examination of many documents, but in the average case the principal item is preparing the brief. The actual court fees are trifling: as regards fees to counsel, it must be observed that, subject to the rule that he must never act without a minimum fee of one guinea, a member of the bar is free to demand what he pleases, and to all intents the whole bar is open to the litigant. Similarly an expert witness may name his own fee. Unless *(1)* counsel and experts be compelled to act for less than what they consider a living wage, *(2)* the rule which provides that evidence shall be given *orally* is altered and (3) litigation can be conducted without copies of all relevant documents for the use of counsel and the judge it is difficult to see how costs can be reduced. It is well to remember, too, that in many a heavy case which occupies the time of a judge for a considerable period, the costs of all parties are slight when compared with the amount at stake in the suit. *(See* ADMIRALTY, HIGH COURT OF; APPEAL; ARBITRATION; COUNTY COURT; EVIDENCE.)

See *The Annual Practice* (London, 1957). **(W. V. B.)**

UNITED STATES

The practice and procedure of the courts in the various jurisdictions of the United States was originally derived from the English common-law system of court administration. But since each state or territory, and the federal government, also, now has its own system of courts and its own procedure, a considerable diversity exists. In general, a reform of the common-law procedure has occurred in many ways similar to the English reforms of the 19th century. The extent of the reform varies in the different jurisdictions. The most far-reaching change was that of the so-called code reform of procedure inaugurated by the code of civil procedure adopted in New York in *1848* and (by the early 1950s) in force in 32 U.S. states and territories and the federal system. A later reform was that of the Federal Rules of Civil Procedure. adopted in the United States courts in *1938* and copied in many of the states. as noted below.

The Code Reform. — In *1847* the New York legislature instructed a commission "to provide for the abolition of the present forms of actions and pleadings in cases at common law; for **a** uniform course of proceeding in all cases whether of legal or equitable cognizance. and for the abandonment of all Latin and other foreign tongues, so far as the same shall by them be deemed practicable, and of any form and proceeding not necessary to ascertain or preserve the rights of the parties" (N.Y. laws, 1847, C. 59, §*8)*. During the following year the commission reported a code which was adopted on April 12, 1848. This measure. which served as the model for other codes in the United States, was largely the work of David Dudley Field, a member of the commission. It is often called the "Field code."

The chief characteristic and most fundamental part of the code is its single form of action for all cases. The distinctions of the common-law actions and of their forms were abolished; the separation in procedure of equitable from legal relief was abandoned. As a substitute, the codifiers planned a blended system of law and equity with only one form of action to be known as the *civil action*. In effect, this is the same step taken in England a generation later in the Supreme Court of Judicature act (1873). The full benefits of this reform were not attained in all the states: for many courts considered the ancient forms of action to rest upon distinctions fundamental in the law. Furthermore, some courts took a hostile attitude toward the attempted union of actions at law and suits in equity. Here the history and tradition of the separate systems of law and equity proved strong obstacles to a complete amalgamation. It has therefore often been held that the theory of the action. whether legal or equitahle. must be pointed out in the pleadings. In fact, however, the difference between law and equity actions is chiefly in the remedy to be granted and this should not be an objection to the single action or the simpler forms of pleading.

Perhaps the obstacle which has seemed greatest to the courts in preventing a complete union of law and equity is the requirement common to the state constitutions that the right of trial by jury shall remain inviolate. This is construed to mean a preservation of the jury trial right substantially as it was at the time of the original adoption of the constitutions. In view of the historical practice of jury trials in courts of law, this means in effect that in modern substitutes for action at law, jury trial is a matter of right, while in equitable claims no such right exists. Some courts in protecting the constitutional right continue to force a division of all actions into "law actions" and "equity actions." A more convenient rule and one more in keeping with the code principle is followed in many states, where the question of the form of trial is not allowed to affect the pleading in advance of the trial. If an issue arises at the trial as to the existence of a right to jury trial in either party, it is then determined by the nature of the issues developed in the pleadings in the light of the historical method of trying such issues.

Another important characteristic of the code is its emphasis upon pleading facts, not conclusions of law or evidence. *Fact pleading* was substituted for the *issue pleading* of the common law. This part of the code reform has been comparatively unsuccessful, because no clear line of demarcation exists between statements of fact and statements of law. An additional change wrought by the code was the adoption of the equity principles of greater freedom of joining parties and of rendering judgments in part for or against the various parties, as the justice of the case may require (the *split judgment* of equity). In spite of the fact that the code reform has not met with the same degree of success in all the states! it seems in general to have been in accord with the desires of the people for simpler judicial procedure. Modern plans for further reform are all in the direction of a greater simplification of practice.

Federal Rules of Civil Procedure. — These plans found realistic embodiment in the Federal Rules of Civil Procedure. adopted by the supreme court of the United States for regulation of the practice in the United States district courts. The rules represent the culmination of a long struggle for reform in the federal system carried on by leaders of the bar. Traditionally the procedure in these trial courts had been divided, although a single judge sat in both law and equity cases. In equity the practice was uniform in the many district courts under rules promulgated by the supreme court. But on the law side each district court was supposed to conform to the practice at law in the courts of the state where it was sitting, subject, however. to a considerable and constantly increasing number of congressional statutes dealing with specific procedural details. The resulting hodgepodge had led the American Bar association to press with vigour from *1912* on for the grant of complete rule-making authority to the supreme court. so that a single uniform system might be developed. Legislation was not forthcoming for several years, however, because of long opposition from senators convinced of the need of preserving their local practice. At length, upon adoption of the Rule-Making act on June *19,* 1934 (now *28* U.S.C., §*2072*, as amended!, the supreme court appointed an advisory committee of lawyers and lam teachers to consider and present a draft of rules. The committee consulted extensively with members of the bar and bench and teachers in the law schools and, after the publication and revision of preliminary drafts. made its final report, which the court accepted in 1937. After the set of rules was reported to and lay before congress for a full session, as required by the statute! they became eifective on Sept. *16, 1938*. The committee remained in office: recommending amendments from time to time. of which those effective March 19, *1948,* brought the rules extensively down to date, and that effective Aug. 1, 1951, added a complete rule governing the taking of property by eminent domain (Rule 71A, Condemnation of Property).

This system, both in the manner of its adoption — upon report of a court-appointed drafting committee — and in the substance of the procedure set forth. became a model for reform generally throughout the states. The directly imitating states arc noted below; but there is hardly a state which has not been affected by the movement in some degree or at least had its bar fired with zeal for thoroughgoing reform. The system was designed to employ all the best features of English and U.S. state practice acts or codes, and it is generally regarded as materially ensuring simple, flexible and effective court administration.

State of Pleading. — It has been customary to classify the U.S. states as "code" or "noncode," depending upon whether they have adopted the Field code or not. Since the federal rules represented in essence an advanced and refined stage of code pleading, the distinction still had validity thereafter, although the lines of demarcation became more blurred. The system inaugurated in New York in 1848 had by mid-20th century been adopted in the following jurisdictions: Alaska (1900); Arizona (1864); Arkansas (1868); California (1850); Colorado (1877); Connecticut (1879); Illinois (1934); Indiana (1852); Iowa (1851); Idaho (1864); Kansas (1859); Kentucky (1851); Minnesota (1851); Missouri (1849); Montana (1865); Nebraska (185j); Nevada (1860); New Jersey (1948); New Mexico (1897); New York (1848); North Carolina (1868); North Dakota (1862); Ohio (1853); Oklahoma (1890); Oregon (1854); Puerto Rico (1904); South Carolina (1870); South Dakota (1862); Utah (1870); Washington (1854); Wyoming (1869); Wisconsin (1856); and the United States — the vast federal system, consisting of 86 district courts having exclusive federal jurisdiction and the courts of the District of Columbia and Guam.

In Arkansas, Iowa, Kentucky and Oregon a formal distinction between actions at law and suits in equity, and in Illinois a formal labelling, is still maintained, though the same judges hear both in the same courts.

The federal rules, as applicable in the United States courts, were also fully adopted in the following jurisdictions: Alaska (1949); Arizona (1940); Colorado (1941); Minnesota (1952); New Jersey (1948); New Mexico (1942); Puerto Rico (1943); Utah (1950); and Delaware (1948) for the courts of law only. Beyond this they have been followed extensively, although not completely, in revisions of practice in Florida (1950), Iowa (1943), Rlissouri (1944) and Texas (1941); while at various intervals specific sections have been adopted in Maryland, New York, Pennsylvania, South Dakota and Washington, and individual rules in California, Connecticut and North Dakota. An occasional rule, notably Federal Rule 16, authorizing the holding of pretrial conferences by the judge, has been adopted yet more widely. In Nebraska, where the rules were adopted in 1943, they were immediately repealed by the state legislature — a unique experience matched only by the action of Florida in first adopting (1870) and then repudiating (1873) code pleading in the hectic reconstruction days following the American Civil War.

Of the above jurisdictions Delaware, Florida, Maryland, Pennsylvania and Texas have not been traditionally viewed as code states; but their approach to the federal system makes them at least "quasi code" states, a somewhat vague classification indicating considerable resemblance to the code system, in which should certainly be included Massachusetts and Michigan. States which had adopted the federal pretrial rule by mid-century included New Hampshire, Virginia and West Virginia. A partial revision of procedure in Virginia in 1950 did not follow the federal model, although an extensive motion practice, in lieu of a formal complaint and answer, tended toward modern adaptability. So, too, the Georgia practice has long had a considerable flexibility; and the Louisiana code of practice, based upon the civil law of that state, has naturally a lessened emphasis upon formal pleading. Less trace of the modern approach appears in Alabama, Maine, Mississippi, Rhode Island and Tennessee, although these can hardly be termed "common-law" jurisdictions. For the ancient practice has been ameliorated in many ways, such as the breaking down of the old distinctions between law and equity, by the pleading of "equitable defenses" in '.actions at law" and the free transfer of cases from one side to the other of the court, and by the blotting out or broadening of the former forms of action. True, the surface diversity thus shown among U.S. jurisdictions is accentuated by such barriers as the localization of the bar, so that an attorney of one state cannot appear as counsel in the courts of another state except by special permission requested of and granted by the court for the limited occasion. Underneath, however, is a substantial similarity of objective which could be more easily and fully achieved by uniform rules identically followed throughout the union. Wide state adoption of the federal rules is an obviously desirable trend toward such uniformity.

Course of Proceedings in a Civil Action. — Notice to the defendant at the institution of suit and an opportunity to present his side of the case are essential to the U.S., as to any, system of justice. In many of the states (some of which have adopted the code procedure), the traditional practice of issuing a writ in the name of the state directing the sheriff to make the summons is followed. In others, however, the writ of the sovereign is supplanted by a simple written summons to appear, signed by the plaintiff or his attorney and served upon the defendant by anyone not a party — usually by a clerk in the office of the plaintiff's attorney. Even in these jurisdictions, when the plaintiff claims some extraordinary or provisional remedy, such as attachment of the defendant's property, arrest of the defendant or an injunction, notice is given in the form of a court order served by some public officer, such as the sheriff. It is necessary that proper *service* of the summons be had, for unless the defendant is legally notified of the action, no *jurisdiction* is acquired over his person. Moreover, unless the action is brought to the proper court, *jztrisdiction over the subject matter* does not exist. Next come the pleadings, the first step being the filing by the plaintiff of his *complaint* or *petition* (the *declaration* or *count* of the common law). This contains the names of the parties and the court, a statement of the facts constituting the plaintiff's cause of action and a demand for the judgment to which he thinks himself entitled. The complaint is served upon the defendant with the summons or after the parties are in court or else is supplied to the defendant by the court clerk. If the defendant desires to defend. his first move is to enter an *appearance,* which may be done, without his presence in court, by a written notice of appearance by his attorney or by filing an *answer* to the complaint. By *demurring,* the defendant may question the legal sufficiency of the complaint. But if the demurrer is abolished. as in Illinois and New York, he moves for judgment and thus raises the same issue. In the defendant's answer he may deny the plaintiff's allegations or he may admit them and allege new matter in his defense or as a basis for a *counterclaim* against the plaintiff. To this the plaintiff under most codes may file a *reply* (corresponding to the common-law *replication*), and at this stage the pleadings are generally required by the statute to come to an end. Thereafter follows the actual trial with the production of evidence by the parties, followed by the verdict, if a jury is present, and judgment. If the defeated party so desires he may then take an appeal to some appellate tribunal. (*See* APPEAL.) When the judgment is finally effective, extensive proceedings are available to secure its enforcement.

The new federal system followed this same course in substance, but with some change of emphasis from formal pleadings of fact to short and succinct statements of claim or defense, ending usually with the answer or, in any event, with a reply to a counterclaim. The old demurrer was abolished and objections may be presented either by answer or by a motion, including a motion for summary judgment, supported by affidavits or depositions on the merits. Stress is placed on reaching the merits quickly, rather than on form. Hence, that each party may be thoroughly apprised of all elements of the case at once and may thus prepare his case completely in advance of trial, there is an extensive system of discovery by the taking of depositions, submission of interrogatories, requests for admission and the production of documents and so on. Wide adoption of the optional provision for pretrial conference, settling the issues and dispensing with formalities of proof of detail, adds to this sense of full preparation and often facilitates settlements. There is practically complete freedom of joinder of actions, both of parties and of causes, as well as of counterclaims. New parties may be summoned in or impleaded to answer claims developed in the case. Provisions governing trials, including waiver of jury trial by failure to make seasonable claim therefor, simplifying the appeals and abolishing the noting of formal exceptions and other like restrictions, round out the system. This is often supported by an accompanying movement, also supported by the American Bar association, for improved court structure and administration, of which the main feature is a unified court, sitting in various divisions as required, under a single administrative control headed by the chief justice, assisted by an administrative director.

Criminal Procedure.— Here again the English practice is the source. Indictment by a grand jury is still an essential step in a criminal prosecution in many jurisdictions for capital and many other serious crimes. This body varies in number in the different jurisdictions but usually consists of not less than 12 and not more than 23 persons, at least 12 of whom must concur in presenting an indictment. It may act upon its own knowledge, upon an information of the prosecutor or upon a complaint made under oath by a private person before a committing magistrate. The indictment, which is usually prepared beforehand by the prosecutor and given to the grand jury for its consideration, serves as the prosecution's complaint at the trial. A number of technical rules apply to the indictment, making criminal procedure very rigid. Thus, in many jurisdictions unless the indictment describes the offense with great particularity, including its time and place of occurrence and the accused's name, it may be quashed. Such technicalities are a relic of ancient common-law times when the accused was favoured because of the serious penalties imposed for minor offenses. But as the reason for these rules is now gone, authorities today advocate a procedure requiring only that reasonable notice of the ground of complaint be given the accused. In a considerable number of states an information by the prosecutor was substituted for the indictment by the grand jury. An information suffices in the federal courts except in offenses punishable by more than one year's imprisonment. Trial by jury is usually a constitutional guarantee except in minor offenses. But in Maryland and Connecticut the accused may elect a trial to the court if he so chooses. The American Law institute, an organization of judges, lawyers and law teachers with headquarters in Philadelphia, Pa., recommended an advanced and simplified Model Code of Criminal Procedure (1931), which has been adopted in some states, as substantially in Connecticut in its pleading aspects as early as 1929. More lately the supreme court, under statutory authority and following its plan of drafting first employed as to the civil rules, adopted the report of its Advisory Committee on Rules of Criminal Procedure recommending the Federal Rules of Criminal Procedure, which became effective throughout the federal system on March 21, 1946. (See ADMIRALTY JURISDICTION; APPEAL; ARBITRATION; CRIMINAL LAW; EVIDENCE; JUDICIAL REFORM; PROBATE; SUPREME COURT OF THE UNITED STATES.)

Clark, *Cases on Modern Pleading* (1952); George H. Dession, *Criminal Law Administration and Public Order* (1948); William W. Barron and Alexander Holtzoff, *Federal Practice and Procedzrre with Forms* (1950–51); James W. Moore, *Federal Practice*, 2nd ed. (1948–) *Judicial Administration Series, by* various authors on selected topics, in 7 vol., under the auspices of the National Conference of Judicial Councils (1939–49). There are many editions, official and nonofficial, of the Federal Rules of Civil and of Criminal Procedure and Advisory Committees' Notes; special case series include *Federal Rules Service* (1939 *et seq.)* and *Federal Rules Decisions* (1941 *et seq.*); while teaching casebooks, law review articles and local state practice books abound. In England the yearly *Annual Practice*, or "White Book," long edited by Sir W. Valentine Ball, and later by R. F. Burnand (and others) is standard. *See* also W. Blake Odgers, *Principles of Pleading and Practice in Civil Actions in the High Court of Justice*, 10th ed. (1930); R. M. Jackson, *The Machinery of Justice in England* (1940); Claud Mullins, *In Quest of Justice* (1931); E. S. Greenbaum and L. I. Reade, *The King's Bench Masters and English Interlocutory Practice* (1932); Lord Chorley, "Procedural Reform in England," in Alison Reppi, ed., *David Dudley Field Centenary Essays (1949).* (C. E. CL.)

PRAEMUNIRE, in English law an offence so called from the introductory words of the writ of summons issued to the defendant to answer the charge, "Praemunire facias A.B.," etc., *i.e.*, "cause A.B. to be forewarned." From this the word came to be used to denote the offences, usually ecclesiastical, prosecuted by means of such a writ, and also the penalties they incurred. From the beginning of the 14th century papal aggression had been particularly active, more especially in two forms. The one, the disposal of ecclesiastical benefices, before the same became vacant, to men of the pope's own choosing; the other, the encouragement of resort to himself and his curia rather than to the courts of the country. The Statute of Provisors (1306), passed in the reign of Edward I., was, according to Coke, the foundation of all subsequent statutes of praemunire. This statute enacted "that no tax imposed by any religious persons should be sent out of the country whether under the name of rent, tallage, tribute or any kind of imposition." A much greater check on the freedom of action of the popes was imposed by the Statute of Provisors (1350–51) and the Statute of Praemunire passed in the reign of Edward III. The former ordained the free election of all dignities and benefices elective in the manner as they were granted by the king's progenitors. The Statute of Praemunire (the first statute so called), 1353, enacts "that all the people of the king's ligeance of what condition that they be, which shall draw any out of the realm in plea" or any matter of which the cognizance properly belongs to the king's court shall be allowed two months in which to answer for their contempt of the king's rights in transferring their pleas abroad. Many other statutes followed that of 1353, but that passed in the 16th year of Richard II.'s reign is usually referred to as *the* Statute of Praemunire. The Royal Marriage Act, 1772, is the last which subjects anyone to the penalties of a praemunire. A peer charged with praemunire is not entitled to trial by his peers, but is to be tried by a jury. The most famous historical instance of a prosecution of the Statute of Praemunire was that of Cardinal Wolsey in 1529.

PRAENESTE (mod. Palestrina), **a** very ancient city of Latium, lies 23 m. E. of Rome by the Via Praenestina (see below), on a spur of the Apennines facing the Alban hills. To the natural strength of the place and its commanding situation Praeneste owed in large measure its historical importance. Objects in metal and ivory discovered in the earliest graves prove that as early as the 8th or 7th century B.C. Praeneste had reached a considerable degree of civilization and stood in commercial relations not only with Etruria but with the East. In 499 B.C., according to Livy, it formed an alliance with Rome. After Rome had been weakened by the Gallic invasion (390) Praeneste joined in a long struggle with Rome which culminated in the great Latin War (340–338), in which the Romans were victorious, and Praeneste was punished by the loss of part of its territory. It continued in the position of a city in alliance with Rome down to the Social War, when it received the Roman franchise.

As an allied city it furnished contingents to the Roman army and possessed the right of exile (*ius* exilii), *i.e.*, persons banished from Rome were allowed to reside at Praeneste. The nuts of Praeneste were famous and its roses were amongst the finest in Italy. The Latin spoken at Praeneste was somewhat peculiar, and was ridiculed by the Romans, e g., by Plautus. In the civil mars the younger Marius was blockaded in the town by the Sullans (82 B.C.); and on its capture Marius slew himself, the male inhabitants were massacred in cold blood. and a military colony was settled on part of its territory, while the city was removed from the hill-side to the lower ground at the Madonna dell' Aquila, and the temple of Fortune enlarged so as to include the space occupied by the older city. Under the empire Praeneste, from its elevated situation and cool salubrious air, became a favourite summer resort of the wealthy Romans, whose villas studded the neighbourhood. Horace ranked it with Tibur and Baiac, though as a fact it never became so fashionable a residence as Tibur or the Alban hills. Still, Augustus resorted thither; here Tiberius recovered from a dangerous illness, and here Hadrian and Marcus Aurelius had villas. Amongst private owners were Pliny the younger and Symmachus.

But Praeneste was chiefly famed for its great temple of Fortune and for its oracle, in connection with the temple, known as the "Praenestine lots" (sortes praenestinae). The oldest portion of the sanctuary was, however, that situated on the lowest terrace but one. Here is a grotto in the natural rock, containing a beautiful coloured mosaic pavement, representing a sea-scene—

a temple of Poseidon on the shore, with various fish swimming in the sea. To the east of this was a basilica in two storeys. As extended by Sulla the sanctuary of Fortune occupied a series of five vast terraces, which, resting on gigantic substructions of masonry and connected with each other by grand staircases, rose one above the other on the hill in the form of the side of a pyramid, crowned on the highest terrace by the small round temple of Fortune. This immense complex, probably by far the largest sanctuary in Italy, must have presented a most imposing aspect, visible as it was from a great part of Latium, from Rome, and even from the sea.

The modern town of Palestrina, a collection of narrow alleys, stands on the terraces once occupied by the temple of Fortune. On the summit of the hill (2,471 ft.), nearly a mile from the town, stood the ancient citadel, the site of which is now occupied by a few poor houses (Castel San Pietro) and a ruined mediaeval castle of the Colonna. Considerable portions of the southern wall of the ancient citadel, built in very massive Cyclopean masonry of blocks of limestone, are to be seen; and the two walls, also polygonal, which formerly united the citadel with the town, can be traced. The calendar set up by the grammarian M. Verrius Flaccus in the forum of Praeneste was discovered in 1771. Excavations made in the ancient necropolis, which lay on a plateau surrounded by valleys at the foot of the hill, have yielded important results for the history of the art and manufactures of Praeneste. The Ficorni casket, engraved with pictures of the arrival of the Argonauts in Bithynia and the victory of Pollux over Amycus, was found in 1738. (J.G. Fr.; R. S. Co.; T. A.)

PRAESEPE, a loose star-cluster in the constellation Cancer having a "bee-hive" shape. It is a favourite object for telescopes of low power. The cluster is located at a distance from the sun of about 600 light-years.

PRAETOR, originally a military title (a leader; Lat, *prae . . .* ire), was the designation of the highest magistrates in the Latin towns.

Under the republic the Roman consuls were at first called praetors; by the Licinian law of 367 B.C., a new magistrate was created who was to be a colleague of the consuls, though with lesser powers. This new magistrate was entrusted with the jurisdiction in civil cases; in other respects his powers resembled those of the consuls. His title was the city praetor (praetor *urbanus*), and when the number of praetors was increased, the city praetor always ranked first. To this new magistrate the title of "praetor" was thenceforward restricted. About 242 B.C. the increase of a foreign population in Rome necessitated the creation of a second praetor for the decision of suits between foreigners (peregrini) or between citizens and foreigners (praetor *peregrinus*). About 227 two more praetors were added to administer the provinces of Sicily and Sardinia. The conquest of Spain occasioned the appointment of two more in 197. The number of praetors remained stationary until Sulla's time (82 B.C.). But in the interval their duties multiplied. On the one hand, five new provinces were added to the Roman dominions; on the other new and permanent jury courts (quaestiones perpetuae) were instituted at Rome, over which the praetors were called on to preside. To meet this increase of business the tenure of office of the praetors and also of the consuls was practically prolonged from one to two years, with the distinction that in their second year of office they bore the titles of propraetor and proconsul instead of praetor and consul. The prolongation of office formed the basis of Sulla's arrangements. He increased the number of the praetors from six to eight, and ordained that henceforward all the eight should in their first year administer justice at Rome and in their second should as propraetors undertake the government of provinces. The courts over which the praetors presided, in addition to those of the city praetor and the foreign praetor, dealt with the following offences: oppression of the provincials by governors (repetundarum), bribery (ambitus), embezzlement (*peculatus*), treason (maiestatzs), murder (de sicariis *et veneficis*), and forgery (falsi). Later, more provinces were added and more courts constituted, including that of *Gallia Cisalpina.* Iulius Caesar increased the number of praetors.

The praetors were elected, like the consuls by the *comitia* centuriata (see Comitia) and with the same formalities. They held office for a year. The insignia of the praetor were those of the higher Roman magistrates—the purple-edged robe (toga praetexta) and the ivory chair (*sella curulis*); in Rome he was attended by two lictors, in the provinces by six. The praetors elect cast lots to determine the department which each of them should administer. A praetor as a civil judge at or before his entry on office published an edict setting forth the rules and law procedure by which he intended to be guided. These rules were often accepted by his successors, and corrected and amplified from year to year, became, under the title of the "perpetual" edicts, one of the most important factors in moulding Roman law. Their tendency was to smooth away the anomalies of the civil law by substituting rules of equity for the letter of the law.

Under the Empire.—Under the empire various special functions were assigned to certain praetors, such as the two treasury praetors (praetores aerarii), appointed by Augustus in 23 B.C.; the ward praetor (praetor tutelaris), appointed by Marcus Aurelius to deal with the affairs of minors; and the liberation praetor (praetor de liberalibus *causis*), who tried cases turning on the liberation of slaves. Of the praetorships with special jurisdiction (especially the ward praetorship and the liberation praetorship) some lasted into the 4th century and were copied in the constitution of Constantinople.

Besides their judicial functions, the praetors as colleagues of the consuls, possessed the consular powers, which they exercised in the absence of the consuls; but in the presence of a consul they exercised them only at the command either of the consul or the senate. (For the praetor as provincial governor see Province.)

PRAETORIANS. In the early Roman republic, praetor (*q.v.*) meant commander of the army: later praetor and propraetor were the usual titles for provincial governors with military powers. Accordingly, the general's quarters in a camp came to be called *praetorium,* one of the gates porta praetoria and the general's bodyguard *cohors* praetoria. Under the empire *cohortes* praetoriae formed the imperial bodyguard. This, as founded by Augustus, consisted of nine cohorts. each 1,000 strong. some part of which was always with the emperor, whether in Rome or elsewhere. Tiberius concentrated this force on the eastern edge of Rome in fortified barracks.

The men were recruited voluntarily, in Italy or Italianized districts, and enjoyed better pay and shorter service than the regular army; they were commanded by *praefecti praetorio*. This force was the only body of troops in Rome (save a few cohortes *urbanae* and some non-Roman personal guards of the emperor) or, indeed, anywhere near the capital. Accordingly it could make or unmake emperors in crises—at the accession of Claudius in A.D. 41, in 68–69, and again late in the 2nd century.

PRAETORIUS, MICHAEL (1571–1621), German musical historian, theorist and composer. was born at Kreuzberg, Thuringia, on Feb. 15. 1571. His father's name was Schulz or Schultze, and the name was latinized as Praetorius. He studied philosophy at Frankfurt-on-Oder, and on the death of his brother, on whose support he relied, he was given a post as organist in the town. In 1604 he became organist and later *Kapellmeister* and secretary to the duke of Brunswick-Wolfenbüttel, and was rewarded for his services with the priory of Ringelheim, near Goslar. He died at Wolfenbüttel on Feb. 15, 1621.

The most important of his compositions are: *Polyhymnia* (15 vol.), *Musae Sioniae* (16 vol.) and *Musa Aonia* (9 vol.), all written partly to Latin and partly to German words. But more precious than all these is the *Syntagma musicum* (3 vol. and an appendix of plates; Wittenberg and Wolfenbuttel, 1614–20).

PRAGMATIC SANCTION, originally a term of the later Roman law, is found in the Theodosian and Justinian codes (Lat. *pragmatica* sanctio, from the Gr. πρᾶγμα, business). It was a decision of the state dealing with some interest greater than a question in dispute between private persons, and was given for some community (*universitas hominum*) and for a public cause. In later times it was adopted by those countries which followed the Roman law, and in particular by despotically governed countries, to signify an expression of the will of the sovereign defining the limits of his own power or regulating the succession.

Justinian regulated the government of Italy by pragmatic sanctions after it had been reconquered from the Ostrogoths. In after ages the king of France, Charles VII, imposed limits on the claims of the popes to exercise jurisdiction in his dominions by the pragmatic sanction of Bourges in 1438.

The emperor Charles VI settled the law of succession for the dominions of the house of Habsburg by pragmatic sanction that was first published on April 19, 1713 (see AUSTRIA, EMPIRE OF). Philip V, the first of the Bourbon kings of Spain, introduced the Salic law by a pragmatic sanction, and Ferdinand VII revoked it by another. The term was not used in England.

PRAGMATISM, a term of philosophy (from Greek *pragmata*, "acts," "affairs," "business") chosen by the U.S. logician C. S. Peirce (*q.v.;* 1839–1914), apparently in the course of discussions with William James and others in the 1870s, to stand for a way of making our ideas clear or, more accurately, for "a method of logic, a method of determining the meanings of intellectual concepts, that is, of those upon which reasoning may hinge" (Collected Papers *of* Charles Sanders Peirce, ed. by Charles Hartshorn and Paul Weiss, vol. 5, p. 464; Cambridge, Mass.: Harvard, 1935). Pragmatism was popularized by the writings of James during the first decade of the 20th century; but the later publication of Peirce's Collected Papers showed that the two fathers of the doctrine diverged considerably in their interpretations of it.

Peirce's original formulation of the pragmatist principle was: "Consider what effects, that conceivably might have practical bearings, we conceive the object of our conception to have. Then our conception of these effects is the whole of our conception of the object" (Collected Papers, vol. 5, p. 2). A more readily intelligible and apparently equivalent formula of James is that "the whole ineaning of a conception expresses itself in practical consequences, either in the shape of conduct to be recommended or in that of experience to be expected if the conception is true, which consequences would be different if it were untrue: and must be different from the consequences by which the meaning of other conceptions is in turn expressed" (William James in James Mark Baldwin, Dictionary of Philosophy and *Psychology;* New York: Macmillan Company.,1902). Both statements make a point which is closely related to the central teaching of British empiricism; but where traditional empiricism has taught that none of our conceptions (or the verbal expression of them) has a meaning unless it has been derived from some elementary sensory impression, pragmatism teaches that no conception has meaning unless it can be applied, directly or indirectly, in the location and description of something of a kind that might be revealed to our senses.

Regarded in this way, the positive content of pragmatism is simple enough; viz., that all our conceptions, even the most abstract, derive their peculiar point or meaning from things or from differences in such things as we can actually observe and point to. But pragmatism has certain features which constitute a further important development of traditional empiricism. Two things differ practically, or differ for us, in so far as we find ourselves compelled to treat them differently or to expect different reactions from them. Similarly, according to pragmatism, two words (or conceptions) have different meanings, not because of some direct relation between word and thing in either case, but in virtue of their different uses; *i.e.,* in virtue of the different ways in which they help to express or communicate different procedures—involving expectation and adjustment — with regard to the things in queston Thus pragmatism contains, or rests upon, what might be called a procedural theory of meaning. Moreover, Peirce's principle has proved a most searching tool of criticism. We are all liable to confuse highly abstract and erudite conceptions, not only in metaphysics but also in the mathematical and natural sciences; but if one conception does not differ "practically" (in Peirce's sense) from a second, then our employment of it adds nothing to our employment of that second conception. Again, we are sometimes tempted to engage in speculations which have no assignable "practical hearings": but in that case, according to pragmatism, our thoughts and words have no assignable meaning whatsoever. Men of science. Peirce claimed. have always unconsciously applied the pragmatist method to distinguish better conceptions which common sense treats as one or to identify conceptions which common sense has traditionally regarded as several. Unfortunately philosophers have not made much use of the method.

Thus far Peirce and James were in agreement; the grounds of their divergence were more complex than either of them appreciated. In the first place, for example, James wished to use the pragmatist method to vindicate — not simply to elucidate — our basic moral and religious beliefs by reference to their beneficial practical consequences on our conduct and temper. Peirce was on the whole averse to applying the pragmatist method to moral or to religious concepts, which seemed to him of a kind that could not be made clear; and certainly he was flabbergasted by some of James's ventures in this field. Second, as the basis, to a large extent, of these ventures, there was James's "pragmatist" account of our conception of truth, his view that a belief or theory is true in so far as it "works" or "pays." To be sure, James has often been cruelly misunderstood in this connection. yet it is questionable whether his account of truth can be regarded as an inevitable —and still more questionable whether it can be regarded as the one and only possible — result of applying the pragmatist method to our normal uses of the word "true." Third, underlying most of James's applications of the pragmatist method (including the case of "truth") was his strong prejudice in favour of whatever is concrete and particular and against whatever is abstract and general. This finds expression in his statement that the meaning of any proposition "can always be brought down to some particular consequence in our future experience . . . the point lying rather in the fact that the experience must be particular, rather than in the fact that it must be active" (William James: Collected Essays and Reviews, p. 412; New York: Longmans. Green & Co., 1920). Peirce explicitly repudiated this view. Fourth, the last-named prejudice of James mas closely connected with his hankering after that form of metaphysics — "radical empiricism" he called it—according to which the fundamental reference of all discourse is "pure experience." something which is in itself neutral as between mind and matter and which is exemplified in the content of our sensations and the felt transitions between our sensations. (For example, "truth" on this view stands for certain experienceable transitions between one "bit" of experience and other bits with which it can be brought into harmonious and successful relation.) James openly confessed that he was attracted to pragmatism because he thought it would help him to vindicate his radical empiricism—of which indeed it seemed to him to be simply the logical facet. Peirce on the other hand vehemently rejected the suggestion that any doctrine of logic should be preferred for its metaphysical affinities. "Pragmatism is no doctrine of metaphysics."

Of these four grounds of divergence the last two are fundamental. In them we see the transition, from Peirce's account of the meaning of a term or statement as an attribute of certain prescribable and justifiable procedures, to James's account of it as an attribute of certain describable, because individually experienced. processes. The illegitimacy of this transition seemed plain to Peirce from the fact that his pragmatist principle was put forward, as has been said. as a method of "determining the meanings of intellectual concepts. that is, of those upon which reasoning may hinge." For all reasoning is. in Peircian phrase, subject to "logical control" (*i.e.,* to agreed logical canons); but whatever is amenable to control by rules must be in the nature of a habit or general procedure of action. Hence it can only be to concepts (or their verbal expression) which are irreducibly general (*i.e.,* such that they can be employed by any rational being in any situation of appropriate general kind) that the pragmatist principle can apply. Alternatively we can say: Pragmatism, according to Peirce, teaches thdt our descriptions of things are to be understood as mays of dealing with those things — but of dealing with them from the standpoint. in some respects highly specialized, but in other respects entirely general, of reasoning; *i.e.,* of finding out how observation. hypothesis, deduction and checking of consequences shows them to behave. But while making this protest against James's misuse of his pragmatist principle, Peirce was no less strenuous than James in emphasizing its empiricist purpose; only in so far as an intellectual concept (or its verbal expression) refers to "compulsory perceptions" of a certain sort — perceptions forced upon anyone who uses it — does it possess distinctive and genuine meaning.

Largely because of these disagreements between its originators, partly also because of their respective literary failings — James's writings at their worst are intolerably slapdash, Peirce's at their worst distressingly obscure — pragmatism was subjected during the first quarter of the 20th century to scathing criticisms from philosophers both of the realist and of the idealist schools. For later readers, the annals of this interschool battle are neither lively nor illuminating.

But the inner vitality of Peirce's pragmatist teaching is sufficiently shown by the variety of first-class minds that subsequently described themselves or allowed themselves to be described as pragmatists. Among these may be mentioned the English philosopher F. C. S. Schiller, whose very uneven writings contain some admirable expositions of the "question-and-answer" character of all purposive thinking; John Dewey (*q.v.*), whose "instrumentalist" theory of knowledge owes much to Peirce and whose naturalistic metaphysics of experience would have appealed greatly to James; G. Mead, who developed in the most suggestive manner Peirce's conception of inquiry as a socially controlled activity. C. Lewis drew on Peirce's teaching to restate the Kantian distinction between a *priori* and empirical elements in knowledge.

PRAGUE (CZECH PRAHA), the capital of Czechoslovakia, is situated in the Prague region along both banks of a large meander of the Vltava (Ger. Moldau), a tributary of the Elbe. The Vltava is here crossed by 13 bridges. Prague lies 650 ft. above sea level and is approximately 160 mi. N.W. of Vienna and 75 mi. S.E. of Dresden. Area 72 sq.mi. Pop. (1961) 998,493.

The modern town has spread along the winding river banks, up the steep terraced hill slopes and into the side valleys. The hilly position of the town forms a serious barrier to modern communications but adds greatly to its beauty which is enhanced by the many medieval and baroque buildings with their towers and spires and by the numerous parks, of which Stromovka and the Petrin orchards and gardens are the most extensive. A few industrial districts are situated on the left bank, but the chief factories are along the right bank. The residential quarters lie farther away from the centre of the town and form part of greater Prague which has engulfed the surrounding towns, from which daily over 100,000 people travel to work in the capital.

The historical parts of the town, which have retained their ancient appearance, are kept up by the state. The vast 16th- to 17th-century fortified palace on Hradcany hill, now the residence of the president of the republic and formerly that of the ancient kings of Bohemia, dominates the entire town. The castle has a number of halls including Vladislav hall in late Gothic style and the Spanish hall in 15th-century baroque. In the inner castle yard stands St. Vitus cathedral, begun in 1344 and finally completed in 1929. Other important buildings on the castle hill include the Romanesque basilica of St. George (912) and the Renaissance Belvedere. The Little Town below the castle is a district of picturesque streets overshadowed by the baroque dome of St. Nicholas' cathedral (1703). Overlooking the many fine squares and narrow streets stand numerous palaces, which are used today for various public purposes. The Little Town is joined to the Old Town by the famous Charles bridge (1357), now flanked by baroque statues. The Old Town abounds in monuments and quaint relics of the history of the district. Its most remarkable features include the Old Town square with the ruins of the town hall, burned down during the 1945 uprising, and the ancient clock of the seasons. On the opposite side of the square rises the 14th-century Tyn church, built in the Prague Gothic style, containing the tomb of Tycho Brahe, the Danish astronomer. The church was the religious centre of the Hussite movement and in the centre of the square is a monument (1915) to John Huss. Close by are the remnants of the old Josef's town (the Jewish ghetto) and a 13th-century Jewish cemetery and synagogue.

Passing out of the Old Town through the 15th-century gate, or Powder tower, to Prikopy, the site of the former moat round the old walls, there is a change from ancient beauty to modern, commercial life with department stores, hotels, restaurants and offices. The centre of the modern town is Wenceslas square with the statue of St. Wenceslas (1913) and the National museum (1894). Other sights worth mentioning include the Tyl theatre, where Mozart's Don *Giovanni* was first performed; the National theatre (1883); Vysehrad hill with the church of St. Peter and St. Paul and the poets' corner; the national monument at Zizkov with the mausoleum; the statue of the Hussite leader Jan (John) Zizka by Bohumil Kafka (1950); and the large Stalin monument on Letna hill.

Education and Culture. — Prague university, founded by Charles IV in 1348, was the first in central Europe. The Technical university, founded in 1707, has developed a great number of faculties. Other centres of learning include the Prague School of Economics, the arts and crafts school (1885), the Academy of Graphic Arts (1799), the Academy of Music, Dancing and Film (1948), the Conservatoire (1811) and the Institute of Physical Training. The Czechoslovak Academy of Sciences carries out its research in numerous buildings.

Besides the National museum (founded 1818) there are a technical, an ethnographical, an arts and crafts and a Jewish museum, and museums of Czechoslovak literature and of the Working Class Movement. The National gallery contains pictures and sculptures by famous Czech, Slovak and foreign artists and has a unique collection of Gothic art. In addition to the central municipal library there is the university library which on-11s a collection of precious manuscripts and old prints. Prague maintains its claim to be a centre of culture and has 26 theatres, including 3 belonging to the National Theatre, where drama, opera and ballet are performed, special theatres for children, (puppets) and a theatre of recorded music. A number of symphony orchestras, headed by the Czech Philharmonic, avail themselves of the numerous concert halls.

Industry and Communications. — As a capital, Prague is the seat of the ministries, foreign trade corporations, the chamber of commerce and the highest church dignitaries. It is also a big industrial town. Most of the industries are highly specialized, with more than half the production capacity devoted to heavy and precision engineering. All works have been greatly expanded and brought up to date since nationalization in 1945. Products include cars, motorcycles, omnibuses, airplanes, railway engines and carriages, machine tools, boilers, mining and foundry equipment, cranes, machinery for the chemical industry, etc. Other big industries include the manufacture of foodstuffs (mills, dairy produce, breweries), clothing, and chemical and pharmaceutical products. There are also printing works, phonograph and film industries, and tanneries.

The electric power for the city is brought by grid from the brown coal basin in northwestern Bohemia, which also supplies gas. There are hydroelectric power stations on the Vltava at Stechovice, at Vrane and at the Slapy dam (1955).

Prague is the meeting place of rail and air routes joining the north and south of Europe and, especially, the east and west. There are three railway stations. The airport, Ruzyne, is 7 mi. from the centre of the town. Holesovice, the inland harbour, is the terminus of Elbe-Vltava shipping.

History. — There is evidence that the site on which Prague stands has been inhabited since Paleolithic times. Its fertile soil and mild climate (average temperature 35° F. in January, 67° F. in July), its easy fords across the river and the possibilities of defense and of trade, favoured the growth of a town which later became the political centre of Bohemia (*q.v.*). The ruling dynasty of the Premyslides (until 1306) succeeded in defeating all foreign attempts at subjugation and preserved the territorial integrity of the country.

The earliest settlements. documented from about the 9th century. were found at the foot of the ancient castles built on two dominating hilltops, Yysehrad on the right bank of the river and Hradcany on the left, which were residences of the Bohemian princes and later kings. On the right bank a small settlement formed the market centre for the isolated homesteads in the neighbourhood. This developed into Stare Mesto (Old Town), and on the opposite bank King Premysl Otakar II founded Mala Strana (Little Town) in 12j;. Under Charles IV, king of Bohemia (1346–78) and Roman emperor. Nove Mesto (New Town) was built adjacent to the old town, and the ghetto was developed.

In the 14th century Prague was already one of the most important towns in central Europe. It n-as a vital crossroad of trade routes running from north to south and from east to west, and it was also a centre of culture, its university attracting scholars and students from all over Europe. Charles IV, besides founding the university, was personally responsible for extensive building activities in the town according to an elaborate plan. Outstanding examples are the Charles bridge joining the Little Town to the Old Town, the Carolinum (the central auditorium of the university) and the town hall as well as several churches and monasteries in the New Town.

Foreigners who came to settle in Prague contributed toward its growth, and the German and Italian merchants grew into a rich patriciate who ruled the town. They could usually rely on the support of the king in all measures designed to curb the guilds formed by Czech craftsmen. Many conflicts arose between the two social groups and were waged with an eye to nationality. Disputes between guild masters and their journeymen incited numerous town paupers to minor uprisings, which went on prior to and throughout the period of the Hussite wars.

Among the scholars of the university. John Huss soon assumed a leading role in the struggle that ended with the Kutna Hora decree (1409), in which Wenceslaus IV granted the Czechs a predominant position in the university. Huss, basing his criticism on the theoretical writings of Wycliffe, publicly voiced sharp criticism of the church and of the sinful life of the clergy. His sermons, delivered in the Bethlehem chapel (restored to its original appearance in 1954), gained him support among the common people. Repressive measures on the part of the church and the patriciate led to violent uprisings in 1419 during which the radical elements, led by John Zelivsky, rose to power. Prague came to the aid of the people's uprisings in the countryside, which were led by the Hussite supporters, who had established a model community at Tabor in southern Bohemia. The Taborites. led by Zizka, helped Prague and gained a decisive victory in the battle of Vitkov hill in 1420. After the defeat of the radicals the town gradually changed sides until, toward the end of the Hussite wars, Prague stood in the ranks of the opponents. (See HUSSITES.)

The town's significance grew under the rule of George of Podebrad and the Jagellon dynasty, during which Prague was enriched by the building of churches and halls (*e.g.*, Vladislav hall) in Late Gothic style. The following centuries witnessed the growing opposition to the Habsburgs who had become kings of Bohemia on the death of Louis II of Hungary and were endeavouring to reintroduce Catholicism by force. Opposition to those measures and attempts to put an end to the feudal might and Catholic influence of the monarchy and the church led to the defenestration of Prague (May 23. 1618), one of the steps leading to the Thirty Years' War (see BOHEMIA: *Habsburg Rule, 1526–1918*).

During the Hussite wars the town was a Czech stronghold, but after the defeat of the Protestants at the battle of the White mountain in 1620, and after the public execution of Czech noblemen and I'rague commoners on the Old Town square in 1621, the German predominance increased again. Prague ceased to be the chief town of the German empire and its significance began to wane. At the very end of the Thirty Pears' War the town was partially occupied by Swedish armies and shared in the general chaos and decline suffered by the whole of central Europe for many decades after the cessation of hostilities. On May 6, 17j7, Frederick the Great won his first great victory over the Austrians at the Battle of Prague during the Seven Years' War. (See SEVEN TEARS' WAR.)

In the baroque period, rich merchants and the mainly foreign nobility (German, Spanish, Italian) who had settled in Prague and its surroundings invited some outstanding architects and artists, who were later aided by Czech masters, to come and embellish the general appearance of the town. At the time when Mozart lived in Prague. the city, especially Little Town, boasted of large gardens, aristocratic palaces and baroque churches.

Prague's most rapid expansion. however, came with the advent of industrialization. mainly engineering. which took advantage of the proximity of coal mines and ironworks at neighbouring Kladno and Kraluv Dvur. In the 19th century, with the rapidly changing social and economic relations within the town population. Prague became the centre of a great cultural drive for the revival of the Czech national heritage. During the revolutionary wave of the year 1848, a Slav congress was convened at Whitsuntide, the townspeople attempted to put up resistance to the repressive measures of the Austrian generals, but the fighting on the barricades ended in surrender. Nevertheless. Czech feeling and cultural life gained in significance and in 1861 the Czechs won a majority in the town administration. At the conclusion of World War I the independent republic of Czechoslovakia was established with I'rague as its capital city. In March 1939 the country was occupied by the Germans, and Hitler established a protectorate with a puppet government. On May 5, 1945, the citizens of I'rague rose against the German occupying forces, erecting barricades and holding out against superior German forces until the entry of the Soviet army four days later. Prague once again became the capital of the Czechoslovak republic. (T. GR.)

PRAGUERIE, THE, a revolt of the French nobility against King Charles VII in 1440, so named because a similar rising had recently taken place in Prague, Bohemia. It was caused by the desire of the princes and great vassals to regain control of the king's council. The instigator was Charles I. duke of Bourbon, who three years before had attempted an unsuccessful rising. He and his bastard brother Alexander were joined by the former favourite Georges de la Trémoïlle, by John V, duke of Brittany, who allied himself with the English, by John II, duke of Alençon, by Louis, count of Vendôme, and by captains of mercenaries like Antoine de Chabannes and Jean de la Roche who were opposed to the recent military reforms.

The duke of Bourbon gained over to their side the 16-year-old dauphin Louis — afterward Louis XI — and proposed to set aside the king in his favour, making him regent. Louis was readily induced to rebel: but the country was saved from a serious civil war by the energy of the king's officers and the solid loyalty of his "good cities." The constable de Richemont marched with the king's troops into Poitou, his old battleground with Georges de la Trémoïlle, and in two months he had subdued the whole country. Charles VII then attempted to ensure the loyalty of the duke of Bourbon by the gift oi a large pension, forgave all the rebellious gentry and installed his son in Dauphiné (see LOUIS XI).

PRAIRIE, the grassland biome (formation) of North America, the main body extending from southern Alberta to Texas and from the western arid desert eastward to contact with the humid forests. Other grasslands are the desert plains, extending southward from western Texas and Arizona into Mexico, the California prairie of central California and the Palouse prairie of the northwestern states of the U.S. Grasslands ecologically equivalent to various prairies, including the steppe of Russia, the veld of south Africa and the pampas of South America, occur on all continents.

Perennial grasses gave the prairies their special character, but numerous colourful flowering plants, particularly legumes and composites, were conspicuous in spring and autumn. Bison and pronghorn antelope, grazing animals originally abundant on the prairies, disappeared in the earliest days of exploration and settlement. The coyote, jack rabbit, badger, prairie dog, prairie chicken and many kinds of grasshoppers, robber flies and other 'insects are representative of a rich variety of animal life.

Prairie climate is marked by low, irregular rainfall, high summer temperatures, strong winds, high rates of evapotranspiration and intense late summer drought, and is increasingly rigorous from east to west. Along this gradient of decreasing water supply tall grass prairie, of sod-forming grasses 8–10 ft. high, occupied the more humid eastern area to about the 100th meridian, where it graded into the mixed prairie of bunch and sod grasses reaching heights of about 4 ft. Westward, on the high plains leading to the Rocky mountains, sod grasses only a few inches high characterized the short grass plains.

Deep, fertile, organic soils and climate favourable to grain farming led to early destruction of most prairies; only vestiges remain in the highly productive corn and wheat belts. (M. E. B.)

PRAIRIE CHICKEN or PRAIRIE HEN (*Tympanuchus cupido*), a North American grouse (*q.v.*) inhabiting the prairies of the Mississippi valley north to Manitoba and south to Louisiana and Texas. The male has a neck tuft of ten or more rounded feathers, reduced in the female. The lesser prairie hen (T. *pallidicinctus*). smaller, with more buff above, is confined to southwest Kansas and western Texas. The Attwater prairie hen (T. a. *attwateri*) inhabits the coast districts of Louisiana and Texas.

PRAIRIE DOG (*Cynomys*), a heavy-bodied, short-tailed ground squirrel of the western United States and northern Mexico, named for its barking voice. The black-tailed species (C. *ludovicianus*) of the Great Plains lives in large colonies or towns. Formerly these areas covered many miles and contained many thousands of these rodents. but they have been nearly exterminated.

The burrows have raised funnel-shaped entrances, serving to keep out water. Three white-tailed species are found in mountain meadows and high plateaus in the Rockies. All species are buff-coloured, from 10 to 12 in. long, plus tail 2 to 3 in. Rattlesnakes, burrowing owls and the large black-footed ferret are also found in the burrows. but this does not indicate a happy family arrangement, since these animals prey on young "dogs." *See* RODENTIA. (J. E. HL.)

PRAIRIE DU CHIEN, the seat of Crawford county in southwestern Wisconsin, U.S.. owes its existence to the military and economic importance of its site, a point on the Mississippi river about 3 mi. above the mouth of the Wisconsin river. The French and British each maintained a trading post and fort there before the territory became part of the United States in 1783. Ft. Cran-ford. erected in 1816. was for the next four years a link in the chain of military outposts guarding the Indian frontier. After 1820. when the American Fur company erected a depot there. the settlement continued to be the area's trading centre. The development of varied industries ensured its permanence and in 1572 it received its city charter. Campion academy, located in the city. is a widely known residential high school for boys. Villa Louis. home of Hercules Dousman. a factor of the American Fur company, is maintained by the state historical society as a museum. For comparative population figures see table in WISCONSIN: *Population.* (R. F. F.)

PRAKRIT LANGUAGES, in its widest sense, denotes those languages of India which chronologically are Middle Indo-Aryan as distinguished on the one hand from Old Indo-Aryan, *i.e.,* Vedic and Sanskrit; and on the other hand from Modern Indo-Aryan; *i.e.* the present-day languages of north India and Pakistan (see INDO-.%RYAN LANGUAGES). It is thus used by modern scholars both in the west and in India. In this sense it includes the literary Prakrits and Apabhraṁśas used by Hindu. Jain, and Buddhist writers, the languages of many inscriptions and other nonliterary documents ranging from the 3rd century B.C. to the 4th century A.D., the Pali language of Southern Buddhism, and Buddhist Hybrid Sanskrit, in which the Northern Buddhist scriptures were written. The word Prakrit has been used in more restricted senses, especially by the scholars of medieval India. Some have included only the four most important literary Prakrits; others have extended the list greatly, some even to include the Dravidian literary languages, which are not Indo-Aryan at all but have borrowed many Indo-Aryan words. In general these Indian scholars have included only the literary Prakrits used by Hindu and Jain writers: excluding the Buddhist languages and the inscriptional Prakrits. They have listed and characterized briefly many varieties which are claimed to be vernaculars, but of which nothing is otherwise known. There was a tendency to exclude the Apabhramia dialects.

Several etymologies have been given of the Sanskrit word *prākṛta* which denotes these languages. One is that it is derived from *prakṛti* "nature" and means "the natural language" as opposed to Sanskrit (*saṁskṛta*), "the refined (or literary) language." Another involves *prakṛti* in its meaning "basis"; *prākṛta* is then "derived from the basis (Sanskrit)." In either case it is implied that Sanskrit is the norm and the Prakrits are departures from the norm and in a way inferior.

Two slightly differing dialects of Old Indo-Aryan became literary languages in the last two millennia B.C. One is that of the Vedas. The other is classical Sanskrit as formulated by a succession of grammarians ending with Pāṇini (probably 5th century B.C.). From a very early period. other dialects were already developing, differing from these two in the direction of Middle Indo-Aryan. The literary languages after their standardization remained practically unchanging in usage, but the vernaculars continued to diverge. As time went on, the users of the literary languages composed in the literary forms but spoke normally in dialects which were closer to Middle Indo-Aryan. There are even traces of their vernaculars, *i.e.,* Prakritisms, to be found in their literary compositions.

The Prakrits in their turn began to be written, and many of them received literary cultivation. The early chronology is very uncertain, but, it may be that the earliest 'literature is the religious texts of the Buddhists and Jains. The Buddha (6th–5th centuries B.C.) directed that each of his disciples should teach in his own vernacular dialect. It is thought that in the first few generations after the Buddha numerous Middle Indo-Aryan dialects were used in preaching and teaching. This state of affairs seems to be reflected in the multiplicity of Prakrit dialects found in the religious inscriptions of the Buddhist emperor Aśoka (3rd century B.c.). As certain Buddhist centres gained influence, the dialects of these centres came to be used as literary languages to the exclusion of the others, although it is notable that there was much dialect mixture. These teaching dialects, like Sanskrit itself, became standardized, and gradually the spoken vernaculars diverged from them. Of the Buddhist languages, Pali became the standard language of Southern Hinayrtna Buddhism and the vehicle of a great body of canonical and exegetical literature. Other Buddhist schools, including many of the Mahāyāna schools, which are known as Northern Buddhism, seem to have used another Prakrit for a voluminous literature. As controversy with Hinduism began to flourish, Sanskrit came to be used by Buddhists, especially in polemic philosophical discourses. The use of Sanskrit infected this Prakrit, and resulted in a partial Sanskritization of the prose written in it and even of verse texts. The result is that there survive no pure examples of this hypothetical Prakrit; the texts that survive are all more or less Sanskritized, and the language is generally known now as Buddhist Hybrid Sanskrit (BHS). Both chronology and locality are very uncertain. It may be that BHS originated in a more westerly Prakrit dialect and Pali in a more easterly one, which however is still to be identified as central or west central in the Ganges valley. Crystallization of both dialects was complete in the pre-Christian period. A version of one Buddhist text, the Dharmapada (Pali and Prakrit Dhammapada), was found in a central Asian excavation at the end of the 19th century, written in a Prakrit which was different from that at the base of BHS and which belonged originally to northwest India. In all probability there were in the early centuries of Buddhism literatures in other Prakrits than these three that have survived.

For the Jain religion the situation is somewhat similar. The canonical texts of the Śvētāmbara sect are in two dialects of Ardhamāgadhī. Later texts, especially commentaries on the canon, but also others such as the epic *Paümacariya* of Vimala Sūri (perhaps 4th century A.D.) are in Jain Māhārāṣṭrī. The Digambara sect used Jain Śaurasēnī.

In the literature of the Hindus also, Prakrit in several dialects came to be used probably at the end of the pre-Christian era. Later, Māhārāṣṭrī was especially used in composing lyric poetry, possibly on the basis of a popular oral lyric in the dialect; it began to flourish in the 3rd–4th centuries A.D. The most important independent work of this kind that is preserved is an anthology by Hāla, called the *Sattasaī* (Sanskrit title *Saptaśatī* "the 700 verses"); it was compiled between the 3rd and 7th centuries. Māhārāṣṭrī is the language of the lyric verses in the classical period of the Sanskrit drama beginning (in what survives to the present) with Kālidāsa. In this dialect there were also composed epics of the *kāvya* or belles-lettres type. The most important specimens are the *Rāvaṇavaha* or *Sētubandha* (attributed to Pravarasēna, possibly 6th century A.D. dealing with the subject of the Rāmāyaṇa, and the *Gaüḍavaha* of Vākpati (8th century A.D.), celebrating the conquest of Bengal by Yaśōvarman, king of Kanauj. Others exist, including the *Kumārapālacarita*, or the last eight cantos of the poem *Dvyāśraya-mahākāvya* written by Hēmacandra (12th century A.D.) to serve as a series of illustrations to his Sanskrit and Prakrit grammar, the *Siddha-hēmacandra*. These cantos in Prakrit illustrate the Prakrit section of the grammar.

The Sanskrit drama is an important source for knowledge of Prakrit. From its beginning its dialogue must have been intended as a realistic linguistic picture. In it educated men, like kings and brahmans, spoke and also sang in Sanskrit, the literary language par excellence. All others, with few exceptions, spoke the vernacular; *i.e.,* Prakrit. It must have been the case, however, that people of various classes or castes spoke differing dialects, and that people of different localities appeared in the plays speaking their own local dialects. By the time of the earliest specimens now preserved conventions had begun to harden, and by the time of the classical theatre of Kālidāsa and his successors various types of characters were always provided with dialogue in the dialects which were considered appropriate and which had taken on conventional, unchanging forms. Most women, if not of low caste. speak Śāurasēnī, but sing in Māhārāṣṭrī; some children and various other characters, including the brahman clown, speak Śāurasēnī. Various types of servants! fishermen, lowcaste men and many others speak Māgadhī. Other dialects appear in the drama. Unfortunately, after the grammarians had prescribed the forms of the dramatic Prakrists, the dramatists seem to have composed according to rule rather than from any real knowledge of the dialects as living forms of speech.

A Prakrit called Pāiśācī is known through grammarians' statements. According to literary tradition it was the language in which Guṇāḍhya's *Bṛhatkathā* was composed, before A.D. 500 and possibly in the 1st or 2nd century A.D. This work is known through much later reworkings, especially Sōmadēva's *Kathāsaritsāgara* (11th century A.D.), but unfortunately the Pāiśācī text has not yet come to light.

Of nonliterary materials in Prakrit there are early coin inscriptions and inscriptions on stone (3rd century B.C. to 4th century A.D.). Beside the inscriptions of Aśoka, which are the earliest, the most interesting are probably the materials from Niya in Chinese Turkestan. These are official documents from the Kroraina kingdom and date from the 3rd century A.D. Their Prakrit is close to that of the Dhammapada. The original home of the language was northwest India, probably the region of Peshawar; it seems to have been the administrative and literary language of the Kushan empire and its central Asiatic offshoots.

Some of the other Prakrits may be located geographically with some accuracy. Śāurasēnī was the dialect of Śūrasēna, the country around Mathurā (Muttra). It was the language of the Gangetic Doab, and probably extended westward as far as Lahore and eastward as far as the confluence of the Jumna and the Ganges. Its use extended also to Rajputana and Gujarat. Māgadhī was spoken in the eastern half of the Ganges valley, extending westward prohably as far as Banaras. Māhārāṣṭrī was the language of Mahārāṣṭra, the "great Kingdom" south of the Nerbudda river, where in modern times Marāṭhī is spoken. Not all the dialects may be located with equal exactitude. Pāiśācí, for example, may have been spoken in the northwest, although the Vindhya region south of the Ganges valley seems more probable.

Because of the literary pre-eminence of Māhārāṣṭrī, it is the Prakrit described at greatest length by the Indian grammarians, *e.g.,* by Vararuci (before A.D. 700, perhaps much earlier) and Hēmacandra (12th century A.D.). The other Prakrits used in the dramas, as well as numerous others which never appear in the literature, are described sketchily in terms usually of their deviations from Māhārāṣṭrī.

After various Prakrits had been given standard literary form, the vernaculars continued to diverge from these standards. Again at a later period various dialects received literary form; the earliest reference to a literary use of these seems to be in the 7th century A.D. They are known by the name apabhraṁśa ("departure from correct speech"). One dialect; western apabhramia, belonged to the region of Śāurasēnī Prakrit, and is represented by numerous texts. most of them by Jain authors, such as Dhanavāla's *Bhavisatta-kaha* (probably 10th century A.D.), Haribhadra's *Sanatkumāracaritam* (A.D. 1159), and Somaprabha's ***Kumārapāla**-pratibōdha* (A.D. 1195). There are also texts in a southern apabhraṁśa, corresponding to Māhārāṣṭrī, and a few in an eastern apabhraṁśa, corresponding to Māgadhī.

The apabhraṁśa dialects are the immediate predecessors of the modern Indo-Aryan vernaculars, the older stages of which seem to have been recognized by the Indian grammarians as early as the 12th century A.D. The relations. however, between the various Middle Indic dialects and the modern languages are not yet clearly known in detail.

Characterization of the Languages.—The Middle Indo-Aryan languages are marked by progressive changes from the type of the Old Indo-Aryan languages. (Skt. = Sanskrit; Ś = Śaurasēnī; M. = Māhārāṣṭrī.)

Phonetic change is conspicuous. The complex consonant clusters of Skt. are simplified. most frequently by assimilations or losses, sometimes by insertions of vowels, *e.g., putra* "son" > *putta, ratna* "jewel" > *Ś. radaṇa,* Māgadhī *ladaṇa.* Stop consonants between vowels were liable to many sorts of changes. Voiceless stops (k, *t, p*) remained in Pali, became voiced (*g,* d, v) in some dialects, *e.g.,* Ś and apabhramia. but were lost in M., *e.g.,* Skt. *śata* "100" > Pali sata, Ś. *sada,* M. saa. The cumulative effect of all changes was to produce words which are very far from their Skt. origins, *e.g.,* Vappaïrāā = Skt. *Vākpatirājā* "king Vākpati"; *prākṛta* "Prakrit" > Ś *pāüda,* M. *pāüa.*

Noun morphology tends toward simplification; *e.g.,* by loss of the dual number. The eight-case system of Skt, is reduced by loss and amalgamation of cases. Dative forms are completely lost in some dialects; syntactically the dative merges with the genitive. In feminine stems in *ā,* the instrumental. genitive, and locative singular have identical forms. In the apabhraṁśa stage case declension had gone a long way toward the Modern Indo-Aryan system of practically only two cases, absolute and oblique. The system of three genders remains intact until in apabhraṁśa masculine and neuter came near to a complete merging. The numerous declensional types of Skt. are somewhat reduced in number. Especialiy, the consonant stems tend to add vowels and merge with the vocalic declensions.

Verb conjugation shows even greater departures from the Skt. system. With some exceptions, the Skt. consonantal conjugation has been replaced in Prakrit by the conjugation type in which a vowel appears between the final consonant of the root or stem and the inflectional suffix. In Middle Indo-Aryan the vowel is often -a- as in Skt., hut there has been a great extension of use also of *-ē-*, which derives from *-aya-* of the Skt. causative and denominative conjugations. The causative stem on the other hand often has a suffix *-vē-*, in which *v* represents Skt. *p* which in Skt. appears in only a few verbs. Exceptional remnants of the Sanskrit consonantal conjugation include the highly irregular enclitic verb "to be", *e.g., mhi* "I am" (< *asmi*), si "you are" (< asi), etc.; the 3rd singular form atthi (< *asti*) is not enclitic. The past tenses are completely remade into one fairly well unified system in Pali. but in the Prakrit dialects very little remains of them, except such forms as *āsī* "was, were" (< *āsīt*). The present tense has an imperative and an optative. The future remains, usually formed with a suffix *-issa-* or *-ihi-* (< Skt. *-iṣya-*) added to the present stem. Passive stems either derive from Skt. passive stems: with Skt. *-y-* appearing in M. as *-jj-* (*e.g., dijjaï* "it is given" < Skt. diyate), or add a suffix (Ś *-ïa-*, M. *-ijja-*) to the present stem. Infinitives, gerunds, gerundives and present participles all survive from Skt., with many phonetic and other changes. Most important is the past participle, which is passive in transitive verbs and active in intransitive verbs. Syntactically, it occurs most frequently with an instrumental case of a noun, to replace the old past tense and its subject; this is the precursor of the peculiar past tense of Modern Indo-Aryan. Very frequently the past participle shows a suffix Ś. *-ida-*, M. *-ia-* (< Skt. *-ita-*) added to the present stem. This part of the verb system shows more irregularities of form than any other, because of inheritance of old forms from Skt., *e.g.,* Ś. gada-, M. *gaa-* "gone" (< Skt. gata-) beside present stem gacch-; Ś. kida-, M. kaa- "made" (< Skt. *kṛta-*) beside present stem kar-; Ś. *ṇāda-*, M. *ṇāa-* "known" (< Skt. *jñāta-*) beside present stem *jāṇ-*.

The vocabulary of Prakrit is in general derived from Old Indo-Aryan, but there are also many words not so derivable. called *dēśī* or "provincial" words. Lists of these were produced by the Indian grammarians.

See also SANSKRIT LANGUAGE AND LITERATURE ; PALI LANGUAGE; AND JAINS.

PRANDTL, LUDWIG (1875–1953), German physicist famous for his work in aeronautics, was born at Freising. Bavaria, on Feb. 4. 1875. He qualified at Munich in 1900 with a thesis on elastic stability, and was professor of applied mechanics at Göttingen from 1904 until his death there on Aug. 15, 1953. In 1925 he became director of the Kaiser Wilhelm institute for fluid mechanics. His discovery (1901) of the "boundary layer" which adjoins the surface of a body moving in air or water led to an understanding of skin friction drag and of the way in which streamlining reduces the drag of airplane wings and other moving bodies. His work on wing theory, published in 1918–19, which followed that of F. W. Lanchester (1902–07) but was carried out independently, elucidated the flow over airplane wings of finite span. This body of work is known as the Lanchester-Prandtl wing theory (*see* AERODYNAMICS).

Prandtl made decisive advances in boundary layer and wing theories, and his work became the basic material of aerodynamics. He also made important contributions to the theories of supersonic flow and of turbulence, besides contributing much to the development of wind tunnels and other aerodynamic equipment. In addition he devised the soap-film analogy for the torsion of noncircular sections and wrote on the theory of plasticity and on meteorology. (H. B. S.)

PRASEODYMIUM (symbol Pr, atomic number 59, atomic weight 140.92, stable isotope Pr^{141} [100%]) is a metallic element of the rare-earth group. It was discovered by Carl Auer von Welsbach in 1885 when he separated salts of the so-called element didymium into two fractions (praseodymium and neodymium); the name is derived from *praeseodidymium,* meaning "green didymium," reflecting the green colour of its salts. The metal occurs along with the other rare earths in the minerals monazite, cerite and allanite; it is also found among the fission products of uranium, thorium and plutonium. In the past it was usually separated by fractional crystallization employing first a double magnesium nitrate and finally the double ammonium nitrate. Many other procedures have been used but all of them involved long-continued fractional crystallization or fractional precipitation or decomposition. Since 1945 it has been rapidly separated by means of adsorption columns (see RARE EARTHS). The oxide is an almost black powder the composition of which varies according to the method of preparation. It is usually considered to be Pr_6O_{11}; it can be reduced in hydrogen to give Pr_2O_3. The higher valency state of the praseodymium is in question, some authorities claiming it to be tetravalent and others pentavalent. The evidence is slightly in favour of the pentavalent state; thus. Pr_6O_{11} would be a double oxide, $2Pr_2O_3.Pr_2O_5$. The black oxide dissolves in acids. with the liberation of oxygen. to give green solutions or green salts such as $Pr_2(SO_4)_3.8H_2O$. Only the trivalent forms are known in solution; they show a strong characteristic absorption spectrum and are paramagnetic.

The metal is prepared by the electrolysis of the fused halides or by thermoreduction oi its salts with the alkali metals or alkaline-earth metals. Two allotropic forms are known. The α form (somewhat distorted hexagonal close packed, $a = 3.662$ Å, $c = 5.908$ Å) has a calculated density = 6.776 g. per cubic centimeter. The β iorm (cubic close packed, $a = 5.151$ Å) has a calculated density = 6.803 g. per cubic centimeter. The metal melts between 940° C. and 960° C. Alloys of the metal, particularly misch metal (*see* CERIUM), have found various uses. Its salts have found application in the ceramics industry for colouring glass and glazes. *See* RARE EARTHS. (F. H. SG.)

PRATAPGARH (formerly PARTABGARH), a town and district in the Fyzabad division of Uttar Pradesh, India. The town, headquarters of the district. lies about 25 mi. N. of Allahahad, on the Varanasi-Lucknow railway.

PRATAPGARH DISTRICT (area, 1,460 sq.mi.; pop. [1961] 1,251,-402) lies in the southeast of Uttar Pradesh with the Ganges forming its southwestern boundary. The general aspect of the district is that of a richly wooded and fertile plain, relieved by gentle undulations and broken into ravines near the rivers and streams. Smallish barren tracts impregnated with saline efflorescence (reh) occur in places. The only mineral products are salt. saltpetre and *kankar* (nodular limestone). Main crops are rice. barley, pulse, millets and sugar cane; hemp and hides are also produced.

PRATAPGARH is also the name of a town in Chittorgarh district of Rajasthan, India, and of a former princely state. The walled town lies 75 mi. S.E. of Udaipur. Pop. (1951) 14.586. It was founded in 1698 by Maharamat Pratap Singh and became the capital of the princely state, which was once tributary to Indore (Holkar). It came under British protection in 1818 and was merged with Rajasthan in 1945. The people are mostly Bhils and other aborigines (*see* BHIL). Pratapgarh was once well known for its engraved gold enameled work inlaid on emerald-coloured glass. (S. M. T. R.j

PRATINAS (fl. c. 490 B.C.), Greek poet of the Dorian city of Phlius, who brought his satyr plays to Athens and was reckoned as the inventor of this kind of drama. He composed tragedies also, but of the 50 plays claimed for him by the Suda lexicon 32 were satyric, which may indicate that he began to produce before the competition was organized in tetralogies. including one satyr play. His son Aristias competed in 467 with a set of Pratinas' plays, so that he probably died shortly before that date. Unfortunately nothing of his plays survives. Athenaeus quotes a hyporcheme of his (a type of lyric sung by a chorus to the accompaniment of vigorous dancing), which gives a fine impression of his lyric powers: the chorus energetically overwhelm their overpretentious flute player and teach him his place, as their accompanist. This is often stated, against Athenaeus' explicit evidence, to be a fragment of a satyr play. (A. M. DE.)

PRATINCOLE, a shore bird belonging to the genus *Glareola* of the old world family Glareolidae, the best-known being the common pratincole, *Glareola pratincola.* The pratincoles, of which more than 20 species have been described, are small birds, slenderly built and delicately coloured, with a short stout bill, a wide gape, long pointed wings and a deeply forked tail. In some of their habits they are thoroughly ploverlike, running swiftly and breeding on the ground. but on the wing they have much the appearance of swallows and. like them. feed, at least partly, while flying G. *pratincola* breeds in many parts of Spain, north Africa and Sicily, along the valley of the Danube and in southern U.S.S.R.

The black-winged pratincole, G. *nordmanni*, which has black instead of chestnut inner wing coverts, accompanies or, farther east. replaces it; other species occur in Asia, Africa and Australia. *See* also PLOVER.

PRATO IN TOSCANA, a town and episcopal see of Toscana, Italy, in Firenze province, 11 mi. by rail N.W. of Florence, 207 ft. above sea level. Pop. (1957 est.) 93,046 (commune). It is situated on the Bisenzio, and was dominated by a castle built by Frederick II (*c.* 1250). The cathedral was begun in the 12th century; to this period belongs the narrow nave with its wide arches; the raised transepts and the chapels were added by Giovanni Pisano in 1317–20; the campanile dates from 1340, while the façade, also of alternate white sandstone and green serpentine, belongs to 1413. It has a fine doorway with a bas-relief by Andrea della Robbia over it and an open-air pulpit, erected in 1439 by Donatello and Michelozzo for displaying the Virgin's girdle, brought from the Holy Land by a knight of Prato in 1130. The pulpit itself has reliefs of dancing children; beneath it is a splendid bronze capital. The Chapel of the Girdle has a statue of the Virgin by Giovanni Pisano, and a handsome bronze openwork screen. The frescoes in the choir, with scenes from the life of St. John the Baptist and St. Stephen, are by Fra Filippo Lippi (1456–66) and are his best work. The massive old Palazzo Pretorio (13th century) contains a small but good picture gallery. A beautiful Madonna by Filippino Lippi (1498) is in a small street shrine at the corner of the Via Santa Margherita. The Madonna del Buon Consiglio has some good reliefs by Andrea della Robbia, by whom is also the beautiful frieze in the Madonna delle Carceri. This church, by Giuliano da Sangallo (1485–91), is a Greek cross, with barrel vaults over the arms and a dome; it is a fine work, and the decoration of the exterior in marble of different colours (unfinished) is of a noble simplicity.

PRATT, CHARLES (1830–1891), U.S. businessman. one of the creators of the Standard Oil combination, and. as such, ranking high among the men who gave form and substance to U.S. business in the 20th century, was-born at Watertown, Mass., on Oct. 2, 1830. After early training in a mercantile establishment, he became a partner in Raynolds, Devoe & Pratt. manufacturers of paints and oils, then in 1864 formed his own firm, Charles Pratt Manufacturing company, to refine and market petroleum products. He produced "Pratt's Astral Oil," a high-quality kerosene, which he sold widely at home and abroad. In 1874 Pratt decided to join the Standard Oil group of firms, and he immediately became a leading figure in the growth of that business institution. As a member of the executive committee that managed that giant business enterprise, Pratt was a spokesman for conservative policies contributing to the growth of the first great industrial business in the United States. The Pratt Institute Free library in Brooklyn. N.Y., is one of several living indications of his philanthropic interests.

Pratt died on May 4, 1891.

See Ralph W. Hidy and Muriel E. Hidy, *Pioneering in Big Business, 1882–1911* (1955), and references cited. (R. W. HY.)

PRATT, EDWIN JOHN (1883–), the leading Canadian poet of our time; was born at Western Bay, Nfd., on Feb. 4, 1883, the son of a Methodist clergyman. After a preparatory education in Newfoundland and some experience in teaching, he came to Victoria college in the University of Toronto, where he was graduated in 1911. He then studied theology and published *Studies in Pauline Eschatology* (1917). but his academic interests turned to psychology and finally to English literature, which he taught at Victoria college from 1919 until his retirement as professor emeritus in 1953.

His first collection of poems, *Newfoundland Verse* (1923), draws on his early impressions, especially of the hardships and courage of the fishermen in their constant. battle with the sea. Even when lyrical, the poems show an interest in and a distinctive command of the techniques of narrative. to which Pratt turned in *The Witches' Brew* (1925) and *The Titans* (1926), the second of which is made up of two long poems, "The Cachalot," and "The Great Feud." "The Cachalot," an account of a whale hunt, is one of his most brilliant and widely read poems. All three are in octosyllabic couplets, and show a lively humour and the free play of an exuberant imagination that marked Pratt out as a strikingly original poet in a quite new genre. Pratt's fascination with themes of shipwreck broadened and deepened in *The Roosevelt and the Antinoe* (1930) and *The Titanic* (1935), where a more sombre sense of the indifference of nature to human values prevails.

With *Brébeuf and His Brethren* (1940), a blank-verse chronicle of the martyrdom of Jesuit missionaries by the Iroquois, Pratt was established as Canada's most influential poetic personality. (For the importance of his influence *see* CANADIAN LITERATURE [ENGLISH]). Three volumes after *Newfoundland Verse* contain the bulk of his shorter poems: *Many Moods* (1932), *The Fable of the Goats and Other Poems* (1937), *Still Life and Other Verse* (1943). Many of these poems are still concerned with the sea and seafaring life, but there is a growing awareness of the poet's social responsibilities, reflected in the title poem of *Still Life*, in some bitter anti-Nazi satire, and in some philosophical verse, notably *The Iron Door* (1927) and the remarkable dialogue "The Truant" in *Still Life*.

After the outbreak of World War II, Pratt turned mainly to topical themes, especially in *Dunkirk* (1941). His *Collected Poems*, with a preface by William Rose Benet. appeared in 1944 (U.S. edition, 1945; 2nd ed., 1958). *Behilzd the Log* (1947) commemorates the heroism of the Canadian convoy fleet in running supplies to Murmansk through the war, and *Towards the Last Spike* (1952) tells of the building of the Canadian Pacific railway (1870–85). Many features of Pratt's work have made him not simply a respected but a genuinely popular poet in Canada: his preoccupation with the Canadian scene, both historical and geographical; his power of storytelling; his unforced use of the imagery of machinery and technology.

Pratt was awarded the highest civilian honour in Canada, the companion of the Order of St. Michael and St. George, in 1946. and has received many honorary degrees from Canadian universities.

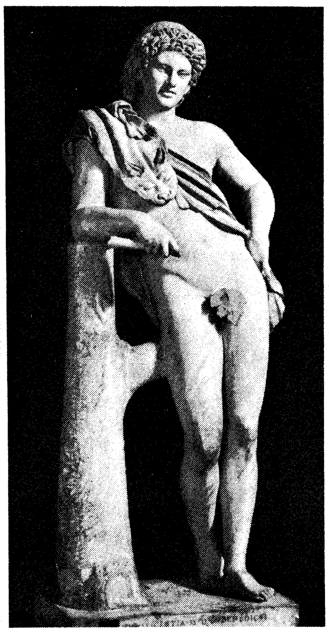
PRAXITELES, of Athens, greatest of the Attic sculptors of the 4th century B.C., was active from perhaps *c.* 370 B.C. to 330 B C. Ancient writers sing his praises. and they are borne out by what would seem to be the only major original work that has survived, *i.e.*, the marble statue of Hermes carrying the infant Dionysus. It was found at Olympia in the temple of Hera, in the very place where it was seen and described by Pausanias (v, 17, 3). The delicate modeling and exquisite finish of the surface enable one to add these qualities in one's imagination to the other works by him that exist only in Roman copies. His most celebrated work was the Aphrodite which he made for Cnidus, considered by Pliny not only the finest statue by Praxiteles but in the whole world. Numerous copies have been recognized — statues, heads and statuettes (in the Vatican and in the Terme museum in Rome; in the Louvre, Paris, at Toulouse; etc.).

Many other statues, both of marble and bronze, are mentioned by ancient writers as works by Praxiteles, but comparatively few have been identified in Roman copies. Chief among them are: the Apollo Sauroctonus, in which the god is shown as a boy leaning against a tree trunk, about to kill a lizard with an arrow; the Artemis Brauronia perhaps reproduced in the charming Artemis of Gabii in the Louvre; and several Erotes and Satyrs.

Two sculptures that can be connected with Praxiteles stand apart. One is a base decorated with Marsyas and the Muses described by Pausanias as in a temple at Mantineia and supporting the statues of Leto, Apollo and Artemis by Praxiteles. Three slabs of this base have actually come to light, and, though probably not executed by Praxiteles himself, for the execution is cursory, they presumably reproduce his design. The other nork is the bust of a youth, found at Eleusis. It seems to be an original Greek work of the 4th century and has by some been thought to be the Eubuleus known to have been made by Praxiteles. It approximates, though it does not equal, the workmanship of the Hermes.

According to Pliny, when Praxiteles was asked which of his statues he valued most highly, he replied "those to which Nicias (a famous painter) has put his hand; so much did he prize the application of colour (circumlitio) of that artist." To visualize the sculptures of Praxiteles it is well to remember how much this colour must have added to the general effect.



ALINARI

"THE CAPITOLINE FAUN," COPIED FROM AN ORIGINAL SCULPTURE ATTRIBUTED TO PRAXITELES. IN THE MUSEI CAPITOLINI ROME

Praxiteles was one of the most original of Greek sculptors. He transformed the 5th-century style of detachment and majesty into one of gentle grace and sensuous charm. His favourite material was marble. of which he was perhaps the greatest exponent. Diodorus says of him that "with consummate art he informed his marble figures with the passions of the soul." It is indeed this subtle, personal element. combined with an exquisite finish of surface, that imparts to his figures their singular appeal.

The influence of Praxiteles was widespread. Figures standing in graceful, sinuous poses and lightly leaning on some support became favourite representations and were later further developed by the sculptors of the Hellenistic age. *See* also GREEK ART.

PRAYER, a term used generally for any humble petition, but more technically, in religion, for that mode of addressing a divine or sacred power in which there predominates the mood and intention of reverent entreaty (from Lat. *precari,* entreat; Ital. *pregaria;* Fr. *prière*).

Prayer and its Congeners.—Prayer in the latter sense is a characteristic feature of the higher religions, and we might even say that Christianity or Mohammedanism, ritually viewed. is in its inmost essence a service of prayer, At all stages of religious development, however, and more especially in the case of the more primitive types of cult, prayer as thus understood occurs together with, and shades off into, other varieties of observance that bear obvious marks of belonging to the same family.

Confining ourselves for the moment to forms of explicit address, we may group these under three categories according as the power addressed is conceived by the applicant to be on a higher, or on much the same, or on a lower plane of dignity and authority as compared with himself. (1) Only if the deity be regarded as altogether superior is there room for prayer proper, that is, reverent entreaty. Of this we may perhaps roughly distinguish a higher and a lower type, according as there is either complete confidence in the divine benevolence and justice, or a disposition to suppose a certain arbitrariness or, at any rate, conditionality to attach to the granting of requests. In the first case prayer will be accompanied with disinterested homage, praise, and thanksgiving, and tends to lose its distinctive character of entreaty or petition, passing into a mystic communing or converse with God. In the second case it will be supported by pleading, involving on the one hand self-abasement, with confession of sins and promises of repentance and reform, or on the other hand self-justification, in the shape of the expression of faith and recitation of past services, together with reminders of previous favour shown. (2) If the worshipper place his god on a level with himself, so as to make him to some extent dependent on the service man contracts to render him, then genuine prayer tends to be replaced by a mere bargaining, often conjoined with flattery and with insincere promises. This spirit of *do ut des* will be found to go closely with the gift-theory of sacrifice (*q.v.*) and to be especially characteristic of those religions of middle grade that are given over to sacrificial worship as conducted in temples and by means of organized priesthoods. So when the high gods are kind for a consideration, the lower deities will likewise be found addicted to such commerce; thus in India the hedge-priest and his familiar will bandy conditions in spirited dialogue audible to the multitude (cf. W Crooke, *Things Indian, s.v.* "Demonology," pp 132, 134) (3) Lastly, the degree of dependency on human goodwill attributed to the power addressed may be so great that. instead of diplomatic politeness, there is positive hectoring, with dictation, threats, and abuse Even the Italian peasant is said occasionally to offer both abuse and physical violence to the image of a recalcitrant saint; and antiquity wondered at the bullying manner of the Egyptians towards their gods (cf. Iamblichus, *De mysteriis,* vi. 5–7). Westermarck supplies many instances from Morocco of *'âr* the "conditional curse," applied to saints in order to make them attend, on pain of disaster if they are recalcitrant (*History and Development of the Moral Ideas,* passim). This frame of mind, however, is mainly symptomatic of the lower levels of cult. Thus the Zulu says to the ancestral ghost, "Help me or you will feed on nettles"; whilst the still more primitive Australian exclaims to the "dead hand" that he carries about with him as a kind of divining-rod, "Guide me aright, or I throw you to the dogs."

So far the forms of address are explicitly directed towards a power that, one might naturally conclude, has personality, since it is apparently expected to hear and answer. At the primitive stage, however, the degree of personificaticn is, probably, often far slighter than the words used would seem to suggest. The verbal employment of vocatives and of the second person may have little or no personifying force. serving primarily but to make the speaker's wish and idea intelligible to himself. When the rustic talks in the vernacular to his horse he is not much concerned to know whether he is heard and understood; still less when he mutters threats against an absent rival, or kicks the stool that has tripped him up with a vicious "Take that!"

These considerations may help towards the understanding of a second class of cases, namely, forms of implicit address shading off into unaddressed formulas. Wishings, blessings, cursings, oaths, vows, exorcisms, and so on, are uttered aloud, partly that they may be heard by the human parties to the rite, but in many cases that they may be heard, or at least overheard, by a consentient deity, perhaps represented visibly by an idol or other cult-object.

From Suggestion to Prayer.—To address and entreat a fellow-being is a faculty as old as that of speech, and, as soon as it occurred to man to treat sacred powers as fellow-beings, assuredly there was a beginning of prayer. We are not likely to know how religion first arose, and the probability is that many springs went to feed that immense river. Thus care for the dead may well have been one amongst such separate sources. It is natural for sorrow to cry to the newly dead "Come back!" and for bereavement to add "Come back and help!" Another source is mythologic fancy, which, in answer to child-like questions: "Who made the world?" "Who made our laws?" and so on, creates "magnified non-natural men," who presently made their appearance in ritual (for to think a thing the savage must dance it); whereupon personal intercourse becomes possible between such a being and the tribesmen, the more so because the supporters of law and order, the elders, associate themselves as closely as possible with the supreme law-giver. From Australia comes a certain amount of evidence showing that, in the two ways just mentioned. some inchoate prayer is being evolved. On the whole, the absence of prayer from the magico-religious ritual of the Australians is conspicuous. Uttered formulas abound; yet they are not forms of address, but rather seli-sufficient pronouncements charged with *mana* (*q.v.*). They involve a wonder-working recognized as such, the core of the mystery consisting in the supposed transformation of suggested idea into accomplished iact by means of that suggestion itself. To the man endowed in the opinion of his iellows (and doubtless of himself) with this wonderful power of effective suggestion, the output of such power naturally represents itseli as a kind of unconditional willing. When he cries "Rain, rain," or otherwise makes vivid to himself and his hearers the idea of rain, expecting that the rain will thereby be forced to come, it is as if he had said "Rain: now you must come," or simply "Rain, come!" and me find that suggestional formulas mostly assume the tone of an actual or virtual imperative, "As I do this, so let the like happen," "I do this in order that the like may happen," and so on. Now it is easy to "call spirits irom the vasty deep," but they do not always come. Hence such imperatives have a tendency to dwindle into optatives. "Let the demon of small-pox depart!" is replaced by the more humble "Grandfather Smallpox, go away!" where the affectionate appellative (employed, however, in all likelihood merely to cajole) signalizes an approach to the genuine spirit of prayer. Again, the user of suggestion conscious of his limitations will seek to supplement his *mana* by tapping, so to speak, whatever sources of similar power lie round about him. A notable method of borrowing power from another agency involving *mana* is simply to breathe its name in connection with the spell that stands in need of reinforcement; as the name suggests its owner, so it comes to stand ior his real presence. Even the more highly developed forms of liturgical prayer tend, in the recitation of divine titles, attributes and the like to present a survival of this formalist use of potent names.

Prayer as a Part of **Ritual.**—By an exactly converse process prayer actually generates formalism, instead of growing out of it. In advanced religion, indeed. prayer is the chosen vehicle oi the free spirit of worship. Its mechanism is not unduly rigid, and it is largely autonomous, being rid of subservience to other ritual factors. In more primitive ritual, however, set forms of prayer are the rule, and their function is mainly to accompany and support a ceremony the nerve of which consists in action rather than speech. Hence, suppose genuine prayer to have come into being, it is apt to degenerate into a mere piece of formalism; and yet, whereas its intrinsic meaning is dulled by repetition according to a well-known psychological law, its virtue is thereby hardly lessened for the undeveloped religious consciousness, mhich holds the saving grace to lie mainly in the repetition itseli. But a formula that depends ior its efficacy on being uttered rather than on being heard is virtually indistinguishable irom the purely suggestional type of utterance, though its origin is different. A good example oi a degenerated prayer-ritual comes from the Todas (*see* W. H. R. Rivers, *The Todas,* ch. x.). The prayer itseli tends to be slurred over, or even omitted. On the other hand, great stress is laid on a preliminary citation of names of power followed by the word *idith*. This at one time seems to have meant "for the sake of," carrying with it some idea oi supplication; but it has now lost this connotation, seeing that it can he used not merely after the name oi a god, but after that of any sacred object or incident held capable of imparting efficacy to the formula. Even the higher religions have to fight against the tendency to "vain repetitions" (often embodying a certain sacred number, *e.g.* three), as well as to the use of prayers as amulets, medicinal charms, and so on. Throughout we must carefully distinguish in theory, though hard in practice, between legitimate ritual understood as such, whether integral to prayer, such as its verbal iorms, or accessory, such as gestures, postures, incense, oil or what not, and the formalism of religious decay, such as generally betrays itseli by its meaninglessness, by its gibberish phrases, sing-song intonation and so iorth.

Silent Prayer. — .% small point in the history of prayer, bearing on the subject of its relation to magic, is concerned with the custom oi praying silently. Charms and words of power being supposed to possess efficacy in themselves are guarded with great secrecy by their owners, and hence, in so far as prayer verges on spell, there will be a disposition to mutter or otherwise conceal the sacred iormula. Thus the prayers of the Todas already alluded to are in all cases uttered "in the throat," although these are public prayers, each village having a iorm oi its own. At a later stage, when the distinction between magic and religion is more clearly recognized and an anti-social character definitely assigned to the former, on the ground that it subserves the sinister interests of individuals, the overt and, as it were, congregational nature of the praying comes to be insisted on as a guarantee that no magic is being employed, a notion that suffers easy translation into the view that there are more or less disreputable gods with whom private trafficking may be done on the sly. Thus, in accordance with the outlook of the classical period, Plato in his *Laws* (909–910) prohibits all possession of private shrines or periormance oi private rites; "Let a man go to a temple to pray, and let anyone who pleases join with him in the prayer." Nevertheless, instances are not wanting amongst the Greeks of private prayers of the loftiest and the most disinterested tone (*cf.* L. R. Farnell, *The Evolution of Religion,* p. 202 *et seq.*). Finally, in advanced religion, at the point at which prayer is coming to be conceived as communion, silent adoration is sometimes thought to bring man nearest to God.

The Moralization of Prayer. — As to the moral quality of the act of prayer, this contrast between the spirit of public and private religion is iundamental for all but the most advanced iorms of cult. In its public rites the community becomes conscious oi common ends and a common edification. Even a very primitive people such as the Arunta of Australia behaves with the greatest solemnity at its ceremonies, and professes to be made "glad" and "strong" thereby. Of his countrymen, whom he would not trust to pray in private, Plato testifies that in the temples during the sacrificial prayers "they show an intense earnestness and with eager interest talk to the gods and beseech them" (*Laws,* 887). In acts of public worship at any rate, therefore, prayer and its magico-religious congeners are at all stages resorted to as a "means of grace," even though such grace does not constitute the expressed object of petition. Poverty of expression is apt-to cloak the real spirit of primitive prayer, and the formula under which its aspirations may be summed up, namely, "Blessings come, evils go," covers all sorts of confused notions about a grace to be acquired and an impurity to be wiped away, which, as far back as our clues take us, invite interpretations of a decidedly spiritualistic and ethical order. To explicate, however, and purge the meaning of that "strong heart" and "clean" which the savage after his fashion can wish and ask for, remained the task of the higher and more sell-conscious types of religion. A favourite contrast for mhich there is more to be said is that drawn between the magico-religious spell-ritual, that says in effect, "My will be done," and the spirit oi "Thy will be done" that breathes through the highest forms of worship. Such resignation in the face of the divine will and providence is, however, not altogether beyond the horizon of primitive faith, as witness the following prayer of the Khonds of Orissa: "We are ignorant of what it is good to ask for. You know what is good ior us. Give it to us." (E. B. Tylor, *Primitive Culture,* 4, 369 [1903]). At this point prayer by a supreme paradox virtually extinguishes itseli, since in becoming an end in itself, a means of contemplative devotion and of mystic communing with God, it ceases to have logical need ior the petitionary form. Thus on the face of it there is something like a return to the self-sufficient utterance of antique religion; but, in reality, there is all the difference in the world between a suggestion directed outwardly in the fruitless attempt to conjure nature without first obeying her, and one directed towards the inner man so as to establish the peace of God within the heart.

(R. R. M.)

PRAYING WHEEL, used by the Buddhists of Tibet as a means of offering invocations. The smallest kind consists of a cylinder of metal or other substance turning on a handle as pivot. Outside it and on strips of paper within is inscribed the invocation to Avalokiteśvara or his consort, *Om Manipadme hūm.* A weight hangs at the side, and with a slight movement of the hand the cylinder revolves. Larger wheels are made to revolve by means of wind or water.

PREACHING, the proclamation of a Divine message, and the regular instruction of the converted in the doctrines and duties of the faith. is a distinctive though not a peculiar feature oi the Christian religion. The Mohammedans exercise it freely, and it is not unknown among the Buddhists. The history of Christian preaching with mhich alone this article is concerned has its roots (1) in the activity of the Hebrew prophets and scribes, the former representing the broader appeal, the latter the edification of the iaithful, (2) in the ministry of Jesus Christ and His apostles, where again we have both the evangelical invitation and the teaching of truth and duty. Whichever element is emphasized in preaching, the preacher is one who believes himseli to be the ambassador of God, charged with a message which it is his duty to deliver.

The Patristic Age, to the Death of St. Augustine, 430.—From the Acts of the Apostles we gather something as to the methods adopted by St. Peter and St. Paul, and these we may believe were more or less general. The Apostles who had known the Lord would naturally recall the iacts of His liie, and the story oi His words and works would form a great deal oi their preaching. It is not until we come to Origen (d. 254) that we find preaching as an explanation and application of definite texts, a usage that Christianity adopted irom Greek rhetoricians. The iourth century marks the culmination of early Christian preaching. In an age of doctrinal controversy, the intellectual presentation of the Christian position was thus developed. Preaching flourished chiefly in the East; especially noteworthy are the three Cappadocians, Basil (*q.v.*) of Caesarea, cultured, devout and practical; his brother Gregory (*q.v.*) of Nyssa, more inclined to the speculative and metaphysical; and Gregory (*q.v.*) of Nazianzus, richly endowed with poetic and oratorical giits, the finest preacher oi the three. Foremost oi all stands John of hntioch, Chrysostom (*q.v.*), who in 386 began his 12 years' ministry in his native city, and in 398 the six memorable years in Constantinople, where he loved the poor, withstood tyranny and preached with amazing power. In the West the allegorical method of Alexandria had more influence than the historical exegesis cultivated at Antioch. This is seen in Ambrose of Milan and in Hilary of Poitiers. Rut the only name of first rank in preaching is that of Augustine, and even he is curiously unequal. His iondness for the allegorical and his manifest carelessness of preparation disappoint as oiten as his profundity, his devout mysticism and his practical application attract and satisiy. Augustine's *De doctrina Christiana,* bk. iv., is the first attempt to formulate the principles oi homiletics.

The Middle Ages.—After the days of Chrysostom and hugustine there was a great decline of preaching. The West did better than the East: at Rome Leo the Great and Gregory the Great could preach, and the missionaries Patrick, Columba. Columbanus, Augustine, Wilirid, Willibrord, Gall and Boniface are known by their iruits. Then came the age when the papacy was growing out oi the ruins of the old Roman empire, and the best talents were devoted to the organization of ecclesiasticism rather than to the preaching of the Word. But certain iorces were at work which were destined to bring about a great revival, *e.g.,* the rise oi the scholastic theology, the reiorms oi Pope Hildebrand and the preaching of the First Crusade by Pope Urban II. (d. 1099) and Peter the Hermit. In the 12th century the significant ieature is the growing use of the various national languages in competition with the hitherto universal Latin. The most eminent preachers of the century were Bernard of Clairvaux (1091–1153), the two mystics of St. Victor, Hugo and Richard, and Peter Waldo of Lyons, who preached a plain message to the poor and lowly. The 13th century saw the culmination of mediaeval preaching, especially in the rise of the tu-o great mendicant orders of Francis and Dominic. Representative Franciscan names are Antony of Padua (d. 1231). who travelled and preached through southern Europe; Bertold von Regensburg (d. 1272), who, with his wit and pathos, imagination and insight, drew huge crowds all over Germany; and Francis Bonaventura, the schoolman and mystic, who wrote a little book on *The But of Preaching.* Oi the Dominicans Thomas Aquinas (d. 1274), the theologian, was perhaps also the greatest preacher. With the 14th century a new note, that of reformation, is struck; but on the whole there was a drop irom the high level of the 13th. Among the popular preachers vigour was often blended with coarseness and vulgarity, Mysticism is represented by Suso, Meister Eckhart, above all Johann Tauler (*q.v.*) of Strasbourg (d. 1461), a true prophet in an age of degeneration. Towards the close of the century comes John Wycliffe (*q.v.*) and his English travelling preachers, who passed the torch to Hus and the Bohemians, and in the next age Savonarola.

The Reformation Period, 1500–1700.—The Reiormers gave the sermon a higher place in the ordinary service than it had previously held, and they laid special stress upon the interpretation and application oi scripture. The controversy with Rome, and the appeal to the reason and conscience of the individual, together with the spread oi the New Learning, gave preaching a new force and influence which reacted upon the old iaith. Most of the Reiormation preachers read their sermons, in contrast to the practice of earlier ages. The English Book of Homilies (see HOMILY) was compiled because competent preachers mere comparatively rare.

The 17th-century preaching was, generally speaking, a continuation of that of the 16th century, the pattern having been set by the Council of Trent and by the principles and practice of the Reiormers. In Spain and Germany, however, there was a decline of power, in marked contrast to the vigour manifested in France and England. In France, indeed, the, Catholic pulpit now came to its perfection, stimulated, no doubt, by the toleration accorded to the Huguenots up to 1685 and by the patronage of Louis XIV. The names of Bossuet, Fléchier, Bourdaloue, Fénelon and Massillon, all supreme preachers, despite a certain artificial pompousness, belong here, and on the reformed side are Jean Claude (d. 1687) and Jacques Saurin (d. 1730). In England, among Anglicans, are Andremes, Hall, Chillingworth, Jeremy Taylor, Barrow and South; among Puritans and Nonconiormists, Baxter, Calamy, the Goodwins, Howe, Owen and Bunyan. The sermons of these men were largely scriptural, the cardinal evangelical truths being emphasized with reality and vigour, but with a tendency to abstract theology rather than concrete religion.

The early years of the 18th century were a time of torpor as regards preaching. Generally speaking, sermons were unimpassioned, stilted and formal presentations of ethics and apologetics, seldom delivered extempore.

The Modern Period.—This dates from 1738, the year in which John Wesley began his memorable work. The example and stimulus given by him and by Whitefield were almost immeasurably productive. In their train came the great field preachers of \Vales, like John Elias and Christmas Evans, and later the Primitive Methodists, who by their camp meetings and itinerancies kept religious enthusiasm alive when Wesleyan Methodism was in peril of hardening. Meanwhile, in America the Puritan tradition, adapted to the new conditions, is represented by Cotton Mather, and later by Jonathan Edwards, the greatest preacher of his time and country. Whitefield's visits raised a band of pioneer preachers, cultured and uncultured, men who knew their Bibles but oiten interpreted them awry.

Preaching, in modern times, has been so varied, depending, as it largely does, on the personality of the preacher, that it is not possible to speak of its characteristics. Nor can one do more than enumerate a few outstanding modern names, exclusive oi living preachers. In the Roman Catholic Church are the Italians Ventura and Curci, the Germans Diepenbrock and Foerster, the French Lacordaire, Dupanloup, Loyson (Père Hyacinthe) and Henri Didon. Of Protestants, Germany produced Schleiermacher, Claus Harms, Tholuck and F. W. Krummacher: France, Vinet and the Monods. In England representative Anglican preachers were: Newman (whose best preaching preceded his obedience to Rome), T. Arnold, F. W. Robertson, Liddon, Farrar, Magee; of Free Churchmen, T. Binney, R. W. Dale. Joseph Parker and J. H. Jowett (Congregationalist); Robert Hall, C. H. Spurgeon, Alexander Maclaren and John Clifford (Baptists); W. M. Punshon, Hugh Price Hughes, Peter Mackenzie and W. L. Watkinson (Wesleyan); James Martineau (Unitarian). The Scottish churches gave Edward Irving, Thcmas Chalmers, R. S. Candlish, R. M. McCheync and John Caird. In America, honoured names are those of W. E. Channing, Henry Ward Beecher, Horace Bushnell, Phillips Brooks, to mention only a few.

See A. E. Garvie, *The Christian Preacher* (1920). (A. J. G.)

PREBLE, EDWARD (1761–1807), U.S. naval officer, whose reputation was earned in the action against Tripoli in 1803–04, was born in Portland. Me.. on Aug. 15, 1761. the son of a Revolutionary War soldier. He joined a privateer at the age of 16, and later, as a midshipman in the "Protector" of the Massachusetts state navy. fought in two severe actions. In 1781 Preble was a prisoner for a time in the notorious British prison ship "Jersey"; then he served as lieutenant in the Massachusetts ship "Winthrop" during a period in which five prizes were captured. After the Revolution he spent 15 years in the merchant service before becoming a lieutenant in the U.S. navy in 1798. Preble commanded the brig "Pickering" under Commodore John Barry during the quasi-war with France. In Aug. 1803 he set out as commodore of a squadron sent against Tripoli. Acting under Preble, Stephen Decatur with a small force destroyed the "Philadelphia," one of Preble's ships, which had been captured before Preble's arrival, in a daring action under the fortress guns of Tripoli. Preble's squadron made five attacks on the city, capturing three enemy gunboats and sinking three others. If he had remained in command a satisfactory peace probably would have been concluded with Tripoli, but a policy of rotation caused the navy department to send out a new commander in Sept. 1804. Preble died in Portland on Aug. 25, 1807. (J. B. HN.)

PRE-CAMBRLAN TIME. The Pre-Cambrian, as the name implies. includes all geologic time before the Cambrian period and all rock formations older than the basal beds of the Cambrian system (*q.v.*), the earliest period of the Paleozoic era, as indicated on the accompanying geologic time chart.

This article is divided into several sections and subsections dealing with the characteristics of Pre-Cambrian time, the economically important mineral deposits in Pre-Cambrian rocks and the more important occurrences of rocks that comprise the Pre-Cambrian record. In addition to the cross references to related material given in the several sections of this article, *see* also GEOLOGY: *Historical Geology* and geology sections of articles on continents, as AFRICA; EUROPE, etc.; and countries, as AUSTRALIA, COMMONWEALTH OF; CANADA, etc.

Following are the main divisions of this article:

Geologic Time Chart

System and Period	Series and Epoch	Distinctive Records of Life	1,000 Years
		CENOZOIC ERA	
Quaternary . .	Recent	Modern man . . .	11
	Pleistocene	Early man	1,000
Tertiary . . .	Pliocene	Large carnivores . . .	
	Miocene	Whales, apes, grazing forms	
	Oligocene	Large browsing mammals .	
	Eocene	Rise of flowering plants .	
	Paleocene	First placental mammals .	70,000
		MESOZOIC ERA	
Cretaceous		Extinction of dinosaurs .	130,000
Jurassic		Dinosaurs' zenith, primitive birds, first small mammals	160,000
Triassic		Appearance of dinosaurs .	200,000
		PALEOZOIC ERA	
Permian		Reptiles developed, conifers abundant	235,000
Carboniferous			
Upper (Pennsylvanian) . . .		First reptiles, coal forests	260,000
Lower (Mississippian) . . .		Sharks abundant . . .	285,000
Devonian		Amphibians appeared, fishes abundant	320,000
Silurian		Earliest land plants and animals	350,000
Ordovician		First primitive fishes . .	400,000
Cambrian		Marine invertebrates . .	500,000
		PRE-CAMBRIAN TIME	
		Few fossils . .	3,500,000–4,000,000

I. CHARACTERISTICS

Throughout most of the world where the contact of the Cambrian and Pre-Cambrian is exposed, a great unconformity or gap in the succession of formations separates the Camhrian from the Pre-Cambrian. In a few regions, however, there seems to be no unconformity, the Cambrian beds passing without interruption downward into strata believed to be of Pre-Cambrian age. Most of the Cambrian and later strata of the Paleozoic contain numerous fossils—evidence of varied and abundant life—while in contrast with this there are almost no fossils in the Pre-Cambrian.

Wherever erosion has removed the Paleozoic and later formations. Pre-Cambrian rocks are usually present. They are exposed over one-fifth of the land surface of the earth and, except where intruded by igneous rocks of later age, exist everywhere at a depth beneath Paleozoic and later strata. They occur in areas of two kinds: (1) the deeply denuded parts of mountain chains where they have been uplifted by mountain building; and (2) in widely extended areas of relatively low elevation, called shields because of their gentle outward slopes resembling roughly the surface of a shield. The occurrences in mountain chains are much more restricted in extent than in the shield areas.

The formations of the Pre-Cambrian are, for the most part, highly folded and intruded by masses of granite, granite gneiss and other igneous rocks, most of which came in at depth as the Pre-Cambrian mountain-building folding was in progress. On the margins of the Pre-Cambrian shield areas, Cambrian and later beds in many places lie on the upturned edges of Pre-Cambrian strata. This relationship shows that, prior to the Cambrian, the Pre-Cambrian mountains were worn down to a relatively low land area over which the Cambrian sea advanced.

Although most Pre-Cambrian rocks have been subjected to the deformation and alteration that accompanies mountain building, many of the shield areas have suffered little change through all the later eras; and original structures even of the earliest Pre-Cambrian have been remarkably well preserved. It has been found possible in many Pre-Cambrian regions, by means of detailed mapping. to determine the structural succession of formations over considerable areas. Only a relatively small part of the Pre-Cambrian has been mapped in this way; and because of the absence of fossils, much intensive geological work will be necessary before the rocks can be correlated with certainty even within most of the separate Pre-Cambrian areas.

1. Dating.—The discovery that radioactive elements slowly disintegrate into other elements affords a may in which the approximate age of Pre-Cambrian rocks can be determined. Thus from the time a uranium-bedring mineral is formed. its uranium slowly breaks up into helium and isotopes of lead.

Since the rate of disintegration of the uranium is known, it is possible to determine the age of the mineral from the amounts of lead isotopes relative either to one another or to the uranium present. Many pegmatites and other igneous rocks of the Pre-Cambrian contain uranium-bearing minerals, the oldest of which was determined in 1939 to have an age of about 2,500,000,000 years. The rocks in which these occur, however, are intrusive into older formations, and it has been estimated that the oldest Pre-Cambrian rocks on the earth's surface have an age of at least 3,500,000,000 to 4,000,000,000 years. See also GEOCHRONOLOGY.
