2. The Pre-Cambrian World.—For all of Pre-Cambrian time for which there is a geological record. conditions on the surface of tht earth appear to have been similar in most respects to those of later eras. Mountain building and volcanic activity recurred as in the later periods of the earth's history; water played the same role as it does today; rocks were deeply eroded; and conglomerates, sandstones and other sediments were deposited in the same manner as at the present time. There is evidence also that ice sheets similar to the one now covering most of Greenland existed in Canada, India. South Africa. Australia and elsewhere.

II. ECONOMIC IMPORTANCE

Because most valuable mineral deposits are found in association with igneous rocks of deeply denuded mountainous or formerly mountainous regions, the Pre-Cambrian parts of the earth's surface are of special economic importance. Most of the world's largest gold mines, including those of the Transvaal and Southern Rhodesia (Africa), South Dakota (U.S.), northern Ontario and Quebec (Canada), Brazil and western Australia, are in Pre-Cambrian rocks. The important iron deposits of the Lake Superior region in the United States, the iron deposits of Labrador-Quebec, the iron ores of Brazil and northern Sweden, the great nickel-copper ore masses of Sudbury, Ont., the silver-bearing cobalt-nickel veins of Cobalt. Ont., the occurrences of uranium in South Africa and Canada, and many important copper deposits belong to the Pre-Cambrian. It also includes a great variety of useful nonmetallic minerals. Among these are garnet, talc, mica, graphite, feldspar and magnesite.

III. THE PRE-CAMBRIAN RECORD

A. North America

Pre-Cambrian rocks occur in North America mainly in the Canadian Pre-Cambrian shield that occupies most of the northeastern part of the continent. They also occur, however. in numerous scattered areas in the western or Cordilleran part and in places in the eastern belt of folded rocks that extends from Alabama to Newfoundland.

The Canadian shield is the world's largest area underlain by Pre-Cambrian rocks. It includes most of northeastern Canada and the greater part of Greenland, and extends into the United States west and south of Lake Superior and in northern New York state. It has a total area of about 2,780,000 sq.mi., of which about 800,000 sq.mi. are in Greenland; 1,905,000 in Canada; and 75,000 in the United States.

The limits of the shield are sharply defined on the east, except in eastern Greenland, by the Atlantic ocean; and on the south and west by south- and southwest-dipping sediments of later age that outcrop in a succession of alternating lowland and north- or northeast-facing scarp belts. On the north the boundary is less definite, the Pre-Cambrian surface disappearing first beneath scattered remnants, and finally beneath a most irregular border of Paleozoic or later sediments.

Only a very small part of the shield has been mapped geologically in detail but, taken as a whole, its rocks belong naturally to two major divisions—the Archean (or Archeozoic) or Early Pre-Cambrian and the Proterozoic or Late Pre-Cambrian. The major break in deposition or unconformity used as the standard of reference for the separation of the Archean from the Proterozoic was originally observed in 1845 on Lake Timiskaming on the border between Ontario and Quebec by Sir William Logan, first director of the Geological Survey of Canada; and was later found to extend with reasonable certainty from Lake Mistassini in northern Quebec to the region south of Lake Superior in the United States, a distance of more than 900 mi. Formations beneath this unconformity in the southern part of the shield are classed as Archean (Early Pre-Cambrian), those above as Proterozoic (Late Pre-Cambrian). Rocks in the northern parts of the shield are either assigned on their lithological and structural similarity to the Archean or Proterozoic; or are unclassified under the designation Archean and/or Proterozoic. In places, the Archean classification of formations is confirmed by physicochemical age determinations of minerals.

1. Canadian Shield Archean.—The Early Pre-Cambrian or Archean (from the Greek for "ancient") formations of the Canadian shield, classified according to their lithological character and mode of origin, belong to two entirely different types In the territory extending from the north end of Lake Hurcn to the Strait of Belle Isle, the Adirondack region in New York state, Baffin Island and Greenland, the Archean rocks are limestone and associated sediments of the types laid down in the sea adjacent to land of low relief; whereas elsewhere in the shield limestone is almost wholly absent and the predominant formations are lava flows and clastic sediments (that is, composed of fragments of pre-existing rocks), characterized by features that suggest either deposition on land or in the sea adjacent to mountains.

Information is far too incomplete for setting up a single tabular classification of the Archean rocks of the shield that would hold for its entire area; but in the Timiskaming region of northeastern Ontario and western Quebec, where an area of about 2.600 sq.mi. has been mapped geologically in detail, the succession in descending order (*i.e.*, from youngest to oldest strata) is as follows:

Archean Rocks in Timiskarning Region

GREAT UNCONFORMITY

Archean:

Batholithic intrusives
  Granite and related rocks
Intrusive masses, dykes and sills
  Diorite, gabbro, peridotite and related rocks
Timiskaming
  Conglomerate, graywacke and volcanic rocks

UNCONFORMITY

Pre-Timiskaming batholithic intrusives
  (represented only by pebbles in Timiskaming conglomerate)
Pontiac and Hoyle groups
  Graywacke, lava flows and fine-grained volcanic *ejectamenta* (tuff)
Keewatin
  Lavas, volcanic fragmental rocks (agglomerate) and tuff

In the region northwest of Lake Superior the Archean succession from youngest to oldest is the following:

Archean Rocks Northwest of Lake Superior

Archean:

Algoman batholithic intrusives
  Granite and related rocks
Knife lake, Steeprock lake and Seine river series
  Sediments, lava flows and pyroclastic volcanic rocks

UNCONFORMITY

Laurentian batholithic intrusives
  Granite and related rocks
Keewatin
  Lavas and Soudan iron formation member
Coutchiching*
  Mica schist and gneiss of sedimentary origin

*Relationship of Coutchiching to Keewatin uncertain

Although the above tabulations are from localities more than 600 mi. apart, there is apparently considerable similarity in the succession in the two regions and, for this reason, some correlations have been attempted between them. For example, the name Keewatin (from an Indian word for "north wind"), first proposed by A. C. Lawson in 1885 for volcanic rocks occurring in the Lake of the Woods district northwest of Lake Superior. has been used by almost all geologists for similar rocks occurring in northern Ontario and eastward in western Quebec. Some geologists have also assumed that the post-Timiskaming granites of the Timiskaming region are of the same age as the Algoman (from Algoma, Ont.) granites of the region northwest of Lake Superior. According to these assumptions two separate mountain-building uplifts extended across the whole southern part of the Canadian shield during the Archean era. It is possible that detailed geological mapping in northern Ontario might prove this hypothesis true, but much geological work would be required to establish it.

In the southeastern part of the Canadian shield, where the Grenville (Grenville township, Ont.) sediments, believed to be of marine origin, occur, the most complete succession of formations is in southeastern Ontario. A tabular statement of the sequence of formations in this region, Commencing with the youngest, is as follows:

Archean Rocks in Southeastern Ontario

Archean:

Batholithic intrusives
  Granite, granite gneiss, syenite and related rocks
Diorite, gabbro and related rocks
Hastings series
  Limestone, dolomite, graywacke, mica schist, conglomerate

UNCONFORMITY

Batholithic intrusives
  (represented only by pebbles in Hastings conglomerate)
Grenville series
  Crystalline limestone, dolomite, quartzite, garnet gneiss, mica schist, lava flows, pyroclastic volcanic rocks

Except for the presence of the Hastings (Hastings county, Ont.) series and the Grenville volcanic rocks restricted mainly to south-

BY COURTESY OF GEOLOGICAL SURVEY OF CANADA

PILLOW STRUCTURE IN VERTICALLY FOLDED LAVA FROM THE PRE-CAMBRIAN KEEWATIN FORMATION FOUND IN WESTERN QUEBEC

Pillows are rounded above and flat or V-shaped below, indicating the upper and lower sides of lava flows, and are important in determining Pre-Cambrian structure. Pillows form where lava is extruded into the sea

eastern Ontario, the above succession is similar to that throughout most of the Grenville region or subprovince that extends from the north end of Lake Huron and the Adirondack region northeast to the Strait of Belle Isle. However, at Mt. Wright and Wabush lake about 220 mi. north of the lower St. Lawrence river, recrystallized iron-bearing sediments occur that are believed to be a southern part of the Labrador-Quebec Proterozoic sedimentary belt.

2. Canadian Shield Proterozoic.—Late Pre-Cambrian or Proterozoic (from the Greek for "before" and "life," that is, before the Paleozoic, or era of "ancient life") rocks occur extensively in the southern part of the Canadian shield south and northwest of Lake Superior and in the territory extending northeast from the north shore of Lake Huron to Lake Timiskaming. In the region south of Lake Superior in 1935 they were called Algonkian type and classified by C. K. Leith, R. J. Lund and A. Leith in descending order as follows:

Proterozoic Rocks South of Lake Superior

Proterozoic	Keweenawan	Acidic intrusives Basic instrusives Sandstone, shale, conglomerate, lava flows
		Unconformity
	Upper Huronian	Sediments, iron formation, volcanic rocks
		Usconformity
	Middle Huronian	Basic intrusives, iron formation, sediments
		Unconformity
	Lower Huronian	Dolomite and quartzite
		Unconformity

In the region northwest of Lake Superior, F. F. Grout, J. W. Gruner. G. M. Schwartz and G. A. Thiel in 1951 classified the Proterozoic rocks as follows:

Proterozoic Rocks Northwest of Lake Superior

Proterozoic	Keweenawan	Upper—Sandstone, other sediments Middle—Acid, basic intrusives, lavas Lower—Conglomerate, sandstone
		Unconformity
	Animikie	Slate, iron formation and quartzite
		Unconformity

In the Lake Huron-Lake Timiskaming region in northern Ontario the Late Pre-Cambrian or Proterozoic rocks are classified as follows:

Proterozoic Rocks in Northern Ontario

Proterozoic	Acid and basic intrusive rocks Whitewater series	
		Unconformity
	Cobalt series	
		Unconformity
	Bruce series	
		Unconformity

Of the above, the Bruce series is probably the eastward continuation of the Lower Huronian of the region south of Lake Superior. The Cobalt series. although believed to be in part of glacial origin. is usually classified as Middle Huronian. The correlation of the Whitewater series is in doubt. It was formerly thought to be Keweenawan or possibly Animikie, but in 1956 J. E. Thomson suggested that .it might be oi considerably older age.

In the vast northern part of the shield, extending from the Strait of Belle Isle to Great Bear lake and the Arctic ocean. the rocks of the Proterozoic belong to three main classes: (1) in the northern part of the shield west of Hudson bay, extensive separate areas of flat-lying conglomerate, sandstone and lava flows known from place names as the Coppermine river, Et-then, Dubawnt and Athabasca groups; (2) in the eastern part of the shield, areas or belts of partly folded and partly gently dipping iron formation, dolomite and clastic sediments of the Belcher Islands. Richmond gulf. Labrador-Quebec or similar groups; and (3) in the northwestern part of the shield unconformably beneath the Coppermine river and Et-then rocks, zones of folded dolomite, limestone, quartzite and graywacke called Great Slave, Snare and Nonacho groups. The rocks of class 1 are similar to the Keweenawan of the Lake Superior region; those of class 2 to the Animikie northwest of Lake Superior; and those of class 3 to the Huronian south of Lake Superior.

3. Other North American.—In the western Cordilleran part of North America, the best known section of Pre-Cambrian rocks is that exposed in the Grand canyon of the Colorado river in Arizona. The most extensive occurrence, however, is that of the Proterozoic Beltian (Little Belt mountains. Mont.) formations. These occupy an area 300 mi. wide in northern Idaho, Montana and Washington. and extend discontinuously northwest with a maximum width of about 100 mi. through British Columbia to the Yukon in Canada.

Pre-Cambrian rocks occur in Arizona in the Grand canyon area and are widely scattered in southern, southwestern and western parts of the state. In the Grand canyon gorge the oldest rocks, known as the Vishnu schist, are classed as older Pre-Cambrian. They consist of igneous gneisses and altered sediments. They are cut by dikes of granite and pegmatite. 4 younger group of Pre-Cambrian rocks 12,000 ft. thick, the Grand canyon series, composed mainly of sediments, rests uncomformably on the Vishnu schist. In other parts of Arizona the older Pre-Cambrian rocks are known as the Yavapai or Pinal schist, and the younger as the Apache group.

The rocks of the Beltian system include argillite. impure limestone. quartzite and other sediments. They are estimated to have a thickness up to 35,000 ft. in the United States. In Canada, according to H. M. A. Rice, they have a total thickness of 67,000 ft. and occur in two series separated by an important unconformity.

In the belt of folded rocks that lies parallel with the east coast of North America. there are Pre-Cambrian rocks in eastern Newfoundland, in southeastern Nova Scotia, along the northwest shore of the Bay of Fundy in New Brunswick, and in zones within or adjacent to the eastern part of the Appalachian mountains from the Canadian border to Georgia. In southeastern Pennsylvania and adjacent parts of New York, New Jersey and Maryland. the Pre-Cambrian includes sedimentary and igneous gneisses overlain unconformably by crystalline limestone, dolomite, quartzite, sedimentary gneisses and schists. The older group of rocks is known as the Baltimore gneiss; the younger as the Glenarm series. Farther south the schists and gneisses of the Blue Ridge and the (Piedmont) plateau belts have been classed as Pre-Cambrian by most geologists who have examined them.

B. South America

Pre-Cambrian formations outcrop in South America mainly in two regions: (1) in elongated zones here and there in the western Cordilleran belt of mountains extending from Venezuela to Chile; and (2) in broad masses or scattered areas in the eastern part of the continent, but most extensively in Brazil, southeastern Venezuela. French Guiana, Surinam (Dutch Guiana) and British Guiana. The territory in northeastern South America underlain by Pre-Cambrian rocks lying south of the Amazon basin is known as the Brazilian shield or Amazonia; that north of the Amazon basin as the Guianan shield or Guiania. The zones of the Cordilleran region consist mainly of granite, schists and gneisses, which have been classed as Early Pre-Cambrian largely because of their highly altered condition. The succession of formations in central and southeastern Minas Gerais state, Brazil, is believed to be typical of the Brazilian shield. The oldest rocks of this region include gneisses and schists, presumably transformed sediments, overlain successively by two groups of late Pre-Cambrian sediments. the Minas series composed mainly of quartzite, slate, dolomite, conglomerate and iron formation called itabirite; and the Itacolumi series consisting chiefly of quartzite. All of these have been mountain built, as shown by their highly folded condition and intrusion by granite.

The oldest rocks of the Guianan shield are crystalline schists, limestone, gneisses and granite of Early Pre-Cambrian age. These are overlain in unconformable succession by two groups of Late Pre-Cambrian rocks: (1) the Balling. composed of lava flows with interbedded iron formation and other sediments; and (2) the Orapu, a sedimentary series consisting of conglomerate. quartzite and slate. Mountain building and granitic intrusion followed the deposition of both the Balling and Orapu formations.

Important mineral deposits occur in both the Brazilian and Guianan shields. These include hematite iron ore, manganese, gold, mica and diamonds in Brazil; gold in British Guiana; and hematite-magnetite iron ore in Venezuela.

C. Europe

Small areas or zones of Pre-Cambrian rocks occur widely scattered in Europe wherever deeply eroded folded rocks of mountains or former mountains are present, but by far the largest area underlain by Pre-Cambrian formations is that known as the Baltic shield (Baltica or Fennoscandia), which occupies a large part of Norway, and most of Sweden, Finland and northwestern U.S.S.R. west of the White sea. There are also considerable areas of Pre-Cambrian in the Highlands of Scotland and northeastern Ireland that may be parts of a western extension of the Baltic mass.

The most important mineral deposits in the Pre-Cambrian of Europe are in the Baltic shield. These include magnetite iron ore at Kiruna in Sweden and apatite in the Kola peninsula of U.S.S.R.

1. Fennoscandia (Baltic Shield).—The Pre-Cambrian area of Fennoscandia or the Baltic shield extends from the Arctic ocean to the island of Bornholm in the Baltic sea and from the eastern extremity of Kola peninsula in the U.S.S.R. to the westernmost tip of Norway. In the 1930s J. J. Sederholm classified the Pre-Cambrian rocks of this region into four divisions: (1) Sivonian; (2) Bothnian; (3) Jatulian-Kalevian; and (4) Jotnian, each of which he believed was separated from the underlying and overlying divisions by great unconformities. He also believed that the intervals of erosion represented by these unconformities in every case were preceded by mountain building and intrusion of granitic rocks which were laid bare by erosion before the succeeding formations were deposited. Finnish and Swedish geologists have concluded from later work. however, that mountain building did not intervene between the Sivonian and Bothnian rocks, and that these beiong to a single group. This Sivonian-Bothnian succession of formations includes abundant altered sandy sediments, conglomerate, limestone and interbedded volcanic rocks. They are intruded by basic igneous rocks and post-Bothnian granite. The Jatulian-Kalevian group is composed of conglomerate, ripple-marked quartzite, dolomite and greenstones that have been transformed by folding and intrusion of granite. Curing the Late Pre-Cambrian the peculiar Rapakivi granite was intruded, after which the Jotnian sandstone was deposited. Since the earlier work of Sederholm, considerable progress has been made in the study of the granitic rocks of Fennoscandia; and some Finnish geologists, notably P. Eskola, have concluded that these igneous intrusions are related to two mountain-building uplifts: (1) the Svecofennidic or post-Sivonian; and (2) the Karelidic or post-Kalevian. According to Eskola. the Svecofennidic mountain chain extended east-west through central Sweden and southwest Finland; the Karelidic mountain folding trended northwest from Lake Ladoga through eastern Finland and Lapland. In the folded Caledonian mountains of Norway, thick sandy sediments, known as the Sparagmite or Eocambrian formation, occur extensively at the top of the Pre-Cambrian succession.

2. Scotland.—The Pre-Cambrian of Scotland lies north of the great fault that marks the southern border of its Highlands. In this region there are four main rock groups of Pre-Cambrian or possible Pre-Cambrian age. These are: (1) The Lewisian (from Lewis-and-Harris Island in the Outer Hebrides) complex, consisting of sediments that have been transformed into gneisses and schists, and intruded by granite, igneous gneisses, pegmatite and ultrabasic racks. It occurs in the northwest Highlands and in the Hebrides Islands. (2) The Moine series, composed of metamorphosed sediments, ultrabasic or basic intrusive rocks, and banded gneisses formed by the intrusion of granite into schist. (3) The Dalradian (from region of Dalradia, Scot.) series, a metamorphic group of rocks mainly of sedimentary origin. It occurs in the southeast Highlands north of the Highland boundary fault. (4) Unaltered conglomerate, sandstone, grit and shale—the Torridonian (from Loch Torridon. Scot.) sediments. These are only gently folded. They rest unconformably on Lewisian gneiss in the northwest Highlands, in the Hebrides and other adjacent islands, and are overlain with structural unconformity by Cambrian sediments. The Lewisian presumably belongs to the Early, and the Torridonian to the Late Pre-Cambrian. The Moine sediments have been variously classified as Lewisian, post-Lewisian but pre-Torridonian, Torridonian, or early Paleozoic transformed by Caledonian mountain building. According to James Phemister, the post-Lewisian pre-Torridonian age is probably the most generally accepted hypothesis. The Dalradian rock group is of uncertain age. Some geologists think it Pre-Cambrian but others maintain that it belongs wholly or in part to the Cambrian.

D. Asia

Rocks that are positively known to be Pre-Cambrian, or are probably Pre-Cambrian. are widespread in Asia wherever eroded mountains occur. The most extensive areas, however, are in eastern Siberia, northeastern China, Korea, India and Arabia.

1. Siberia.—The Pre-Cambrian of Siberia occupies two extensive areas in the headwater parts of the Yenisei and Lena river basins. The northeasterly of these is called the Annabar shield and that to the southeast the Aldan shield. The rocks in the central parts of these ancient land masses are called Archean, and include crystalline limestone, quartzites and other metamorphosed sediments. schists, gneisses and intrusions of granite. In their border zones. notably in the Lake Baikal region, the Archean complex is overlain unconformably by a folded succession of two Proterozoic, structurally unconformable, metamorphic series. The lower of these consists of schists, conglomerate and quartzites; the upper of phyllites, sandstone and interbedded lava flows. In parts of the region Cambrian strata rest on the Early Pre-Cambrian complex, and Proterozoic strata are absent. Geologists of the U.S.S.R., noting the wide zone of unfolded Paleozoic rocks that commonly encircle the Pre-Cambrian shield areas, designate the combined shield and surrounding undeformed formations as platforms.

2. China.—In China Pre-Cambrian rocks occur widely from Mongolia southeast, east and northeast to the Siberian border. They belong to three unconformably separate groups: (1) the Tai-Shan or Archean complex of gneisses, schists and altered sediments, intruded by granite and basic igneous rocks; (2) the Wu-T'ai system composed of dolomite, conglomerate and other sediments metamorphosed to schists, interbedded greenstones—probably altered volcanic rocks—and gneisses intruded by granite; and (3) the Sinian system consisting of limestone, quartzite, shale and other sediments. The Wu-T'ai is compared by some authors with the Huronian of North America. The Sinian is similar in many respects to the Beltian sediments of western United States and Canada. In Manchuria and Korea the names Lia-ho and Keirin have been given by Shintaro Nakamura to rocks believed to be the equivalent of the Wu-T'ai and Tai-Shan systems. Geologists conclude that Pre-Cambrian granitic rocks of three ages occur in north China and Korea.

3. India.—The bedrock surface of peninsular India and the adjacent island of Ceylon is composed mainly of highly folded, crystalline schists and gneisses intruded by granite and granite-gneiss, and a widespread group of igneous rocks containing the mineral hypersthene and known as the Charnockite series. This complex was called Vedic and correlated with the Archean by Sir Thomas H. Holland. It includes an abundance of crystalline limestone, and other highly altered sediments, which, as noted by F. D. Adams in Ceylon, resemble the Grenville series in the southeastern part of the Canadian shield.

In parts of the'peninsula the sediments and schists of sedimentary origin within the complex are known as the Dharwar system. These Early Pre-Cambrian rocks are overlain unconformably by great thicknesses of little disturbed rocks called

Purana. They contain no fossils and are believed to be of Late Pre-Cambrian age. The Purana sediments have been variously named in different parts of the peninsula. In central India they are divided into two series separated by an unconformity, the Gwalier and Vindhyan. The gold-bearing veins of the Kolar gold fields in Mysore intersect schists of the Dharwar system. Deposits of white mica (muscovite) occur in pegmatite dikes cutting the Dharwar or similar rocks in several provinces of India. The graphite of Ceylon occurs in veins cutting the older gneisses.

E. Africa

Pre-Cambrian rocks occur in many places in Africa but are most widespread in an irregular zone extending longitudinally from Arabia and Egypt to Cape province of the Union of South Africa, and transversely from the Gulf of Aden almost to the western extremity of the continent. They also underlie most of the island of Madagascar and occur discontinuously in a narrow belt adjoining the west coast from the Gulf of Guinea southward. In most of these regions they are not in contact with Cambrian formations but are overlain with great unconformity by Devonian, Permo-Carboniferous or later strata. Their classification as Pre-Cambrian is, therefore, based largely on their metamorphic condition and lithological character.

In most of the Pre-Cambrian areas of Africa, a highly deformed basal group of Archean-like schists and gneisses, usually called the Basement, is overlain with great unconformity by one or more less altered rock series. A multitude of local names have been given to these various rock groups but only those occupying extended areas can be mentioned. In the Sahara region of north Africa, two major rock divisions have been observed; the lower is known as Suggarien and the upper, Pharusien. To the southwest, in French West Africa, Ivory Coast and Ghana, the names Dahomeyan or Archean, Birrimian and Tarkwaian have been used over a large area. In Kenya and Tanganyika, which are predominantly underlain by Pre-Cambrian rocks, the Pre-Cambrian formations are classified into three main groups: the Basement, Nyanzian and Kavirondian systems. Extensive areas of gneiss and granite intervening in age between the Basement and Nyanzian systems have been mapped as the Granitoid shield by G. M. Stockley.

The major Pre-Cambrian divisional names in southeast Africa are included in the following table:

Name	*Rocks*
Waterberg system	Conglomerate, quartzite, shale, volcanic rocks
Transvaal system	
Pretoria series	Conglomerate, quartzite, shale and lavas
Dolomite series	Dolomite, chert and quartzite
Black reef series	Conglomerate, quartzite and shale
Ventersdorp system	Conglomerate, quartzite, chert, shale and volcanic rocks
Witwatersrand system	
Upper division	Conglomerate, grit and quartzite
Lower division	Conglomerate, arkose, quartzite, slate, lavas

The Witwatersrand rocks are of special interest because they contain the world's largest known deposits of gold. They have a total thickness of more than 24,000 ft. The gold occurs in conglomerate beds known as bankets or reefs. In South-West Africa and western South Africa, a succession of conglomerates, quartzites, dolomite and limestone called the Nama system, because of lithological similarity, has been correlated tentatively with the Transvaal rock group. One of the outstanding features of the South African Pre-Cambrian is the widely extended assemblage of volcanic and intrusive igneous rocks known as the Bushveld complex that occurs in central Transvaal. This igneous activity occurred mainly between late Pretoria and Waterberg deposition. Considerable amounts of tin and chrome ore are found in the intrusive phases of the Bushveld complex.

F. Australia and New Zealand

The Pre-Cambrian formations of Australia and New Zealand occur in either (1) relatively small scattered areas or zones in the cores of mountains or highlands in New South Wales, South Australia, northern Queensland, western Tasmania and southwestern New Zealand; or (2) in the widely extended shield area of western and central Australia. In most of these regions an older group of schists, gneisses or volcanic rocks and intrusive granite classed as Archean is overlain unconformably by less deformed sediments or lavas called Proterozoic. At Broken Hill in New South Wales highly altered sandy, argillaceous and calcareous sediments of the Archean Willyama series are overlain unconformably by the Proterozoic Torrowwangee series composed of limestone, shale and boulder beds.

In New South Wales the older sediments of the Hutchison series and granite gneisses are overlain unconformably by folded limestone, quartzite and slate of the Adelaide series. In the Mount Isa region of northern Queensland, the Pre-Cambrian is represented by four rock groups separated by unconformities. The two older of these, the Kalkadoon-Argylla and Soldier's Cap series, are assigned to the Archean; and the two younger, the Mount Isa and Mount Quamby series, to the Proterozoic. The Mount Quamby rocks, in contrast with the underlying formations, are only gently dipping. In the shield area of western and central Australia, the Pre-Cambrian rocks are classified into two major divisions: (1) a basal, Archean group of mainly volcanic rocks but including some interbedded sediments, the Yilgarn-Kalgoorlie system; and (2) the Proterozoic Nullagine series composed of gently folded unmetamorphosed conglomerate and other sediments, lavas and fragmental volcanic rocks. Masses of granite intrude the older system and are overlain unconformably by the Nullagine series.

A considerable part of the gold of Australia has been obtained from lodes and veins occurring in the Pre-Cambrian shield of west and middle Australia. The silver-lead-zinc ores of Broken Hill in New South Wales are in intensely altered Pre-Cambrian rocks; iron ore is mined from the Archean rocks of the Middleback range in South Australia.

PRECEDENCE here means priority of place. or superiority of rank. Ancient in origin, it has engaged the attention of man since the first civilizations emerged and the organization of society on a hierarchical basis made some guide to the conduct of ceremonies and other social formalities indispensable. But it is only in comparatively modern times that fixed and exhaustive tables of precedence have been drawn up.

In Great Britain. as in most monarchical countries, the crown is the fountain of honour and has the undoubted prerogative to confer such rank and place as may seem 'convenient to it. Precedence is normally regulated by the crown acting through parliament (in the form of a statute), by granting royal charters. letters patent, royal warrants and ordinances, by authoritative letters of state (carrying specific instructions on precedence) and by international treaty. It is also adjusted by local enactments, by ancient usage and by established custom.

Disputes in matters of precedence are settled by the crown in England usually acting on the advice of the College of Arms, in Scotland through the Court of the Lord Lyon, in the British colonies by the governor.

In 1539 an act "for the placing of the Lords in Parliament" (31 Hen. YIII c. 10) was passed at the instance of the king; and by it the relative rank of the members of the royal family, of the great officers of state and of the royal household and of members of the hierarchy and of the peerage was definitely ascertained. Subsequent modifications were enacted in 1j63 (5 Eliz. c. 18) and in 1689 (1 Will. and Mary c. 21). The Acts of Union with Scotland (1joj) and with Ireland (1800) laid down rules of precedence for Scottish and Irish peers. At different times. too, statutes for the reform and extension of the judicial organization have affected the precedence of judges, more especially the Judicature act of 1873. But the statute of Henry VIII "for the placing of the Lords" remains the only measure dealing with any large section of the scale of general precedence; and the law, so far as it relates to the ranking of the sovereign's immediate kindred, the principal ministers of the crown and court and both the spiritual and temporal members of the house of lords, is to all practical intents what it mas made by that statute.

Precedence can be either substantive or derivative or both. Substantive precedence belongs to those whose rank or place are independent of their connection with anyone else; *e.g.*, peers, baronets, knights, etc.. and the holders of certain high offices of church and state such as the archbishop of Canterbury and the prime minister. This precedence cannot be affected by their relationship to anyone else but is inherent in the rank or position that they hold. Derivative precedence. on the other hand, belongs to those whose position is determined by their relationship (by blood or marriage) to someone else; *e.g.*, junior members of the royal family and the sons and daughters of peers. baronets. knights. etc. A peeress by marriage has both substantive and derivative precedence; she enjoys the former because she is a peeress and acquires the latter because she is the wife of a peer.

Precedence can also be either personal or official. Personal precedence (which can be either substantive or derivative) belongs to those whose rank in society entitles them to it: *e.g.*, the royal family, the peerage and certain specified classes of the commonalty. Official precedence (which must be substantive) is conferred' by the office held and not by the rank of the person holding it; *e.g.*, the speaker of the house of commons. If. however, a man's personal precedence is higher than his official rank, he is entitled to the higher place. The precedence of the sovereign is at one and the same time both personal and official.

It will be seen that precedence is thus usually acquired by one or more of the following methods: (1) birth (in the case of royal and most titled families); (2) marriage (in the case of many womenj; (3) accession to the throne or succession to a title or hereditary honour that carries precedence with it (*e.g.*, earl marshal); (4) the creation of a new title or the conferring of some honour or decoration; (5) appointment or election to certain posts or dignities. The first and the third methods must of necessity be limited to certain families. but many people are eligible for the other three. In England no man can acquire precedence by marriage but in some European countries, notably Italy, titles have often been held *jure uxoris* ("by right of the wife").

Not every hereditary honour confers precedence. The duke of Norfolk. for example. has special precedence as earl marshal, but the duke of Beaufort, as hereditary keeper of Raglan castle, has not. Nor does every decoration secure such recognition. Companions of the Distinguished Service Order (D.S.O.) have their place in the table of general precedence, but holders of the Victoria cross, although entitled to place the letters V.C. after their name (in precedence of all other designating initials): do not. The George cross and the military cross fall into the same category. Similarly, members of the Order of Merit and Companions of Honour place the letters O.M. and C.H. after their names but again receive no special precedence. Nor does rank in the Yenerable Order of the Hospital of St. John of Jerusalem (revived in England in 1888) secure recognition in matters of precedence.

Some officials, for instance the lord great chamberlain. enjoy the precedence of their office only when in the actual performance of their duties. The lord high commissioner to the general assembly of the Church of Scotland has the precedence of his office only during the sitting of the general assembly. Other officials have a different place allotted to them if their personal rank is of a sufficient degree. Thus the keepers of the great and privy seals of Scotland come above all other members of the peerage if they themselves are peers but belo the younger sons of dukes if they are commoners.

Certain members of the legal profession (*e.g.*, the lord chancellor, the lords of appeal in ordinary, the lord chief justice, judges, etc.) and of the church (*i.e.*, the archbishop of Canterburp, the archbishop of Tork and the diocesan bishops) have their place in the table of general precedence. Many professions meanwhile have a system of precedence of their own. This is a matter of custom and usage and remains unofficial. Thus military rank as such, however exalted, remains unrecognized by the table of general precedence.

Precedence Within the Peerage.—Precedence within the peerage is calculated according to the rank or degree of the peer. The Acts of Union with Scotland and with Ireland laid down the following order as between peers of equal degree: first, peers of England, next, peers of Scotland. then peers of Great Britain, then peers of Ireland and then peers of the United Kingdom (and of Ireland created since the union) according to the dates of their respective patents. No Irish peerage was created after 1898; and all new creations are now always of the United Kingdom. Baronets, on the other hand. rank among themselves solely according to the dates of their respective patents and irrespective of the country of origin of their title.

Courtesy titles, as the name suggcsts, are a matter of usage and confer no precedence as such. The children of peers enjoy such titles (see FORMS OF ADDRESS), but remain commoners; and their precedence derives from their relationship to their father and not from any courtesy title that they may enjoy.

Foreign titles of nobility conferred on British subjects carry no precedence in the United Kingdom and, strictly, should not be used unless a royal licence has been obtained. One French Canadian title is, however, recognized by the crown and so are the titles borne by the nobility of Malta. The latter enjoy precedence among themselves according to the date of the creation (and irrespective of the degree) of their title.

It is usual to accord to foreign noblemen, who of course have no legal precedence in the United Kingdom, a courtesy precedence equivalent to the rank that they bear in their own country.

The Precedence of Women.—The precedence of women is derived from the rank of their father or husband with the exception of a peeress in her own right. a maid of honour to the queen or to the queen dowager, a privy councillor (the first woman appointed was in 1929) or the holder of an order of knighthood (the British Empire Order has always been open to women and the Royal Victorian Order has since 1936) or companionage (the Imperial Service Order was opened to women in 1908). Any woman bearing a title derived from her husband loses it on remarriage. It is customary for the widow of a peer or baronet to have precedence of the wife of the incumbent of the title. Daughters of peers come immediately after the nives of their elder brothers but before the wives of their younger brothers.

The wives of high officers of state have no special precedence as such. Kor have the wives of archbishops or bishops. The anomaly in the latter case prompted Queen Elizabeth I to say to the wife of the archbishop of Canterbury. "Madam I may not call you; mistress I am ashamed to call you; so I know not what to call you; but howsoever I thank you." As most professions are now open to them women can achieve high rank by their own efforts.

Local Precedence.—There is no official order of local precedence. but in counties H.M. lieutenant (usually called lord lieutenant) has priority of place, and after him the high sheriff. In boroughs the mayor is the first citizen and naturally presides at all municipal occasions. Should, however, both the mayor and the lieutenant be present as guests at the same function (even though it be in the mayor's borough) the lieutenant takes precedence. Neither has any place allotted to him in the scale of general precedence. In the City of London precedence is decided by the terms of the royal charter. which fixes the place of the lord mayor, of the chamberlain and of the recorder, and by resolution of the corporation. There is a fixed order of precedence among the city guilds or livery companies, the 12 great London companies coming first. It is obvious that at any public function given in honour of some guest that that guest will then have precedence next to his host.

The Precedence of the Diplomatic Corps.—As many ceremonies of state involve the diplomatic corps, diplomats occupy a prominent position in social life. The practice of diplomacy. which had occasioned many unseemly disputes (notably that between the Spanish and French ambassadors in London in 1661) was regularized by the decrees of the congresses of Vienna (1815) and of Aix-la-Chapelle (1818) on an agreed basis.

Four categories of representatives mere recognized: (1) ambassadors, legates or nuncios; (2) envoys extraordinary and ministers plenipotentiary: (3) ministers resident; (4) chargés d'affaires. Precedence within the corps was established on the basis of seniority of appointment, so that the doyen (or dean) of the corps is that ambassador who has been accredited to his post the longest; *i.e.*, from the date of his official arrival and presentation of his letters of credence. In most Roman Catholic countries where the church enjoys a special position, the nuncio takes precedence over all his colleagues regardless of the date of his appointment. Even in this case! however, the senior ambassador continues to discharge most of the functions of the doyen. (It may here be mentioned that in Roman Catholic monarchies cardinals would rank with princes of the blood.)

For consular officers (consuls general, consuls, vice-consuls and consular agents) there is a comparative precedence which equates them with certain ranks of the fighting services. Thus consuls general rank with but after rear admirals, major generals and air vice-marshals, while consuls rank with but after captains of the royal navy, colonels and group captains of the royal air force.

In monarchical countries ambassadors usually have precedence after members of the reigning family or high dignitaries of church and state. In England they follow the lord privy seal, while ministers come after dukes but before marquesses. In republics practice varies: thus in France ambassadors come after the presidents of the senate and of the chamber of deputies, whereas in the Cnited States they come after the vice-president and before the chief justice. Most questions of ceremony, of precedence, etc., are settled by the *chef* de protocol (in England H.M. marshal of the diplomatic corps).

The British Commonwealth.—Soon after Canada became a dominion in 1867, the secretary of state for the colonies sent a letter (1868) to the governor general which contained instructions as to precedence. Since then various royal warrants have regulated precedence throughout the rest of the British Commonwealth. Where members of the commonwealth have become republics they have issued their own tables. Broadly speaking, these follow much the same pattern. The governor general (or president in the case of a republic) naturally takes first place. In Canada, New Zealand. South Africa, India. Pakistan and Ceylon the prime minister comes next, but in Australia the governors of states precede the prime minister. High dignitaries of the church rank after the provincial governors in Canada and before the chief justice. whereas in South Africa the chief justice comes before both cabinet ministers and ambassadors. Members of the royal family take precedence after the governor general. although on certain occasions they have been accorded precedence before him.

Considerable confusion has been caused in the commonwealth where there are both state and federal lists of precedence. which do not always accord with one another. There has also been disagreement at times as to whether precedence in England is valid elsewhere in the commonwealth.

In the United Kingdom the high commissioners for the dominions or member states of the commonwealth had all formerly ranked after secretaries of state in order of precedence. In 1948, however. those of Canada. Australia, New Zealand, South Africa. India, Pakistan. Ceylon and Eire were promoted to rank with ambassadors (the high commissioner for Eire was in fact replaced by an ambassador in 1950), their precedence among themselves being based on seniority of appointment, as among ambassadors.

Tendencies of the 20th Century.—As the prevailing policy of the 20th century favours republican forms of government, questions of precedence occupy less attention than heretofore. Even in the few remaining monarchies rank and title possess less significance than before. Thus in Denmark and in Norway all titles have long been abolished. In Japan all titles of nobility were abolished and the house of peers was replaced by a house of councillors in 1945; and the imperial house law of 1947 restricted the emperor's family to his children, his brothers and sisters and their issue, with the result that 51 princes of 11 princely houses became commoners. Most modern orders (for example the Légion d'Honneur in France and the 16 orders created in the U.S.S.R.) do not entitle the recipients to any privileges but are simply marks of recognition of merit and service.

The 17th and 18th centuries were the golden age of court ceremonial; *cf.* the *Mémoires* of the duc de Saint-Simon. Since that time the importance of questions of precedence has grown less and less pronounced. The emphasis has altered from rank and title to office and position. It is in fact a person's office rather than his personal rank or his relationship to someone else that now tends to be the governing factor in determining his precedence.

See the full tables of general precedence for men and women in England, Scotland, Northern Ireland and the commonwealth as set out in *Burke's Peerage* (London, biennial) and *Debrett's Peerage* (London, annual). (S. B.-R. P.)

THE UNITED STATES

Precedence at official functions and ceremonies in the United States is based upon official position and custom. The latter, outside of Washington, D.C.. reflects the social and economic variables found in state and local communities on official occasions. and these affect strictly official considerations in the order of precedence in terms of religion, wealth and other factors determining civic status. Political expediency rather than statutes prevails in the determination of the hierarchical order in public ceremonies. The tendency toward informality at state and municipal functions is in sharp contrast with the more ostentatious public affairs of the 19th century.

Washington, **D.C.**—Precedence in the capital of the U.S is subject to a combined governmental and diplomatic ranking which makes the department of state the arbiter. The division of protocol not only rules on official ranking, but informally provides essential guidance for social functions where official status at the national or international level is involved. Precedence has been established by custom as: the president; vice-president; speaker of the house of representatives; chief justice of the supreme court; ambassadors of foreign powers, ranked according to diplomatic rule of seniority by the date of presentation of credentials; secretary of state; ministers of foreign powers in order of diplomatic seniority; associate justices, according to date of commission; retired associate justices; the president's cabinet (the secretary of state excepted), in the order of the establishment of their offices: secretary of the treasury, secretary of defense, attorney general, postmaster general, secretaries of the interior, agriculture, commerce, labour, and health, education and welfare.

Chairman, the Atomic Energy commission; the director of the budget; the director of civil and defense mobilization; senators; governors of states; representatives; undersecretaries of state: deputy secretaries of defense; chairman, council of economic advisers; chargés d'affaires of foreign powers; secretaries of the army. navy and air force; chairman of the federal reserve system; undersecretaries, or their equivalent, of the cabinet; chairman of the joint chiefs of staff; chief of staff of the army; chief of naval operations; chief of staff of the air force; director of central intelligence.

General Services administrator; special assistants to the president; chairman, civil service commission; five-star generals and admirals; secretaries to the president; the secretary-general of the United Nations; the secretary-general of the Organization of American States; deputy undersecretaries of state; assistant secretaries of government departments; chief of protocol; governors of territories; undersecretaries of the army, navy and air force; four-star generals and admirals; lieutenant generals and vice-admirals; counsellors of foreign powers; major generals and rear admirals; brigadier generals and commodores; subordinate government officials.

States. — Generally speaking. the states of the union follow a rule-of-thumb order of precedence on official occasions. Reception and seating depend upon the obvious political ranking and the expedient religious, economic and social considerations in a given situation involving status. This situation has been facilitated by a departure from large, formal state affairs with a trend toward informality in official entertainment.

Municipalities. — U.S. cities set up their own protocol for the reception of distinguished visitors. This follows a general political pattern of officials, headed by the mayor or his equivalent in other types of urban government or his representative for the occasion. Precedence again is weighed in terms of religious and civic status; it is flexible in its application in order to permit adjustments suitable for each function.

After World War II the increasing number of foreign visitors to the U.S. with official or quasi-official sponsorship made strategically located cities important points of reception. Chief of these is New York city, where the mayor's office has special machinery for extending such hospitality to visitors. The commissioner of commerce and public events is charged with all arrangements; an officer under him works out the problems of reception and precedence. This official is in contact with the state department and the visitor's diplomatic mission in Washington or local consular representation; where the visitor's status warrants extensive ceremonies—a chief of state. head of government, etc.—these are planned by close consultation as to details of time, place and guest list.

U.S. Reception Centres. — Due to the expanding program of special visitors to the U.S. under the state department program of cultural exchanges, reception centres have been established at key points of entry to handle problems of official greeting and orientation. These are New York city. Miami. Fla., New Orleans. La., San Francisco: Calif., Seattle, Wash., and Honolulu. Hawaii. They are maintained by the department of state and operated under the joint sponsorship of the International Educational Exchange service and the International Cooperation administration. Each centre utilizes the community opportunities of the area and provides an official welcome to such visitors. During 1955 these centres served a total of more than 10,000 foreign nationals of various categories entering or leaving the U.S., including a number of diplomatic visitors.

THE UNITED NATIONS

The seat of the United Kations. though geographically located in New York city, enjoys a special international status under the headquarters agreement with the United States. U.S. jurisdiction. national. state or local. operates around the territorial centre of UN activities though there has been no alienation of U.S. territory. The U S organs with their personnel located at the headquarters are guaranteed inviolability in their functioning and the diplomatic status of the representation of all member states is recognized by the U.S. subject to suitable security arrangements.

Precedence is a matter wholly determined by the UN itself in governing its procedures, ceremonies and social functions. Directly under the secretary-general there is a unit at the headquarters to handle problems of precedence similar to that in any foreign office, the chief and assistant chief of protocol. Here all UN precedence. whether procedural. ceremonial or social. is determined. There are no hard-and-fast rules nor any official list. Precedence is a developing process which combines regulations for the functioning of UN bodies. their officials and representatives of member states with appropriate diplomatic conventions currently prevalent in international intercourse.

Basically. UN precedence rests on function and not upori the personal rank of the person discharging the duty. Hence the president of the assembly, irrespective of the delegate's personal rank, is the ranking official of the UN when the assembly is in session. The president of the Security council, the second most important organ in terms of the charter, becomes the chief functionary in terms of protocol if the assembly is not in session. However. since the headship of the Security council rotates each month among the members. the person enjoying this prerogative changes accordingly.

The third post is that of the secretary-general. the executive-administrative officer of the UN who heads the secretariat. Then follow the presiding officers of the specialized organs of the UN, the Economic and Social council, the Trusteeship council. etc., when in session; the heads of the permanent delegations accredited by the member states to the UN of ambassadorial rank; the assistant secretary-general and the undersecretaries: heads of delegations of ministerial rank; the operating heads of the departments into which the secretariat is subdivided.

The diplomatic practice that ambassadors and ministers rank according to the date of their appointment is not followed at the UN; strict observance of the alphabetical order of the countries they represent is the rule in sessions and elsewhere. In sessions of the UN organs. the actual seating facilities of the chambers used at headquarters, at Geneva, Switz., and elsewhere affect the working out of precedence for those occupying places on the rostrum; the alphabetical order in general seating of delegates on the floor rotates from front to rear so that the position of a member state's spokesman moves progressively. meeting by meeting, and no country enjoys a preferred position by reason of its name.

(Cs. H.)

ROMAN CATHOLIC CHURCH

In the canon law of the Roman Catholic Church precedence in the narrow sense means the right to a place of higher dignity in public conventions or manifestations — in synods. processions, elections. etc. More broadly, it means the higher rank or order itself, whence flows the right to walk. or be seated, in the place of greater honour. The general norms that govern precedence are given in canon 106; special norms regarding special personages are given elsewhere in the code. Within the universal church. precedence according to rank and order is the following: cardinals (in this order: cardinal legate a *latere* [papal legate]. cardinal deacon and subdcacon, cardinals of the episcopal, preshyterial and diaconal orders); legates of the Roman pontiff; patriarchs; primates; metropolitans and archbishops in their own provinces; the bishop in his own diocese: archbishops and bishops outside their own provinces: abbots and prelates *nullius* (of no diocese); vicars and prefects apostolic: administrator apostolic and capitulary vicar; vicar-general: canons (dignitaries, titular canons, honorary canons. canons with benefices); vicars forane; pastors; substitute and assistant vicars; curates. Clerics and religious generally precede the laity, except where contrary custom prevails in the case of lay personages of dignity. In determining individual precedence no distinction is made between the secular and the religious clergy. When both orders of the clergy are present as groups, the secular clergy precedes the religious clergy, and within the latter order certain customary rules obtain; *e.g.*, canons regular precede monks, monks precede clerics regular, etc. Within his own diocese the bishop determines the order of precedence, under regard for canon law. and judges controverted cases. From his judgment appeal may be made to various Roman congregations according to the case.

See G. Michiels, *Principia generalia* de *personis* in *Ecclesia*, 681–697 (1955). (X.)

PRECESSION OF THE EQUINOXES, in astronomy, an effect connected mainly with a gradual change of the direction of the earth's axis of rotation. There is a general resemblance between the motion of the earth and that of a spinning top. It is well known that when a top is slightly disturbed its axis precesses round the vertical so that it traces out a cone; the earth's axis similarly describes a cone at the rate of one revolution in about 26,000 years. In applying this analogy we must take the ecliptic (*i.e.*, the plane of the orbit of the earth round the sun) to correspond to the horizontal: the axis about which the earth spins is inclined at $23\frac{1}{2}°$ to the "vertical." and keeping this inclination it turns slowly round the "vertical." It must be emphasized, however, that this correspondence between the earth and a top is superficial, the cause of the precessional motion being upon different principles.

In this nay the north pole of the celestial sphere describes among the constellations a circle of $23\frac{1}{2}°$ radius, making a revolution in 26,000 years. At present it is near the star α Ursae Minoris, which is therefore called the polestar; but it has traveled a considerable distance within historic times. About 3000 B.C. the star a Draconis would have served as polestar; in 13000 B.C., also in A.D. 13000 Vega would he near enough to the pole to mark roughly its position. By this displacement the part of the sky visible from a particular terrestrial station gradually changes; certain constellations cease to rise above the horizon and others appear for the first time. In the time of the early Chaldean astronomers it was not necessary to travel so far south to see the Southern Cross as it is now.

Cause of Precession. — This was first explained by Isaac Newton. It is due to the attraction of the sun and moon on the equatorial protuberance of the earth. the moon being responsible for about two-thirds and the sun for one-third of the motion — the same proportion as the lunar and solar tides. Treating the equatorial bulge as an extra ring of matter surrounding a spherical earth, the attraction of the sun and moon on this ring gives a couple tending to turn the ring into the plane of the ecliptic, since both disturbing agents are in or near the ecliptic. If the earth were not spinning this would turn the earth over until the equator coincided with the ecliptic, but the spinning earth behaves like a gyrostat, so that its axis moves at right angles to the plane of the couple — just as the couple which would upset a top at rest gives the axis of the spinning top a conical motion.

The moon's orbit is inclined at about j° to the ecliptic, but it does not remain still; its nodes travel round the ecliptic in 18.6 years. Averaged over a long period of time the deviations of the moon from the ecliptic cancel out; but at any moment the precession caused by the moon may be greater or less than the average, according to the position at the time of the lunar orbit. In fact the path of the pole among the stars is a slightly sinuous curve. Astronomers distinguish the average secular motion as precession and the periodic fluctuations or sinuosities as nutation.

As the pole (corresponding to the equator) moves round the pole of the ecliptic, so the equinox or intersection of the equator and ecliptic moves round the ecliptic once in 26,000 years. Both right ascensions and longitudes are reckoned from the equinox as zero point; stellar longitudes on this account increase steadily by nearly a minute of arc every year; the effect on the right ascensions is more complicated: but these also continually increase. The vernal equinox is commonly called the first point of Aries, but it has already moved away from that constellation and is now in Pisces. It should be understood that the precession of the equinoxes has no effect on the seasons, and, for example, has no connection with the gradual departure of the spring equinox from March 21 which occurred in the old Julian calendar.

Planetary Precession. — Besides the foregoing lunisolar precession, a phenomenon of much smaller magnitude. known as planetary precession. is recognized. It is due to perturbations by the planets which cause slow changes in the plane of the earth's orbit. Planetary precession changes the position of the ecliptic, whereas lunisolar precession changes the position of the equator; either change affects the equinox. which is the intersection of the two planes. Corrections for precession and nutation are of great importance in most branches of positional astronomy.

PRECIPITATION, in meteorology, denotes all forms of water falling upon the earth's surface. It includes rain and snow and their various modifications such as drizzle. freezing rain, sleet, snow pellets and hail. Precipitation is considered to he one of the most important of all meteorological elements since it is the only important source of fresh water.

The essential difference between a precipitation particle and a cloud particle is one of size. An average raindrop has a mass equivalent to several million cloud droplets. Because of their large size, precipitation particles have significant falling speeds and are able to survive the fall from the cloud to the ground. (See CLOUD.)

Precipitation Formation. — The transition from a cloud containing only cloud droplets to one containing a mixture of cloud droplets and precipitation particles involves two basically different steps: formation of incipient precipitation elements directly from the vapour state: and subsequent growth of these elements through aggregation and collision with cloud droplets. The initial precipitation elements may be either ice crystals or chemical solution droplets.

Development of precipitation through the growth of ice crystals depends upon the fact that cloud droplets usually do not freeze at temperatures warmer than about $-40°$ F. (The reduction of cloud droplets to temperatures below the normal freezing point is termed supercooling.) Within supercooled clouds. ice crystals may form through sublimation of water vapour upon certain atmospheric dust particles known as sublimation nuclei. In natural clouds. ice crystals form at temperatures colder than about $+5°$ F. The exact temperature of ice-crystal formation depends largely upon the physical-chemical nature of the sublimation nucleus.

Once they are formed within a supercooled cloud, ice crystals will coritinue to grow as long as their temperature is colder than freezing. The rates of growth depend primarily upon the temperature and degree of vapour saturation of the environmental air. The crystals grow at the expense of the water droplets. As the crystals grow. the droplets evaporate by virtue of the fact that the saturation vapour pressure over an ice crystal is less than over a supercooled water surface at the same temperature. In favourable conditions, *e.g.*, in a large. rapidly growing cumulus cloud, an ice crystal will grow to a size of about 0.005 in. in three to five minutes after formation. At this size, the rate of growth through sublimation slows down and further growth is largely through aggregation and collision with cloud droplets.

Small solution drops are also important as incipient precipitation particles. The atmosphere contains many small particles of soluble chemical substances. The two most common are sodium chloride. swept up from the oceans by spray and bubbles, and sullate-hearing compounds formed through gaseous reactions in the atmosphere. Such particles, known as giant condensation nuclei, collect water because of their hygroscopic nature and, at relative humidities above about 80%, exist as solution droplets. In tropical maritime air masses the number of giant condensation nuclei frequently is very large. Clouds forming in such air may develop a number of large solution droplets long before the tops of the clouds reach temperatures favourable for the formation of ice crystals.

Regardless of whether the initial precipitation particle is an ice crystal or a droplet formed on a giant condensation nucleus, the bulk of the gromth of the precipitation particle is through the mechanisms of collision and coalescence. Because of their larger size, the incipient precipitation elements fall faster than cloud droplets. As a result they collide with the droplets lying in their fall path. The rate of growth of a precipitation particle through collision and coalescence is governed by the relative sizes of the particle and the cloud droplets, the size and number of cloud droplets, the fraction of the droplets in the fall path which are actually hit by the precipitation particle and the fraction of these droplets which actually coalesce with the particle after collision. Under ordinary cloud conditions it takes between 10 and 20 minutes for an incipient precipitation element to grow into a large raindrop or a large snoaflake.

The efficiencies of the natural precipitation processes are known to be rather low. Although vast amounts of vapour are condensed into cloud droplets to form clouds, most of this water re-evaporates without becoming involved in the precipitation processes. Precipitation particles also suffer considerable loss from evaporation in falling from the cloud bases to the ground. Studies carried out on thunderstorms in the humid eastern part of the United States show that only about 20% of the condensed water reaches the ground as rain. In the arid regions, the bases of clouds may be so far above the ground that most of the rain is evaporated between the clouds and the ground. (See CLIMATE AND CLIMATOLOGY.)

Measurement of Precipitation.—Rain gauges and snow gauges are used for measuring precipitation. The amount of precipitation is expressed in terms of the total equivalent amount of liquid water. Thus snow, caught in a gauge, is melted before measurement. In regions where snow forms an important fraction of the precipitation, it is customary to measure the amount of snow by means of a snow survey. (See SNOW.) In snow surveys it is necessary to determine the density as well as the depth of the snow in order to determine the water content.

The data from rain gauges and snow surveys are subject to large sampling errors, particularly during periods of sho er and thunderstorm activity. The spacing between gauges usually is several times the size of the shower rain area. Over a period of several weeks or months errors due to rain-gauge spacing tend to be averaged out.

Precipitation measurements, when collected from many places, form the basis for estimating the amount of rain falling in a region. Such data are available for regions all over the globe. Because of the problems of sampling rainfall and because of variations in rainfall from one year to the next, climatologists desire at least 40 years of record for computing average annual precipitation amounts.

The development of centimetre wave-length radar during World War II gave the first means of accurately identifying and locating precipitation areas. (See RADAR METEOROLOGY.) When combined with a few scattered rain gauges, radar enables meteorologists and hydrologists to determine the amount of precipitation falling on a given area more accurately than with the rain gauges alone.

Artificial Control of Precipitation.—Throughout recorded history, there have been attempts to control precipitation. Early societies employed various forms of magic in their efforts to increase rainfall. During the latter part of the 19th century, experiments using cannon shots. explosions and large fires were carried out for the same purpose. During World War I it was not infrequently observed that rain occurred during or immediately following major battles. and it was believed by many that the sounds of the cannons were responsible for causing the clouds to release the rain. Subsequent findings disproved this idea.

The first series of systematic experiments designed to discover the physics of precipitation and thereby find a means of producing precipitation were carried out by Vincent J. Schaefer in 1946. These experiments, ultimately involving seeding clouds with silver iodide smokes. were successful in causing light snow to fall from supercooled stratified clouds.

Experiments to increase precipitation rest upon the hypothesis that natural precipitation is limited by a shortage of natural precipitation nuclei. Silver iodide smokes, produced by burning a silver iodide-acetone solution. will supply sublimation nuclei effective at temperatures colder than about 23" F. A different approach to the problem of increasing rain involves the release of giant condensation nuclei, or small waterdrops, into suitable clouds in order to initiate rain through the collision-coalescence mechanism.,

Whether or not the amount of precipitation at the ground can be increased through any of these techniques depends largely upon large-scale meteorological factors governing the formation, growth, duration and dissipation of the clouds.

Because of the fact that natural rain is highly variable in time and space, very carefully designed experiments are necessary in order to determine the efficacy of any given rain-making technique. When rain falls from a seeded cloud, one naturally asks whether or not it would have fallen had the cloud not been seeded When rain fails to fall, one asks whether seeding prevented it. Because of this uncertainty it is impossible to estimate the effect of cloud seeding from a few isolated experiments or from experiments which do not include a group of randomly selected, nonseeded control cases, as statistical methods would require.

From the extensive experiments carried out between 1946 and 1956, it was learned that it is possible to modify some clouds and in some very favourable conditions to cause more precipitation to fall than would have fallen through natural processes. The magnitudes of these increases are not known, although they are usually thought to be less than 10%.

Chemistry.—Precipitation, in chemistry, is the process in which a substance separates from a solution as a solid. Precipitation is an important step in many chemical processes.

It may be accomplished by the concentration of the solution to the point where it is supersaturated, when. upon cooling, a part of the solid separates out, though this process is usually described as crystallization (*q.v.*). It may also be accomplished by the addition of reagents which may combine with the material to form an insoluble compound, or which may displace the material from the original solution.

The application of heat may cause coagulation, as with certain proteins, and the removal of gas may also alter conditions sufficiently to cause precipitation. A change of temperature is another method.

The salting out process as employed in the soap industry is a familiar example of precipitation. The formation of the fibre from a solution of cellulose by causing it to pass into a setting bath is a case of precipitation used in the artificial-silk industry.

PRECISION GAUGES AND COMPARATORS. Interchangeable manufacture, pioneered about 1800 by Eli Whitney, made it essential to maintain close dimensional control of products from widely separated factories. Precision gauges and comparators are the means by which industry achieves the necessary dimensional control.

Limit Gauges.—The reproduction of dimensions of mechanical parts within specified dimensional limits of variation, or tolerances, is facilitated by checking with gauges. such as a "go" gauge representing the maximum-metal limit and a "not go" gauge representing the minimum-metal limit. Limit gauges used on products are also known as inspection or working gauges. Gauges used as standards of comparison for measuring the dimensions of inspection gauges are known as master or reference gauges.

Gauges are manufactured by highly skilled gauge makers in a large variety of forms, corresponding to the forms and dimensions of parts to be gauged and to principles of gauge design.

Master Gauges.—Precision gauges and comparators have been extensively developed since about 1850, when Sir Joseph Whitworth produced the original measuring machine and the system of accurate dimensional standards or master gauges (both end gauges and cylindrical gauges) for use with it.

On the market in the mid-1950s were these forms: (1) Precision gauge blocks or slip gauges, which are end standards of rectangular, square or circular section having accurately flat, parallel ends, available in sets of numerous selected lengths of blocks so that all dimensions, within the range of the set, can be produced in small increments such as 0.00005 in. by combining or wringing the blocks. *(See* METROLOGY.) These were invented in 1896 by C. E. Johansson of Eskilstuna, Swed., who used a hand-lapping method for their production, and are often called Johansson blocks. In 1918 a machine-lapping method was developed by Maj. W. E. Hoke at the national bureau of standards in Washington. D.C. Gauge blocks have since been produced by more than a dozen manufacturers in four standard qualities which are accurate to 0.000002, 0.000004, 0.000008 or 0.000010 in. (2) End measuring rods in the form of steel bars having flat or spherical ends. (3) Master disks which are accurately lapped steel cylinders, frequently preferred to gauge blocks when pieces to be checked by comparators are round. (4) Gauges having composite surfaces. such as screw thread, profile or spline gauges. (5) Angle gauge blocks in sets of 13 or 16 selected angles, combinations of which are wrung together to produce any angle to 90°, or with an additional square block to 360°, to the nearest second by addition or subtraction according to the relative directions in which blocks are assembled.

Measuring Machines. — Horizontal comparators commonly are designated measuring machines. These have means provided for measuring the difference between the test object and the standard, usually a micrometer screw having a divided head. Such comparators also often embody line standards of length, which may be used instead of contact length standards. A massive cast-iron bed is provided with straight ways, on which are mounted the headstock carrying the micrometer screw and one measuring anvil and the tailstock carrying the other anvil. Devices are provided, usually in the tailstock, for ensuring a constant contact pressure, which is necessary to obtain accurate comparisons. However, such devices were absent in the early models, such as the Whitworth and the Rogers-Bond universal comparator patented in 1885. There have been several different measuring machines of the modern type.

A further elaboration of measuring machines is a means for providing high amplification of the displacement of one of the anvils, such as an optical lever in the millionth comparator of J. E. Sears, providing an amplification of 30.000 times, and the Pratt & Whitney electrolimit tailstock, of 5,000 or more.

Vertical Cornparators. — In comparators of the vertical type, the master gauge and work are in turn supported on a substantial and level surface plate or anvil. The measuring contact and the amplifying mechanism which it actuates are adjustably mounted on a vertical column. These widely used instruments are available with various amplifications up to 20,000 (sometimes higher), obtained by means of a mechanical amplifying system as in the mikrokator and various dial comparators or by a combination of mechanical and optical levers as in the Zeiss optimeter and the Sheffield visual gauge or by an inductance bridge circuit as in the Pratt & Whitney electrolimit comparator, Sheffield electrichek or DoAll electric comparator.

The Brooks tilting level comparator compares two gauge blocks directly by a highly sensitive spirit level resting by ball feet on both gauges. The Watts microoptic comparator reads plunger displacement directly on an attached scale by micrometer microscope.

Interferometers. — Gauge blocks of the same nominal length can be compared, using interference of light waves. with the help of two test flats and a source of monochromatic light. The two gauge blocks are wrung edge to edge on one flat, and the second flat is placed so as to make line contact at the common edge of the thicker gauge and the other edge of the thinner. (For a discussion of the "wringing" effect, *see* METROLOGY: ***Calibration.)*** Both gauges are then seen crossed by dark bands parallel to the common edge; these represent contour lines of the air wedge between gauge and flat corresponding to integral numbers of half wave lengths of the light employed Specifically, the number of lines crossing the thinner gauge is equal to the difference in length of the gauges in units of one-half wave length.

Another method, not relying on line contact, uses polychromatic light, such as helium, which produces fringes of various identifiable colours. Here the systems of fringes crossing the two gauges are merely displaced relative to each other, and a given fringe is displaced along the common edge by a number of fringes (not necessarily integral) equal to the difference in height in one-half wave lengths.

Using collimated light and suitably filtered wave lengths, fringes can be seen between the two flats themselves if the separation is not too great. The method of coincidence of excess fractions *(see* LIGHT) can be employed to make direct determination of the length of gauge.

In 1926 a form of Michelson interferometer was devised with one vertical arm, incorporating a monochromator for isolating the various wave lengths. This instrument doubled the measurable length of gauge by working on either side of the central white light fringe system. It still required wringing the gauge to one flat. A later form of Michelson interferometer, in which the wringing is dispensed with, operates by reflecting from both sides of the gauge; it also permits the intercomparison of angle blocks of the same nominal value.

Internal Comparators. — The precise determination of an internal dimension presents special difficulties, which have been largely overcome by the development of internal comparators of different designs. Prior to the availability of such comparators, or in their absence, the sizes of such objects as ring gauges either plain or threaded, were usually estimated by the nature of their fit upon corresponding plug gauges.

When a cylindrical plug and ring are perfectly clean and dry, they will assemble if the largest diameter of the plug is the same or smaller than the smallest diameter of the ring. If well finished and liberally covered with a lubricant having high oiliness properties, a cylindrical plug gauge will enter and pass through a ring gauge which is as much as 0.0002 in. smaller than the plug without damage to either, provided that distribution of the lubricant is maintained by constant relative motion of the gauges.

The following instruments were available for the measurement of internal dimensions: the chord contact machine by G. A. Tomlinson, in which the displacement of a ball-ended piece is measured in a direction perpendicular to its length; the displacement type of internal measuring machine, having a micrometer and a double-ended stylus attached to a sensitive indicating mechanism. by J. E. Sears; the Sheffield internal-external measuring machine having gauging fingers which are positioned by means of precision gauge blocks and which move relatively to each other and actuate an amplifying mechanism; the Pratt & Whitney electrolimit universal internal comparator having one fixed and one adjustable gauging finger; the Swedish internal indicator gauge; and the Leitz Perflectometer, a special microscope.

A precision pneumatic micrometer was invented by Marcel Mennesson of France in 1928. This and other types of air gauges are uidely used to compare internal dimensions. A cylindrical spindle, somewhat smaller than the hole to be measured, has diametrically opposed orifices through which regulated compressed air is forced. The spindle is first inserted in a ring gauge of known size and then in the piece to be measured. The difference in pressure or in rate of flow of the air from the spindle in the two cases is indicated in different makes by a manometer, a pressure gauge or a float in a tapered glass tube which are suitably calibrated to yield measurements of differences in size as small as 0.00001 in. or less.

Automatic Gauging. — By the mid-1950s, rapid advances were being made in controlling machine tools by gauging their products; the products were gauged either while still on the machine or just after leaving it. For these applications, micrometers of the pneumatic or electromagnetic type were the most successful.

Projection Comparators. — The measurement of the dimensions of profile gauges and the thread angles and profiles of screw thread gauges is facilitated by optical projection methods, developed largely during and after World War I by the Kational Physical laboratory in London and the national bureau of standards in Washington, D.C. Further commercial developments of these methods are embodied in projection comparators of the Wilson, Hartness or Jones and Lamson. Bausch and Lomb, Eastman and other types; and in the tool makers' microscopes of Gaertner, Taylor-Hopson and others.

(I. H. F.; S. JN.)

PREDESTINATION, as actually employed in theological literature, is a term of many meanings. In its widest sense predestination is the divine act of foreordaining by which God eternally decrees all that He intends to bring to pass in time. In a narrower sense predestination refers only to those divine decrees by which God foreordains men to their supernatural end, whether to happiness in heaven for those who depart this life in the state of grace, or to eternal punishment for those who die in mortal sin.

Modern usage, horn-ever, restricts predestination to the divine decree foreordaining the happiness of the elect. The decree by which God rejects the wicked is called reprobation.

Theological controversy has further limited the meaning of predestination. Predestination may refer to the whole series of effects by which man is saved, embracing vocation to the Christian faith, election to grace, justification. final perseverance and eternal happiness. In this sense it is called complete or adequate predestination, or "predestination to grace and glory." On the other hand the term may be restricted to any one of these elements, particularly grace or eternal happiness. It is then known as incomplete or inadequate predestination, or "predestination to grace," "predestination to glory" alone.

The counterpart of predestination is reprobation. Here again, if the historical progress of the doctrine is to be rendered intelligible, the various meanings of the term must be distinguished. Positive reprobation is God's eternal decree to inflict everlasting punishment on those who, as He foresees, will die in the state of grave sin. Such reprobation is called antecedent if damnation is foreordained irrespective of the condemned person's sins; it is consequent if it follows upon God's prevision of final impenitence. Negative reprobation is a simple exclusion from heaven rather than a positive destination to hell.

Why God from eternity has chosen definite individuals to whom He gives efficacious graces that guarantee their salvation, whereas He gives other definite persons graces with which He foresees they will not co-operate, is the heart of the mystery of predestination. Theology cannot touch this mystery, as it has no revealed data upon which it may speculate. The principal problem which engages the attention of theological science is the reconciliation between God's will to save all men and the fact that not all are predestined. A further problem is the reconciliation between God's eternal foreknowledge of all events and human freedom of action. Still another difficulty is the relation between human freedom and the efficacious graces by which a person is conducted to eternal happiness.

God truly and sincerely desires the salvation of all men (I Timothy ii, 1–4), and therefore confers on all graces which are at least sufficient to enable them to attain to eternal life. But some men fail to reach this goal (Matthew xxv, 41). Not only does God eternally foreknow that a certain portion of the human race will be saved and who these individuals are, but He has foreordained their salvation (Matthew xxv, 34; Romans viii, 28–30; Ephesians i, 4–14). Thus on the one hand God wills all men to be saved, and on the other predestines only a definite number, known to Himself alone. If God is all-powerful, how can it be that His salvific will remains ineffective with regard to many persons? Those who are predestined will infallibly be saved. the rest will not. Hence the difficulty: how can predestination, which is altogether effective, be reconciled with God's universal salvific will, which remains ineffective with regard to many?

Three solutions to the problem have been proposed, as a historical survey of the doctrine of predestination reveals. Pelagianism simply denies predestination. Predestinarianism denies that God's salvific will is universal. Catholic theology, with which several Protestant systems agree, harmonizes the two by distinguishing between God's antecedent and consequent salvific will. God wills the salvation of all men conditionally, and antecedently to His prevision of their final state; but consequent upon this prevision He wills absolutely the salvation of all who die in the state of grace and the condemnation of those who die in the state of sin. This consequent will is called predestination insofar as it decrees the eternal happiness of the just, and reprobation insofar as it decrees the eternal punishment of the wicked.

The Patristic Period. — During the first four centuries of the Christian era the question of predestination was treated chiefly by the Greek fathers. In the west only a few of the Latin fathers who had come under the influence of oriental theological thought went into the subject. The Greeks taught unanimously that all events, including human actions, were governed by divine providence. God, they held, wishes all men to be saved, and therefore offers to all the grace which is necessary for salvation. Man, however, must freely co-operate with grace if he wishes to attain eternal life.

Greek thought concerning predestination culminates in the teaching of St. John of Damascus, who perfected the earlier doctrine especially by his insistence on the distinction between God's antecedent and consequent salvific will. If God is infinitely good, he asks. how is it that some men are lost? He replies by pointing out that many sin and persevere in their malice. God punishes them only in consequence of their sin. Prior to His prevision of sin He wills the salvation of all, because He is supremely good; if He punishes subsequently to sin, it is only because He is also supremely just. Hence God's antecedent will to save is not absolute, but conditional; His absolute will to reward or punish is consequent upon His foreknowledge of the good or evil will of man. Thus predestination, as an act of God, is in accordance with the divine prevision of man's co-operation with grace. This distinction was to prove of paramount importance in all later speculations on predestination.

However, of all theologians who have grappled with the problem of predestination the most influential teacher was undoubtedly St. Augustine. Against Manichaeism he had ably defended human freedom. He was called upon to put forth much more strenuous efforts to uphold the necessity of grace for good works against the Pelagians and the totality and initiative of the workings of divine grace against the compromise theory of the Semi-Pelagians. Augustine's position with regard to predestination can be appreciated only in relation to his insistence on the sovereign independence of divine grace against these naturalistic systems.

The Pelagians held that grace is not necessary for the observation of the precepts of Christianity; grace merely renders the observance of the law easier. Hence man can work out his salvation entirely of his own free will. In this view God foreknows who will be saved. but does not predestine anyone, except in the sense that He allots heaven as a reward for natural merit.

The Semi-Pelagians, while admitting the necessity of grace for growth in holiness, ascribed the beginnings of salvation and final perseverance until death to man's natural exertions, not to the initiative of God's prevenient grace. God's universal will to save is purely conditional; if men wish to attain heaven, they can do so by their own natural efforts. The sole difference among men proceeds from their natural merits. Predestination and reprobation are wholly dependent on man's free choice.

Confronted with these conceptions, Augustine felt impelled to uphold the gratuity of predestination. Without any merit on our part. he contended. God calls some men to the grace of faith and justification, inspires them to good works and confers on them the grace of final perseverance as a wholly special gift. He summed up the substance of his teachings in his celebrated definition: "Predestination is nothing else than the foreknowledge and foreordaining of those gratuitous gifts by which God makes certain the salvation of all who are saved." Accordingly predestination is free, unmerited and unfailing. The mystery of predestination does not lie in the co-operation between God and man in the working out of salvation, but in the unfathomable secret of the divine decree.

St. Xugustine did not deny the freedom of the will. as his adversaries alleged. nor did he deny the function of supernatural merit as a factor in predestination to glory as such. His whole intent was to propound the necessity and gratuity of grace and the gratuity of predestination completely considered, extending from the beginnings of faith to consummation in glory. By his insistence on the gratuity of predestination he denied the value of natural merit as a reason for predestination.

The difference between St. Augustine and St. John of Damascus is mainly a matter of emphasis. The latter stresses the universality of the divine salvific will; Augustine, because of the controversies in which he played so vital a part. stresses the doctrine of predestination. Although he, too. explicitly taught the universality of God's antecedent will to save, he came more and more toward the end of his life to insist on God's absolute, consequent will, which coincides with predestination. His teaching requires complementing by the wealth of the Greek tradition.

The Predestinarian Controversies. — The concept of predestination commonly known as predestinarianism is a tendency diametrically opposed to Pelagian naturalism. According to the doctrine of predestinarianism some men are predestined. by an absolute divine decree, to good works and to eternal life; others are foreordained to sin and to eternal punishment. The liberty of the will has been completely extinguished by original sin, and so avails nothing toward the attainment of salvation. Grace. which constrains the will in the direction of good, is bestowed only on the predestined. Thus, while Pelagianism and Semi-Pelagianism make salvation depend exclusively on man. predestinarianism makes God alone responsible for man's eternal destiny.

The predestinarian view goes back to a 5th-century interpretation of Xugustine's doctrine on eternal election and reprobation; indeed, throughout the history of the doctrine of predestination, all the adherents of predestinarianism claim Xugustine as their champion. Lucidus. a priest of Gaul, taught that God positively and absolutely predestines some men to eternal life, and others to eternal perdition. The elect have no part in working out their salvation; grace alone impels them toward their happy end. Christ did not die for the nonelect, as they were created expressly for hell. Faustus, bishop of Riez, demanded a retraction of Lucidus, who thereupon submitted. The second Council of Orange, held in 529, put an end to controversies on predestination for three centuries.

The dispute flared up again in the 9th century, and grievously agitated the whole Frankish empire for several decades. The monk Gottschalk of Orbais, claiming that his teaching was derived from Augustine, preached that there was a twofold predestination, of the elect to eternal life and of the reprobate to eternal death. Hence, he stated, Christ died exclusively for those who were from eternity destined for heaven; God's salvific will extends to these alone. Gottschalk's former abbot. Hrabanus Magnentius Maurus, wrote a refutation of his doctrine. At the instance of Hincmar, archbishop of Reims, Gottschalk was degraded at the synod of Quierzy in 849, was forced to burn his writings and was imprisoned in the monastery of Hautvilliers.

A number of scholars, such as Ratramnus of Corbie and Prudentius, bishop of Troyes, took sides with Gottschalk against Hincmar. Soon the whole empire was in turmoil; bishops, theologians and even several provincial and national synods engaged in the controversy. Finally in 860 a synod of the bishops of 14 provinces met at Toucy. A set of propositions on which all could agree was approved. God wishes the salvation of all men, and Christ died for all; the will remains free after original sin, and is aided by grace; the world is saved by grace. and the condemnation of the lost is the result of the abuse of their free will; the predestination of the elect proceeds from divine mercy.

Although this particular dispute came to an end. the fundamental question remained unsettled. The point at issue mas the everlasting conflict between two schools of thought. Some were wholly intent on asserting above all the primacy of the divine will; others stressed the free play of human activity in the process of salvation. The debates of the 9th century contain in germ all subsequent controversies concerning predestination.

The Middle Ages. — Predestination for the great doctors of the middle ages meant primarily "predestination to grace and glory," that is, predestination adequately considered, embracing the entire course from the first call to faith to the actual conferring of the beatific vision of God in heaven. Since man cannot merit the first grace, predestination itself is gratuitous and cannot be merited.

The chief task of the medieval theologians was the harmonization of the diverging points of view emphasized by St John of Damascus and St Xugustine. How could both doctrines be formulated in such a way that neither would exclude the other?

St. Thomas Aquinas, greatest of medieval doctors. succeeded in fusing the best elements of Latin and Greek thought. With Xugustine he taught that predestination completely considered is an entirely gratuitous gift of God With John of Damascus he held that God antecedently and conditionally wills the salvation of all men. But in consequence of His prevision of man's co-operation with grace. God wills absolutely the salvation of the predestined alone, and. as justice demands, decrees the damnation of the reprobate. This distinction restores to prominence the universality of the divine salvific will. which had been somewhat overshadowed since the days of Xugustine.

According to St. Bonaventura, who developed ideas previously sketched by Alexander of Hales, the eternal design with regard to man's ultimate destiny is wholly divine. As to the temporal gift of grace man can at most dispose himself negatively for its reception; on the other hand. man can freely reject the invitations of grace. The glorification of the just and the reprobation of the unjust are in accord with man's deserts: God rewards supernatural merit by the gift of eternal happiness and punishes sin by damnation. For these two doctors God's foreknowledge of supernatural merit or of sin precedes the formal sentence of eternal reward or reprobation.

In the theory of John Duns Scotus, God with sovereign independence predestines some men to eternal life and passes over the rest. Thereupon He determines the means which will effectively lead the elect to beatitude. Duns Scotus is the first to distinguish God's will respecting the end from His will respecting the means, and focuses attention upon incomplete predestination to glory as such, this, he held, is in no nay connected with God's foreknowledge of man's merits. His objective was to stress the completely gratuitous character of both means and end.

The Reformation. — Among the precursors of Protestantism, John Wycliffe held as probable the opinion that God determines creatures in all their acts. Hence some men are predestined to glory after a life of exertion. while others, called the foreknown, are destined to perpetual punishment folloning a life of misery.

Similar viens are developed by the reformers of the 16th century. According to Martin Luther, God is the cause of all that occurs; nhatever God wills necessarily takes place. Human freedom. he taught. has been completely vitiated as a result of original sin; therefore, nhatever man does, even though he attributes his actions to his free will. he does of necessity. Man's destiny is therefore totally in the hands of God, who absolutely predestines the elect to eternal life without regard to merit, and likewise foreordains the means which lead the elect to salvation.

Huldreich Zwingli, proceeding still further, contended that God destines certain men to salvation and others to perdition in order to show forth His justice. In pursuance of this choice God effects faith in the elect.

Philipp Melanchthon, who had originally agreed with Luther, later moderated his views. He advocated a doctrine of predestination which concedes that the promises of the Gospels have been made for the benefit of all. God from eternity elects those who He foresees will believe; those who are not among the elect have only themselves to blame.

But the great doctor of predestination among the reformers is John Calvin, who formed into a system various elements taken from St. Paul. St. Augustine. Wycliffe, Luther and Martin Bucer. Whatever happens, he taught, has been eternally decreed by God. The objective of all divine willing and doing is the glory of God. The first man fell into sin because God judged it expedient; why He so judged is impervious to us; certainly He would not hare thus judged unless He thereby saw that His name would be glorified. God has foreordained a part of the human race to salvation, a part to perdition. This twofold decree of the divine will is predestination. Calvin defines predestination as the eternal decree by which God has determined His will with regard to every man. Not all have been created in equal condition; some have been foreordained to eternal life, others to eternal damnation. In accordance with the end for which each man has been created, he is said to be predestined to life or to death.

This severe doctrine underwent many modifications in the course of the centuries. From the very beginning Calvin's supralapsarian teaching was often abandoned in favour of infralapsarianism. The supralapsarians maintained that God has unconditionally reprobated a part of the human race irrespective of the fall of Adam. The infralapsarians contended that God has decreed such reprobation only subsequent to His prevision of Adam's sin. In the beginning of the 17th century Jacobus Arminius and several other leaders of the Dutch Reformed Church taught that election by God to salvation is conditional, dependent on man's utilization of grace. At the Calvinist synod of Dordrecht (1618–19) the opinions of Arminius and his followers were condemned; his adherents were later expelled from Holland. Even among the stricter Calvinists supralapsarianism was not universally favoured; many preferred infralapsarianism. The decrees of the synod left the question open.

The Jansenistic theory of grace and redemption has many points in common with the infralapsarian form of Calvinism. Cornelius Jansen taught that God has predestined a part of mankind to eternal glory without any consideration of their merits. God does not will the salvation of all who have sinned in Adam. Those who are not predestined fall under the decree of negative reprobation; indeed, they may be said to be positively reprobated, for the divine will to exclude them from eternal life is equivalent to a decree of damnation. Christ did not die for the reprobate, but solely for the predestined.

In England the stricter tenets of Calvinism were never very popular, except among the Puritans. In the United States the Presbyterian Church mitigated some of the sterner features of Calvinism and stressed the universal character of God's love for man.

Roman Catholic Controversies Since the Council of Trent.—By the end of the Council of Trent the certain teaching of the Roman Catholic Church concerning predestination had been clearly formulated. Catholic theologians unanimously agree that predestination to the first grace is utterly incapable of being merited. and hence that complete predestination to grace and glory is in no may connected with God's prevision of merit. They likewise agree that formal condemnation to eternal punishment, or positive reprobation, is decreed by God only in consequence of the divine foreknowledge of death in the state of sin.

But with regard to two perplexing problems Catholic opinion is sharply divided. Is incomplete predestination to glory as such associated with God's foreknowledge of merit? According to revelation eternal glory is a reward for supernatural merit. Does God predestine men to glory in consequence of His prevision of their merits, or is predestination to glory rather to be considered as the reason for merit, and hence for God's prevision of merit? In the former case predestination to everlasting happiness would be conditional, in the latter case unconditional. With this problem another is introduced: is the assumption of an unconditional negative reprobation theologically sound or not?

Dominican theologians, following the lead of Francisco de Vitoria. Melchior Cano. Domingo Báñez and other former professors at the University of Salamanca, hold that predestination to glory is antecedent to God's prevision of man's merits. According to this theory. God in the order of intention predestines certain persons to eternal happiness by an absolute decree, and in consequence of this decree determines to grant them all the graces necessary for salvation. But in the order of execution God follows the reverse order; that is. He first allots the predetermined graces and then grants the happiness of heaven as a reward for the merits acquired by the aid of those graces. This doctrine necessarily involves negative reprobation antecedent to the prevision of sin. Those whom God has not numbered among the elect are simply excluded from heaven or. as Charles René Billuart and others prefer to put it. are left to their own weakness and so inevitably perish. Several of the greater Jesuit theologians. among them Francisco Suarez and St. Roberto Bellarmine, likewise support this view.

Most theologians of the Society of Jesus. however, vehemently disagree and give their allegiance to the doctrine developed by Luis Molina. According to Molinism God knows what every man in every situation in every possible norld order would freely do if granted such and such graces. and with sovereign liberty decrees a definite world order. This choice, in conjunction with God's foreknowledge of every person's co-operation with the graces offered, or rejection of them. is predestination for some, reprobation for others. Therefore predestination to glory as such is consequent upon God's prevision of supernatural merit. The gratuity of predestination is guaranteed by God's free choice of a definite world order. and by His generous bestowal of unmerited grace. This doctrine eliminates the difficulties raised by any theory of antecedent reprobation. Eternal punishment is inflicted only in consequence of God's prevision of the sinner's final impenitence. Such is the theory advocated by eminent Jesuit theologians, as Franciscus Toletus and Leonardus Lessius. and outside the Society of Jesus by St. Francis of Sales. It is held by the large majority of Catholic theologians who do not adhere to the Dominican school of Thomism.

According to Protestant liberals and in the public teaching of the churches the doctrine of predestination is less emphasized. The problem is the reconciliation of human freedom with divine foreknowledge. It has been argued that, if God allows His activity to be limited by human freedom, He may also so limit His foreknowledge as to know free acts as possible and not as actual.

The Number of the Predestined.—This problem has challenged theologians from the days of the Greek fathers to modern times. That the absolute number is very large, all concede; for Apocalypse vii, 4–9 affirms that the multitude of the elect. drawn from all races, nations, tribes and languages. is so huge that no one can count them. As to the proportion of the predestined relative to the reprobate, opinions vary; modern authors incline to greater optimism than their predecessors. In any case, certitude cannot be achieved, as no clear revelation has been granted by God. Thomas Aquinas, after reporting views current in his day that the number of the elect would equal the number of fallen angels. or the number of loyal angels or the number of fallen angels plus that of all the angels created by God, concludes: "It is better to say that the number for whom eternal happiness is reserved is known to God alone" (*Summa theologica*, i, q. 23, a. 7). The best answer of all is that given by Christ who, in response to an anxious query whether only a few would be saved, told the people that they should strive to enter by the narrow gate (Luke xiii, 24).

Bibliography.—The theological literature dealing with predestination is enormous, but there are no satisfactory general accounts or monographs written originally in English. The following are basic works St. Augustine. *De Praedestinatione sanctorum, De Dono perseverantiae;* St. Thomas Aquinas, *Summa Theologicn,* part i; John Calvin, *Institutes;* Luis Molina, *Concordia liberi arbitrii* (1588). *See* also manuals of systematic theology and histories of dogma. (C. V.; X.)

PREDICABLES, in scholastic logic, a term referring to certain relationships which may obtain between the predicate of a simple statement and its subject. The traditional list of these relationships is derived from Boethius' Latin version of Porphyry's *Eisagoge* and consists of five items: genus, species! differentia, property and accident. It is based upon a similar classification set forth by Aristotle in the *Topics* (a, iv–viii), differing only by having species where the Aristotelian list has definition.

Aristotle's treatment of the matter is concerned only with statements of the form "*A* is *B*," where the subject and predicate terms are both universal. He notes that in every true statement of this type the predicate will either be convertible with the subject (*i.e.*, "*B* is *A*" will follow from "*A* is B") or it will not. If the predicate is convertible with the subject and states its essence, then it is the definition of the subject; while if it is convertible but does not state the essence, it is a property of the subject. On the other hand, if the predicate is not convertible with the subject but is part of the definition, it is the genus or differentia of the subject. for a definition always consists of genus and differentia. Finally. if the predicate is not convertible and is not part of the definition, it is an accident of the subject.

In attempting to understand these distinctions one is handicapped by Aristotle's failure to indicate clearly whether he is speaking of relations between linguistic expressions or between the meanings of such expressions. Thus, although definition is explicitly described as a phrase which means the essence. the remaining four predicables seem all to be treated primarily as nonlinguistic.

Some Aristotelian examples may be briefly mentioned. In the true statement "Man is a rational animal," the predicate is convertible with the subject and states its essence. Therefore. "rational animal!' is the definition of man. The statements "Man is an animal" and "Man is rational," while true, are not convertible. Their predicate terms, however, are parts of the definition and hence are the genus and differentia of man. On the other hand, the statement "Man is capable of learning grammar" is true and convertible. since all men are capable of learning grammar and whatever is capable of learning grammar is a man. But "capable of learning grammar" does not state the essence of man. It is therefore a property of man. For an example of an accident, take the predicate of the true statement "Man is featherless." This predicate is not convertible mith its subject, nor is it part of the definition. Accordingly, it expresses only an accidental characteristic of man.

Porphyry gives the following examples: of genus, animal; of species, man; of differentia, rational; of property, risible; of accident, white. (B. Ms.)

PRE-ELEMENTARY EDUCATION. For the purpose of this discussion pre-elementary education is defined as education and training of very young children, *i.e.*, children under compulsory school age or under kindergarten age. Kindergartens, which enroll children between the ages of five and six or seven years, have been rather generally accepted as an integral part of the primary school (*see* KINDERGARTEN; *see* also ELEMENTARY EDUCATION). Thus in this article pre-elementary education means schools for children from two to four-and-a-half or five years or, more usually, for children between three and five. In western Europe and elsewhere there is some variation in the age of compulsory school entrance, the range being from five to seven years.

Historically, the training of children before they entered primary school was considered to be the sole province of the family. An occasional philosopher or educational reformer contemplated the possibilities of improved education of toddlers and young children but the early schools appear to have been philanthropic in purpose, established primarily as substitutes for home care rather than as supplements to the educational functions of the home. In general these early institutions were set up to provide custodial care, safety and health services to destitute and homeless children and those whose mothers could not care for them in the home. These institutions were frequently in the hands of religious orders. To some extent these generalizations still hold. However, as developments in medical science, psychology and education led to better understanding of the nature and needs of the young child (*see* CHILD PSYCHOLOGY AND DEVELOPMENT), there mas increasing concern for making provision for the optimum development of young children in all aspects of their growth—physical health, emotional security, social development and educative experience.

The writings and life work of Friedrich Froebel (*q.v.*) focused attention on the possibilities of educating children before the age of seven. In 1837 he opened the first kindergarten and demonstrated that children could learn through play and without formal instruction. Since Froebel's day other educators (e g., Maria Montessori in Italy, Ovide Decroly in Belgium, Margaret McMillan in Great Britain, Harriet Johnson in the Cnited States) have viewed the preschool years as a period of great educational possibilities. In the 20th century the preschool program came to be viewed increasingly as a desirable supplement to the home—as an agency that can give effective support to parents in the rearing of children as well as offer to the children themselves appropriate experiences that will contribute to harmonious growth and to a healthy, joyous and intellectually stimulating existence.

Wide and at times confusing variation is found in the terms used to describe the institutional arrangements for pre-elementary education. Such terms as infant school (Great Britain), nursery school and day nursery (Great Britain, U.S.) crèche and *école maternelle* (France), *casa dei bambini* (Italy), kindergarten (Germany, U S.) are used. sometimes interchangeably, sometimes with quite precise meanings. These institutions are described in historical perspective in the sections which follow.

HISTORY

Great Britain.— In 1816 Robert Owen, a cotton mill owner in Scotland. founded a "preparatory school for infants" (age range of the pupils was from one to six years) where children were not to be given formal lessons but were to be permitted to play. His aim was "to prevent children from acquiring bad habits, to give them good ones, and to form their dispositions to mutual kindness." The idealism of Robert Owen and the enthusiasm of others in the years following resulted in the founding of many of these infant schools throughout the country and had an influence on the movement toaard infant schools and day nurseries on the continent and in the Cnited States. In time (1870) the infant schools became an integral part of the state system of education in Great Britain, the age of five being adopted as the age of entry to infant school and the age of three fixed as the minimum age at which children in attendance could count for a government grant. As the years passed the infant schools lost their "nursery" character and developed more and more a scholastic tradition in which little provision was made for physical activity, sleep and play. Children of three, four and five years mere required to sit still in rows in large galleries—nith arms folded and without conversing with one another—reciting lessons in which pictures and museum specimens took the place of living plants and animals and spending hours on the "three R's" and on needlenork. Outside the official system, experiments in childhood education were being tried, notably the introduction of the views and methods of Froebel in the setting up of kindergartens for fee-paying pupils and the institution of schemes for the training of kindergarten teachers. The realization came gradually that enlightened and psychologically sound methods of early childhood education ought to be used mith all children irrespective of parents' ability to pay fees, and out of this realization developed the British nursery schools. After 1918 such schools were a recognized part of the national school system with standards for nursery schools defined by law. Margaret McMillan and Grace Owen were pioneers in the movement to improve the health of young children and to provide a suitable environment for their growing minds. Both these leaders saw the nursery school as an extension of home life and as an institution which could improve through education the standard of home care of children. They further maintained that a nursery school is not a place for formal education but rather a community nursery where children up to the ages of five or six years may have appropriate opportunities for physical, mental and social growth through playing in small groups under the supervision of qualified teachers.

Miss McMillan outlined a plan for a three-year course for training teachers for these schools, maintaining that only trained personnel should work with children of these ages. Training centres at hianchester (under Grace Owen), at London (under Lillian DeLissa) and at Deptford (under Margaret McMillan) supplied nursery teachers for the entire Commonwealth as well as for the early nursery schools in the United States. The older infant-school system was modified in the light of principles underlying the nursery school experiments, for the nursery school movement in England was from the first both vigorous and articulate.

Continental Countries. — Jean Frédéric Oberlin, an Alsatian Lutheran pastor, opened what was probably the first pre-elementary school in the western world. Beginning in 1779 he founded a number of schools for young children, which he called *écoles à tricoter* (knitting schools). These were philanthropic in purpose, with religious and moral training constituting their chief objectives. Crèches and *salles d'asile* were also being established about this time in the cities, more with the aim of protecting children from the dangers of the streets than of educating them. The *salles d'asile* changed from private- to state-supported institutions in 1833 when they were made part of the national educational system. These establishments henceforth carried the designation of *écoles ntaternelles*. The objective of these schools is to work toward well-rounded development of the young child, without fatigue, restraint or force.

In Italy around 1835 a Catholic priest Abate Ferrante Aporti, working to establish elementary schools, became dissatisfied with the progress made by children and was led to investigate the conditions under which their preschool years had been passed. As a result he drew up a plan for the establishment of an infant school in which moral habits, intellectual cultivation and physical faculties were all to be emphasized. Early in the 20th century Maria Montessori (*q.v.*) began her experiments with children three to six years of age. She was a physician, who first became interested in the educational problems of mentally defective children but she soon became impressed with the learning potentialities of the normal preschool age child. Her first *casa dei bambini* was established in connection with a tenement-improvement project in Rome. In this school the children were given a special educational apparatus (*see* MONTESSORI SYSTEM). Self-education was the keynote of the plan; a large measure of individual initiative and self-direction characterizing the Montessori philosophy, the teacher would withdraw to the background and merely supervise the use of the apparatus, or "didactic material." This material was not designed to encourage children to play together. What opportunity there was for group activity occurred in connection with the housekeeping activities which the children shared: *i.e.*, keeping the rooms in order, serving the meals, etc. In 1928 Montessori mas invited by the Italian government to institute a six-month training course in the use of her method for religious and lay teachers. In the latter years of her life she traveled extensively in Europe and Asia, and her ideas regarding the education of children under six had an important influence on the development of pre-elementary education in many parts of the world.

The United States. — Beginning around 1920 in the United States, nursery schools developed as the outcome of interest that may be traced to a variety of sources: (1) a scientific interest in early childhood, resulting from new applications in the fields of psychology and medicine; (2) a rapidly expanding background of educational theory; (3) experimental efforts in the fields of psychiatry, child guidance and parent education; and (4) the efforts of individuals and agencies to improve the educational programs of day nurseries already established for the care of children of working mothers. Two national emergencies (the economic depression of the 1930s and World War II) were also responsible for the further development and acceptance of nursery schools in the United States. Because the nursery-school movement sprang from such a variety of social forces, no one type of school may be singled out and described as representative of the movement.

Interest in systematic research into the abilities and development of young children increased rapidly after 1920 and a number of nursery schools were organized in universities to provide laboratories for the study of normal young children. Children two to six years of age were enrolled to furnish subjects for research. but soon it was recognized that such laboratories had an obligation to provide an educational program for the children enrolled and to demonstrate what good educational programs for preschool children entailed Nursery schools were also established at this time as laboratories in which college girl students could study child care and development in preparation for their future roles as mothers. As more nursery schools were founded, colleges also instituted programs for the training of teachers. Prior to 1935 some nursery schools were also set up in conjunction with guidance clinics (as a parent-education effort) and in hospitals as an effort to encourage the recovery of the convalescent child.

The national emergency created by nidespread unemployment and economic distress in the early 1930s resulted in the authorization of emergency nursery schools by the federal emergency relief administration. These schools were set up to provide jobs for unemployed teachers, nurses and affiliated workers and to promote better morale among parents through fostering the physical and social well-being of their children. These nursery schools were under the control of the public school system. were for the most part housed in public school buildings and served to draw the attention of the general public to the desirability of school services for children below school age.

During World War II the number of employed women in the United States increased by more than 6,500.000 and many of these were mothers of young children. Federal legislation in 1942 made funds available to provide facilities for the day care of children whose parents were employed in industries neceiiary for nar production. Supervision of these child-care projects was under local or state departments of education or welfare. When the war was over federal funds began to be withdrawn from these projects and by mid-1946 all federal support had been nithdrann. After that date there nas no direct financial assistance from the federal government in support of schools for children under six.

Married women, honever, continued to work in increasing numbers Day nurseries (*q.v.*) for the care of children whose mothers work have long been provided under philanthropic auspices. Such centres try to meet the needs of children through group care, offering not only substitute mothering and dependable daytime care but also appropriate educational experiences.

Parent co-operative nursery schools (*i.e.*, schools operated by groups of parents who join together to make provision for their children to play together, sometimes hiring a professionally trained teacher and sometimes sharing among themselves the supervision of the children and other duties in connection mith the school) were established in large numbers after World War II. There was a trend also toward church-sponsored nurseries and kindergartens, *i e.*, weekday preschool programs operated in church buildings. some offering religious instruction to the children enrolled, others without emphasis on religious training and enrolling children from different religious backgrounds There were also efforts to offer group experience to preschool children with handicaps of one type or another. for exampie, to children who are mentally retarded, who have cerebral palsy or are otherwise physically crippled, who are blind or deaf or nho are emotionally disturbed. Sometimes this preschool experience is provided by forming small groups of children with similar handicaps and hiring teachers trained to give appropriate therapy to the children in addition to giving them a satisfying experience with peers and adults beyond the family circle. In many instances such schools are also centres for research in the educational problems of the handicapped.

MODERN THEORY AND PRACTICE

Preschool education may be viewed most correctly as an extension upward or outward of the home and family rather than an extension downward of the elementary school. The legitimate activities of the nursery school, as of the kindergarten. are those which supplement the mother's care and the home play of the child in fostering healthy physical and psychological development;

they do not include borrowing from the elementary school or attempting to prepare the child for formal school before he is ready in terms of chronological age and physical and social maturity.

The nursery exists not to replace the home and primary school but to complement them. There comes a time in the young child's life when the resources of his home cannot provide all that is needed to stimulate the development of his potentialities—potentialities for learning new things through firsthand experience. for developing self-confidence and skill in making friends outside the family, for achieving a sense of himself as a person. It is believed that such learnings are useful in preparing a child for entrance into formal school and for the tasks he faces there in learning to read, write, cipher, etc.

The preschool years are said to be of supreme importance in molding the individual's personality, behaviour patterns and attitudes toward himself and others. This is an age of partial weaning from the emotional ties to the family, of the discovery of individuality and of the appearance of new interests, abilities and attachments. It is crucial, however, that ties to the family be strengthened, not broken, and therefore one of the prime requisites of a preschool program is that it maintain a close relationship with each child's home and family. A school for the nursery ages must encourage individual development in relation to each child's personality, capacities and home environment.

The fulfillment of this task requires trained teachers with sound theoretical backgrounds and with practical experience under expert supervision in the guidance of young children. The teacher's task is to maintain. strengthen and enrich each child's personal relationship with his family and at the same time to introduce a wider world of people and opportunities. She must understand that entry into preschool creates a psychological problem for the young child as well as an opportunity for herself to make a contribution to his development. She must know hon to provide a setting appropriate to the physical skills of the children and must understand normal phases of growth throughout the preschool years in order to be prepared for changes in the behaviour of her pupils, for fluctuations in dependence and independence, for confusion between right and wrong and fantasy and fact. so characteristic of these ages. She must have skill in helping children acquire gradually the capacity for harmonious relationships with other children. She must make the proper provision of satisfying activities in play and know how play of different types (dramatic, social, free, organized! artistic and creative) contributes to the flowering of the potentialities of the child and to the solving of his emotional problems. She needs an intuitive sensitivity to the learning problems of young children, for they are ordinarily unaware of their need for help and understanding.

A preschool program may be characterized by a threefold concern for optimum development: (1) physical health, (2) mental hygiene and (3) intellectual stimulation. Children under school age should not be brought together in a group unless the sponsoring agency can demonstrate its concern for good physical care which will result in healthy growth. This includes provision for adequate food, rest, cleanliness, the learning of health habits and some active outdoor play; it also entails concern for safety, watchfulness against accidents and protection against communicable diseases.

Of equal importance is an awareness of good mental hygiene. This involves an atmosphere characterized by affection, friendliness and noncoerciveness; simple rules benevolently enforced; success and praise for effort, which give a sense of achievement; respect from adults, so that children develop self-esteem and respect for others; support from the teacher in developing the capacity for co-operative relationships with others; steadiness and consistency in adults' expectations; and outlets in play for the strong feelings of the child.

Since one of the preschool's prime reasons for being is to offer children an educative experience, such a school must provide good teaching which results in the enjoyment of new experiences and of intellectual stimulation. This means planning a rich environment in the school, including stories and picture books; painting and clay modeling; observation of nature and pets; gardening and science; singing, dancing and rhythms; block building; playhouse activities; games; and simple excursions outside the school. It is important that children engage in these experiences under the tutelage of an adult who understands their level of growth and their ability to comprehend, so that the activities are meaningful and enjoyable. It is believed that young children learn more readily from an active kind of *doing* through the medium of play than through formal lessons.

Common problems relating to pre-elementary education exist throughout the world. There is a shortage of trained teachers along with a lack of agreement as to what constitutes adequate training for teachers. In some quarters a gentle, affectionate disposition is considered sufficient for teaching little children, while in others a qualified teacher is expected to have completed several years of college and even to have postgraduate training. In general it may be said that educational standards are rather low for teachers of children under five or six years of age. Uniformly high standards for the operation of preschools are lacking and suitable housing and equipment are threatened by lack of financial resources. There remains some reluctance on the part of citizens and government authorities to accept preschools as educational rather than welfare agencies.

On the other hand some responsible citizens in every country are concerned with providing children under school age with better health care, greater emotional security and richer educational opportunities. Although this concern does not by any means extend to the entire child population, a beginning has been made everywhere.

PRE-ESTABLISHED HARMONY, in the philosophy of Leibniz constitutes the explanation of the co-ordination of change in substances which are not causally related.

Leibniz asserts for logical reasons that the universe consists of monads, indivisible substances which develop in time. Every characteristic of a monad (the events which happen to it being included among characteristics) is deducible from its own nature. There is thus no causal link between different monads. They are "windowless." Nevertheless everything happens as if by mutual influence, and Leibniz accounts for this by postulating that God created the monads in such a way that each represents the universe from its own point of view. The changes in them are thus necessarily co-ordinated.

The pre-established harmony was most highly valued by Leibniz as affording a solution to the mind-body problem posed by Cartesianism. Descartes's insistence on the complete qualitative difference between mind and body, together with his account of causation, made interaction impossible, although Descartes himself did not appreciate this. His followers, who were acutely aware of the difficulty, introduced the theory of occasionalism, by which the appearance of interaction is explained by the intervention of God on appropriate occasions. For Leibniz the mind is one monad and the body, a group of monads, so that the two are not completely disparate; but his theory of substance precluded him from allowing causal connection, and he substituted for the recurrent miracle of the occasionalists the single creative act of God by which harmony between monads is once and for all established. The term *harmonie préétablie* is first used in the *Explication du nouveau système* (1695), but the essentials of the theory are already present in the *Discours de métaphysique (1686). See* LEIBNITZ, GOTTFRIED WILHELM. (M. KE.)

PREFECT (FRENCH). The prefect *(préfet)* in France is the office of a high official. 4 similar post *(psaefectus)* existed under the Roman empire, from which the title was borrowed, and in France a comparable office *(intendant)* existed under the *ancien régime*. The French office of prefect was created in *1800* by Napoleon, who raised the prefectoral corps to a position of great prestige and influence. The prefects were the administrators of the *départements,* responsible for public order and good government and for ensuring that the central government's policy was effectively carried out throughout the country. Napoleon called them *empereurs à petit pied.*

Under succeeding regimes the power of the corps increased but its prestige declined. Dependent for office on the whim of the government. the prefects became primarily concerned with police and elections, and one of their principal functions was to ensure the government a safe parliamentary majority. They reached the height of their power under the second empire. During the first decades of the third republic the prefects' position was weakened by the frequent nomination of new men by successive governments. However, prefects then became increasingly concerned with social and economic problems, and after World War II, while retaining responsibility for public order and good government, they became the dynamic element in the provinces for promoting and co-ordinating social policies.

Under *1958* conditions, as under those of *1946,* the prefectoral corps consisted of prefects, each responsible for a *département;* secretaries-general, or second in command; subprefects, responsible for the *arrondissements;* and *chefs de cabinet,* who nere the prefects' personal assistants. The prefects are appointed by the president of the republic with the approval of the council of ministers and on the recommendation of the minister of the interior, to whom they are responsible *(1958* constitution, art. *13).* They can be dismissed at any time without cause or notice. but in the second half of the 20th century they enjoyed in fact considerable security of tenure. Sweeping changes were likely only when there was a major change of political direction or regime.

Conditions of service in the corps were laid down in a special statute of June *19,* 1950. A prefect has a wide variety of poners accrued haphazardly over the years; according to one estimate there are as many as *4.000* separate sources of his legal authority. The prefect is constitutionally responsible for "co-ordinating the activities of state officials, the representation of national interests and the administrative supervision of local authorities." He is the sole legal representative of the government and the state in the department; uhen a minister delegates his powers, he is required by law to delegate them to the prefect and not directly to his own officials in the field. The prefect, therefore, acts as the agent through which all powers are transmitted from the centre to the periphery.

The prefect is the general administrator of the *département,* the chief executive officer of the elected departmental authority (the *conseil général*), the principal police authority and the supervisor of the communes in the *département*. His approval is required for many administrative acts of local authorities.

In Paris the prefect of the *département* of the Seine also exercises the municipal powers normally possessed by the mayor of a commune, there being no popularly elected mayor of Paris. There is, in addition, a special prefect of police whose jurisdiction covers the nhole Paris conurbation.

In the eight regional capitals and in Algiers, the prefects have additional emergency powers and authority to co-ordinate the work of the other prefects in the region. They have the additional title of *inspecteur général de l'administration en mission extraordinaire.* (*B.* CN.)

PREFECT (ROMAN), the title *(praefecfzu)* of various Roman officials, civil and military. A prefect nas not a magistrate proper; he was the deputy of a superior magistrate.

City Prefect. — The city prefect (*praefectus urbis*) acted at Rome as the deputy of the chief magistrate or magistrates during his or their absence from the city. He represented the consul or consuls when he or they were absent on a campaign or on other public duties, such as the celebration of the annual Latin festival on the Alban hills. The absence of all the chief magistrates for more than a single day rendered the appointment of a prefect obligatory; after the institution of the praetorship (367 B.C.) the necessity only arose exceptionally, as it rarely happened that both the consuls and the praetor were absent simultaneously. But a prefect was appointed during the enforced absence of all the higher magistrates at the Latin festival. The right of appointing a prefect belonged to the magistrate whose deputy he nas. No formalities in the appointment and no legal qualifications on the part of the prefect were required. The prefect had all the powers of the magistrate nhose deputy he was, but his office expired on the return of his superior.

Under the empire a new city prefecture was introduced. Augustus occasionally appointed a city prefect to represent him in his absence from Italy, although the praetors, or even consuls, remained in the capital. In the absence of Tiberius at Capreae during the last 11 years of his reign *(AD. 26–37),* the city prefecture, hitherto temporary, became a permanent magistracy; henceforth the prefect held office even during the presence of the emperor in Rome. He was chosen by the emperor; his office might be held for years or for life.' The prefect was not alloned to quit the city for more than a day at a time. His duty mas the preservation of peace in the capital; he was, in fact, the chief of the police, with the superintendence of the streets. markets and public buildings. He was entrusted by Augustus nith a summary criminal jurisdiction over slaves and rioters, nhich was gradually extended until it embraced all offenses by whomsoever committed. In the 3rd century A.D. appeals to the emperor in civil cases nere handed over to the prefect. An appeal lay from the prefect to the emperor. The prefect commanded the city cohorts (*cohortes urbanae*), which formed part of the garrison of Rome and ranked above the line regiments, though below the guards *(see* PRAETORIANS*)*. The military power thus placed in the hands of the chief of the police was one of the most sorely felt innovations of the empire. The changes of Diocletian and Constantine extended the power of the prefect, in whom, after the removal from Rome of the highest officials. the whole military, administrative and judicial powers were centred.

Judicial Prefects. — Under the republic judicial prefects (*praefecti iuri dicendo*) nere sent annually from Rome as deputies of the praetors to administer justice in certain tonns of the Italian allies. These towns nere called prefectures (*praefecturae*). After the social mar *(90–89* B.C.), when all Italy had received the Roman franchise, such prefectures ceased to exist.

Praetorian **Prefects.**—Under the empire the praetorian or imperial. guards were commanded by prefects *(praefecti praetorio)*, who were chosen by the emperor and held office at his pleasure. In course of time the command seems to have been enlarged so as to include all the troops in Italy except the corps commanded by the city prefect *(cohorfes urbanae*). Further, the praetorian prefect acquired a criminal jurisdiction which he exercised as the representative of the emperor. A similar jurisdiction in civil cases nas acquired by him not later than the time of Lucius Septimius Severus. Hence a knowledge of law became a qualification for the post, which was held by the first jurists of the age (*e.g.,* Papinian), while the military qualification fell into the background Under Constantine the institution of the *magistri militum* deprived the praetorian prefecture of its military character, but left it the highest civil office of the empire.

Various Other Prefects. — The title of prefect was borne by various other Roman officials, notably the folloning:

1. Praefectus Aegypti (later *Praefectus augustalis*).—The government of Egypt was entrusted to a viceroy with the title of prefect and was surrounded by royal pomp instead of the usual insignia of a Roman magistrate. He was under the immediate orders of the emperor. The exceptional position thus accorded to Egypt was due to its peculiar character and status as an imperial domain and to its high importance as the granary of Rome.

2. Praefectus vigilum.—The title of prefect nas also given to the commander of the *cohortes vigilum,* a night police force instituted by Augustus (*A.D.* 6). One of the principal duties of this force was that of serving as a fire brigade. The *praefectus vigilum,* besides commanding the *cohortes vigilum,* exercised criminal jurisdiction in cases of incendiarism and offenses committed during the night.

PREFERENCE, IMPERIAL: see IMPERIAL PREFERENCE.

PREGL, FRITZ (1869–1930), Austrian chemist who received the 1923 Nobel prize in chemistry for his work on the microanalysis of organic substances, was born in Laibach on Sept. 3. 1569, and was graduated from the *Gymnasium* in that city He received his M.D. degree from the University of Graz in 1894. After teaching in the Physiological institute at Graz for several years, he went to Leipzig in 1904. where he studied methods of physical chemistry with Wilhelm Ostwald and then nent to Berlin where he worked with E. Abderhalden. He returned to Graz in 1904 as professor of physiological chemistry at the Medico-Chemical institute. During the year that followed he investigated the components of albuminous bodies and the analysis of bile acids. From 1910 to 1913 he was professor at the University of Innshruck, returning to Graz in 1913 as director of the hledico-Chemical institute.

Lack of material in Pregl's work with bile acids had impelled him to look for methods requiring smaller amounts nhen making quantitative analyses of elements in compounds. By 1912 he was able to make measurements of carbon, hydrogen, nitrogen. sulfur and halogen, using only 5 mg.–13 mg. of starting material with results as accurate as those obtained by existing methods. Later he perfected his techniques so that as little as 3 mg.–5 mg. were adequate for measurements at least as exact as the results of microanalysis. The development of chemical microanalysis (see CHEMISTRY: *Microanalysis*) marked a great advance in organic elementary analysis. In addition to the general factor of economy, it became indispensable in many research problems of pure science, physiology, medicine and industry. Pregl also contributed a number of micromethods for measuring atomic groups and a sensitive microbalance. In 1917 he published Die *quantitative organische Mikroanalyse* (6th ed., 1949), a monograph. Pregl also perfected the Abderhalden dialysis test for the presence of ferment, so that less serum was needed for a reaction; invented a simple method for determining the functional capacities of the kidneys; and added to medicine an iodine solution, named for him, which is a mild but effective antiseptic. He died at Graz on Dec. 13, 1930.

PREGNANCY. Life has its beginning in the egg cell or ovum. These minute cells, which measure about $\frac{1}{120}$ in. (0 2 mm.) in diameter, are contained in the two ovaries, which lie in the abdomen one on either side of the uterus (womb). During healthy reproductive life one ovum is shed each month from one or the other ovary (ovulation) about the middle (12th–14th day) of a menstrual cycle. Average cycles — measured from the first day of one period to the first day of the next — occupy 28 days and in health are regular within a day or tno. For each day that the period is prolonged beyond the average 28 days, ovulation is delayed for one day, so that if the cycle is 32 days, the ovulation will be betneen the 16th and 18th days. Expressed in other words, ovulation tends to occur about 14 days before the next period regardless of the interval between the periods. After being shed the ovum enters the Fallopian tube, along which it passes to the uterus. If it is not fertilized it succumbs quickly, and it is known that the sperm cells also have a short maximum life span (two–four days), though somewhat longer than that of the ovum. It thus follows that there is only a short critical interval in the cycle during which fertilization is possible, and on either side of this critical period an interval when intercourse is unlikely to be fertile (the so-called "safe period"). If the ovum is not fertilized it escapes in the next monthly loss of blood. If, on the other hand, it is fertilized by a sperm cell (spermatozoon), pregnancy has begun.

Reproductive Physiology. — A brief summary of some matters of reproductive physiology is essential for an understanding of the complex changes which occur during pregnancy. The first factor is the pituitary gland—a small gland at the base of the brain. The front part of this gland (the anterior pituitary) plays a dominant part in the initiation and maintenance of the rhythmic functions of the sexual glands and breasts in the female, and of the sex glands in the male. It is also concerned with the functioning of the thyroid and adrenal glands. The consideration of these questions leads to the science of endocrinology, the science of the internal secretory glands, which is one of the greatest achievements in physiology of the 20th century. The internal secretory glands differ from ordinary glands, such as the salivary glands, in that they pour their secretions or hormones into the blood stream. In this way the hormones are carried to the organs on which they exert their specific actions. Specific hormones of the anterior pituitary are responsible for the periodic functioning of the ovary and the rhythmic shedding of ova. The pituitary energizes the ovary to produce hormones (estrogen and progesterone) which prepare the uterine bed for the reception of the ovum should fertilization occur, preparations which in the nature of things are only relatively rarely required. During reproductive life the ovaries shed between them from 300 to 400 ova (see ENDOCRINE GLANDS; HORMONES).

The ovary through its hormones controls the imbedding of the fertilized ovum in the uterine wall, and this control continues for about 12 weeks, after which it is taken over by the placenta (afterbirth). The placenta is the organ through which the embryo draws its nourishment from the maternal blood. Its vessels ramify freely round the uterine vessels in the placenta, where there is a constant diffusion of nutritive elements from maternal to fetal blood and of uaste products in the opposite direction. The fetal blood passes to the placenta along the tao arteries in the umbilical cord and, after it has been replenished and purified, it passes to the fetus via the umbilical vein. In addition to these combined nutritional and excretory functions the placenta takes over the hormonal functions which are in large part abdicated by the pituitary and ovaries (see PLACENTA).

A special anterior pituitary hormone (prolactin) acts on the breasts and stimulates the production of milk. It is produced in large amounts after labour, and its production by the pituitary gland continues as long as the infant is suckled. The hormonal mechanism by which the active secretion of milk from the breast is delayed till after labour is not well understood. There is some reason for the view that so long as the hormones of the placenta (estrogen and progesterone) are circulating in the blood the lactogenic influence of prolactin is inhibited and that this inhibition is not removed until the placental hormones are excreted in the days following labour (see MAMMARY GLAND).

Among the other physiological changes that are evoked by pregnancy one of the most important is an increase in weight On the average a pregnant woman gains 24 to 28 lb (10.9 to 12.5 kg.) but there are wide differences; some women enjoying apparent health may gain much less, while others may gain much more. The organs of reproduction — the uterus and its contents and the breasts — contribute an average of 11 lb. (5 kg.) to the total increase in weight. Under normal conditions the weight increase in pregnancy is quickly lost after labour, but in some instances this does not occur, and many women retain their weight gain and may even acquire active obesity dating from childbirth.

A considerable part of the normal weight gain of pregnancy is due to the retention in the body of water which is required for the increase in the total volume of the circulating blood; by the 36th week of pregnancy the total amount of blood in the heart and the blood vessels is increased by about 30% over that present in the nonpregnant state. The greater part of this increase is used up in filling the greatly expanded arteries and veins of the womb. The solid elements of the blood—the red blood corpuscles carrying the hemoglobin — are also increased. but not to the same degree. While the fluid part of the blood (the plasma) is increased by 40%, the red blood cells are increased by only about 15%, with the result that there is produced the so-called physiological anemia of pregnancy. Instead of being 100% the hemoglobin is reduced to 87%.

Duration of Pregnancy. — There is a small but appreciable elevation of the body temperature at the time of ovulation. and this. by pinpointing the date of ovulation, has provided a method of determining the interval between ovulation and childbirth. Usually this lies between 266 and 270 days. with extremes of 250 and 285 days The usual method for determining the date of childbirth is to add seven days to the first day of the last menstrual period and count forward nine calendar months. Thus, if the last period began on March 10, the estimated date of childbirth is Dec. 17. This gives a figure of roughly 280 days or ten lunar months. As ovulation occurs about the 14th day of the cycle, it follows that this estimate is in reality about 14 days longer than the true average duration of pregnancy as estimated by the temperature method.

Not infrequently the lam courts are required to pronounce on the legitimacy of a child born after an interval that is greatly in excess of the average figure or, on the other hand. that is much shorter than this figure. Some countries recognize upper and lower limits.

Diagnosis of Pregnancy. — A woman normally recognizes that she is pregnant by the cessation of menstruation (amenorrhea). and within a short time this is confirmed by the increasing swelling of the abdomen. But menstruation may cease and the abdomen increase in size apart from pregnancy, and the doctor often has to adopt other criteria for his diagnosis.

There are, indeed. only three positive signs of pregnancy. The first is the hearing of the fetal heartbeat. which is audible beginning about the 16th to 18th week of pregnancy. It is heard by placing a stethoscope on the lower abdomen, and the sound resembles closely that of a watch beating under a pillow. At the sixth month its rate is 150–160 per minute, while at the end of pregnancy it is 120–140. The second positive sign, the demonstration of the fetal skeleton by X-ray examination, is possible by the 16th week, when the fetal bones are visible. The third positive sign is the recognition of the kicking movements of the fetus, usually noticeable by the 18th to the 20th week. By this time the woman often feels the movements herself; this is the so-called "quickening" that reveals to the mother that her pregnancy has reached its halfway stage.

There are several probable signs and symptoms of pregnancy. Amenorrhea, however, can occur apart from pregnancy, commonly in anemia and other conditions leading to reduced health. Pyschological factors are also often responsible for the cessation of menstruation; *e.g.,* the mental shock associated with the death of a relative, or the anxiety of a woman who has exposed herself to the risk of pregnancy. There is a reverse of this latter condition in pseudopregnancy (pseudocyesis). when a childless woman with a fervent desire for motherhood develops, though she is not pregnant, the signs and symptoms of pregnancy, such as amenorrhea and increasing size of the abdomen and, at the end, may actually go into "labour."

A sense of fullness in the abdomen is often felt from the early weeks, and by the end of the third month the uterus can be felt where it rises from the pelvis. It reaches the level of the navel about the fifth lunar month. In the last weeks there is commonly a sinking down of the womb when the woman may feel more comfortable from relief of pressure ("lightening").

Enlargement and tenderness of the breasts are especially evident in women pregnant for the first time (primigravidae). In women who have had a previous pregnancy these changes are often less evident, though in the second half of pregnancy there is in most women a marked dilatation of the superficial veins and there is fluid in the breast which can be easily expressed from the nipple. In many women, especially brunettes, there is a dark pigmentation of the area round the nipple, which deepens with the advance of pregnancy.

Nausea, usually more evident in the morning ("morning sickness"), is a common symptom. In some women it is such a constant feature in pregnancy that they regard it, when it appears about two or three weeks after the last period missed. as a sure sign of their state. The sickness is sometimes associated with the development of an acute dislike of some ordinary article of food. Morning sickness generally passes off at the end of the third month, but in some cases it may be severe enough to require hospital treatment.

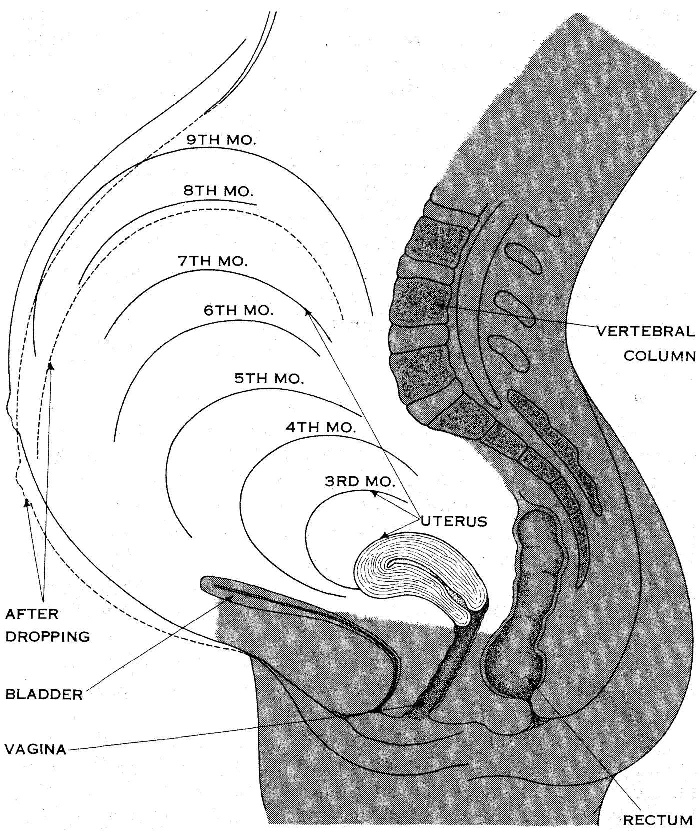
Pigmentation of the breast has already been referred to. In many women pigmentary changes in other parts of the skin are found; *e.g.,* the abdomen, where there is often a dark streak extending from the pubic hair upward as far as and, sometimes, beyond the umbilicus (linea nigra), while some women develop areas of pigmentation on the face, especially the forehead. These pigmentary deposits are believed to be due to excessive activity of the adrenal glands.

As the result of the stretching of the abdominal walls there are often formed the striae gravidarum; *i.e.,* pinkish or purple streaks where the superficial and less active layer of the skin has failed to keep pace with the generalized stretching of the abdominal wall. The pink or purplish streaks mark where the deeper and more vascular areas are thus exposed.

The doctor has access to further evidence for the diagnosis of pregnancy through internal examination, on which he can find enlargement of the uterus as early as the eighth or tenth week.

Finally. in cases of doubt, there are the biological tests for pregnancy. These depend upon the fact that one of the hormones. which is produced by the placenta and which resembles in some ways the hormone of the anterior pituitary, is excreted in the urine of the pregnant woman. When a small quantity of the urine of a pregnant woman is injected under the skin of female mice it produces characteristic changes in the ovaries of the animals. Young virgin mice so treated are killed at the end of 100 hours and the test is positive if characteristic "blood points" are present in the ovaries. The method, called after its inventors the Aschheim-Zondek test, is accurate in 98% of cases and may reveal a pregnancy that has advanced only four days beyond the first period missed. At such an early stage, however. the output of hormone may be small and it is better to wait for a further two or three weeks before having recourse to the test. Where a quick decision is required, a variation of the test that uses a virgin rabbit is generally employed. when the result is available by the end of 24 hours. In a still further animal test the female toad (*Xenopus laevis*) is used. Here a positive result is provided by the external and free escape of ova from the oviduct and is obtained as early as 18 hours.

Antenatal Care. — This includes the continuing supervision of the general health of the woman. the detection of any condition that may necessitate special attention at the time of birth (*e.g.,* contraction of the pelvis) and the detection and treatment of any



"DORLAND'S ILLUSTRATED MEDICAL DICTIONARY," 23RD EDITION, PHILADELPHIA, W. B. SAUNDERS COMPANY

UTERINE LEVELS DURING PREGNANCY

abnormal state that may develop during pregnancy. In addition it provides the opportunity for the establishment of that confidence between the woman and attendant that is peculiarly important in obstetrics. Finally the occasion is taken to discuss the preference of the woman in regard to the place of confinement, whether home or hospital. During the 1930s there was a great increase in hospital beds both to meet the marked rise in the demand by women for hospital care and to meet the increasing awareness of the health authorities of the importance of hospital care in obstetrical abnormalities. At the same time there were not sufficient beds to allow the admission of all women whose sole reason was personal preference. There were, however, several groups of pregnant women with a primary claim on the hospital services for their delivery: most primigravidae, those whose previous labours had been abnormal, women whose homes were unsuitable and women who had had many previous births. It is estimated that the risk of death is doubled when a woman has had six previous children and quadrupled when she has had ten or more. These groups do not include the women who, during the course of pregnancy, develop an unexpected abnormality that requires special attention. The extent of this need alone may be gauged by the records of the hospitals. Thus in one London hospital during one year 43% of the women who had booked for their lying-in (and excluding those who were specially referred by an outside doctor because of abnormalities) required special treatment in hospital during their pregnancy.

The principle underlying antenatal, or prenatal, care is the medical examination of the pregnant woman at periodic intervals throughout her pregnancy. At the first examination. which is made at an early stage of the pregnancy, a full medical history is obtained with special reference to previous illnesses, such as tuberculosis and Bright's disease. The details of any previous pregnancies (*e.g.,* difficulty at the birth and toxemia), the date of the last menstrual period and the expected date of the confinement are noted. A physical examination is made, including the recording of the weight and blood pressure. The urine is examined for abnormal constituents, especially albumin and sugar. The weight, the blood pressure and the state of the urine are recorded at each subsequent examination. The heart and lungs are examined and a sample of blood is removed from a vein to be tested for anemia, for syphilis (Wassermann test) and for the Rhesus and ABO grouping. The next examinations are made at four-weekly intervals up to the 30th week, at three-weekly intervals to the 36th week and weekly from then onward. At each of the later examinations the abdomen is palpated to determine that the position of the fetus in the womb is correct. for at this stage a faulty position often can be rectified. Excessive enlargement of the abdomen may indicate twins, which will demand special care at the delivery. Or there may be excessive fluid in the womb (hydramnios). At the 34th week an estimate of the pelvic shape and size is made with special reference to the discovery of any contraction that may require special care at birth and, in a severe abnormality, Caesarean section.

Nutrition in Pregnancy.—Scientific study indicates that the diet of a pregnant woman should contain 2,400–2,500 calories (*i.e.,* 400–500 more calories than are in the diet of the nonpregnant state) and that when she is suckling it should contain 3,000 calories. In general a woman who is ordinarily accustomed to a well-balanced diet will not require adding more to this regimen than her appetite dictates. There is in health a steady increase in the appetite that is especially marked from the third month onward. The diet thus augmented may be safely trusted to supply the protein, carbohydrates, fat, calcium, iron. vitamins and other elements that are required. Such a diet will contain red meat, eggs and sea food two or three times weekly; green vegetables, fresh fruit and at least one pint of milk daily.

From the 1920s, and especially after the discovery of the dominating influence of vitamins, abnormal nutritional states that have an adverse effect on childbearing and childbirth mere increasingly brought under control. Rickets, for example, resulting from a deficiency of vitamin D or sunshine or both, was responsible for a stunting of the skeleton and a narrowing of the pelvis in the growing child. Later in life this was a common source of difficulty and danger at childbirth, but improvements in the social field and the application of medical knowledge have rapidly reduced this menace.

While in western communities the nutritional standards of women in pregnancy are in general high, there are many less developed countries, especially in the east, where gross malnutrition may exist. There the shortage of vitamin D may result in severe rickets and osteomalacia, and the shortage of vitamins and iron may result in aggravated and dangerous anemia. (See also DIET AND DIETETICS ; NUTRITION.)

Toxemias of *Pregnancy.*—Among the most prominent of the abnormal conditions that make the periodic examination essential are the toxemias. They are of two kinds. The commoner is pre-eclampsia, which, unless recognized early and vigorously treated, may pass into a grave, convulsive form. The other kind is characterized by severe vomiting. Because of their superficial resemblance to a toxic state, these diseased conditions have been classified as toxemias, despite the fact that in neither case has intensive research revealed the existence of a causative toxic agent.

Pre-eclampsia usually develops insidiously in the latter half of pregnancy. The first sign may be the swelling of the ankles and legs and sudden increase in weight, but. while they should always arouse suspicion, these signs are often present without toxemia. Commonly the first significant sign is an elevation of the blood pressure which is first detected at a routine antenatal visit. The presence of albumin in the urine is the second most important sign. In the milder forms of toxemia ambulant home treatment, consisting of rest, is often permissible on the understanding that the patient visits the clinic or is seen by a doctor or midwife at short intervals. Where the initial signs are marked or where there is a progressive worsening of the state. the patient is admitted to a hospital or nursing home. In the 1940s, thanks to the early recognition and treatment of pre-eclampsia the risk of its passage into the grave convulsive form (eclampsia) was greatly reduced. In the graver manifestations termination of the pregnancy is called for in the interest of both mother and child. Even in the cases which become convulsive the mortality has been greatly diminished. Nevertheless this type of toxemia is the cause of nearly one-third of all maternal deaths, and until more is known about its cause it will remain the greatest challenge with which the obstetrician is faced.

Nausea, with or without vomiting ("morning sickness"), occurs in 50%–60% of women, commencing about the 6th week and subsiding about the 12th. Rarely it persists in an aggravated form (hyperemesis gravidarum), calling for the termination of pregnancy.

Rhesus Factor.--One of the reasons for an examination of the pregnant woman's blood at the first antenatal visit is to determine her blood group. Eighty-five per cent of Europeans contain in their blood an antigen similar to that present in the Rhesus monkey and are therefore classed as Rhesus positive (Rh+). The remainder of the population (*i.e.,* 15%) have no such antigen and are classed as Rhesus negative (Rh—). If the father is positive, the baby may be Rh+ ; if, in such a case, the mother belongs to the Rh— group, the bloods of mother and baby are "incompatible." In the placenta the Rhesus antigen passes into the maternal blood and stimulates the formation in the mother of antibodies which enter the fetal circulation and destroy the red blood cells (agglutination and hemolysis), uith the production of anemia or jaundice or both (erythroblastosis fetalis). The risk is small during a first pregnancy, unless the mother has by mischance previously received an incompatible transfusion; *i.e.,* of Rhesus positive or Rh+ blood.

With each succeeding pregnancy in which the fetus is Rh+ the antibodies in the mother's blood increase, and with them the risk to the fetus. In cases where the woman's blood is Rh— the husband's blood is grouped, and where it is positive the woman's blood is tested for antibodies monthly from the sixth month onward. Where the child is erythroblastotic the sole effective treatment is the replacement of the child's blood by compatible blood from a donor. Mother-fetus incompatibility similar to that found in the

Rhesus blood group occurs with other types of antigen; *e.g.,* the ABO group. See BLOOD GROUPS.

Exercise.—Walking exercise in the open air should be a daily routine for the pregnant woman, but too long walks or exhausting exercise of any kind should be avoided. Women vary greatly in these respects, and any advice given is weighed against the woman's natural habits. The prescription of special exercises became fashionable in the 1940s, and much can be said in favour of the so-called relaxation classes organized in relation to antenatal clinics. These classes are a valuable addition to the educational functions of the clinic. There the care of the body can be discussed and the facts of labour explained, so that, as Grantly Dick Read correctly stated, the young expectant mother is encouraged to forsake her fear and to adopt a more confident attitude to pregnancy and labour. These are advantages of great value, but there is no reliable evidence that by physical exercises or by psychological measures directed to the relief of anxiety the stages and duration of labour can be influenced. How far such preparation for labour can lessen the pain or make it more tolerable is not an easy matter to assess.

Vital Statistics.—The marked fall in the birth rate that occurred in western countries after the latter part of the 19th century due to voluntary restriction brought with it important consequences to public health, including maternity. The dwindling replacement at one end of the population scale and the marked lowering of the death rate at the other end of this scale greatly increased the proportion of old people. The fall in the average size of the family meant an increase in the ratio of first births, which carry greater risks to mother and child. The postponement of the date of marriage, which is especially marked in the more prosperous social orders, added to these risks by increasing the average age of motherhood. Against this there was a sharp fall in the number of women with many children (the "grand multiparae"), for whom additional births involve greater risks from such conditions as toxemia of pregnancy and difficult labour.

Maternal Mortality.—Maternal mortality declined sharply during the 1940s and 1950s. From a figure in 1938 of 3.10 deaths per 1,000 live births in England and Wales, and 4.30 in the United States maternal mortality fell steadily till, by 1955, it stood at under 1 per 1,000. This decline began in 1936 and is explained chiefly by the introduction of the sulfonamides and, later, of penicillin, which caused a sharp drop in the deaths from puerperal sepsis; this once caused approximately 40% of the maternal deaths but by 1959 caused only 2%. However, while this is the dominant cause of the decline in maternal mortality, it is not the sole cause; deaths from toxemia, hemorrhage and the accidents of childbirth have also fallen, and this must be ascribed to the improvement in the standard of medical and nursing practice and the more adequate provision and use of obstetric services—antenatal care, hospital and blood transfusion.

This decline in the maternal death rate is found in all social classes, in nearly all socially advanced countries in the world and in many backward countries as well, though there are still groups of mothers who have failed to profit fully by the improved services. Illegitimate births, for example, are associated with a maternal mortality more than twice greater than the average rate, and deaths from sepsis in association with abortion (*q.v.*) are more than three times than those from sepsis at childbirth.

Infant Mortality.—As in the case of the mother, there was during the 1940s and 1950s a steady decline in infant mortality, which is seen in the stillbirth and in the neonatal death rates. Between, 1928 and 1936, the stillbirth rate in England and Wales was about 40 per 1.000 live and stillbirths; thereafter there was a steady decline to 23.7 in 1948, after which it remained more or less stationary. In the United States the figure in 1948 stood at 16.7 per 1,000 births and declined to 13 by 1956. Unlike the maternal death rate, the stillbirth rate exhibits a sharp social gradient, and it also rises steeply with the age of the mothers after 25 and is markedly higher in first births; it is at its lowest in women who have had only one previous child. The neonatal death rate—the number of deaths under 28 days per 1.000 live births—declined steadily during the 1940s and 1950s, the rate in 1955 for England and Wales being 17.2 and that of the United States. 19.1. More than two-thirds of infant deaths occur during the first month of life. Like the stillbirth rate, the neonatal death rate has a marked social gradient; an important cause of this is the higher frequency of premature births in the more poorly nourished, lower social classes.

Premature Birth.—Five to eight per cent of babies are born prematurely, and these constitute a considerable proportion of infants that die at birth or soon after. As the maturity of a child is sometimes difficult to assess and as, in any case, from the medical standpoint the size of the child is more important than the age. "premature" babies are by international agreement defined as those weighing under 5½ lb. (2,500 g.), regardless of the maturity. In this way the study of the causes and the care of this class of infant can be standardized. Poor social conditions and poor health of the mother are important factors; *e.g.,* the incidence of prematurity is about six times greater in women of stunted stature and poor physique than in tall, healthy women. The spacing of births in a family has an important influence on the risk of prematurity; when the interval between two births is less than two pears the risk of prematurity is greater than if the interval were two to four years. The closer spacing of the births in the larger families of the less prosperous social classes contributes to their higher prematurity rate, and these considerations are a strong argument in favour of family planning (see PREMATURE BIRTH.)

PRE-HELLENIC ARCHITECTURE. This article deals nith the architecture that developed around the Aegean sea and in the near east from earliest times through the Archaic period of Greece (6th century B C.). The architecture of the subsequent period is discussed in GREEK ARCHITECTURE. Though belonging within the greater context of this discussion, the architectural history of Egypt will be found in EGYPTIAN ARCHITECTURE.

The maritime kingdom of Crete, by virtue of its central position betneen Europe, Asia and Africa, had early contacts with Egypt and the ancient near east and seems to have played an important intermediary role in the transmission of architectural influences to Greece. It is for this reason that near eastern architectural development is included here. The architecture of Achaemenid Persia, contemporary to early Greek architecture and therefore not strictly speaking pre-Hellenic, is included here also for the sake of geographic unity.

Since the chronology of pre-Hellenic times in the regions discussed in this article is subject to controversy, the dates given here are not necessarily identical with those given in other articles. In each case the author's dates are used. For further historical information see the articles about the specific places involved (*e.g.,* BABYLONIA AND ASSYRIA; CRETE; etc.).

MESOPOTAMIA

Mesopotamian civilization was theocratic; consequently it is in religious buildings that the architecture of this region finds its earliest and fullest expression. (See BABYLONIA AND ASSYRIA.) The beginnings of mud-brick architecture in the Ubaid period (4th millennium B.C.) may be seen in the earliest temples at Abu Shahrain in the south of Mesopotamia and Tepe Gawra in the north. Platforms, buttresses and recessed portals. perennial traits of Mesopotamian architecture down to the Hellenistic period, were already established at both sites. A recessed portal is part of the entrance façade of the earliest temple at Tepe Gawra, and at Abu Shahrain a similar building was placed on a platform and approached by a flight of steps.

These characteristics were repeated at Uruk (Erech, mod. Warka), with the added development that the platforin of Abu Shahrain mas replaced by the ziggurat (q *v.*), a tall staged tower nith outside staircases and a shrine at the top.

Walls and columns of early Mesopotamian temples were covered with a patterned facing of coloured clay cones that were inserted into the mud plaster: this primitive decorative technique gave rise to the later Assyrian practice of covering entire walls with richly polychrome glazed and molded brickwork. The arch was used in Mesopotamia, and false. or corbeled, vaults (*i* e., vaults constructed of successive series of projecting courses) were occasionally employed for tombs

The transition to the Early Dynastic period (*c.* 3000–2340 B.C.) brought with it certain innovations. The plano-convex brick. flat on one side and curved on the other, was invented. Both religious and secular buildings were built around a central court; the entrances to temples were generally flanked by towers and approached by a stairway.

The oval temple precinct at Khafajah is a typical example of Early Dynastic architecture. There, as at Abu Shahrain, the whole layout was elevated on a low platform. A flight of steps led up to an outer gateway flanked by two high towers. A small forecourt led to another gate which opened upon a spacious inner court. containing a well, several shallow ablution basins and the sacrificial altar. The temple proper, which probably had buttresses and recessed walls, was placed on a second platform approached by another flight of steps. Basically, this is also the type of complex at Tell Asmar and Tell Agrab. Later the square or oblong plan became more common.

Little is known about the architecture of the Akkadians, a Semitic dynasty which assumed power over Mesopotamia in the middle of the 3rd millennium B.C. This dynasty was ousted by the Guti. who were. in turn, driven out of Mesopotamia by the Sumerians at the end of the 3rd millennium, which began a time of great architectural activity.

The city of Lagash (mod. Telloh) flourished under King Gudea, but few remains of his architecture have come to light. Ur-Nammu. the first king of the 3rd dynasty of Ur (c. 2250 B.C.), erected a great ziggurat at Ur, his capital. It stands within an oblong court and is oriented to the points of the compass. Buttresses on its outer face give it added strength. Three monumental stairways with bastions in their angles converge at the first stage from which a single stairway ascends to the top of the second stage. A temple no doubt crowned the summit of the structure, but this has disappeared without a trace.

The 3rd dynasty of Ur is also represented by buildings at Uruk, Nippur, Mari (mod. Tell el Hariri). Xshur and Tell Asmar. The temple-palace of Gimil-Sin at Tell Xsmar deviates little from the development already described. The temple portion of the complex consists of a square central court, with the cella at the far end, surrounded by massive buttressed walls and entered by a towered gateway. The palace of the local ruler joins this temple at an angle and consists of antecella, cella, central court. throne room and great hall. Surrounding these large ceremonial spaces were small administrative offices; the living quarters seem to have been situated on a second floor.

Ur fell early in the and millennium B.C., and the succeeding phase is known as the Isin-Larsa period (2025–1763 B.c.). The temple of Ishtar-Kititium at Ishchali belongs to this period. Although related to, and developed from, the Early Dynastic complex at Khafajah, the original single-chambered shrine at Khafajah was there elaborated into an architectural complex with forecourt, court and cella.

A palace at Mari has been tentatively identified with the reign of Hammurabi (1792–1759 B.c.). the ruler and lawgiver of the 1st dynasty of Babylon which flourished contemporaneously with Isin and Larsa to the south.

A foreign dynasty, the Kassites, invaded southern Mesopotamia in about 1600 B.C. Their accession to power inaugurated a new era of building activity at Ur, Uruk and Dur-Kurigalzu, the new capital 20 mi. to the nest of modern Baghdad.

While the Assyrians in general adhered closely to established architectural schemes, they also brought about several important deviations from the early Mesopotamian norm. The latest Ishtar temple at Xshur and the Xshur temple at nearby Tukulti-Ninurta, built during the reign of Tukulti-Ninurta I (c. 1250–1210 B.c.), established the type that became characteristic for Assyrian temples. The latter was built against a ziggurat. as at Mari, and incorporates a dual entrance system: one entrance faces the cella as in earlier buildings; the other enters at a right angle. The cella is on a podium that lies in front of a recess cut out of the body of the ziggurat, and the ziggurat itself no longer incorporates a staircase. In fact, it may have been entirely inaccessible. The practice of setting a series of stone slabs, called orthostates, at the bottom of a wall below the mud-brick upper parts becomes common in the Assyrian period and will be seen again in Hittite architecture.

During the Late Assyrian age (c. 1000–612 B.C.), Ashur, Babylon. Nineveh, Nimrud, and Dur-Sharrukin (mod. Khorsabad) flourished as royal residences, but since only Ashur and Dur-Sharrukin have been at all fully excavated. we shall confine our remarks to the palace of Sargon II (722–705 B.c.) in Dur-Sharrukin.

The palace area occupies about $7\frac{3}{4}$ ac., of which two-thirds are given over to the palace proper and the temple. the remainder being occupied by a large ziggurat probably composed of seven stages with an external spiral ramp. Basically, this plan is an elaboration of the traditional units that occur at Tell Asmar: square court, throne room. great hall. Each side of the court measures 300 ft., and its walls were revetted with monumental reliefs. In addition. great stone sculptures of monsters and genii, such as those that flanked the doorways, must also be considered as part of the architecture.

The final rebuilding of Babylon by Nebuchadnezzar II (605–j62 B.C.) marks one of the greatest building achievements ever attempted by man. Excavations during the first decades of this century by R. Koldeway and the German Orient society revealed no less than four gigantic castles on this site. It was during the reign of Nebuchadnezzar II that the fabled "hanging gardens" were built. The Ishtar gate of Nebuchadnezzar's palace, decorated with lively bulls and dragons executed in molded and glazed brick, has survived well and ranks as the finest monument of this great period. Of the ziggurat of Babylon. the biblical Tower of Babel, little remains today other than the ground plan and a description of the Greek traveler and historian. Herodotus.

MINOAN CRETE

The great maritime civilization of Crete (*q.v.*) crystallized around the palaces such as exist at Knossos, Phaistos. Hagia Triada. Mallia and Tylissos. The immensely important "Palace of Minos" at Knossos, excavated and reconstructed early in the 20th century by Sir Arthur Evans, offers evidence of unbroken architectural and artistic development from Neolithic beginnings, culminating in a brilliant display of building activity during Middle Minoan III (1700–1580 B.C.), and continuing until the invasion of the Achaeans in the 12th century. However, the palace is essentially a structure of the last two Middle Minoan periods (1800–1580 B.C). It no doubt rivaled near eastern and Egyptian palaces in monumentality. As in these. a quadrangular complex of rooms and corridors is grouped around a great central court, at Knossos roughly 17j ft. × 100 ft. At the northern end. toward the sea. a grand portico of 12 pilasters gave access to the central court. At this end, also, is situated the grand theatrical area, a rectangular open-air theatre perhaps used for ritual performances. The east wing of the palace is divided into two parts by a long east-west corridor and rose four or five stories above the slope of the valley. The southeast portion of the palace contains domestic apartments elaborately supplied with plumbing and flushing facilities as well as a sanctuary. A wide stairway led to an upper story which no longer exists. The northeast portion of the palace is occupied by offices and storerooms. The west portion is again divided by a long corridor, over 200 ft. long, running north and south. Behind this corridor was discovered a series of long narrow storerooms containing great numbers of pithoi, or man-size storage vessels for oil. On the other side of the corridor, toward the central court, are the rooms of state, including the throne room with its unique gypsum throne and world-famous griffin frescoes.

Light was supplied from above by an ingenious system of "light wells," and several colonnaded porticoes provided ventilation during the hot Cretan summers. Brilliantly hued frescoes played an

important part in both the interior and the exterior decoration of the palace.

The development of the other Minoan palaces (Phaistos, Mallia, Hagia Triada, Tylissos) roughly parallels that of Knossos. Each has its special interest, and Phaistos is particularly fascinating. due to extensive Italian excavations. Maritime hegemony enabled the Cretan sea kings to build these palaces in low and unprotected places; consequently there is a conspicuous absence of fortification walls, as contrasted to the great walls of Mesopotamian palaces Since Cretan worship seems to have been largely in the open air, there are no real temples as in the near east. Yet, the disposition of the various parts of the palace around the central court and the avoidance of outside windows as much as possible are characteristics that seem to indicate an early contact with the near east A taste for long, straight palace corridors, as well as a highly developed hydraulic system, may also have been inherited from older civilizations to the east. The column made its first European appearance in the Cretan palace, where it is often employed individually to divide an entrance way.

The development of funerary architecture in Crete proceeds from the old chamber ossuaries of the Early Minoan period (2 750–2000 B.C.) to the developed tholoi or beehive tombs of the Mesara plain and the elaborate temple-tombs of Knossos at the end of the Middle Minoan period.

On the crest of Minoan prosperity came the great crash. An invasion from the mainland c. 1400 B C. destroyed the palaces and resulted in the removal of power to Mycenaean Greece. Architectural remains in Crete which are pre-Greek and yet subsequent to this catastrophe are very rare. Several country shrines belong in this postdestruction period, and at Prinias a unique temple building may be as late as 700 B C. The doorway of this temple is now in the Candia museum and has low reliefs on its architectural members. The opening above the lintel is flanked by seated figures, while the lintel itself is carved on its underside with figures of a goddess and of animals. That the Minoan tradition was not entirely extinct is indicated by the column which seems to have stood in the middle of this doorway. as at the "palace of Minos." (For a further discussion of Minoan palatial architecture. towns, sanctuaries and tombs, see CRETE. Archaeology.)

MYCENAEAN GREECE

The sudden architectural awakening of the Mycenaean Greek mainland is intimately connected with the zenith and decline of Minoan Crete and can only be understood against the background of a long Cretan development. Unlike Minoan Knossos, the archaeological remains on the mainland are fragmentary. In order to obtain an idea of Mycenaean architecture, we must draw on our knowledge of at least three sites: Mycenae. Tiryns and Pylos. Since the important architectural monuments visible today date largely from Late Helladic times (1580–*c.* 1100 B.C.) and since little earlier architecture is preserved, our brief survey shall be confined to this period. (See also AEGEAN CIVILIZATION.)

Fortification. — The tremendous building activity of the 14th century B.C. reflects an age of warfare, when powerful Greek-speaking kings built fortresses in key defensive positions on the mainland. The cyclopean walls of Mycenae and Tiryns (*i.e.,* the walls in which great blocks of untrimmed stone were employed) and the strategically placed Lion gate at Mycenae were constructed in this period. The latter consists of two colossal door jambs that support a monolithic lintel. The wall above the gate is so constructed as to form a relieving triangle over the lintel, and this empty space is blocked with the famous relief panel of two heraldic lions. which has given the gate its name. This method of construction provides an ingenious substitute for the arch which was unknown to the Mycenaeans.

Also justly famed are the concealed galleries of Tiryns, where the primitive corbeled vault makes its first appearance in mainland Europe.

Palaces. — Mycenaean palaces have been unearthed at Mycenae, Tiryns. Pylos, Gla and Phylakopi (Cyclades). The palace at Pylos is a typical mainland palace of the Heroic Age as described in the poetry of Homer. The characteristic plan comprises four elements: (1) a narrow court on which the structure fronts; (2) a double-columned entrance portico; (3) a vestibule (*prodomos*); and (4) the richly frescoed domos, or hall proper. The latter had a fixed throne at one end and a central fixed hearth between four wooden columns that supported an open towerlike structure rising above the roof for light and ventilation. Archives, comparable to those of the Hittite kings at Bogazkoy, were associated with this palace. Private houses, such as have been discovered at Mycenae, exhibit similar features as well as the basement storage magazines mentioned by Homer.

Tombs. — The earliest royal burials known from Mycenae are those of the two grave circles, the first discovered by H. Schliemann in 1878 and the second by A J. B. Wace in 1951. These grave circles have no architectural character, consisting essentially of vertical shafts cut into the bedrock.

More important architecturally are the tholoi or beehive tombs. The evolution of these family sepulchres began in Minoan Crete, but culminated in the so-called "treasury of Atreus" at Mycenae, now believed to have been constructed as late as *c.* 1250 B.C. This most impressive monument of the Mycenaean world is a pointed dome built up of overhanging (*i.e.,* corbeled) blocks of conglomerate masonry cut and polished to give the impression of a true vault. The diameter of this tomb is almost 50 ft ; its height is slightly less. The enormous monolithic lintel of the doorway weighs 120 tons and is 29½ ft. long, 16½ ft deep and 3 ft. high. It is surmounted by a relieving triangle similar to that over the Lion gate and decorated uith relief plaques in a manner not yet established with certainty. A small side chamber hewn out of the living rock contained the burials, whereas the main chamber was probably reserved for ritual use. Two engaged half-columns of Cretan type (now in the British museum) were secured to the façade which was approached by a dromos, or ceremonial passageway, revetted with cyclopean blocks of masonry and open to the sky. Other tholoi, though not as excellently preserved, exist at Mycenae and Orchomenos.

TROY

Excavations at Troy (mod. Hissarlik, on the eastern shore of the Dardanelles) have distinguished no less than nine stratified levels extending from prehistoric into Roman times.

Houses at Troy I (c. 3200–2600 B.C.) and Troy II (c. 2600–2300 B.C.) were formed of long narrow groups of rooms that already seem to bear a relationship to the rectangular megaron, or large hall, of the Mycenaean dwelling, sharing, as they do, the fixed hearth. deep vestibule and most of the other architectural features of megara on the Mycenaean mainland. Defensive gates flanked by towers at Troy II recall the military architecture of Hittite Anatolia to the east.

Troy VI (c. 1900–1300 B.C.), the immediate predecessor of Homer's Troy, was largely demolished by leveling operations in Roman times and at the end of the 19th century by Schliemann. This city possessed a symmetrical layout, impressive walls and, like Troy II, gate towers of splendid masonry that could be the prototype of Mycenaean as well as classical Greek propylaea. A large megaron of Troy VI incorporates a row of three columns along a central axis in its plan, again anticipating a development of Greek architecture (*e.g.,* the first temple of Hera at Samos).

Another feature of interest at Troy is the un-Mycenaean use of sun-baked brick for walling, probably a link with the construction techniques of Mesopotamia.

As more becomes known about the peculiar un-Minoan Bronze-Age civilization of Troy, other parallels with the architectural evolution of pre-Hellenic and Hellenic Greece will no doubt emerge. It is not unlikely that Troy will eventually take its place as an important intermediary for the transmission of ideas from the ancient near east to the younger cultures of the west. (See also TROY AND TROAD.)

HITTITE ANATOLIA

Because of recent excavations at Bogazkoy, Alaca Huyuk and Kultepe in Turkey, it is now possible to talk with a good deal of certainty about Hittite architecture. These three cities possess the earliest remnants of Hittite civilization. Their architecture is of a rude and primitive kind, yet not uninfluenced by the more developed architecture of older civilizations in Syria and Mesopotamia. Stones of colossal dimensions were employed in corbeled vaults for the construction of tunnels. gates and tombs. Monolithic orthostates, often decorated with reliefs: are common. At Bogazkoy (anc. Hattusas or Khattushash), the capital and most important city of the Hittites, as well as at other Hittite sites, such carved orthostates form the lowest masonry courses of palaces and temples. The absence of the column, employed by all neighbouring cultures. is conspicuous in Hittite architecture. square pillars serving in their stead. Also noticeable in the architecture of the Hittites is an apparent lack of axial planning. Hittite temples and palaces are built on an agglomerate principle, with rooms of varying dimensions grouped in tiers around a rectangular court. Internal communication must have been difficult.

Few buildings of architectural distinction remain from the Early Hittite period (1650–1460 B.C.), although from this period are the beginnings of monumental architecture on the Anatolian plateau. The flowering of Hittite architecture takes place during the three centuries of imperial expansion (1460–1190 B.C.), when the might of the Hittite kings was felt as far abroad as Egypt.

From this period date the great Hittite temples. Five such temples have been uncovered at Bogazkoy. In each of these. many small rooms are disposed about a large central courtyard. It was in this courtyard that the worshipers assembled. The cult statue was hidden in a remote holy of holies and seems to have been accessible only to the priesthood. In Temple I at Bogazkoy. this holy of holies projects from the core of the temple building. apparently in order that the cult statue could be illuminated by side windows. Numerous subsidiary rooms seem to have served administrative and storage purposes.

Architecturally, the palaces are closely related to the temples. As in the temples. the rooms of the palaces were grouped around a central courtyard. In contrast to the tightly organized palace-complexes of Crete and Mesopotamia, the palace of the Hittite kings at Bogazkoy consists of a number of isolated structures loosely disposed in a semicircular formation. Most of these buildings were multistoried. and. in addition to the royal habitation, an archive and a palace shrine have been identified. Two other excavated Hittite palaces of this period, at Kultepe and Huyuk. do not seem to differ substantially from that at Bogazkoy. The collapse of the Hittite empire at about 1200 B.C. is marked by destruction levels at these three sites. Subsequently. a short afterblossoming of Hittite culture took place in northern Syria at several centres where displaced Hittites, Aramaeans and nomads reassembled: and considerable architectural remains of this period have been uncovered at Carchemish, Tell Halaf and Zincirli in the foothills of the Taurus.

The employment of carved orthostates to adorn the lower part of a wall is a characteristic feature that unifies the architecture of these scattered sub-Hittite principalities and relates it to that of the Hittite empire at the height of its expansion. Another feature of the conglomerate architectural style that distinguishes these petty autocracies seems to be of Syrian, rather than Hittite, origin. This is the bit *hilani*, or pillared porch, the supports of which often rested on animal bases. (See also HITTITES. THE.)

ACHAEMENID PERSIA

The origins of the monumental architectural style that appeared in Persia with the foundation of the Achaemenid empire in j39 B.C. are disputed. *(See* PERSIA: History: The *Achaemenid* Em*pire.')* It has been suggested that the Persians learned the art of cyclopean building from the Urartaeans of Lake Van to the north; other elements of Persian architecture are often traced to Mesopotamia and even Egypt. It is known for certain that Greeks were among the foreign craftsmen employed in the construction of the great Achaemenid residences. The presence of horizontally fluted column bases in the Achaemenid palace at Pasargadae, similar to those of the Archaic Greek temples at Samos. Ephesus and Naukratis. is only one of several examples of their influence.

Yet. notwithstanding the presence of such foreign elements, it cannot be denied that the architecture of Achaemenid Persia is remarkably original. Veritable forests of columns and square halls of vast proportions radically differentiate Achaemenid buildings from the contemporary architecture in Greece and are more reminiscent of the native Persian development in Islamic times.

A great columned hall exists already in the palace of Cyrus at Pasargadae, the earliest of the three Achaemenid dynastic residences (other two: Persepolis and Susa). This palace was elevated on a series of man-made platforms and approached by a system of impressive stairways. A colonnaded gatehouse fronted by Assyrianizing bull-monsters gave access to the parklike enclosure in which stood the numerous pavilions and subsidiary buildings that comprised the palace. Among these there was the audience hall surrounded by four porticoes, each with a double row of pillars. Another building, believed to be the palace proper. has double porticoes flanking an almost square hall containing 30 columns arranged in j rows of 6 columns each distributed over the entire space.

The best-known. best-preserved and most spectacular of the Persian palaces is that at Persepolis (c. 521–388 B.C.). This enormous complex of buildings, terraces and stair ramps consisted, among other elements, of the palace of Darius I (522–486 B C.), Xerxes I (486–465 B C) and Artaxerxes III (359–338 B C.), a harem, a treasury, the Gate of Xerxes, the Hall of the Hundred Columns and a number of other buildings.

The Hall of the Hundred Columns at Persepolis is 22j ft. square, though its columns are only 37 ft. high as compared to 67 ft. in the smaller Hall of Xerxes at the same site. The gateways of the Hall of Xerxes are flanked by colossal winged genii similar to those associated uith Assyrian palaces; flanking the stairway leading to the Audience Hall of Darius were discovered the famous reliefs of tribute bearers that have since found their way into museums throughout the norld. Everywhere, sculpture was combined with architecture to produce a total effect of grandeur hardly surpassed by the great architectural complexes of Egypt.

At Susa, the palace is in part similar to that at Persepolis, in part related to the palace of Nebuchadnezzar at Babylon. The widespread use of glazed coloured bricks in the architecture of Susa also associates this palace with the earlier architecture of nearby Mesopotamia.

The aniconic religion of the Persians required only simple open-air fire altars for the perpetration of its rites. Consequently, there is no temple architecture, and only tombs remain to be mentioned. At Pasargadae, an early Achaemenid tomb, probably correctly identified as that of King Cyrus, consists of a rectangular single-roomed sarcophagus chamber with a gable roof recalling the tombs of Caria and Lycia in southwestern Turkey. The entire structure and the pedestal of six steps on which it stands are built of great blocks of well-dressed masonry and were formerly surrounded by a colonnade. Later Persian monarchs were interred in the cliff-hewn tombs at Naksh-i-Rustam near Persepolis. See also TEMPLE ARCHITECTURE; RELIGIOUS ARCHITECTURE; ETRUSCANS.

PREHNITE, a relatively uncommon calcium and aluminum hydrous silicate mineral, is generally light green in colour and occurs in rounded masses of crystals. The individual crystals are not usually distinct to the unaided eye. Prehnite resembles certain varieties of the hydrous zinc silicate hemimorphite (*q.v.*). It can be distinguished from that mineral most readily by its lower specific gravity and by its type of geologic occurrence and associated minerals.

Prehnite occurs most commonly as crystal masses lining cavities in mafic (basic) igneous rocks such as basalt and diabase. Characteristically associated with it are calcite, quartz. zeolites, datolite and pectolite. Some notable localities of this type of occurrence in the United States are Paterson and Bergen Hill, N.J., Farmington, Conn., Westfield, Mass.; and the Lake Superior copper district. It has been found at Cradock, Cape Province, U. of S. Af., in the south of Scotland, the French and Tirolean Alps, the Hartz mountains and other localities. Prehnite also occurs less commonly and less strikingly in other types of rocks, such as schists, amphibolites and metamorphosed sedimentary carbonate rocks. The composition of prehnite is expressed by $Ca_2Al_2Si_3O_{10}(OH)_2$. Small amounts of ferric iron (Fe^{3+}) may be present in place of some of the aluminum. (D. M. H.)

PRELATE, an ecclesiastical dignitary of high rank. In the early middle ages the title prelate was applied to secular persons in high positions and thence it passed to persons having ecclesiastical authority. The De prelatis of Valerian is concerned with secular princes, and even as late as the 14th century the title was occasionally applied to secular magistrates. In medieval ecclesiastical usage the term might be applied to almost any person having ecclesiastical authority. The term occurs very frequently in the rule of St. Benedict and other early monastic rules.

In more modern usage in the Roman Catholic Church, prelates, properly so-called, are those who have jurisdiction in *foro* externo, but a liberal interpretation has given the title a more general significance. Prelacy is defined by the canonists as "pre-eminence with jurisdiction." and the idea supposes an episcopal or quasi-episcopal jurisdiction. But gradually the title was extended to ecclesiastical persons having a prominent office even without jurisdiction, and later still it has come to be applied to ecclesiastical persons marked by some special honour though without any definite office or jurisdiction.

We may therefore distinguish true from titular prelates. The true prelacy is composed of the persons who constitute the ecclesiastical hierarchy; jurisdiction is inherent in their office and gives pre-eminence, as with patriarchs, archbishops and bishops. The true, no less than the titular, prelates have their various ranks. differing as regards title, precedence, clothing and other insignia. The distinguishing colour of a prelate's clothing is violet; the form, like the greater or less use of violet. depends on the rank of the prelate, Four classes may be distinguished: (1) great prelates, *e.g.*, cardinals, archbishops and bishops; (2) exempt prelates, *i.e.*, abbots and religious superiors. who are withdrawn from the ordinary diocesan jurisdiction and themselves possess episcopal jurisdiction; (3) Roman prelates, (a) active and (*b*) honorary. The title is applied to numerous ecclesiastics attached by some dignity, active or honorary, to the Roman court (see CURIA ROMANA).

In the Reformed churches the title was retained in England, Sweden, Denmark and Germany. The cathedral chapter of Brandenburg consists of two prelates, the dean and the senior, besides eight other members. The chapter of Merseburg contains five prelates, viz., the dean, senior, provost, *custos* and *scholasticus*. In Baden the general synod is presided over by the prelate (*prelat*); *i.e.*, the principal "superintendent." In the Church of England the term prelate has been since the Reformation applied only to archbishops and bishops.

PREMATURE BIRTH is defined by the World Health organization as the birth of an infant weighing $5\frac{1}{2}$ lb. (2,500 g.) or less. Another and preferable standard, birth at less than 37 weeks after conception, requires facts often unobtainable. Prematurity (by the standard of weight) occurs in about 7%–9% of pregnancies in white women in the United States, and in 10%–12% of those in Negro women; the rate in the latter is higher probably because of poorer socioeconomic conditions. In the U.S. prematurity is directly or indirectly responsible for at least 50% of all deaths of newborn infants.

A presumptive reason (usually multiple pregnancy, maternal toxemia or hypertension, abnormal attachment of the placenta or congenital malformation of the infant) can be found for 40%–60% of premature births, but fully half those of single infants are of unknown cause. Poor maternal health, hygiene and nutrition increase the likelihood of prematurity; maternal accidents and acute illnesses are insignificant as causes. The chief specific causes of death among premature infants are respiratory disturbances (hyaline membrane disease, atelectasis), infections (usually pneumonia) and hemorrhages, especially into the brain or lungs and often not caused by injury. With good care about 85% of all premature infants born alive should survive. In the large group born at 4-5-54 lb. (2,000–2,500 g.) 95% or more should survive; among the few born at less than $2\frac{1}{4}$ lb. (1,000 g.) the survival rate may be less than 10%. An infant of $1\frac{3}{4}$ lb. (800 g.) rarely survives. In other words, chances of survival increase in direct proportion to weight.

Prevention of premature birth is not yet possible. Treatment of the infant begins with skillful obstetric management under minimal anesthesia during premature delivery, followed by specialized nursing and pediatric care in an environment approved as a premature infant nursery by public health authorities. This must provide the space, equipment and trained personnel for isolation against infection, regulation of temperature and humidity, feeding of human milk or special mixtures by tube or dropper and prompt relief of respiratory crises. Subsequently, instruction of the mother, supervision of home care and special attention to the nutritional requirements of rapid growth are needed.

Prematures weighing over four pounds (1.800 g.) at birth are usually born after 32 weeks, and they have much the same outlook for later growth and development as do term infants. Those of three pounds (1,350 g.) or less, especially if born before 28 weeks, are more liable to reduced stature and disturbed neuromuscular development. Research must therefore not only find means of preventing prematurity, or of increasing survival if prevention is impossible; it must also lead to normal growth and development after premature birth. See also FETAL DISORDERS; INCUBATORS; CHILDBIRTH.

See Herman N. Bundesen *et al.*, *Progress in the Prevention of Needless Neonatal Deaths (1951)*; Ethel C. Dunham, *Premature Infants: a Manual for Physicians*, 2nd ed. *(193'5)*. (C. A. SM.)

PREMIER: see PRIME MINISTER.

PREMONSTRATENSIANS, also called Norbertines, and in England White canons. from the colour of the habit; an order of Augustinian canons founded in 1120 by St. Norbert, afterward archbishop of Magdeburg. He had made various efforts to introduce a strict form of canonical life in various communities of canons in Germany: in 1120 he was working in the diocese of Laon, and there in a desert place, called Prémontré, in Aisne, he and 13 companions established a monastery to be the cradle of a new order. They were canons regular and followed the so-called rule of St. Augustine (see AUGUSTINIAN CANONS), but with supplementary statutes that made the life one of great austerity. St. Norbert was a friend of St. Bernard of Clairvaux, and he was largely influenced by the Cistercian ideals as to both the manner of life and the government of his order. But as the Premonstratensians were not monks but canons regular, their work was preaching and the exercise of the pastoral office, and they served a large number of parishes incorporated in their monasteries. The strength of the order is in Belgium.

PREMYSL, the reputed ancestor of the Premyslide line of dukes and kings which ruled in Bohemia from 873 or earlier until the murder of Wenceslaus III in 1306. According to legend Premysl was a peasant of Stadice who attracted the notice of Libusa, daughter of a certain Krok, who ruled over a large part of Bohemia, and is said to have been descended from the 7th-century hero Samo. Premysl married Libusa, the traditional foundress of Prague, and during the 8th century became prince of the Bohemian Czechs. His family became extinct when Wenceslaus III died. but through females the title to Bohemia passed from the Premyslides to the house of Luxembourg and later to the house of Habsburg.

PRENDERGAST, MAURICE BRAZIL (1861–1924), U.S. painter, one of the first Americans to make intelligent use of the technical advances in Post-impressionism. was born in Roxbury, Mass , on Oct. 27, 1861. He began drawing in childhood and reached a painting career through executing show cards and carving picture frames. The latter craft maintained him and his brother Charles all their lives. During the 1880s Maurice spent two years studying art in Paris; on a second trip in 1898–99 he discovered the work of Paul Cézanne and painted water colours in Venice. In his water colours he developed a mosaiclike pattern of transparent touches which successfully conveyed the gaiety appropriate to their subjects of crowded parks and beaches. In his later oils calligraphic drawing and opalescent colour in rich impasto drew a veil of wistfulness over similar scenes. His audience was never large, but with them his reputation was made secure by the works shonn in the controversial Armory show in New York (1913). The only important official honour he received was the third W. A. Clark prize from the Corcoran gallery, Washington, D.C., in Dec. 1923. He died in New York city on Feb. 1, 1924.

PREPARATORY SCHOOLS in Great Britain form part of the public-school system. (In the United States the term is used for those schools which prepare for higher education, and they are discussed in the articles SECONDARY EDUCATION: *United* States, and EDUCATION, HISTORY OF: *United* States)

In Great Britain before Thomas Arnold in the 1830s excluded boys of under 12 years of age from Rugby there were few of these schools, but they later became very numerous. They are privately owned and are free of government control; however, they have usually invited inspection by her majesty's inspectors of schools and indeed are now compelled by law to undergo such inspection periodically. The majority of preparatory schools are linked together by membership in an incorporated association. They cater, for the most part, for boys between the ages of 7 and 14 years, and outside the large tonns and cities most of the pupils are boarders.

BIBLIOGRAPHY.—Board of Education, *Report on Preparatory Schools,* ed. by Michael Sadler (1900) ; *Preparatory Schools' Review,* issued by the Incorporated Association of Preparatory Schools (thrice yearly) ; I.A.P.S., *The Preparatory Schoolboy aad His Education,* ed. by E. H. Allen and L. P. Dealtry (1951).

PREROGATIVE, in English law, means the residue of discretionary powers and legal immunities which, by common law, are at any given time legally left in the hands of the king.

A distinction has to be made at the outset between prerogatives peculiar to the king in his "natural" capacity and confined to him—such as the rule that he is personally exempt from all jurisdiction, criminal or civil, and cannot be sued for debt—and prerogatives which belong to his "politic" capacity and as such extend to the whole government—such as the immunity of "the crown" at common law from being sued by ordinary civil process (see PETITION OF RIGHT). English law has, however, never clearly distinguished between the two capacities. The whole history of "constructive treason" is a witness to this dualism, as when the judge held that "every rebellion intendeth as its natural consequence the death of the king." The king was completely identified with the state, and even modern British constitutional law knows no such term as "the state." The state is the king.

All statutory powers conferred upon the government are declared to be conferred on "his majesty in council." All money voted by parliament is voted to "the king," even though appropriated by statute to public services from which the king cannot divert it.

The Crown.—The distinction between the king's government and his person, is used intermittently but, strictly speaking, the crown is only "a chattel in the Tower which has been entailed upon the Hanoverian dynasty." The common law, apart from statute, makes no distinction between debts due to the king's household and debts due to the crown, so that, at common law, debts due to the king personally and taxes due to his government enjoy the prerogative of priority over all other claims against the estate of a debtor, a bankrupt or a deceased person.

Similarly a royal palace and a post office are equally exempt from the payment of rates, one of the prerogatives being that "the king" is not bound, in the absence of express words, by a taxing statute. The same identification of the "natural" king and the "politic" king is in the rule that the king's government could never, in any circumstances, be used for wrongful, *i.e.*, tortious, acts. The immunity of the latter was based historically on the rule that the "king can do no wrong," which did not mean originally the perfectibility of the king, but the simple feudal fact that the king could not be tried or sued in his own courts.

As the king was, and is, the "government," the rule found a new application in the principle that no governmental acts or defaults could be the subject of legal proceedings. Had this application been carried to its logical conclusion, it would have resulted in the immunity of all the king's officers from being sued for their wrongful acts. But English lam was, and is, too practical to be logical, and a consequence so disastrous to the rights of the subject was avoided by the evolution of the principle, laid down by the judges, that no servant of the crown could be allowed to plead the command of the king, even where such a command had actually been issued, as a defense for an unlawful act, for to admit such a plea would, they held. be to impute wrong to the king, and the king could not only "do" no wrong but could not even "think a wrong."

The failure of the law to make any distinction between the natural and political capacity of the king led to some desperate fictions. of mhich the supreme example is the legal maxim that "the king never dies." Otherwise the death of the king would have dissolved the state in the interregnum between the decease of one king and the coronation of his successor. Indeed. this was actually the situation before the invention of the fiction. In spite of the fiction that "the king never dies," until 1867 the death of the king operated to dissolve parliament; the king was, and is, a constitutional element in parliament and the summons of a parliament was regarded as an act so personal to him that nhen he died his parliament died with him. The Demise of the Crown act of 1867 provided that the death of the king should not involve a dissolution. On the other hand the death of the king still operates to dissolve the whole privy council from the date of his death until his successor reappoints the members.

Exercise of the Prerogative.—The prerogative pon ers of the king, as distinct from powers conferred on him by statute, have all one feature in common: they can no longer be exercised by the king in person but only on the advice of ministers or in particular forms and by the use of particular instruments. Long before "responsible government" made its appearance in England and at a time when the commons even repudiated responsibility for the government of the country, parliament insisted that the royal prerogative in certain matters could only be exercised by the use of certain seals, notably the great seal and the privy seal. which were in the custody of certain great officers of state. For the use or misuse of these seals their custodians could be brought to book by impeachment (*q.v.*) in parliament. In the same nay the common-law courts laid down the rule at the beginning of the 17th century, that even in the court of king's bench, held before the king and in mhich medieval kings had presided in person, the king could no longer administer justice in person. There still remained the residuary jurisdiction of the king in council which could be, and was, exercised by him in person. With the abolition of the star chamber in 1641 this jurisdiction disappeared.

Pre-Cabinet Government.—So long, however, as it was in the power of the king to remove judges for decisions adverse to the exercise of his personal will or to dismiss ministers who refused to carry out his wishes, he retained *de facto* control over his prerogatives even when their exercise was subject to the formal rules described above. The efforts of parliament were therefore directed to limiting the scope of the prerogative. The chief examples are afforded by statutes such as the Petition of Right, the Bill of Rights and the Act for the Abolition of the Star Chamber, statutes abolishing respectively the prerogative of the king in taxation to supply his needs, in raising and keeping a standing army to enforce his will and in exercising a jurisdiction to punish his opponents. Parliament thus went further than the courts were prepared to go. Parliament eventually refused to accept the king's command as a defense to the impeachment of one of his ministers, as in Danby's Case (1679), while by the Act of Settlement (section 3) it enacted that the king's prerogative of pardon under the great seal should not be pleadable to an impeachment. So long, however, as the king was not dependent on supplies for the ordinary expenses of the government he could neglect to summon a parliament for as many years as he pleased and impeachment was thereby made impossible. What mas really decisive in securing the exercise of the king's prerogative by ministers in accordance with popular will was the transfer, principally as the result of Edmund Burke's reforms, of all governmental expenses from being a charge on the hereditary revenues of the crown, or the civil list, to the annual estimates. In strict law the king can still appoint and dismiss ministers as he pleases, and he is under no statutory obligation to summon parliament. But if he did the one and omitted the other. he and his ministers would be without money to carry on the government.

As with the king's ministers, so with "his" judges. By virtue of the Act of Settlement (1701) the king can no longer dismiss judges at his pleasure; they are removable only on an address by both houses of parliament. Even appointment, though technically the act of the king, is the act of a minister, the lord chancellor. Thus the prerogatives are no longer an instrument of arbitrary government. They have, constitutionally speaking, passed into the hands of the cabinet.

Modern Scope of the Prerogative.—The chief prerogative powers may be summarized as follows:

1. Foreign *Relations*.—In foreign relations the king has the exclusive power of making war and of declaring peace. The power is usually exercised by a proclamation and an order in council, and as such it is binding on the courts who must accord it the same "judicial notice" as an act of parliament. In practice the power is never exercised except with the approval of parliament.

The treaty-making power may be regarded as an exercise of the same prerogative. Whether the king can, by the negotiation of treaty, cede British territory has been much disputed; no king—in other words, no English ministry—has ventured to exercise such a prerogative since 1894 without seeking the consent of parliament in the form of a statute, and it may be regarded as settled usage that the crown will always, in the case of a treaty of peace involving cession or annexation, seek statutory powers to carry such a treaty into effect. However. the crown has often, as in the case of certain African protectorates, annexed "foreign" territories by mere prerogative in the form of an order in council. Furthermore it rests with the crown and the crown alone to "recognize" the foreign governments as de *jure* governments. Such recognition is binding on the courts and so is a declaration by the crown that a particular person is entitled to the status of a foreign sovereign, and as such is immune from the jurisdiction of the courts. So, too, with the status of an ambassador and the diplomatic immunity of himself and his suite. The king's prerogative in relation to foreign affairs is generally understood to cover also his powers over persons owing no allegiance to him. The exercise of such a prerogative, or "act of state." is a defense to an action brought against a servant of the crown.

2. Defense.—The king is head of the naval and military forces of the country and can alone recruit them. It is a statutory ofiense for any other person to "recruit." The Bill of Rights limited the exercise of this prerogative by making the raising and maintaining of a standing army in time of peace illegal. It does not prohibit the exercise of the power in time of war, and the prerogative is unaffected as regards the navy. With certain limitations, the king can requisition the subject's property and enter on his land in time of war, though this prerogative is entirely regulated by statute. The need of an annual statute to put in force the code known as the Army act has made of the army "a statutory not a prerogative force."

All army expenditure is subject to the annual vote of the army estimates. It is, in fact, impossible for the king to "make war," as distinct from declaring it, without the consent of parliament. (See also MARTIAL LAW and MILITARY LAW.)

3. *Legislation*.—The requirement of the king's assent to a bill passed by both houses of parliament before it can be "enacted" is an aspect of the royal prerogative in that the king may, in law. withhold his assent. This prerogative is not dead but it was not exercised after the reign of Queen Anne. The crown cannot of itself legislate either by proclamation or by order in council. Nor can the king dispense individuals from or suspend the operation of the laws made by parliament.

In the case of colonies acquired by conquest or cession. however, the prerogative is absolute. And the king can disallow an act to which his local representative, the governor, has assented.

4. Parliament.—It is the sole prerogative of the king to summon. prorogue and dissolve parliament. This is an executive. not a legislative, act and is of course performed on the advice of ministers. After 1924 the king could not under any circumstances refuse to dissolve parliament when a request to that effect was preferred by a prime minister. But he might still dissolve parliament himself, and against the wishes of his prime minister, when a prime minister having been defeated on a direct vote of confidence in the commons refused either to resign or to ask for a dissolution.

5. Executive.—The theory of the law is that the government of the country is still entirely a matter of prerogative, although, of course, many if not most of the powers now exercised by the crown have been conferred upon it by statute. (See STATUTE LAW: Delegated Legislation.) All ministers are appointed by the king—on the nomination of the prime minister.

In the choice of a prime minister the king has a discretion; he sends for whom he will when the outgoing prime minister has resigned, but his choice is usually limited to the leader of the opposition. All military and naval officers are appointed by a "commission" from the king, as are governors of the colonies. As he appoints, so he dismisses. Every officeunder the crown, except that of the judges and the comptroller and auditor general, is held "during pleasure," a doctrine with important legal consequences in that the king's ministers can terminate any commission or contract of service nhenever they please, and the servant of the cronn, civil or military, has no remedy.

Moreover, the crown cannot fetter its future executive action by special agreement. Thus the prerogative may operate to invest ministers with legally uncontrolled power. No servant of the crown has, apart from statute, any legally enforceable right to pay, pension or security of tenure.

6. General.—The king is the supreme landowner, a relic of feudal doctrines, which in the case of a man dying intestate and without heirs used to mean that his land "escheated" to the crown (see ESCHEAT). The king also is the depositary of the prerogative of mercy: he can pardon those who offend against his "peace"; the prerogative is now exercised exclusively on the advice of the home secretary. He is the "fountain of honour": the sole grantor of titles such as peerages, baronetcies and knighthoods; his power in this respect is subject to no limitations except those contained in peerage law, but "honours" are rarely conferred by him except on the advice of ministers. He is the "supreme governor" of the church in virtue of the Acts of Supremacy and Uniformity. The prerogatives of the crown in the courts are dealt with in the article PETITION OF RIGHT.

Effect of Statutes on the Prerogative.—Parliament has frequently intervened to abolish some particular prerogative, deemed to be oppressive, and after the Revolution of 1689 it has never been doubted that such a statute will bind not only the king who actually assented to it but all his successors. It was for long a matter of considerable doubt and speculation whether a statute could curtail a prerogative in the absence of express words to that effect. Thus it has been successfully contended that the crown is not bound by the Statute of Limitations and it has obtained judgment in proceedings against a subject, by Information of Debt, on a claim *30* years old. But the presumption in favour of the crown in the interpretation of a statute is no longer as strong as it was. In this respect the great case of *Attorney-General* v. *De Keyser's Hotel (1920)* A.C. (Appeal Cases) is decisive to the extent that when parliament has by statute regulated "the whole field of the prerogative," that particular prerogative can be exercised in no other way than that prescribed by the statute. *See* also ATTORNEY GENERAL; COMMON LAW; CONSTITUTION AND CONSTITUTIONAL LAW.

PREROGATIVE COURTS, the name given to the English provincial courts of Canterbury and York, as far as regarded their jurisdiction over the estates of deceased persons. They had jurisdiction to grant probate or administration where the diocesan courts mould not entertain the case owing to the deceased having died possessed of goods above the value of £5 (*bona notabilia)* in each of two or more dioceses. The jurisdiction of the prerogative courts was transferred to the court of probate in 1857 by the Probate Court act, and was vested in the probate, divorce and admiralty division of the high court of justice by the Judicature act of 187j. In the U.S. state of New Jersey the court having jurisdiction over probate matters came to be known as the prerogative court.

PRESBYTER, the title borne from very early times by certain officers or ministers of the Christian church intermediate between bishops and deacons. The word is the original form of priest. See MINISTRY, THE CHRISTIAN; EPISCOPACY; PRIEST; PRESBYTERIAN.

PRESBYTERIAN, the distinguishing name of a group of Christian churches which took form during the British Reformation and subsequently gave rise to other churches bearing the same name in the Americas, Asia and Africa. Also, the specific name of a form of church constitution or polity which claims for itself origin in the Christian church during apostolic times and reformulation during the Swiss Reformation. Subsequently, this system was adopted with variations by many churches in other countries, some using the original name "Reformed Church," others the name "Presbyterian Church," or other names.

THE PRESBYTERIAN CHURCHES

England. — During the Reformation in England several groups arose, each with a different religious and political outlook according to which it sought to shape English life. In time, one of these groups assumed the name Presbyterian. Its name came from its form of church government, but its total program was an all-embracing right-wing Puritan system which took into account theology, ethics, politics and economics. The basis of the whole system was a conception of covenant or contract. William Tyndale had introduced this conception into England in his Bibles and other religious and political writings. The idea had been used in various religious and political systems of the middle ages. Tyndale seems to have gotten it from the reformers of the Rhineland cities, Zurich, Basel and Strasbourg, where it was being made the basis of a Protestant theology and a democratic-republican political theory. Other early English reformers such as John Bale and John Hooper, also used this system in their writings.

Under Edward VI (1547–53) the English Reformation went forward with royal aid. Numerous scholars from the Rhineland, Martin Bucer, Peter Martyr and others, went to England. A strong movement was created based on an Augustinian piety and theology, deeply influenced by humanism, devoted to the Bible, to ethical reform and to democratic political ideas. The covenant-contract notion underlay all of these views, as it did in the Rhineland. Queen Mary (1553–58) restored Roman Catholicism and the leading reformers fled to the continent. During this "Marian exile" the English reforming movement developed three wings. One regarded the moderate reform set up under Edward VI as typically English and final. Another group demanded further reforms, especially doctrinal, along lines laid out by John Calvin in Geneva. A third group, mostly underground in England, was working for reformation by small groups, each free in every way.

Queen Elizabeth (1558–1603) re-established Protestantism, but did so on the basis of a series of compromises framed in the interests of her royal power. After some adjustments most of the Edwardean group of reformers. led by their bishops, accepted Elizabeth's plan. The Genevan group was shunted to one side, since in both theology and politics their ideas were considered too radical. The third group of reformers remained underground and were considered as dangerous and subversive sects.

As the meaning of Elizabeth's policy became clear, open opposition to it arose. Yet, so ably did Elizabeth pursue her course that her opponents were effectively turned against each other. The "vestiarian" controversy of 1567–68 was an attempt to break the Elizabethan compromise settlement by demanding the elimination of all ministerial vestments and church furnishings formerly associated with Catholicism. The name "Puritans" was coined during this struggle. The bishops defeated this attempt by making it to appear as a quarrel over wholly peripheral matters. Then came a frontal attack by a party which came to be known as "Presbyterian."

Thomas Cartwright led a powerful movement, 1570–73, aimed at eliminating the entire episcopal system through which Elizabeth worked. He advocated a presbyterian system, modelled on the system of Calvin, in which the people chose their own pastors and then elected lay elders to share with the pastor in governing the local church. Central authority was vested in representative bodies of ministers and laymen which were chosen by the churches themselves, or by the lower judicatures. Such a system, Cartwright declared, could and would reform the church in England.

This first Presbyterian attempt at reforming the church was defeated. However, it did set in motion endeavours which shortly resulted in the working out by Cartwright and others, of a coherent and comprehensive understanding of Christianity which formed the basis for all subsequent forms of Presbyterianism. its underlying structure was that of covenant-contract, but now in a much more fully worked out form. The backbone of the system had its nearest likeness in the covenant system of the Rhineland-Netherlands reformers. Its church government theory had its nearest parallel in Calvin's theory. Its austerity, its blue laws and its theocratic outlook have often been traced to Calvin. Yet, mediaeval England and mediaeval Geneva had known blue laws, and Calvin's own attitudes on them had come to him from Zurich via Strasbourg. The Presbyterians were sabbatarian and anti-liturgical, as were the Rhineland-Netherlands reformers. Calvin was the obverse. The Puritan and Presbyterian "prophesyings" were borrowed from Zurich. On decisive doctrines such as faith, repentance, law and gospel, the church, the ministry and the two sacraments the Presbyterians stood nearest to the Rhineland-Netherlands reformers, not to Calvin or Luther. Politically their closest foreign counterparts were the Huguenots.

As early as 1572 (at Wandsworthj Presbyterians began to organize small local bodies in secret. Rather open organization was effected on the Channel Islands by *1576,* and among English merchant settlements in Holland by 1585. Secret bodies were in existence in London, Oxford, Cambridge, Warwick, Northamptonshire and elsewhere by *1585.* Because of the need for secrecy these bodies came into being as exclusively ministerial: with no lay representation and little or no real participation by the churches. This fact became decisive for the subsequent history of English Presbyterianism. It became a ministerial movement, contending for control of the English Church through the aid of the parliamentary party. with no great popular appeal or support,. As the Great Rebellion began (1641) the coalition of parliamentary-presbyterian forces took the lead in the opposition to the royal-episcopal absolutism. In the early phases of the struggle they maintained their leadership through the co-operation of the centre and left-wing Puritans and, particularly, through the aid of the ultra-Presbyterian Scots whom the two Bishops' Wars had brought to their aid. As events moved steadily toward control of England by the parliamentary-presbyterian party, episcopacy was abolished in the church by act of parliament. Then, an Assembly of Divines was summoned by parliament to act as its advisers on religious affairs. The assembly, later known as the Westminster Assembly of Divines, was chosen to be representative of each of the English counties. It included some mild episcopalians and five Independents. The rest were Presbyterians.

The excesses of the king in 1642–43 drove the Scots once more into an alliance with his enemies. The parliamentary party now signed (1643) the Solemn League and Covenant with the Scots. This agreement pledged the civil and religious unity of England, Scotland and Ireland under a presbyterian-parliamentary system. The parliament now ordered the Assembly of Divines to proceed, with the aid of six Scottish advisers, to the drafting of a complete religious constitution for the three kingdoms. The English Church thus gave up its Thirty-Nine Articles and other constitutional documents, while the Scots gave up their Confession of 1560, and other documents. The assembly then elaborated (1643–49) a *Confession of Faith*, a *Larger* and a *Shorter Catechism*, a *Form of Government* and *Directory for* Public *Worship*. These documents, the results of years of keen debate by many able scholars, put in classic form a consistent federalism (*i.e.* covenant-contract theory). Since this Assembly of Divines was but an advisory committee of the English parliament its constitutional documents met an odd fate. The Scottish Church and the Scottish parliament accepted them speedily. The English parliament delayed accepting them because of the growing power of the Independents. The English Church never had an opportunity to consider them.

Even with the aid of the Scots the military fortunes of the parliamentary party were unfortunate. It became necessary, at length, to allow Oliver Cromwell to create the New Model army which, although it proved invincible against the king, also proved invincible as the left-wing Puritans' (Independents) force against the right-wing (presbyterian-episcopal) Puritans. The army, not parliament, became supreme in England. Their political-religious program alienated the Scots, and the right-wing Puritan-parliamentary group sought vainly to dissolve the army, without due pay, in order to avoid a military state. The army several times invested London and forced parliament to do its bidding. Some right-wing leaders began to have intelligence with the king, believing that a government of law and order, though despotic, was better than army rule by sectaries. Eventually, in 1648, Col. Thomas Pride's soldiers purged parliament of all Presbyterians (140), leaving about 50 left-wing Puritans in the commons. This Rump parliament tried and executed Charles I, set up a military dictatorship under Cromwell, terminated the Presbyterian establishment and granted freedom to all religious groups while giving special privileges to Congregationalism under a modified form of establishment.

Hopeless chaos reigned after Cromwell's death. Gen. George Monk reassembled the Long parliament, thus putting great powers in the hands of the presbyterian-parliamentary group formerly purged by Colonel Pride. They re-established Presbyterianism, although granting tolerance to other Protestant bodies. Something better than army rule, however, was needed. Hence, all the right-wing groups, parliamentary and Presbyterian, royalist and episcopal, joined in restoring Charles II unconditionally. Charles quibbled briefly with the Presbyterians, who were now in full control of the church with about 8,000 beneficed ministers and professors. These ministers offered to accept a modified form of episcopacy first elaborated by Archbishop James Usher. Charles, realizing that his real supporters were the royalist-episcopal group, rejected this offer and demanded capitulation. About 6,000 ministers accepted reordination, unqualified oaths of obedience to bishops and king, abjuration of the Solemn League and Covenant. Two thousand were ejected, of whom approximately 1,500 were Presbyterian and 500 Independent. Later, many of these (about 500) conformed to the episcopal terms.

The Revolution of 1689 brought to the throne a king genuinely friendly to Presbyterianism. In view of the total situation, however, no more was gained by his accession than a measure of toleration for all Protestants. Under this toleration and its subsequent enlargements, a number (often given as high as 500) of Presbyterian congregations existed. In almost no recorded instances did any of these churches have elders or any lay leadership. Ministerial thought continued to develop along extremely autocratic and high-church lines. Such presbyteries as existed were almost exclusively ministerial. Since many of the stronger churches became endowed, actual control of them passed into the hands of the minister and a few trustees. Laymen lost all part in them. In the early part of the 18th century many of these ministers became Unitarians and numerous others conformed lo the Anglican establishment. The greater number of those who cherished the older Puritan ideals became Independent-Congregationalist under the impact of the movement known as the United Brethren, organized under the Heads of Agreement of 1691. By the close of the 18th century English Presbyterianism had become virtually extinct.

The most complete, and even the classic formulation of Presbyterianism had indeed been made by the English Puritan Presbyterians. Lack of popular support, reliance upon parliamentary forces and consequent fear of the Independents, had led to a form of strategy which destroyed English Presbyterianism by making it an exclusively ministerial movement. This unfortunate clericalism had not been the deepest aspect of the movement nor of its ideals. Its basic intent had been to reform the church on genuinely Protestant lines and to give to the people their rightful place. This Presbyterian ideal was first to be achieved in Scotland, whence also Presbyterianism was to be replanted on English soil.

Scots began coming into England in increasing numbers after the union of 1707. Many of these were Seceders, hence rigorous Presbyterians. Soon they had several congregations. In 1847 these, together with certain of the surviving English Presbyterian congregations and other Scottish groups, merged as the United Presbyterian Church. This body joined with the remaining English Presbyterians and most of the other various Scots churches in England to form in 1876 the Presbyterian Church of England. It then had 259 congregations with about 50,000 members. A theological college was founded at London in 1844, which later was moved to Cambridge under the name of Westminster college. By mid-20th century the church had about 71,000 members, 385 ministers, 360 churches; missionary work was being carried on by 30 missionaries at ten stations in China, India, Singapore and Malaya.

Scotland.—Though Presbyterianism as such took form in England, and there received its definitive theoretical delineation by the Westminster Assembly of Divines, it was in Scotland that Presbyterianism was to take its deepest roots. Moreover, although the Scottish Reformation was begun under essentially Genevan Calvinistic patterns, it adopted in time, and became the very incarnation of, the patterns of English Presbyterianism. It was able, however, to give to laymen a real place in the life of the church. Consequently in no country did Presbyterianism so deeply affect the national life. In many ways, therefore, Scottish history provides the best available illustration of Presbyterianism at work.

Scotland's first reforming martyr was Patrick Hamilton (1504–28). He had been influenced by personal contact with Martin Luther, Tyndale and other reformers. George Wishart, burned 1546, had travelled in England and Switzerland. His ideas were essentially Zwinglian. His assistant, John Knox, was to become the real leader of the Reformation in Scotland. Before long Knox had to flee and found refuge in England. During the reign of Edward VI he was an active leader in the English Reformation. When Queen Mary restored Roman Catholicism, Knox fled to the continent with numerous English reformers. Eventually he became pastor of an English refugee church at Geneva. In 1555–56 he visited Scotland and preached vigorously in the interests of the Reformation. The next year, certain nobles, the "Lords of the Congregation," led the Scottish reforming group in signing the first great covenant binding themselves to support the Reformation. Knox returned permanently to Scotland in 1559. A year later the reforming group, through English pressure on the Scottish regent, gained its first great victory. The Scots Confession (of 1560) was drawn up and accepted by parliament. A *Book of*

Common Order (Knox's Liturgy), a *Metrical Psalter* and a *Book of Discipline (The First Book of Discipline*, 1561) were also drawn up by the reformers. Parliament did not ratify these, but the church was deeply influenced by a rather general acceptance of them. These documents were all decisively Genevan in character. Knox, who had been deeply influenced by Calvin, was the leader in their framing. The *Book of Discipline* was an advance on Calvin's system in that it applied Genevan ideals on a national scale, following a lead given by the Huguenots. A general assembly was instituted as the national meeting of representatives of the church. Here, in free debate, issues were to be determined by a body of ministers and laymen met under their own chairman and at their own call. This gave the church genuine control of its own affairs. Also a governing body, the church session, was instituted for each local church. This body consisted of elders elected by the people, and had as its chairman the pastor of the church. The people themselves were given the right to elect their pastor and this election, rather than ordination by other ministers, made a man a minister. Episcopacy was abolished, but several superintendents were named to itinerate in areas without ministers and to have some limited administrative duties. The religious prerogatives and authority of bishops were not given to them, however. and they did not preside over the church courts.

The last four decades of the 16th century witnessed the defeat of the reformed, or Presbyterian, Scottish Church in spite of several notable temporary victories. In 1581 the Presbyterians gained parliamentary sanction for their *Second Book of Discipline*, and for the so-called Negative Confession of Faith. Moreover, regional church governing bodies, the presbyteries, began to be set up. Yet, the Black acts of 1584 placed bishops in control of most of the church and the more prominent Presbyterian leaders were forced to flee to England. In 1592 the Presbyterians were able to extort from the king sanction for a parliamentary law which has ever since been regarded as the Magna Carta of Scottish Presbyterianism. Five years later the king, working through bishops forced upon the church, gained almost complete control of the entire church, a control which was to last until the first of the Bishops' Wars in 1639. James became king of England also in 1603 and then set out to make the Scottish Church the principal instrument of his absolutism in Scotland. From 1603 to 1612 he brought the church wholly under the power of his bishops. From 1612 until his death he was occupied in shaping the life and work of the church to serve his general policies. So well did he succeed that at his death Scotland was under an unqualified absolutism.

Charles I continued the Tudor-Stuart policy of using the episcopacy as an instrument in the furtherance of royal absolutism. In Scotland Archbishop John Spottiswoode was his chief agent. When, however, Charles, Archbishop William Laud, and Spottiswoode attempted to force the last degree of submission upon the Scottish Church, namely "Laud's liturgy," popular resentment came to the aid of the church. In a wave of public feeling expressing opposition to the whole of Stuart absolutism, the covenant of 1557 was "renewed" by signatures of all classes all over Scotland. Spottiswoode and all but 4 of his 50 fellow bishops fled to England. In the two Bishops' Wars which followed the Scots demanded, basically, free parliaments and free general assemblies. Charles lost the wars and granted the demands. Parliament and the general assembly abolished the entire episcopal regime in church and state and restored Presbyterianism as of its "Magna Carta" of 1592.

In 1643 the two parliaments signed the Solemn League and Covenant between England and Scotland. Upon this basis of a union of England, Scotland and Ireland in state and church, the two presbyterian-parliamentary groups worked together in opposing the episcopal-royalist absolutism. One aspect of this cooperation was the adoption by the Scottish Church of the religious constitution framed by the Westminster assembly. Scottish Presbyterianism thus passed from a Genevan-Calvinistic pattern to a Puritan-lederalist pattern. When the Independents gained control in England, purged the Presbyterians and executed Charles I, many of the Scots objected and proclaimed Charles II. Cromwell defeated the Scots' armies and held the country under military occupation. During this occupation the church was not persecuted. It had. moreover, a great series of religious awakenings under Covenanter leadership.

The English restored Charles II in 1660. He brought back the episcopacy as an instrument of royal absolutism into Scotland as well as into England. Under Archbishop James Sharp a veritable Inquisition reigned in Scotland, "the killing times," as the Covenanter movement was wiped out. When William and Mary came to the throne in 1689 Presbyterianism was restored finally by constitutional act. However, despite some opposition, most of the former episcopal clergy retained their pastorates.

After 1689 Scotland was unquestionably Presbyterian, but new problems arose. Within the established state church were now two parties—one a group of convinced Presbyterians who had only recently been terribly persecuted by king and bishop; and the other, a group who had served the persecutors and now served the current regime with no great concern for it or against it. The next generation saw the rise of a large group of essentially professional clergymen known as the Moderates, whose deepest interests were in social life, in culture and in their prerogatives within a state establishment. An Evangelical group sought to promote the older reformation ideals. In 1707 the Scottish and the English parliaments were united. Five years later the parliament restored patronage in Scotland. This meant that the local landowner, or patron, had the right of nominating the minister for the congregation, and the people lost the right of electing their pastors. This system of patronage quickly brought the Church of Scotland under the control of the Moderate ministers and the wealthy landowners. As many protests were made against patronage, the Moderates claimed supreme powers for the general assembly which they controlled, and did not hesitate to resort to the use of military escorts and to the imprisonment of dissenting ministers to enforce their dictates.

By 1733 resistance to the Moderates and to patronage led to the deposition of four ministers. Led by Ebenezer Erskine they formed a secession church, the Associate Presbytery. This body "renewed" the Solemn League and Covenant in 1742 and 1744. Even so some members desired greater attachment to the old Covenanting ideals and withdrew to form the Reformed Presbytery (1743). In 1811 this group became the Reformed Presbyterian Church. Within the Seceder group also the covenanting principle raised the problem of their relation to the state. which supported the church from which they had seceded. In 1747 they divided into two groups, known after 1788 as the General Associate synod (Antiburgher; *i.e.*, against taking the burgher's oath in various cities); and the Associate synod (Burgher; *i.e.*, willing to take the oaths). By 1799 and 1805, the problem of the civil government's authority in religious matters broke both of these bodies into Auld Licht and New Licht sections.

Meanwhile patronage and the Moderate party caused further discontent. In 1761 Thomas Gillespie (deposed in 1752 for resistance to the general assembly), founded the Presbytery of Relief, a tolerant, evangelical, non-Covenanter body designed to provide relief for ministers and congregations who wished to withdraw peacefully from the establishment. In 1773 it assumed the name the Relief Church of Scotland.

These new groups grew rapidly. and were greatly strengthened by the evangelical revivals, the Sunday-school movement and the new missionary spirit. In 1820 a United Secession Church was formed by certain segments of secession bodies, and in 1827 others formed the Associate Synod of Original Seceders. These unions involved Burghers, Antiburghers. Auld Lichts and New.

From 1833 to 1843 a severe struggle took place within the Church of Scotland between the Moderates and the Evangelical group, now greatly strengthened by the revivals and the Sunday schools. Finally uhen the government in London supported on legal grounds the entire Moderate structuie, the Disruption led by Thomas Chalmers took place. A Free Church of Scotland was formed by 474 ministers and thousands of lay people, free of state control, free of patronage and zealously evangelical. All but one of the Church of Scotland's missionaries, and most of its best scholars, joined the Free Church. Henceforth the Free Church led all Christian causes in Scotland.

The United Presbyterian Church was founded in 1847 by the union of the Relief Church with the United Secession Church. In 1852 about one-half of the Associate Synod of Original Seceders joined the Free Church of Scotland. The year 1876 witnessed the union of the majority of the Reformed Presbyterians with the Free Church. Union negotiations between the United Presbyterians and the Free Church raised many problems. A small group left the Free Church in protest against the union and formed the Free Presbyterian Church. Eventually, in 1900 the United Free Church was formed by a merger of the Free Church and the United Presbyterians. A small group remained outside as the Free Church of Scotland. In many ways this new United Free Church was the most vigorous and popular religious body in Scotland.

Before long attempts were made to unite the United Free Church and the old Church of Scotland. Patronage had been abolished in 1874, and the old Moderate party had given way to a better leadership in the Church of Scotland. The issue of an established state church proved insoluble, however, until after World War I. Both churches had drawn closer together in the meanwhile. In 1921 the state by law severed its old relation with the Church of Scotland, leaving it "the national church" but not the established state church. This allowed union negotiations to make progress, and in 1929 the two churches united under the original name of the Church of Scotland. A small group remained outside and continued the name United Free Church.

Vast changes, meanwhile, had greatly altered the total religious situation in Scotland. The Lowlands had become industrialized, and had brought in large numbers of Irish workmen, most of whom were Roman Catholics. The Highlands were being depopulated by changing economic conditions. Presbyterianism as a whole enrolled only a fourth of the population of Scotland, and three-fifths of the Scots were nominally in no church. The Church of Scotland had lost heavily among the labouring classes and in the rural areas. Various movements were under way, each seeking in some measure to improve conditions: a high-church liturgical movement; a movement to bring together in the church the labouring classes and student groups (Iona group) ; and a movement for the recovery of a more adequate theology. The Church of Scotland continued to be active in missionary work, and to take a leading part in the ecumenical movement among the Protestant churches throughout the world.

Six Presbyterian bodies remained in Scotland at mid-20th century. The Church of Scotland had (in 1955) 1,307,573 members. 2,289 congregations, about 3.300 ministers. 42.289 elders; 310 missionaries in stations in Pakistan. India. Africa, Arabia. New Hebrides, West Indies. The United Free Church (continuing) had (1948) 23.863 members. 123 congregations, 81 ministers, 1,154 elders; 8 missionaries in Bechuanaland, Africa. The Free Church of Scotland had (1948) 5,500 members, 160 congregations. 111 ministers; with missionaries in South Africa. Peru and India. The Reformed Presbyterian Church had (1948) 800 members. 7 congregations, 4 ministers. 30 elders; 6 missionaries at 3 stations in North Syria. The Free Presbyterian Church of Scotland had (1948) approximately 800 members. The Original Secession Church which, in 1948. had 1,953 members, 18 congregations, 14 ministers, 94 elders, and 10 missionaries in India, rejoined the Church of Scotland in 1956.

Ireland. — Except for scattered Puritan groups. Irish Presbyterianism began with the Irish plantation of 1610. These Presbyterians were first in the established Church under the tolerant Archbishop Usher. Charles I and Archbishop Laud drove them out. During the Great Rebellion they had ups and downs almost the same as those of the Scottish Presbyterians. William III gained for them only partial toleration. Until 1869 their unduly harsh lot led hundreds of thousands to migrate to North America,

Scottish controversies usually had their counterparts in Ulster. Seceders appeared in 1741, and organized in 1750; Reformed Presbyterians came in 1752 and organized in 1792. The Synod of Ulster was the Main Presbyterian body. but did not include the Presbyterians in Dublin, and south and west Ireland. These formed the Synod of Munster. Severe doctrinal controversies occurred in both the 18th and the 19th centuries. Each time a Unitarian group left the church. Consequently Irish Presbyterianism became very conservative in theology. In 1840 the Secession Church and the Synod of Ulster merged as the Presbyterian Church in Ireland. The Synod of Munster joined them in 1854. This body in 1956 had 133.422 members, about jj6 congregations. 75 other preaching points. j62 ministers. 4,228 elders; 39 missionaries at 10 stations in north China and west India. The Reformed Presbyterian Church had (1948) about 3,400 members; missionary work was being carried on in North Syria.

Wales.—The Presbyterian Church in Wales, known also as the Calvinistic Methodist Church, grew out of the evangelical revival of the 19th century. Howell Harris and other friends of George Whitefield led the movement and gave to it the general society character of the Wesleyan societies, but the doctrinal convictions of Calvinistic Puritanism. Its earliest organization outside the Church of England in Wales took place in 1811 on a Presbyterian form of polity. Two synods, or associations, were formed, one for South Wales and one for North Wales. Twelve years later a Calvinistic, Presbyterian creed was officially adopted. In 1864 a general assembly was formed to unite, but not to control, the two associations.

The church is distinctly Welsh in all ways. About one-fourth of the congregations use the English language in some measure. The church in 1948 had a membership of 172,754 in 1,467 congregations, with 674 ministers and 7,256 elders; 54 missionaries were at work at 15 stations in India and in Brittany, Fr.

Canada. — Presbyterianism first took real root in Canadian territory after the treaty of Paris in 1763. Settlement of Scots in Nova Scotia brought many Presbyterians there. In 1817 the various elements united as the Synod of Nova Scotia in Connection with the Church of Scotland. Then, 1835, the Synod of New Brunswick in Connection with the Church of Scotland was formed. These bodies were all at work in eastern Canada.

Farther to the west the Church of Scotland was also sending ministers and aid. Secession groups had already organized, in 1826, the United Presbytery of Canada. In 1831 the Synod of the Presbyterian Church of Canada in Connection with the Church of Scotland was organized. These two bodies united in 1840.

The Disruption of 1843 in the Church of Scotland caused parallel ruptures in all the Canadian Presbyterian churches. In 1845 there were seven separate bodies. Thirty years later, in 1875, all had reunited in the Presbyterian Church in Canada, with several colleges and a strong body of congregations and ministers. Their next task was set by Canada's westward expansion.

The 20th century brought new problems to Canada, theological, social and economic. Roman Catholicism was growing. The sparse population of the Canadian prairies put a severe drain on all Protestant home mission efforts. The changing scene in Canada had made Protestantism too greatly urban. As early as 1890 projects for uniting Canadian Protestants had been broached rather widely. The Church of England in Canada quickly dropped out of these negotiations, but the two largest Protestant bodies, the Presbyterians and the Methodists, together with the much smaller Congregational Church, united as the United Church of Canada in 1925. A sizable minority of Presbyterians refused to enter the union and continued as the Presbyterian Church in Canada.

The United Church of Canada continued to maintain official connections with other Presbyterian and Reformed Churches throughout the world. In government the church is essentially Presbyterian, although in doctrine and other matters it allows great latitude to points of view traditionally non-Presbyterian, because of its Methodist and Congregational constituencies. In 1955 it had 894.556 members, 2.691 congregations, 6.222 additional preaching points. 3,178 ministers. 38,066 elders; missionaries were at work in stations in Trinidad. Africa and Asia.

The Presbyterian Church in Canada in 1953 had 179.248 members. about 900 congregations. 1,149 additional preaching points. 721 ministers, 7,957 elders: 40 missionaries at 7 stations in Asia, Trinidad, British Guiana and Poland.

Australia. — Australian Presbyterianism was essentially Scottish in origin and character. The first organized body was founded in 1826 by Church of Scotland ministers. During the stormy years following, the divisions of the homeland had their counterparts in the South Pacific. Reunions of fragments formed the Presbyterian Church of New South Wales in 1865; the Presbyterian Church of Victoria in 1870; and smaller bodies in Queensland, West Australia, South Australia and Tasmania. A federal union of most of these bodies was formed in 1886, and in 1901 all united in the Presbyterian Church of Australia. Considerable local autonomy was granted each of the regional bodies. From 1918 to 1923 strenuous efforts were made to achieve a union among Presbyterians, Methodists and Congregationalists similar to that achieved in Canada, but without success.

This church in 1948 had 104,944 members, 584 congregations, 174 additional preaching points, 704 ministers, 5,018 elders; plus missionary work in Asia and the New Hebrides.

New Zealand. — Presbyterianism in New Zealand arose in two distinct migrations. To the northern regions came Church of Scotland ministers as early as 1840. The first presbytery was founded at Auckland in 1856. Later it grew into the Presbyterian Church of New Zealand. In the southern area Scottish Free Churchmen founded a model religious colony at Dunedin in 1848. Their church grew first into the Presbytery of Otago (1854), then into the Presbyterian Church of Otago and Southland. In 1901 these bodies united as the Presbyterian Church of New Zealand.

The church in 1948 had 61,799 members, 354 congregations, 1,027 additional preaching points, 364 ministers, 2,877 elders; missionary work was being conducted in Asia and the New Hebrides.

Africa. — Scottish Presbyterians first organized in South Africa in 1892. The Presbyterian Church of South Africa was formed in 1897. This body did not include the native congregations, and the problem continued to agitate the church. Eventually, in 1923, it was solved by creating a Bantu Presbyterian Church wholly separate from the white church but with fraternal relations. This arrangement, however, resulted in little more than qualified segregation. As race tensions mounted after World War II the Presbyterians made great efforts to frustrate the all-out movement for total segregation known as *apartheid.* The entire status of missionary educational and medical work was also challenged, and the Presbyterians made strenuous efforts to improve native-white relations.

The Presbyterian Church of South Africa in 1948 had 20,996 members, 83 congregations, 53 additional preaching points, 95 ministers, 621 elders; also missionary work in South Africa. The Bantu Presbyterian Church of South Africa had 30,308 members, 61 congregations, 750 additional preaching points, 49 ministers, 1,061 elders.

Other African Presbyterian bodies, with 1948 statistics, are: the Presbyterian Church in Basutoland, about 25,000 members; the Presbyterian Church of Central Africa, 105,558 members, 116 congregations, 57 ministers, 2,192 elders; the Presbyterian Church of Gold Coast, 30,132 members, 51 congregations, 70 ministers, 895 elders; the Ewe Presbyterian Church, 15,742 members, 210 congregations, 23 ministers, 235 elders; the Synod of the Nile, 24,200 members, 168 congregations, 162 ministers and 235 elders.

United States. — The 11 Presbyterian bodies in the U.S. at mid-20th century made up the largest group in the Presbyterian family. Two of these bodies accounted for nearly 3,200,000 members, and more than 98% of all U.S. Presbyterians were in the four largest bodies. Repeated attempts at union had failed, largely because of nonreligious; *i.e.,* political, social and regional causes.

The Presbyterian Church in the U.S.A.—The earliest Presbyterian churches in the American colonies were planted on Long Island by New England Puritans who preferred the Presbyterian way to the Congregationalist. Very soon after Scotch-Irish, English and other settlers formed Presbyterian churches in Maryland, Delaware and Pennsylvania. In 1706, some of these joined in a loosely organized presbytery which in 1716 was expanded to a synod of three presbyteries. The church continued to be a blend of New England Puritan Presbyterians and Ulster Presbyterians, plus Welsh and other elements.

Shortly, repercussions of British struggles against Arianism brought trouble to the new colonial church. A Scotch-Irish group, led by John Thomson, asked for unqualified subscription by all to the Westminster Confession and a powerful centralized church government as bulwarks against heresy. The New England group, led by Jonathan Dickinson, resisted, asserting that no human creed could be absolutized, that ecclesiastical authority could not prevent heresy and that only a deeper piety would suffice. In 1729 the synod compromised by adopting the confession, but allowing men to distinguish between its essential and its nonessential points. The church government issue was avoided. The compromise did not satisfy all.

In 1733, a new group, led by William Tennent and his son Gilbert, began in Presbyterianism the revival later termed the Great Awakening. The Thomson group fought the revival bitterly, and would have driven it out of the church but for the chance appearance of George Whitefield, whom the Tennents persuaded to aid them. Whitefield won mass popular support for the Tennents, and drew the New England group closer to them. In a typical frontier controversy both the Thomson and the Tennent groups went to extremes. Serious moral failures weakened the hold of the Thomson group on the people. The climax came in 1741 when the Thomson group gained momentary control of the synod and illegally expelled the Tennents.

The Dickinson group, the more stable and best-based section of the church, sought first to mediate. Rebuffed by the Thomson group, they joined the Tennents in forming a new church, the Synod of New York, popularly called the New Side. They stood for an American, democratic, evangelistic church of all nationalities, with a deep concern for ethics, led by a ministry trained in the colonies. In 17 years they trebled their membership, established the College of New Jersey (later Princeton university) and expanded as far as western Pennsylvania and the Carolinas. The Thomson group took the name the Synod of Philadelphia, (popularly the Old Side). They stood for an autocratic ministry, a church committed to being Scottish-Scotch-Irish in all things and opposed to revivals. From 1741 to 1758 this group lost ground steadily.

The schism was at length healed in 1758, by mutual concessions, and the name of the Synod of New York and Philadelphia was adopted. In the synod there was now a preponderance of directly or indirectly New England-trained ministers, and the strongest presbyteries were those composed of churches with New England backgrounds. Beginning in 1760, however, several hundred thousand Scotch-Irish immigrants arrived in the colonies. Many of these joined the Presbyterian Church, and the character of the church gradually changed to a Scotch-Irish pattern.

In the struggles leading up to the Revolutionary War the Presbyterians took a vigorous part. They formed an alliance with the Congregationalists of New England in order to prevent the settling of Anglican bishops on the colonies, because they feared an intolerant establishment was contemplated. The struggle for colonial independence was, in time, called a Christian cause. In personnel and property the church suffered heavily in the war. The near triumph of deism among Americans after the war came as a staggering blow to the church. During the years 1785–88 a general assembly was founded with an explicit constitution. Some resistance was offered by those who feared extreme centralization. In the constitution all reserve powers were, therefore, left with the presbyteries, and the higher, central, courts were given limited and fixed powers only. Doctrinal subscriptions continued to be flexible.

The church took up frontier missions, benevolent work, the founding of schools, etc. with vigour. A series of revivals greatly increased the church's strength, despite some concurrent problems. Charles G. Finney and Lyman Beecher were active evangelistic leaders of the second quarter of the 19th century.

In 1801 the church entered into a Plan of Union with the New

England Congregationalists. These churches themselves did not merge. but they federated their home missionary work on the frontier. This did, however, draw the two denominations closer together everywhere, and reraised the old Scotch-Irish *v.* New England antipathies of 1741–58. Moreover. New England theology was restless and inquiring. The Scotch-Irish considered theology a finished structure which must now be protected against innovation. In the south the church was almost wholly Scotch-Irish, and proslavery sentiment there kept most northern Scotch-Irish Presbyterians either proslavery or neutral. The New England background Presbyterians were generally antislavery.

After years of turmoil a majority in the asembly of 1837 abrogated the Plan of Union, expelled illegally all the federated churches and demanded total subjection by all to the assembly. During the ensuing year about four-ninths of the church refused to recognize these acts and joined the expelled group in declaring themselves to be the genuine Presbyterian Church and the group who had ousted them to be a schism. The civil lower courts declared them to be the continuing church, but the appellate court reversed the decision. They continued the name the Presbyterian Church, U.S.A., and added "New School." The other group took the same name but added "Old School."

The New School denomination continued, as before 1837, to work in close co-operation with the Congregationalists in home and foreign missions, in antislavery, temperance and other work. They had a few congregations in the south (these withdrew in 1856–57), but were largely a northern church. The Congregationalists abrogated the Plan of Union in 1852, though the two churches continued some joint work. Even so, the abrogation was a setback for the Presbyterians. In frontier missions, education and benevolent work they made great contributions. Union Theological seminary, New York City, became their great centre. During the Civil War the church was active on the northern side.

The Old School Presbyterians built a well-organized church on the basis of their doctrinal, racial and social homogeneity. Though spread over all the nation, their great strength was among the Scotch-Irish and the Scottish groups. Princeton seminary became their focal point. A solid denominational structure enabled them to make great strides in missions, colleges and Sunday-school work. The Civil War brought new issues. The O.S. assembly of 1861 passed the Gardiner Spring resolutions which so wholly committed the church to the northern view that the entire southern section of the church seceded to form the Presbyterian Church in the Confederate States of America.

After the war the north-south groups of the two churches could not agree to reunite. Unions took place instead of New School and Old School, in the south to form the Presbyterian Church, US. (see below), and in the north, the Presbyterian Church, U.S.A.

The northern reunited church took up frontier mission work anew, built new colleges and institutions, expanded Sunday-school, youth and benevolent work, as the nation moved westward. A quarter of a century of achievement was interrupted by a major controversy which arose as a result of the influence of the new scientific views upon Christian thought. There came first (about 1892) a long struggle over biblical criticism, followed (about 1910) by the organization, on an international scale, of an interdenominational group, strongly Presbyterian, to defend the "fundamentals" of the faith. By World War I the Fundamentalist-Modernist controversy was intense. Moderate groups pleaded for comprehension within the church of all essentially Christian views, but without success. The struggle now assumed a new form. The Fundamentalist group attacked various boards and institutions of the church as unorthodox and founded within the church rival institutions of their own to compete with the church's institutions. This brought judicial process in the church courts against J. Gresham Machen and other Fundamentalist leaders. Most Fundamentalists then drew back from the controversy. A few, however, joined with Machen in founding the Presbyterian Church in America.

Between World Wars I and II the Presbyterian Church, U.S.A., came to have one of the largest foreign missionary enterprises in the world. In the U.S. the church had more than 50 colleges and 9 theological schools. As national and international co-operative ventures among churches were launched the Presbyterians took an active part. Negotiations for union were had also with other Reformed and Presbyterian bodies and with the Methodists and the Episcopalians. In only two instances did success come. The Cumberland Presbyterian Church (see below) re-united with the U.S.A. Presbyterians in 1906. The Welsh Calvinistic Methodists merged with the Presbyterians in 1920. On the foreign field Presbyterians moved to turn their missionary work over to independent native churches. In China and India Presbyterians united with other denominations to form new "younger churches." A Presbyterian Church of Brazil and a Presbyterian Church of Mexico, each self-controlled, were founded. In other countries local leaders took charge.

World War II brought havoc to many regions. As peace came the Presbyterians raised nearly $27,000,000 to aid in reconstruction, principally in Europe and on mission fields in former war areas. Wholly new approaches also were worked out by the church to Sunday-school studies. to youth work, etc.

In 1957 union negotiations with the United Presbyterian Church of Xorth America (see below) were completed. The Church in 1957 had 2,809,603 members, 8,658 congregations, 9.841 ministers, 70,391 elders, 1,368 missionaries at 151 stations in Africa, India, Japan. Korea. Mexico, Iran; the Philippines, Thailand, South America, Central America, Syria and Mesopotamia.

The Presbyterian *Church* in the United States.—This body, commonly called the Southern Presbyterian Church, came into being during the Civil War. Prior to the war, furious controversy had split the Presbyterian Church, U.S.A., in two bodies—New School and Old School. These divisions were not geographical; N.S. and O.S. congregations existed in both north and south. The south was predominantly O.S. The N.S. was unofficially the antislavery force in the central states, while the O.S. was officially neutral on the issue and actually proslavery in most regions. The coming of the war brought a wave of nationalism over the north, one aspect of which was the adoption in 1861 by the O.S. general assembly of the so-called Gardiner Spring resolutions which put the church so unequivocally behind the federal government that the O.S. churches in the Confederate states seceded to form the Presbyterian Church in the Confederate States of America.

The war cut off other southern Presbyterian bodies also from their northern brethren. Older lines of cleavage lost their meaning. In 1864 the United Synod of the South (largely N.S.) merged with the Confederate Presbyterians, so also did certain small units of Seceders and Covenanters. Border state Presbyterian bodies, at first neutral, joined also: Synod of Kentucky, 1869; Synod of Missouri, 1874. After the war, the name Presbyterian Church in the United States was adopted.

The church continued to devote its energies to the so-called southern states, Texas, Arkansas and hfissouri marking in general its western boundaries. The church is essentially Scottish, Scotch-Irish in membership and traditions. Its homogeneity racially, geographically and socially make it a very close-knit body. Traditionally the church divides between a spiritual and a political approach to problems. The latter approach has always been rejected. As a result the church has been very conservative on all religious, political and social issues. Yet in educational and benevolent enterprises the church has long been a leader in the south. Its educational and missionary ventures have been especially significant. In its polity great care has been taken to promote local initiative and to restrict the powers of all central agencies.

The church in 1954 had 756.884 members, 3,776 congregations, 3,068 ministers; in 1949 it had 19,270 elders; 346 missionaries in Africa, Brazil, Mexico and Asia.

Southern Presbyterians and northern Presbyterians continued to talk of reunion from the 1870s. The two churches adhered to almost identical constitutions, but continued to be separated by essentially nonreligious differences; *i.e.*, the continuing problem of the Civil War Reconstruction. While the northern church is less conservative all ways than is the southern, north-south relations remain the serious obstacle to reunion. Fraternal relations between the two bodies have long been excellent, and ministers, members and students freely transfer from one church and its institutions to the other. There is little overlapping of territory, less of competition and a growing area of co-operative endeavour (*i.e.,* joint schools, common missionary projects. etc.).

The United Presbyterian Church of North America.—Covenanter, or Reformed Presbyterian, people began coming to North America, principally from Ireland, before 1750. In 1774 their first presbytery was founded. Seceder Presbyterians organized a presbytery in 1758. Both groups were located principally in Pennsylvania. In 1782 the Reformed Presbyterians and some of the Associate (Seceder) Presbyterians united, and these together with other Secession groups merged to form in 1858 the United Presbyterian Church of North America. Covenanter and Secession backgrounds made this church very conservative in doctrine and worship. At first the church practised closed communion, sang only psalms in public worship and adhered to the Solemn League and Covenant. Gradually, however, changes came as the memory of Scottish issues faded away. The church was early engaged in the antislavery cause and other significant reform movements. Because of its solid Scottish, Scotch-Irish background its main strength lies in the regions of Pennsylvania, Ohio, New York. Illinois and Iowa. The church in 1956 had 244,-973 members. 833 congregations, 967 ministers. 6.93; elders; approximately 117 missionaries were at work in Egypt, India, the Sudan and Abyssinia.

The Cumberland Presbyterian Church.—The Cumberland Church grew out of a purely American situation; *i.e.,* frontier conditions. Differences of opinion regarding the great Kentucky revival of 1799–1802, impatience with high educational requirements for a frontier ministry, excessive use of ecclesiastical authority and differences on the subject of predestination brought about a separation in 1810 from the Presbyterian Church, U.S.A., of a group on the Kentucky-Tennessee frontier. They founded the Cumberland Presbyterian Church, stressed evangelism, repudiated predestination and avoided highly centralized church authority. Their membership was almost wholly second and third generation Scotch-Irish from the southern Atlantic states. During the 19th century the church spread through Ohio, Pennsylvania, Missouri and Texas. Until the Civil War Negroes, lay and ministerial, had a significant place in the church. In 1869, however, they formed a church of their own.

Early in the 20th century negotiations for reunion with the Presbyterian Church. U.S.A.. began. A majority of the Cumberland Presbyterians rejoined the older church in 1906. Others. however, continued as a distinct group under the Cumberland name. The church in 1954 had 84,393 members. 1,104 congregations and in 1949 more than 750 ministers. Missionary work was being done in China and South America.

The Cumberland Presbyterian *Church, Coloured.*—This church, set off from the above in 1869. reported in 1949 approximately 30,-000 members in 121 churches.

Churches Continuing the Covenanter-Secession Tradition.—These include: (1) The Associate Reformed Presbyterian Church (General Synod), which in 1954 had 27.481 members in 151 congregations; (2) the Associate Reformed Presbyterian Church of North America, which in 1954 had 400 members in j congregations; (3) the Reformed Presbyterian Church (Old School), with 6.442 members in 74 congregations (1954); and (4) the Reformed Presbyterian Church (General Synod), with 1,335 members in 11 congregations in 1954.

Later Bodies.—The Fundamentalist-Modernist controversy of the 20th century was particularly severe within the Presbyterian Church, U.S.A. From that church a Fundamentalist group led by J. Gresham Machen formed in 1936 the Presbyterian Church in America. Further doctrinal controversy broke this group into two distinct bodies in 1938: (1) the Orthodox Presbyterian Church, a body stressing classical Presbyterian orthodoxy and very conservative in worship, organization and practice, with 8.611 members. 72 congregations (1954) and 98 ministers (1949); and (2) the Bible Presbyterian Church. a body stressing revival evangelism, Bible institute work and much more loosely organized than the above, had 8,428 members and 88 congregations in 1954.

THE PRESBYTERIAN SYSTEM

The Presbyterian way of ordering the life of the church intends to be no more than a systematic and consistent attempt to follow the general principles laid out in the New Testament. It is confessed that the New Testament presents no single, definite, complete pattern. However, the very nature of what is there said of the Gospel, the church, the ministry, etc., is taken by those who hold this system as an adequate indication of the basic elements essential to the ordering of the church's life.

The name "Presbyterian" when used of this system is one of late origin. John Calvin and his associates, who rediscovered and reformulated the system during the 16th century, did not name their system as such. The name came into general use only during the controversies of the following century. The name is derived from a Greek word meaning "elder," and therefore the name designates specifically that aspect of the system which has to do with the ministry of the church. As Calvin and his colleagues elaborated the system, however, its distinctive and basic feature was the doctrine of the church, which in turn was based on their understanding of the Gospel.

Calvin learned much from the earlier reformers, and his work was not wholly original. His greatest contribution lay in his bringing into one clear, systematic statement the general Reformed view. Not all who have called themselves Reformed have ever followed him in all things, but the system is best described by reference to his presentation of it.

The Church.—Calvin's view of the church was shaped by his understanding of the Gospel. The Gospel was the "good news" of God's forgiveness of man, and the call to man to return and be reconciled to God; *i.e.,* to repent. Forgiveness and reconciliation were inseparably bound together, as Calvin saw it. This he took to mean that men were to be reconciled to God by receiving His forgiveness, and to be reconciled to their fellow men by their mutual forgivenesses. To be reconciled to God was to come into His fellowship, and to be reconciled to one's fellows was to come once again into their fellowship. On that basis, Calvin believed, there could be no private, or individualistic salvation. He declared that salvation was intensely personal, because the Christian became a responsible actor, but never a matter involving only the individual soul and God. He mas, therefore, much opposed to mysticism and its view that each individual sought God alone and directly. In this connection he quoted the old saying, "Outside the Church there is no salvation." No one could invent his own way to heaven. This view became of great importance in Calvin's doctrine of the sacraments also.

This sense of community, or fellowship, in Calvin's opinion, was to be seen also in God's method of redeeming men. It was God who sought men, rather than men who sought God. Yet, God did not work directly, but through agents, through means. This idea was basic to all of Calvin's thinking about the church. God redeemed men through the agency of their fellow men. Consequently God's love which brought men to Himself was given to men through other men, thereby forming a bond of unity among them greater than any other conceivable bond. Calvin applied this same idea also to all aspects of life. God, he declared, was the source of all good, spiritual and temporal. But because He dispensed this good to men by the labours of others, each owed to the other that which he had received. Therefore, mutual sharing was necessary. This was part of reconciliation and love.

The church, then, according to Calvin, had as its sole function the task of telling men of God's forgiveness and of leading them to reconciliation with God and their fellows. This involved several other things. Men could not accept forgiveness and agree to be reconciled to God and man without confessing that they were in need of so doing. Moreover, to be reconciled. Calvin interpreted as meaning to be reconciled to the service of God among one's fellow men. This meant that the Christian life was to be lived among God's people for their good and God's glory, not for any selfish desire for temporal or eternal gains. Ethics, therefore, were always part of theology in Calvin's thinking. Political and moral problems dominated his activities. Though the economic application was stated in principle, it was never as fully worked out.

Following St. Paul, Calvin made great use of the idea of the church as the Body of Christ. Here again the community, or corporate, aspect of the church was to the foreground. The members, he pointed out, are held together, directed and governed by the Head in one common life which fulfils the will and purpose of the Head. It is the Head, not the members, to whom all things about the church are to be referred.

Since there is only one Christ, or Head, Calvin declared, there can be only one church or Body. Wherever Christ is present redeeming men in a manner essentially agreeable to the pattern He Himself laid down, there men are to know is the church. Wherever a religion contrary to Christ's own pattern was being offered to men, there, Calvin believed, men were to know that there was no church of Christ. This, he said, was the one basic difference between the papacy and the reformers. The unity, continuity and universality of the church were all to be found in the redeeming presence of Christ, not in any particular form of government, doctrine, leadership or lineal descent of ministers.

The church was the Body of Christ on earth among men, and therefore plainly visible to all, Calvin said. Yet, he continued, because it is all too human there are senses in which it is impossible for men to mark out its exact boundaries. In that sense the church is invisible, and we are "to believe the Church," he said; *i.e.*, we are to believe that this very imperfect community is truly the Body of Christ.

The **Ministry.**—Two aspects of the nature of the Church, Calvin said, provide the occasion or reason for the ministry, namely that the church is a community and that its own life and felicity are not the reasons for its existence. It exists for the service of God. Consequently direction and leadership are needed, and this the government or ministry of the church is instituted to provide.

The one Head of the church is Christ, Calvin declared, and no one is ever His substitute or yicar. However, Christ moves His people to elect from their membership various persons to discharge the various aspects of the church's function. Some are to preach, some to teach, some to care for the poor and sick, some to exercise discipline. As Calvin believed, God Himself called His ministers, but He did it through the church. The ministry does not exist parallel to, or prior to the church. God, working through the people's election, calls the ministry. The ministry is not a sacred or spiritual order of men. It is a group of officeholders within the Body of Christ.

The church ordered its life in the service of God, then, in Calvin's thinking, by means of a ministry exercised by a variety of officeholders: pastors, teachers, elders and two types of deacons. The pastors were to preach the Gospel, to administer the sacraments and to serve as president of the other officers. Because they had the most responsible office within the total ministry, they might be called "the ministers." The teachers were to devote their whole time to teaching. Elders were to share with the pastors the spiritual oversight of the church. Deacons, men and women, were to care for the poor and the sick. No one was to exercise any function to which he had not been elected, and election to an office by the people was the sole necessary qualification. No matter to what office a man had been elected he remained merely one of the brethren. Calvin rejected the distinction between clergy and laity. All were priests on behalf of all.

God's call, made known through election by the people, was for Calvin all that was needed to make anyone the holder of any office in the ministry. Ordination by other ministers, he asserted, could not make anyone eligible to serve any office. When the ceremony of ordination was used, it meant, he declared, no more than that the ministers ied the people in a solemn prayer that God would recognize as His act that which they had done in electing the man in accord with what they believed was His will.

Those who hold offices in the ministry do so only within the church. They have no personal authority or virtue, Calvin said. Consequently, they may act only on the authority and prerogatives given them. (This view determined certain aspects of Calvin's doctrine of the sacraments.)

The Sacraments.—Because, Calvin asserted, it is God who seeks His prodigal children rather than they who seek Him, and because it is God who directs His church in the life which it lives in His service, public worship is primarily the assembling of the people of God to hear what He has to say to them. They do not assemble to seek Him, but to meet Him and to hear His word. When this takes place, they respond by receiving His love, His grace, His fellowship; and then they present their prayers and petitions.

The action of public worship was for Calvin the hearing of the Gospel, and the joyful communion with God to which that Gospel summoned men. By preaching and teaching the Gospel was to be made known and understood in the church. In the sacraments there were provided ways whereby men could actually appropriate and receive the grace offered in the Gospel.

The sacraments in themselves possessed no particular powers. Whatever man received he received by faith. The sacraments, therefore, Calvin said, are not independent of faith. They are rather a "lively preaching" intended to call forth faith. By this very fact they could not be considered necessary to salvation. Yet, since Christ commanded the church to carry out its mission in this manner, and since He did by means of the sacraments truly call forth faith, it was the duty of the church faithfully to use these "means of grace." Preaching and the sacraments could never be separated.

Baptism.—The promise of God in the Gospel, Calvin said, is that God will forgive and receive into His fellowship those who have forsaken Him. That promise was fulfilled, or sealed, when Jesus Christ came, and was crucified and raised from the dead for man's redemption. What remains to be done, Calvin believed, is that man must actually return to the fellowship of God and become a member of the community of believers who make up the church, the Body of Christ. This must be done as an act of faith, and under normal circumstances; it is to be done through receiving baptism.

Baptism symbolizes the death, burial and resurrection of Christ, according to Calvin. By accepting baptism, in an act of faith, men confess that they hope for salvation only in Christ, and that they do in fact return to God. This is their part in the sacrament. God, then and there, "incorporates" the believer into the Body of His Son, the church. This is the all-important aspect, for Calvin.

Calvin elaborated, not a doctrine of "infant baptism," but a doctrine of "Christian baptism," and then urged that children as well as adults might receive it. Children were to be given the promise held out in baptism and then brought up to exercise such faith as their growing years and perception might enable them to do. Until they exercised faith their baptism would be incomplete. Yet, Calvin thought, since their salvation depended upon God's love, and not upon baptism itself, they were safe in God's care while unable to exercise faith. Baptism was intended by God as an aid to faith, not as an indispensable rite necessary for salvation. God could, therefore, dispense with it if He chose. Men, however, were never to omit it, unless unable to use it.

Baptism could be administered by any method, Calvin believed (immersion, sprinkling, etc.), provided only that the method used clearly symbolized and proclaimed the death and resurrection of Christ. Baptism ought to take place only in the midst of the public worship of the church because it symbolized entrance into the Christian communion. Also, only those who led in public worship should baptize. There could be no private baptism because there was no private salvation. There could be no "emergency baptism" because baptism had no such character about it as to create any emergency.

The Lord's Supper.—The Lord's Supper, Calvin believed, was instituted by God to support, nourish and increase the faith of the Christian church. It was rooted in the event of Christ's death on the cross and symbolized that death. It proclaimed, therefore, the fact that God had fulfilled His promise, and that men had been forgiven. Moreover, it invited men to "take," to receive, the offered mercy of God. Receiving the sacrament in an act of faith meant, Calvin said, that one believed that God truly held out something to man in it, and that man truly received in it just what God offered, namely forgiveness, reconciliation, continued fellowship and communion with God.

The elements (bread and wine) themselves, Calvin thought, had no particular merit or significance beyond their historical connection with Christ's last supper with the disciples. Nothing in the ritual changed the elements in any way. Christ was indeed present during the sacrament as He was present in preaching or in baptism. But His presence was not associated with the bread and wine. He was present to meet with, and commune with His followers.

The sacrament should follow each occasion on which the Gospel was preached, Calvin urged. In the sermon the Gospel was proclaimed; in the sacrament it was set before men symbolically. In faith they were to receive it.

The setting for the sacrament demanded a table, Calvin said. Thus Christ instituted the sacrament, and thus it should be continued. The table symbolized the fact that God is offering to man, and that man is to come, to receive. The altar, Calvin declared, symbolized that man is offering something to God. Also, the sacrament belongs to the whole church, not to the ministers. It is to be administered only in the public worship of the congregation. All were to be invited to come. Any who feared they were "unworthy" were to know that only the confession of need could constitute worthiness. Those who came inwardly ungodly and unrepentant rejected God's mercy in the sacrament just as they rejected it when they heard it preached. Calvin believed that private communion, even for the sick, obscured the true nature of the church as a community and fostered superstitious ideas about the sacrament.

Church Government. — Though Calvin believed that the system of church government which was used by himself and his associates in Strasbourg and Ziirich was based upon the Bible and the experience of the church, he did not claim for it exclusive divine right. He acknowledged the English Church under Archbishop Thomas Cranmer, and the Lutheran Churches of Germany under their consistorial system as true and complete churches. Cranmer and the Lutherans also acknowledged the Reformed Churches.

The primary elements of Calvin's theory of church government may be summed up as three. The church is a community, or body in which Christ only is Head, and all other members are equal under Him. The ministry is given to the whole church, and is there distributed among many officers according as God has gifted and called them. All who hold office do so by election of the people whose representatives they are. The church is to be governed and directed by assemblies of officeholders, pastors and elders, so chosen as to provide just representation for the church as a whole.

Since the Reformation the various Reformed Churches, Presbyterian Churches and others, have made many adaptations of this basic structure, generally without departing from it in essentials.

PRESBYTERY, in architecture. that portion of the chancel (*q.v.*) of a church in which the high altar is placed, and which is generally raised a few steps above the rest of the church. It is reserved for the priests and differs from the choir, the stalls in which are occasionally occupied by the laity. In Westminster abbey the space east of the transept is the presbytery, and the same arrangement is found in Canterbury cathedral. In S. Clemente at Rome the presbytery is enclosed with a marble balustrade or screen. For the use of the word in church government *see* PRESBYTERIAN.

PRESCOT, an urban district in the Huyton parliamentary division of Lancashire. Eng.. 8 mi. E. of Liverpool by road and 4 mi. S.W. of St. Helens. Pop. (1951) 12,474. Area 1.4 sq.mi. It is of considerable antiquity and received a grant for a market and fair from Edward III. A church existed in the 13th century. The present church of St. Mary is in various styles, with a lofty tower and spire and carved timber roof After John Miller brought the industry from Yorkshire (1730) the town has been noted for watches and watch tools. Electric cables are manufactured. To the north is Knowsley park, seat of the earls of Derby.

PRESCOTT (SPOFFORD), HARRIET ELIZABETH (1835–1921), U.S. author, was born on April 3, 1835, at Calais, Me. Her family later moved to Newburyport, Mass., where she attended the Putnam free school. For a short time, she was also a student at the Pinkerton academy at Derry, N.H.

Her father, Joseph Newmarch Prescott, a merchant, was stricken with a chronic illness about 1850, and she turned to writing in an attempt to help support the large family. Encouraged earlier by Thomas W. Higginson (*q.v.*), Harriet Prescott first gained recognition in 1859 when the *Atlantic Monthly* published "In a Cellar," an adventure story distinguished by rich description. Her reputation grew rapidly and she became a popular contributor to leading periodicals.

She published *Sir Rohan's Ghost* (1860), a novel dealing with the plight of a man who falls in love with the daughter of a mistress he tried to kill; *The Amber Gods, and Other Stories* (1863), a collection of stories in the romantic tradition; and *Azarian: An Episode* (1864), the story of egocentric, artistic Azarian who could not understand another's idealism.

Her magazine contributions of romantic tales, poems and articles were later collected in a number of books, which include *New-England Legends* (1871); *A Scarlet Poppy and Other Stories* (1894); *In Titian's Garden and Other Poems* (1897); *Hester Stanley's Friends* (1898); *Old Madame and Other Tragedies* (1900); and *The Elder's People* (1920).

After her marriage in 1865 to Richard Smith Spofford, Jr., a lawyer, she spent a great deal of time in Washington, D.C. Interested in the local colour of Washington, she later wrote *Old Washington* (1906), a novel.

She died on Aug. 14, 1921, at her home on Deer Island, in the Merrimack river, near Newburyport, Mass.

PRESCOTT, WILLIAM (1726–1795), U.S. soldier, was born in Groton, Mass., on Feb. 20, 1726. A descendant of John Prescott, one of the early settlers of Lancaster, Mass., Prescott lived as a farmer on his estate at Pepperell, Mass. He returned there after having served as an officer with the provincial army during King George's War and the French and Indian War. He had refused the offer of Gen. John Winslow, his commanding officer during the Nova Scotia expedition, to become an officer in the regular army.

Prescott helped supply food to Boston in 1774, when it was closed by the British parliament, and in the same year he was appointed a colonel in command of a regiment of minutemen. Prescott and his troops attempted to intercept the detachment of British regulars which had been sent by Gen. Thomas Gage, royal governor of Massachusetts, to Concord, where colonists had begun to store military supplies. Prescott and his force did not arrive in time to join the engagement at Lexington April 19, 1775, and he continued to Cambridge, where he joined the council of war. The majority of his troops volunteered to continue serving with him.

With about 1,000 men, he left Cambridge on June 16, 1775, to defend Charlestown, Mass. While historians have disagreed whether Prescott or Israel Putnam (*q.v.*) was in general command of the American forces at the battle on June 17, 1775, at Bunker hill, Charlestown, Prescott played a vital part in that action. *(See* BUNKER HILL.)

The alleged famous order which tradition gives as "Don't fire till you see the white of their eyes" may have been given at

Bunker hill by Prescott. Israel Putnam, it is said, relayed it as "Men, you are all marksmen—don't one of you fire until you see the white of their eyes."

Although Prescott participated in military actions in 1776 and 1777, he had sustained an injury in farm work and had to retire from military life. Returning to his estate at Pepperell, he served for a number of years as a representative in the Massachusetts legislature. He died at Pepperell on Oct. 13, 1795. In 1881 a statue of Prescott by William Wetmore Story was erected on Bunker hill.

PRESCOTT, WILLIAM HICKLING (1796–1859), U.S. historian, was born in Salem, Mass., on May 4, 1796, his grandfather being Col. William Prescott (1726–95), a commander at the battle of Bunker hill, and his father, a well-known lawyer. Although he was blinded in one eye by a crust of bread flung in the Harvard Commons, he graduated with honour in 1814 and entered his father's office as a student of the law.

The verdict of physicians abroad was that the injured eye was hopelessly paralyzed and that the preservation of the sight of the other depended upon the maintenance of his general health. His further pursuit of the legal profession seemed to be out of the question, and on his return to Boston he remained quietly at home. On May 4, 1820, he was married to Susan Amory.

Prior to his marriage he had made a few experiments in composition, but he now finally decided to devote his life to literature. A review of Lord Byron's *Letters on Pope* in 1821 constituted his first contribution to the *North American Review*, to which he continued for many years to send the results of his slighter researches. He next turned to French literature and to the early English drama and ballad literature. Of the direction and quality of his thought at this time he left indications in his papers on *Essay-Writing* (1822) and on *French and English Tragedy* (1823). In pursuance of his method of successive studies he began in 1823 the study of Italian literature, passing over German as demanding more labour than he could afford. In the following year he made his first acquaintance with the Iiterature of Spain under the influence of his friend and biographer. George Ticknor; and, while its attractiveness proved greater than he had at the outset anticipated, the comparative novelty of the subject as a field for research served as an additional stimulus.

In the meantime his aims had been gradually concentrating. History had always been a favourite study, and G. Bonnot de Mably's *Observations sur l'histoire de France* appears to have influenced him. After prolonged hesitation he recorded in Jan. 1826 his decision "to embrace the gift of the Spanish subject." The choice was certainly a bold one. He could only use the eye which remained to him for brief and intermittent periods, and as travelling affected his sight prejudicially he could not anticipate any personal research among unpublished records and historic scenes. He was happy, however, in the possession of ample means and admirable friends. His method of work is an excellent illustration of his resourcefulness and perseverance. Seated in a darkened study, he kept his writing apparatus (a noctograph) before him, and his ivory stylus in his hand to jot down notes as his assistant read aloud. These notes mere in turn read over to him until he had completely mastered them, when they were worked up in his memory to their final shape. So proficient did he become that he was able to retain the equivalent of 60 pages of printed matter in his memory, turning and returning them as he walked or drove. The rate of progress was necessarily slow, apart from any liability to interruption by other undertakings and illness. He still continued his yearly experimental contributions to the *North American Review*, elaborating them with a view as much to ultimate historical proficiency as to immediate literary effect, the essays on *Scottish Song* (1826), *Novel-Writing* (1827), *Molière* (1828) and Washington Irving's *Granada* (1829) belonging to this preparatory period. On Oct. 6, 1829, he began the actual work of composition of his *History of the Reign of Ferdinand and Isabella*, the concluding note being written June 25, 1836. Another year, during which his essay on *Cervantes* appeared, was spent in the final revision of the *History* for the press. Its success was immediate. From the position of an obscure reviewer Prescott suddenly found himself elevated to the first rank of contemporary historians.

After considering for a short time the project of a life of Molière, he decided to follow in the track of his first work with a history of the conquest of Mexico. Irving, who had already made preparations to occupy the same field, generously withdrew in his favour. Prescott's five years of labour on this second book were broken by the composition of various reviews and by the preparation of an abridgment of his *Ferdinand and Zsabella.* In Dec. 1843 the *Conquest of Mexico* was published with a success proportionate to the wide reputation he had won. The careful methods of work which he had adopted from the outset had borne admirable fruit. While the consultation of authorities had been no less thorough, his style had become more free and less self-conscious; and the epic qualities of the theme were such as to call forth in the highest degree his powers of picturesque narration. It was only a step from his great work on Mexico to that on Peru, and scarcely three months elapsed before he began to break ground on the latter subject. In Feb. 1845 he received the announcement of his election as corresponding member of the French Institute in place of the Spanish historian M. Fernbndez Navarrete, and also of the Royal Society of Berlin. The winter found him arranging for the publication in England of his *Critical and Historical Essays* (New York ed., *Biographical and Critical Miscellanies).* The *Conquest of Peru* was completed in Nov. 1846 and published in the following March.

Prescott was now over 50 and his sight sho ed serious symptoms of enfeeblement. Although during the composition of the *Ferdinand and Zsabella* it had been of very intermittent service to him, it had so far improved that he could read with a certain amount of regularity during the writing of the *Conquest of Mexico*, and also, though in a less degree, during the years devoted to the *Conquest of Peru.* Now, however, the use of his remaining eye had been reduced to an hour a day, divided into portions at wide intervals, and he was driven to the conclusion that whatever plans he made must be formed on the same calculations as those of a blind man. He had been for many years collecting materials for a history of Philip II, but he hesitated to attempt a work of such magnitude, occupying himself in the meantime with the slighter labours of a memoir of John Pickering for the Massachusetts Historical society and the revision of George Ticknor's *History of Spanish Literature.* But in March 1848 he set himself with characteristic courage to the accomplishment of the large project. Through the aid of Don Pascual de Gayangos, then professor of Arabic literature at Madrid, he was enabled to obtain material not only from the public archives of Spain but from the muniment rooms of the great Spanish families. With an exceptional range of information thus afforded him. he wrote the opening of his history in July 1849; but, finding himself still unsettled in his work, he decided in the spring of the following year to carry out a long projected visit to England, where he was received with great honour. In Nov. 1855 the first two volumes of his uncompleted *History of Philip II*, were issued from the press, their sale eclipsing that of any of his earlier books. This was his last great undertaking; but a year later he published in revised form William Robertson's *Charles V*. A slight attack of apoplexy on Feb. 4, 1858, foretold the end, though he persevered with the preparation of the third volume of *Philip II* for the press, and with the emendation and annotation of his *Conquest of Mexico.* On the morning of Jan. 28, 1859, a second attack occurred, and he died in the afternoon of the same day.

Prescott's power lies chiefly in the clear grasp of fact, in selection and synthesis, in the vivid narration of incident. For extended analysis he had small liking and faculty; his critical insight was limited in range and he confined himself almost wholly to the concrete elements of history. When he does venture upon more abstract criticism, his standards are often commonplace and superficial, and the world scheme to which he relates events is less profound than the thought of his time altogether warranted. Moreover, the authorities on whom he relied had to be corrected later in many points of detail in the light of later archaeological research. Few historians have had in higher degree that artistic feeling in the broad arrangement of materials which ensures popular interest.

BIBLIOGRAPHY.—The definitive or Montezuma ed. of Prescott's works was edited by W. H. Munro (1904). His *Life* was written by George Ticknor (1864; rev. 1875). There are later lives by R. Ogden (1904) and H. T. Peck (1905). *See* also the chapters on Prescott and J. L. Motley in J. S. Bassett, *The* Middle *Group of American Historians* (1917) and *The Cambridge History of American Literature* (vol. 2, 1918); and sketch by M. A. D. Howe in *American Booknzen* (1898).

PRESCOTT, seat of Yavapai county in west central Arizona, U.S., about 100 mi. N.W. of Phoenix, is located in a mile-high basin among pine-dotted mountains rich in minerals. Gold mining brought the first settlers; farmers and cattlemen followed. To protect them from Indian raids an army post, Ft. Whipple, was built in the 1860s about 17 mi. N. of the present city, and in 1864 the first government of Arizona territory was set up near it. Later that year the fort and the government were moved to the area of the present city and the first legislature met in the "governor's mansion," a log-walled house preserved as a historic site.

The location of the capital alternated between Prescott and Tucson until 1889, when Phoenix was made the state capital. A railroad reached Prescott in 1893 and was extended to Phoenix in 1895.

Prescott is a trade centre for cattle ranches and farms in the valleys; mining also continues to be important and small industries are increasing. The city was named for the historian William Hickling Prescott; founded in 1864, it was incorporated as a city in 1881 and in 1955 adopted a council-manager form of government. The inhabitants of Prescott boast that the rodeo staged by competing cowboys on July 4, 1888. was the first public rodeo to be given anywhere; over the years the celebration developed into a lively three-day event — Prescott Frontier Days. For comparative population figures *see* table in ARIZONA: *Population*. (A. *M*. PE.)

PRESCRIPTION, in the broadest sense, the acquisition or extinction of rights by lapse of time. The prescription of Roman law (and of modern systems based upon it) is both acquisitive and extinctive. It looks either to the length of time during which the defendant has been in possession, or to the length of time during which the plaintiff has been out of possession.

In English law prescription is used in a comparatively narrow sense. It is acquisitive only, and is very limited in its application. A title by prescription can be made only to incorporeal hereditaments and to certain exemptions and privileges. The rights claimable by prescription for the most part consist of rights *in alieno solo*. The most important are advowsons, tithes, commons, ways, watercourses, lights, offices, dignities. franchises. pensions, annuities and rents. Land or movables cannot be claimed by prescription. The foundation of prescription is the presumption that a person in undisturbed enjoyment of a right did not come into possession by an unlawful act. In England this was based upon the fiction of a lost grant. After one or two previous enactments the date was finally fixed by the Statute of Westminster the First (3 Edw. I. c. 39) at the reign of Richard I., which was interpreted to mean the first year of the reign of Richard I. (1189). This is still the law with respect to claims not falling within the Prescription Act, 1832. By that act (extended to Ireland in 1858, but not to Scotland) claims to rights of common and other profits *à prendre* are not to be defeated after 30 years' enjoyment by any person claiming right thereto without interruption for 30 years by showing only the commencement of the right, and after 60 years' enjoyment the right is absolute and indefeasible unless had by consent or agreement by deed or writing (s. 1). In claims of rights of way or other easements the periods are 20 years and 40 years respectively (s. 2). The beforementioned periods are to be deemed those next before suits, and nothing is to be deemed to be an interruption unless acquiesced in for one year (s. 4). The time during which a person otherwise capable of resisting a claim is an infant, idiot, *non compos mentis, feme covert* or tenant for life, or during which an action or suit has been pending until abated by the death of a party, is to be excluded in the computation of the periods unless where the right or claim is declared to be absolute and indefeasible (s. 7). An act to define the period of prescription for a *modus decimandi*, or an exemption from tithes by composition, was passed the same year. The claim under the statute must be one which may be lawfully made at common law. The principal rules upon the subject are these: (1) The title is founded upon actual usage. The amount of actual usage and the evidence necessary to prove it vary according to the kind of claim. (2) The enjoyment must (except in the case of light) be as of right — that is to say, peaceable, openly used, and not by licence. (3) The prescription must be certain and reasonable. Inhabitants cannot, however, claim by prescription, as they are an uncertain and fluctuating body, unless under a grant from the Crown, which constitutes them *a* corporation for the purposes of the grant. (4) The prescription must be alleged in a que *estate* or in *a* man and his ancestors. Prescription in a que estate lies at common law by reason of continuous and immemorial enjoyment by the claimant, a person seised in fee, and all those whose estate he had. Prescription in a man and his ancestors is not of ordinary occurrence in practice. Corporations, however, occasionally claim by a prescription analogous to this, viz. in the corporation and its predecessors. Such claims by either a person or a corporation are not within the Prescription Act, which applies only where there are dominant and servient tenements. By 32 Hen. VIII. *c*. 2 (1540) no person can make any prescription by the seisin or possession of his ancestor unless such seisin or possession had been within three score years next before such prescription made. (5) A prescription cannot lie for a thing which cannot be granted, as it rests upon the presumption of a lost grant.

Prescription must be carefully distinguished from custom. Some rights may be claimed by custom which cannot be claimed by prescription, *e* g., a right of inhabitants to dance on a village green, for such a right is not connected with the enjoyment of land.

International Law uses the term "prescription" in its wider or Roman sense. "The general consent of mankind has established the principle that long and uninterrupted possession by one nation excludes the claim of every other" (Wheaton, *Int. Law*, s. 165). Historic instances of rights which were at one time claimed and exercised by prescription as against other nations are the sovereignty of Venice over the Adriatic and of Great Britain over the Narrow seas, and the right to the Sound dues long exacted by Denmark. But such claims were rejected by the highest authorities on international law (*e.g.*, Grotius), on the ground that they were defective both in *justus titulus* and in *de facto* possession. In private international law prescription is treated as part of the *lex fori* or law of procedure. (J. WIL.; X.)

Scotland. — In the law of Scotland "prescription" is a term of wider meaning than in England, being used as including both *prescription* and *limitation* of English law. In its most general sense it may be described as the effect which the law attaches to the lapse of time, and it involves the idea of possession held by one person adverse to the rights of another. Though having its basis in the common law, its operation was early defined by statute, and it is now in all respects statutory. Prescription in Scots law may be regarded (1) as a mode of acquiring rights — the positive prescription; (2) as a mode of extinguishing rights — the negative prescription; (3) as a mode of limiting rights of action — the shorter prescriptions. It must, however, be observed with reference to this division that the distinction between (1) and (2) is rather an accidental (due to a loose interpretation of the language of the act of 1617, c. 12) than a logically accurate one. It is, moreover, strictly confined to heritable rights, having no application in the case of movable property.

Positive Prescription. — The positive prescription was introduced by the Act of 1617, *c*. 12, which regulated the prescription of land rights till 1874. The provisions of the Act of 1874 are repealed as from Jan. 1, 1930, by the Conveyancing Act, 1924 (s. 16). As from that date the prescription will be 20 years without allowance for legal disability. The Acts of 1874 and 1924 provide that possession for 20 years upon "an *ex facze* valid irredeemable title recorded in the appropriate register of sasines" should in future give the same right as 40 years' possession upon charter and sasine under the earlier laws. These Acts also provide that the 20 years prescription is not to apply to servitudes, rights of way and public rights generally.

Negative Prescription.—This prescription was introduced by the Act of 1469, c. 28, and was substantially re-enacted by the Act of 1474, c. 55 The negative prescription accordingly extinguishes *in toto* the right to demand performance of an obligation after 40 years, the years being reckoned from the day on which fulfilment of the obligation can be first demanded. Such a lapse of this period of time creates a conclusive presumption—one incapable of being reargued—that the debt or obligation has been paid or fulfilled. But it must be kept in view that the negative prescription does not per se—without the operation of the positive-establish a right to heritable property (Erskine, *Inst.* bk. iii. tit. 7. s. 8). The negative prescription of heritable debts (Act of 1617) is reduced to 20 years without allowance for legal disability as from Jan. 1, 1930, by the Conveyancing Act 1924 (s. 17). This reduction of period does not apply to the prescription of servitudes and public rights.

United States.—Prescription in the United States though often used synonymously with adverse possession is technically confined as at common law to the acquisition of rights to incorporeal hereditaments, chiefly easements The common law doctrine of presuming a lost grant after a certain period of undisturbed enjoyment of the right prevailed in the States. Upon an analogy to the period of limitations prescribed by the Statute of James I., undisturbed enjoyment of the right for 20 years was deemed to raise the presumption of a lost grant. Some differences of opinion have prevailed as to whether the presumption is a matter only of fact and hence rebuttable or is conclusive as a matter of law, the latter view being the majority rule. Thus prescription has in many States been assimilated to the acquisition of title to land by adverse possession. Statutes have commonly dealt with prescription, abolishing the lost grant presumption and substituting the doctrine of acquisition of title through adverse possession. As at English common law the adverse use must be open and notorious and not under licence of the owner; it must be uninterrupted for the statutory period, and the right acquired is limited to the extent of the use and the enjoyment of it during the period of prescription. No easement can be acquired save as appendant to an absolute estate in land. No right to maintain a nuisance can be acquired by prescription nor can a right of user be acquired by prescription against the State.

PRESERVING AND BOTTLING, terms used for methods of saving perishable foods from moulds, yeasts and bacteria. (See FOOD PRESERVATION.) In the United States the term "canning," instead of "bottling," is used for the preservation of food in containers, whether of glass or tin, and the word "preserves" implies that sugar is added to the food material.

The application of heat in some form is one of the commonest means of destroying bacteria, yeasts and moulds, and is utilized in jam-making (see JAMS AND JELLIES), bottling, canning, pickle-making, drying and crystallizing. Pickle-making is a method of preserving in which heat, vinegar, sugar or salt, or both, are used to destroy the micro-organisms contained in fruit and vegetables. The acetic acid in the vinegar acts as an antiseptic and prevents further growth of bacteria, moulds or yeasts. Chutneys, pickles, catchups and sauces are examples of foods preserved with vinegar.

BOTTLING FRUIT

The aim when bottling is to sterilize the contents of the bottle, and having done so to prevent any germs from entering by sealing it. Bottling is one of the simplest, but most useful methods of preserving fruit and vegetables, for their character and flavour is unaltered, whereas in jam and pickle-making both taste and appearance are changed. Provided attention be paid to a few important points success is assured, and a lavish supply of peas, beans, cherries, currants, etc., is available for winter use at little cost beyond the initial expense of buying a supply of vacuum jars. These are not essential, however, for ordinary jam jars can be used, although special care and precautions must be taken to obtain an airtight seal. When bottling is done regularly it is advisable to purchase a supply of vacuum jars and a sterilizer.

Vacuum jars or bottles consist of (a) a glass container with wide neck. It should be without flaws and it is important that the rim should not be chipped; (b) a metal or glass lid; (c) a rubber band, which acts as a washer between the bottle and lid; (d) a metal screw band or clip. When bottling is carried out on a large scale special sterilizers are employed, but in the home a large zinc bath, fish kettle, bath or even a large clothes boiler or copper, can be used. As bottles are liable to crack if they are placed in immediate contact with the heated bottom of the pan some good non-conductor of heat must come between them. A simple slatted wood board to fit the copper, bath or fish kettle makes an excellent false bottom.

Selecting and Preparing the Fruit.—(I) Select sound fruit which is very slightly under-ripe, with the exception of pears, which are better bottled when fully ripe. (2) Wash to remove dust, grade according to degree of ripeness and pack neatly and firmly, using a smooth piece of wood or bone spatula. The bottle should be shaken from time to time to ensure a tight pack. Loose packing is responsible for the fruit rising when sterilized, leaving a space of one to two inches at the bottom of the jar. (3) Fill each jar with cold water and pour away. This is to rinse the fruit as it is handled during the packing process. (4) Fill the jars with syrup or water, taking care that the fruit is completely covered. The flavour is improved when syrup is used, but if sugar is scarce or unavailable water can be used. (5) Put the rubber rings, lids and screw bands or clips in position. When screw bands are used, they should be screwed down tightly and then unscrewed for rather less than a half turn to allow the steam and air to escape. (6) Stand the bottles in the sterilizer or bath, which should contain sufficient cold water to cover the bottles completely, and apply gentle heat until the correct temperature is reached. This varies according to the variety of fruit' from 125° F for small soft fruit, such as raspberries and blackberries, to 185° F for fruit salad, plums, cherries and pears. The process must not be hurried and approximately $1\frac{1}{2}$ hours should be taken in bringing the water to the correct temperature. (7) Allow the bottles to remain at this temperature for from 10 to 30 minutes. Most soft fruit requires about 1j minutes and pears and apples about 30 minutes. (8) When sterilizing is completed remove the bottles from the boiler, stand on a wooden table or some other good non-conductor, tighten the screw bands and leave until cold. (9) Next day examine the bottles to see if they are airtight. To do this, remove the screw bands and clips, hold the bottles by the lid and raise them. If the lid is firm and secure the seal is perfect. Should the lid show the slightest signs of movement or come off the seal is imperfect, and the bottle should be re-sterilized

To Make the Syrup.—Dissolve four to six pounds of sugar in a gallon of water—according to the sweetness of the fruit being bottled—bring to the boil and when cool fill the bottles.

BOTTLING VEGETABLES

Vegetables require rather more severe treatment than fruit, particularly peas and beans, as they contain nitrogen, which renders them favourable to the growth of certain micro-organisms, Prepare brine of a suitable strength by dissolving 23 oz. salt in one gallon of water and adding 5 fluid oz. or $\frac{1}{4}$ pint lemon juice, when preserving peas and beans. Boil the water, add the salt and the exact quantity of lemon juice. When cold it is ready for use.

Peas must be cleaned thoroughly by washing, and as a precaution it is advisable to soak them for 15 minutes in a weak solution of permanganate of potash. Sufficient crystals should be added to the water to produce a deep magenta colour. Remove the pods and shell the peas. Put them loosely in muslin and dip in a saucepan of boiling water for $1-1\frac{1}{2}$ minutes Then place in cold running water for about 10 minutes. Pack into the bottles and fill with acidified brine.

French and Runner Beans.—Wash the beans thoroughly, using a nail brush if necessary to remove soil from the pods; string (the runner beans will also require slicing); pack lengthways in the jars. After packing, rinse out the jars with water, cover with acidified brine and place the rubber ring, glass lid and screw band in position. (See detailed instructions for fruit bottling.) Put in the sterilizer or boiler, bring very slowly to the boil and boil for $1\frac{1}{2}$ hours. If, after the bottles have been boiling the brine has boiled away, remove the jars and fill up with boiling brine. Replace the rings and complete the cooking. Next day examine and test the seal as when fruit bottling.

CANNING

The same principles and methods are used in canning as bottling, the chief difference being that metal, and not glass, containers are used, and the method of sealing is therefore different.

Canning has the advantage that it occupies less time than bottling and less care is necessary as there is no risk of breakage. It has not been widely practised by housewives, chiefly owing to the fact that until recently soldering was necessary, a process which the majority of women found difficult. This drawback no longer exists, for a small hand sealing machine is now available which eliminates soldering. Numerous tests with the machine have been carried out and the results are invariably extremely satisfactory and reliable. In conjunction with the hand sealer, special straight sided sanitary cans with open ends must be used. The cans may be either plain or lacquered. The latter are preferable, as they prevent the acid fruit coming in contact with the tin. The outer rim of the lid has a groove which is treated with rubber solution and which acts in the same way as the flat rubber band used when fruit bottling.

Method of Canning.—(I) Wash the cans thoroughly in hot water before use. Pack with prepared fruit or vegetables, and cover entirely with boiling syrup or brine. (2) Put the lids in position and with the aid of the sealing machine close the can. As the escape of steam exhausts the air it is important to seal the can whilst very hot; therefore only two or three should be filled with boiling syrup at one time, otherwise they cool down before there is time to seal them. (3) When all the cans have been sealed, place them in any large container, such as a clothes boiler, large pan or zinc bath containing sufficient boiling water to cover them completely. (4) Bring to the boil and boil gently for 15–40 minutes, according to the fruit. Small soft fruit requires 15 minutes only, and pears from 35 to 40 minutes. The time must be calculated from the moment the water boils again after all the cans have been put in. Small bubbles rising from the can whilst it is in the water indicates that it is not airtight, and has been sealed imperfectly. The contents must be removed, put into a new can and resealed. (5) When sterilizing is complete, cool the cans quickly by placing them in a bath or sink of cold water. When cold, dry and label. (See also FOOD PRESERVATION.)

(D. D. C.-T.)

In the United States processing is the term applied to the heating of the material to a temperature and for a length of time that will kill bacteria producing spoilage, and the following methods are used: (A) Water-bath canner, in which the containers are set far enough apart to allow free circulation of the water. This must be boiling when the sealed containers are set in (glass jars being preheated to avoid breakage) and must come over the top of the containers. (B) Steam-pressure canner, in which only enough water is put to come almost to the rack on which the containers are set.

The hot-pack method of canning is recommended by the United States Department of Agriculture. The food material is first heated to boiling point in a minimum of water, is packed while boiling hot into the containers, then processed. In the cold-pack method the material is packed cold into the container (often after first being blanched), then processed. (I. E. L.)

PRESIDENCY, an administrative unit of the Indian empire. The word is derived from the title of president or chief of the council of a principal factory under the East India Company—a title which lasted until governors were appointed under act of parliament in 1784. It thence came to be applied to the three original provinces of Bengal, Madras and Bombay. It is now restricted to Madras and Bombay, in distinction to the lieutenant-governorships. In Anglo-Indian usage, "presidency" was also applied to the capital city as opposed to the country beyond, termed the "mofussil"; and this usage lingers in such phrases as "presidency town," and "presidency magistrate."

PRESIDENT, a style of title of one who presides. In classical Latin the title praeses, or president, was given to all governors of provinces, but was confined in the time of Diocletian to the procurators who, as lieutenants of the emperor, governed the smaller provinces. In this sense it survived in the middle ages. Du Cange gives instances from the capitularies of Charlemagne of the style praeses *provinciae* as applied to the count; and later examples of praeses, or praesidens, as used of royal seneschals and other officials having jurisdiction under the Crown.

In England the word survived late in this sense of royal lieutenant. Thus, John Cowell, in his Interpreter of Words (1607) defines "president" as "used in common law for the king's lieutenant in any province or function; as president of Wales, of York, of Berwick, president of the king's council." In some of the British North American colonies (New Hampshire, Pennsylvania, South Carolina) there was a president of the council, usually elected by the council; and when Pennsylvania and New Hampshire became States, one member of the executive council was called president. The chief (and single) executive head in Delaware, South Carolina and New Hampshire (1784–92) was called president.

During the revolutionary struggle in America from 1774 onwards, the presiding officer of the continental congress was styled "president" and when the present constitution of the United States was framed in 1787 (in effect 1789) the title of president was transferred to the head of the Federal Government. "President" thus became the accepted style for the elected chief of a modern republic.

In the simple sense of "one who presides" the word "president" preserved its meaning alongside the technical use implying royal delegation. In ecclesiastical terminology *praesidens* was sometimes used for the head of cathedral chapters, instead of dean or provost; and it was sometimes the title given to the principal visitor of monasteries. In Great Britain the heads of many colleges are styled "president," the title being of considerable antiquity in the case of one college at Cambridge (Queens', founded in 1448) and four at Oxford (St. John's, Magdalen, Corpus Christi, Trinity). At five Cambridge colleges (Pembroke, Gonville and Caius, St. Catherine's, St. John's, Magdalene) the title "president" is borne by the second in authority, being the equivalent of "vice-master." In the United States "president is the usual style of the head of a college and also of a university wherever this has developed out of a single college. "President" is also the style of persons elected to preside over the meetings of learned, scientific, literary and artistic academies and societies, *e.g.*, the president of the Royal Academy (P.R.A.) in London; the title of the president of the Royal Society (P.R.S.) dates from its foundation in 1660. In the United States the style "president" is also given to the person who presides over the proceedings of financial, commercial and industrial corporations (banks, railways, etc.), in Great Britain usually styled "chairman," but in the Bank of England and certain other banks "governor."

In France, besides the president of the republic, there are presidents of the senate and of the chamber of deputies. In Germany the word Priisident is used in most of the English senses of "president," *e.g.*, of a corporation, assembly or political body.

PRESLAV, a village of Bulgaria, situated on the north edge of the Balkans, south of Shumen (*q.v.*). Preslav was the second capital of the mediaeval Bulgarian tsars, and was raised to great splendour by Tsar Symeon (893–927). It was then compared to Constantinople, and described as "full of high palaces and churches, with countless stones, woods and paintings, so adorned with marble and copper, silver and gold, that the visitor knows not wherewith he shall compare it." It fell into decay on the fall of the first Bulgarian Empire, and was later plundered to adorn the new capital of Trnovo (*q.v.*). It is now a heap of ruins.

PRESOV, a town in Presov region, Czech., 25 mi. N. of Kosice. Situated on the left bank of the river Tarcza, a tributary of the Theiss, it is a very old town but has been almost entirely rebuilt since a great fire in 1857. Following the foundation of the town by German colonists in the 12th century its history has been much affected by the nodal character of its site; today it is the seat of the district authorities, the centre of a Greek Catholic diocese and an important railway junction for the Carpathians and Poland. In the neighbourhood of the town is an opal mine and mineral springs, but importance rests on its administrative functions supplemented by small manufactures. Pop. (1950) 22,843.

PRESS. For the history of the liberty or freedom of the press *see* CENSORSHIP; CIVIL LIBERTIES; also NEWSPAPER and PERIODICAL. For the punishment of "pressing" see PEINE FORTE ET DURE. For the "press gang" *see* IMPRESSMENT.

PRESS ASSOCIATION, THE, the oldest and largest news agency operating exclusively in Britain, was founded by provincial newspapers on a co-operative basis in 1868, and began active work on February 5, 1870, when the post office took over the private telegraph companies which had previously supplied the provincial papers with news. For 50 years the P.A. transmitted news by press telegrams, but in 1920 it leased private telegraph wires from the post office. Its private wire system embraces over 3,000 miles of telegraph circuits radiating from London and serving either direct or through centres at Birmingham, Bristol, Manchester, Leeds, and Glasgow, about 120 provincial morning and evening newspapers. It also operates a direct printer system to offices in London. The P.A. has always had the exclusive right to supply in the provinces Reuters' (*q.v.*) imperial and foreign news services. The two agencies are closely associated. With the Exchange Telegraph Co., Ltd., the P.A. operates in the provinces a joint telephonic service for the rapid collection and distribution of racing results, etc., and cricket and football scores.

The P.A. is governed by a board of seven directors. One new director is elected annually by the shareholders (the provincial newspapers). The association's new headquarters' building, which it occupied in July, 1939, is at 85 Fleet Street, London. From this building it supplies news to all the London daily and Sunday newspapers, provincial newspapers, and trade journals and other periodicals. (H. C. Ro.; X.)

PRESSBURG: *see* BRATISLAVA.

PRESSED METAL, a broad term which includes that class of product made by the process of bending, shaping and forming sheets, strips, plates or bars of metal in either hydraulic or mechanically-driven presses. Metal formed in this manner is referred to as "pressed metal," "stampings" or, if deformation is severe, "deeply drawn stampings." All ductile metals and alloys may be pressed and for many. it is a process of industrial importance. Great amounts of low carbon steel sheets and aluminum and aluminum alloy sheets are formed in this way. Substantial amounts of alloy steel, stainless steel, brass, bronze, copper, nickel, magnesium, zinc, titanium and zirconium are pressed.

Pressed metal is generally assumed to mean the cold forming of metal at room temperature with suitable tools in power-driven presses. However, certain metals and alloys of hexagonal close-packed atomic structure are rather poor in ductility at room temperature. Their ductility is better at elevated temperature and in moderately difficult formations both sheet and die are heated to 500° to 1,050° F. Typical examples of this type material are magnesium, zinc, titanium, zirconium and their alloys. Castings and forgings constitute the classes of metallic products that have been heavily replaced by pressed metal. Pressed metal differs from both castings and forgings in that while either a casting or forging may have a solid section of varying degrees of thickness, pressed metal has a flat or hollow form, such as a shell, the walls of which are of the same order of thickness throughout. While in some shapes and by specially constructed tools it is possible to make a wall of varying thickness, it generally follows that if the sheet of metal which is used as raw material is $\frac{1}{8}$ in. thick, the walls of the finished pressed metal form will also be substantially $\frac{1}{8}$ in. thick. However, heavily formed parts may be reduced in thickness to $\frac{3}{32}$ in. or more.

Cold forming of metal first became industrially important through its adoption by bicycle manufacturers. When bicycles became popular, pressed steel replaced forgings and castings because of the need of producing a lighter vehicle at a lower cost. Cast iron cooking utensils were soon being replaced by enameled pressed steel and later by pressed aluminum and stainless steel. The really great advance in the use of pressed metal was by the automobile manufacturers. By the early 1930s, apart from units such as the engine and front axle gears, automobiles were being made almost entirely of pressed steel. Fortunately, at the same time great advances were being made in the method of rolling sheet steel. The old method of hot rolling of individual sheets by hand feeding into rolling mills and the further hot rolling of packs of three to the finished sheet thickness, was giving way to massive wide continuous hot mills. A slab comprising $\frac{1}{3}$ of an ingot was reduced, in a series of mills in line, from the original thickness of about 4 to 5 in. to as low as $\frac{3}{32}$ in. without any reheating. At the same time powerful cold mills were developed to reduce further the thickness to the popular thicknesses of $\frac{1}{32}$ to $\frac{1}{16}$ in. The cold reduced steel was then annealed. The product of these continuous mills was considerably lower in cost, and much better in quality from the standpoint of finish, uniformity of gauge and forming quality. Concurrently aluminum was becoming available in quantity and continuous mills were being introduced in the aluminum, brass and copper industry.

Other manufacturers, finding a good supply of quality sheets and strip at lower prices and perceiving the advantage of pressed metal over castings and forgings, changed their methods so that pressed metal went into many other manufactured products It is impossible here to give a complete list, but some of the better known products are kitchen utensils, appliances, lighting fixtures. home and office furniture, filing cabinets, office equipment. vending machines, gasoline pumps, cartridge cases and much general hardware such as bolts, nuts, nails, hinges and latches. Metal pressings are extensively used in the construction of railway freight and passenger cars, highway freight trailers, jet engines and aircraft structures. Wherever a large number of individual units are demanded pressed metal has in the majority of cases been utilized.

The equipment used for the manufacture of pressed metal carries the general term of press. Presses, which vary widely in size, are of two general classes: hydraulic and mechanical. The great majority, however, are belt-driven and mechanically powered. The press furnishes the power for forming and the means of holding the tools that do the actual forming of the metal. These tools, in their simplest form, consist of an upper or male section, which is known as a punch, and the lower or female section, which is known as a die. In the actual operation a piece of metal is accurately positioned over the lower section (the die) and the upper section (the punch) is brought down by the power press, thus pushing the metal into the die and cold forming the desired shape. In many of the more complex shapes the use of these simple tools results in a part with undesirable wrinkles or buckles. In these cases an upper and lower blank holder become essential additional parts of the forming tools. The punch is surrounded by a separate upper blank holder and a mating lower blank holder is an integral part of the die. A sheet of metal is accurately positioned over the die and lower blank holder, then the upper blank holder is brought down by the power press to hold the sheet, around its periphery, against the lower blank holder. The punch next descends and forms the part. The blank-holder pressure is adjusted to restrain the metal from flowing into the die excessively and thus a part is made without wrinkles. The majority of pressed metal parts are made by several successive operations. **A** certain shape of flat blank receives the first operation in one set of tools. It is then passed along to a second press carrying a second set of tools and is trimmed or further formed, and so on through various stages of forming, trimming, flanging, sharpening of radii and piercing of holes.

It is sometimes necessary to heat-treat the metal between these various operations as cold pressing makes metal harder, stronger and less ductile. A point is therefore reached, depending on the original ductility of the metal, when further formation results in breakage. The proper heat-treatment of cold pressed metal removes the effect of cold work and restores the ductility of the original blank. The strength of a metal or alloy may be increased as much as 30% in a forming operation. In most cases this increase is desirable in the finished part so that heat-treatment is avoided if at all possible. In certain metals and alloys going into service at elevated temperature a final heat-treatment becomes necessary to eliminate embrittlement and dimensional change at operating temperature.

A pressed metal part has a smooth surface that normally requires no metal finishing or machining, while both forgings and castings require extensive machining operations. Pressed metal has replaced wood in many cases. (R. W. E. L.)

PRESSENSÉ, FRANCIS DE (1853–1914), French politician and man of letters, was born in Paris on Sept. 30, 1853, being the son of Edmond de Pressensé, and was educated at the Lycée Bonaparte. He served on General Chanzy's staff in the War of 1870, and was taken prisoner at Le Mans, but after the war entered the public service. After a short period at the ministry of public instruction he entered the diplomatic service, and was appointed first secretary at Washington. In 1882 he returned to France and took up journalism, becoming in 1888, foreign editor of the Temps. At the time of the Dreyfus case (1895) De Pressensé identified himself with the cause of the prisoner. He wrote in support of General Picquart, and in consequence of his advocacy of Émile Zola's cause was struck off the roll of the Legion of Honour. This led to his resignation from the Temps, and he came forward as a socialist politician, being in 1902 elected socialist deputy for the Rhône. He took part in the debates on the question of the separation of church and state, and a bill brought in by him formed the basis of the one finally carried by Briand.

He died in Paris on Jan. 19, 1914.

His works include Le ***Cardinal Manning*** (1896), and ***L'Irlande et l'Angleterre depuis l'acte d'union jusqu'à nos jours, 1800–1888*** (1889), besides ***many*** articles in the ***Temps,*** the ***Revue des Deux Mondes, Aurore*** and ***Humanité.***

PRESS GANG. The press gang was the name given to the naval parties who, until the beginning of the 19th century, were used forcibly to take or impress men for service in the British fleet. From medieval times the crown claimed the power to impress able-bodied subjects for the defense of the realm, and as early as the time of Edward III complaints are recorded in parliament of the excessive use of this power. From the earliest time, England depended upon her professional seamen, the merchantmen, to man her fighting ships: but it was not until the end of the 16th century that fishermen, watermen and mariners were exempted by law from being pressed as soldiers: they remained liable to impressment for service in the navy. The needs of Elizabeth I's fighting fleet became so large that the Vagrancy act was passed, rendering all "disreputable persons" liable for impressment for service in the fleet: the sheriffs and mayors being bound, upon the production of the warrant of the "takers" or "press gang," to produce the number of men required. This naturally led to jail clearance; the law remaining unaltered, throughout the 17th and 18th centuries there were constant complaints from naval officers of the quality of men supplied. In the 18th century certain exemptions were made, in the case of apprentices, a proportion of fishermen, seamen employed in the coastwise coal trade, but even at the height of Britain's maritime power, from 1780 to 1815, the press gang was the chief means of recruiting the fleet.

The action of English cruisers in pressing men from the merchant ships of the American colonies was one of the causes that led to the War of Independence. A favourite means of completing the complement of warships was by stopping homeward-bound merchantmen and removing some of their seamen. Service became so unpopular that in 1795 the press gangs and the jails failed to provide sufficient men. An act was passed directing each county to provide a quota of men, with the result that the authorities of each district handed all malcontents and agitators over to the press gangs, by whom they were taken to the guard ships stationed round the coast for drafting into the fleet. The introduction of this bad element into the navy was one of the causes of the mutiny of 1797 which nearly brought disaster to the country. The insistence of the right to press British subjects in America was one of the chief causes of the war between Great Britain and the United States in 1812.

The press gangs were not used after the close of the Napoleonic wars in 1815, although it is lawful to this day to impress men for service in the navy, though not in the army. By an act of 1835 a pressed man is exempt after five years' service and seamen in the merchant service, fishermen and certain other persons are exempted from impressment. With the introduction of the long service system in 1853 all need for impressment disappeared and since that date there have always been more volunteers than could be accepted for service in the Royal Navy. (S. T. H. W.)

PRESSING: see PEINE FORTE ET DURE.

PRESS SYNDICATE. Press syndicates are intended to spread the cost of expensive features over as many subscriber newspapers as possible. These organizations sell the exclusive rights to a feature to one subscriber in each territory in contrast to the wire news services (see NEWS AGENCY), such as the Associated Press, United Press International and Reuters, which offer their reports to all papers in a given area. The business grew enormously after 1930, especially in the United States, with its extensive area and many markets.

Irving Bacheller of Brooklyn, N.Y., started the first modern syndicate (1883) which offered and distributed fiction and household departments. In 1884 S. S. McClure founded the syndicate which still bears his name. He first offered fiction and secured the rights to several stories by Rudyard Kipling that were widely published. He also helped to introduce the stories of Sir Arthur Conan Doyle and others in the United States.

The features then offered were mostly literary material and pictures (see PHOTOGRAPHY: *Photo* Syndicates). An important change came in 1896, however, when the big New York Sunday newspapers began to produce and publish comic pages such as "Foxy Grandpa," "The Yellow Kid" (originally called "Hogan's Alley") and "Li'l Mose." In 1907 the comic strip (see CARICATURE AND CARTOON) in daily papers was introduced. Two artists, "Bud" Fisher and George Herriman, were credited with drawing the first strips. Previously a strip by Clare Briggs had a brief run in Chicago. This form of art gradually changed the whole character of the business and made it more profitable. The strips are shipped in matrix form to the subscribers for simultaneous publication. Originally they were comic, intended to make readers laugh, but later many became continued stories with no humour. When "Mutt and Jeff" by "Bud" Fisher was first bought and published in England in 1920 many British readers scoffed at the idea. However, English editors later originated many of their own strips in competition with the U.S. products. By the latter 1950s U.S. comics were translated into several languages and sold all over the world.

Before the modern syndicate was developed there had been a few sporadic efforts to distribute political and fashion letters. In 1875 A. N. Kellogg of Chicago began to sell stereotyped plates carrying literary and pictorial material to weekly papers. Kellogg was followed in this technique by Major O. J. Smith in England (1882) and by directors of political parties and factions in Germany. The Community Press Service in the 1950s distributed plates and matrices to small dailies and weeklies.

In the 1950s a great variety of material was available from press syndicates, including columns on a wide range of subjects, dress patterns, crossword puzzles with substantial prizes offered for the correct solution, etc. No single newspaper could afford to produce strips and pages for itself alone, because of the high costs. Several newspaper chains had their own syndicates which were profitable.

The leading organizations in the latter 1950s were King Features, owned by the Hearst papers; United Features, an offspring of Scripps-Howard; Bell Syndicate; A.P. Newsfeatures; General Features; and Chicago Tribune-New York News syndicate. Prominent British syndicates were Central Press, Exchange Telegraph Co.. Ltd. and Incorporated Press of Great Britain.

PRESSURE CHEMISTRY. Pressure has a pronounced influence on both the physical and chemical states of matter and on the changes that matter undergoes in industrial chemical processes. The study of this influence is pressure chemistry. The

Haber process for the synthesis of ammonia from hydrogen and nitrogen, developed in Germany prior to World War I by the Badische Anilin und Soda Fabrik, was the first industrial chemical process to use high pressure for a chemical reaction. Many other substances are manufactured under conditions which include elevated pressure. These include methanol, ethanol and other alcohols, phenol, polyethylene, amines and naphtha or gasoline from coal or gas. Pressure which ordinarily changes a gas or vapour into a liquid is used in the production of oil from wells, in purification and separation operations and in changing carbon into diamond.

Pressure performs several functions. It has an effect on some chemical reactions so that at equilibrium a greater amount of product is formed. It causes some reactions to take place at a faster rate, so that much more of the desired product is formed in a given time. It may maintain water or organic substances in a liquid state at a higher temperature than would be possible under ordinary pressure. This is beneficial in some chemical reactions.

Chemical Equilibrium.— According to H. L. Le Chatelier's principle, when a system at equilibrium is subjected to a constraint, the system will change in a manner to oppose the constraint. Thus, when a system in chemical equilibrium is subjected to pressure it will react to reduce its volume. Pressure favours a chemical reaction in which the volume of the products is less than that of the reactants. The effect of pressure on chemical equilibrium may be stated more precisely in terms derived from thermodynamics. *e.g.*, the reaction of hydrogen and nitrogen to form ammonia is favoured when it is carried out under elevated pressures. This reaction is $1/2N_2+3/2H_2 \rightleftharpoons NH_3$. Each mole of ammonia is formed from two moles of hydrogen and nitrogen and, according to Le Chatelier's principle, the reaction is favoured by elevated pressure. The fugacity f may be considered as a corrected pressure for each of the elements and compounds involved in the reaction. The ratio of the fugacities, as expressed below, must have a value fixed by the temperature according to the equation by Samuel Glasstone:

$$RT \ln\left[\frac{f\,NH_3}{f^{3/2}_{H_2}\,f^{1/2}_{N_2}}\right]=9{,}130-7.46T\ln T+3.69\times10^{-3}T^2-0.235\times10^{-6}T^3+12.07RT,$$

where R is the gas law constant in cal./(gram-mole$\times$°K.) and T is in °K. From this equation the extent to nhich the reaction proceeds may be determined. Starting with a mixture of 3 moles of hydrogen to 1 mole of nitrogen, the resulting mixture will contain 3.85% ammonia at equilibrium under 10 atm. pressure. 25.1% under 100 atm. and 79.8% under 1.000 atm., all at 400° C. This illustrates the effect of increasing pressure in forming more ammonia at equilibrium.

Pressure has a similar effect on the equilibrium between carbon monoxide and hydrogen to form methanol, according to the reaction $CO+2H_2 \rightleftharpoons CH_3OH$.

Rate of a Chemical Reaction.—A chemical reaction may reach equilibrium slowly or quickly. In many industrial processes it is important that reactions take place quickly, and pressure sometimes increases the rate of reaction.

For example, when ammonia is formed in a reactor under identical conditions except that the pressure is varied, the rate of formation is 1 mole/(hr.$\times$cu.ft. of catalyst) at 100 atm. and 10.5 mole/(hr.$\times$cu.ft.) at 300 atm., representing a 10.5-fold increase in the rate of the chemical reaction as a result of a 200 atm. increase in the pressure.

Effects on the Physical State.—A pressure of 5,000 p.s.i. (pounds per square inch) is used to maintain a mixture of chlorobenzene and sodium hydroxide solution in a single liquid phase at 360° C. Under these conditions, a reaction occurs which produces sodium phenolate. The latter is neutralized with hydrochloric acid to produce phenol. In this process the caustic soda solution and chlorinated benzene are mixed and passed through a heated pipe autoclave under pressure. The pressure increases the mutual solubility of the components of the reaction mixture and provides suitable conditions for the hydrolysis of the chlorobenzene. This illustrates the action of pressure in maintaining a liquid phase.

The phase relation between liquids and vapours in equilibrium is often complex when mixtures of several components are considered. Mixtures of hydrocarbons under pressures as high as 10,000 p.s.i. are found in oil and gas wells. Normally, a vapour phase is formed when the pressure on a liquid mixture is decreased or when the temperature is increased. A liquid is formed from a vapour by the reverse procedure.

However, for many mixtures there are limited ranges of pressure and temperature near the critical point where retrograde condensation occurs. Within these ranges a liquid phase is formed when the pressure is lowered. Repressuring operations that take advantage of this situation are conducted in the oil fields. The pressure in the underground structure is not allowed to decrease beyond a certain point. This pressure maintains a single gaseous phase underground. The single phase is brought to the surface where the pressure is reduced somewhat and a liquid phase separates. The remaining gas phase is returned to the ground to maintain the high pressure there.

Synthetic Ammonia Process.—The synthesis of ammonia is an example of a high-pressure chemical process. Pressure increases the amount of ammonia formed from hydrogen and nitrogen at equilibrium. However, the reaction takes place too slowly to be of commercial importance unless a catalyst is used. In the presence of a catalyst. increased pressure also increases the rate of reaction. The process is then commercially successful. The catalyst is iron, but the method of preparation and the nature of the iron surface on which the reaction takes place are of great importance. A smooth iron surface or iron shavings are ineffective. Other noncatalytic agents should also be present in the iron to promote its activity. A typical catalyst, before it is made active, contains 66% Fe_2O_3, 31% FeO, 1.0% K_2O and 1.8% Al_2O_3. These materials must be free from impurities which would act as catalyst poisons. The mixture is fused into a solid mass by passing an electric current through it. Then it is broken up and screened. and the -3 to $+6$ mesh (per inch) fraction is used, although it

(After A. V. Slack, H. Y. Allgood and H. E. Maune)

must be activated before it will produce ammonia. Activation consists of reducing the iron oxides by passing the hydrogen and nitrogen synthesis gas over them according to a predetermined time schedule. with gradually increasing temperature. After the catalyst is activated it cannot be exposed to air and must be kept continuously in a reducing atmosphere. Impurities such as sulphur, phosphorus and arsenic will poison the catalyst permanently. reducing its activity! while oxygen. water vapour and carbon oxides are temporary poisons and reduce the activity only as long as they are present in the synthesis gas stream.

The synthesis reaction is carried out in a large complicated pressure vessel called a converter. The catalyst is maintained at a temperature in the range from 750° to 1,050° F., according to the process and the condition of the catalyst. The high temperature is confined to the inner regions of the converter; the walls which must withstand the pressure are at a much lower temperature, not over 120° F. in some cases. The synthesis gas entering the converter is relatively cool and is heated to the reaction temperature by heat exchangers within the converter. The heat generated by the reaction in the catalyst bed must be removed to prevent overheating and damage to the catalyst.

A typical converter designed for operation in the high-pressure range, at about 1,000 atm., is a thick-walled carbon steel vessel containing a basket, or cartridge, which includes both a heat-exchanger and tubes of catalyst. (See fig. 1.) The heat exchange is carried out in the same region as the catalytic reaction. The cold incoming gas enters at the bottom and moves upward through a narrow passage between the inside of the converter wall and the cartridge, keeping the wall cool. The catalyst tubes are arranged in closely spaced concentric circles and are fitted with internal baffles to aid in removing the heat of reaction. The region outside the tubes also is provided with baffles to improve the gas flow distribution and provide local high·velocity and turbulence to improve the heat transfer. Synthesis gas enters the cartridge near the top. flows downward around the catalyst tubes and into a mixing chamber where it may he heated electrically if necessary. It then flows upward through the catalyst tubes. The reaction is rapid in the lower part of these tubes and slow in the upper part so the gas is cooled considerably before it leaves the catalyst. Each converter contains about 16.5 cu.ft. of catalyst and produces from 250 to 400 lb. of ammonia per hour per cubic foot of catalyst.

For use at lower pressures. in the range from 250 to 350 atm., the walls of the converter are made of medium-carbon steel and are kept cool by a portion of the cool synthesis gas entering at the top and flowing down through an annular space inside the converter wall. The main flow of synthesis gas enters at the bottom and, after mixing with that from above: flows upward around the tubes of a heat exchanger. There it receives heat from the hot gases which have just left the catalyst and which are flowing down inside the tubes. The catalyst is in a continuous bed above the heat exchanger, and tubes for the partially preheated synthesis gas pass up through this bed. The reacting gas flows downward through the bed.

Such a converter contains about 144 cu.ft. of catalyst and produces about So lbs. of ammonia per hour per cubic foot of catalyst. (See fig. 2.)

In the high-pressure process, hydrogen for the reaction is obtained from steam and natural gas, while the nitrogen comes from the air. The synthesis gas is prepared and then carefully purified and compressed to reaction pressure. Only a part of the hydrogen-nitrogen mixture is converted to ammonia in one pass through a converter. This ammonia is condensed and removed and the remaining gas is passed through a second converter. The unconverted gas is then mixed with make-up gas and recirculated to the first converter.

At 1,000 atm. the conversion per pass through the synthesis reactor is considerably greater than at lower pressures. Approximately one-seventh as much catalyst and converter volume is required to produce the same quantity of ammonia, and about one-fifth as much gas must be pumped and piped on the basis of actual volume at synthesis conditions. Economic factors at each plant location dictate operating conditions.

Other High-Pressure Processes.—The process for synthesizing methanol is in general similar to that for ammonia. The catalyst consists of aluminum oxides, copper and zinc oxide containing chromium. Typical operating conditions are 200 atm. and 750° F. With a similar catalyst: which is made alkaline by the addition of potassium carbonate or chromate, and at temperatures from 750° to 1,000° F. and pressures from 200 to 1,000 atm., higher alcohols are formed.

Fig. 3 shows the manufacture of phenol from chlorobenzene; the raw materials are sodium chloride brine and benzene. The brine is fed to an electrolytic cell and the chlorine produced in this cell is used to chlorinate the benzene. An 18% sodium hydroxide solution derived from the cell is mixed with the chlorobenzene; this mixture is raised to a pressure of 5,000 p.s.i. and passed through a continuous-pipe pressure reactor constructed of 2 in. diameter pipe in long coils in a furnace. This mixture is heated to 360° C.; the pressure maintains a single phase and increases the mutual solubility of the ingredients; the hydrolysis reaction takes place, and sodium phenolate is formed. The sodium phenolate is neutralized with hydrochloric acid, regenerating a salt brine, and the phenol is distilled from the mixture.

The successful synthesis of diamonds was announced by the General Electric company in 1955. Diamonds are a crystalline form of pure carbon. They are formed when carbon is subjected to extremely high pressure and high temperature for sufficient

FIG. 3.—FLOW SHEET OF A COMMERCIAL PROCESS FOR MANUFACTURING PHENOL FROM CHLOROBENZENE AT 5,000 LB. PER SQUARE INCH

time. The details of the synthesis mere not revealed but P. W. Bridgman stated that pressures of more than 100,000 atm. and temperatures of 2,500° C. were maintained for hours at a time.

Equipment. — Chemical reactions are carried out in steel or alloy vessels at high pressure. In continuous processes high-pressure tubing, fittings and compressors are required. Closures and fittings are frequently of a special design so that the internal pressure assists in making a tight seal. A large number of designs are available for high-pressure equipment to be used under a variety of special conditions.

A variety of alloys are often used in a single piece of equipment. The wall of an ammonia converter, for example, may be selected to resist the high internal pressure at low temperature, while the liner material may be chosen to resist the corrosive action of the contents. The catalyst tubes may be selected to resist the combined action of high temperature, hydrogen and nitrogen, but not to confine the high pressure.

At high pressure both hydrogen and nitrogen attack steel and certain alloys. Hydrogen apparently is absorbed on the surface of steel. It ionizes and the protons pass through the openings of the metal lattice. They slowly react nith carbon in the steel to form methane, which accumulates at the grain boundaries. The internal pressure built up by the methane forces the grains apart, resulting in such permanent damage as intercrystalline cracking, fissuring, blistering and decarburization.

The introduction of strong carbide-forming elements such as titanium and vanadium has helped materially to reduce the effects of hydrogen. Austenitic stainless steels and beryllium-copper are examples of alloys which do not seem to be subject to hydrogen attack.

PRESSURE GAUGE, in general terms, an instrument or instrument system for measuring pressures of gases and liquids. Types of pressure gauges include vacuum gauges (see VACUUM: *Measurement* of *Low* Pressures), barometers, manometers and dead weight piston gauges, as well as the more common Bourdon tube gauges. Also included is equipment for measuring rapidly changing pressures such as engine indicators, or piezoelectric crystal pickups or other pressure transducers, arranged to indicate or record pressure variations by use of an oscillograph, or other means. Pressure gauges may indicate or record pressure at the location of the pressure-sensing element, or pressure information may be transmitted to a remote point for observation.

Pressure gauges are available for accurate measurement of the minute pressures existing in vacuum systems, to pressures of several hundred thousand pounds per square inch necessary in research and some industrial processes. Various types of instruments are specifically designed for making measurements of pressures over a wide range of pressure rate-of-change, from static or slowly changing pressures. such as atmospheric pressure, to the very rapidly changing pressure transients of explosions.

Pressure gauges may be designed for measurement of absolute pressure, gauge pressure or differential pressure as explained below. Pressure measurement is of primary importance in the chemical process industry, in power plants, aeronautics and meteorology.

Industrial Gauges. — The present article is limited primarily to a treatment of pressure gauges used industrially, with only mention of the broader variety of gauges used in scientific research and development.

The pressure element of the majority of mechanical pressure gauges is usually in one of three forms: a Bourdon tube; a corrugated diaphragm or diaphragm capsule; or a bellows. Of these the Bourdon tube type is the most common.

Bourdon Tube. — The Bourdon gauge is one in which the pressure is indicated directly by an attached pointer and scale. The Bourdon tube is elliptical or flattened in cross section and bent into circular form. One end is soldered to a central block through which the fluid enters. and the other end is sealed and coupled by a link to a pivoted quadrant with teeth meshing with those of a pinion on the pointer spindle. Backlash between the teeth is absorbed by a hairspring exerting constant force on the pinion. An increase of pressure uithin the tube tends to change its cross section from elliptical to circular, and the tube consequently uncoils slightly, thus turning the pointer.

If the case enclosing the gauge is made airtight and the air is exhausted from within the case, the gauge measures absolute pressure (psia or pounds per square inch absolute); if the pressure inlet of such a gauge is then opened to the atmosphere the gauge would read atmospheric pressure, approximately 14.7 psia. If the airtight case is provided with a pressure inlet the gauge may be used to measure differential pressures existing betneen two sources of pressure connected to the two pressure inlets. Usually the case of the gauge is not airtight and the external surface of the Bourdon tube is thus subjected to ambient atmospheric pressure. Such a gauge measures "gage" pressure (psig or pounds per square inch gauge). *i.e.,* the value of the inlet pressure above atmospheric pressure. This instrument may be used as a vacuum gauge, measuring pressure, below atmospheric pressure; the reduction in pressure causes the Bourdon tube to coil further, and the mechanism must be arranged in reverse fashion to cause the pointer to move clockwise with increasing vacuum. A compound gauge reads for both pressure and vacuum. the dial markings for vacuum being placed to the left of the zero of the pressure scale.

Diaphragm Capsule. — One direct-reading gauge utilizes as the elastic pressure-sensitive element a hollow sealed disk-shaped capsule made from two corrugated metal diaphragms. Changes in pressure cause motion of the centre of the capsule, and this motion is amplified by a mechanical linkage to control movement of the pointer over a calibrated dial. When proper precautions are taken in design to reduce hysteresis, temperature effects and the like, sustained accuracies on the order of two or three parts in 1,000, or better, are obtainable.

For measurement of absolute pressure, as in the aneroid barometer, the capsule is evacuated. and the varying atmospheric pressure acts on the exterior surface of the capsule. A spring is arranged to supplement the elastic resistance of the capsule to the force of atmospheric pressure, and the motion of the centre of the capsule is transmitted to the indicating pointer by appropriate linkage.

Bellows.—A metal bellows may be used in a pressure gauge designed for pressure ranges of from a few inches of water (*i.e.,* the pressure produced by a column of water a few inches high) to 10 or 15 lb. per square inch. The large deflection of the bellows for small pressure changes provides the high sensitivity needed in gauges for such low-pressure ranges.

Materials. — Bourdon tubes are commonly of phosphor-bronze, beryllium-copper or Monel metal (a nickel-copper alloy), for pressures up to a few hundred pounds per square inch; above this pressure or for elevated temperatures. the tubes are made of steel to obtain a greater elastic range and a smaller change of elasticity with temperature. Diaphragms are most frequently made of phosphor-bronze, beryllium-copper or Ni-Span (a nickel-tin alloy). Bellows are usually of brass although bellows of stainless steel and beryllium copper are also available.

Reading Instruments. — All of these gauges are also available in designs to provide a continuous record of pressure. A circular-chart gauge, comprising a Bourdon element of several complete turns, has a pen arranged to trace a record on a circular chart driven by clock work. A microbarograph records absolute atmospheric pressure on a paper strip wound around a drum driven by clockwork. The necessary high sensitivity is obtained by use of an evacuated bellows element whose motion is magnified by the pen linkage. The pressure range of the instrument is generally 28.5 to 31 in. of mercury (about 14 psia to 15.2 psia), for which range the recording pen moves about 6 in.

Remote Indicators. — For remote indication of pressure, or for control purposes, the pressure is often converted into an analogue quantity. This quantity is commonly a direct current voltage or an air pressure. Direct current voltage is used frequently in telemetering systems, and air pressure in industrial recording and control equipment.

One such instrument, designed for use in measuring the pressure at points remote from a pressure recorder, has the elastic motion of a hollow metal cylinder exposed to the pressure arranged to vary the electrical resistance of strain gauges attached to the surface of the cylinder. The strain gauges are connected in a bridge circuit in such a way that the bridge output voltage varies in a linear fashion over the range from zero to perhaps jo millivolts as the cylinder pressure varies from zero to the rated pressure of the instrument, the rated pressure being from a few hundred psig to 50,000 psig. The output voltage, proportional to the pressure, may be recorded or displayed by use of appropriate electrical instruments. For rapidly changing pressures, to which this instrument will respond, the output voltage is usually recorded by use of an oscillograph.

A common system is that in which the pressure to be measured is converted by use of a force-balance mechanism into an analogue pneumatic pressure in the range 3 to 1j psig. The instrument may be adjusted to have an input pressure range from a small fraction of the analogue pressure range to several times the analogue pressure range. The analogue pressure may be transmitted to a remote location and connected to an indicator, recorder, or used for control purposes. The pressure-sensitive element of the pressure transmitter is a diaphragm acting against a coil spring. Slight motion of the diaphragm due to change in pressure causes a relatively large change in the pneumatic pressure in the force-balance bellows assisting the spring, and the analogue pressure is the pressure in the bellows necessary to maintain the diaphragm near its mid-position. The permitted motion of the force-balance bellows and of the diaphragm and main spring is extremely small, and the system is characterized by high sensitivity and low hysteresis.

Other methods for converting the motion of a mechanical pressure element to an analogue voltage include the use of variable resistors (potentiometers). differential transformers, variable capacitances and variable inductance or variable reluctance devices. In another method the motion of a diaphragm varies the tension, and thus the frequency, of a vibrating wire maintained in motion by a magnetic field acting on an alternating current passing through the wire. The pressure is then represented by an electrical frequency equal to the wire frequency.

Primary Pressure Gauges.—A11 instruments of the types described above require calibration against known pressures. The two principal instruments used for such calibration are liquid column instruments such as the manometer and barometer (*q.v.*) and dead-weight piston gauges.

A dead-weight piston gauge, comprises a vertical cylinder, the upper end of which is closed by a weight-loaded piston. The cylinder is filled with oil, and a pressure connection is provided at the lower end to which an instrument under test may be connected. A pump, operated by a handwheel, is provided to adjust the volume and pressure of the system so that the weight-loaded piston assumes a floating position in the cylinder. The pressure developed by a dead-weight piston gauge is nominally equal to the weight of the piston and its load divided by the cross-sectional area of the piston.

Such instruments are capable of high precision, on the order of one part in 10,000, or better; when precision greater than about one part in 200 is desired corrections must be made including corrections for a number of environmental variables. The following are the most important corrections that must be considered: change in effective piston area due to temperature changes, amounting to 10 to 20 parts per million per degree Centigrade; difference in value of local gravity from standard value of 980.665 cm./sec./sec., amounting to more than one part in 1,000 in some localities; variation in effective area of piston due to elastic distortion of piston and cylinder under pressure, amounting to perhaps 100 parts per million per 1,000 psi in some designs; the buoyancy of the liquid on submerged protuberances of the piston, applicable only for pistons of nonuniform cross-sectional area: the hydrostatic head of liquid between the bottom of the piston and the point of pressure measurement; and the buoyancy of air on the weights, frequently amounting to about one part in 7,000.

For high accuracy at high pressures the controlled clearance piston gauge has been developed, in which a variable hydrostatic pressure is applied to the exterior surface of the cylinder to reduce errors due to elastic distortion.

For pressures below about jo psig piston gauges are available in which the working fluid is air, and the piston and cylinder operate as an air bearing.

PRESTEIGNE, an urban district and the county town of Radnorshire in the Brecon and Radnor parliamentary division of Radnorshire, Wales, 26 mi. N.W. of Hereford by road and on the Lugg, which there forms the boundary between Wales and England. Pop. (1951) 1,255. Area 4.3 sq.mi. The village, lying on the English side of Offa's dyke, was in the lordship of Moelynaidd until the 14th century, when Bishop David Martin of St. David's (1296–1328) conferred market privileges upon his native place. There is an annual May fair.

In 1542 Presteigne was named as the meeting place of the county sessions for Radnorshire in conjunction with New Radnor; a winter and summer assize court is held. It has the fine parish church of St. Andrew, dating chiefly from the 1jth century but with traces of Norman work; curfew is rung from it at eight o'clock every evening.

Presteigne is the most easterly spot on the Welsh border; hence the expression "from St. David's to Presteigne.!' The main industries are agriculture and forestry.

PRESTER JOHN, a fabulous medieval Christian monarch of Asia. The history of Prester John no doubt originally gathered round some nucleus of fact, though what that was is extremely difficult to determine. Before Prester John appears upon the scene we find the way prepared for his appearance by a kindred fable, which entwined itself with the legends about him. This is the story of the appearance at Rome (1122), in the pontificate of Calixtus II, of a certain oriental ecclesiastic, whom one account styles "John, the patriarch of the Indians." and another "an archbishop of India." This ecclesiastic related wonderful stories of the shrine of St. Thomas in India, and of the miracles wrought there by the body of the apostle, including the distribution of the sacramental wafer by his hand.

Nearly a quarter of a century later Prester John appears upon the scene, in the character of a Christian conqueror and potentate who combined the characters of priest and king, and ruled over vast dominions in the far east. This idea was universal in Europe from about the middle of the 12th century to the end of the 13th or beginning of the 14th.

The Asiatic story then died away, but the name remained, and the royal presbyter mas now assigned a locus in Ethiopia. Indeed, it is not improbable that from a very early date the title was assigned to the Abyssinian king, though for a time this identification was overshadowed by the prevalence of the Asiatic legend. At the bottom of the double allocation there was, no doubt, that confusion of Ethiopia with India which is as old as Virgil and perhaps older.

The first mention of Prester John occurs in the chronicle of Otto. bishop of Freisingen. This writer states that when at the papal court in 1145 he met with the bishop of Gabala (Jibal in Syria). who related how "not many years before one John, king and priest (*rex* et sacerdos), who dwelt in the extreme Orient beyond Persia and Armenia, and mas, with his people, a Christian but a Nestorian, had made war against the brother kings of the Persians and Medes, who mere called Samiards (or Sanjards), and captured Echatana their capital. After this victory Presbyter *John*—for so he was wont to be styled—advanced to fight for the Church at Jerusalem; but when he arrived at the Tigris and found no means of transport for his army, he turned northward, as he had heard that the river in that quarter was frozen over in wintertime. After halting on its banks for some years in expectation of a frost he was obliged to return home."

About 1165, a letter was circulated purporting to be addressed by Prester John to the emperor Manuel. This letter, professing to come from "Presbyter Joannes, by the power and virtue of God and of the Lord Jesus Christ, Lord of Lords," claimed that he was the greatest monarch under heaven, as well as a devout Christian. The letter dealt at length with the wonders of his empire. It was his desire to visit the Holy Sepulchre with a great host, and to subdue the enemies of the Cross. Seventy-two kings, reigning over as many kingdoms, were his tributaries. His empire extended over the three Indies, including that Farther India, where lay the body of St. Thomas, to the sun rising, and back again down the slope to the ruins of Babylon and the toner of Babel. All the wild beasts and monstrous creatures commemorated in current legend were to be found in his dominions, as well as all the wild and eccentric races of men of whom strange stories were told, including those unclean nations whom Alexander the Great walled up among the mountains of the north and who were to come forth at the latter day—and so were the Amazons and the Brahmans. His dominions contained the monstrous ants that dug gold and the fish that gave the purple; they produced all manner of precious stones and all the famous aromatics. Within them was found the Fountain of Youth. the pebbles which give light, restore sight and render the possessor invisible; the Sea of Sand was there, stored with fish of wondrous savour, and the River of Stones was there also, besides a subterranean stream whose sands were of gems. His territory produced the worm called "salamander," which lived in fire and which wrought itself an incombustible envelope from which were manufactured robes for the presbyter. which were washed in flaming fire.

In war 13 great crosses made of gold and jewels were carried in wagons before Prester John as his standards. and each was followed by 10.000 knights and 100,000 footmen. There were no poor in his dominions, no thief or robber, no flatterer or miser, no dissensions, no lies and no vices. His palace was built after the plan of that which St. Thomas erected for the Indian king Gondopharus. Before it was a marvellous mirror erected on a many-storied pedestal; in this speculum he could discern everything that went on throughout his dominions, and detect conspiracies.

Prester John was served by 7 kings at a time, by 60 dukes and 365 counts; 12 archbishops sat on his right hand, and 20 bishops on his left, besides the patriarch of St. Thomas's the protopope of the Sarmagantians (Samarcand?), and the archprotopope of Susa. where the royal residence was. Should it be asked why, with all this power and splendour, he calls himself merely "presbyter." this is because of his humility, and because it was not fitting for one whose chamberlain was a bishop and king, and whose chief cook was an abbot and king, to be called by such titles as these.

How great was the popularity and diffusion of this letter may be judged in some degree from the fact that Friedrich Zarncke in his treatise on Prester John gives a list of close on 100 manuscripts of it. Of these 8 were preserved in the British Museum, 10 at Vienna, 13 in the great Paris library, 1j at Munich. There are also several renderings in old German verse.

Many circumstances of the time tended to render such a letter acceptable. Christendom would welcome gladly the intelligence of a counterpoise arising so unexpectedly to the Mohammedan power, and the statements of the letter itself combined a reference to and corroboration of all the romantic figments concerning Asia which already fed the curiosity of Europe, which figured in the world maps and filled that fabulous history of Alexander which for nearly a thousand years supplanted the real history of the Macedonian throughout Europe and western Asia.

The only other surviving document of the 12th century bearing on this subject is a letter of which manuscript copies are preserved in the Cambridge and Paris libraries. and which is also included in medieval chronicles. It is a letter purporting to be written by Pope Alexander III on Sept. 22, 1177, to *carissimo* **in** *Christo filio Johanni, illustro et magnifico indorum* regi. The pope recites how he had heard of the monarch's Christian profession. diligence in good works and piety by various narrators and common report, but also more particularly from his physician and confidant Philip, who had received information from honourable persons of the monarch's kingdom, with whom he had intercourse in those (eastern) parts.

Philip had also reported the king's anxiety for instruction in Catholic discipline and for reconciliation with the apostolic see in regard to all discrepancies, and his desire to have a church in Rome and an altar at Jerusalem. The pope goes on to say that he mould dispatch Philip to communicate instruction to him. And on accepting Philip's communications the king should send back honourable persons bearing sealed letters, in which his wishes should be fully set forth. "The more nobly and magnanimously thou conductest thyself, and the less thou vauntest of thy wealth and power, the more readily shall we regard thy wishes both as to the concession of a church in the city and of altars in the church of SS. Peter and Paul, and in the church of the Lord's supper at Jerusalem, and as to other reasonable requests," the letter advises the king. There is no express mention of the title "Prester John" in nhat seem the more genuine copies of the letter. But the address and the warning against a boastful spirit in the passage quoted above (which evidently alludes to the vaunting epistle of 1165) indicate that the pope supposed himself to be addressing the author of that letter.

It is not known how far the imaginations about Prester John retained their vitality in 1221, 44 years after the letter allegedly written by Pope Alexander, for there was no mention of Prester John in the interval. In that year a rumour came out of the east that a great Christian conqueror was taking the hated Moslems in reverse and sneeping away their power. The name ascribed to the conqueror was David, and some called him the son or the grandson of Prester John of India. The conqueror was in fact the famous Jenghiz Khan: but the delusion was slowly dissipated.

European travelers in Asia looked for a prince to whom the legend of Prester John could be attached. Carpini (1248) makes him the king of the Christians of India the Greater; Rubruquis (1253) gives the title of "King John" to Kushluk, king of the Naimans, and makes him a brother of Ung Khan (d. 1203), the ally of Jenghiz. In Marco Polo's narrative "Unc Khan," alias Prester John, is the lord of the Tatars up to the advent of Jenghiz Khan. This story is repeated by other writers. Both Marco Polo and Friar John of Montecorvino speak of the descendants of Prester John as holding territory in the plain of Kuku Khotan (about 300 mi. northwest of Peking). Friar Odoric gives a circumstantial account of this kingdom, and with this Prester John disappears from Asia to figure in African legend.

It is indeed probable that, however vague may have been the ideas of Pope Alexander III respecting the geographical position of the potentate whom he addressed from Venice in 1177, the only real person to whom the letter can have been sent was the king of Abyssinia. The "honourable persons of the monarch's kingdom" whom Philip had met with in the east must have been the representatives of some real power, and not of a phantom. It must have been a real king who professed to desire reconciliation with the Catholic Church and the assignation of a church at Rome and of an altar at Jerusalem.

Moreover. we know that the Ethiopic Church did long possess a chapel and altar in the Church of the Holy Sepulchre, and, though we have been unable to find travelers' testimony to this older than about 1497, it is quite possible that the appropriation may have originated much earlier. We know from Marco Polo that about a century after the date of Pope Alexander's epistle a mission was sent by the king of Abyssinia to Jerusalem to make offerings on his part at the Church of the Sepulchre; and it is extremely likely that the princes of the "Christian families" who had got possession of the throne of northern Abyssinia should have wished to strengthen themselves by a connection with European Christendom, and to establish relations with Jerusalem, then in Christian hands.

From the 14th century onward Prester John had found his seat in Abyssinia. It is there that Fra Mauro's great map (1459) presents a fine city with the rubric, "Qui il Preste Janni fa residentia principal." When. nearer the end of the century (1481–1495), King John II of Portugal was prosecuting inquiries regarding access to India his first object was to open communication with "Prester John of the Indies." nho nas understood to be a Christian potentate in Africa. When Vasco da Gama went on his voyage from Mozambique northward he began to hear of "Preste Joham" as reigning in the interior — or rather, probably, by the light of his preconceptions of the existence of that personage in East Africa he thus interpreted what was told him.

More than 20 years later, when the first book on Abyssinia was composed — that of Alvarez—the title designating the king of Abyssinia is "Prester John," or simply "the Preste."

Bibliography.—For the older aspects of the subject, *see* Ludolf's *Historia Aethiopica* and its *Commentary,* passim. The excellent remarks of M. d'hvezac, comprising a conspectus of almost the whole essence of the subject, are in the *Recueil de voyages et de mémoires* published by the Société de Géographie, iv, 547–564 (Paris, 1839). Two German works of importance which have been used in this article are the interesting and suggestive *Der Presbyter Johannes in Sage und Geschichte,* by Gustav Oppert (2nd ed., Berlin, 1870), and, most important of all in its learned, careful and critical collection and discussion of all the passages bearing on the subject, *Der Priester Johannes,* by Friedrich Zarncke of Leipzig (1876–79). *See* also Sir H. Yule's *Cathay* and *the Way Thither,* p. 173 *seq.,* and in *Marco Polo* (2nd ed.), i, 229–233, ii, 539–543.

PRESTIDIGITATION: *see* Conjuring.

PRESTO (Ital., "ready, nimble") in music denotes an extremely high rate of speed, exceeded only by its own superlative, prestissimo. The term is occasionally applied to any passage or movement in very fast tempo.

PRESTON, ANN (1813–1872), U.S. physician, reformer and educator. who was a pioneer in medical education for women, was born in Westgrove, Pa.. Dec. 1. 1813. the daughter of a Quaker minister. Although at an early age she assumed the responsibility of caring for her invalid mother and six brothers, she found time to join the local literary society, and to write poetry. She published *Cousin Ann's Stories for Children* in 1848. She also joined the abolition, temperance and woman's rights movements and served as secretary of the Clarkson Anti-Slavery society, and as secretary (1848) of the Woman's Temperance convention of Chester county. She was sent as a delegate to the state legislature in 1848, to argue for temperance legislation.

Interested in medical problems, Ann Preston was preparing herself to lecture on physiology and hygiene when she heard that the Woman's Medical college was to be opened in Philadelphia. Deciding that a medical career offered a more useful and satisfying life, she dropped her lecture plans and enrolled with the first class, graduating in 1852. In the following year she was named professor of physiology and hygiene, the first woman to be appointed to the faculty of the Woman's Medical college.

Because her women students were barred from internships in the Philadelphia hospitals and unable to obtain clinical experience. Ann Preston undertook the task of establishing a hospital for women, staffed by women physicians. Her efforts were successful, and in 1861 the Woman's Hospital was established in Philadelphia. She served as consulting physician, corresponding secretary and member of the board of managers, and in 1866 was made the 'first dean of the college.

Her distinguished work as a physician lent weight to her defense of the right of women to practise medicine and added validity to her vigorous reply. made in 1867, to the Philadelphia County Medical society's resolution condemning women physicians. In her answer she said: "We must protest against the injustice which places difficulties in our way — not because we are ignorant or pretentious, or incompetent or unmindful of the code of medical or Christian ethics, but because we are women."

Ann Preston died in Philadelphia on April 18. 1872.

See F. E. Willard and M. A. Livermore, *A Woman of the Century* (1893).

PRESTON, HARRIET WATERS (1836–1911), U.S. author and translator, who was an authority on Provençal literature, mas born at Danvers. Mass., on Aug. 6, 1836. Educated privately, she lived in Europe for a number of years and traveled in England, France and Italy. In the United States she contributed articles to various periodicals and in 1868 published *Portraits of Celebrated Women,* a translation from C. A. Sainte-Beuve's nork in French.

Harriet Preston's translation of Frédéric Mistral's *Mirèio,* a Provencal poem, later won wide critical acclaim. Other contributions in Provençal literature were *Troubadours and Trouvères* (1876) and "The Troubadours 1090–1290" in C. D. Warner's *Library of tlze World's Best Literature,* vol. 20 (1897). She nrote a novel on New England life, *A Year in Eden* (1887), but is not remembered for her fiction.

With Louise Preston Dodge. a niece, she published *The Private Life of the Romans* in 1893. She had previously translated from the French, Paul de Musset's *The Georgics of Virgil* (1881) and also contributed translations from a number of Roman poets to volume 21 of Warner's *Library* (1897).

Other translations included *Memoirs of Madame Des-bordes Valmore,* by Sainte-Eeuve, and Paul de Musset's biography of Alfred de Musset (1877). She edited *The Complete Poetical Works of Elizabeth Barrett Browning* (1900). Harriet Preston died at Cambridge, Mass., on May 14, 1911.

PRESTON, THOMAS (1860–1900), Irish physicist, who made a number of interesting original contributions on heat. magnetism and spectroscopy, and carried out experiments on the influence of magnetic fields on spectral lines. was born in Kilmore, County Armagh, Ire., on May 23, 1860. He studied in Dublin and became professor of natural philosophy in University college, Dublin, in 1891. He mas elected a fellow of the Royal society of London in 1898. The same year Preston discovered an empirical rule concerning types and structures of P. Zeeman's patterns which contributed to the solution of a definite problem in spectroscopy.

He wrote two remarkable textbooks of a high standard, *The Theory of Light* (1890) and *The Theory of Heat* (1894), both of which continued to appear in revised form long after his death, the first reaching a fifth edition in 1928 and the second a fourth edition in 1929. Preston died in Dublin on March 7, 1900.

(D. McK.)

PRESTON, a municipal, county and parliamentary borough and port of Lancashire, Eng., 21 mi. S.S.E. of Lancaster. Pop. (1961) 113,208. Area 8.9 sq.mi. It is built on a ridge rising above the Ribble where that river is crossed (about 15 mi. above its mouth) by the west coast road and railway to Scotland. It is the administrative centre of the county of Lancashire.

From early days its geographical position made it a trade centre with an agricultural market. Its importance progressively increased after the advent of the cotton industry, to which have been added a wide range of manufactures including engineering. aircraft and vehicles, chemicals and soap, boilers and ships, paper, electrical appliances, textiles and optical goods.

Preston became an independent port in 1843, the corporation acquiring the docks in 1883. The main wet dock is 3,240 ft. long and 600 ft. wide. There is a total quayage of 8,500 ft. and the depth of the channel at ordinary spring tides is 22–25 ft.

Preston is the chief mart for the produce of the great Fylde agricultural district, with two large covered markets: for general produce (wholesale and retail) ; and for fish. There are also corn, butter and egg markets and a wholesale fish market at the railway station. The important cattle market holds thrice-weekly sales throughout the year. There are horse sales each month.

The numerous parish churches include that of St. John (18; 5) which occupies a site that has carried a church' from early times. Among several Roman Catholic churches is that of St. Walburge (1854). The town hall was almost destroyed by fire in 1947. The Harris art gallery, library and museum were established by the trustees of E. R. Harris in 1879, and a new building was opened in 1893. This contains William Shepherd's library, the Francis Thompson collection and the Spencer collection of children's books, the Newsham collection of pictures and collections of pottery, glass, costumes, etc. The grammar school, dating from 1550

(Preston had a schoolmaster as early as 1339) is housed in a modern building in Moor park. The parliamentary borough returns two members. The county borough was created in 1889.

History.— Preston, otherwise Prestune. was near the Roman station at Walton-le-Dale, and the great Roman road running from Warrington passed through it. It is mentioned in Domesday Book as one of Earl Tostig's possessions which had fallen to Roger de Poictou, and on his defection it was forfeited to the crown. Henry II (about 1179) granted the burgesses a charter—the first of 14 royal charters granted to Preston (there is evidence of an even earlier charter of 1100–01). Elizabeth I (1j66) granted the town its great charter which ratified and extended all previous grants. Charles II (1662 and 1685) granted charters, by which an additional weekly market on Wednesday was conceded and a three-day fair, beginning on March 16. The most important industry used to be woollen weaving. Other early industries were glovemaking and linen weaving. The first cotton-spinning mill was built in 1777 in Moor lane, and in 1791 John Horrocks built the Yellow factory. In 183j there were 40 factories, chiefly spinning, yielding 70,000 Ib. of cotton yarn weekly.

A guild existed perhaps in Saxon times, but the grant of a guild merchant dates from Henry II's charter, about 1179. The first guild of which there was any record was celebrated in 1328, at which time it was decided to hold a guild every 20 years. Up to 1542 they do not appear to have been regularly celebrated, but after that year they were held at regular intervals of 20 years except that the 1942 guild was postponed because of World War II. The mayor elected for the year in which the guild is held is known as the guild mayor. The first mention of a procession at the guild is in 1500. One of the most important items of business was the enrolling of freemen, and the guild rolls are records of the population. The statement that Preston was burned in 1323 by the Scots is probably false. The town suffered severely from the Black Death (1349–50), and again from pestilence in the year Nov. 1630 to Nov. 1631. During the Civil War Preston became the Lancashire royalist headquarters. In Feb. 1643 a parliamentary force marched from Manchester and successfully assaulted it, but in March the earl of Derby recaptured the town. The royalists did not garrison it, but after demolishing the greater part of the works left it unfortified. After the battle of Marston Moor Prince Rupert marched through Preston in Sept. 1644 and carried the mayor and bailiffs prisoners to Skipton castle. On Aug. 17. 1648, the royalist forces under the duke of Hamilton and Gen. Marmaduke Langdale were defeated at Preston by Cromwell. During the rebellion of 171j the rebel forces entered Preston Nov. 9. and after proclaiming the chevalier de St. George king, remained there for several days, during which the government forces advanced. The town was assaulted, and on Nov. 14, Gen. Thomas Forster surrendered his army to the king's forces. In 1745 Prince Charles Edward marched through on the way south and north. The borough returned two members from 129j to 1331, then ceased to exercise the privilege till 1529, but after that date (except in 16j3) it always sent two representatives to parliament. In the 18th century Preston had a high reputation as a centre of fashionable society, and earned the epithet still familiarly associated with it, "proud." Sir Richard Arkwright (1732–92) was born there.

See H. Fishwick, *History of the Parish of Preston* (1900); W. F. Fitzgerald, "The Ribble Basin," *Journ., Manchester Geog. Sac.* (1927).

PRESTONPANS, a small burgh and seaside resort of East Lothian, Scot., on the Firth of Forth, 9 mi. E. of Edinburgh by road. Pop. (1951) 2,907. The name refers to the pans. or ponds, in which the priests of Newbattle abbey (a 1zth-century Cistercian foundation now a college for adult education) made salt by evaporation.

The chief occupation is coal mining, and there are manufactures of firebricks, tiles and pottery, besides brewing and soapmaking. Fisheries are less important than formerly. There are harbours at Morrison's Haven to the west and at Cockenzie and Port Seton to the northeast, which form one small burgh with a population (1951) of 3,180.

A mile to the east of the village is the site of the battle of 1745, in which Prince Charles Edward and his Highlanders gained a complete victory over the royal forces under Sir John Cope.

PRESTWICH, SIR JOSEPH (1812–1896), English geologist, was born at Clapham, Surrey, on March 12, 1812. He was educated in Paris. Reading and at University College, London. He was a wine merchant in London, and devoted his leisure more especially to the study of the Thames basin. In 1853 he was elected F.R.S.

Prestwich published in 1851 *A Geological Inquiry Respecting the Water-Bearing Strata of the Country Around London,* which became a standard authority. With Hugh Falconer and Sir John Evans, Prestwich examined the implements discovered by Boucher de Perthes in the gravels of the Somme valley; their investigations proved that man existed contemporaneously with the Pleistocene mammalia (*Phil. Trans.,* 1861 and 1864). In 1874 Prestwich was appointed to the chair of geology at Oxford. During his professorship he wrote his great work. *Geology: Chemical, Physical and Stratigraphical* (vol. i, 1886); vol. ii, 1888). He died on June 23, 1896, at Shoreham.

See Life and Letters of Sir Joseph Prestwich, ed. by his wife (1899).

PRESTWICH, a municipal borough in the Middleton and Prestwich parliamentary division. Lancashire, Eng., 4 mi. N.W. of Manchester by road. Pop. (1961) 34,191. Area 3.8 sq.mi. It has cotton and rayon mills but is mainly residential. It is contiguous with the cities of Manchester and Salford. It was incorporated in 1939. There are traces of the Roman occupation but the place name is of Anglo-Saxon origin. The present parish church dates from the 15th century.

PRETORIA, city in the Transvaal province and administrative capital of South Africa. Pop. (1960) 298.632 (including 154.789 Europeans, 4,852 Asiatics, 7,167 coloured [mixed] and 131,824 natives).

BY COURTESY OF SOUTH AFRICAN TOURIST CORP

THE RAADSAAL. OVERLOOKING CHURCH SQUARE. CENTRE OF PRETORIA. BEFORE THE SOUTH AFRICAN WAR THE RAADSAAL HOUSED THE LEGISLATURE OF THE SOUTH AFRICAN REPUBLIC. AFTER UNION (1910) IT BECAME THE SEAT OF THE TRANSVAAL PROVINCIAL COUNCIL

The city is built in a hollow about the Apies river, a tributary of the Limpopo. The central area of Pretoria is laid out in rectangular blocks. At the centre is Church square. on the south side of which are the provincial council buildings and other public offices. erected in 1892 in the Renaissance style. On the north side are the Palace of Justice and the headquarters of the South African Reserve bank, and on the west. the post office. The Union government building. built in 1910–13 on Meintjes' Kop, cost £1.800.000

and overlooks the city. The lower slopes of the hill are laid out in beautiful terraced gardens in which stands the statue of Louis Botha, the Union's first prime minister. Pres. Paul Kruger's house was excellently restored and has been declared a national monument. The Voortrekker Memorial hall was opened in 1931 and to the south of the city stands the Voortrekker monument inaugurated on Dec. 16. 1949, as a lasting tribute to the *voortrekkers* (pioneers). Pretoria has an Anglican cathedral, a Roman Catholic cathedral, numerous English and Afrikaans churches, several high schools. a normal training college and the University of Pretoria, which includes an agricultural faculty, an experimental farm and the only faculty in South Africa for training veterinarians. Considerable industrial development took place during and after World War II. Production of iron and steel is the capital's most important industry.

Founded in 1855, Pretoria became capital of the South African republic (Transvaal) in 1860, when the *volksraad* held its first meeting there. Until 1864. however. when the civil war in the Transvaal ended, Potchefstroom remained the virtual capital of the country. As revenue flowed in from the gold mines on the Rand, many buildings were erected in the capital. which was linked by railway with Cape Town (and Durban) in 1893 and with Lourenço Marques in 1895. During the South African War Pretoria was declared an open city. On May 31, 1902, the articles of peace (known as the peace of Vereeniging) whereby the Boer leaders recognized British sovereignty were signed at Pretoria and five years later the first parliament of the Transvaal as a self-governing state of the British empire assembled there. On the establishment of the Union of South Africa in 1910 Pretoria became its administrative capital. (H. P. H. B.)

PRETORIUS, the family name of two of the early leaders of the Trek-Boers—Andries Wilhelmus Jacobus Pretorius and Marthinius Wessels Pretorius, father and son.

1. ANDRIES PRETORIUS (1799–1853), a Dutch farmer of Graaff-Rcinct, Cape Colony, and a descendant of one of the earliest Dutch settlers in South Africa, left his home in the Great Trek, and by way of what is now the Orange Free State crossed the Drakensberg into Natal, where he arrived in Nov. 1838, at a time when the emigrants there were without a recognized leader. Pretorius was at once chosen commandant general and speedily collected a force to avenge the massacre of Piet Retief and his party. who had been treacherously killed by the Zulu king Dingaan the previous February. Pretorius' force was attacked on Dec. 16 ("Dingaan's day") by over 10.000 Zulus, who were beaten off with a loss of 3,000 men. In Jan. 1840 Pretorius, with a commando of 400 burghers, helped Mpande (Panda) in his revolt against his brother Dingaan and was the leader of the Natal Boers in their opposition to the British. In 1842 he besieged the small British garrison at Durban. but retreated to hiaritzburg on the arrival of reinforcements under Col. (subsequently Sir) Josias Cloete and afterward exerted his influence with the Boers in favour of coming to terms with the British.

He remained in Natal as a British subject, and in 1847 was chosen by the Dutch farmers there to lay before the governor of Cape Colony the grievances under which they laboured as a result of the constant immigration of natives, to whom locations were assigned to the detriment of Boer claims. Pretorius went to Grahamstown. where Sir Henry Pottinger (the governor) then was; but Sir Henry refused to see him or receive any communication from him. Pretorius returned to Natal determined to abandon his farm and once more trek beyond the British dominions. With a considerable following he was preparing to cross the Drakensberg when Sir Harry Smith, newly appcinted governor of the Cape, reached the emigrants' camp on the Tugela (Jan. 1848). Smith promised the farmers protection from the natives! and persuaded many of the party to remain, but Pretorius departed, and on the proclamation of British sovereignty up to the Vaal fixed his residence in the Magalisberg, north of that river. He was chosen by the burghers living on both banks of the Vaal as their commandant general.

At the request of the Boers at Winburg Pretorius crossed the Vaal in July and led the anti-British party in their "war of freedom." occupying Bloemfontein on July 20. In August he was defeated at Boomplaats by Smith, and thereupon retreated north of the Vaal. where he became leader of one of the largest of the parties into which the Transvaal Boers were divided, and commandant general of Potchefstroom and Rustenburg, his principal rival being Commandant General A. H. Potgieter. In 1851 he was asked by the Boer malcontents in the Orange River sovereignty and by the Basuto chief Moshesh to come to their aid, and he announced his intention of crossing the Vaal to "restore order" in the sovereignty. His object. however, was rather to obtain from the British an acknowledgement of the independence of the Transvaal Boers. The British cabinet having decided on a policy of abandonment, the proposal of Pretorius was entertained. A reward of £2.000 which had been offered for his apprehension after the Boomplaats fight was withdrawn.

Pretorius then met the British commissioners at a farm near the Sand river, and concluded the Sand River convention (Jan. 17, 1852) by which the independence of th'e Transvaal Boers was recognized by Great Britain. Pretorius recrossed the Vaal, and at Rustenburg on March 16 was reconciled to Potgieter, the followers of both leaders approving the convention, though the Potgieter party was not represented at the Sand river.

Pretorius died at his home at Magalisberg on July 23, 1853. In 1855 a new district and a new town were formed out of the Potchefstroom and Rustenburg districts and named Pretoria in honour of the commandant general.

2. MARTHINIUS PRETORIUS (1819–1901), the eldest son of Andries, was appointed in Aug. 1853 to succeed his father as commandant general of Potchefstroom and Rustcnburg, two of the districts into which the Transvaal was then divided. In 1854 he led his burghers against a chief named Makapan, who had murdered a party of 23 Boers, including ten women and children. The natives were blockaded in a great cave in the Zoutpansberg, and about 3,000 were starved to death or shot as they emerged.

Having thus chastised Makapan's clan, Pretorius created a strong central government! and from 1856 onward set to work to form one Boer state to include the Orange River burghers. In Dec. 1856 representatives of the districts of Potchefstroom, Rustenburg and Pretoria met and drew up a constitution, and on Jan. 6 the "South African republic" was formally constituted, Pretorius having been elected president on the previous day. Though the Boers of the Lydenburg, Utrecht and Zoutpansberg districts refused to acknowledge the new republic, Pretorius, with the active co-operation of Paul Kruger (*q.v.*), endeavoured (1857) to unite the Orange Free State and the Transvaal, and a commando crossed the Vaal to support Pretorius. The attempt at coercion failed. but in Dec. 1859 Pretorius was elected president of the Free State. Pretorius had just effected a reconciliation of the Lydenburg Boers with those of the other districts of the Transvaal, and he assumed office at Bloemfontein in Feb. 1860. But the anarchy in the Transvaal effectually weaned the Free State burghers from any thought of immediate amalgamation with their northern neighhours. Pretorius, however, continued to intervene in the affairs of the Transvaal and at length (April 15, 1863) resigned his Free State presidency. Acting as mediator between the various Transvaal parties Pretorius in Jan. 1864 ended the civil strife, and in May following once more became president of the South African republic—now for the first time a united community.

To Pretorius more than any other man was due the welding of the Transvaal Boers into one nation. Pretorius contemplated indefinite expansion of the Transvaal state north, east and west. In April 1868, on the report of gold discoveries at Tati, he issued a proclamation annexing to the Transvaal on the west the whole of Bechuanaland and on the east territory up to and including part of Delagoa bay. Portugal at once protested, and in 1869 its right to the bay was acknowledged by Pretorius, who in the same year was re-elected president. The Boer claim to the whole of Bechuanaland was not pressed by Pretorius in the iace of British opposition, but in 1870, when the discovery of diamonds along the lower I'aal had led to the establishment of many diggers' camps, an attempt was made to enforce the claims of the Transvaal to that district. Pretorius held repeated conferences with the Bechuana chiefs, but failed to persuade them to join the Transvaal to "save" their territory from the British. Finally, without consulting his colleagues, he agreed to refer the question of the boundary to the arbitration of R. W. Keate, then lieutenant governor of Natal. The award, given on Oct. 17, 1871, was against the Boer claims. Pretorius loyally accepted the decision, but it aroused a storm of indignation in the Transvaal. The *volksraad* refused to ratify the award and thereupon Pretorius resigned the presidency (Nov. 1871). Pretorius then temporarily retired from politics, but after the first annexation of the state by Great Britain he acted (1878) as chairman of the committee of Boer leaders who were seeking the restoration of their independence. He was arrested in Jan. 1880 by order of Sir Garnet Wolseley on a charge of treason. (*See* the Blue Book [C. 2584] of 1880 for details of this charge.) He was admitted to bail, and shortly afterward urged by Wolseley to accept a seat, which he declined, on the executive council. In December of the same year he was appointed, with Paul Kruger and P. Joubert, to carry on the government on the part of the insurgent Boers. He was one of the signatories to the Pretoria convention, and acted as a member of the triumvirate until the election of Kruger as president in May 1883. He then withdrew from public life; but lived to see the country reannexed to Great Britain, dying at Potchefstroom on May 19. 1901. Within four months of his death he had visited Louis Botha and Schalk Burger, on behalf of Lord Kitchener, with the object of ending the war.

For the elder Pretorius *see* G. M. Theal, *Compendium of the History and Geography of South Africa*, 3rd ed. (1878), *History of South Africa*, vol IV [1834–54] (1893). For the younger Pretorius see vol. v of the same series.

PREVARICATION, a divergence from the truth, equivocation, quibbling, a want of plain-dealing or straightforwardness, especially a deliberate misrepresentation by evasive answers. It is often used as a less offensive synonym for a lie. The Latin *praevaricatio* was specifically applied to the conduct in an action at law in which an advocate (*praevaricator*), in collusion with his opponent, put up a bad case of defense. *Praevaricare* meant literally to walk with the legs very wide apart, to straddle, hence to walk crookedly. to stray from the direct road, *varicus*, straddling. being derived from *varus*, bowlegged, a word which scholars connected etymologically with German *quer*, "transverse," "across," and English "queer."

The word was used by Richard Vines before 1655 in *A Treatise on the Institution of the Sacrament of the Lord's Supper:* "I . . . shall clearly without any fraud or prevarication declare my opinion." Edmund Burke in *Two (Four) Letters . . . on the Proposals for Peace with the Regicide Directory of France* (1795–97) wrote, "Fraud and prevarication are servile vices."

PREVENTIVE MEDICINE. The prevention of disease is the true ideal of medicine. Its application is twofold — the preventive medicine of. the community, which is generally termed public health or state medicine, and the prevention of disease or its sequelae in the individual.

HISTORICAL DEVELOPMENT

Ancient Origins. — Hippocrates (b. 460 B.C.) classified causes of disease into those concerned with seasons, climates and external conditions and those more personal causes such as irregular food, exercise and habits of the individual. Through the middle ages the principles of preventive medicine were ignored, in spite of the scourges of leprosy and plague. Then with the Renaissance came the new learning on the nature both of health and disease, which revolutionized the whole content of medicine and gave it a fresh centre of gravity and new outlook. Leonardo da Vinci — whose genius suggested some of the great discoveries of modern science — and Andreas Vesalius of Padua were followed in the 17th century by Galileo, William Harvey, Jean Baptiste van Helmont and the experimentalists, and the great practitioners who observed the relation of the seasons, of telluric conditions and of contagion to the incidence of disease. This was followed by new knowledge of anatomy, physiology and pathology.

Practical Needs. — Concurrently with the growth of medical knowledge there was an empirical movement of practical prevention. Long before the days of Hippocrates men had sought to stem the tides of disease which threatened to overwhelm them. In Britain, also, it was the ravages of pestilence in the middle ages — of leprosy from the 12th century, of the Black Death from the 14th, of sweating sickness in the 16th and of cholera and smallpox subsequently — which compelled attention to the conditions which seemed responsible for these scourges. The great monastic orders and some of the historical cities — Rome, Venice and London — provided comfort, refuge and sustenance for the victims, and in 1388 there was passed the first Sanitary act in England, directed to the removal of nuisances. In 1443 came the first plague order recommending quarantine and cleansing; in 1518 the first rough attempts at notification of epidemic disease and isolation of the patient were made; as time passed men began to see that environment was one of the principal factors in the origin and spread of disease.

Experimental Method. — In the 17th century Harvey indicated the true experimental method; 50 years later Thomas Sydenham, another practitioner, laid the basis of epidemiology by his observation of cases, his deduction of laws of prevalence and his suggested hypothesis of "epidemic constitutions."

Bernardino Ramazzini, in Italy, published a treatise on occupational disorders in 1700. Richard Mead, an English practitioner in the first half of the 18th century, published works on poisons, on plague and methods of its prevention, on smallpox, measles and scurvy. John Fothergill described "putrid sore throat" and Haberman, chicken pox. John Huxham of Totnes, an authority on the treatment of fevers, recommended vegetable dietary in cases of scurvy and Devonshire colic. Sir George Baker traced the latter to lead in vats and cider presses. Edward Jenner introduced vaccination. James Lind issued the first treatise on scurvy and the health of seamen. John Howard pointed out the evils of typhus as a "gaol fever." Oliver Wendell Holmes demonstrated the contagiousness of puerperal fever. John Snow published his classic on cholera and William Budd on typhoid fever. P. L. Panum studied the epidemiology of measles in the Faeroe Islands.

Concurrently with these clinical discoveries, advances in related sciences, notably mathematics were occurring. John Graunt initiated the study of mortality statistics in England in the 17th century and William Farr firmly established this basic principle of preventive medicine in the 19th century. Sweden made a modern census in 1748, the U.S. in 1790, England in 1801.

Modern Era. — Louis Pasteur's discovery of the role of living microbes as the cause of infections opened a new era in preventive medicine. Robert Koch demonstrated the tubercle bacillus in 1882; Karl Joseph Eberth the typhoid bacillus in 1880. Soon many other disease-producing organisms were discovered.

In 1893 Theobald Smith established the principle of insect-borne transmission of infections. Shortly afterward Sir Ronald Ross demonstrated the *Anopheles* mosquito as a transmitter of malaria, and the team of Walter Reed, James Carroll, Jesse Lazear and Aristides Agramonte implicated the *Aedes* mosquito in yellow fever in 1900. William Gorgas promptly employed this discovery for control of yellow fever in the Panama Canal Zone.

Serological tests were developed, such as the Widal reaction of typhoid fever (1896), Wassermann (serological) test for syphilis in 1906. An understanding of the principles of immunity led to the development of active immunization to specific diseases. The discovery and culture of viruses provided new tools for control of virus diseases. Concurrently with these laboratory discoveries epidemiology emerged as a science. through the work of Charles Chapin, W. H. Frost, and Major Greenwood.

Parallel advances in treatment opened other doors for prevention — in diphtheria by antitoxin (Emil von Behring) and in syphilis by Salvarsan (Paul Ehrlich). In 1932 the sulfonamide drugs and later a group of antibiotics such as penieillin, streptomycin, aureomycin and chloromycetin afforded new opportunities of prevention and cure.

After 1900 there were many advances in medicine other than those related to infectious diseases. The use of X-ray, radium and radioactive substances in the diagnosis and treatment of disease (*e.g.,* tuberculosis and cancer) as well as in fundamental physiological research opened new possibilities. A greater understanding of endocrine functions, with the production of prepared extracts such as insulin (Sir Frederick Banting and Charles Best, 1921), thyroid, pituitary extract and hormones, led to preventive measures in certain metabolic diseases. The apparently dramatic effects of ACTH and cortisone offered new hope in the treatment and prevention of sequelae of hitherto recalcitrant conditions.

The role of nutrition in health and disease and the isolation of many essential food factors illustrated the importance to health of adequate diet. Other advances in preventive medicine include psychiatry and psychology in relation to total health, new surgical techniques, new methods of anaesthesia, genetics and the application of statistical methods to medical problems. (See BACTERIAL AND INFECTIOUS DISEASES; DIET AND DIETETICS; ENDOCRINOLOGY; EPIDEMIOLOGY; IMMUNITY; MEDICINE; PSYCHIATRY; RADIOLOGY; SERUM THERAPY; VACCINE THERAPY.)

INTERNATIONAL HEALTH

International co-operation in the prevention of the spread of disease had its origin in the dim past. In 1851 France called an international conference to formulate a plan for control of cholera. This and five succeeding conferences produced no definitive results. At the Paris conference of 1903 a proposal for a permanent bureau of health was adopted. By the Rome arrangement four years later the International Office of Public Health was set up in Paris. Under its auspices international sanitary conventions were drafted in 1912–26 and 1933. Each country consistently sought to protect itself against imported disease and to aid its commerce.

The Pan American Sanitary bureau was established in 1902 sponsored by all 21 American republics. The bureau received and relayed epidemiologic information, provided technical assistance and sponsored research co-operation and fellowships.

The Health section of the League of Nations, established in 1923, acted to halt epidemics, established international standards for biologics, sponsored studies on cancer, leprosy, syphilis, nutrition, malaria and rural hygiene and assisted in the reorganization of some national health departments. The World Health organization, established in 1946, assumed the functions of the International Office of Public Health and of the Health section of the League of Nations. The Pan American Sanitary bureau became a regional office of WHO in 1949. (See HYGIENE; PUBLIC HEALTH.)

THE UNITED STATES

Preventive medicine in early America was concerned with epidemics, primitive sanitary conditions and the over-all problem of enough competent doctors to care for a population rapidly conquering a vast continent. Urban centres were plagued by contaminated water supplies, sewage and filth. Epidemics of exotic diseases such as cholera, yellow fever, malaria and typhus fever entered the country and spread widely. Typhoid fever and dysentery took a heavy toll. Emergency local regulations and boards of health were set up for epidemic control but lapsed when danger passed.

Lemuel Shattuck, in his "Report of the Sanitary Commission of Massachusetts" in 1850, charted a course of action in a remarkable document virtually unrecognized for two decades. C.-E. A. Winslow in 1948 said of it, "I know of no single document in the history of that science quite so remarkable in its clarity and completeness and in its vision of the future."

Prompted by recurring epidemics, advances in medical science and a growing social consciousness, city health boards were created in Baltimore (1798), Charleston, S.C. (1815), Philadelphia (1818), and elsewhere. As a result of the growing need for greater co-ordination, state boards of health were formed. Massachusetts being the first (1869). By 1919 each state had an organized department of health and the number of full-time local departments continually increased after 1914. Yet, by mid-20th century more than a third of the nation's population lived in areas without such basic full-time health services.

Concerned initially with such matters as sanitation, nuisances, acute communicable disease control, state and local health services by mid-century embraced also improved nutrition, maternal and child health services. mental hygiene, treatment of tuberculosis and the venereal diseases, control of cancer, cardiovascular and other chronic diseases. Knowledge from the biological and social sciences made it possible for medicine to shift its emphasis from cure and alleviation of illness to prevention.

Federal Program. — Prior to the creation of local and state boards of health, the congress in 1798 passed an act for the care of seamen of the merchant marine. Under its provisions, physicians were appointed in each port to furnish medical care, 20 cents being deducted from monthly wages to finance the program. Thus was initiated the earliest compulsory medical insurance in the U.S. and the basis laid for the far-flung activities of the public health service 150 years later. In 1878 authority was granted to investigate the origins and causes of epidemic diseases. In 1901 the Hygienic laboratory was established and in 1912 the title of the "United States public health service" was conferred.

The federal government assumed increased responsibility for national health in 1935 with the passage of the Social Security act which authorized a national program of grants-in-aid to states and training of health personnel. The National Cancer act, 1937, and the Venereal Disease Control act, 1938, the Mental Health act of 1946, the Hospital Survey and Construction act of the same year and a greatly expanded program of research grants have broadened the preventive concept. In 1939 the Social Security board, public health service, children's bureau, office of education, Food and Drug administration and related services were brought together under the new Federal Security agency.

Over many years, many bills have been introduced into the congress to provide a system of national medical insurance. None have been passed and opinion has been sharply divided regarding each of the diverse proposals.

Voluntary Health Agencies.—Voluntary agencies in the U.S. have played a leading role as pioneers in health promotion. They are concerned with the prevention of specific diseases (*e.g.,* tuberculosis, poliomyelitis); with disorders of specific organs (*e.g.,* eyes, heart); with health of specific groups (*e.g.,* children, mothers). They depend entirely on private contributions for their existence and range from national to local in extent. Examples are the National Tuberculosis association, American Heart association and Commission on Chronic Illness.

Other types of nongovernmental organizations which have contributed greatly to the growth of preventive medicine are: (1) foundations financed by private philanthropy such as the Rockefeller foundation, Commonwealth fund, Milbank Memorial fund and many others; (2) professional associations such as the American Public Health association; and (3) industries and insurance companies and labour unions.

The inability of most families to pay the cost of prolonged medical care has resulted in the formation of many voluntary, nonprofit, prepayment medical or hospital insurance plans to meet this unpredictable risk. The insurance principle in relation to social problems of the poor was advocated as long ago as 1697 by Daniel Defoe, yet in the U.S. prepayment of sickness costs has been recent and on a nongovernmental basis. Labour contracts with employers increasingly include sickness insurance provisions.

Schools. — Preventive medicine in the United States has been stimulated by special schools for public health education. The Rockefeller foundation financed schools at Johns Hopkins university, Baltimore, 1916; Harvard university, 1922; the University of Toronto, Ont., 1925; and has aided others at the University of Michigan, Ann Arbor, the University of California, Berkeley, and elsewhere. In 1950, 11 graduate schools of public health mere accredited by the American Public Health association (California, Columbia, Harvard. Johns Hopkins, Michigan, the University of Minnesota, Minneapolis, the Cniversity of North Carolina, Chapel Hill, the University of Pittsburgh, Pa., Toronto, Tulane university, New Orleans, and Yale). The A.P H.A. also has set up qualifications for various types of public health personnel including accreditation by a specialty board for physicians especially skilled in preventive medicine and public health.

BRITISH PRACTICE

Legislative Action.—The applications of state medicine, in the 19th century, found their inspiration in England in two sources, the recurrent outbreaks of cholera and consequent commissions of inquiry, and popular demand for reform, which was realized after each of the four extensions of the franchise (1832–1918). Understandable alarm caused by ravages of cholera in 1831 led to the first steps in administrative sanitary reform; in 1849 there was a second visitation of cholera and in 1854 a third.

Concurrently with and following upon these epidemics there were various commissions of investigation. In 1838–39 the Poor Law commissioners drew attention to the prevalence of epidemic disease and its relation to poverty. The reports by Neil Arnott, Sir James Kay-Shuttleworth, Southwood Smith and Sir Edwin Chadwick were the predecessors of another famous series of investigations in 1859–65 by Edward Greenhow and his colleagues under the privy council into epidemic diarrhoea, pulmonary disease. infant mortality and ague; also into adequate food supply, sufficient house accommodation, healthful physical surroundings and wholesome industrial circumstances. They led the way to the new application of medicine for the removal of nuisances: the prevention of contagion and infection and industrial hygiene and welfare.

In 1843 Sir Robert Peel, at the instigation of Chadwick, advised appointing a royal commission to inquire into the outbreaks of disease in large towns and the best means of improving the public health. the report of which led to the passage of the comprehensive sanitary measure in 1848, the establishment of the general board of health and the appointment of medical officers of health. In 1869 the Royal Sanitary commission was appointed; on it sat Sir Thomas Watson. Sir James Paget, Sir Henry Acland. Sir Robert Christison and William Stokes, and before it Sir John Simon, Budd and Farr gave evidence. Speaking broadly, the 1843 commission found the existence of a serious national evil of insanitation and ill-health and recommended a legislative remedy, whereas the 1869 commission found that the remedy had proved ineffective and recommended that "the present fragmentary and confused sanitary legislation should be consolidated." They proposed for the first time a ministry of health; the case miscarried; the local government board was created in 1871.

Registration of Sickness and Death.—Although bills of mortality were published in London as early as the reign of Queen Elizabeth I it was not until the Births, Marriages, and Deaths Registration act of 1836 that any reasonably accurate measure of mortality was obtained. William Farr, the first registrar-general, established an efficient office of vital statistics; including in 1860 occupational mortality and morbidity analyses.

In 1889 the Infectious Disease Notification act was passed applying only to a limited number of diseases. Others have been added. such as tuberculosis in 1912. The Notification of Births act of 1907, made compulsory in 1915, required notice to the local health authority within 36 hours following birth, opening the way for more efficient maternal and infant care.

Public Health Act, 1875.—This act emerged from the labours of a royal commission. It led during 20 years to laws designed to prevent river pollution, to protect water supplies, to improve housing and isolation hospitals and to notification and prevention of infectious diseases.

Sir Robert Peel's commission in 1845 had recommended that each local governing body should have a medical officer "to ascertain the true causes of disease and death, more especially of epidemics increasing the rates of mortality. and the circumstances which . . . injuriously affect the public health." In the period 1845–75 the Vaccination acts and the elementary Education act (1870) also should be recorded.

After **1900.**—In the period 1900–24 the sanitary environment improved. It must always remain a foundation of preventive medicine. and in various new departures dependent upon the principles established by the growth of medical knowledge. Typical of this era was the progress in personal hygiene as distinct from environmental hygiene. Its centre is the person rather than the premises.

In 1909 a royal commission appointed to inquire into the "Laws relating to the Relief of Poor Persons within the United Kingdom" presented majority and minority reports. The latter, signed by George Lansbury, Frances Chandler, Russell Wakefield and Beatrice Webb, contained the significant findings of this commission, with suggestions adopted almost in their entirety in 1929.

The school medical service was organized in 1907 and the National Insurance act, passed in 1911, provided a system of insurance against ill-health for a large portion of the working population, although not for dependents. The act also allowed for the use of some of the funds for medical research, and the Medical Research committee was established. In 1920 it was reconstituted as the Medical Research council under the privy council.

In 1919 a comprehensive ministry of health was entrusted with the Health and Poor law powers and duties of the local government board, duties of the Insurance commission and supervision under the Midwives act, among others. The Local Government act of 1929 produced further changes in preventive medicine. The Poor law boards of guardians were abolished, health policy was separated from "pauperism," local authorities were authorized to provide general hospitals for the sick and co-operation with voluntary hospitals was encouraged. The Public Health act (1936), which incorporated, revised or repealed certain statutes relating to public health. greatly simplified administration.

Concurrently with these developments advances were made in industrial hygiene, commencing with the Factory act of 1878. In 1898 T. M. Legge, afterward Sir Thomas Legge, the first medical inspector of factories, pioneered in the study of occupational risks in health and in preventive legislation.

In relation to mental health, the Lunacy act of 1890 was the basis of the modern attitude. A royal commission report in 1926 resulted in the Mental Treatment act, 1930, which provided for the care of mentally ill and also for voluntary care in public mental hospitals.

The relationship of preventive medicine to all the social sciences as well as to the medical sciences emerged during this early period of the 20th century. The war period of 1939–45 further emphasized the need of closer integration of all preventive medical and social services. The Beveridge report of 1942 urged full employment, family allowances and comprehensive health services as fundamental for security of the individual and the family. With this came the concept of medical care for all as a right. In 1946 the National Health Service act was passed and came into force in 1948. This act unified the health services providing hospital and specialist services, services furnished by local health authorities, general medical, dental, ophthalmic and pharmaceutical services, bacteriological and blood transfusion service as well as research. These were made available to all persons at the time of need. Other acts of importance to health are the Education act, 1944; Family Allowances act, 1945; National Insurance act, 1946; National Insurance (Industrial Injuries) act, 1946; National Assistance act, 1948; Children act, 1948; Housing act, 1949; and the Food and Drug act, 1955. These acts have resulted both from a broad concept of the role of preventive medicine and from the need to consider all aspects of the environment in relation to health.

(T. P.)

PREVEZA, or Prevesa, seaport, southern Epirus, in Greece; at the entrance to the Gulf of Arta, an inlet of the Ionian sea. Pop. (1951) 11,008. The town is surrounded by dense olive groves. The harbour is small, and closed to large vessels by a bar of sand. Préveza exports dairy produce, valonia, hides and wool, olives and olive oil. About 3 mi. N. are the ruins of Nicopolis (*q.v.*). Préveza was seized by Ali Pasha in 1798 and recovered by Greece in 1912 during the first Balkan War. In April 1941 it was occupied by Italy.

PREVOST, ANTOINE FRANÇOIS (1697–1763), French author and novelist, was born at Hesdin, Artois, on April *1*, 1697. He was educated at the Jesuit school of Hesdin, and in 1713 became a novice of the order in Paris, pursuing his studies at the same time at the college of La Fleche. At the end of *1716* he left the Jesuits to join the army, but he soon tired of life in barracks, and returned to Paris in 1719 with the idea, apparently, of resuming his novitiate. He is said to have travelled in Holland about this time; in any case, however, he returned to the army, this time with a commission. He joined in 1719–20 the learned community of the Benedictines of St. Maur, with whom he found refuge, he himself says, after the unlucky termination of a love affair. He took the vows at Jumièges in 1721 after a year's novitiate, and received in *1726* priest's orders at St. Germer de Flaix. He resided for seven years in various houses of the order, teaching, preaching and studying. In *1728* he was at the abbey of St. Germain-des-PrCs, Paris, where he was engaged on the *Gallia christiana,* the learned work undertaken by the monks in continuation of the works of Denys de Sainte-Marthe. who had been a member of their order. His restless spirit made him seek from the Pope a transfer to the easier rule of Cluny; but without waiting for the brief. he left the abbey without leave (1728), and, learning that his superiors had obtained a *lettre de cachet* against him, fled to England.

In London he acquired considerable knowledge of English history and literature, traceable throughout his writings, and he has left an interesting account of English life in his famous memoirs. Before leaving the Benedictines Prévost had begun his most famous romance, *Me'moires et aventures d'un homme de qualitd qui s'est retiré du monde,* the first four volumes of which were published in Paris in 1728, and two years later at Amsterdam. In 1729 he leit England for Holland, where he began to publish (Utrecht, 1730) a romance, the material oi which, at least, had been gathered in London—Le *Philosophe anglois, ou Histoire de Monsieur Cleveland, fils naturel de Cromwell, écrite par lui-mesme, et traduite de l'anglois* (Paris 1731–39, *8* vols., but most of the existing sets are partly Paris and partly Utrecht). Meanwhile during his residence at the Hague, he translated the *Historia* of De Thou, and, relying on the popularity of his first book, published at Amsterdam a *Suite* in three volumes, forming volumes v, vi and vii of the original *Mdmoires et aventures d'un homme de qualitd.* The seventh volume contained the famous *Manon Lescaut,* separately published in Paris in 1731 as *Les Aventures du chevalier des Grieux et de Manon Lescaut, par Monsieur D. . . .* The book was eagerly read, chiefly in pirated copies, as it was forbidden in France. In 1733 he left the Hague for London, and Miss M. Robertson gives an entry showing that he was in prison in London in December on a charge of iraud.

In the autumn of 1734 Prévost was reconciled with the Benedictines and returning to France, passed through a new, though brief, novitiate. In 1735 he was dispensed irom residence in a monastery by becoming almoner to the Prince de Conti. and in 1754 obtained the priory of St. Georges de Gesnes. He continued to produce novels and translations from the English and with the exception of a brief exile (1741–1742) spent in Brussels and Frankfort, he resided for the most part at Chantilly until his death on Dec. 23, 1763.

For the bibliography of Prévost's works, which presents many complications, and for documentary evidence of the facts of his life *see* H. Harrisse, *L'Abbé Prévost* (1896); also a thesis (1898) by V. Schroeder.

A critical edition by M. Robertson of the 5th vol. of the *Mémoires et Aventures* dealing with Prévost's adventures in London, was published in 1927.

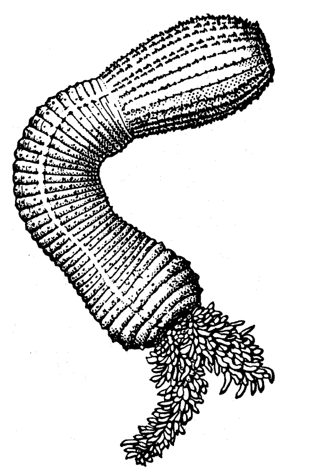
PRÉVOST, EUGENE MARCEL (1862–1941), French novelist, was born in Paris on May *1, 1862.* He was educated at Jesuit schools in Bordeaux and Paris, entering the École Polytechnique in *1882.* He published a story in the *Clairon* as early as 1881. but for some years after the completion of his studies he applied his technical knowledge to the manufacture of tobacco. He published in succession, *Le Scorpion* (1887), *Chonchette* (1888), *Mademoiselle Jauffre* (1889), *Cousine Laura* (1890), *La Confession d'un amant* (1891), *Lettres de femmes* (1892), *L'Automne d'une femme* (1893), and in *1894* he made a great sensation by an exaggerated study of the results of Parisian education and Parisian society on young girls, *Les Demi-vierges,* which was dramatized and produced with great success at the Gymnase on May *21, 1895. Le Jardin secret* appeared in *1897*; and in 1900 *Les Vierges fortes* and a study of the question of women's education and independence in two novels, *Frédérique* and *Léa. L'Heureux ménage* (1901), *Les Lettres à Françoise* (1902), *La Princesse d'Erminge* (1904), *L'Accordeur aveugle* (1905) and *Lettres à Françoise Mariée* (1908) were among his later novels. In 1904 *La* Plus *faible* was successfully produced at the Comédie Française. In 1909 he was elected to the Academy.

PRIAM, in Greek legend, the last king of Troy *(q.v.),* son of Laomedon. According to Homer *(Iliad,* iii *184)* in his youth he fought on the side of the Phrygians against the Amazons. He had fifty sons and twelve daughters and immense wealth. He was slain by Neoptolemus, son of Achilles, during the sack of Troy.

PRIAPEA, a collection of 85 or *86* short Latin poems in various metres. including hendecasyllables, choliambics and elegiacs, on the subject of the fertility god Priapus, who, with his sickle, protected gardens and vineyards against thieves and from whose axe-hewn image of figwood or willow protruded an erect, red-painted phallus. Though a few of the poems are inoffensive, the majority, despite occasional flashes of humour, are remarkable only for their obscenity. Most appear to belong to the Augustan age or to a date not much later and show evidence of indebtedness to Ovid. They in turn influenced Martial. Some may originally have been the leisure products of aristocratic voluptuaries; others, genuine inscriptions on shrines of Priapus. Donatus says that Virgil wrote some *Priapea,* and the first three poems of the *Catalepton* in the *Appendix Vergiliana* are of this genre; but, though Pliny says that Virgil composed "verses far from staid" *(aersiculos severos parum),* there is no proof that these are Virgil's. In *Tibullus,* i, *4,* an elegy of *84* lines, Priapus assumes the unique role of a professor of venery *(magister amoris)* and instructs the poet how best to secure the affection of the boy Marathus. A companion piece to this poem is Horace, *Satires,* i. *8* (50 hexameters), in which Priapus tells how he frightened away two witches from the site of the Esquiline cemetery when his figwood buttocks burst with a disconcerting pop. Martial's *Priapea* include epigrams *16, 49* and *73* in book vi, and *40* in book viii.

See F. Biicheler (ed.), *Petronius,* 6th ed. (1922). (H. H. HY.)

PRIAPULIDA, a small group of marine worms formerly included in the obsolete phylum Gephyrea. Of uncertain affinities, they are now generally conceded phyletic rank. Resemblances to the gephyrean groups Sipunculida (*q.v.*) and Echiurida (*q.v.*) appear to be of a superficial nature, and the same may be said of the theory, advanced by W. Fischer, that they are related to holothurians (a class of the Echinoderma, *q.v.*). According to O. D. Hammersten, whose observations were extended by K. Lang, the larva has features in common with Rotatoria, Kinorhynca (*q.v.*) and Gastrotricha (*q.v.*). Although this hypothesis, which would place the priapuloids among pseudocoelomate phyla, is an attractive one, it must be admitted that the homologies of the body cavity are uncertain; and Libbie Hyman, in *The Invertebrates: Protozoa through Ctenophora* (1940), has classified them as schizocoelous coelomates.



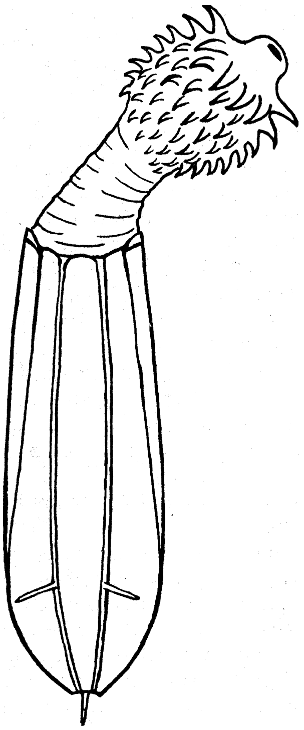
FROM THEEL, "NORTHERN AND ARCTIC INVERTEBRATES"

FIG. 1.—PRIAPULUS BICAUDATUS, A WORMLIKE MARINE ANIMAL OF THE ARCTIC AND NORTH ATLANTIC SEAS

The body is cylindrical and consists of an annulated but unsegmented trunk and a retractile proboscis. In the genus *Priapulus* there are one or two caudal appendages considered to be gills. The surface of the muscular body wall is provided with rings of spines and papillae, the latter possibly sensory in function. The epidermis secretes a thick cuticle, which is shed at intervals during growth. There are 25 rows of spines on the surface of the proboscis, converging toward the mouth, which is itself surrounded by several five-toothed rings of chitinous teeth, thus giving rise to the supposed resemblance to echinoderms. The mouth leads into a muscular, eversible pharynx anchored by retractor muscles originating in the trunk. The cuticular lining of the pharynx is provided with numerous small projecting teeth. The mid-gut is straight and communicates with a short hind-gut; the anus is either terminal or opens at the base of the caudal appendages when these are present. The body cavity, which in *Priapulus* extends into the ramifications of these hollow, gill-like structures, is extensive but its developmental homologies are unknown. There is no vascular system and the coelomic fluid must subserve, in part, a respiratory function.

The nervous system, consisting of a circumesophageal ring and ventral nerve cord, retains its primitive connection with the ectoderm. There is no evidence of segmental ganglia. A visceral plexus is connected anteriorly with the nerve ring.

The excretory system is protonephric; tufts of solenocytes discharge into the paired urinogenital ducts, which lie suspended in the body cavity and open posteriorly. The sexes are usually separate, but hermaphrodite individuals have been recorded; the gonads develop in the walls of blind evaginations of the urinogcnital ducts. Fertilization is external. The earliest stages of development were studied by K. Lang in 1939; segmentation differs irom that of polychaets and most nearly resembles that of the rotifer *Asplanchna*. Intermediate stages are unknown, but the gastrula is believed to develop, perhaps directly, into the loricate larva. This larva has a spiny, retractile proboscis, and the body is protected by chitinous shields; in *Priapulus* there are two pairs of feelers and a bifurcatcd tail.



BASED ON DRAWINGS AND PHOTOGRAPHS BY LANG, FROM "K. FYSIOGR. SALLSK, LUND, FORH," VOL 9

FIG. 2.—LORICATE LARVA OF PRIAPULUS CAUDATUS, SHOWING PLATES CONNECTED BY FLEXIBLE MEMBRANES' FEELERS AND FOOTLIKE CAUDAL APPENDAGE

There are only two genera: *Priapulus* and *Halicryptus*, the latter without caudal appendages. The animals are of small to medium size and live in burrows in the sand or mud which they ingest; a secretion of the circumanal glands is used to cement the walls of the burrows. Priapuloids are found in the cold seas oi both the northern and southern hemispheres but are confined to relatively shallow coastal waters.

BIBLIOGRAPHY.—A comprehensive review of the group, published in 1931, is given by F. Baltzer in Kukenthal and Krumbach's *Handbuch der Zoologie,* Bd. 2. Hfte. 2. Larval stages are described by K. Lang, K. *Fysiogr. Sällsk. Lund, Förh.,* vol. 9. (G. E. P.)

PRIAPUS, a god of fertility, personification of the fruitfulness of nature, chief deity of Lampsacus on the Hellespont (Dardanelles). He was represented as a man. usually grotesquely ugly, with an enormous and erect sexual organ. Locally, he was thought to he the son of Dionysus and Aphrodite. His cult reached Grcece somewhat late in the classical epoch, not becoming really important until Alexandrian times. Later still, it penetrated to Italy. Various legends, all of them late, bring him into connection with the gods of the Greek pantheon. particularly Aphrodite, often represented as his mother, Hermes, Dionysus and other deities connected with fertility. In Bithynia he is a warlike god, associated with Ares. He absorbed. or was closely identified with, a number of minor rustic deities of similar type; *e.g.,* Phales, Conisalus. Tychon, etc.

He is perhaps best known as a god of gardens, where his image was commonly erected. both to give supernatural protection against thieves and for practical use as a scarecrow. But as the phallus is a common luck-bringing object, he was worshipped by persons in need of luck, such as hunters and fishermen, and also was frequently employed to keep off the evil eye.

PRIBILOF ISLANDS (FUR SEAL ISLANDS). islands of Alaska, including St. Paul *(3j* sq.mi.), St. George (27 sq.mi.) and two islets lying in the Bering sea, about 180 mi. N. of Cnalaska. They were first visited in 1786, by the Russian sea captain Gerasim Pribilof. who discovered their famous iur seal rookeries. Control of the islands was transferred from Russia to the Cnited States with the purchase of Alaska in 1867 *(see* ALASKA: *History).*

Fur Industry.— The seals are a distinct species *(Cullorhinus ursinus)*, with fur superior to other species. They visit the Pribilofs from April to November. The older and stronger bulls gather harems, the younger "bachelors" congregating separately. By taking the "bachelors" when ashore, the herd may be conserved. However, sealing at sea (pelagic sealing) permits no selectivity, and half the animals killed are lost.

In 1870 sealing rights were leased to the Alaska Commercial company. During the 1880s vessels of several nations engaged in pelagic sealing, and the islands' herds were vanishing. In 1886 U.S. vessels began seizing Canadian schooners sealing off the Pribilofs. A tribunal ruled against the United States in 1893. Since 1910 the U.S. bureau of fisheries has had direct supervision of the sealing.

In 1911 the Cnited States, Great Britain, Japan and Russia signed the North Pacific Sealing convention abolishing pelagic sealing north of latitude 30° N., and providing that each nation should share in the skins collected on the Pribilofs. The treaty was ended by Japan's withdrawal in 1941, on its contention that the seals were despoiling Japanese fisheries.

In 1957 an interim convention on conservation of North Pacific fur seals was signed between the U.S., Japan, Canada and the U.S.S.R., which created the North Pacific Fur Seal commission to supervise research.

The herd increased from 125,000 to 4,000,000 between 1911 and the early 1950s. About 65,000 skins were being harvested yearly in the 1950s. See also ALASKA: History: *Diplomacy Involving Alaska.*

Population.—In 1950 the population consisted of 546 Aleuts and a few government officials.

Natural History and Climate.— The islands are of volcanic origin. The flora is restricted to ferns, mosses and grasses. creeping willows and small shrubs. White and blue foxes, gulls, auks and cormorants abound. The mean annual temperature is about 35.7° F. The rainfall is about 3j in. annually. Fogs are heavy and frequent. (J. E. CL.)

PRIBRAM, ALFRED FRANCIS (1859–1942). Austrian historian. was born in London, Sept. 1, 1859. He studied in London and Vienna and in 1894 became professor of modern history at the University of Vienna. being also elected a member of the Viennese Xkademie der Wissenschaften.

Pribram's main works are: *Oesterreich und Brandenburg* (2 vol., 1884–85); *Der Rheinbund* (1888); *Franc von Lisola und die Politik seiner Zeit* (1894); *Das böhmische Commerzcollegium* (1898); *Oest. Staatsverträge* (England) (2 vol., 1907–13); *The Secret Treaties of Austria-Hungary 1879–1914* (English, German and French ed., 1919–23); *Austria-Hungary's Foreign Policy 1908–1918* (1923); *England and the International Policy of the Great European Powers 1879–1914* (1931). Pribram also finished and issued vol. ii and iii of Friedjung's ambitious work *Das Zeitalter des Imperialismus.* His *Secret Treaties* threw much light on modern history in 1929.

PRICE, RICHARD (1723–1791), British moral philosopher, famous also in his own day as a supporter of the American and French Revolutions and as an expert on insurance and finance, was born at Tynton in Glamorgan on Feb. 23, 1723. The son of a dissenting minister, he himself ministered to English Presbyterian congregations in the vicinity of London, notably at Stoke Newington and at Hackney, where he died on April 19, 1791.

Price's *Review of the Principal Questions and Difficulties in Morals* (1758; 3rd ed., enlarged, 1787) criticizes the moral-sense theory of Francis Hutcheson and is one of the best statements of ethical intuitionism or rationalism, foreshadowing Immanuel Kant's ethics in some respects and 20th-century intuitionism in many. In 1767 Price published *Four Dissertations,* including a reply to David Hume's essay on miracles, and in consequence received the degree of D.D. from Marischal college. Aberdeen. Price and Hume met and corresponded with mutual esteem. Another of Price's philosophical opponents, Joseph Priestley, was a close personal friend. They published jointly A *Free Discussion of the Doctrines oj Materialism and Philosophical Necessity* (1778), which doctrines Priestley held and Price attacked.

Price was elected F.R.S. in 1765 for work on a problem in the theory of probability. which he then applied to actuarial questions. *Observations on Reversionary Payments* (1771) laid the foundations of a scientific system of life insurance and of old-age pensions. It also recommended the re-establishment of the sinking fund to deal with the national debt. a proposal amplified in *An Appeal to the Public on tlze Subject of the National Debt* (1772).

Price's views influenced French governmental policy through Robert Turgot and Jacques Necker and, later. British policy through Lord Shelburne (*see* LANSDOWNE, MARQUESSES OF), an intimate friend, and the younger Pitt.

Price was a friend of Benjamin Franklin and became a leading advocate of American independence. His *Observations on the Nature of Civil Liberty, the Principles of Government, and the Justice and Policy of the War with America* (1776) and *Additional Observations . . .* (1777) had an enormous sale in both England and America. He was given the freedom of the city of London in 1776, was invited by the U.S. congress in 1778 to advise it on finance and was made LL.D. together with George Washington by Yale college in 1781. Price welcomed the French Revolution in a celebrated sermon on *The Love of Our Country* (1789), to which Burke's *Reflections on the Revolution in France* was a reply.

BIBLIOGRAPHY.—Price published various other sermons and tracts. For his life and works *see* Roland Thomas, *Richard Price* (London, 1924); and C. B. Cone, *Torchbearer of Freedom* (Lexington, 1952). *The Review oj the Principal Questions in Morals* is ed. *by* D. D. Raphael (Oxford, 1948). For discussion of that work *see* J. Martineau, *Types of Ethical Theory,* 3rd ed. (Oxford, 1901); W. H. F. Barnes, in *Philosophy,* vol. xvii (London, 1942); C. D. Broad in *Aristotelian Society: Proceedings,* new series, vol. xlv (London, 1944–45); D. D. Raphael, *op. cit.* and *The Moral Sense* (London, 1947). (D. D. R.)

PRICE, STERLING (1809–1867), American general, was born in Prince Edward county, Virginia, on Sept. 14, 1809. He was educated at Hampden Sidney college and afterwards studied law. In 1830 he removed to Missouri and from 1840 to 1844 served in the Missouri State legislature as speaker of the house of representatives. He was elected a U.S. representative in 1844 but resigned in 1846 to raise and lead the 2nd Missouri Cavalry Regiment in the Mexican War. In 1847 he was commissioned brigadier-general of volunteers and made military governor of Chihuahua. He was governor of Missouri, 1853–57, and State bank commissioner, 1857–61. In 1861 he was appointed major-general of the State militia. Upon the outbreak of the Civil War Price gathered 9,000 Confederate troops at Carthage, Mo., and defeated a small force of Union troops under Franz Sigel. Joined by other troops from Arkansas, Price fought the battle of Wilson's Creek, defeating the Union forces under Gen. Lyons. In the battle of Lexington, shortly afterward, Price captured over 3,000 Union troops, but he was forced to retreat before Gen. Frémont. In March 1862, he was commissioned major-general in the Confederate forces. He commanded under Van Dorn at the battle of Pea Ridge, Ark., on March 7, 1862, and in several engagements around Corinth, Miss. On July 4, 1863, he fought a sharp battle at Helena, Ark., and later prevented Steele's advance to the Red river. In Sept. 1864 he invaded Missouri and advanced to the environs of both St. Louis and Jefferson City, but was repulsed in his attacks at these places. After the war Price went to Mexico in the interest of a colonization project but he returned to Missouri and died at St. Louis on Sept. 29, 1867.

PRICE, THOMAS (1852–1909), Australian statesman, was born at Brymbo, North Wales, on Jan. 19, 1852. He was educated at a penny school in Liverpool, and became a stonecutter. He went to Australia for his health in 1883, where after a time he again found employment as a stonecutter, working on the parliament buildings in Adelaide. He was secretary for two years (1891–93) of the Masons' and Bricklayers' Society of South Australia, and then obtained a seat as Labour member in the House of Assembly. In 1900 he was made secretary of the Labour Party, and in 1901 became its parliamentary leader. He held office as prime minister of South Australia from 1905 until his death on May 31,. 1909, at Hawthorn, near Adelaide.

PRICE. What prices are and what price, as a general conception, means would seem to be obvious enough. Yet economists, dealing with the relations of prices to different forms of economic activity and with their own interrelations find that they must take pains if they are to keep their conceptions of price clearly defined and consistent. Thus one may speak of the whole amount of money paid for a quantum of goods as their price, or—if the goods are of a homogeneous or standardized kind, sold by measure, weight, or tale—the amount of money given for each unit of the goods may be regarded as the price. Alternatively, price may be defined, not as a quantity of money but as a ratio between a quantity of money and a quantity of goods. This is generally the more useful conception, but the prices of unique goods, such as works of art, cannot be said to be ratios of quantities. The price ratio is usually stated as so many monetary units (shillings, pounds, dollars) per unit of commodity (ton, yard, bushel). In some markets, however, the ratio is expressed inversely, as so many ounces or yards per shilling, pound, or dollar. This would be a negligible difference if it were not that, as the makers of index numbers have found, where prices or percentage changes in prices are averaged or otherwise combined, precautions must be taken if the results are not to be affected by the particular form in which the price ratios are expressed.

A distinction may also be made between the conceptions of price as a ratio of quantities and as a ratio of values. If ten units of money are required to purchase one unit of a commodity, it may be inferred that a unit of the commodity is ten times as valuable as a unit of money and that the price ratio merely gives expression to that fact. That price is "value expressed in terms of money" is a standard definition. This should not be taken to mean that the values of goods are determined independently of or prior to the determination of their prices, or that the values of goods and of money are determined separately. The factors which determine the values both of goods and of money operate through the processes of exchange, and the values which are thus determined appear in the guise of money prices. It is probable, indeed, that the abstract notion of exchange value is nothing more than a generalization of the simpler idea of price. When we say that price is a ratio of values or that price is value expressed in terms of money, we logically imply, not that value is antecedent to price, but either that in respect of each particular transaction the limits within which the ratio of exchange can vary are established by the general state of the market, or that in analysing the factors which determine the price of any one commodity, the value or general purchasing power of money, may often, without too large an error, be assumed to be constant. The conception of the value of money, in turn, rests upon nothing more tangible than a broad view of all the various prices of different goods and services, but it is nevertheless a useful conception.

The Problems of Price.—The economic theory of price has two principal divisions. One division has to do with the interrelations of the prices of different goods and services, and with the way in which changes in production, consumption, and trade operate directly upon some prices and indirectly upon others. This division of price theory includes that important part of economics sometimes called the theory of value and distribution (or sometimes simply the theory of price-making) and also parts of other fields, such as the theory of international trade. It is concerned both with the tendencies which continually make for a coherent and consistent system of prices and with the subversive forces which make continuously for change. The other division of the theory of prices has to do with the causes of general movements of prices to a higher or lower level—movement which may continue gradually through a long period of years, but which may be broken by shorter movements, convulsive or cyclical in nature. The study of the long-continued general trends of price, and, in considerable measure, of their shorter movements as well, is commonly made a part of the general theory of money. The reason is not that general changes of prices are always attributable to the action of monetary factors alone, but that they are reflected in and in fact are changes of the value of money. They can be studied most conveniently and effectively by enquiring into the changing relations between the supply of money and credit and the volume of production and trade. In recent years especial attention has been given to what might be called the distortions of the whole interrelated structure of prices which accompany changes in their general level. The movements of certain classes of prices, for example, generally lag behind the movements of other classes of prices in a more or less systematic way.

Commodity prices are not the only prices with which economists are concerned. Securities such as bonds or debentures, stocks or shares and bills or notes, have their prices. Railway rates are prices. Foreign exchange rates express the price of current funds in one market in terms of current funds in another market. Wages, of course, may be regarded as the price of labour, rent as the price of the use of land or of other durable goods, and interest as the price of advances of money. Profits, however, are not prices, for they are not proportioned in any definite way to the amounts of goods or services supplied, but are contingent upon the success of particular undertakings. Nor are taxes prices, for the governmental services for which taxes pay are diffused, and not apportioned to different taxpayers in accordance with their respective contributions. Not even the fees which are paid to Government offices for licences or for particular services are in all respects like prices, for the amount of the fee is usually proportioned very loosely, if at all, either to the value of the service to the recipient or to its cost to the Government. But the charges which Governments make for supplying such things as water, gas, electricity and transport may be governed more or less completely, according to the circumstances of the particular case, by the principles in accordance with which prices are determined.

Equilibrium Price. — This is a price at which supply and demand are equal. A distinction has to be made between a temporary equilibrium, such as would express a balancing of the immediate factors which are operative in the market at any given time, and such an equilibrium as would be reached eventually if the particular factors now known to be at work could have their full effects. Equilibrium, then, is always relative to time. All economic equilibria are unstable, but it is convenient in analysis to take separate account of the factors which, if they were neither impeded nor deflected, might finally lead to a stable equilibrium. Market price is the price which will be found in a given market at a given time. It may be regarded as the limiting form of short-time or temporary equilibrium price. Normal price is a price just high enough to cover the expenses of production, including whatever profits are necessary to induce men to undertake the risks of productive enterprise. Because some firms produce at smaller expense than others, because the expense per unit of production often varies, directly or inversely, with the volume of output, and because of the difference, at any given time, between the average expense incurred per unit of product in a given establishment and the expense of producing an additional unit, the conception of normal price is attended with serious, though not altogether insuperable diiiiculties.

Competitive Price. — This is the price which results from the activities of many buyers and sellers, each of whom can affect the outcome only by buying or selling larger or smaller quantities according as the price is at one point or another. Monopoly price is a price fixed with a view to his or their own advantage by a single (exclusive) seller or buyer, or by a combination of sellers or buyers acting as a unit. Class price (or differential or discriminatory price) is possible only when a monopolist seller is able to deal separately with different classes of buyers or to manage in some other way to sell his goods in what are virtually separate markets. A speculative price is a present price which is influenced by estimates of what the price of the same commodity or security will be in the future. A contract price, or what is sometimes called in speculative markets a "future," is the present price for an exchange which is to be completed by delivery or by taking delivery in the future. Mint price is the price of gold in terms of money at a Government's mint or at a bank which acts as agent for the mint. Gold price is the rather misleading name sometimes given to the result obtained by dividing a price which is quoted in terms of some depreciated paper currency by the price, in terms of the same currency, either of gold or of funds payable in some other country where a gold monetary standard is at the time effective.

Demand Price. — This is the price at which some specified quantity of a given commodity will find purchasers. A schedule of demand prices or demand schedule, exhibits the general relation between the price of a commodity and the amount of it which will be purchased. Supply price, similarly, is the price at which a specified quantity of a given commodity will be offered in the market. The form of the supply schedule depends upon the conditions under which the particular commodity is produced and also upon the period of time which is taken into account. Thus a sudden general increase in demand (in the sense of a general upward movement of a schedule of demand prices) would have the effect of increasing the price at which a specified quantum of a given commodity would be offered for sale. But if the commodity is produced under conditions of increasing returns (*i.e.,* if the output can be increased without a proportionate increase of costs), an increase of demand, continued over a period of years, will have an opposite effect upon its supply price. Indeed, the gradual lowering of the supply prices of commodities produced under conditions of increasing returns need not wait upon a general increase of demand. It is necessary only that demand should be elastic, *i.e.,* that the demand price of successively larger quantities should not fall off too rapidly. It follows that when an adequate period of time is taken into account, a schedule of supply prices may show that larger quantities will be supplied at lower instead of higher prices. A corresponding schedule of supply prices for a commodity produced under conditions of diminishing returns (*i.e.,* with increased output procurable only at a more than proportionate increase of costs) would, of course, like a schedule of short-period or "instantaneous" supply prices, show higher prices associated with larger quantums of supply. (See also ECONOMICS, SUPPLY AND DEMAND, and VALUE.) **(A. Yo.)**

PRICE-CUTTING, the term used to indicate the practice of selling standard merchandise at a price below that advertised by the manufacturers. With many trade-marked articles the manufacturer attempts to maintain the price at which his products are sold to consumers. The idea is that both wholesalers and retailers should make a profit on his merchandise; otherwise they might refuse to handle it. When an article becomes so well known that it is widely accepted as a standard, it is a common practice for retailers having similar goods that they sell under the store label to reduce the price of the trade-marked article and use it in their advertising as a special attraction. Their clerks are instructed to try to sell the substitute bearing the store label instead of the trade-marked article requested. This practice is disadvantageous to the manufacturers inasmuch as the cut-price often makes the article unprofitable for other retailers and they also attempt to substitute other brands for the one advertised. When the distributor departs from the usual practice and sells for cash where most stores would extend credit, and when he refuses to deliver goods and requires the customers to carry their own purchases, he is expected to sell at a lower price because he gives less service. The reduced price of the "cash and carry" stores is not usually included in the term price-cutting. In most countries price-cutting is prevented by contract between the manufacturer and distributors. That form of contract was not legal in the U.S. until the passage of fair trade laws by most of the separate states. Price maintenance remained illegal, by contract, except in states having these enactments.

In 1951 the U.S. supreme court held that state fair trade laws did not apply to retailers who would not make pricing agreements with manufacturers. (H. E. A.; X.)

PRICE MAINTENANCE. The subject of price maintenance, or, more specifically, resale price maintenance, is one that demands special consideration among the various types of price fixing, both from the legal and the economic aspects. Other forms of price fixing are treated elsewhere. For agreements and understandings as to prices among competing manufacturers, wholesalers or retail dealers, see TRADE ORGANIZATION, and also POOLS, IN INDUSTRY and CARTEL; for concentrations of industry in monopolistic, or quasi-monopolistic, forms, see MONOPOLY; for price fixing by legal monopolies. such as railroads and other privately onned public utilities. see PUBLIC UTILITIES The following discussion relates to resale price maintenance exclusively.

Resale price maintenance is the term applied to various devices by which individual manufacturers or distributors of particular trade-marked, branded, or otherwise identified articles fix minimum resale prices. The most widespread and important manifestation of resale price control is seen where the manufacturer of an article, by contract, fixes a price below which retailers shall not sell it to the public.

The practice has been fostered in the United States by manufacturers who sell trade-marked and well advertised commodities such as breakfast foods, toilet goods, proprietary medicines, books and musical instruments, and has been supported by trade associations of manufacturers and dealers in various lines of products. Supporting dealer organizations have the further objective of inducing the fixing of minimum prices high enough to insure a margin satisfactory to the dealer. In Great Britain there exists an association, known as the Proprietary Articles Trade Association, whose main object is to encourage and enforce this system. A similar association was founded in Canada in 1925 but was later disbanded when it was adjudged to be a combination in restraint of trade.

It is contended by the advocates of resale price maintenance that the maker of an article which bears a trade-mark that he has made valuable by extensive advertising should be entitled to stipulate the price at which it shall be sold by dealers to the public. It is claimed that the manufacturer cannot adequately protect his intangible property—the good will attaching to his trade-mark or brand—unless he restrains dealers who sell his products at a lower price than he suggests, sometimes less than cost, as a "leader" or a "draw" to customers. This use of "leaders," it is maintained, sometimes causes competing retailers to refuse to handle the goods because they can neither make a profit by meeting the low prices, nor sell at the manufacturers' higher resale prices, thus destroying good will of the dealer and reducing the number of dealer outlets.

In England, the legal status of resale price maintenance is based largely upon court application of common law rules respecting freedom of contract and'the reasonableness of agreements in restraint of trade. The courts interpret the right of contract broadly and permit manufacturers to make resale price maintenance agreements among themselves and wrth their distributors provided undue restraint of trade is not shown. Resale price maintenance was considered by official committees in 1920 and again in 1931. The report of 1931 neither condemned, nor did it give unqualified approval to the practice.

Canadian policy follows quite closely that of England but is somewhat more restricted. In certain cases resale price maintenance has been declared to be against public policy, but the practice itself has not been passed upon. Resale price control by a combination of manufacturers, jobbers, and retailers of drugs was condemned in 1927, and a similar combination to control prices of tobacco products was likewise condemned as a combine within the meaning of the Canadian Combines Investigation Act.

In the United States prior to 1936, in cases coming before the U.S. Supreme Court, resale price maintenance was permitted in cases of goods distributed through bonafide agents rather than independent dealers, but otherwise goods sold under a trade name or mark were not exempted from the common law and statutory provisions against monopolies and restraints of trade. As early as 1907 the courts held that a system of contracts entered into by the manufacturer of a proprietary medicine with a large part of the wholesale and retail druggists stipulating the resale price of the product was unlawful and unenforceable on the grounds that it restrained trade (*Park and Sons* v. *Hartman,* 153 Fed. 24), and in 1911 the U S. Supreme Court rendered a similar decision in the Dr. Niles case (*Dr. Miles Medical Co.* v. *Park and Sons Co.,* 220 *U.S.* 373). Patented and copyrighted articles have also been held to be within the scope of the Dr. Miles case, and agreements to maintain resale prices thereon declared unlawful.

In 1915, the Federal courts refused to issue an injunction restraining the manufacturer of a breakfast food from carrying out the policy of refusing to sell to those dealers unwilling to maintain resale prices. In 1922, the US. Supreme Court held that a corporation may have and announce a policy of refusing to sell to cutrate dealers and withhold its goods but may not consistently go beyond this act and by contracts or combinations, express or implied, unduly hinder or obstruct the free and natural flow of commerce (*F.T.C.* v. *Beech-Nut Packing Co.,* 257 U.S. 441).

Throughout the period from the Dr. Miles decision in 1911 to the enactment of the National Industrial Recovery Act in June 1933 (48 Stat. 195), bills to legalize resale price maintenance in interstate commerce in the United States were continually presented to the Congress, but all failed of passage. In 1931, however, the State of California enacted a law legalizing resale price maintenance by contract between manufacturers or distributors and retail dealers within the State of California. With the setting up of the National Recovery Administration under the National Industrial Recovery Act, interest in the enactment of further State laws waned due to the fact that numerous codes contained price control provisions and a number provided for some form of resale price maintenance. Following the decision of the U.S. Supreme Court in the Schechter case (*Schechter Poultry Corp.* v. *US.,* 295 U S. 495) which declared portions of the National Recovery Act unconstitutional, the movement to enact State resale price maintenance laws again gained momentum. By the end of 1935, ten States had enacted such laws, generally similar to the 1931 California act. Late in 1936, the U.S. Supreme Court declared the State laws of California and Illinois to be constitutional (*Old Dearborn Distributing Co.* v. *Seagram Distillers Corp*, 299 U.S. 183, and *The Pep Boys, Manny, Moe & Jack of California, Inc.* v. *Pyroil Sales Co., Inc.,* 299 U.S. 198). These decisions provided such a stimulus that by 1939 44 of the States had legalized resale price maintenance. by laws commonly designated as Fair Trade Acts.

In 1937, the Tydings-Miller Act amended the Sherman Antitrust Act by exempting from the application of that act, "contracts or agreements prescribing minimum prices for resale of a commodity which bears, or the label or container of which bears the trade mark, brand, or name of the producer of such commodity, and which is in fair and open competition with commodities of the same general class produced or distributed by others when contracts or agreements of that description are lawful as applied to intrastate transactions, under any statute, law, or public policy now or hereafter in effect in any State. Territory, or the District of Columbia," and further declared that the making of such contracts "shall not be an unfair method of competition under the Federal Trade Commission Act." This exemption. however, is specifically stated in the act not to make lawful "horizontal" agreements or understanding on prices between competitors, whether they be manufacturers or distributors, and such "horizontal" agreements are still a violation of law when in restraint of trade or commerce among the States.

While resale price maintenance appears presently to find legal sanction in the United States and in the United Kingdom. consumer organizations and economists generally are opposed to the practice from the standpoint of its effects on the public, and many in the United States advocate returning to former policies on the ground that the evils inherent in a system of fixed retail prices outweigh the benefits of resale price maintenance to manufacturers of some lines of merchandise and a segment of the retail trade.

PRICES, STATISTICS OF. In the United Kingdom and the United States. and in some other countries. price quotations for a number of important commodities are available from the middle of the 19th century; there are some quotations in earlier periods. However, there have been many changes in the nature and quality of the commodity and in the type of price quotation; in only a few cases have the changes been small enough to permit the compilation of a continuous series of prices on a reasonably comparable basis. A series of single prices, however interesting they may be, cannot be taken as indicating general movements in prices. What is required for this purpose is a set of indicators shoning the general course of prices, in convenient major groups of commodities. over time in a particular country. Such indicators can only be constructed in the form of index numbers (see INDEX NUMBERS) which are generally averages of the changes in prices of certain commodities selected to represent the various groups. The averages can be computed in various ways giving different results. Moreover. the index numbers depend on the accuracy and continuity of the price quotations used and any one compilation is generally limited to comparisons of prices in a relatively short period, perhaps no more than 10 or 20 years. For longer-run comparisons. different index numbers need to be "spliced" together and the results are more approximate.

The most obvious feature in the general world picture is the effect of major wars on wholesale prices. During the French Wars (1793–181j) prices rose rapidly and were then maintained at a high level, though with considerable oscillations. Prices fell after Waterloo but it was not until the 1820s that they had fallen to the level of the years before 1793. The American Civil War (1861–65) gave rise to the second major peak in wholesale prices in the U.S. but the effect in the U.K., and in many other countries, was much smaller. World Wars I and II exercised an even sharper effect on prices. Moreover, the course of prices was broadly similar in the two mars. at least in the United Kingdom and the United States—an immediate and pronounced rise, followed by a slower increase as measures of price control became effective and finally another sharp rise after the close of hostilities. The main difference between the two mars was that price control was effective sooner in World War II, and the postwar increase in prices mas more protracted.

Between wars the trend of prices was generally downward and, at the outbreak of one war, the level of prices was little different from that immediately before the previous war. Closer inspection, however, reveals major fluctuations disturbing the general course of prices. One cause of disturbance was the discovery of new gold fields or the rapid development of gold production. A growth in the supplies of gold coming forward pushes up prices in domestic currencies which are based on gold. The discovery of gold in California and Australia raised wholesale prices after 1850 and prices did not sink below the level of 1849 until about 1880. The effect of the new gold supplies on prices is to be seen clearly in the series for the U.K. where the American Civil War mas a very minor disturbing factor. The development of the South African gold fields was the main influence in the steady rise in prices following the low point attained in 1896, a rise which continued until the outbreak of World War I.

Other major fluctuations. generally working themselves out in a period of less than ten years, are those associated with booms and depressions. The pattern is boom, commercial crisis, recession and recovery. Commercial crises generally appear as peaks in the course of wholesale prices; *e.g.,* those of 1839 and 1847 in the first half of the 19th century and that of 1907 at the beginning of the 20th. No earlier depression, however, had quite the same catastrophic effect as that following the crisis of 1929. Both in the U.K. and in the U.S., wholesale prices in 1929 stood about 35% higher than in 1913: by 1932–33, prices had fallen to nearly 10% below the 1913 level; *i.e.,* a decline of more than 30% in less than four years.

A remarkable feature of the course of prices in modern times is the broad similarity between the movements in the U.K. and the U.S. There are, of course, many factors which exert little more than a local influence. For example, the Franco-Prussian and South African wars had relatively little effect on prices in the U.S. and the American Civil War influenced prices outside the U.S. to a relatively small extent. However, major wars, severe commercial crises and gold discoveries are events which are international in their impact on economic affairs and they affect prices everynhere. For this reason it can be said that there has been a level of world prices, the movements of which can be distinguished in a broad historical survey.

In an index of the general level of nholesale prices, the movements in the prices of commodities of many different kinds are averaged. Individual price quotations are to be expected to show greater fluctuations than the general a erage as is nell illustrated by the price of English wheat (Table IV and fig. 3). Up to about 1880. imports of wheat into the U.K. uere small and the price was largely dependent on the supplies of domestic wheat available and hence on the condition of the harvest. The price of nheat showed very large fluctuations, many of which did not correspond at all with movements in the general price level. After 1880, with increasing supplies of wheat coming in from the western hemisphere and other overseas areas, the price of English wheat was determined more by world prices than by the British harvest. The result was. first, that the price was reduced in relation to other prices and, second, that there were less violent fluctuations in price Though still showing wider variations than the general price level, the price of English wheat followed fairly closely the general course of prices. (R. G. D. A.)

UNITED STATES

In the United States, as in other countries, statistics of prices became available in greater quantity and in more varied forms than data reflecting other major aspects of the economy such as production and employment. The wealth of price data was steadily enhanced by the contributions of government departments and private business and research groups, and information about historical prices and price movements was expanded by the painstaking work of individual scholars.

In this section of the article three main tasks are undertaken. First, an effort is made to indicate the nature and sources of the price data available in the United States. Secondly, the data are drawn upon to describe the movement of the general price level in the period between the founding of the republic and the latter 1950s, and to analyze changes in the relationships of prices for different kinds of goods within the last 50 or 60 years of this period. Finally, a summary is presented of the cyclical behaviour of the price level and of price relationships.

NATURE AND SOURCES OF U.S. PRICE DATA

Statistics on prices are available in two forms: (1) price quotations for specified commodities, services or securities; and (2) index numbers which usually are designed to summarize the average amount of change in the prices for a specified group of commodities, services or securities between two or more dates. Despite the careful efforts of price statisticians in business and government who supervise the collection of price data and the compilation of price indexes. the numerous practical and theoretical difficulties involved in their work cannot be completely overcome. Although these problems need not be considered in detail here, some understanding of their general nature is essential to proper interpretation of the price data discussed below.

The central problem of price collection is to gather a sample of prices representative of the various price quotations for each of the commodities under study. Sampling is almost always necessary because it is not feasible to obtain a record of every single transaction. Price collection must be planned so that observed diflerences betneen the prices of any two dates (any two places, when place-to-place rather than time-to-time price differences are being studied) will reflect changes in price and price alone. In order to exclude the influence of variation in quality, commodity prices are frequently collected in accordance with detailed specifications (i e, descriptions) such as "wheat, no. 2 red winter, bulk. carlots. f.o.b. Chicago, spot market price, average of high and low. per bushel."

When the correct average prices for a commodity for successive dates have been determined. they may be expressed as percentages of the price for a particular date or "base period." These percentages are called "price relatives." The problem of constructing price index numbers is to combine either the prices themselves or the price relatives in such a way that the central tendency of the movement of the whole group of prices from one period to another is accurately described. Although a number of problems are encountered at this stage, the one that is perhaps the most important to an understanding of the limitations of price indexes is the weighting problem. This arises because not all commodities for which prices have been obtained are of equal importance in the price universe under study. The price of wheat, for example, should be given more weight in an index of wholesale prices in the domestic economy than the price of pepper, because either in physical terms or in value terms wheat is much more important in trade. The difficulty is that the relative importance of commodities changes over time. Furthermore, some commodities drop out of use and new ones appear, and often an item changes so much in composition and design that it is doubtful whether it can properly be considered the same commodity. Under these conditions, the pattern of weights selected can correspond accurately to the relative importance of the various commodities in only one of the periods for which the index numbers have been calculated. The greater the lapse of time between the period of the weighting pattern and other periods, the less relevant the pattern is likely to be for one of the periods, and therefore the less meaningful the price comparisons become. Price indexes thus can give relatively accurate measures of price change only for periods close together in time. Mills found also that the dispersion of price relatives computed on a given base year tends to increase with time; this means that the price index numbers become less representative of the central tendency of the whole distribution of the price relatives for the various commodities.

Sources of Data on Actual Prices.—The most important single source of price statistics in the United States at mid-20th century was the bureau of labour statistics (BLS) of the U.S. department of labour. The BLS was publishing monthly prices for about 900 different commodities at the primary market level (*i.e.*, 'the stage of marketing at which the goods were first sold), and for approximately 50 foods and for various types of fuels at the retail level. All the retail prices and roughly half of the wholesale prices were obtained directly from sellers. Most retail prices were collected during store visits by price agents trained to price goods in accordance with established specifications. A few retail prices, such as those for fuel and those primary market prices obtained directly from sellers, were secured by mail. The other primary market prices were obtained from such recognized trade journals as *Iron Age* and the *Oil, Paint and Drug Reporter*.

Another important governmental source of price data was the department of agriculture, collecting both "local market prices" and "wholesale prices" of farm products, the latter referring to prices at central markets. Estimates of Dec. 1 crop prices and Jan. 1 farm values of livestock are available since 1867, monthly prices of commodities sold by farmers since 1908 or 1910. Prices of articles bought by farmers were published annually from 1910 to 1922 and quarterly (for most items) subsequently. At mid-century, the department was receiving reports on farm product prices from about 9,000 respondents (mostly buyers or dealers) and reports on prices paid by farmers from about 17,000 respondents (mainly independent retailers serving the farm population). The prices thus obtained were available in the department's publication *Crops and Markets*.

The trade journals were, perhaps, the most readily available nongovernmental source of commodity price data. Prices for highly standardized commodities traded on organized markets (*e.g.*, wheat, coffee and sugar) and prices for stocks and bonds were also reported in the financial pages of many metropolitan newspapers.

Survey of Available Price Indexes.—The prices from all these sources were being used to compute a wide variety of index numbers at mid-century. The most generally used index numbers were those computed by the bureau of labour statistics, particularly its wholesale price and consumers' price indexes. Before describing these indexes. it may be well to survey the more important price indexes in the U.S., taking into consideration first commodity price indexes at both wholesale and retail levels and then indexes of the prices of services, construction and securities.

In the group of predominantly commodity price indexes were the department of agriculture indexes of prices received and prices paid by farmers. These indexes, based on the department's price data collection described above, were used in the determination of parity prices. Among the more widely known nongovernmental price indexes published in the 1950s were indexes designed to measure price changes for commodities highly sensitive to business movements, particularly raw and semiprocessed materials prices. The Associated Press prepared a daily index of this character and many of the leading financial services (such as Moody's) and jour-

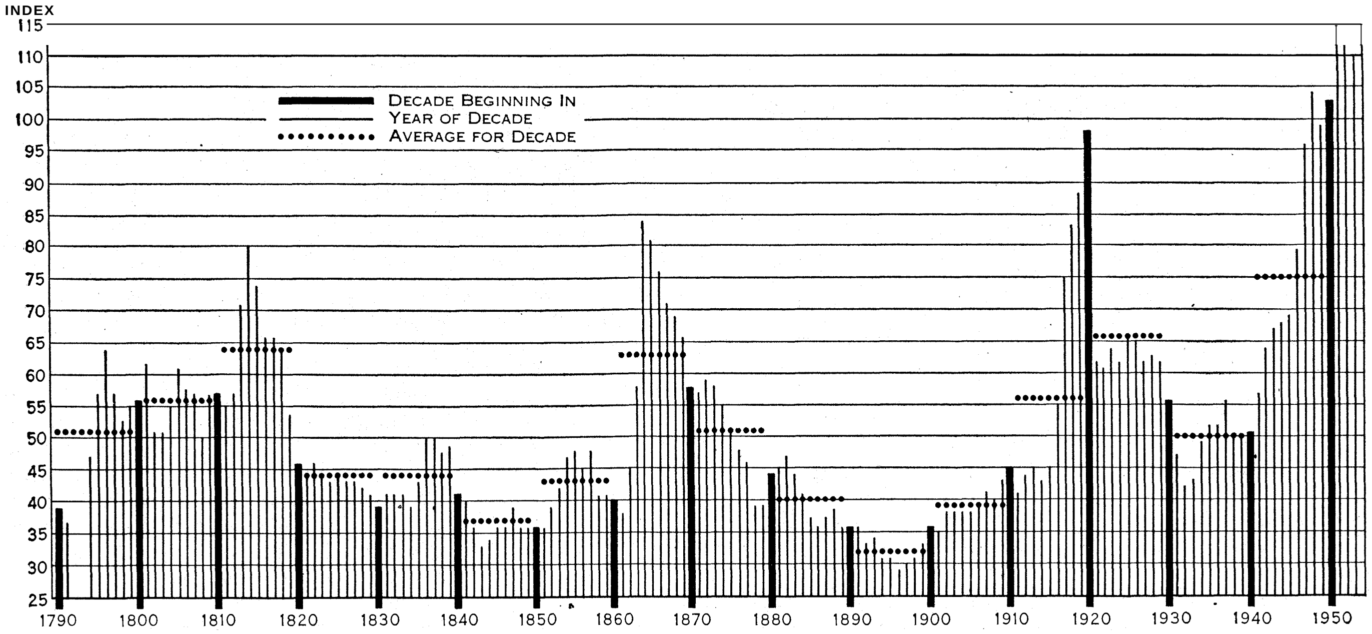

FIG. 1.— MOVEMENTS OF WHOLESALE COMMODITY PRICES IN THE UNITED STATES, 1790–1953 (1947–49=100). FROM 1790 TO 1889 THE WARREN-PEARSON-STOKER INDEX (STOKER BEFORE 1797) IS USED: FROM 1890 TO 1953 THE OFFICIAL INDEX OF THE BUREAU OF LABOR STATISTICS

nals (such as the *Journal of Commerce*) issued indexes of a similar nature. The National Bureau of Economic Research computed wholesale price indexes based on BLS prices but combined according to a different commodity classification (F. C. Mills, *The Structure of Postwar Prices* [1948]). A number of the privately computed indexes of the 1920s and 1930s were abandoned as the government indexes came into greater use.

A large number of wholesale price index numbers of more limited commodity coverage mere available in the trade journals. *Iron Age*, for example. published an index of finished steel prices which was a weighted average of the prices (in cents per pound) of ten major finished steel products.

In addition to these and similar commodity price indexes that were in the realm of public information, a number of business firms computed special-purpose price indexes for their own uses, especially in connection with marketing and purchasing activities.

At the retail level, a distinction must be made between those indexes including services and those including commodity prices only. The consumers' price indexes of the BLS and the National Industrial Conference board were in the former category. while the U.S. department of commerce and Fairchild Publications indexes of retail prices were examples of the latter group. The National Industrial Conference Board index, available since 1914, was similar to the BLS index (described below) but included a number of small cities not in the BLS sample and was based on prices obtained by mail questionnaires. The department of commerce index of prices at retail stores, which mas available for 1929 and 1933 and after 1939, differed from the BLS consumers' price index in that it omitted services (medical care. transportation, recreation, etc.) and included building materials, farm machinery and other nonconsumer goods sold through retail stores The index of the Fairchild Publications. available since 1930, covered the prices of piece goods, apparel and home furnishings. All four of the retail and consumers' price indexes just mentioned were published monthly.

Different in concept from any of the indexes treated thus far was Carl Snyder's "index of the general price level." This was designed to measure changes in prices of commodities at all Ievels from primary to retail markets and shifts in the prices of services and property as well as of commodities. The index was extended from 1938 back to 1791 *(Review of Economic Statistics*, p. 2j [Feb. 1934] and p. 40 [Feb. 1928]). Comprehensive price indexes embracing both services and commodities were also derived, largely with the aid of existing price index numbers. in the course of estimating national income in terms of constant prices. Such indexes were available for 1919–38 in S. Kuznets and others, *National Income and Its Composition, 1919–1938*, pp. 141 ff. (1941). Similar series, referring to price changes in the gross national product and 10 or 12 of its major segments are available for the period 1929–53 in *National Income, 1954 Edition: A Supplement to the Survey of Current Business*, pp. 216–217. U.S. department of commerce. These series will be carried on and, if the past custom is followed, will be found each year in the July issue of the *Survey of Current Business*.

Aside from the services included in the consumers' price index, the most readily available indicators of the changing price of services were indexes of hourly earnings and wage rates. The BLS series on average hourly earnings of production workers in manufacturing industries, available since 1909, was the most general of

Sources: Whole-ale and consumers' price series are the BLS indexes described in text. Hourly earnings are HLS series for production workers in manufacturing. Prices paid (for living and production) and received by farmers are from Department of Agriculture. The construction cost index is from the Engineering Sews-Record and the stock prices are the Standard and Poor's composite index numbers of 400 to 500 stock prices.

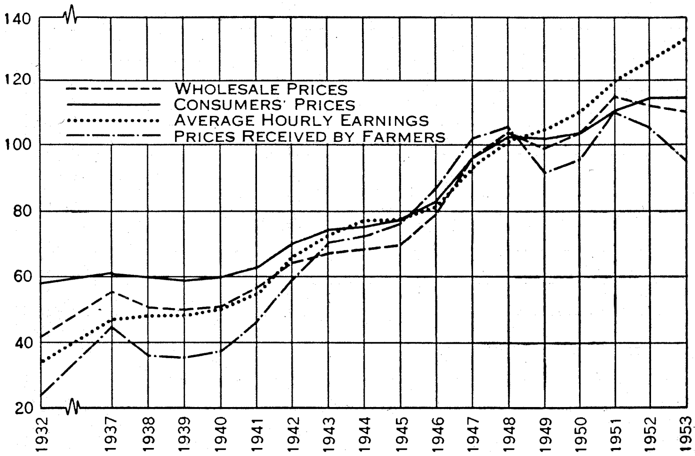

FIG. 2.— MOVEMENTSOF VARIOUS PRICE INDEXES 1932–53 (1947–49=100)

these series. Indexes of wage rates were restricted to particular groups of workers such as organized workers in the building and printing trades

A field in nhich it was necessary to combine wages and commodity prices to derive indexes was construction. These were not price indexes in the strict sense but construction cost indexes. A number of these indexes were being published in the 1950s by private business groups in or servicing the construction industry; in addition, government agencies were publishing index numbers of construction costs in such fields as railroad. highway and farm construction Most construction cost index numbers went back to the 1910–13 period. Mention may be made of the construction cost indexes of the *Engineering News-Record*, the Aberthan Co . the American Appraisal Co., the Associated General Contractors of America, Inc., and E. H. Boeckh and Associates, Inc.

The last category of price indexes deserving consideration here consists of the indexes of security prices. Among the leading indexes of stock prices at mid-century were those prepared by the New York Stock exchange. Moody's Investors Service; Standard and Poor's Corp. and Dow Jones & Co. The first of these indexes was based on the average price obtained by dividing the market value of all listed stocks at the end of the month by the number of shares. The other indexes were based on a more limited but more constant group of sample stocks selected to represent different groups of stocks. The Dow Jones averages, for example, were based on 30 industrials, 20 railroads and 15 utilities; the Standard and Poor's indexes, based on 400 to joo stocks, were available for a more detailed industrial classification. Indexes of bond prices were also computed by the New York Stock exchange, Standard and Poor's and others; such indexes generally derived the bonds prices from average yields.

The general user of price indexes could find data for almost all of the price index series mentioned above in the *Survey of Current Business*, monthly publication of the department of commerce. Sources of the statistics for former years and brief descriptions of many of the indexes were available in *Historical Statistics of the United States, 1789–1945, 4 Supplement to the Statistical Abstract of the United States*, and in the *Statistical Supplement to the Survey of Current Business*. The data in the former publication were carried down to 1952 in *Continuation to 1952 of Historical Statistics of the United States*.

The **BLS** Indexes.— The BLS official wholesale price index numbers date from 1890. The methods of computation and the number of commodities included in the index varied from time to time; but the revisions were made so as to retain comparability of the series. A major revision extending back to Jan. 1947 was issued early in 1952. The most significant changes were the extension of the commodity coverage of the index from about goo items to about 2.000, and the use of the 1947 Census of Manufactures as the source of weights. The larger number of commodities for which prices were collected made it possible to improve the sample of prices for some subgroups in the index and to include for the Erst time other groupings (*e.g.,* machinery) which had been omitted. The result was to make the index representative of prices in all primary market commodity transactions (including the domestic aspects of import and export transactions).

Since the index included the primary market price of goods of all degrees of fabrication. the same commodity was often priced at several stages of production. For example, cotton was priced in the form of raw cotton, cotton yarn. cotton gray goods, cotton piece goods and cotton clothing. Indexes were published monthly for 1 j major groups (*see* Table I), 88 subgroups and a larger number of "product classes" (*i.e.,* minor commodity groups). Indexes for individual commodities were also issued. Prior to 1952, prices for a specific day in each week were averaged to obtain monthly prices for most commodities; beginning in 1952, the price used in the index was generally the one that prevailed on Tuesday of the week containing the 15th of the month.

The BLS specified that the "official" wholesale price index consisted of the old series up to the end of 1951 and the revised series thereafter. This was done to avoid disputes between parties to private contracts in which the price to be paid was to be changed in accordance with movements in the official BLS wholesale price index. Such escalator clauses are sometimes put in contracts that run over a period of time.

The BLS also issued a meekly wholesale price index, which was intended to provide an estimate of what the monthly index would be were it computed each week. After 1952, the weekly index was no longer corrected subsequent to its issuance to make it conform to the movements shown in the monthly index. The BLS, in addition, published a daily index of spot market prices which was intended to serve as a sensitive gauge of changes in market conditions. The monthly, weekly and daily indexes were being published on a 1947–49 base in the mid-1950s.

The BLS wholesale price index had been extended back to 1801 on the basis of price indexes for 1801–40 computed by A. H. Hansen (*Publications* oi the American Statistical association: pp. 804–812 [Dec. 1915], and BLS *Bulletin S o . 367*, pp. 235–48) and data for 1841–89 contained in the Aldrich committee's comprehensive report, "Wholesale Prices. Wages and Transportation," *Senate Report No. 1394,* 52nd congress, 2nd session, part i. p. 9. Hansen's data were based on prices published in Boston. Mass., newspapers for the period 1801–25 and for the period 1825–40 on New York prices published in the "Report of the Secretary of the Treasury on the State of Finances" for the year ending June 30, 1863.

The BLS index was also extended by G. F. Warren and F. A. Pearson back to 1797, and H. Stoker extended it to 1720. This work was based primarily on New York city prices obtained directly or indirectly from newspaper sources and from the treasury report mentioned above (Warren and Pearson. *Prices* [1933]).

Although not directly linked to the BLS index, mention should be made also of a series of careful investigations of early price records in New York city, Boston. Philadelphia (Pa.), Charleston (S.C.), New Orleans (La.) and Cincinnati (O.). A summary of the results of these studies was prepared by A. H. Cole (*Wholesale Commodity Prices in the United States, 1700–1861* [1938]).

The BLS consumers' price index was designed to measure changes in prices of a fixed list of living essentials, not changes in the total amount families spend for living. (*See* COST OF LIVING.) The living essentials relevant for purposes of the index were those of urban wage earners and lower salaried clerical workers. The sample of items and the weights for the various prices were derived from a 1950 survey of the incomes and expenditures of about 12,500 families or single consumers. The weighting pattern of the index was modified from time to time on the basis of later though more limited family expenditure surveys. Methods of computation, the number of items priced and the number of cities covered varied after the index was initiated in World War I, but the revisions were made so as to maintain the continuity of the series as far as possible. In the mid-1950s the index was being published on a 1947–49 base and was derived from the price movements of about 300 items including go foods, 75 articles of apparel, 35 housefurnishings and 10 fuels. Prices were collected in 46 cities, but except for food, rent and certain other items not all cities were surveyed each month. Prices were collected so as to refer to a date near the 15th of each month.

In addition to the consumers' price index for all cities of the nation as a whole, the BLS published indexes measuring time-to-time changes in consumers' prices in 20 different cities. In a very different category were place-to-place comparisons of the cost of living which the BLS made between a number of cities.

Although consumers' price indexes, or cost-of-living indexes as they were formerly called, were calculated for the 100 years preceding the beginning of the BLS series (1913), most of these estimates were based on wholesale price changes in whole or part. Several of these indexes were linked together by the Federal Reserve Bank of New York to form a single series for the period 1820–1913.

The consumers' price index was the index generally cited in escalator clauses in labour-management agreements. It was estimated that early in 1951 wages of several million employees were being adjusted in accordance with changes in the index.

THE LONG-TERM MOVEMENT OF PRICES

It is difficult to describe the movement of prices because, as is evident from the preceding survey of prices and price indexes, there are many different kinds of prices in the economy. It is true that such broad groups of prices as primary market prices, retail prices, wages and security prices could be combined in some way to give an index of prices in general. Carl Snyder's "index of the general price level" represented such an attempt. However, it is hard to interpret the meaning of changes in such an index; it is composed of elements that are too heterogeneous, What is required for most business and public purposes is a knowledge of the behaviour of one or more of the broad groups of prices and sometimes of the major or minor subgroups or even of particular items. depending upon the nature of the specific problem.

It happens that data on wholesale commodity prices, which represent a group of prices of strategic importance in the economy, are available for a longer period than information about other broad groups of prices. Hence. discussion of the long-term movements of prices in the United States may most conveniently run in terms of wholesale prices.

Changes in the Price Level.—Two relevant questions about the long-term movements of prices are: (1) what was the direction of the trend? and (2) what was the degree of fluctuation around the trend? Answers to both of these questions will be sought largely in terms of the BLS wholesale price index which was previously discussed and is set forth in Table I and fig. 1. For the longer sweep of history, the index is extrapolated backward to 1790 by using the Warren-Pearson-Stoker index. Reference will also be made to other indexes which may be found in Table II.

The answer to the first question is that despite the popular notion that prices have been rising in the long run, the figures for the period 1790–1953 do no reveal any persistent upward movement extending over more than a few decades. The popular view is apparently based on a heavy weighting of later experience. During the last two decades of the period, a large and well-sustained upsurge carried prices to higher levels than had ever been reached before. Prices in the peak year, 1951, were more than double the average level for all but 4 of the 16 decades in the nation's history. For the period preceding 1790 the data summarized by Cole (op. *cit.*, pp. 106–107) seem to indicate a slowly rising trend from 1720 to a peak associated with the Revolutionary War. Cole suggested: however, that the period 1720–45 was characterized by level or moderately declining prices and that it was followed by a long price upswing to a Revolutionary War peak with the subsequent trough coming in 1789. By 1796, prices had recovered to a higher level which was only slightly above that of 1801.

As for the question relating to the degree of fluctuation: the answer is that the course of prices from 1790 to 1953 was characterized by relatively moderate changes except for the violent movements associated with war and postwar periods.

In examining these movements, it is easy to pick out the major price peaks, but the troughs are more difficult to select (see fig. 1). This is due to the fact that periods of high prices were confined almost entirely to well-defined short spans of war years, while relatively low prices generally characterized the long interwar periods. The index of wholesale prices passed the 80-mark only in years associated with the War of 1812, the Civil War and World Wars I and II; during almost half of the years from 1790 to 1953 the index was in the 35 to 50 range.

Bearing in mind the approximate nature of price comparisons over long periods of time and the more arbitrary aspect of the selection of trough years among years of generally low prices, the extremes of the historical movements in wholesale commodity prices are shown in Table III.

TABLE 111.—Peaks and Troughs in U.S. Prices

Troughs		Peaks		Trough to peak		Peak to trough*	
Year	Index (1947–49=100)	Year	Index (1947–49=100)	Total period	Annual rate	Total period	Annual rate
1789	38	1814	80	+112%	+3.1%	—	—
1843	33	1864	84	+154%	+4.5%	—58%	—2.9%
1896	29	1920	98	+235%	+5.2%	—65%	—3.2%
1932	42	1951(?)	115	+174%	+5.4%	—58%	—6.9%

*1814–43, 1864–96 and 1920–32.

The annual rates of change suggest that the amplitude of the later swings was greater. It is, however, impossible to generalize on the basis of so limited a number of long swings, particularly since there is such a great margin of error in the earlier index numbers. Furthermore, it must be borne in mind that the calculations are based on the differences between the index numbers at the terminal dates of each period and do not necessarily characterize the period as a whole. Thus, for example, while it is true that the decline in the index from 98 in 1920 to 42 in 1932 represented an annual rate of decline of 6.9%, the significant declines in the index came in 1920–21 and 1929–32; the computed average decline is a poor description of the behaviour of prices during the period as a whole, particularly for 1921–25 when the index rose slightly. The figures showing the fluctuations in the index from trough to peak and peak to trough must therefore be interpreted in the light of the original data in fig. 1.

The periods of upswing from the troughs to the peaks correspond to what have sometimes been referred to as long periods of predominantly good times and the downswings from peaks to troughs to what have been described as long periods of predominantly bad times. There is, indeed, some evidence that the contraction phase of business cycles was shorter during the long upswings both in terms of absolute length of time and as a proportion of length of the full cycle. Despite the likely existence of this relationship, however, it is impossible to state any simple causal connection between the duration of business cycles and the long-term movement of prices.

The first of the upswings indicated above, 1789–1814, was associated with the effects of the Napoleonic Wars and the Industrial Revolution; the second, 1843–64, with the discovery of gold, the building of railroads and the Civil War; and the third, 1896–1920, with electrification and motorization and World War I. The fourth, 1932–51 (if. indeed. 1951 proved to mark the end of this upswing), reflected World War II. the Korean war and the greatly expanded sphere of governmental activity in the economy. The downswings were generally explained in terms of the eventual loss of impetus in the technological innovations which played the major role in the preceding upswings.

Changes in Price Relationships.— The amplitude of fluctuations in the individual price series may have been greater than that of the composite index; unless the peaks and troughs of the various constituent prices come simultaneously, an index representing the average of all the prices would not reveal fully the extremes of the actual fluctuation in prices. Furthermore. the over-all index cannot show the changing relative positions of individual commodity prices or groups of prices in the whole system of prices. In any given movement of the price index. all prices will not, of course, change in the same proportion. Some idea of the changes in price relationships that occurred during the various shifts of the over-all index may be obtained by studying Table I, which shows the index numbers for the major commodity groups in the BLS wholesale price index. In the lower part of Table I, the 1951 group indexes have been expressed as percentages of the same indexes for 1890 (the first year for which the BLS official group indexes were available). for each peak and trough year (1896, 1920 and 1932) and for an intermediate year between each trough and peak (1913, 1926 and 1939). The results show that the major difference in the structure which prevailed after World War II from the price structures of the 50 years preceding that war was the rise in the prices of farm products and foods relative to other commodity prices. This shift in exchange values in favour of farm products was the result of government agricultural policies, high domestic incomes and large exports.

Another group index that rose by a much greater percentage than the over-all index was the building materials price index. This was attributable chiefly to the sharp rise in the price of lumber between 1939 and 1951; lumber prices nearly quadrupled, while most of the other types of building materials (cement, brick, tile, etc.) hardly doubled in price. The commodity groups that had low values in terms of other goods in 1951 relative to their exchange values of former years mere metals and metal products and chemicals (comparisons for this group were of limited validity because its composition was not the same before and after 1926). Hides and leather products and fuel and lighting materials had lower relative prices in the first 10 or 20 years of the period 1890–1949 than in the rest of the period.

These changes and the even greater diversity of changes in relationships among individual commodity prices both influence the price level and are influenced by the price level. Changes in the supply and demand conditions for the individual commodities or for groups of commodities may be active factors in affecting the general level of prices On the supply side, one of the most important factors affecting prices is technological change. Because the rate of technological change is uneven and affects particular industries rather than all industries at once, relative prices are often altered. This is illustrated by the behaviour of prices of tires and tubes in 1939–48. In 1938 these prices were not much different in dollar terms from 1939; since they failed to keep pace with the rise of other commodity prices! which more than doubled during this ten-year period, tire and tube prices fell relative to other commodity prices. An example of the influence of demand upon relative prices during the same period was provided by the great increase in lumber prices noted above; these increases might be attributed to the large quantities of lumber demanded during the war and postwar construction booms.

Relative prices are also influenced by changes in the price level, because some goods and groups of goods respond more readily than others to such changes. In this connection, it is interesting to contrast the price behaviour of the farm-product group and metals and metal-product group in Table I. In the 64-year period 1890–1953, the latter index numbers (annual averages) fell within a 20-point range (50 to 70) in 41 of the years; only 27 of the annual farm-product price index numbers could be found in any 20-point range. and even the range in which this number of observations was found (25 to 45) was typical only of the early years of the period. Such differences in price fluctuations are discussed below in connection with cyclical changes in prices.

F. C. Mills. studying the period 1893–1926 in The Behavior of Prices, estimated that about 40% of the shifts in relative prices could he attributed to changes in the general level of prices (assuming that the causal relation runs from price-level change to alterations of price relationships). while the other 60% would have occurred even if the general level of prices had been constant.

So much for the pattern of wholesale commodity prices, and how this pattern altered between 1890 and 1953. What happened to the relationship of 11-holesale commodity prices to other prices in the economy? The data required to answer this question. available only since 1913, may be found in Table II. In the lower part of this table. the 1951 indexes have been expressed as percentages of the indexes for five earlier years in order to facilitate the comparison of the 1951 price structure with former ones.

The relative increase in farm-product prices noted in connection nith the analysis of wholesale commodity prices is reflected in Table II in two nays: (1) the prices received by farmers had increased more between almost any of the five base dates and 1951 than any other wholesale or retail commodity price series in the table; and (2) among the consumers' price groups, food nas relatively more expensive, compared with other living essentials, than it had been in the 50 years before World War II.

Perhaps the most significant fact is the notably greater rise in average hourly earnings of production workers in manufacturing compared with the rise in consumers' prices; the spread between these two increases is a measure of the rise in average hourly earnings in real terms (*i.e.*, power to buy goods). The total increase in real earnings is not, of course. fully indicated in these figures; less unemployment existed in 1951 than in most of the base periods. The wholesale price index had wider amplitude of fluctuation than the consumers' price index (by about 50%). Stock prices recovered from the depression lows more quickly and generally remained farther above the depression levels than commodity prices. If 1939 rather than 1932 is taken as the basis of the comparison, however, stock price increases did not surpass commodity price indexes until after the sharp rise in stock prices that began in 1950.

THE CYCLICAL BEHAVIOUR OF PRICES

There is a close correspondence between the movements of commodity prices and the business cycle turning points used by A. F. Burns and W. C. Mitchell (Measuring *Business* Cycles, p. 78 [1946]). Mills, who studied 209 price series for cyclical variation during the ten cycles from the revival of 1892 to the revival of 1924, found that an average of 71% of the series had upturns during revivals and downturns during the succeeding recessions (op. *cit.*, pp. 387–389). Of course, some individual price series do not conform to the general business cycle at all, and there have been times when even the over-all wholesale price index moved in a different direction from business activity (*e.g.*, 1938–39). The fluctuations observed in the business cycle are, of course, in the broadest sense changes in aggregate values produced, traded or consumed; these changes in values may be regarded as the net results of changes in prices and quantities. Thus even as a symptom of what is transpiring in the business cycle, price changes must be considered in connection with concomitant changes in quantity.

The price and quantity movements of 64 commodity series during business cycles were analyzed by Mills in *Price-Quantity Interactions* in Business Cycles (1946). For the composite of all 64 commodities and of all cycles, the movement of prices and quantities at various points in the general business were summarized by expressing each of these series as a percentage of its average for the whole cycle:

	Prices	Quantities
Initial trough	94	90
Peak	112	112
Final trough	90	94

The average amplitude of each phase of the composite cycle was thus 20% for both prices and quantities. However, in expansion, prices rose only 80% as much as quantities did, but in contraction they declined 23% more than quantities. Also, quantities tended to rise in the final stage of contraction while prices were still falling. About five-sixths of the commodities studied conformed to the cycle, but with wide diversity in amplitude of price and quantity movements. For farm products, foods, consumers' goods and nondurable goods, prices varied more than quantities during the course of the cycle, but the combined variation of both price and quantity (*i.e.*, value) was characteristically low. On the other hand, for durable goods, capital equipment and nonfarm products, prices mere relatively stable and cyclical influences mere reflected in relatively large changes in quantities.

Mills pointed out that the groups of commodities with flexible prices are those close to the initial extractive stages or those close to the final stage oi consumption. The stability of output in the extractive industries and the relatively stable character of consumption (especially of nondurables) throws the burden of cyclical adjustment upon price.

Although there is general agreement that certain industries adjust to falling demand primarily through reduction in output with prices remaining relatively stable while in others the reverse is true, not all students interpreted the underlying factors in the same terms as Mills. G. Means, for example, attributed the inflexibility of certain prices mainly to control over prices placed in the hands of business administrators in industries characterized by a relatively small number of sellers. Means's measure of price flexibility was based on frequency of price change. According to this criterion, most commodity prices during the period 1926–33 were either very flexible or very inflexible; few fell in the middle range ("Industrial Prices and Their Relative

Inflexibility," *Senate Document* No. *13*, 1st session, 74th congress [1935]). Those prices changing least frequently were found to have the smallest amplitude of fluctuation (S. Nelson and W. Keim, "Price Behavior and Business Policy," Temporary National Economic Committee, *Monograph No.* 1, p. 170 [1940]).

Price Changes in World War 11.—Some aspects of the impact of World War II on the U.S. price structure have already been mentioned. The peak year of the price swing associated with World War II was in 1948 when the wholesale price index averaged 104 (1947–49=100). This was almost double the level of 1941, the year of Pearl Harbor, and more than double the average for 1939, the year of the beginning of hostilities in Europe. The rises in the index associated with World War I and with the Civil War were similar in magnitude to that of World War II, but the more than doubling of the index occurred over a somewhat shorter span of years (1861–64 and 1915–20). The consumers' price index rose by more than 70% between 1939 and 1948; it had doubled between 1914 and 1920. The price decline in the year following the peak year was much more moderate after World' War II than it was after World War I. The record of the later of the two wars was also unique in that price increases were held in check with remarkable success by price controls during the four years of actual hostilities despite the shortages of materials and labour involved in the unprecedented production of the war economy; in 1945, the year hostilities ended, the wholesale price index averaged 69 compared with 57 in 1941 and 50 in 1939, and the increases in the consumers' price index were comparable.

As a matter of fact, the wartime price increase in the United States was less than that of almost all other countries (Canada, and if consumers' prices are taken into account, possibly Australia and New Zealand, were the chief exceptions). The great inflation in U.S. prices came in the three pears after the end of the fighting, particularly after the abandonment of price controls in mid-1946. This rise brought the total increase in U.S. prices since 1939 beyond the increases that had occurred in most nations of the British Commonwealth, the Scandinavian countries and Switzerland. Elsewhere, the 1939–48 price inflation was generally greater than in the U.S.

The outbreak of the Korean war of 1950–53 brought another upswing in prices which reached a peak in 1951.

UNITED KINGDOM

The movement of the general level of wholesale prices in the U.K. during the 19th century, between the close of the French Wars and the South African War, can be summarized best by reference to three periods. Between 1820 and 1850 there was a general downward movement, combined with considerable fluctuations, from about 155 in 1820 to about 90 in 1850 (1913=100). From 1850 to 1870 the price level was first raised and then maintained, apart from fluctuations, as a result of great economic developments (in industry, transport, etc.) backed by the new supplies of gold from California and Australia. The earlier downward trend was resumed after 1870, when the level was around 115 (1913=100), until a low point of a little over 70 was reached in 1896. Before the end of the century, therefore, wholesale prices in general were less than half the level ruling immediately after Waterloo.

Following the South African War and the development of the South African gold fields, wholesale prices moved upward fairly steadily until 1914. The immediate effect of the outbreak of war in 1914 was a sharp rise in prices. In the first three years, Aug. 1914 to Aug. 1917, wholesale prices rose by an average amount of 2% a month. Control of prices then began to take effect and there mas even some decline after the armistice in Nov. 1918. The postwar rise, however, was the most rapid recorded to that date; wholesale prices increased by more than 40% in the year April 1919–April 1920. The reaction was just as spectacular, and prices generally were halved by the end of 1921. The subsequent further fall, between 1924 and 1929, was caused at least in part by the restoration of the gold standard (May 13, 1925). The depression following the crisis of 1929 was severe, though the effect on wholesale prices mas somewhat offset by the abandonment of the gold basis (Sept. 21, 1931). The period of 25 years 1913–38 was marked by price fluctuations of the most violent kind; but at the end of the period mholesale prices in general were little more than 5% above the level of 1913.

There were differences of great significance between the movements of wholesale prices of different groups of commodities, and between wholesale prices on the one hand and retail prices of comparable commodities on the other. The broad comparisons of greatest interest are those between the prices of foodstuffs and the prices of textiles and clothing. The relevant data for the period of nearly 60 years up to 1938 are shown in Table *VI*.

TABLE IV.—*Wholesale Price, United Kingdom, 1790–1953*

Year	Wheat price* (*s* per qtr.)	Statist index† (1913=100)	Year	Wheat price* (*s* per qtr.)	Statist index† (1913=100)

*Wheat price: English *Gazette* price of wheat, in shillings per quarter of 480 lb
†Statist index: from 1847, index compiled by the *Statist* newspaper, London, continuing the original calculations of A. Sauerheck, with base shifted from 1867–77=100 to 1913=100; before 1847, index compiled by W. S. Jevons (*Journal* of the Royal Statistical Society, London, 1865) equated to the *Statist* index at the average of the decade 1853–62.

TABLE V.—Prices in 1948 (*1938=100*)

	Wholesale	Retail
Prices of food products before subsidies	255	200
Prices of food products after subsidies	175	150

Source: R. G. D. Alien, "Wholesale Prices, 1938–48," *Economic Journal* (London, 1949).

In the period of booms, depressions and wars, 1880–1938, there is one broad conclusion which stands out—foodstuffs tended to become relatively cheaper and textiles and clothing relatively dearer. Moreover, this divergence is greater in retail prices than in wholesale prices. Retail and wholesale prices of food (and also of textiles and clothing) marched together quite closely up to 1914 hut, in the general decline of prices between 1924 and 1938, wholesale prices fell more rapidly than retail. The increased margin between wholesale and retail prices arose, at least in part, because of the greater importance of distributive

*Wholesale prices: constituents of *Statist* index (*see* Table IV); food and textile material; are group index numbers, coal is a single price quotation (Wallsend Hetton in London to 1916, then Rest Yorkshire house). †Retail prices: estimates by A. L. Bowley, *Wages and Income in the United Kingdom Since 1860* (Cambridge University Press, 1937), continued by constituents oi the cost of living index compiled from 1914 by the Ministry of Labour, London.

and marketing services. This mas particularly true of textiles and clothing: in 1937–38 wholesale prices of textile materials stood approximately at the level of 1913 but retail clothing prices were more than double those of 1913. A similar comparison for foodstuffs shows a less marked difference: retail food prices in 1937–38 were about 40% above 1913 while wholesale prices of foodstuffs had risen by about 10% in the same period.

Wholesale prices of coal and retail prices of fuel showed a similar divergence. Wholesale prices of coal increased in the late 19th century but, at the end of the 1920s, they stood little higher than they were before World War I. On the other hand. retail prices of coal, gas and electricity were 70% higher in 1928–29 than in 1913. The 1930s were characterized by an upward movement in fuel prices, while other prices generally tended to fall

The mocement of prices during World Wai 11 and the postwar period can be followed with the aid of index numbers of more elaborate construction than those used for earlier periods. The data are summarized in Table VII. Changes in the general level of wholesale prices in World Wars I and 11 were broadly similar (*see* fig. 3). According to the index shown in Table VII, there was a rapid rise in prices, amounting to about 55% in the first three years of war, 1939–42. This was followed by a period of slowly rising prices, as price control became effective, and prices at the close of the war mere generally only 5%–10% higher than in 1942. The price rise was accelerated in the postwar period and amounted to 30% in the three years 1945–48. The increases shown by the index of Table VII are less than those recorded by the *Statist* index (fig. 3). The latter comprises mainly the prices of basic commodities whereas the former includes prices of many mandfactured products which were subject to price control and, in particular, to the effect of subsidies. The general comparison with World War I, however, is clear Though the price movements were similar in general direction, the initial rise in prices after 1939 was more moderate, price controls were more effective and operated more quickly, and there was no repetition after 1945 of the postwar crisis of 1920.

The feature of price control, in the postwar period of 1945–48 as much as during the war, was the effect of subsidies (including trading losses in government purchasing) in moderating the rise in prices. Subsidies were largeiy, though by no means entirely, concentrated on the main foodstuffs and they affected both wholesale and retail prices. If a range of prices of food products is taken for comparison at wholesale and at retail, the results shown in Table V (in round figures) are obtained.

A similar result is found for clothing prices in the period before the removal of clothing subsidies at the beginning of 1948. Subsequently, the continued operation of the "utility" clothing scheme acted as a cushion in absorbing part of the rise in prices of textile materials. Another effective group of subsidies was that on iron and steel products, taking the form of trading losses in government purchases of imported ores, scrap, pig iron and steel.

The general upward movement in prices continued until the middle of 1948 (when there was a downturn in world prices of foodstuffs and raw materials) ; it was normal during the war in Korea in 1950–51. The effect of lower world prices in 1948–50 and after 1951 on British prices at wholesale and at retail, was more than counterbalanced by two particular factors. The first was the policy of limiting the cost of subsidies, introduced early in 1949 with increases in the price of iron and steel products and of certain foodstuffs. The second was the devaluation of sterling (Sept 18, 1949) which was followed by rises in the sterling prices of manv imported commodities and then by rising domestic prices, both wholesale and retail.

OTHER COUNTRIES

The course of prices in various countries can only be assessed and compared after reference to the rates of exchange between national currencies. A suitable standard of comparison is the course of prices in the U.S. and the rates of exchange required are then the rates between various national currencies and the U.S. dollar (see Table VIII).

As an illustration of the relevance of rates of exchange, prices in France, expressed in terms of the French franc and related to 1913 as a base year, should be considered. At parity in 1913 the French franc was equivalent to 19.3 U.S. cents. The rate of exchange varied after World War I before settling down, in 1927–31, at the devalued rate of 3.92 cents per franc. Later, on the devaluation of the dollar, the franc appreciated and the rate of exchange in 1934–35 was 6.60 cents per franc. Wholesale prices in the U.S. varied as follows: 1913, 100; 1929, 137; 1935, 115.

If wholesale prices in France had followed the same course, except that they were denominated in French francs instead of U.S. dollars, then the index figure in 1929 would have been nearly five times as great as that for the U.S. (19.3 divided by 3.92) and in 1935 nearly three times as great (19.3 divided by 6.60). Wholesale price index numbers for France would then be: 1913, 100; 1929, 675; 1935, 340. The recorded levels of wholesale prices in France (in round figures) were: 1913, 100; 1929, 630; 1935, 340.

There are many factors, such as changes in freight rates, domestic costs and taxes or subsidies, that operate to make domestic prices

*Wholesale prices: index compiled by the Board of Trade. London. with base switched from 1930=100 to 1938=100.

†Retail prices: estimates by London and Cambridge Economic Service, London School of Economics (see *Bulletin* ior Feb. 1949); clothing and household goods is a combination of three groups (clothing; household durable.;; miscellaneous goods) in the interimindex of retail prices compiled since 1947 by the Ministry of Labour, London.

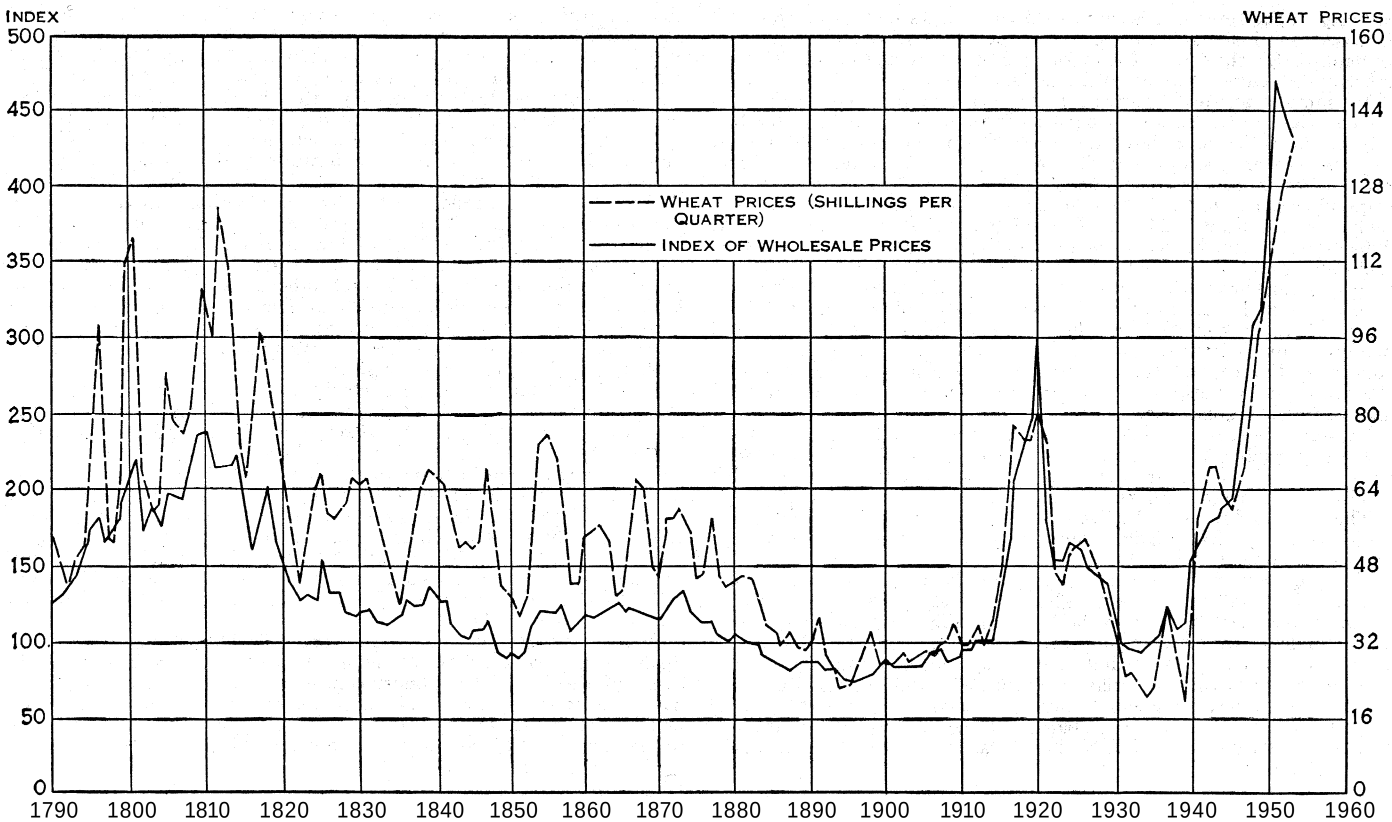

FIG. 3—WHOLESALE PRICES AND WHEAT PRICES. UNITED KINGDOM (1913=100)

diverge from world or import prices. In most important countries, however, wholesale prices are in fact largely determined by world prices, and particularly by prices in the U.S., at least during periods of stable rates of exchange. The correspondence between French wholesale prices in francs and U.S. wholesale prices was close in 1929 and 1935, each year being related to 1913.

In the period between World Wars I and II the pound sterling diverged little from parity with the U.S. dollar, except during the period before the restoration of the gold standard in the United Kingdom in 1925, and again briefly about 1932 when the gold standard mas suspended 18 months before the U.S took similar action. The general movements of prices (*e g* , a comparison of prices in 1929 or 1938 with those of 1913) are broadly comparable in the U.K. and the U.S. without modification for changes in the sterling-dollar exchange rates. The

validity oi the foregoing account of price changes in the two countries is based on this fact. The same is true of other countries, such as Canada or South Africa, Denmark or Sweden, whose currencies were more or less closely related to the dollar or sterling.

In some, countries, however, there were limited depreciations or appreciations of the national currencies in terms oi sterling and the U.S. dollar. Australia depreciated the Australian pound in terms of sterling in 1930. In any comparison of periods before and after 1930, therefore, prices in Australia will be found to have risen more than corresponding prices in the U.K. On the other hand, the Netherlands and Switzerland did not follow the U.S. off the gold standard in 1933. and when their currencies were revalued in 1936, they did not depreciate them as far as the U.S. did. After 1933 the Netherlands and Switzerland had currencies which were appreciated relative to sterling and the U.S. dollar and their price levels were correspondingly lower. There were still other countries in which inflation following World War I proceeded much further than elsewhere. The interwar years in such countries — France and Italy being among the more important — were characterized by periods of instability iollowed by currency reforms and periods of greater stability. The exchange rate in terms of the U.S. dollar fluctuated between stability and instability, but always much depreciated as compared with the rate in 1913. The course of prices showed similar fluctuations but always around much higher levels (as compared with 1913) than reached in the U.K. or the U.S.

The year of highest prices aiter World War I was generally 1920. There mas a general fall in wholesale prices irom 1921, steep at first and then more gradual. In most countries the fall continued slowly until 1929, though there was a subsidiary rise in prices around 1924, followed by a fall in 1926–27. This is, in fact, the broad pattern set by the movement of prices in the U.K. and the U.S. The closeness of correspondence of price movements was greater for countries on the gold standard and these included, by 1925, the U.K., the British dominions, Sweden, the Netherlands, Switzerland and others, in addition to the U.S. There were some important deviations from the general pattern. In France and Italy in particular, depreciation of the currency relative to sterling and the U.S. dollar was resumed in 1922 and continued in the following years; the French franc and Italian lira were not stabilized until 1927–28. The fall in mholesale prices in France and Italy mas halted in 1922 and prices then rose rapidly in France, and more moderately in Italy, until 1926, in which year the price level was above that reached immediately after the war. From 1926, prices in both countries, as in other countries, decreased slowly until 1929. In Japan prices remained high in the whole period irom 1921 to 1925 and only began to fall with the stabilization of the currency in 1926.

Aiter the stock market crash in the U.S. late in 1929, wholesale prices declined everywhere, following to a greater or less extent the rapid fall in prices in the U.S. The gold standard was suspended in the U.K. in Sept. 1931, and in the U.S. in March 1933. The devaluations of the two currencies were approximately equal in amount so that they bore about the same relation to each other after 1933 as in 1929. In both countries, wholesale prices fell to a low point in 1932–33 when their level was not quite 70% of the 1929 level. The effect of the world-wide depression on prices in other countries was varied but three broad groupings can be distinguished.

In a first group are countries which devalued their currencies about the same time as the U.K. in 1931. Some countries devalued to the same extent hut others, like Sweden and Denmark and also Australia, decided upon a greater devaluation. The currencies of these latter countries depreciated in terms of the U.S. dollar, not only in 1931–33, but also aiter the devaluation in the U.S. in 1933. This depreciation of national currencies offset to some extent the fall in world prices and, though the low point of wholesale prices was still reached about 1932, the level was 75%–80% of 1929 rather than 70% or less. Japan followed much the same course; but wholesale prices had already fallen to 70% of the 1929 level by 1931 (before devaluation) and then recovered immediately.

In a second group of countries, represented in Tables VIII–X by Spain, Argentina and Peru, the national currencies were depreciated in terms of the U.S. dollar almost continuously irom 1929 to 1932–33. The offset to the fall in world prices mas greater, though the currency depreciation was in no case quite sufficient to prevent wholesale prices in the national units from falling. Low points in the level of wholesale

*Wholesale prices: official index numbers, based on or with base switched to average 1913 or 1914=100 with two exceptions, the index for Italy being computed by Riccardo Rachi (1921–29) and that for Japan by the Bank of Japan. The index numbers relate to general wholesale prices except for Australia (Melbourne only), Egypt (Cairo only), India (Calcutta only! and Japan (Tokyo only).

†Retail prices: official index numbers of the cost of living or retail prices to working-class families based on or with base switched to average 1914 or July 1914=100 except those for the Setherlands (average 1911–13=100) and Peru (average 1913=100). The index for Japan computed by the Bank of Japan. Some index numbers relate to the principal city, others to a group of large towns in the country concerned. All index numbers comprise prices of food, rent, fuel and clothing except those for Spain (food and fuel only) and **Japan** (rent excluded: Data extrarted from the League of Nations *Statistical Yearbook.*

‡Important break in the comparability of series of index numbers.

prices were reached, in 1932–33, at 90%–95% of the 1929 figures.

The last group of countries comprises those which did not devalue their currencies with the U.K. and the U.S. in 1931–33. Devaluation was postponed, generally until 1936. The Netherlands, France and Switzerland belong to this group and, despite some differences, Italy can be added to the list. The governing fact here is that national currencies appreciated in terms of sterling from 1931 and in terms of the U.S. dollar from 1933. The fall in world prices was amplified in translation into wholesale prices in national units. The fall in domestic wholesale prices was of greater extent and operated over a longer period than in the U.K. and the U.S. Low points were reached generally about 193j and at levels between 55% and 655% of 1929.

The recovery in prices from the bottom of the depression was almost as rapid as the preceding fall and, except in France and Italy, it had come to an end by 1937. In that year wholesale prices in the U.K. and the U.S. stood about 20% above the level of 1913 and a little below the 1929 figures. In some countries, like the Netherlands and Switzerland, whose currencies appreciated in relation to sterling and the U.S. dollar in the 1930s, the 1937 level of wholesale prices was rather lower—a little above the 1913 level but 20%–25% below 1929. On the other hand, in countries like Spain, Argentina and Peru where the national currency continued to depreciate in the late 1930s, wholesale prices in 1937 stood higher, often at levels about double that of 1913 and well above 1929. The price situation in France, and to a lesser extent in Italy, was exceptional in the years immediately before World War II. As in the Netherlands and Switzerland, the rise in prices began late because of the postponed devaluations of currency. But in France and Italy the revaluation of the currency was much more drastic and the price rise from 1936 was rapid and also continued beyond 1937. By 1939, the level of wholesale prices was above that of 1929 but the process of adjustment was not complete and prices would probably have risen further even if war had not inter\-ened.

*Official index numbers of general wholesale prices; and of cost of living or retail prices to working-class families, comprising prices of food, rent, fuel, clothing and miscellaneous items. Some index numbers relate to the principal city only. All have base switched to average 1948=100, except 15here noted otherwise. Data from UN *Statistical Yearbook.*
†Average 1949=100. ‡Domestic goods only.

Early in World War II, most countries devalued their currencies or allowed them to depreciate in terms of the U.S. dollar; after the war there were many adjustments, a few upward but most downward in relation to the dollar. The position in 1948 was that a small group of countries, including Canada, Sweden and Switzerland, had maintained or restored their currencies to parity with the U.S. dollar. Another group, including the Netherlands and Denmark as well as the countries of the sterling area, had devalued to a moderate amount in relation to the U.S. dollar. The difference was larger in Spain and many countries of Latin America, following long periods of almost continuous depreciation in terms of the dollar. The most drastic devaluations of all were in the French franc and Italian lira, occurring for the most part after the war.

The relative levels of wholesale prices in the various countries after the war were largely dependent on these currency adjustments, though there were considerable divergencies from the general pattern. Prices rose during the war and even more sharply in the early postwar years. By 1948 wholesale prices in the U.S. were rather less than douhle those in 1937; in the U.K. the change was somewhat greater, the 1948 price level being a little more than double that of 1937. The position in the British dominions, Denmark, Sweden and Switzerland was broadly the same, though there were some variations; for example, the price increase from 1937 in Australia was relatively small and in Switzerland relatively large. In the Netherlands, the price level in 1948 was higher, about two and one-half times the 1937 figure, following a rapid rise after liberation of the country. In Spain. and in some Latin American countries for which data were available, wholesale prices in 1948 were between three and four times the level of 1937, as were prices in Egypt and India. The most striking effects of inflation and currency devaluation are to be seen in price changes in France and Italy. French wholesale prices in 1945 were already more than 4 times those of 1937, but in 1948 they were about 20 times the 1937 figure and still rising. It was not until 1949 that prices in France were brought under control.

The inflation was even more rapid in Italy, particularly between 1944 and 1947, and wholesale prices in lire reached a level nearly 60 times that of 1937. A greater degree of stability in Italian prices was attained in 1948 and 1949; despite some fluctuations, the general rise in prices was halted in these years.

The countries of the sterling area, following the lead of the U.K., devalued their currencies in terms of the U.S. dollar in Sept. 1949. The currencies of most countries in western Europe were devalued at the same time. although not all to the same extent as sterling (*see* Table VIII). Wholesale prices in these countries rose immediately, reversing a tendency toward lower prices which had become evident earlier in 1949, and which continued throughout the year in the United States.

There is much less correspondence between retail prices in different countries (allowance being made for exchange rates) than between prices at wholesale. Many prices at retail are less dependent upon world prices of commodities and some are almost completely insulated against price changes outside the country concerned. Retail prices of commodities are influenced by domestic costs, controls, subsidies and taxation. and index numbers of retail prices, generally relating to the cost of living of working-class families, include rent and other services. A general pattern, however, does emerge. Following the boom and collapse after World War I, retail prices were generally higher (relative to 1913–14) than wholesale prices and the difference was accentuated during the interwar period. On the other hand, retail prices generally rose less between 1937 and 1948 than wholesale prices. This was largely the result of price controls, particularly on rents as well as important commodities, and to the continuation after World War II of wartime policies of subsidizing foodstuffs and other commodities purchased by working-class families. In those countries where wholesale prices in 1948 were about double those in 1937, retail prices had generally increased by about 50%–80% in the same period.

International comparisons of the purchasing power of national currencies are peculiarly difficult to make. The level of retail prices in one country needs to be compared, with allowance for the exchange rate, with the level of retail prices in another country; it is not sufficient to compare the movements of retail prices over time in one country with similar movements in another country. The most complete calculations are those made by Colin Clark (for his *The Conditions of Economic Progress*, see *Bibliography*).

PRICHARD, HAROLD ARTHUR (1871–1947), a leading member of the Oxford "intuitionist" school of moral philosophers, spent most of his life teaching at Oxford, where he was fellow of Hertford college from 1895 to 1898 and of Trinity college from 1898 to 1924 and White's professor of moral philosophy from 1928 to 1937.

Prichard held that the notion of duty or "ought" is ultimate and irreducible. We become aware of this notion by reflecting on instances of it; in particular circumstances we know directly and immediately. by intuition, that a particular action is our duty. regardless of proof or argument. Moreover, "good" and "ought" are two distinct and mutually irreducible concepts; no proposition about the first can entail a conclusion about the second. Nor can our particular duties be deduced from some more general rule of duty; on the contrary, the ordinary moral rules are themselves generalizations of what we see to be our duty in particular cases.

Prichard also maintained that the rightness of an action does not depend in any way upon its motive; if this seems paradoxical, it is because we are liable to confuse motive with intention. With regard to the experience of conflicting obligations, he held that different obligations have different degrees of stringency and that in a particular case we can see which of two conflicting obligations is the more stringent. To account for cases of disagreement about duty, he contended that the capacity of direct moral apprehension may be more fully developed in one man than in another. In his last years Prichard came to think that duty depends not upon the situation as it actually is, but upon what a person believes the situation to be. He also devoted much attention to the concept of promising and concluded that "I promise to do so and so" is not a statement conveying true or false information, but that the utterance of these words itself constitutes the act of promising.

Prichard's theory of knowledge was a development of the "realistic" views of Cook Wilson. Knowing, he held, is something ultimate and *sui generis*, which differs in kind from any sort of belief or opinion; it is, as it were, the direct confrontation of mind and reality. But he eventually came to be dissatisfied with the "realistic" theory of sense perception. Instead he held that sense perception is a kind of illusion and that what is called seeing a chair consists of two distinct factors: (1) seeing a colour, whose *esse* is *percipi*, as Berkeley had said; and (2) mistaking this colour for a body of a certain sort. On this view, the material world cannot be known at all, in Prichard's strict sense of the word "know." Nevertheless, by means of a complicated argument from perceptions to their causes, he thought we could find good grounds for *believing* that material objects exist and for believing many detailed propositions about them.

For his arguments see *Kant's Theory of Knowledge* (Oxford, 1909), *Duty and Interest* (Oxford, 1928), *Moral Obligation* (Oxford. 1949) and- nowl ledge *and Perception* (Oxford, 1950), the latter two ed. by Sir W. D. Ross. (H. H. PE.)

PRICHARD, JAMES COWLES (1786–1848), British physician and philologist, whose specialty was the study of human races, was born on Feb. 11, 1786, at Ross, Herefordshire. He received his early education at Bristol, and early acquired knowledge of European and oriental languages. After attending St. Thomas's hospital. London, he went to Edinburgh, where he took his M.D. in 1808. Later he spent some time at Cambridge and at Oxford, but in 1810 settled in Bristol. He was appointed physician to St. Peter's hospital in 1811 and to the Bristol infirmary in 1814.

His Researches as to the Physical History of *Man* (1813) was expanded into a five-volume work (1836–47). In 1843 appeared his classic *Natural* History of *Man*, in which he concluded, accurately, that all mankind belongs to a single species. He was also deeply interested in Egyptology and in 1819 traced the early connection between the Hindus and the Egyptians and published a hieroglyphic alphabet. His Eastern Origin of *the* Celtic Nations (1831) established the place of Celtic languages as a branch of Indo-European. Prichard was also a pioneer in the scientific study of mental diseases, and was responsible for the concept of moral insanity as a distinct disease. Prichard was elected a fellow of the Royal society in 1827, and at the time of his death was president of the Ethnological society. In 1845, on being made a commissioner in lunacy, he moved to London, where he died on Dec. 23, 1848. (W. J. BP.; X.)

PRICKLY ASH (Zanthoxylum *americanum*), a North American shrub or small tree of the rue family (Rutaceae), called also a toothache tree, found in woods and thickets from Quebec to Minnesota and southward to Virginia and Missouri. While usually a shrub it sometimes attains a height of 25 ft. and a trunk diameter of 6 in. It bears alternate, pinnate leaves, composed of from 5 to 11 ovate, dark-green, somewhat pointed leaflets, with the twigs and leafstalks usually prickly. The small greenish flowers, which appear before the leaves in early spring, are borne in short axillary clusters; the fruit is a black ellipsoid capsule about one-sixth inch long, containing one or two seeds.

The similar but larger Herculesclub (*Z.* clavaherculis), known also as sea ash and pepperwood, occurs along streams from southern Virginia to Florida west to Kansas and Texas. Hercules'-club or devil's-walking-stick, *Aralia spinosa* of the ginseng family, a spiny shrub or small tree common in rich woods and on river banks from New York and Illinois to Florida and Texas, is also known as prickly ash and angelica tree. See ARALIA.

PRICKLY LETTUCE (Lactuca scariola), an annual or biennial herb of the family Compositae, closely allied to the garden lettuce (*q.v.*), native to Europe and widely distributed in temperate regions as a naturalized weed. It is a whitish green, usually smooth plant, with a stiff, erect stem, two to seven feet high, bearing oblong, more or less toothed or cut leaves, with spiny midribs and edges, usually clasping the stem by a more or less eared or heart-shaped base. The numerous heads of yellow flowers are borne in a large open panicle. The plant is noteworthy in that the leaves exhibit a marked tendency to become vertical. Moreover, when growing in open places, equally exposed to the sun during either half of the day, the vertical leaves often assume a north and south direction. Because of this characteristic the designation compass plant is sometimes applied to this species of lettuce, as it also is to various other plants of similar habit.

PRICKLY PEAR, the name given to cacti of the genus Opuntia, from the appearance of their fruit. There are about 250 species, all originally American, but several have been introduced elsewhere and, in some places (*e.g.*, Australia), have overrun the countryside. Most species have flattened, jointed stems, and the flowers are white or red. The prickly pear proper is O. vulgaris; O. ficus-indica is Indian fig. The fruit of both of these forms is edible. O. subulata is remarkable in that the leaves are large and functional. From O. tuna, the tuna hedges are grown in the West Indies, where it is also used as a food plant for the cochineal insect (Coccus cacti). See CACTUS.

PRIDE, THOMAS (d. 1658), Parliamentarian soldier in the English Civil War, was of obscure origins and early life. At the beginning of the Civil War he served as a captain under the earl of Essex and was gradually promoted to the rank of colonel. He distinguished himself at the battle of Preston, and with his regiment took part in the military occupation of London in Dec. 1648, which was the first step toward bringing the king to trial. Pride is chiefly remembered for the expulsion (Dec. 6, 1648) of the Presbyterian and Royalist elements in the house of commons. This was resolved by the army council and carried out by Colonel Pride's regiment. Taking his stand at the entrance of the house of commons with a written list in his hand, he caused the arrest or exclusion of the obnoxious members, who were pointed out to him. After about 140 members had been thus dealt with ("Pride's

Purge"), the mutilated house of commons proceeded to bring the king to trial. and Pride was one of the judges of the king.

Pride commanded an infantry brigade under Oliver Cromwell at Dunbar and Worcester. He took no conspicuous part in commonwealth politics, except in opposing the proposal to confer the kingly dignity on Cromwell. He was knighted by the Protector in 1656, and was also chosen a member of the new house of lords. He died at Nonesuch house, Surrey, on Oct. 23, 1658. Alter the Restoration his body was ordered to be dug up and suspended on the gallows at Tyburn along with those of Cromwell, Henry Ireton and John Rradshaw, though it is said that the execution of this sentence was evaded.

PRIDEAUX, HUMPHREY (1648–1724), English clergyman and Oriental scholar. born at Place. Cornwall, on May 3. 1648. was educated at Westminster school and Christ Church, Oxford. His account of the famous Arundel marbles just given to the university, *Marmora* Oxoniensia (1676). won for him the favour of Heneage Finch, who secured his rapid preferment. Prideaux held several livings, was Hebrew lecturer at Christ Church (1679–86), and dean of Norwich (1702–24). He died on Nov. 1. 1724.

Prideaux's most important work was *The Old and New Testament connected in the History* of *the Jews* (1716), which not only displayed but stimulated research.

PRIDE OF CALIFORNIA (Lathyrus *splendens*), a name given to a North American plant of the pea family (Leguminosae), native to the mountains of southern California, called also campo pea. It is closely allied to the sweet pea of the gardens, and bears showy clusters of brilliant red flowers.

PRIENE (mod. *Samsun* kale), an ancient city of Ionia on the foothills of Mycale, about 6 mi. N. of the Maeander. It was formerly on the seacoast. but now lies some miles inland. It is said to have been founded by Ionians under Aegyptus, a son of Neleus. Sacked by Ardys of Lydia, it revived and attained great prosperity under its "sage," Bias, in the middle of the 6th century. Cyrus captured it in 545; but it was able to send 12 ships to join the Ionian revolt (500–494). Disputes with Samos, and the troubles after Alexander's death, brought Priene low, and Rome had to save it from the kings of Pergamum and Cappadocia in 155. Orophernes, the rebellious brother of the Cappadocian king, who had deposited a treasure there and recovered it by Roman intervention, restored the temple of Athena as a thank offering. Under Roman and Byzantine dominion Priene had a prosperous history. It passed into Moslem hands late in the 13th century. The ruins, which lie on successive terraces, were excavated mainly in the late 19th century. The city, as rebuilt in the 4th and 3rd centuries: was laid out on a rectangular scheme. It faced south. its acropolis rising nearly 700 ft. behind it. The whole area was enclosed by a wall 7 ft. thick with towers at intervals and three principal gates. On the lower slopes of the acropolis was a shrine of Demeter. The town had six main streets, about 20 ft. wide, running east and west and 15 streets about 10 ft. wide crossing at right angles, all being evenly spaced; and it was thus divided into about 80 *insulae*. Private houses were apportioned four to an *insula*. The systems of water supply and drainage can easily be discerned. The houses present many analogies with the earliest Pompeian. In the western half of the city, on a high terrace north of the main street and approached by a fine stairway, was the temple of Athena Polias, a hexastyle peripteral Ionic structure built by Pythias, the architect of the Mausoleum. Under the base of the statue of Athena were found in 1870 silver tetradrachms of Orophernes, and some jewelry, probably deposited at the time of the Cappadocian restoration. Fronting the main street is a series of halls, and on the other side is the fine market place. The municipal buildings, Roman gymnasium, and well-preserved theatre lie to the north, but, like all the other public structures, in the centre of the plan. Temples of Isis and Asclepius have been excavated. At the lowest point on the south, within the walls, was the large stadium, connected with a gymnasium of Hellenistic times.

PRIEST, the contracted form of "presbyter" (πρεσβύτερος, "elder"; see PRESBYTER), a name of office in the early Christian church, already mentioned in the New Testament. Rut in the English Bible the presbyters of the New Testament are called "elders," not "priests"; the latter name is reserved for ministers of pre-Christian religions. The reason of this will appear more clearly in the sequel; it is enough to observe at present that, before our English word was formed, the original idea of a presbyter had been overlaid with others derived from pre-Christian priesthoods, so that it is from these and not from the etymological force of the word that we must start in considering historically what a priest is. The theologians of the Greek and Latin churches expressly found the conception of a Christian priesthood on the hierarchy of the Jewish temple, while the names by which the sacerdotal character is expressed—ἱερεύς, sacerdos — originally designated the ministers of sacred things in Greek and Roman heathenism, and then came to be used as translations into Greek and Latin of the Hebrew *kōhēn*. *Kōhēn*, ἱερεύς, sacerdos, are, in fact, fair translations of one another; they all denote a minister whose stated business was to perform, on behalf of the community, certain public ritual acts, particularly sacrifices, directed Godwards. Such ministers or priests existed in all the great religions of ancient civilization.

Early Priesthoods. — Among the Babylonians and Assyrians magic and soothsaying were intertwined with priestly functions, as was the case in early Hebrew pre-exilian days with the *Kōhēn*. The *barû* (from *barû* to see, inspect) was a soothsaying priest who was consulted whenever any important undertaking was proposed, and addressed his inquiries to Samaš the sun god (or Adad) as *bêl biri* or lord of the oracle (accompanied by the sacrifice of lambs). (See DIVINATION.)

As contrasted with the *barû* or soothsaying priest we have the *ašipu*, who was the priest-magician who dealt in conjurations (*šiptu*), whereby diseases were removed, spells broken, or in expiations whereby sins were expiated. Now, as the conjurations were addressed to the deity, *ašipu,* according to the definition given above, comes more reasonably under the category of priest. In Babylonia priesthoods were endowed with great wealth and power, and even the king stood in awe of them. (See Johns, Babylonian and Assyrian Laws, Contracts and Letters, p. 212 sqq.) These powerfully-organized priesthoods, as well as the elaborate nature of their ritual and apparatus of worship, must have deeply and permanently impressed the exiled Jewish community. Thus arose the more developed system of Ezekiel's scheme (xl.–xlviii.) and of the Priestly code and the high dignity which became attached to the person of the High Priest (reflected in the narrative of Uzziah's leprosy in 2 Chron. xxvi. 16–20).

Among the ancient Egyptians the local god was the protector and lord of the district. Consequently it was the interest and duty of the inhabitants to maintain the cultus of the patron-deity of their city who dwelt in their midst. Moreover, in the earlier times we find the prince of the nome acting as the High Priest of the local god, but in course of time the state, represented by the king, began to an ever-increasing degree to take oversight over the more important local cults. Thus we find that the Egyptian monarch was empowered to exercise priestly functions before all the gods. We constantly see him in the wall-paintings, portrayed as a priest in the conventional attitudes before the images of the gods. In the chief sanctuaries the chief priests possessed special privileges, and it is probable that those in the immediate entourage of the king were elected to these positions. The highest nobility in the nome sought the honour of priesthood in the service of the local deity. One special class called kher heb was charged with reciting the divine formulae, which were popularly held to possess magical virtue. In the middle empire (VIIth to XIIth Dynasties) the lay element maintains its position in religious cultus despite its complexity. But under the new empire (Dynasties XVIIIth and following) the professional priest had attained to ominous power. Priests increased in number and were divided into ranks; temples possessed larger estates and became more wealthy.

Ancient Greece. — Homer speaks of special priests who preside over ritual acts in the temples to which they are attached; but his kings also do sacrifice on behalf of their people. The king, in fact, both in Greece and in Rome, was the acting head of the state religion, and when the regal power came to an end his sacred functions were not transferred to the ordinary priests, but either they were distributed among high officers of state, as archons and prytanes, or the title of "king" was still preserved as that of a religious functionary, as in the case of the rex *sacrorum* at Rome and the archon basileus at Athens. In the domestic circle the union of priesthood and natural headship was never disturbed; the Roman paterfamilias sacrificed for the whole family. On the other hand, gentes and *phratriae,* which had no natural head, had special priests chosen from their members; for every circle of ancient society, from the family up to the state, was a religious as well as a civil unity, and had its own gods and sacred rites. We cannot speak of priestly power and hardly even of a distinct priestly class.

In Greece the priest, so far as he is an independent functionary and not one of the magistrates, is simply the elected or hereditary minister of a temple charged with "those things which are ordained to be done towards the gods" (see Aristotle, Pol. vi. 8), and remunerated from the revenues of the temple, or by the gifts of worshippers and sacrificial dues. The position was often lucrative and always honourable, and the priests were under the special protection of the gods they served. But their purely ritual functions gave them no means of establishing a considerable influence on the minds of men, and the technical knowledge which they possessed as to the way in which the gods could be acceptably approached was neither so intricate nor so mysterious as to give the class a special importance. There was, indeed, one sacred function of great importance in the ancient world in which the Greek priests had a share. As man approached the gods in sacrifice and prayers, so too the gods declared themselves to men by divers signs and tokens, which it was possible to read by the art of Divination (*q.v.*). In many nations divination and priesthood have always gone hand in hand; at Rome, for example, the augurs and the XV. viri *sacrorum,* who interpreted the Sibylline books, were priestly colleges. In Greece, on the other hand, divination was not generally a priestly function, but it did belong to the priests of the Oracles. (See ORACLE.) The great oracles, however, were of Panhellenic celebrity and did not serve each a particular state, and so in this direction also the risk of an independent priestly power within the state was avoided.

In Rome, again, where the functions of the priesthood were politically much more weighty, where the technicalities of religion were more complicated, where priests interpreted the will of the gods, and where the pontiffs had a most important jurisdiction in sacred things, the state was much too strong to suffer these powers to escape from its own immediate control: the old monarchy of the king in sacred things descended to the inheritors of his temporal power; the highest civil and religious functions met in the same persons (*cf.* Cic. De dom. i. 1); and every priest was subject to the state exactly as the magistrates were, referring all weighty matters to state decision and then executing what the one supreme power decreed. And it is instructive to observe that when the plebeians extorted their full share of political power they also demanded and obtained admission to every priestly college of political importance, to those, namely, of the pontiffs, the augurs, and the XV. *viri* sacrorum. The Romans, it need hardly be said. had no hereditary priests.

Aryan Religions.—In historical times the priesthood in India is rigidly confined to members of the Brahman caste. But at an earlier date the warrior caste often became priests. The power of the priesthood began with the delegation by the king of his sacrificial duties to an appointed official. This power grew with the growing importance of the sacrifice and the complication of its ceremonial. In the post-Vedic period "right" or "wrong" simply meant the exact performance or the neglect, whether intentional or unintentional—of all the details of a prescribed ritual, the centre of which was the sacrifice. At this period the priestly caste gained its unbounded power over the minds of men. For further details as to the development of the priestly caste and wisdom in India the reader must refer to HINDUISM.

Among the Zoroastrian Iranians, as among the Indian Aryans, the aid of a priest to recite the sacrificial liturgy was necessary at every offering (Herod. i. 132), and the Iranian priests (bthravans, later Magi) claimed, like the Brahmans, to be the highest order of society; but they did not acquire the powers of the Indian priesthood; in particular, the priesthood, as it was not based on family tradition, did not form a strict hereditary caste. Nevertheless, it formed a compact hierarchy not inferior in influence to the clergy of the Christian middle ages, had great power in the state, and were often irksome even to the great king. But the monarchs had one strong hold on the clergy by retaining the patronage of great ecclesiastical places.

The Persian religion throughout all its multitude of purifications, observances and expiations was a constant warfare against impurity, death and the devil. Amid all the ceremonialism of its priesthood there were also high ideals set forth in Zoroastrian religion of what a priest should be. Thus we read in Vendidâd xviii., "Many there be, noble Zarathustra, who bear the mouth bandage, who have yet not girded their loins with the law. If such a one says 'I am an Athravan' he lies, call him not Athravan, noble Zarathustra, said Ahura Mazda; but thou shouldst call him priest, noble Zarathustra, who sits awake the whole night through and yearns for holy wisdom that enables man to stand on death's bridge fearless and with happy heart, the wisdom whereby he attains the holy and glorious world of paradise."

Semitic Races.—Among the nomadic Semites there was no developed priesthood. Religion partook of the general simplicity of desert life; apart from the private worship of household gods and the oblations and salutations offered at the graves of departed kinsmen, the ritual observances of the ancient Arabs were visits to the tribal sanctuary to salute the god with a gift of first-fruits or the like (see NAZIRITE and PASSOVER), and an occasional pilgrimage to discharge a vow at the annual feast and fair of one of the more distant holy places. (See MECCA.) These acts required no priestly aid; each man slew his own victim and divided the sacrifice in his own circle; the share of the god was the blood which was smeared upon or poured out beside the stone set up as an altar or perhaps as a symbol of the deity We find therefore no trace of a sacrificial priesthood, but each temple had one or more doorkeepers, whose office was usually hereditary and who had the charge of the Temple and its treasures.

The sacrifices and offerings were acknowledgments of divine bounty and means used to ensure its continuance; the Arab was the "slave" of his god and paid him tribute, as slaves used to do to their masters, or subjects to their lords; and the free Bedouin, trained in the solitude of the desert to habits of absolute self-reliance, knew no master except his god. The decision of the god might be uttered in omens which the skilled could read, or conveyed in the inspired rhymes of soothsayers, but frequently it was sought in the oracle of the sanctuary, where the sacred lot was administered for a fee by the *sādin.* The sanctuary thus became a seat of judgment, and here, too, compacts were sealed by oaths and sacrificial ceremonies. These institutions, though known to us only from sources belonging to an age when the old faith was falling to pieces, are certainly very ancient. The fundamental type of the Arabic sanctuary can be traced through all the Semitic lands, and so appears to be older than the Semitic dispersion.

With the beginning of a settled state the sanctuaries rose in importance and all the functions of revelation gathered round them. A sacrificial priesthood arose as the worship became more complex (especially as sacrifice in antiquity is a common preliminary to the consultation of an oracle), but the public ritual remained closely associated with oracle or divination, and the priest was, above all things, a revealer. That this was what actually happened may be inferred from the fact that the Canaanite and Phoenician name for a priest (*kōhēn*) is identical with the Arabic *kāhin,* a "soothsayer." Soothsaying was no modern importation in Arabia; its characteristic form—a monotonous croon of short rhyming clauses—is the same as was practised by the Hebrew "wizards who peeped and muttered" in the days of Isaiah. The *kāhin,* therefore, is not a degraded priest but such a soothsayer as is found in most primitive societies, and the Canaanite priests grew out of these early revealers. In point of fact some form of revelation or oracle appears to have existed in every great shrine of Canaan and Syria, and at Hierapolis it was the charge of the chief priest, just as in the Levitical legislation.

The Hebrews, who made the language of Canaan their own, took also the Canaanite name for a priest. But the earliest forms of Hebrew priesthood are not Canaanite in character; the priest, as he appears in the older records of the time of the Judges, Eli at Shiloh, Jonathan in the private temple of Micah and at Dan, is more like the *sādin* than the *kāhin*. The whole structure of Hebrew society at the time of the conquest was almost precisely that of a federation of Arab tribes, and the religious ordinances are scarcely distinguishable from those of Arabia, save only that the great deliverance of the Exodus and the period when Moses, sitting in judgment at the sanctuary of Kadesh, had for a whole generation impressed the sovereignty of Jehovah on all the tribes, had created an idea of unity between the scattered settlements in Canaan such as the Arabs before Mohammed never had. But neither in civil nor in religious life was this ideal unity expressed in fixed institutions, the old individualism of the Semitic nomad still held its ground. Thus the firstlings, first-fruits and vows are still the free gift of the individual which no human authority exacts, and which every householder presents and consumes with his circle in a sacrificial feast without priestly aid.

As in Arabia, the ordinary sanctuary is still a sacred stone set up under the open heaven, and here the blood of the victim is poured out as an offering to God. (See especially 1 Sam. xiv. 34, and cf. 2 Sam. xxiii. 16, 17.) The priest has no place in this ritual; he is not the minister of an altar, but the guardian of a temple, such as was already found here, and there in the land for the custody of sacred images or other consecrated things (the ark at Shiloh, 1 Sam. iii. 3; images in Micah's temple, Judges xvii. 5; Goliath's sword lying behind the "ephod" or plated image at Nob, 1 Sam. xxi. 9; no doubt also money, as in the Canaanite temple at Shechem, Judges ix. 4). Such treasures required a guardian; but, above all, wherever there was a temple there was an oracle, a kind of sacred lot, just as in Arabia (1 Sam. xiv. 41, lxx.), which could only be drawn where there was an "ephod" and a priest (1 Sam. xiv. 18, Sept., and xxiii. 6 seq.). The Hebrews had already possessed a tent-temple and oracle of this kind in the wilderness (Exod. xxxiii. 7 *seq.*), and ever since that time the judgment of God through the priest at the sanctuary had a greater weight than the word of a seer, and was the ultimate solution of every controversy and claim (1 Sam. ii. 25; Exod. xxi. 6, xxii. 8, 9, where for "judge," "judges," of A.V. read "God" with R.V.).

The temple at Shiloh, where the ark was preserved, was the lineal descendant of the Mosaic sanctuary and its priests claimed kin with Moses himself. In the divided state of the nation, indeed, this sanctuary was hardly visited from beyond Mt. Ephraim; and every man or tribe that cared to provide the necessary apparatus (ephod, teraphim, etc.) and hire a priest might have a temple and oracle of his own at which to consult Jehovah (Judges xvii., xviii.); but there was hardly another sanctuary of equal dignity. The priest of Shiloh is a much greater person than Micah's priest Jonathan; at the great feasts he sits enthroned by the doorway, preserving decorum among the worshippers; he has certain legal dues, and, if he is disposed to exact more, no one ventures to resist (1 Sam. ii. 12 seq, where the text needs a slight correction). The priestly position of the family survived the fall of Shiloh and the capture of the ark, and it was members of this house who consulted Jehovah for the early kings until Solomon deposed Abiathar.

Ultimately, indeed, as sanctuaries were multiplied and the priests all over the land came to form one well-marked class, "Levite" and legitimate priest became equivalent expressions, as is explained in the article LEVITES. But between the priesthood of Eli at Shiloh or of Jonathan at Dan and the priesthood of the Levites as described in Deut. xxxiii. 8 seq. there lies a period of the inner history of which we know almost nothing. It is plain that the various priestly colleges regarded themselves as one order, that they had common traditions of law and ritual which were traced back to Moses, and common interests which had not been vindicated without a struggle. The kingship had not deprived them of their functions as fountains of divine judgment (cf. Deut. xvii. 8 seq.); on the contrary, the decisions of the sanctuary had grown up into a body of sacred law, which the priests administered according to a traditional precedent. According to Semitic ideas the declaration of law is quite a distinct function from the enforcing of it, and the royal executive came into no collision with the purely declaratory functions of the priests. The invective of Hos. iv. equally with the eulogium of Deut. xxxiii. proves that the position which the later priests abused had been won by ancestors who earned the respect of the nation as worthy representatives of a divine Torah.

The ritual functions of the priesthood still appear in Deut. xxxiii. as secondary to that of declaring the sentence of God, but they were no longer insignificant. With the prosperity of the nation, and especially through the absorption of the Canaanites and of their holy places, ritual had become much more elaborate, and in royal sanctuaries at least there were regular public offerings maintained by the king and presented by the priests. (Cf. 2 Kings xvi. 15.) Private sacrifices, too, could hardly be offered without some priestly aid now that ritual was more complex; the provision of Deut. xviii. as to the priestly dues is certainly ancient, and shows that besides the tribute of first-fruits and the like the priests had a fee in kind for each sacrifice, as we find to have been the case among the Phoenicians according to the sacrificial tablet of Marseilles. Their judicial functions also brought profit to the priests, fines being exacted for certain offences and paid to them (2 Kings xii. 16; Hos. iv. 8; Amos ii. 8). The greater priestly offices were therefore in every respect very important places, and the priests of the royal sanctuaries were among the grandees of the realm (2 Sam. viii. 18; 2 Kings x. 11, xii. 2); but there is not the slightest trace of an hereditary hierarchy officiating by divine right, such as existed after the exile. The sons of Zadok, the priests of the royal chapel, were the king's servants as absolutely as any other great officers of state; they owed their place to the fiat of King Solomon, and the royal will was supreme in all matters of cultus (2 Kings xii., xvi. 10 seq.); indeed the monarchs of Judah, like those of other nations, did sacrifice in person when they chose down to the time of the captivity (1 Kings ix. 25; 2 Kings xvi. 12 seq.; Jer. xxx. 21).

The detailed steps which prepared the way for the post-exile hierarchy, the destruction of the northern sanctuaries and priesthoods by the Assyrians, the polemic of the spiritual prophets against the corruptions of popular worship, which issued in the reformation of Josiah, the suppression of the provincial shrines of Judah and the transference of their ministers to Jerusalem, the successful resistance of the sons of Zadok to the proposal to share the sanctuary on equal terms with these new-comers, and the theoretical justification of the degradation of the latter to the position of mere servants in the Temple supplied by Ezekiel soon after the captivity, need not here be dealt with. Already in the time of Josiah altar service and not the judicial or "teaching" function had become the essential thing in priesthood (Deut. x 8, xviii. 7); the latter, indeed, was not forgotten (Jer. ii. 8, xviii. 18), but by the time of Ezekiel it also has mainly to do with ritual, with the distinction between holy and profane, clean and unclean, with the statutory observances at festivals and the like (Ezek. xliv. 23 seq.). What the priestly Torah was at the time of the exile can be seen from the collection of laws in Lev. xvii.–xxvi., which includes many moral precepts, but regards them equally with ritual precepts from the point of view of the maintenance of national holiness. The holiness of Israel centres in the sanctuary, and round the sanctuary stand the priests, who alone can approach the most holy things without profanation, and who are the guardians of Israel's sanctity, partly by protecting the one meeting-place of God and man from profane contact, and partly as the mediators of the continual atoning rites by which breaches of holiness are expiated. In the old kingdom the priests had shared the place of the prophets as the religious leaders of the nation; under the second Temple they represented the unprogressive traditional side of religion, and the leaders of thought were the psalmists and the scribes, who spoke much more directly to the piety of the nation.

But, on the other hand, the material influence of the priests was greater than it had ever been before; the Temple mas the only visible centre of national life in the ages of servitude to foreign power, and the priests were the only great national functionaries, who drew to themselves all the sacred dues as a matter of right and even appropriated the tithes paid of old to the king. When the high priest stood at the altar in all his princely state. when he poured out the libation amidst the blare of trumpets, and the singers lifted up their voices and all the people fell prostrate in prayer till he descended and raised his hands in blessing, the slaves of the Greek or the Persian forgot for a moment their bondage and knew that the day of their redemption was near (Ecclus. 1). The high priest at such a moment seemed to embody all the glory of the nation, as the kings had done of old, and when the time came to strike a successful blow for freedom it was a priestly house that led the nation to the victory which united in one person the functions of high priest and prince. From the foundation of the Hasmonean state to the time of Herod the history of the high priesthood merges in the political history of the nation; from Herod onward the priestly aristocracy of the Sadducees lost its chief hold over the nation and expired in vain controversy with the Pharisees.

The influence of the Hebrew priesthood on the thought and organization of Christendom was the influence not of a living institution, for it hardly began till after the fall of the Temple, but of the theory embodied in the priestly code of the Pentateuch. Two points in this theory were laid hold of—the doctrine of priestly mediation and the system of priestly hierarchy. The first forms the text of the principal argument in the Epistle to the Hebrews, in which the author demonstrates the inadequacy of the mediation and atoning rites of the Old Testament. and builds upon this demonstration the doctrine of the effectual high priesthood of Christ, who, in His sacrifice of Himself, truly "led His people to God." not leaving them outside as He entered the heavenly sanctuary. but taking them with Him into spiritual nearness to the throne of grace.

The idea that presbyters and bishops are the successors of the Old Testament priesthood first appears in full force in the writings of Cyprian. The further development of the notion of Christian priesthood was connected with the view that the Eucharist (*q.v.*) is a propitiatory sacrifice which only a consecrated priest can perform. It is sufficient to remark here that the presentation of the sacrifice of the mass came to be viewed as the essential priestly office. so that the Christian presbyter really was a *sacerdos* in the ancient sense. Protestants, in rejecting the sacrifice of the mass, deny also that there is a Christian priesthood "like the Levitical," and have either dropped the name of "priest" in reference to any specific office, or use it in a quite emasculated sense.

PRIESTLEY, J. B. (JOHN BOYNTON) (1894–), English novelist, playwright and critic. who distinguished himself in all three fields. was born in Bradford, Yorkshire, on Sept. 13, 1894. He served in World War I with the duke of Wellington and Devon regiments, rising from the ranks to become an officer and being three times wounded before he was invalided out. He was educated at Trinity Hall. Cambridge (1919–22), where he partly paid his way by writing critical and other articles. He went to London in 1922 and made his first reputation as a critic: many of his reviews appearing in the *Saturday Review* and the *Weekend Review*. Both in his novels and his plays Priestley depicted the English man in the street and represented his point of view. His first successful novel was *The Good Companions* (1929; dramatized with Edward Knoblock. 1931), which was followed by *Angel Pavement* (1930), *Faraway* (1932), and The *Doomsday Men* (1 9 3 Quickly mastering stage technique, he wrote such successful plays as *Dangerous Corner* (1932), *Laburnum Grove* (1933), *Time and the Conways* (1937), *Home is Tomorrow* (1948). He served as the United Kingdom delegate to the Cnited Nations Educational. Scientific and Cultural organization (UNESCO) in 1946–47. He also became a very popular radio broadcaster.

PRIESTLEY, JOSEPH (1733–1804), a dissenting English clergyman, by avocation a chemist and as such the celebrated discoverer of oxygen. He is equally well known in his native land and in the United States where he spent the last ten years of his life. Born at Fieldhead, near Leeds, on March 13, 1733, the son of strict Calvinists, he was destined for the ministry. Displaying an independent mind, he soon rejected the authority of the established churches and became a dissenting minister at 22. and five years later a teacher of classics and literature at a private school in Warrington. There he wrote an essay on education and a compilation on eminent men of all ages, which earned him a doctor of laws degree from the University of Edinburgh. This study necessitated frequent trips to several cities, including London, where he met and was befriended by Benjamin Franklin. At the latter's suggestion he wrote a *History of Electricity,* which proved so successful that he was admitted, at the age of 33, to the Royal society.

Following a disagreement with the trustees of Warrington academy he resigned in 1767 and became pastor of Mill Hill chapel, near Leeds. Living next to a brewery, he became interested in the "fixed air" (carbon dioxide) that lay over the liquids in the fermentation vats. On moving to another location he continued his studies with this gas, which he made by pouring acid on chalk. He dissolved the gas in water and obtained "an exceedingly pleasant sparkling water, resembling Seltzer water." For this application, which was his first contribution to the chemistry of gases. the Royal society awarded him the Copley medal in 1773. About this time Priestley was fortunate in meeting a fellow sympathizer with the cause of the American colonies, Lord Shelbourne (later marquess of Lansdowne). He became librarian and literary companion to this wealthy nobleman, with enough leisure to indulge in scientific pursuits.

With the aid of a newly acquired burning glass, he obtained on Aug. 1, 1774, a new gas from mercuric oxide that was five or six times as pure as ordinary air. He even foresaw its future uses: "it may be peculiarly salutary for the lungs in certain cases" and thus anticipated its use in oxygen tents. This discovery, which greatly increased his fame, led to a meeting in Paris with Antoine Lavoisier and other noted scientists to whom he related his findings. Lavoisier at once repeated Priestley's experiments with the new gas, which he named oxygen because of its acid-forming properties. It gave Lavoisier the clue to demolish the phlogiston theory of which, nevertheless, Priestley remained a lifelong adherent. Meanwhile, the theological heresies of Priestley strained the relations with his patron to such extent that he resigned in 1780 to become minister to a dissenting congregation in Birmingham. In this city Priestley found kindred souls with liberal outlooks in politics and religion who induced him to join the so-called "Lunar society" (outsiders called it "lunatic") which met on Monday nights nearest to full moon.

In Birmingham, where Priestley spent the happiest decade of his life, he wrote the final two of his six volumes *On Different Kinds of Air.* An abridged edition in three volumes appeared in 1790. Priestley's nontechnical writings, particularly his *History of the Corruptions of Christianity,* his espousal of the cause of the American colonists and later of the French Revolution, and especially his outspoken reply to Edmund Burke's attack on the new regime in France, made him exceedingly unpopular with the public. The smouldering resentment against Priestley and his friends came to a head on the second anniversary of the fall of the Bastille (July 14, 1791). Mob rule existed in Birmingham for three days. Priestley's church, his house and his laboratory were burned and he himself escaped in disguise to Worcester. Later he settled in London, where he spent three unhappy years. On April 7, 1794, he left for America to join his three sons who had already found new homes there. Arriving in New York city in June 1794, he was offered a professorship and a ministry, both of which he declined. He built himself a house and laboratory in the town of Northumberland. Pa.. and there he died on Feb. 6, 1804.

Priestley's multiplicity of interests has often been commented upon. Trained as a theologian, he was open-minded, fearless and progressive in matters of religion and politics; in science, to which he came later in life, he was orthodox, timid and as he himself stated "not apt to be very confident" about conclusions from his observations. Even so, he had the attributes of a born investigator: an intense curiosity, a passion for "experimental philosophy" and a native honesty and frankness. He was an ingenious manipulator. Being the first to collect gases over mercury. he discovered. in addition to oxygen. several other new gases. Some of these are highly soluble in water and thus had escaped the attention of contemporary chemists. Another significant contribution to chemistry was Priestley's work on "the purification of air by plants and the influence of light on that process." which provided the stimulus for subsequent studies by Jan Ingenhousz, Jean Senebier and others on respiration and photosynthesis.

BIBLIOGRAPHY.— An excellent account of Priestley's contributions to chemistry is found in J. R. Partington, *A Short History of Chemistry*, 2nd ed. (1948), which contains numerous references. For a popular account of his life and work see B. Jaffe, *Crucibles* (1934), and J. G. Gillam, *The Crucible* (1954). His work on oxygen has been republished in *The Alembic Club Reprints,* no. 7 (1901) and in H. M. Leicester and H. S. Klickstein, *A Source Rook in Chemistry* (1952). A good account of Priestley's relations with Lavoisier mas given by R. E. Oesper in *J. Chent. Educ.*, 13:403 (1936).

The centennial of the discovery of oxygen, celebrated by a group of American chemists at Priestley's home in Northumberland, mas followed by the founding of the American Chemical society in 1876. The semicentennial meeting oi the society led to the issue of a "Priestley Number" of the *J. Chem. Educ.*, 4:145–199 (1927), which contains illustrations and details of his life in America. (H. S. V. K.)

PRIEUR, PAUL (*c.* 1626–*c.* 1676), French enamel painter. He married Marie (1610–1677), sister of Jean Petitot, as her second husband. In 1669 he was in England, painting a miniature of Charles II and another of Lady Castlemaine, both after Cooper, for the king of Denmark. In 1670 he was in Poland, painting for the Danish monarch a portrait of King Michael. and in the following year was in Denmark executing a remarkable series of portraits of the children of Frederick III. All these, with some beautiful enamel badges for the Order of the Elephant, are in the Danish royal collection. By Christian V he is said to have been sent to Spain and Russia, where several examples of his work. dated 1676, are to be seen in the Hermitage, Leningrad. He died in Denmark, in 1676. He was a Huguenot, and was said to possess secret colours in enamel, especially a blue. which were not known to his Petitot relations. (G. C. W.)

PRIEUR DE LA MARNE [PIERRE LOUIS PRIEUR] (1756–1827), French politician. was born at Sommesous (Marne) on Aug. 1. 1756. He practised as a lawyer at Châlons-sur-Marne until 1789, when he was elected to the states-general. He became secretary to the assembly. and the violence of his attacks on the *ancien régime* won him the nickname of "Crieur de la Marne." In 1791 he became vice-president of the criminal tribunal of Paris and in May 1796 president of the convention, hiding from May 1795 until the amnesty proclaimed in the autumn of that year. In 1816 he was banished as a regicide. He died in Brussels on May 31, 1827.

PRIEUR-DUVERNOIS, CLAUDE ANTOINE, COMTE (1763–1832), French politician. was born at Auxonne on Dec. 2, 1763. and was known as Prieur de la Côte d'Or. He was a member of the legislative assembly and of the convention. In 1793 he was employed in breaking up the Federalist movement in Normandy, but he was arrested by the Federalist authorities of Caen, and only released in July 1793 after the defeat of their forces at Vernon. On Aug. 14, 1793, he became a member of the committee of public safety, allying himself with L. N. M. Carnot in the organization of national defense. Under the directory he sat in the Council of the Five Hundred, retiring after the coup d'état of 18 Brumaire (Nov. 9, 1799). In 1808 he was created a count of the empire, and in 1811 retired from the army with the grade of *chef* de *brigade*. He was one of the founders of the École Polytechnique, and shared in the establishment of the Institute of France: the adoption of the metric system and the foundation of the bureau of longitude were also due to his efforts. Prieur died at Dijon on Aug. 11, 1832.

PRILEP, a town in Macedonia, Yugoslavia. Pop. (1953) 29,776. The town owes its chief importance to a large annual fair. The town is famous in Serbian history as the birthplace and capital of Marko Kralyevich, one of the favourite national heroes, who held his kingdom, after the fall of Serbia in 1389. as a vassal of the Turks. Legend says that before his death he buried his sword deep in the rocks of Prilep and left his magic horse Sharatz to nibble the moss near by, with the promise of reappearing in his country's hour of need. In the Balkan Wars (1912–13) the Serbs successfully stormed the heights, reputed to be impregnable. In 1941 the town was occupied by Bulgaria.

PRIM, JUAN, MARQUIS DE LOS CASTILLEJOS, COUNT DE REUS (1814–1870), Spanish soldier and statesman, was born at Reus, Catalonia, on Dec. 12, 1814. He served in the volunteers of Isabella II in 1834, becoming lieutenant-colonel during the Carlist war. In 1839. as a progressist opposed to the dictatorship of Espartero, he was exiled. Elected deputy for Tarragona in 1843, he defeated Espartero at Bruch and entered Madrid in triumph with Serrano. The regent Maria Christina made him major-general and count of Reus. Narvaez, the prime minister, who did not understand what constitutional freedom meant, sentenced Prim to six years' imprisonment in the Philippine Islands; the sentence was not executed, and until the amnesty of 1847 Prim remained an exile in England and France. On his return he was made captain-general of Porto Rico and military representative with the sultan during the Crimean War. Elected to the *cortes* in 1854, he supported O'Donnell, who promoted him lieutenant-general in 1856. He was made marquis de los Castillejos and a grandee of Spain for his valuable services in Morocco (1860). A member of the opposition against Narvaez, at his death (1868) Prim and Serrano raised the standard of revolt at Cadiz, with Admiral Topete commanding the fleet. In July 1869 Serrano was elected regent, and Prim became president of the council and was made a marshal. He was shot by unknown assassins on leaving the chamber of the *cortes* on Dec. 28, 1870.

Blairet, *Le Général Prim et la situation actuelle de l'Espagne* (1867); Guillaumot. *Juan Prim et l'Espagne* (1870); H. Leonardon, *Prim,* bibl. (1901); F. González Llanos, *Biografiá politica y militar del . . . general . . . Prim . . .* (1860).

PRIMARIES are meetings of voters at which the first steps are taken toward the nomination of candidates for office. They may be informal gatherings or elections held under the same safeguards as final elections. They may be partisan in the sense that participation is limited to persons affiliated with the same party; or nonpartisan, in that nominees are chosen without regard to party affiliation. Partisan primaries may be indirect or direct. In the former, delegates are chosen to nominating conventions and the primary is equivalent to a caucus, but in the direct primary the party membership chooses the nominees and the primary becomes a preliminary election in the electoral process.

The formalized, legally regulated primary election and the direct primary are peculiar to the United States. Nominating conventions, instituted by the parties as reform measures, became subject to abuses which led first to their regulation and ultimately to their elimination for most offices. Observance of early laws relating to selection of delegates was optional, parties being permitted but not required to conform to their provisions, and the laws were limited to certain areas. After 1890 mandatory regulations of a sweeping character transformed the primary into an election conducted by public officers at public expense. Even before these laws were tested direct nominations were demanded. The direct primary was used by the Democratic party in Crawford county. Pa., as early as 1842, but it was not until the 20th century, when the Progressive movement tended to divide both parties, that the system came into general use. In 1903 Wisconsin, under the leadership of Gov. Robert M. La Follette. passed the first mandatory, state-wide direct primary law. The movement spread so rapidly that by 1917 all but four states had adopted the direct primary for some or all state-wide nominations. After the passage of laws in Utah (1937), New Mexico (1938), Rhode Island (1947) and Connecticut (1955), some form of direct primary was used in all states. By the 1950s primaries in most states were mandatory and covered nominations to all state and county offices, but optional primaries survived in several southern states, and Michigan. New York and Indiana mere among the states which used conventions for nominations to some state offices. In most states provisions applied only to parties polling a fixed minimum at the last election.

Beyond this, few generalizations are possible; direct primaries in the states vary widely in detail, and dates of primary elections vary from spring to fall. Various methods are used to place names on the ballot. The simplest is a declaration of candidacy, with or without a filing fee. The more popular method is by petition signed by a certain number of political supporters of the aspirant. These formal requirements are frequently supplemented by informal procedures. "Slates" of candidates are proposed by groups identified with the party organization or by unofficial gatherings of party members. An interesting development was the formalization by law of preprimary conventions in Colorado, Connecticut, Massachusetts and Utah. The Connecticut law limits the competition in the primary to those who received 20% of the vote on any roll call at the preprimary convention. In Rhode Island party committees are empowered to designate individuals whose names appear on the primary ballot as endorsed candidates and who are given preferential treatment as to position. In most states an aspirant for nomination may compete only in the primary of the party in which he claims membership, but in a few states it is possible for the candidate to seek the nomination of both parties simultaneously. This practice of "double filing" or "cross filing" has been used extensively in California, and the same person has sometimes won both nominations.

Particularly interesting and important are the variations in qualifications for voting in the primary. Some primaries are "open" in the sense that no declaration of party affiliation is required; the voter may participate in the primary of either party and move from one party to another in successive contests. Sometimes, as in Wisconsin, the participant receives the ballots of all parties and may decide which to use in the privacy of the voting booth, whereas in those states following the Minnesota plan a "blanket" ballot is provided on which the names of all candidates are arranged in party columns. In 1935 Washington adopted a blanket ballot which permitted the voter to cross back and forth between the parties at the same primary; *e.g.,* he might vote for a Republican aspirant for the gubernatorial nomination and at the same time express a choice for a Democrat for the nomination for United States senator. The "closed" primary, used in a majority of the states by the latter 1950s, limits participation in the primary to party members. Voters are required to enrol as members of a party at the time of registration, to state their party choice at the polling place, or to swear that they meet a specified test of party membership if their right to participate in the primary is challenged. The usual tests are support of the party's candidates at the last general election or the intention to support the candidates of that party at the next general election.

The merits of open and closed primaries have been widely debated. It is argued that the open primary permits participation by independents who are unwilling to declare a party affiliation and that it prevents intimidation of voters. Its opponents say that it destroys party responsibility by permitting those who have no continuing allegiance to the party to control its nominees, and that it permits members of one party to "raid" the primaries of the other party.

In most states the candidate polling the highest number of votes becomes the nominee, but by the mid-1950s ten southern states, in which Democratic nomination is equivalent to election: required a second or "run-off" primary if no candidate received a majority of the votes in the first contest. Preferential voting (*i.e.,* indication of a first, second and third choice), tried by several states, had been abandoned by all of them.

Studies made in the 1950s tended to support the hypothesis that the primaries had altered the character of political competition, at least in the case of nominations for state legislative posts. Even in two-party areas the effective choice had tended to be transferred to the primaries of the majority party, and the vitality of the minority party was weakened.

Attempts have been made to extend the idea of direct nominations to the presidency of the United States. By election of delegates to the nominating conventions, and by preference votes for president, or both, some states have attempted to bring the national conventions within the control of the party membership. The first presidential primary law was adopted by Wisconsin in 1905, and by 1916 laws varying widely in type and effectiveness were in operation in 24 states. After that the movement lost ground, and by the latter 1950s mandatory laws were in effect in only 17 states.

Nonpartisan primaries have been widely used for judicial and local offices in the United States and have been extended to members of the state legislature in Minnesota and Nebraska. In reality a double election system in which party labels play no part, nonpartisan elections and primaries were introduced in an attempt to remove these offices from influence by national party politics. Although nonpartisan in form, they frequently become partisan in fact.

The closest parallel to the U.S. primary has been the "preselection" ballot of the Australian Labour party, in which candidates in each locality have been selected by party members in that locality from those offering themselves for the preselection vote.

PRIMARY EDUCATION: *see* ELEMENTARY EDUCATION.

PRIMATE, a title applied during the 4th and 5th centuries A.D. to both secular and ecclesiastical officials. The Theodosian code mentions primates of towns, districts and fortified places (*Primates urbium, vicorum, castellorum*). A pragmatic sanction of Justinian also mentions primates governing a district, *primates regionis;* and in this sense the title survived, under Turkish rule, in Greece until the 19th century. An official called "primate of the palace" is mentioned in the laws of the Visigoths. Primas also seems to have been used loosely during the middle ages for "head" or "chief."

Charles du Fresne, Sieur du Cange cites *primas castri.* The title has been more generally used to denote a bishop with special privileges and powers. It was first employed almost synonymously with metropolitan to denote the chief bishop of a province having his see in the capital and certain rights of superintendence over the whole province. At the Council of Nicaea (A.D. 325) the metropolitan constitution was assumed as universal. and after this the terms metropolitan, and primate, to denote the chief bishop of a province, came into general use. The title of primate was used more generally in Africa, while elsewhere metropolitan was more generally employed.

At a later date primate became the official title of certain metropolitans who obtained from the pope a position of episcopal authority over several other metropolitans and who were, at the same time, appointed vicars of the Holy See. This was done in the case of the bishops of Arles and Thessalonica as early as the 5th century. The archbishop of Reims received the title of *primas inter primates.* By the False Decretals an attempt was made to establish such a primacy as a permanent institution, but the attempt was not successful and the dignity of primate became more or less honorary.

The overlapping of the title is illustrated by the case of England, where the archbishop of York still bears the title of primate of England and the archbishop of Canterbury that of primate of all England.

BIBLIOGRAPHY.—*See* Du Cange, *Glossarium;* Hinschius, *Kirchenrecht* (Berlin, 1869); Moeller, *History of the Christian Church,* translated from the German by Andrew Rutherford (1902); Bingham, *Origines ecclesiasticae* (1840).

PRIMATES, an order of mammals, including man, the apes, monkeys, tarsiers and lemurs. The name, meaning "chiefs," was given by Carolus Linnaeus in 1758. Linnaeus also included the bats, assigned to a separate order by modern zoologists.

Structure and Habits.—Primates are primarily arboreal animals tvith hands and feet adapted for climbing. The fingers and toes are provided with nails (rarely compressed as claws). The great toe of the hind foot is usually more or less divergent and the foot functions as a grasping organ, branches of trees being seized between the great toe and the four outer toes. The hands serve both for climbing and for manipulating food. The limbs are relatively long and slender, with free movements of rotation and supination. The lower primates (lemurs) are practically quadrupeds that run and leap in the trees but in the more advanced monkeys and apes there is an increasing tendency to climb with the arms extended above the head and the weight of the body suspended beneath the branches (brachiation). On the other hand, in the baboons the limbs plainly show secondary adaptation for running on the ground, both in their somewhat dog-like proportions and in the reduction of the great toe.

In the stem type of arboreal monkeys, vision is dominant over smell, whereas in typical ground-dwelling mammals the reverse is the case. Hence the occipital poles of the brain, which are connected with vision, are much enlarged. The adjustments for balancing in such actively climbing animals are extremely various and rapid; this requires a correspondingly complex development of the cerebellum and of the cerebral areas of the brain concerned nith the movements of the limbs and body. As intelligence increases the prefrontal lobes of the brain develop. Thus the brain of monkeys is proportionately larger and more complexly convoluted than in ordinary ground-living animals. As a whole the brain of the old world monkeys presents the ground plan of the human brain without the special developments and complications connected with man's superior mentality.

The bony brain case closely follows the shape of the brain, except in front, where the large eye sockets jut forward, thus enabling the achievement of binocular, stereoscopic vision. Owing to the forward growth of the temporal lobes of the brain the greater wings of the sphenoid are moved forward to form the backwall of the orbits, which are thus separated by a bony partition from the temporal fossae.

Hearing is acute and the temporal lobes are large. A thin bony shell, the auditory bulla, on the underside of the brain case behind the socket for the lower jaw, covers the lower side of the cavity of the middle ear and is connected by a bony tube tvith the root of the external ear; the latter resembles that of man but usually has a point on its upper rim and lacks a lobule below.

In the more primitive primates, *e.g.* lemurs, the jaws are long and slender and the muzzle pointed. In typical monkeys, however, the jaw is shortened and deepened and the muzzle broad, the nose and lips assuming more or less the human aspect. The opposite halves of the lower jaw are fused in front even in young animals. The dentition is adapted for a mixed diet, with fruits or vegetation prevailing. The teeth in an adult old world monkey number 32, as in man. The incisors are cutting teeth, the lower ones slightly inclined iormard There are two pairs in both upper and lower jaw The canines are sharp and adapted for biting; the upper premolars are bicuspid, *i.e.*, with single, outer and inner cusps: and the low-crowned molars are surmounted by low cusps.

The female reproductive organs are fundamentally as in man (except in details) and there is likewise only a single pair of breasts in the female. The placenta, except in the Lemuroids, is disk-shaped and intimately attached to the wall of the uterus.

Thus a typical monkey differs from an ordinary mammal such as a dog in its thorough adaptation to arboreal life, in the greater activity of the visual as coinpared with the olfactory powers. in its more advanced type of brain and in its much greater likeness to man in the entire ground plan of its anatomy.

Such a monkey is structurally connected on the one hand with lower primates (including new world monkeys, tarsiers and lemurs) and on the other hand with the higher primates, the anthropoid apes and man Even the still existing species of primates form a fairly gradual transition from the tree shrews at the base to highly specialized forms like the spider monkey, the orangutan and man, which stand far out on widely divergent branches.

SUBORDER PROSIMII

Here are included the lower primates, animals very different in appearance from monkeys and apes. Structurally they also differ widely, many authors considering the lemurs distinct enough to be given ordinal rank.

Tupaioidea.—The tree shrews are often classed as Insectivora (*q.v*) but they are undoubtedly much like the stock from which the other primates arose.

The pen-tailed tree shrew *(Ptilocercus)* of Borneo is a mouse-like arboreal animal. Its hands and feet are five-toed and provided with claws, the thumb and great toe somewhat divergent. Food includes insects and fruit; the upper molar teeth are tritubercular, the lower molars tuberculo-sectorial (see MAMMALIA). The skull is lemur-like, especially in the ring-shaped orbit and inflated auditory bulla, which completely encloses the ring-like tympanic bone and eardrum. The brain is pritnitive in having relatively unreduced olfactory parts and very feebly developed neopallium or higher part of the brain. *Tupaia* and related genera of India and the Malayan region are in many ways more advanced toward the lemur type. Fossil tree shrews not greatly different from modern forms were found in the Lower Oligocene of Mongolia.

Lemuroidea.—In the Palaeocene and Eocene of North America occur the fossil teeth and jaws of ancient primates belonging to several groups. The orbits open into the temporal fossae beneath the postorbital bar. The thumb and first toe are opposable

Family Plesiadapidae is the earliest of these groups; it also occurred in Europe. The incisors are shrew-like, the lower one large and procumbent, while the molar teeth resemble those of Recent lemurs.

Family Adapidae lived in the European and North American Eocene. The skull was broad, with large, forward-looking orbits, massive cheek arches and high crests. The molars were four-cusped, with sharp cross-crests. These ancient primates approached in many skeletal features the modern lemurs, to which they were either ancestral or closely related.

Family Norharctidae confined to the North American Lower and Middle Eocene, included forms ranging from the size of a squirrel to that of a cat. The first and second upper molar teeth gradually evolved from a three-cusped to a four-cusped stage. Apparently the entire family then became extinct. but some of them may possibly have given rise to the ancestral South American monkeys. In *Notharctus osborni* from the Middle Eocene of Wyoming, the hands and feet were of the grasping, climbing type, much like those of existing lemurs. The skull was far less specialized than that of contemporary tarsioids, both skull and dentition retaining the primitive features of lemurs on the one hand and monkeys on the other. Thus the dental formula of *Notharctus* ($i\frac{2}{2}$, $c\frac{1}{1}$, $p\frac{4}{4}$, $m\frac{3}{3} \times 2=40$) is the primitive one for all primates. The brain case is primitive with no great expansion of the brain and with an unreduced nasal chamber. The orbits were protected behind by a rim of bone, not by a fully developed partition. The auditory region and base of the cranium, backbone, forearm, pelvis and hind feet were like those of lemurs.

Family Lemuridae became confined in modern times to Madagascar and the smaller adjacent islands. The lemurs have a fully arboreal skeleton, with grasping hands and feet. The animals run and leap on the tops of branches. The second toe bears a claw, while the other digits are armed with flat nails The lower incisors and much reduced lower canines are sharply inclined forward, compressed and pointed. This structure was thought a "comb," used in grooming the fur, but it is more probably used in feeding on soft fruits. The upper canines are large, but the incisors are small, widely separated medially. The upper molars have two sharp outer cusps and a medial crescentic one; the first two molars, in addition, have two small internal cusps. The lower molars are four-cusped. The opposite halves of the lower jaw are not fused in front as in the higher primates but remain free. The placenta is diffuse with a large allantois, and separates from the uterine wall at birth, without destruction of maternal tissue; *i. e.*, it is not deciduous. In this feature the members of this family resemble the ungulates and differ widely from the higher primates. Lemurs have only one pair of mammae situated on the breast.

The true lemurs *(Lemur)* have a dental formula $i\frac{2}{2}$, $c\frac{1}{1}$, $p\frac{3}{3}$, $m\frac{3}{3}$. The head has a fox-like muzzle and rounded occiput. The eyes are very large and protrude from their sockets, while the ears are large and movable. A long fringe of hair often surrounds their chin and cheeks. The ring-tailed lemur *(L. catta)* is one of the best known species, somewhat like a small. slender raccoon in appearance. It is ashy gray in colour, paler on the legs and sides, and white on the under parts, cheeks. ears and forehead. The blackish tail is ringed with white, giving this lemur its name. The ruffed lemur *(L. variegatus)* is characterized by the fringe of hair on the sides of the head and neck. This species varies greatly in colour. Usually the face is blackish, as are the under parts. tail and feet, while the upper parts and sides are white, cream-coloured or reddish. This species is the largest of the true lemurs. The black lemur *(L. macnco)* has tufted ears and a ruff. The male is black, while the female is said to have a white ruff and ears; the body is dark brown, lighter on the rump. Other races of this species are reddish or gray and may show stripes. The mongoose lemur *(L. mongoz)* is small, with dull reddish-brown. woolly fur; the face, chin, the middle of the forehead and a line above the eyes are black. The smooth-eared black lemur (L. *rubriventer)* lacks a fringe on the ears and has a small ruff; the female has reddish feet. The under parts are often reddish.

The gentle lemur (*Hapalemur griseus)* has a rounded head, short muzzle and small ears. Its colour is dark iron gray with a tinge of reddish. This species is said to be nocturnal and to feed on bamboo shoots and leaves. A closely related lemur mas described as H. *simus,* characterized by broader muzzle, and there are no spines on the forearm above the wrist.

The weasel or sportive lemur (*Lepilemur mustelinus*) is about 10 in. long. with a tail some 14 in. The small ears are naked, uhile the muzzle is long and pointed. Considerable variation in colour is shown by this species. There is frequently a black stripe down the back; the general colour is gray tinged with yellow or reddish, while the under parts are grayish or yelloxvish nhite. The upper incisors are generally lost in adults, but a single small pair may persist. *L. ruficaudus,* the red-tailed sportive lemur, is smaller than the preceding, the head shorter and broader, with the ears short-haired.

Subfamily Cheirogaleinae includes the mouse lemurs, referable to three genera. The face is short and the bony palate extends behind the last cheek tooth. *Cheirogaleus major* is about 8 in. long. with the tail about 9 in. The base of the tail becomes swollen with fat stored there during the summer and the animal hibernates in a nest in a hollow tree. The silky fur is grayish brown, often fawn-coloured or washed with rufous. A blackish ring surrounds the eyes. while between them the fur is pale. The eyes are large, while the ears are moderate in size, oval and sparsely haired. The heel bone is lengthened, while the hind limbs are larger than the fore. In habits the mouse lemur is nocturnal; it feeds on fruits and possibly honey. Several smaller species are known. *Microcebus* has four mammae, two on the breast. two on the abdomen. In the skull the brain case is high, while the facial region is reduced. The foot is long. the result of a lengthening of the cuboid and navicular bones. *M. murinus,* the typical form, is pale reddish gray. with nhite under parts; it is 5 in. in length with a 6 in. tail. M. *coquereli* is characterized by its soft woolly fur which is grayish brown washed with reddish. It is larger, 8 in. or more long, with the tail 13 in. It is said to build a nest of twigs in which it spends the daytime, to emerge at night in search of insects, fruit and leaves. *Phaner furcifer,* the forked-striped mouse lemur, receives its name from the blackish stripe running back from each eye to the occiput and continuing donn the back. The rest of the body is grayish.

Subfamily Megalodapinae includes a large extinct lemur of the Madagascar Pleistocene or early Recent. the skull about 12 in. long, which indicates an animal the size of a small hog. The three-cusped molars resemble those of the lemurs and mouse lemurs. The orbits were small and widely separated. The upper incisors were lost and the canines took their place. The skull vaguely resembles that of a hippopotamus.

Subfamily Archaeolemurinae contains two Lower Pleistocene genera, *Archaeolemur* and *Hadropithecus*. The former was about the size of a rhesus macaque and the skull was very monkey-like, with reduced face and large, rounded brain case. The eyes were large and directed forward. The dental formula is $i\frac{2}{2}$, $c\frac{1}{0}$, $p\frac{2}{2}$, $m\frac{3}{3}$, the first premolar functioning as a canine. *Hadropithecus* was much more specialized with massive zygomatic arch and large brain case.

Subfamily Indriinae contains the higher lemurs characterized by large, rounded brain case and small face, long hind legs; short thumb and short index fingers, but large first toes. The other toes are partly united by a web. They progress by leaps. The ears are generally naked, buried in the fur. The indriine lemurs live on vegetation and have a capacious caecum. The indri or endrina (*Indri indri)* has a short tail and large, tufted ears. The face, hands. feet and most of the body of this animal is velvety black; the lower back, tail, the sides of the hind limbs, the forearm and elbow region are white, as are a cheek fringe and the top of the head. The flanks are often pale. In contrast to the common lemurs, the indri is diurnal in habit. The cries of this species are plaintive and mournful. The sifakas (*Propithecus)* differ from the indri by their long tails; their ears are shorter, and they are largely white in colour, marked nith yellow. The face is black and nearly naked. *P. diadema,* the crowned sifaka, takes its name from the band of white hairs running across the forehead; this unites with grayish hair on the cheeks to surround the face. In southern Madagascar this species is almost white, while in the north the colour is blackish; the range of the species extends along the entire east coast of the island. Verreaux's sifaka *(P. verreauxi)* is a smaller species (head and body 18 in., tail 22 in.) restricted to the western, southern and northern parts of Madagascar. It has a crest of blackish hairs on the forehead. Some are largely white, with reddish patches on the thigh and arm; in others the head is reddish brown, with the limbs ashy gray. The avahi or woolly lemur *(Avahi laniger).* has a long tail and short muzzle. It is the smallest of this subfamily. the head and body about $12\frac{1}{2}$ in. long, the tail somewhat longer. In colour the avahi is mottled reddish brown and blackish, the sides and limbs are pale, while the under parts are grayish. Individuals may be whitish. Avahis are nocturnal and solitary; they leap considerable distances from branch to branch, but are awkward on the ground, as are their relatives.

Family Daubentoniidae contains only the ape-aye, *Daubentonia madagascariensis* (formerly known as *Chiromys*), one of the most extraordinary of all mammals. It is noted for the rodent-like incisor teeth, a single chisel-like pair in each jaw in nhich the enamel is restricted to the front and which are ever-groning. Canines are absent and the cheek-teeth, $\frac{4}{3}$, have flat crowns. There are, however, in the young aye-aye milk canines in the upper jaw, and the cheek teeth are more lemuroid. The general anatomy of the aye-aye is strongly lemur-like. The ears are large and naked, the head short and rounded. The tail is bushy. about 20 in. long. while the body is about 16 in. The thumb is clawed but opposable. The fourth finger is longest, while the third is almost as long and remarkably slender. The first toe is opposable with a flat nail, the other toes with pointed claws. In colour it is blackish, with the pale bases of the hair showing through. Arboreal in habit and nocturnal, the aye-aye feeds largely on the larvae of wood-boring beetles which it detects by its keen hearing The rodent-like teeth are used to gnaw through bark and wood, while the long, slender middle finger is said to be used as a grapple to insert into the holes of the insect prey and drag out the grub. In addition, it feeds on fruit, leaves and birds' eggs. Fossil jaws with gnawing front teeth suggestive of those of the aye-aye are known from the French Eocene. These are more or less intermediate between the primitive lemurs and the modern aye-aye.

Family Lorisidae includes the lemuroids of southeastern Asia and of Africa, which agree with the true lemurs in the curious comb-like lower front teeth, but differ in many features. The tympanic ring forms part of the auditory bulla, while in the lemurs it is ring-like, inside of the bulla. The internal carotid artery runs entirely external to the bulla instead of sending a branch, the stapedial artery, to run through it. The zygomatic or jugal bone is separated from the lachrymal by the maxillary, while the ethmoid forms part of the orbit.

Subfamily Lorisinae contains four genera. They have woolly fur, pointed face and broad, rounded head, large eyes. The index finger is small or rudimentary, the thumb and first toe are opposable, and the second toe is clawed. The tail is short, usually hidden by fur. *Loris tardigradus,* the slender loris, is confined to the lowland forests of southern India and Ceylon. It is a large-eyed, small-snouted, nocturnal animal, with extremely slender, long limbs and no tail. The limbs are generally strongly bent and the general appearance is that of an emaciated animal. In size this species is'about like a squirrel, the head and body about 8 in. long. Its colour is dark gray, with more or less reddish on the back, the underside pale gray; the young are more rusty in colour than adults. The index finger, though small, has three complete joints. The slender loris lives entirely in trees and sleeps during the day, grasping its perch by hands and feet. It is slow in movement, but is more active than its relatives. Succulent leaves, buds, honey, insects and birds' eggs form its diet.

Nycticebus coucang, the slow loris, is larger and much plumper than the slender loris, with smaller eyes and ears. It is about the size of a cat (15 in. long), tailless. The hind limbs are about the same length as the fore limbs. The colour varies considerably in different parts of its range, which extends from Assam, to Cochin China and the islands of Sumatra, Java, Borneo and some of the southern Philippines. This species is generally ashy gray with a buffy or reddish wash, although it may be silvery. Dark-brown markings surround the eyes, and a stripe of the same colour runs down the back, sometimes connecting with the circumocular rings, or there may be a large brown area on the crown. The fur is woolly and dense. The middle upper incisor tooth is much larger than the lateral one, and the upper canines are large. The female, as also in the slender loris, bears a single young one. The slow loris is nocturnal and hardly differsin habit from its slender relative. It lives solitary or in pairs, moving deliberately about the branches, upside down as readily as on top of them.

Perodicticus potto, the potto, closely resembles the slow loris in build. The muzzle is longer and broader; the eyes are farther apart, though large. The tail is about 2 in. in length while the head and body equal some 8 in. The potto is found in West Africa from Sierra Leone to the eastern Congo. Its close, woolly fur is reddish brown. A dorsal stripe of black runs down the back, and there is a dark ring around the eyes. The index finger is smaller than in the Asiatic lorises. Pottos feed on insects and vegetation; in stalking flies they move with extreme deliberation but are usually successful. So slow are their movements that African folk tales say a potto may starve to death travelling between one tree and another.

The awantibo, *Arctocebus calabarensis,* is much more rare than the potto, from which it differs by smaller size and lighter build, slender. pointed muzzle and rudimentary tail. The ears are large and pointed. The index finger is a small tubercle and the third finger is reduced. In the feet the second and third toes are about half the length of the fourth and fifth. In colour the awantibo is yellowish brown, somewhat paler below. A line down the nose is white. In the skull the palate has large perforations behind the incisors. This species is restricted to the Calabar coast of southeastern Nigeria. The African lorisids have strangely paralleled the Asiatic species, the awantibo showing many resemblances to the slender loris, while the potto is much like the slow loris.

Subfamily Galaginae are the long-legged lemuroids of Africa resembling in many ways the Madagascar mouse lemurs. The heel and navicular bones of the ankle are lengthened. The ears are large and naked; they can be folded up so as to lie nearly flat on the head. The galagos have molariform last premolars. *Galago crassicaudatus,* the greater galago, is widely distributed in eastern and southern Africa. It is the size of a small cat, some 13 in. long, with the tail 16 in. or more. The muzzle is longer and heavier than in the other representatives of this group. The feet are broad, with disk-like pads at the tips of fingers and toes. In habits these animals are agile and they leap great distances.

G. senegalensis is smaller, like a squirrel in size, with short face and large eyes. The tail is slender, with longer hair at the tip. In colour this species is pale gray, the tail yellowish or brownish, while the under parts are white. The pygmy galago, G. *demidoffi,* is about 6 in. long, with the tail some 43 in. It is generally reddish brown above, but the colour may be drab, the end of the tail somewhat darker and the under parts cream colour.

Euoticus elegantulus differs from its close relatives in having first upper premolar resembling the canine in shape and only a little smaller. This species is restricted to the forests of West Africa.

Tardoidea. — The tarsioids are of equal antiquity with the earliest lemurs, being represented in the Palaeocene and Lower Eocene of France, Wyoming and New Mexico. Even at this date the two groups were quite distinct and had become diversified into distinct genera and subfamilies.

Family Anaptomorphidae includes these ancient tarsioids. *Necrolemur* of France was distinguished by the angle of the mandible which was produced into a large hook-like flange. The canine teeth were not prominent. *Omomys* of Wyoming had a long jaw symphysis, with broad, tricuspate upper molars and unpaired anterior cusp on the lower molars. *Paromomys* of the Middle Palaeocene had enlarged lower incisors. The upper molars were broad, but short anteroposteriorly. Numerous related genera and species were described both from North America and Europe.

Anaptomorphus homunculus also from the Lower Eocene of Wyoming is well known from having been thought at one time to have been ancestral to man. The external upper incisor is small and set close to the canine which was small. The molars were broad, with three cusps. In size this species was about that of *Tarsius,* with eyes large but less extreme than in that species. Another species (*A. aemulus*) did not exceed the size of a squirrel.

Family Tarsiidae contains only the tarsiers (*Tarsius*) found in the forests of Sumatra, Borneo, Celebes, the Sangir Islands and the southern Philippines. The various island populations vary in colour and minor cranial characters, and several species may be recognizable. The tarsier is small, about 6 in. long, with tail 10 in. The hind legs are longer than the body and the hind feet are also long. permitting extraordinary leaps from branch to branch. The lower part of the heel bone and the navicular bone are lengthened and rod-like, somewhat like the foot bones of the frog. The fingers and toes are long and spreading, ending in flattened disk-like pads which aid in holding on to branches of trees in which the tarsier lives. The tail is long, terminating in a tuft. The head is rounded, with short, pointed muzzle, large, naked ears and enormous eyes, set close together, the orbits hardly separated by the nose. The thick, woolly fur is grayish-brown, the under parts are paler. The brain, although large. is remarkably primitive as compared to higher primates. Accordingly the skull, which largely reflects the character of the brain and sense organs, reveals enormous circular orbits, a swollen brain case, expanded auditory bullae and a reduced, greatly constricted nasal chamber. The jaws are slender and the teeth small, the upper molars being transversely widened with low, rounded cusps. *Tarsius* appears to be the rather specialized survivor of a very old primitive stock structurally intermediate between the tree shrews and lemurs below and the monkeys, apes and man above. Most of the known Eocene tarsioids are too specialized in their teeth to be the ancestors of monkeys (with possible exceptions noted below). The foot structure of at least two of these forms already showed more or less of the characteristic elongation of the heel bone and navicular.

SUBORDER ANTHROPOIDEA

The monkeys, apes and man differ from the lower primates in numerous ways. Cranially the orbits are separated from the temporal fossae by bony walls. The tympanic bulla is not inflated. The brain is highly developed, with numerous convolutions. The uterus is single and rounded; the placenta involves both embryonic and maternal tissue—at birth the lining of the uterus is lost (deciduous)—and it is discoidal or doubly so in shape.

Ceboidea.—The American monkeys are differentiated from those of the old world by widely separated nostrils facing laterally, whence the name "platyrrhine" (flat-nosed). The head is rounded with relatively small jams and the ears lack the pointed tip common in old world monkeys. The buttocks do not bear callosities and the thumb is never truly opposable to the other digits; it may be vestigial or even absent. The opposable great toe of the hind foot bears a flattened nail. but the nails of the other digits of both hand and foot are frequently compressed laterally and in the marmosets become claws.

The American monkeys are all arboreal The recent genera inhabit the tropical forests of South America. a few species extending northward into Central America. spider monkeys and howler monkeys even to Mexico. Except from Ecuador northward. the Andes limit the western range of monkeys, though some howlers spider monkeys and sapajous reach an elevation in Guatemala of 6,000 to 7.000 ft. A fossil cebid *Homunculus,* found in Lower Miocene formations in Patagonia, indicates the great antiquity and former wide range of the family.

Family Cebidae, comprising all the platyrrhine monkeys except the marmosets. is divided into some ten distinct genera. Many monkeys of this group have prehensile tails. capable of curling around a branch and supporting the weight of the body. When the tail is not so efficient a grasping organ it may assist in balancing. The teeth number 36 ($i\frac{2}{2}$, $c\frac{1}{1}$, $p\frac{3}{3}$, $m\frac{3}{3}$) and the molars are four-cusped, the inner pair of cusps somewhat crescentic. The brain varies in development, but the cerebral hemispheres are convoluted and cover or almost cover the cerebellum. Many of the smaller species have brains that are large relative to the body's size The cebids are all forest-living; none of them is very large.

The titis, *Callicebus,* are probably the most primitive of the group. These monkeys range from Panama to the southern border of the forests. although best represented in Brazil and neiahbouring countries The species are usually reddish in colour; they are small; the head and body 12 to 14 in, the tail is about the same length and bushy. not prehensile. The eyes are medium-sized, the ears smaller than usual in the family. Titis are diurnal in habit They feed on fruit, insects, birds and birds' eggs.

Closely allied to the titis are the dourocoulis, *Aotus* (often called *Nycticebus*), the only nocturnal monkeys. The toil is long but not prehensile. The large, closely approximated eyes and short face. surrounded by a ruff of pale fur, and the large, white spot over each eye give these little animals a peculiarly owl-like expression A central and two lateral black lines border the pale spots. The nostrils are closer together than in other platyrrhines, probably correlated with the closeness of the eyes to each other. The ears are small, almost hidden by the fur. There is considerable variation in colour from iron gray to gray mixed with orange brown, and the fur may be short and soft, or long and lax. There may well be only a single species, although several are recognized by zoologists The face around the eyes and nose is naked The dourocoulis feed on fruits and insects which they hunt at night. remaining hidden by day From the behaviour of *Aotus* and the high development of the olfactory parts of the brain. it is thought that the sense of smell is well developed more so than in other monkevs. The eves, unlike those of other Anthropoidea are adapted for nocturnal vision, and the central area of the retina lacks the fovea or island of pure cones. *Aotus* is found from Panama to Peru and Brazil.

The sakis and their relatives ***(Pithecia)*** have procumbent lower incisors, somewhat like those of the lemurs, and separated from the large canines by a gap. The tail is bushy and not prehensile; it may be long or short. The nostrils are widely separated. The thumb is comparatively well developed. The hair is generally long, often forming bushy side whiskers. In the white-headed saki (P. *pithecia),* the males are black with white head, while the females are grizzled with a yellowish wash. This species is found in the Guianas and northern Brazil. The race found along the Rio Negro, Brazil, has the head of the male buffy and the hairs are short. The hairy or monk saki (P. *monacha)* has harsh, long fur, a hood of forwardly directed hairs on the head and neck. In colour both sexes resemble the females of the preceding species, but the hands and feet are white. The monk saki occurs on the Upper Amazon from eastern Peru. Ecuador and western Brazil. On the Lower Amazon a rare variety or closely related species (P. *albicans*) occurs; it has pale grayish head, neck and limbs, but is otherwise like *monacha.* These three species are about the size of large cats, nearly a yard in total length, of which the bushy tail is half. The red-backed saki (P. *chiropotes*) of Venezuela, the Guianas and Upper Amazon is smaller. with soft fur and less bushy tail. The long hair on top of the head is parted and suggests a poorly fitting wig, and the beard of the males is also divided. The black saki (P. *satanus*) resembles the preceding form but is blackish, the females and younger animals with brown overlay on the back. It occurs along the Lower Amazon and around Pará (Belem). The white-nosed saki (P. *albinasa)* of western Brazil, is a large black species with red nose and upper lip, a triangular white mark on the nose and naked face. The back may be grizzled. These three species show many cranial characters connecting the sakis with the uakaris. The uakaris (often considered a separate genus called *Cacajao* or, wrongly, *Brachyurus*) differ from all other American monkeys in their short tails (about 6 in. long). P. *melanocephala,* the black-headed uakari, is brown in colour except for black head and face; it occurs along the Rio Negro in northern Brazil. P. *rubicundus,* the red uakari, is brighter in colour than most mammals, rich rufous, the bare face bright vermilion; it is confined to the upper Amazon between this and the Ica river. The bald uakari (P. *calvus*) differs from its close relatives in having the fur sandy white; the face is red as that of the red species. The naked area of the face extends to the ears and the crown of the head, the underside of the body is dark brown. The uakaris are some 20 in. long.

The howling monkeys *(Alouatta,* often wrongly *Mycetes)* are the largest of the new world monkeys, the size of a small dog (some 20 in. long with tail about the same length). The howlers are notorious for their extraordinary vocal powers, their roars being audible for several miles. The powerful prehensile tail is naked at the tip and friction ridges similar to those on our hands and feet have developed. There is a beard in males. The head is high and the skull pyramidal, with greater prognathous development of the face than in other American species. The lower jaw is deep and the hyoid bone of the male is curiously expanded, forming a great bony cup, with the thyreoid cartilage also dilated. The intelligence of howlers is not high, and the brain is small and poorly developed, unlike that of other new world species. The Indians have tamed most monkeys of the Brazilian forest but not the howlers. The red howler *(A. senicula*) is dark reddish chestnut. paler on the back and sides. It occurs from Venezuela and northern Bolivia to the Guianas.

The black howler (*A. belzebul*) is found along the south bank of the Amazon to Rio Tapajoz. East of there a race with a reddish back and hands occurs, although individuals may be almost pure black. The carava *(A. caraya*) occurs from Goyaz province, Brazil, through the Matto Grosso to northern Argentina. The adult males are black, while the females and young are ashy gray. The brown howler (*A. guariba*) of the mountains of eastern Brazil, is either reddish brown or blackish mixed with buffv. The mantled howler (*A. palliata*) is found from southern Mexico to Ecuador: it is blackish, sometimes grizzled on the back, with a gray or brownish mantle along the sides.

The squirrel monkeys (*Saimiri,* often wrongly *Chrysothrix)* are handsome, diminutive forms, about the size of squirrels. The face is short, almost vertical, with large eyes set close together. The ears are large, the nostrils widely separated. The tail is long, rounded and somewhat club-shaped; it is not prehensile. Their heads are produced backwards, the skull articulating near its middle with the spinal column. The brain is relatively larger than even that of man; the cerebral hemispheres overhang the cerebellum to a greater extent than in any other primate. Although smooth externally, the main grooves or sulci are evident in dissection. *S. sciurea* of Brazil, eastern Peru and northern South America has a gray head, the back gray or washed with gold. *S. oerstedi* of Panama, Costa Rica and Guatemala has a black crown, reddish-gold body, gray tail with black tip, white cheeks and throat.

The sapajous or capuchin monkeys *(Cebus)* are the most familiar of the new world primates, aptly called by H. O. Forbes "the typical genus of the American monkeys." The common names sapajou and capuchin are applied to these familiar monkeys. They are vivacious and relatively hardy; individuals having been known to survive in captivity for 25 years in the North Temperate zone. The thumb is well developed, though not opposable and the hands are used in a great variety of manipulations. The tail is slightly prehensile and usually carried curved toward the underside. With the superior functional adaptation of the hands is correlated a large, highly-developed brain and an intelligence comparable to that of the old world monkeys.

C. capucinus, the white-fronted sapajou, occurs from Honduras to Colombia. The body is black, the face and forehead naked, flesh-coloured, the forehead, cheeks, throat and chest yellowish white. *C. albifrons* is similar, with dull brown instead of black; it is found in Colombia, Ecuador and Peru. The brown capuchin of Ecuador, C. *aequatorialis,* is grizzled brown in colour, the crown, limbs and tail darker. *C. apella,* the smooth-headed capuchin of the Guianas and Venezuela, is fuscous in colour, more grayish on the forelimbs and face, the tail and feet dark. The tufted capuchin *C. fatuellus,* is found from Colombia to the Matto Grosso of Brazil and northern Bolivia. It has a black crown, reddish body, the feet and tail dark dull brown. Considerable variation occurs even in members of the same band. *Cebus* ranges from near sea level to about 7,000 ft. elevation.

A group of closely related monkeys comprises the woolly monkeys, *Lagothrix;* the spider monkeys, *Ateles* (or *Ateleus*); and, intermediate between these, the woolly spider monkey, *Brachyteles.* These are fruit-eating monkeys, all considerably larger than *Cebus.*

Lagothrix has particularly soft, woolly fur, grayish or brownish in colour, and a naked black, peculiarly human face. The generic name means "hare-hair," from the resemblance between fur of the typical forms and that of the hare. The hair of the head is short and stands upright. The common woolly monkey (L. *humboldti*) is heavily bodied, iron gray in colour with darker head and feet. The tail is prehensile and the thumb is moderately developed. This species is found from Colombia to Peru and the Cpper Amazon. Throughout this range the colour varies from pale gray to dull reddish brown, and the pelage is long and woolly or short and soft. *L. hendeei* of Peru is very different. The back is rich reddish black, almost dark vinaceous, the head, sides and under parts black. The fur is silky, very long on the underside. A white triangular spot is on the nose; the long hair on the scrotum and the underside of the tail tip are pale golden colour.

The spider monkeys have coarse hair; the thumb is vestigial or absent externally, while the other fingers are elongated to form highly serviceable, hook-like hands for rapid swinging from branch to branch. The limbs and tail are also elongated. Spider monkeys frequently walk erect. The black spider monkey *(Ateles paniscus*) is represented by the typical form in the Guianas and northern Brazil. The face is red and naked, while the hair of the back is long. The variegated spider monkey (A. *belzebuth*) is black with buffy or whitish under parts, the inner sides of the lower legs and forearms similarly buffy. A white or golden triangular or band-like forehead patch is often present. The cheeks are often white or buffy. This species ranges from the Upper Orinoco to eastern Peru and the Lower Amazon on its southern bank. A Colombian race is pale grayish brown sprinkled with black. The brown-headed spider monkey *(A. fusciceps)* is black or blackish brown with head distinctly paler than the back. The hair of the crown is shorter than usual and does not project over the forehead. The black-handed species of Central America, north to Veracruz district, Mexico, *(A. geoffroyi*) may be recognized readily by the black hands, feet and head and reddish-brown or yellowish body fur.

Brachyteles arachnoides, the woolly spider monkey of southeastern Brazil, forms a link between *Lagothrix* and *Ateles.* Its fur is woolly; the thumb is small but still visible externally. The body is yellowish brown, darker on the back of the head. The females are grayer. The hairs on the head are directed backward.

These three genera all have long and powerful prehensile tails, of which the extremity is naked on the underside and provided with friction ridges like a finger. This organ is used not merely in climbing but also for picking up objects. These monkeys are easily tamed, affectionate and intelligent. The brain, especially in *Ateles,* is exceptionally large and complex.

Callimico, a peculiar type previously assigned to the genus *Callithrix,* has most of the external features, including claws, like the Callithricidae, but the skull, though essentially that of a marmoset, has certain likenesses to the Cebidae, the most important being the retention of the third molars. O. Thomas proposed a new subfamily, Callimiconinae, which he was inclined to place in the Cebidae. The callimico is about 8 in. long with a tail little more than a foot in length. Its colour is dark brown, the limbs, under parts and tail black, with white tufts in front of the ears and on either side of the back near the loins. The place of origin is between the Rio Ucayali and the Madeira, western Brazil.

Family Callithricidae contains the marmosets, the smallest of the Anthropoidea. They are handsome little animals, some smaller than squirrels. These were considered by some the most primitive American monkeys. but they probably represent dwarfed descendents of ancient cebids. Marmosets have only 32 teeth ($i\frac{2}{2}$, $c\frac{1}{1}$, $p\frac{3}{3}$, $m\frac{2}{2}$); the last molar was lost rather than one of the premolars, as was the case in the old world monkeys. The digits, except the hallux, bear sharp, curved claws in place of nails, forming in such small creatures highly efficient organs for climbing. The hands are used for grasping food, but they are not used much in manipulation as in higher primates, and the intelligence of the marmosets is decidedly inferior to that of the cebids. In the hind foot the great toe is smaller and less opposable than in other primates. The cerebrum, though large, is almost devoid of convolutions. Marmosets live in small bands; they are diurnal and feed on insects and fruit. They commonly breed in captivity, producing two or three young at a birth, instead of one as in monkeys in general.

The common marmoset or ouistiti. *Callithrix jacchus,* is an inhabitant of eastern Brazil, between Pará and Bahía west to the Rio Tapajoz. It is some 9 in. long with a tail of 12 in. The back is barred with black and grayish, as is the tail. while white ear-tufts distinguish this species from its close relative, the black-eared marmoset (C. *pencillata*) of southeastern Brazil which, except for its black head, is otherwise similar. The white-tufted marmoset (C. *aurita*) has the back variegated black and reddish or yellowish, and a ringed tail. A spot on the forehead and the ear-tufts are whitish. This species occurs in São Paulo province, Brazil. The white-headed marmoset (C. *geoffroyi*) of east-central Brazil has black ear-tufts and resembles the black-eared species in body colour, but the head is pure white in front of the ears. It is about 8 in. long, with a tail of the same length.

The yellow-headed marmoset, *C. flaviceps,* also from the east coast of Brazil above Rio de Janeiro, has a whitish face and forehead, the head, neck, shoulders and arms yellowish buff or reddish. The body is variegated black. gray and tawny. the latter colour disappearing on the lower back leaving black and gray bands which extend on the tail. The elegant marmoset (*C. petronius*) of Minas Geraes, Brazil, has long hair, coal black except for a few yellowish bands on the back. The forehead and upper parts of the ear-tufts are white; the hands and feet, as well as the pale bands of the tail, are pale gray. The golden marmoset (*C. chrysoleuca*) of lower Rio Madeira, Brazil, has silky hair, white on the body with golden under parts, limbs and tail, the latter obscurely barred with white. The silvery marmoset (C. *argentata)* is silky white with the tail black, the limbs are dark fuscous in one race and the body ashy gray. The white-shouldered marmoset *(C. humeralifer)* of Bahia, Brazil, is blackish, mottled with white on the back and with whitish nape, shoulders and ear-tufts. *C. leucippe,* the gilded marmoset of the Rio Tapajoz, is white with legs and tail pale gold. Unlike the similarly coloured golden marmoset, the ears are without tufts. The pygmy marmoset *(C. pygmaea)* is found in the upper Amazon region, eastern Ecuador and Peru and western Brazil. It is about 6 in. long with tail about 7 in. The head and shoulders are ticked black and buffy, the back mottled black and buff and the tail is vaguely banded. The ears are untufted.

The tamarins *(Leontocebus)* have short lower incisors, leaving the canines projecting high above the tooth row. The tail is unbanded and almost always black, and the ears lack the tufts characteristic of *Callithrix.* The white-lipped tamarin *(L. labiatus*) of the Upper Amazon is mostly blackish, the hack mixed with gray, the under parts and inner sides of limbs rich orange red. The tail. rusty at the base, becomes purplish black. The red-headed tamarin *(L. pileatus*) is found along the upper tributaries of the Amazon in eastern Peru and western Brazil. It is blackish except for the rufous forehead and crown, while the sides are brownish and the back somewhat mixed with gray. Around the mouth there are long white hairs. The imperial tamarin *(L. imperator*) ranges from eastern Ecuador and the Rio Negro to northern Bolivia; it has a long, upward-curling, white moustache, extending beyond the face. The body is gray, with a red-orange rump and base of the tail, black ear-tufts and end of the tail. The red-handed tamarin (*L. midas*) is relatively large, with large ears; its back is grizzled while the hands and feet are reddish golden. This species comes from the Guianas and was one of the first to become known to science. The negro tamarin *(L. ursulus*) lives along the Lower Amazon, is closely allied to the preceding species, but is distinguished by its black hands and feet; the back and outside of the legs have a reddish mixture. The face is hairy, the hair of the head not elongate, while the ears are large and naked. *L. leucopus,* the white-footed tamarin of northeastern Colombia, is dark gray with white hands, feet and head, the latter parts short-haired; the tail is black with a white tip. The brown-headed tamarin *(L. fuscocollis*) of the Upper Amazon is black variegated with yellowish ochre colour, the head yellowish buffy. The lion or golden tamarin *(L. rosalia),* found around Rio de Janeiro, is characterized by an extensive mane, suggesting that of a lion; its naked face is blackish violet. It is about a foot long, with slightly lonrer tail. The gold-and-black tamarin *(L. chrysomelas*), which comes from the coastal region of Bahia, Brazil, has body, face, underside and upper arms black, the legs blackish red, the head and forearms golden yellow. The pinché or silky marmoset (L. *oedipus*) of northern Colombia has a plume-like crest on the head, white in colour, as are the under parts and limbs. The back and thigh are brownish. The base of the tail is brown while the distal end is black. Geoffroy's marmoset (L. *spixi*) represents this species in Panama. It is similar in colour, but the hair on top of the head is not elongated, while the crown and nape are reddish brown.

A number of other species are known; the variation in colour and hair pattern is astonishing in this group.

Origin of the New **World** Monkeys.—The monkeys of South and Central America form an entirely different series from the monkeys of the old world and in spite of their general similarity to the latter, they probably were derived from a different ancestral stock.

In the first place the face in new world monkeys differs widely from that in old world monkeys, especially in the fact that in the new world or platyrrhine series the nostrils are usually widely separated at the base and are directed laterally. Other external differences from the old world monkeys were noted above. The new world monkeys may also be at once distinguished by the fact that there are three bicuspid or premolar teeth on each side, both in the upper and in the lower jaws, whereas in old world monkeys there are two. In the region of the middle ear, on the lower side of the skull, new world monkeys have a large ring-like tympanic bone, whereas in old world monkeys the same element forms a bony gutter, completely covering the drum-membrane on the lower side of the skull. Moreover, the cheek-bone of new world monkeys has a broad contact with the parietal bone, which is never the case in old world monkeys. The placenta in new world monkeys is disk-like, without the secondary placenta seen in old world monkeys.

All known new world monkeys both living and fossil stand on a rather high plane of evolution and there are no "living fossils" to connect the group definitely with any older fossil family. It is also difficult to be sure which is the most primitive living genus, but after repeated analyses of the characters of the skull and teeth it seems probable that the most primitive are certain small monkeys of the family Cebidae, especially the owl monkey (*Aotus*) and *Callicebus.* As noted above, the olfactory region of *Aotus* is less reduced than in most Cebidae and marmosets. These little monkeys have large orbits, short deep lower jaws, short muzzles and unreduced molar teeth. They agree with certain North American Eocene tarsioids in their dental formula $(i\frac{2}{2}, c\frac{1}{1}, p\frac{3}{3}, m\frac{3}{3}) \times 2 = 36$ and in the general form of the skull, but they differ from all known tarsioids in that the tarsal bones are not elongated. On the other hand, it is not impossible that the skeleton of the South American monkeys may have been derived from the type illustrated in the Iiorth American Eocene *Notharctus,* but in the present state of knowledge this inference is unsafe in view of the prevailing resemblances of the dentition and skull of *Aotus* to the tarsioids rather than to the notharctids. Finally there is the possibility that the new world monkeys may be derived from early extinct lemuroids resembling *Archaeolemur.*

Typical platyrrhine monkeys (*Homunculus*) in the Lower Miocene of Patagonia were found in association with a peculiar mammalian fauna which for millions of years had its headquarters in South America; but some of the ancestral stocks of this fauna were found in far earlier (Eocene) deposits of Iiorth America. In view of other available evidence, an ultimate North American origin for the new world primates seems quite possible. The monkeys now inhabiting Central America are closely related to those of Guiana and Brazil.

The new world monkeys as a whole exhibit a profound adaptation to arboreal life and probably originated in some heavily forested region such as they now occupy.

The old world or Catarrhine primates comprise two superfamily groups.

Cercopithecoidea.—Only family Cercopithecidae, the tailed monkeys, is included here; these monkeys are distinguished from the American species by features mentioned above. Two subfamilies are recognized: Cercopithecinae, including the macaques, baboons, mangabeys and guenons; and Colobinae, comprising the langurs and guerezas or colobus monkeys.

Subfamily Cercopithecinae all have cheek pouches in which food may be temporarily stored. The stomach is simple and these monkeys feed on insects and other animal matter as well as vegetable matter. Of this group the macaques, probably the best known of all monkeys, are widely distributed in India and the East Indies, north to China and Japan, while one species inhabits North Africa and the Rock of Gihraltar.

The macaques are among the most generally adaptable of monkeys and are hardy and long-lived in captivity. Though agile climbers, they are by no means exclusively arboreal and some are entirely terrestrial. They are usually omnivorous, and the crab-eating macaque of India lives chiefly on Crustacea. They have fore and hind limbs of about equal length. The thumbs, though short, are opposable and the animals have considerable manual dexterity. There is a median air sac connected with the larynx. The ischial callosities are well developed. The tail may be long, short, or practically absent as in the Barbary ape, *Macaca sylvana.* The lion-tailed macaque (*M. silenus)* occurs in India. Its colour is black with an enormous gray beard and ruff which surrounds the black face with the exception of the middle of the forehead. The tail is tufted at its extremity like that of a lion. The crab-eating macaque (*M. irus*) also has a long tail but lacks a mane. These monkeys feed on crustaceans along the shores and river-banks and swim readily. The colour is grayish or brownish and this species ranges from Siam to Timor in the East Indies, the Nicobars and the Philippines. The bonnet and toque macaques (*M. sinica* and *M. radiata)* have odd wig-like topknots, radiating from a central point; the former lives in southern India, the latter in Ceylon. They have long tails, about the same length as the head and body. The commonest species and the hardiest is the rhesus or Bengal macaque (*M. mulata*) found all over northern India, Burma, Indo-China and southern China. The tail is short, about half the length of the hind leg. The colour is grayish brown, becoming reddish on the rump and tail. The Himalayan macaque (*M. assanensis)* is similar but lacks the reddish on the rear parts and has woolly, thick hair. The Formosan macaque (*H. cyclopsis*) is also closely allied to the rhesus. but is olive gray in colour. The pig-tailed macaque (*M. nemestrina*) is larger, reaching the size of a large dog, and has a long face. The tail is only about 8 in. long. The fur is olive brown. The pig-tailed monkey is found from Burma to Sumatra and Borneo. The stump-tailed macaque (*M. speciosus*) has also a short tail; it is found from Tibet to Malaya, while the short-tailed brown Japanese macaque (M. *fusca*), with its red face, is confined to the Japanese Islands. The Celebes or Moor macaque (*M. maura*) is brownish black, with grayish limbs and a stump of a tail.

The black ape (*Cynopithecus niger*) with baboon-like face, has no tail. The head bears a tuft or crest of hair and the brow ridges are large. This species, a close relative of the macaques, is found in Celebes and Batjan Island.

Mangabeys (*Cercocebus*) are long-tailed monkeys found in the forested parts of tropical Africa. Their upper eyelids are white and their hairs are not banded. *C. torquatus*, the collared mangabey of southeastern Nigeria and the Cameroons, is blackish gray in colour with a bright bay crown and white collar, cheeks and chest. *C. atys,* the sooty mangabey, lives in West Africa from French Guinea to Liberia; it is grayish black above, paler below; the crown patch is speckled with olive. The face is flesh coloured except for the nose, mouth and chin, which are blackish. A race from the Gold Coast (*C. a. lunulatus*) has a white crescentic spot on the crown; the colour is more brownish. *C. agilis,* the gray mangabey of the Congo and eastern Cameroons forests, is dark grayish brown speckled with yellowish buff, especially on the front part of the body and thighs. The side whiskers are outstanding. The underside of the typical race is dirty whitish, but a race south of the Belgian Congo forests (*C.* a. *chrysogaster*) has under parts which are orange. The crested gray mangabey (C. *galeritus*) is found only along the Tana river, Kenya; it resembles the preceding species except for the long, pointed tuft on the top of the head, and it is smaller. The gray-cheeked mangabey (*C. albigena*) is dull black with horn-like eyebrows and a sooty bronn or grayish mantle on the shoulders; the typical race comes from the southern Cameroons and probably also Gabun. The eastern race, from Uganda and the Ituri forest. has a paler mantle and the head is more brownish, while a slightly different form occurs in the northern Cameroons and southeastern Nigeria. *C. aterrimus,* the crested black mangabey. is glossy black, with a vertical peak-shaped sagittal crest of fur and long, grayish cheek whiskers; it lacks the eyebrow tufts and mantle. This species inhabits the forests south of the Congo river.

The gelada or lion baboon (*Theropithecus gelada)* inhabits the mountains of Ethiopia. It is a large, blackish, ground-living monkey, with a long mantle of dark hair, the cheeks and rear parts grayish, while the end of the tail is tufted. The face is long and baboon-like, with nostrils tubular and well back from the end of the muzzle. thus resembling the macaques.

The true baboons *(Papio)* have the nostrils at the end of the muzzle, the tail is shorter than the head and body, and in some forms it is much shorter. These large, ground-living monkeys are a modified branch of the macaque group. In captivity there have been cases of hybrids between macaques and baboons. The sacred baboon *(P. hamadryas)* is the species represented in the ancient sculptures of Egypt. It is found in the Sudan, Ethiopia, Eritrea, Somaliland and southwestern Arabia and is characterized by its speckled gray colouration and the long mantle of the males. Typical baboons are found from the Cape to the Sudan, chiefly where the country is rocky. They are referred to several species, chiefly because of their colouration, which varies from golden and red to dark olive brown. The chacma *(P. comatus)* of South Africa, and the anubis baboon *(P. doguera)* of Kenya and Uganda are dark, while the yellow baboon *(P. cynocephalus)* of Tanganyika, the small yellow species (P. *kindae*) found in Northern Rhodesia and the Katanga and the red baboon (P. *papio*) of the Guinea region, are brightly coloured forms.

The mandrill (P. *sphinx)* might be called the rib-faced baboon, from the ridges on either side of the muzzle in the adult male. The massive head with its swollen blue muzzle, lined with reddish, the yellowish beard and the stump of a tail are distinctive. The general colour is dark olive brown, while the naked skin of the buttocks is bright crimson. The females are much smaller and are difficult to separate from the next species. The mandrill lives in West Africa, from the Sanaga river in the Cameroons to the Gabun and Middle Congo of French Equatorial Africa. The drill (P. *leucophaeus*) of the northern Cameroons is similar in build but the face is black; each side of the muzzle bears a single ridge, the top of which may be flesh coloured; the lip is crimson as are also the bare buttocks, while the face is outlined with white. These two species are frequently considered to form a distinct genus, *Mandrillus.*

The guenons, *Cercopithecus* (or *Lasiopyga)* comprise a number of species found over most of Africa south of the Sahara. The last lower molar tooth has only four cusps rather than the five found in old world monkeys considered thus far. The fur is ticked, the hairs many-banded with dark and light colours, and some species are brightly coloured. Guenons are mostly small monkeys living in trees and subsisting on fruit, leaves and insects. They have well-developed cheek pouches. The Diana monkey *(C. diana*) of West Africa (Liberia and the Ivory Coast) is named from the white crescent on the forehead above the eyes. The face and front of the beard are black, but the cheeks, throat, chest, front of shoulders and a bar on the thigh, are white. The body is blackish, finely speckled white, a broad bay streak runs down the back and the back of the thighs. In Nigeria the local race, *C. d. roloway,* has a longer white beard. The dryas guenon *(C. dryas*) lives in the forests south of the Congo river; it is closely allied to the Diana, with a short, full beard, but the general colouration is greenish gray. The De Brazza guenon *(C. neglectus)* is found from the Cameroons to the eastern and southern Belgian Congo. This species has a white beard and muzzle, and white hip-stripe; its orange-buff forehead band is broad, margined above with black: the body is a pale olive gray and the arms, hands, feet and tail are black. It takes readily to water, unlike most of its relatives.

C. aethiops, the common guenon, is found from Senegal to Ethiopia and south to the Cape, but avoids the rain forest areas for the most part. The grivet (*C. a. aethiops)* is olive gray with cheeks and eyebrow marking white; this race lives in Ethiopia and adjacent lands. The vervet of South Africa *(C. a. pygerythrus*) is more greenish with black hands, feet and distal third of the tail; the root of the tail is reddish. In Mozambique this is represented by a more reddish form *(C.* a. *rufoviridis*); in East Africa there is a yellowish race *(C. a. johnstoni*), while *a* dull grayish type invaded the eastern Belgian Congo *(C.* a. *centralis*). In West Africa is found the green monkey *(C. a. sabaeus)* with fur mixed black and yellow; the tail is yellowish, sometimes quite orange and the forehead is blackish although a narrow white band sometimes occurs. Another race, the malbrouck *(C. a. cynosuros*), with flesh-coloured face, well-marked white forehead band, grayish cheeks, and grayish-green colouration, comes from Angola and southern Belgian Congo.

The moustache monkey (C. *cephus*) is small, with a short face, the upper lip and nose ornamented by a broad bluish-white marking. It has well-developed cheek whiskers of yellow, bordered below by black, whitish under parts and reddish tail. This species is found from the mouth of the Belgian Congo river, north to eastern Nigeria. *C. erythrogaster* of *W.* Cameroons is closely related but lacks the light markings on the face. The nose is black, there is a large light cheek patch and reddish under parts. The lesser spot-nosed monkey (C. *petaurista*) is reddish in colour with a heart-shaped white spot on the nose and white or yellowish cheek whiskers often divided by black, and the brows are also black. The underside is white. Various local races of this monkey are found in forested regions from Liberia to Katanga and East Africa (North of Lake Victoria Nyanza.)

The hocheur or large spot-nosed monkey *(C. nictitans)* is found on the island of Fernando Po, and from Liberia to the Ubangi river. The tail is long, the colouration of the body and basal half of the tail dark blue gray, the back of the head, forelegs and end of the tail black. The white nose-spot is large and is somewhat rhombic in shape. In the western parts of its range the under parts become white or whitish (C. *n. martini)*.

The mona *(C. mona)* comes from West Africa. It is dark reddish olive, becoming blackish on the lower back, and there is a white spot on the rump on either side of the tail. The under parts are white, while the cheek whiskers are straw-coloured. A crescentic band of gray extends across the forehead from ear to ear, bordered below by black. Closely related forms, lacking the white spot beside the base of the tail, and with several minor differences in colour range from Sierra Leone to the eastern Belgian Congo. *C. pogonias,* from Fernando Po, the Cameroons and Gabun, has three black stripes on the head, one medial and one on either temple, while the hands, feet and tail are black. The extensive side whiskers are yellowish and the general colouration of this monkey is yellowish gray.

The diadem monkey *(C. mitis)* is typically bluish gray, with black limbs, under parts and tail. The forehead has usually a whitish bar, and the throat is white. In the Kivu mountains an orange-red race (C. m. *kandti)* occurs, while in East Africa *(C.* m. *albogularis*) the under parts and throat are white, the back is reddish. The golden Stair's monkey *(C. m. staiusi)* of Mozambique also belongs to this group, yellowish having replaced the whitish bands and the black bands having become pale. The owl guenon, *C. hamlyni,* is a large greenish-gray guenon of the eastern Belgian Congo, with black under parts, limbs and face, except for a white stripe down the nose. and frosted thighs and tail. The white-ruffed guenon *(C. l'hoesti)* has black face, under parts, tail-tip and limbs; the white ruff and throat contrast strongly with this; the head and tail are blackish gray, while the back is dark, rich reddish. The white ruff extends up on the cheeks and the hairs are directed upward. There is strong resemblance in this colour pattern to that seen in the white-throated diadem monkey of East Africa, but the upwardly directed hairs of the ruff and the black limbs distinguish it. This species is found in the eastern Belgian Congo, while a race (C. *l'h. preussi*) with speckled thighs is found in the west (Mt. Cameroon and Fernando Po).

The talapoin or dwarf guenon (C. *talapoin*) is found from the Cameroons to Angola and the eastern Belgian Congo, although in large parts of this range it was not found. It is about 10 in. long with the tail about 16 in.; the general colouration is grayish buff, the nose is black and the cheek whirl whitish as are the under parts. The face is extremely short and the last upper molar tooth has generally three cusps instead of four.

The huzzar or nisnas monkeys *(Erythrocebus patas*) are large and reddish, ground-living animals. The western race (E. *p. patas*) has the nose, a band above the eyes and the outer side of the upper arm black. In East Africa *(E. p. pyrrhonotus*) has a white nose and the upper arms are reddish. The huzzar monkey lives in the savanna country from Senegambia to the Upper Nile; this species is represented on ancient Egyptian monuments and was probably the Cebus of ancient writers.

The blackish green guenon (*Allenopithecus nigroviridis*) is found only along the middle section of the Congo river. It is blackish olive in colour, the face, hands, feet and upper side of the tail black and this colour predominates down the back. The cheeks, throat and under parts are grayish white, the latter mixed with ochraceous and black. The cheek teeth are high-crowned, the cusps drawn together, leaving narrow, longitudinal grooves between them and the limbs are short and stout.

The monkeys of subfamily Colobinae have a sacculated stomach and lack cheek pouches. The teeth are sharp-cusped and the diet is largely leaves, shoots and young twigs of trees, although fruit is also eaten. The African colobus monkeys *(Colobus)* are thumbless. The ursine colobus (C. *polykomos)* of West Africa (Ivory Coast to Sierra Leone) is black, with whitish cheeks, throat and tail. A white-thighed race (C. *p. vellerosus)* represents it in the Gold Coast and Togo. The black colobus (C. *satanus*) is similar to the preceding but lacks white markings; it is found in Fernando Po, the Cameroons and the Gabun. The guereza or mantled colobus *(C. abyssinicus)* occurs from Ethiopia to Tanganyika, the mouth of the Congo and eastern Nigeria. It is black with a long mantle of white along the sides, white cheeks, beard and supraorbital bar, and white-tufted tail. The extent of white varies somewhat and several races are recognizable. The Angola colobus *(C. angolensis)* ranges from the lower Congo to East Africa. The white hairs of the cheeks are long, the shoulder tufts are white and so is the distal part of the tail. The face is pinched, like that of a frail old woman, while the broad muzzle of the guereza suggests an elderly but healthy sailor with white whiskers and beard. The olive colobus *(C. verus)* is the smallest species (the head and body about 21 in., the tail 24 in.). The back is greenish brown, the limbs and tail dark olive, while the under parts are silvery gray. This species is restricted to West Africa, Liberia to the Gold Coast. The bay colobus monkeys (C. *badius)* vary locally and in consequence numerous races are recognized. The typical form comes from West Africa (Sierra Leone to the Ivory Coast) ; it is black, with bay forearms, legs and under parts. In French Congo a red form (C. *b. tholloni)* occurs, while farther east in Belgian Congo *C.* b. *powelli* is reddish brown, with dull yellowish-brown limbs. The Zanzibar colobus (*C. kirkii*) is also reddish, its hands, feet and shoulders are black, while a pale yellowish crest on top of the head is parted and falls over the ears and forehead. The red-crowned colohus (*C. rufomitratus*) is brownish gray in colour, with a reddish crown, black supraorbital band and a black transverse crest above the ears. This rare species is known only from the vicinity of Tana river, Kenya.

The langurs or leaf monkeys of Asia are slender-bodied, the limbs are long, as is usually the tail. Unlike their African relatives, the thumb is well developed. The sacred langur or hanuman (*Semnopithecus entellus)* of India and Ceylon is white or pale grayish in colour, the hands, feet and face are black, as are the overhanging eyebrows of stiff hair.

The black langurs of Peninsular India (*Kasi johnii*) are small, about 2 ft. in length with tail nearly 3 ft. The hair is fine and glossy, blackish in colour, while the head is yellowish brown and the rump is grayish. The young are black or grayish. The purple-faced monkey *(Kasi senex*) of Ceylon is closely allied to the preceding, but its face is distinctive, the hairs of the cheeks, chin and throat whitish. The general colour varies from uhite to black.

The shaggy langurs (*Trachypithecus*) have golden young, the hair of the crown is generally smooth going back to a peak. The nasal profile of the skull is straight. The capped langur (T. *pileatus)* of Assam and Upper Burma is dusky gray with golden, reddish or whitish under parts, a blackish tail. The white-mouthed langur (T. *phayrei*) lacks the cap, the hairs of the crown being like those of the cheek and neck; the areas around the eyes and the mouth are whitish. This species ranges throughout Burma, south to Tenasserim and east to Indo-China. The white-naped langur (T. *obscurus)* is found in the Malay peninsula; like the preceding species, it has a white mouth and white eyelids, but the nape and back of the head are pale, sharply contrasting with the brownish colour of the rest of the upwer parts. The silvered leaf monkey (T. *pyrrhus*) occurs from Indo-China and Tenasserim to Borneo and Bali. It is blackish, dark brown or gray, with a frosting. of pale gray or buffy on the hair tips. A red phase occurs in the islands.

The lesser leaf monkeys (*Presbytis*) have the young .whitish with a blackish cross-like marking on the back and dark hands and feet. One or several whorls of hair on the head give an odd. tousled appearance to these animals. The skull has the nasal profile convex. A great variety of colour and hair patterning occurs in these monkeys and they are difficult to describe. Even in the same species colour

LEMURS AND MONKEYS OF THE OLD AND NEW WORLDS

1. The ruffed lemur (Lemur *variegatus*) of the Malagasy region. It is coloured either black and white or reddiih brown, and feeds on birds, reptiles, eggs, insects and fruit
2. The potto (*Perodicticus potto*) or West African slow lemur, an almost tailless primate somewhat larger than a squirrel
3. Bush baby (*Galago crassicaudatus*) of Africa, a small arboreal lemur with long pointed muzzle and very large eyes and ears
4. Woollv saki (*Pithecia* monacha), a tropical American monkey characterized by a bushy tail and whiskers of long, loose fur
5. The common, or white-eared marmoset (*Callithrix jacchus*), a diminutive American monkey that feeds on insects and fruit
6. An immature woolly monkey (*Lagothrix lagotricha*) of tropical America, distinguished by the naked, singularly human face and the powerful prehensile tail used for picking up objects as well as for climbing
7. Spider monkey (*Ateles geoffroyi*) of tropical America, so designated because of its extremely slender limbs. The tail Is very long and prehensile and the hand is thumbless. It is easily tamed
8. White-faced capuchin monkey (*Cebus capucinus*), a vivacious American species that derives its name from the cowl-like form assumed by the hair on the crown of the head. It is common in captivity
9. Guereza (*Colobus abyssinicus*), an arboreal African monkey hunted for its fur which forms a black and white mantle on the sides and back

OLD WORLD MONKEYS AND APES

1. Gelada baboon (*Theropithecus gelada*), a large terrestrial monkey of southern Abyssinia. On the old males the hair develops into a mantle-like mane which covers the forequarters, leaving the chest bare

2. Chimpanzee (Pan troglodytes), the smaller of the two great man-like apes inhabiting equatorial Africa. It seldom exceeds $4\frac{1}{2}$ feet in height and is almost completely arboreal, sleeping in nests in trees

3. Guenon (*Cercopithecus aethiops*), a small arboreal monkey of the African savannas. It subsists chiefly on fruits and leaves

4. Capped langur (Trachypithecus *pileatus*) female and young of the Malay Peninsula. In common with other langurs it has slender limbs and a very long tail, and feeds on leaves

5. Group of mountain gorillas (Gorilla *beringei*), Belgian Congo, showing two males and two females, the standing male being in characteristic posture of thumping his chest. The male at the left is in the position generally assumed by the gorilla when moving about on the ground

6. Siamang (*Hylobates [Symphalangus] syndactylus*) Malay Peninsula and Sumatra: largest of the gibbon group with an average height of 3 feet. It is distinguished from other gibbons by a laryngeal air sac

7. Orangutan (Pongo *pygmaeus*), "man of the forest," the least man-like of the three great anthropoid apes. It inhabits Borneo and Sumatra

8. The silvery gibbon (Hylobates *moloch*), one of the small arboreal apes of the Indo-Malay peninsula and East Indies

varieties red, black and white often occur. These monkeys are restricted to the Malay region, reaching the islands of Borneo, Sumatra, Java and Bali, where 25 forms are known.

The snub-nosed monkeys (*Rhinopithecus*) inhabit western China and eastern Tibet. Four species are known: R. roxallanae, the golden monkey of western Szechwan, has a bright-blue iace, the under parts and lower limbs are golden, while the back is more or less grayish black, overlaid by silver hair-tips. Females are paler. R. bieti, from northern Yunnan, is brown with white under parts. R. brelichi is the largest Asiatic monkey. It is slate-coloured, with an oval white patch between the shoulders; the head is yellowish and the tail black. R. *avunculus* of Tonkin is blackish with yellowish under parts, creamy cheeks and white-tufted tail.

The doucs or pied langurs (*Pygathrix*) are found in Indo-China. The body in P. *nemaeus* is mottled grizzled gray, the face, hands and feet are yellow. The outsides of the upper limbs black, but the lower legs are chestnut, the forearms are white, as well as the tail and the loner back. P. *nigripes* has the posterior limbs black, the forearms gray, the body also gray.

The proboscis monkey (*Nasalis larvatus*) is restricted to Borneo. It is buffy brown with yellowish-gray rump, tail and limbs. The nose in old males is enormous and inflatable. This monkey lives in trees along river banks. The pig-tailed langur (*Simias concolor*) of the Mentawei Islands, off Sumatra, is the only short-tailed langur. It is smoky brown in colour and has a short, upturned nose. These monkeys are probably related to the golden monkeys and the pied langurs of the mainland.

The old world or catarrhine monkeys are widely distributed, mostly in tropical Asia and Africa, a few outlying forms reaching as far north as Tibet, China and Japan, while the baboons extend southward to South Africa. A single species, the Barbary ape oi North Africa inhabits the Rock of Gibraltar in Europe. In the Pliocene, however, fossil monkeys of various species were recorded in England, Germany, France, Italy, Greece, North Africa and India. In the Miocene of Tuscany there was a large form (*Oreopithecus*), in which certain features of the molar teeth suggest remote relationship with the anthropoid apes. In the Lower Oligocene of Egypt was found a small lower jaw fragment, *Apidium*, the lower molars of which may be transitional from the tuberculo-sectorial or primitive mammalian type to the bilophodont form (with two cross-crests) of the old world monkeys. The group seems to have originated somewhere either in Africa or in the European-Asiatic landmass and negative palaeontological evidence indicates their complete absence from America and the Australian region.

No known fossil forms definitely connect the old world stock with the new world series, tarsioids, lemuroids or tree shrews. The new world series, for reasons given above, seems entirely independent; while the known fossil tarsioids appear too peculiarly specialized to be direct ancestors of the old world stock; get such tarsioids as *Necrolemur* and Microchoerus are the only forms so iar known that have even the appearance of evolving toward the catarrhine stage. This is broadly characterized as follows.

Nostrils, closely approximated and opening downward, tending to form a V; molars with two cross-crests; dental formula $i\frac{2}{2}$, $c\frac{1}{1}$, $p\frac{2}{2}$, $m\frac{3}{3}$. Tympanic bone forming a gutter leading to the outer ear; stomach simple or (in Colobinae) highly complex; habits primarily arboreal, the animals climbing as pronograde quadrupeds, mostly on top of the branches. Hands and feet prehensile. Thumb opposable, more or less flattened nails on all digits. Tail long, short or wanting, never prehensile. Cheek pouches in most genera. Large callous areas on buttocks, with corresponding flattening on lower ends of pelvis. Placenta double, consisting of a primary and secondary discoidal area, except in the baboons, with smooth chorion between them.

Although it has not yet been possible to trace the direct fossil ancestors of the old world group into formations older than at most Lower Oligocene, even the known living and extinct tree shrews, lemuroids and tarsioids preserve the broad stages by which arboreal insectivorus mammals with a relatively low type of brain were transformed into monkeys with a relatively high type of brain, with binocular, stereoscopic vision and an advanced method of intra-uterine nourishment of the young.

Hominoidea.—The anthropoid apes and mankind form a group distinct from other old world Primates. The anthropoid apes include the gibbons, the orang, chimpanzee and gorilla (*q.q.v.*); these are recognized as resembling man more closely than monkeys; they are tailless, their teeth and internal anatomy are very like those of man, and the placenta and embryonic stages show the same agreement. The gibbons are frequently considered to form the family Hylobatidae ("tree-walkers"), while the great apes are grouped in the family Pongidae.

Family Hylobatidae's range is now restricted to southeastern Asia, especially the Malay peninsula, Borneo, Sumatra and some other East Indian islands, though in the Miocene gibbons extended into Europe and in the Pliocene as far north as central China. They are slender, long-limbed, monkey-like apes, the most striking feature being the enormously elongate arms, which reach the ground when the animal stands erect. Like other anthropoids, they are tailless. They differ widely from the tailed monkeys in their mode of progression, as they do not run on all fours, either in the trees or on the ground, but hang and swing from branches by their long arms and hook-like fingers, making almost incredibly long leaps in the manner of a trapeze gymnast. This mode of arboreal locomotion was called "brachiation" by Sir Arthur Keith. While travelling thus by the hands, gibbons use the feet for prehension and carrying food. They sit upright and when on the ground run swiitly in an erect position, holding the arms out as balancers. Gibbons differ from most old world monkeys in the absence of cheek pouches and in the pattern of the molars, which is essentially that of the great apes and man. They also in common with these iorms have a vermiform appendix and flattened sternum. They nevertheless retain some old world monkey characters; for example, the small ischial callosities are present, and the central bone in the wrist is retained as a separate element. Air sacs, formed as extensions of the laryngeal ventricles, well-developed in the Pongidae, are present only in the siamang. Gibbons have remarkable vocal powers, their high-pitched cries being audible ior a mile or more.

Seven species of gibbons (Hylobates) may be distinguished. The hoolock (H. hoolock) of Burma, Assam and Western Yunnan (China) varies from pale yellowish gray to black; the brow is white and the hands and feet are never pale. The white-handed gibbon (H. *lar*) ranges from Lower Burma and Cambodia, Indo-China to Sumatra; it also occurs in pale and black colour phases. The hands and feet are always paler than the rest of the limbs, and the face is framed in white. The agile gibbon (H. *agilis*) is found from the Malay States to Sumatra; it differs from H. lar in having dark hands and feet. The gray gibbon (H. *moloch*) of Java and Borneo is ashy gray, sometimes with a brownish tinge, and the top of the head is usually dark. The under parts are blackish in some races. The black gibbon (*H. concolor*) generally has the hands and feet, and a patch on the head white or pale, but may be entirely black. The white forehead band is lacking. This species occurs in Siam, Indo-China and Hainan.

The large, black siamang, H. (*Symphalangus*) syndactylus, is found in Malaya and Sumatra. It stands 3 ft. or more in height; the second and middle toes are joined by a web. The chin is better developed than in other anthropoids, but the most conspicuous character is the large, inflatable laryngeal air sac. The dwarf gibbon (*H. klossi*) of the Mentawei and Siberoet Islands, west Sumatra, is intermediate in many characters between the siamang and the other gibbons. It is the smallest of the gibbons and is black in colour.

The three genera of great apes constituting family Pongidae, the orangutan of Borneo and Sumatra, and the chimpanzee and gorilla of the African forests, are by far the closest of all animals to man. Their divergences from man, striking though some of them are, are nearly all differencesin degree rather than in kind, and these apes are nearer anatomically and physiologically to man than to any of the tailed monkeys. Their differences from man are largely correlated with habit. Man has become terrestrial, while the apes have retained their primary arboreal habit, and have even developed further arboreal adaptations in varying degrees. In the orang these have become greatly exaggerated, while in the gorilla, which has become partly terrestrial, they are less marked. The chimpanzee is intermediate. The arms have become long and the relatively short legs retain the opposable great toe. This disproportion of limbs results in a peculiar secondary type of quadrupedal progression on the ground, the hands resting on the knuckles and the fore part of the body somewhat elevated. The spinal column has a suggestion of the curves seen in man, but the balance of the head on the neck, the weight of the long arms, form of pelvis and weak gluteal and calf muscles, collectively preclude an habitual erect bipedal gait, though the animals often stand erect. Divergence from the old world monkeys and likeness to man is seen in the absence of ischial callosities and cheek pouches and in the presence of the vermiiorm appendix. The development of laryngeal air sacs, apparently a point of difference, is in reality a likeness, since man retains homologous vestiges of these in the laryngeal ventricles. In the chimpanzee and gorilla (but not in the orang) the central bone of the wrist becomes fused with the scaphoid during embryonic life, as in man. The menstrual cycle has the same phases as man and in the chimpanzee the interval is the same. In the three apes the period of gestation is nine months and the placenta is essentially of the human type. The secondary placenta, present in old world monkeys, is absent. Even the brain, though roughly only about one-third the size of that of man, is essentially a miniature of the human brain, no part or organ of one being absent in the other, but the differences being differences of proportion of certain parts. The susceptibility of anthropoids to many human diseases to which other animals are relatively immune, indicates the close chemical similarity, and the well-known precipitin tests bv G. F. Nuttall showed the blood of these anes to be essentially identical with that of man, while differing from' that of old world monkeys.

Of the three great apes, the least man-like is the orangutan (Malay, "man of the forest") which inhabits swampy coastal forests of parts of Borneo and Sumatra. This animal is completely arboreal, rarely descending to the ground, and exhibits exaggerated brachiating adaptations. It is a large ape, over 4 ft. high, with heavy body and short feeble legs but very long arms extending to the ankles when the animal stands erect. The digits of both hands and feet are elongated and hook-like, except the relatively short thumb and great toe. Though the orang is rather deliberate in his motions and does not leap through the trees as does the gibbon, the elongation of the arms permits an extended reach from branch to branch and enables it to progress with considerable rapidity. Among structural characters the following may be noted: there are but 12 pairs of ribs as in man; the cranium is rounded and lacks the prominent supraorbital crest of the African anthropoids; the carpus retains the central bone as in monkeys and gibbons; the laryngeal air sacs are enormously developed, extending far down under the arms and on the chest in adult animals; the hair is coarse and sparse but very long and bright red in colour; a feature frequently, but not always, present in old males is a pair of prominent ridges of connective tissue on the cheeks. The orang feeds on fruits, especially the durian. There is probably only one species, with several local varieties. It is properly known as *Pongo pygmaeus,* but is often called *Simia satyrus.* A fossil jaw ascribed to Pongo in the Upper Pliocene and a molar tooth *(Palaeosimia)* from the Upper Miocene, indicate the ancient differentiation of the orang line.

The chimpanzee, properly known as *Pan* (= *Antropopithecus*), and the gorilla *(Gorilla)* inhabit the rain forests of central Africa, the chimpanzee having far the wider range. The latter is smaller, more agile and more completely arboreal in habit. The gorilla, probably owing to its great weight (males exceed 400 lb.), is largely terrestrial, though it climbs readily and in the west coast species the females and young are said to sleep in nests built in trees. Though the arms are somewhat longer than those of the chimpanzee, the hands have shorter fingers and are less adapted for brachiation; the feet show distinct secondary adaptation to walking on the ground. The foot of the mountain gorilla (*G. beringei*) of the eastern Belgian Congo presents the closest approach to the human foot found among primates. In both chimpanzee and gorilla the ribs number 13 pairs, one more than in man, but the total number of presacral vertebrae is the same, and a 13th rib in man is not uncommon. In both apes the hair is mainly black. In the chimpanzee the skin is usually light coloured in early life, tending to become dusky later; in the gorilla the face is intensely black. In both animals a heavy brow ridge overhangs the eyes and in the gorilla the cranial form in adult males becomes greatly altered by the development of huge crests for muscle attachment. The gorilla has well-marked alae of the nose, separated from the cheeks by distinct grooves. *See* CHIMPANZEE, GORILLA.

Origin and Evolution.— Of the fossil gibbons the best known is *Pliopithecus antiquus* from the Miocene of middle Europe. This differs from the recent gibbons in the lesser specialization of the canines and front lower premolar. A fossil humerus and femur of *Pliohylobates eppelsheimensis* from Eppelsheim, Germany, are close to those of the recent gibbons.

The earliest known forerunner of the gibbons and possibly also of the great apes and man is the fossil lower jaw named *Propliopithecus haeckeli,* from the Lower Oligocene of Fayûm, Egypt. This little jaw, while no bigger than that of a small monkey, already shows the relatively great depth characteristic of all anthropoids and of early man; its molar teeth also have the five main cusps arranged substantially as in the higher forms. Many nominal species of fossil anthropoid apes of the genera *Dryopithecus, Sivapithecus* and others are known.

MAN

The origin and evolution of man is fully discussed in other articles (ANTHROPOLOGY; BRAIN; MAN, EVOLUTION OF, etc.).

(W.K.G.; J. H. McG.; J. E. HL.)

PRIME MINISTER, BRITISH. Though a Wolsey or a Cecil might achieve for a time a predominant position among the counsellors of the English crown, the persistence of the doctrine that ministers were all equally royal servants, severally responsible to the sovereign for their respective departments. was for centuries fatal to the recognition of any such predominance in theory. Thus G. Burnet describes Clarendon as "chief, or the only, minister." but the latter knew only too well that the style "first minister" was "a title so newly translated out of French into English that it mas not enough understood to be liked. and every man would detest it for the burden it was attended with." Even in the 18th century it is more usual to find partnerships of two or three individuals, such as Marlborough and Godolphin, Harley and St. John, Stanhope and Sunderland, Townshend and Walpole. Newcastle: Henry Pelham and Hardwicke, sharing the principal burden of government. But the place vacated by the sovereign when, from 1717 onward, he ceased to attend cabinet meetings, had necessarily to be filled by a single individual, and this presiding officer developed almost inevitably into a prime minister. Sir Robert Walpole, though he "unequivocally denied" the title, is usually reckoned the first of the linc, and certainly during his last spell of office (1721–42) he developed many of the attributes of premiership. He was master of his cabinet; he insisted on a general subscription by his colleagues to the Whig principles; he dismissed his opponents; he dispensed the royal patronage; and, with reservations. he may be described as commanding a majority in the house of commons. How novel, how unpopular. such a position still was may be gathered from the proceedings of both houses in 1741. "According to our Constitution." said Sandys, "we can have no sole and prime minister . . . every . . . officer has his own proper department; and no officer ought to meddle in the affairs belonging to the department of another." And the minority in the house of lords was, if possible. even more downright. "We are persuaded," they protested. "that a sole, or even a first minister, is an officer unknown to the law of Britain, inconsistent with the Constitution of the country and destructive of liberty in any Government whatsoever."

On the fall of Walpole the further development of the office was checked, first, by the group system and consequent group coalition governments of the latter half of George II's reign, and later, by the interference of George III, who aspired to be himself "the only element of coherence in a ministry." Thus Grenville (1763–65) thought that "Prime Minister is an odious title," and North (1770–82) would not countenance it even from his own family. It was the younger William Pitt who, on the fall of personal government, consolidated the work of his predecessors and by his long tenure of power (1783–1801) accustomed the nation to the office, if not to the name. The extent of his achievement can be measured by the terms of his famous interview with Lord Melville in 1803. He "stated not less pointedly and decidedly his sentiments with regard to the absolute necessity there is in the conduct of the affairs of this country, that there should be an avowed and real minister, possessing the chief weight in the council, and the principal place in the confidence of the king. In that respect there can be no rivalry or division of power. That power must rest in the person generally called the first minister, and that minister ought, he thinks, to be the person at the head of the finances. . . ." Nevertheless. old prejudices die hard. In 1806 it could still be said in parliament that "the Constitution abhors the idea of a prime minister," and in 1829 that "nothing could be more mischievous or unconstitutional than to recognize by act of parliament the existence of such an office" Such recognition was not granted until 1905, when the prime minister became known to the law merely as one who had precedence next after the archbishop of York.

The prime minister is appointed by the sovereign. "I offered," said Sir Robert Peel (1834–35, 1841–46) on his resignation of office. "no opinion as to the choice of a successor. That is almost the only act which is the personal act of the sovereign; it is for the sovereign to determine in whom her confidence shall be placed" And. as late as 1894, Queen Victoria could call Lord Rosebery (1894–95) without consulting the retiring prime minister. Gladstone (1868–74, 1880–85, 1886, 1892–94), or the wishes of the parliamentary majority. Nevertheless, the Crown's freedom of choice is narrowly circumscribed. The "economic" reforms of Rockingham's administration (1782), by reducing the royal patronage, made it less easy for the sovereign to put ready-made majorities at the disposal of whatever minister he might fancy. and the Reform bills of the 19th century made the ministry dependent on parliament and the electorate rather than on the royal favour. The prime minister is normally the acknowledged head of the party commanding a majority in the house of commons. and it is only. therefore. on occasions when no party commands an absolute majority of the house, or when the majority party has no acknowledged head. that there is room for the exercise of the royal discretion.

The prime minister has no salary as such. He merely draws the emoluments of whatever office he may happen to hold. At the close of the 17th century the lord treasurer was already regarded as the most important government official, and since the treasury came to be put into commission. the leading minister has normally held the office of first commissioner, or first lord. and it is by virtue of that office that he draws his salary of £10,000 a year. But Chatham (1766–68) was lord privy seal: Salisbury (1885–86, 1886–92, 1895–1902), successively secretary of state and lord privy seal; and Ramsay MacDonald (1924, 1929–35), simultaneously first lord of the treasury and secretary of state. In addition, the prime minister is usually the leader of the house, though David Lloyd George. Clement Attlee and Winston Churchill each at times found this burden excessive and transferred it to other shoulders. In the 18th century, when cabinets were almost exclusively composed of peers, the leading minister, curiously enough, was recruited most of the time from the commons; in the 19th century, when commoners came to form the bulk of the cabinet, the prime minister was, more often than not, a peer But with the expansion of the franchise and the reduction in the powers of the lords (notably by the Parliament act of 1911) it became increasingly difficult for a peer to exercise the premiership effectively. No peer was prime minister after Lord Salisbury. and when Lord Curzon was passed over for the premiership in favour of Stanley Baldwin in 1922 this was generally regarded as a decisive demonstration of the need for a prime minister to be in the commons.

"As the cabinet stands between the sovereign and parliament," wrote Gladstone, "so the prime minister stands between the sovereign and the cabinet." He it is who, with the king's consent, appoints his fellow ministers to their respective posts. Originally, of course. the sovereign exercised an unfettered choice. Even so old and faithful a servant as Cecil never knew whom the queen would appoint to her council. In Anne's reign it required the united and persistent pressure of a ministry to get a Harley out or a Sunderland in. Pitt, at the close of the 18th century, had to put up with Thurlow, "the king's chancellor:" and. at the dawn of the 19th century, to do without Fox, the king's *bête noire*.

So even today, when the prime minister's choice is theoretically as free as was originally the crown's, the pressure of party, the claims of talent and the prescriptive rights of previous officeholders render that freedom largely nugatory. Finally, it is the prime minister individually and not his cabinet collectively who advises the king to dissolve parliament. In the event of a cabinet dispute this places him in a very strong position, especially since with it is coupled the right of dismissal. However the responsibility of the cabinet to the prime minister and the remaining functions of the latter belong properly to the history of the cabinet (*q.v.*).

The history of the second quarter of the 20th century, with its recurring crises, showed that the position held by the prime minister was still subject to development and still dependent upon personal factors. In the financial crisis of 1931 the king exercised his prerogative of choosing a prime minister other than the leader of the largest parliamentary party. He chose. as leader of a "national" coalition. James Ramsay MacDonald. the leader of a minor section in a defeated and divided Labour party. not Stanley Baldwin, who was leader of the largest party. For a time the office of prime minister was inevitably weakened. The abdication crisis (1936), on the other hand, temporarily gave to the prime minister (Baldwin) the sovereign's prerogative of acting as liaison between the prime ministers of the dominions. The much greater crisis of 1940 produced further drastic changes. When Winston Churchill was appointed he was not the acknowledged leader of any party. The stresses of war and the personal ascendancy of Churchill increased the importance and prestige of the prime minister as such. He assumed a responsibility for the armed forces and for their direction almost equivalent to the responsibility held by the president of the United States. He became more of an ambassador-at-large than any predecessor and spoke for his country even before the U.S. congress. Radio broadcasting put him into an intimate relationship with the whole country. quite without precedent and far transcending his indirect relationship with the electorate through parliament.

The prime minister's position was, on the whole, strengthened vis-à-vis his cabinet colleagues, vis-à-vis parliament and perhaps vis-à-vis the electorate. He commands a significantly increased volume of patronage: almost 80 ministerial posts alone are his exclusive appointment. In the 19th century Gladstone was thought to be abnormal in having a policy of his own, and most prime ministers before 1914 were, at best, no more than strong chairmen in their cabinets. Later prime ministers were in this respect far more Gladstonian than Gladstone. This met with criticism, but. by concentrating its attacks upon the central figure, the opposition unwittingly did much to consolidate the prime minister's dominance More than once too, a prime minister has seemed to say to his parliamentary critics what Benjamin Disraeli accused Gladstone of saying in 1873: "Unless you are prepared to put someone in my place. your duty is to do whatever I bid you." Although in 1945 the electorate appeared to be offered a choice between a party program (Labour's) and a party leader (Churchill) and appeared to prefer the program to the personality, yet in general 20th-century elections were increasingly a choice between rival candidates for the premiership. (For lists of the prime ministers and other principal government officials, see MINISTRY.)

BIBLIOGRAPHY.—Such books as *The Prime Ministers of Britain, 1721–1921*, 4th ed. (1924), by Clive Bigham, give certain dates and facts, but the history and functions of the office can be authoritatively studied only in the memoirs and biographies of the statesmen themselves and in the party, ministerial and cabinet histories.

PRIMER (percussion or friction), flame-producing device actuated by impact or friction and intended to ignite either the powder charge in a gun or the detonator of a high explosive charge. Electrically ignited primers are also in use. (See DETONATORS; EXPLOSIVES; MERCURIC FULMINATE.)

PRIMITIVE METHODISTS, a community of nonconformists. formed in consequence of the belief that Methodism as founded by the Wesleys tended, after the first generation, to depart from the enthusiasm that had marked its inception and to settle down to the task of self-organization. There were some ardent spirits who continued to work along the old lines and whose watchword was revivalism; and from their efforts came the Bible Christian, the Independent Methodist and the Primitive Methodist denominations. One of the zealous evangelists to whom Primitive Methodism owes its existence was Hugh Bourne (1772–1852), a millwright of Stoke-upon-Trent, Eng. He joined a Methodist society at Burslem. but, business taking him at the close of 1800 to the colliery district of Harrisehead and Kidsgrove, he was so impressed by the prevailing ignorance and debasement that he began a religious revival of the district. His open-air preaching mas accompanied by prayer and singing. One of the afterfruits of this revival was the conversion (Jan. 1805) of the joint founder of Primitive Methodism, William Clowes (1780–1851) of Burslem, who threw his house open for love feasts and prayer meetings and did a great deal of itinerant evangelization among the cottages of the countryside. Lorenzo Dow, U.S. revivalist, introduced the idea of the "camp meeting." The first camp meeting was held on Mow Cop, since regarded as the Mecca of Primitive Methodism. It lasted from 6 A.M. to 8 P.M., and Bourne and his friends determined to continue the experiment as a counterblast to the parish wakes of the time, which were little better than local saturnalia; but serious difficulties were presented by the antagonism of the Wesleyan Methodist circuit authorities. But Bourne and his friends persisted against both conference and the local superintendent, who issued bills declaring that no camp meeting would be held at Norton in Aug. 1807. The meeting was held, and ten months later Bourne was expelled by the Burslem quarterly meeting. Camp meetings went steadily on, and in 1810 the methods of the meetings organized by Bourne and Clowes were found to be incompatible with those of Wesleyan Methodism. A chapel was built at Tunstall, which became the nucleus of a circuit. In May 1811 the Camp-Meeting Methodists and the Clowesites united to form the connection which took the name "Primitive Methodists" in 1812. Clowes and James Crawfoot, a former Wesleyan local preacher, were set apart as preachers to "live by the Gospel."

The period 1811–43 was a time of rapid expansion for the new sect. Enthusiasts pressed forward through the "Adam Bede" country to Derby (which became the second circuit in 1816); Nottingham, where a great camp meeting on Whit Sunday 1816 was attended by 12,000 people; Leicestershire, where Loughborough became the third circuit, with extensions into Rutland, Lincolnshire and Norfolk; and ultimately to Hull, which became the fourth circuit and where a meeting which deserves to be called the first conference was held in June 1819. The Hull circuit during the next five years, through its Yorkshire, western, northwestern and northern missions, carried on a vigorous campaign with great success, especially among the colliers of Durham and Northumberland. Simultaneously Tunstall circuit, having thrown off its lethargy, was carrying on an aggressive evangelism. Work in the Black Country was extended to Liverpool and Manchester on the one side and south Shropshire on the other; and thence to Herefordshire, Glamorganshire and Wiltshire. Thenceforward, while the Oxford movement was awakening one section of the people of England the Primitive Methodists mere making themselves felt among other classes of the population. The early Primitive Methodists had to meet mob violence that oiten amounted to sheer ruffianism, especially in Wessex and the home counties. On the other hand, there was legal persecution all over the country, and the preachers suffered many things from the hands of rural clergy and county magistrates. There are a score of cases of serious imprisonment, and a countless number of arrests and temporary detention. Local preachers received notice to quit their holdings, labourers were discharged, those who opened their cottages ior meetings were evicted and to show any hospitality to a travelling preacher was to risk the loss of home and employment.

The years 1842–53 mark a transition period in the history of Primitive Methodism. From being a loosely jointed home missionary organization, the movement developed on the lines of a real connectionalism. One of the first steps was to move the Book Room and the meeting place of the executive committee to London. Soon after came the gradual process by which the circuits handed over their mission work to a central connectional committee. The move to London was proof that the leaders mere alive to the necessity of grappling with the rapid growth of towns and cities, and that the connection, at first mainly a rural movement, had also urban work to accomplish. The period 1853–85 finds Primitive Methodism as a connection of ten federated districts, a unity which may be described as mechanical rather than organic. Conierence—the supreme assembly—was a very jealously guarded preserve, being attainable only to preachers who had travelled 18 and superintended 12 years and to laymen who had been members 12 and officials 10 years. This exclusiveness naturally strengthened the popularity and power of the districts, where energy and talent found a scope elsewhere denied. Thus, Hull district inaugurated a bold policy of chapel buildings; Norwich that of a foreign mission; Sunderland and Manchester the ideal of a better-educated ministry; Nottingham district founded a middle-class school; Leeds promoted a union of Sunday schools, and the placing of chapel property on a better financial footing. The period as a whole had some anxious moments; emigration to the gold fields and the strife which afflicted Wesleyan Methodism brought loss and coniusion between 1853 and 1860. Yet when conference met at Tunstall in the latter year to celebrate its jubilee it could report 675 ministers and 11,384 local preachers, 132,114 members, 2,267 chapels, 167,533 scholars and 30,988 teachers.

Work in Australia and New Zealand prospered, and the former country finally contributed more than 11,000 members to the formation of the United Methodist Church oi Australia, New Zealand with its 2,600 members preferring to remain connected with the home country. In the United States there had been a quiet but steady growth since the first agents went there in 1829. There are three conferences—the eastern, Pennsylvania and western, with about 70 ministers, 100 churches and 7,000 members. The Canadian churches had a good record, consummated in 1884 when they contributed 8,000 members and 100 ministers to the United Methodist Church oi the dominion. In Jan. 1870 the first piece oi real foreign missionary work was begun at Fernando Po, followed in December of the same year by a mission on the Orange river in South Africa. This station is the centre of a polyglot circuit or district and carries on an efficient institution for training teachers, evangelists and artisans. In 1899 another South African mission was started, and a few years later work was begun in southern Nigeria.

Following 1885 Primitive Methodism developed from a connection into a church, the designation employed since 1902. In England a union for social service was formed in 1906, the natural outcome of Thomas Jackson's efforts for the hungry and distressed in Clapton and Whitechapel, and of similar work at St. George's hall, Southwark. Other significant episodes have been the unification of the funds, the equalization of districts and the reconstruction of conference on a broader basis, the Ministers' Sustentation fund and the Church Extension fund, and the enlargement and reorganization of the college at Manchester. This undertaking owed much to the liberality of Sir William P. Hartley, whose name the college, which is affiliated to the Victoria University oi Manchester, now bears. The Christian Endeavour movement in Great Britain derives, perhaps, its greatest force from its Primitive Methodist members; and the appointment of central missions, connectional evangelists and mission vans, which tour the more sparsely populated rural districts, witness to a continuance of the original spirit of the denomination, while the more cultural side is fostered by the Hartley lecture. In 1932 the Primitive Methodists contributed 222,021 members to the Methodist Church in England through merger. In the United States in the early 1950s there were approximately 12,000 members. (*See* also METHODISM.)

A Centenary Memorial of the P.M. Church* (1908). (A. J. G.; X.)

PRIMO DE RIVERA, MIGUEL (1870–1930), Spanish soldier and statesman, known as the marquis de Estella, was born at Jerez de la Frontera Jan. 8, 1870, and studied at the Rladrid Military academy. After four years in Toledo, he went to Morocco in 1892 as lieutenant of the infantry regiment of Extremadura, and in Oct. 1893 became a captain. In 1895 he was adjutant to Gen. Arsenio Martínez de Campos in Cuba, and rose to be major commanding the infantry battalion of Zamora.

He served in the Philippines in 1897, and negotiated the treaty of Biagnabato (Biacabato) on Dec. 12, 1897. He then held commands at Barcelona, on the general staff and at Algeciras. In 1915 he was appointed governor of Cadiz, but he was relieved from the office after advocating the exchange of Gibraltar for Ceuta or other North African territory and criticizing the government's policy in Morocco. However, he was soon afterward promoted to general and chief of the 1st infantry division in Madrid. In 1921 Estella was elected senator for Cadiz, but after urging the nation to relieve itself of the Moroccan burden he once again lost his post. He then became captain general of Catalonia with a view to ending the reign of terror there, and he soon reaped a measure of success. He saw the chaos in Catalonia as an indirect consequence of the parliamentary breakdown, and issued the manifesto dated Sept. 12, 1923, suspending the constitution and proclaiming in its place a directorate consisting of military and naval officers. (*See* SPAIN: *History: Dictatorship of Primo de Rivera* (1923–30).) Primo dissolved the directorate on Dec. 3, 1925, and substituted a government of civil as well as military ministers. The dictator became premier. He resigned on Jan. 28, 1930, and died in Paris on March 16, 1930.

PRIMOGENITURE, a term used to signify the preference in inheritance which is given by law, custom or usage to the eldest son and his issue, or in exceptional cases to the line of the eldest daughter.

The history of primogeniture is given in the article LAW OF SUCCESSION. *See* also INHERITANCE; INTESTACY.

PRIMROSE, common name for the genus *Primula,* containing about 300 species distributed throughout the cooler parts of. Europe and .Asia, and found also on the mountains of Ethiopia and Java; a few are American. They are herbaceous perennials. with a permanent rootstock from nhich arise tufts of leaves and flower stems which die down in winter; the new growths formed in autumn remain in a budlike condition ready to develop in spring. They form the typical genus of the primrose family (Primulaceae; q *v.*), the floral conformation of which is very interesting botanically.

The variation in the length of the stamens and of the style in the flowers of Primula has attracted much attention since Charles Darwin investigated them. Some of the flowers have short stamens and a long style, while others have long stamens or stamens inserted so high up that the anthers protrude beyond the corolla tube, and a short style. Gardeners and florists had for centuries been familiar with these variations. calling the flowers from which the anthers protruded "thrum-eyed" and those in which the stigma appeared in the mouth of the tube "pin-eyed."

Darwin showed by experiment that the most perfect degree of fertility as shown by the greatest number of seeds and the healthiest seedlings, mas attained when the pollen from a short-stamened flower was transferred to the stigma of a short-styled flower, or when the pollen from the long stamens was applied to the long style. Since in any given flower the stamens are short (or low down in the flower tube) and the style long, or conversely, it follows that to insure a high degree of fertility cross fertilization must occur, and this is effected by the transfer of the pollen from one flower to another by insects. Incomplete fertility arises when the stigma is impregnated by the pollen from the same flomer. The size of the pollen grains and the texture of the stigma are different in the two forms of flower.

The best-known species are the common primrose (*Primula* vulgaris), a European perennial with basal, wrinkled leaves and prevailingly yellow flowers — some are purple or blue — but now found in many varietal colours; the cowslip (P. veris), also with basal leaves and a long-stalked flower stem bearing a cluster of generally yellow flowers with a dark-coloured eye at the centre and scalelike folds at the mouth; and the oxlip (P. elatior), similar to the cowslip, but without the folds at the flower's mouth. All of these are found wild in Great Britain and elsewhere and are widely cultivated, especially in the fine horticultural varieties of many colours. The above plants are cool-loving sorts which will grow well in heavy soils in slight shade; sloping land (especially an eastern exposure). quite moist in summer but with good drainage, is an ideal situation. In the U.S., about 15 species are native in the region of Oregon and Washington where their needs are satisfied.

The *auricula* (*q.v.*) of the garden is derived from P. *auricula,* a yellow-flowered species, native of the Alps and the easiest of all the primroses to grow. The Himalayas are rich in species of primrose, often difficult of determination or limitation: certain forms being peculiar to particular valleys. Of these P. *denticulata, stuarti, sikkimmensis, nivalis* and *floribunda* may be mentioned as frequently cultivated, as well as the lovely rose-coloured species *P. rosea.* The royal cowslip (P. *imperialis*) resembles P. *japonica* (see below) but has leaves measuring 18 in. long by 5 in. wide. It grows at an elevation of 9.000 ft. in Java and has deep-yellow or orange flowers. Several small-growing hardy species, among which are the choice alpine varieties, afford fine rock garden displays in cool locales; they must be placed where they are secure from excessive dampness (their worst enemy) during the winter and excessive sunlight in the summer.

One of the most popular of winter and early spring decorative plants is the Chinese primrose *Primula sinensis,* of which some superb strains have been obtained. P. *japonica,* a bold-growing and very beautiful Japanese plant. is hardy in sheltered positions in England but must be grown in the cool greenhouse over most of the U.S. *Primula cortusoides* of Siberia and P. *sieboldi* of Japan, of which there are many lovely forms, are suitable for outdoor culture and under glass. Many of these are beautiful potted plants of the florist trade. Among the greenhouse primroses, P. ohconica has hairy leaves which may cause a skin rash in susceptible persons. Two other Chinese species. *P. forresti* and P. *bulleyana,* orange-yellow flowered. 2½ to 3 ft. in height, are hardy in favoured spots in the rock garden.

Cultivated primroses may be found in a considerable variety of colours. ranging from the palest yellow to deep crimson and blue. Most hardy sorts may be propagated by seed sown indoors in early spring; seedlings, kept cool and moist in moderate shade, should be transplanted a few times until they are set in the permanent spot in the garden in early autumn. **A** light mulch will give adequate protection in the winter. Since primroses do not reproduce true to seed, special varieties may be increased by the division of crowns in early autumn.

JOHN MARKHAM

COMMON PRIMROSE (PRIMULA VULGARIS)

Evening primrose belongs to the genus Oenothera (*q.v.*) of the evening primrose family (Ongraceae). The Cape primrose comprises hybrid forms of Streptocarpus, a South African genus belonging to the family Gesneriaceae. The Arabian primrose is *Arnebia* cornuta of the borage family (Boraginaceae) a garden annual. (N. TR.)

PRIMULACEAE, the primrose family of gamopetalous dicotyledons belonging to the order Primulales and containing about 800 species in 25 genera (the genus Primula has nearly 500 species). The family is cosmopolitan in distribution but the majority of the species are confined to the temperate and colder parts of the northern hemisphere and many are arctic or alpine. Eight genera with 21 species are represented in the British flora; there are in North America, 9 genera with about 80 species.

The plants are herbs, sometimes annual as in scarlet pimpernel (*Anagallis* arvensis), but generally perennial, rarely suffruticose. In *Primula* the plant persists by means of a sympodial rhizome and in *Cyclamen* by means of a tuber formed from the swollen hypocotyl. The leaves form a radical rosette as in *Primula* (primrose. cowslip, etc.) or there is a well-developed aerial stem which is erect as in species of *Lysimachia,* or creeping as in *Lysimachia nummularia* (creeping jenny or moneywort). Hottonia (water violet) is a floating water plant with submerged leaves cut into fine linear segments. The leaves are generally simple, often with a toothed margin: their arrangement is mostly opposite or whorled but may be alternate. The flowers are solitary in the leaf axils as in scarlet pimpernel, moneywort, etc., or umbelled as in primrose. where the umbel is sessile, and cowslip, where it is stalked, or in racemes or spikes as in species of *Lysimachia.* Each flower is subtended by a bract, but there are no bracteoles, and corresponding with the absence of the latter the two first developed sepals stand right and left. The flowers are hermaphrodite and regular with parts in fives (pentamerous) throughout, though exceptions from the pentamerous arrangement occur. The sepals are leafy and persistent; the corolla is generally divided into a longer or shorter tube and a limb which is spreading as in primrose, or reflexed as in *Cyclamen* and *Dodecatheon;* in *Soldanella* it is bell-shaped; in *Lysimachia* and others the tube is often very short. the petals appearing almost free: in *Coris* and *Omphalogramma* the corolla is zygomorphic; in *Glaux* the petals are absent. The five stamens spring from the corolla tube and are opposite to its lobes; this anomalous position is generally explained by assuming that an outer whorl of stamens opposite the sepals has disappeared, though sometimes represented by scales as in *Samolus* and *Soldanella.* The suoerior ovarv — half-inferior in *Samolus*—bears a simple style ending in a capitate entire stigma, and contains a free-central placenta bearing generally a large number of usually semianatropous ovules, which are exceptional in the group Sympetalae in having tno integuments. The fruit is a capsule, dehiscing by five, sometimes ten. teeth or valves, or sometimes transversely (a pyxidium) as in *Anagallis.*

ROCHE

SHOOTING STAR (DODECATHEON), AMERICAN GENUS OF THE PRIMROSE FAMILY

Cross pollination is often favoured by dimorphism of the floner, as shonn in species of *Primula.* The two forms have long and short styles respectively. the stamens occupying corresponding positions half-way down or at the mouth of the corolla tube. The pollen grains are also dimorphic and their size corresponds with that of the stigmatic papillae of reciprocal flowers (*see* PRIMROSE). Basic to these morphological differences the plants exhibit a certain amount of genetic self-incompatibility.

The family is divided into five tribes by characters of the corolla, ovary and capsule, and by the presence or absence of tubers. Despite its sympetalous corolla it is generally thought. on flower and ovary characters, to be allied to the polypetalous Caryophyllaceae.

The chief British genera are *Primula, Lysimachia* (loosestrifes) and *Anagallis.* The principal American genera are *Primula, Samolus* (water pimpernels or brookweedsj, *Lysimachia* and *Dodecatheon* (shooting stars or American cowslips). In cultivation the chief genera are *Primula, Cyclamen, Androsace, Omphalogramma* and *Lysimachia.*

See F. Pax and R. Knuth, "Primulaceae," *Pflanzenreich* 22, iv, *237:* I-386 (1905). (P. S. GR.)

PRINA, GIUSEPPE (1768–1814), Italian statesman. He was an adherent of Napoleon Bonaparte, and when Eugène Beauharnais became viceroy of Italy, uas appointed minister of finance His skill in devising fresh taxes to meet the enormous demands of Napoleon's government made him the best-hated man in Lombardy. After the emperor's forced abdication in 1814 Prina's party moved in the senate that delegates should go to Vienna to request that Eugène Beauharnais be raised to the throne of a free Italian kingdom. This provoked the formidable riot in which Prina mas dragged about the town for four hours, until almost torn to pieces, he received his death-blow.

PRINCE, MORTON (1854–1929), U.S. psychologist and physician, a distinguished pioneer in and contributor to the development of a psychological orientation in the study of functional nervous disorders, was born in Boston. Mass., Dec. 21. 1854, and was educated at Harvard university (B A., 1875; M D., 1879) uith subsequent study at Vienna. Strasbourg, Paris and Nancy. Prince formulated such concepts as "neurograms" (the neurological record of psychological behaviour); the "co-conscious" (a parallel, possibly rival, well-organized system of awarenesses comparable with ordinary consciousness); and the derivation of the psychoneuroses from the total experiential life of the patient, with dissociation, subconsciousness and varying levels of integration regarded as primary considerations. He recognized the motivational forces of emotional conflict but disagreed with Freud's rigid insistence upon a fundamental underlying theme of sexuality. Prince's concept of psychotherapy was based upon a resynthesis of dissociated or amnesic complexes and experiences by means of a deep integrational process. He was a pioneer in utilizing hypnosis as a fundamentally significant exploratory agent and for reeducational therapy.

In addition to studying and teaching abnormal psychology at Harvard, Prince practised medicine. was president of both the American Neurological and the American Psychopathological associations and founded (1906) and edited (1906–29) the *Journal of Abnormal Psychology.* He died Aug. 31, 1929.

He was the author of six books, the best known of which was his study of a multiple personality, *Dissociation of a Personality* (1906). Among others were *The Nature of Mind and Human Automatism* (1885), *The Unconscious* (1913) and *Clinical and Experimental Studies in Personality* (1929). (M. H. EN.)

PRINCE, a title implying either political power or social rank. The Latin word *princeps* originally signified merely "the first." As an honorary title it was applied in the Roman republic to the *princeps senatus; i.e.,* the senator first on the censor's list. The assumption of the style of *princeps senatus* by Augustus (*q.v.*) first associated the word with the idea of sovereignty and dominion. From Italy the title spread — first, with the crusaders, to the Holy Land. where Bohemund, son of Tancred. took the style of prince of Antioch; next: with the Latin conquerors. into the East Roman empire, where in 1205 William de Champlette. a cadet of the House of Champagne, founded the principality of Xchaea and the Morea. This example was followed by lesser magnates. who styled themselves loosely, or were so styled by the chroniclers. "princes." From the east the fashion was carried back to France: but there the erection of certain fiefs into "principalities." which became common in the 1jth and 16th centuries: certainly implied no independent sovereignty, and the title of "prince" ranked below that of "duke," being sometimes borne by cadet branches of ducal houses. On the other hand the title of "prince" was borne from the time of Charles VII or Louis XI by the sons of the royal house. so-called "princes of the blood." To these were added, from the time of Louis XIV, the *princes légitimés,* recognized bastards of the sovereign.

In Germany. Austria and other countries formerly embraced in the Holy Roman empire the title of "prince" had a somewhat different history. During the first period of the empire the "princes" were the whole body of the *optimates* who took rank next to the emperor. In the 11th century. with the growth of feudalism. all feudatories holding in fief of the Crown ranked as "princes." Toward the end of the 12th century, however, the order of princes *(Furstenstand)* was narrowed to the more important spiritual and temporal feudatories who had a right to a seat in the diet of the empire in the "college of princes" (*Fürstenbank*). Finally, in the 13th century, seven of the most powerful of these separated themselves into a college which obtained the sole right of electing the emperor. These were called "prince electors" (*Kurfürsten*) and formed the highest rank of the German princes (*see* ELECTORS).

In Germany. with the decay of the empire the title "prince" received a sovereign connotation, though it ranked. as in France, below that of "duke." There were, however, in the countries formerly embraced in the Holy Roman empire other classes of "princes." Some of these inherited titles, sovereign under the old empire but "mediatized" during the years of its collapse at the beginning of the 19th century; others received the title of "prince" at the end of the empire as "compensation" for ceded territories. There were also in Austria and Germany "princes," created by the various German sovereigns: and some dating from the period of the old empire, who took a lower rank as not being "princes of the Holy Roman empire" nor entitled to any royal privileges. All these princes were styled *Fürst,* having the predicate "Serene Highness" (*Durchlaucht*). The word *Prinz,* actually synonymous with *Fürst,* was reserved as the title of the nonreigning members of sovereign houses and. nith certain exceptions (*e.g.,* Bavaria), for the cadets of mediatized ducal and princely families. The heir to a throne was "crown prince" (*Kronprinz*), "hereditary grand duke" (*Erbgrossherzog*) or "hereditary prince" (*Erbprinz*). The heir to the crown of Prussia, when not the son of the monarch, had the title of "prince of Prussia" (Prinz von *Preussen*). In Italy the title "prince" (*principe*) is also of unequal value. Heads of great families sometimes bear the title of "prince," sometimes that of "duke." The title of "prince of Naples" is attached to the eldest son of the king of Italy.

"Prince" is also the translation of the Russian title *knyaz*. In general, though the title "prince" implies descent from one or other of the ruling dynasties of Russia, it is in itself of little account owing to its being borne by every member of the family.

The title of "prince" is also borne by the descendants of those Greek Phanariot families (see PHANARIOTES) who formerly supplied hospodars to the Turkish principalities on the Danube. One of the few instances in Europe of "prince" as a completely sovereign title is that of the prince of Monaco.

Great Britain. — In Great Britain "prince" and "princess" as titles are confined to members of the royal family, though nonroyal dukes are so described in their formal style (see DUKE). Nor is this use of great antiquity, the custom of giving the courtesy title of "prince" to all male descendants of the sovereign to the third and fourth generation being foreign to English traditions. It was not till the reign of Henry VII that the king's sons began to be styled "princes"; and as late as the time of Charles II the daughters of the duke of York, both of whom became queens regnant, were called simply the Lady Mary and the Lady Anne. The title of "princess royal," bestowed on the eldest daughter of the sovereign, was borrowed by King George II from Prussia. Until recent years the title "prince" was never conferred on anybody except the heir apparent to the Crown, and his principality is a peerage. Since the reign of Edward III the eldest sons of the kings and queens of England have always been dukes of Cornwall by birth and. with a few exceptions, princes of Wales by creation. Before that Edward I had conferred the principality on his eldest son, afterward Edward II, who was summoned to and sat in parliament as prince of Wales. But Edward the Black Prince was the original grantee of the principality as well as of the dukedom under the special limitations which have continued in force to the present day. The entail of the former was "to him and his heirs the kings of England" and of the latter "to him and his heirs the first-begotten sons of the kings of England." Hence when a prince of Wales and duke of Cornwall succeed to the throne the principality in all cases merges at once in the Crown and can have no separate existence again except under a fresh creation, while the dukedom, if he has a son, descends immediately to him or remains in abeyance until he has a son born. If, however, a prince of Wales and duke of Cornwall should die in the lifetime of the sovereign, leaving a son and heir, both dignities are extinguished, because his son. although he is his heir, is neither a king of England nor the first-begotten son of a king of England. But, if instead of a son he should leave a brother his heir, then —as was decided in the reign of James I on the death of Henry, prince of Wales, whose heir was his brother Charles, duke of York—the dukedom of Cornwall would pass to him as the first-begotten son of the king of England then alive, the principality of Wales alone becoming merged in the crown.

But even now the children of the sovereign other than his eldest son, though by courtesy "princes" and "princesses," need a royal warrant to raise them de *jure* above the common herd; and even then they remain "commoners" till raised to the peerage. In 1905 King Edward VII established what appeared to be a new precedent, by conferring the titles of "princess" and "highness" upon the daughters of the princess Louise, duchess of Fife, created "princess royal."

PRINCE ALBERT, a city in the province of Saskatchewan, Can., is on the North Saskatchewan river 220 mi. ndrth of Regina, near the central northern extremity of the settled part of the province. Founded in 1866 as an Anglican mission station. near the site of a fur trade post established in 1776, it became a centre for the lumbering industry in the early 1900s. Now Saskatchewan's northern "capital," it serves a large agricultural and forest region and a vast northern hinterland. It is a northern provincial government headquarters and has good railroad, highway and air services, a television and radio station and a daily newspaper. It is the site of a federal penitentiary. Its industries include an oil refinery, wood preserving plants, a plywood plant, woodworking shops and a packing plant. Pop. (1961) 24,168. (C. S. BR.)

PRINCE EDWARD ISLAND, in the gulf of St. Lawrence, is the smallest province of Canada. The arc of the crescent-shaped island roughly parallels the curving southern shore of the gulf; it is separated from the mainland by Northumberland strait, which has a maximum width of 25 mi. The province has less than 1% of the population and area of Canada and plays a very minor role in the economy and politics of the country. Yet "the island" is cherished by thousands of its former residents and their families, widely scattered over North America. The almost feudal system in which its lands were held for nearly a century makes its history of unique interest; and L. M. Montgomery's Anne of Green Gables made its national park, which enshrines a near replica of "Green Gables," a tourist mecca.

Size, Shape and Location. — The curving island has a maximum length of 145 mi. From a maximum width of 34 mi. it narrows to isthmuses which in two places. northeast of Charlottetown (the capital) and near Summerside (the other town), are less than 3 mi. from tidewater to tidewater.

The three lobes thus pinched off roughly correspond to the three counties. from east to west, Kings, Queens and Prince. The land area is 2,184 sq.mi.

Physical Geography. — The bedrock, well covered by dune sand on the gulf shore and glacial ground moraine elsewhere, is exposed in low cliffs on the eastern and southern shores. An unusually uniform red sandstone, it does grade off both to sandy siltstones and shales and coarser conglomerates. The age of the formation is thought to be Permian (150.000.000 years). The apparently horizontal strata actually dip toward the northeast and must be younger than similar beds exposed on the mainland to the south. The dip and cliffing suggest the remnants of an old cuesta, elsewhere dismembered or drowned beneath the waters of the gulf. In this soft sandstone block stream erosion has carved a gently rolling plain grading to rougher hills of over 400 ft. elevation west of Charlottetown and to some few stretches really flat to the eye west of Malpeque bay. The intricate serration of the shoreline with many deep estuaries bring sea and land into intimate relation; no point of the island is more than 10 mi. from tidewater.

The soils. everywhere developed from the thick mantle of glacial drift, tend to be coarse-textured sandy loams. There are more clayey phases and a good deal of swamp and bog; at the other extreme are the dunes that line much of the northern shore. The soils are strongly acid Podzols, rather low in plant nutrients.

As elsewhere in the Atlantic provinces and New England states the weather is markedly variable; the island lies on one of the most heavily traveled storm tracks in North America. There is much sunshine but, on the average, every third day has some precipitation; the annual 40 in. normally includes 9 or 10 ft. of winter snow. An occasional dry summer month and extremes of open, or deeply snowbound, winters point up the variability. Monthly temperature means lie between February's 17° F. and July figures in the upper 60s; the effect of the sea is seen in a long, laggard. chilly spring and in a late, warm and truly glorious autumn.

When Jacques Cartier visited the island in 1534 it was covered with a dense mixed forest, its trees of both boreal coniferous and northern hardwood types. There is a good deal of tree cover, predominantly spruce. on farm woodlots but the 16th-century forest has disappeared. With it have gone most of the larger animals (bear, moose, caribou. deer, seals, walrus and even beaver) but smaller animals and a wide variety of birds, including migratory ducks and geese. are still plentiful as are the fish and shellfish (cod, hake, halibut, herring, gaspereaux, mackerel, trout. salmon, eels, lobsters and clams) of its streams, estuaries and offshore coastal banks.

History. — Cartier was the first European of record to visit the island. Afterward it was largely ignored by the French until the

18th century, although, much earlier, it acquired the name Île St. Jean (St. John's Island) which it was to retain until 1798, when its present name was chosen (after that Duke of Kent whose daughter was to become Queen Victoria).

It received more attention from the French, as an adjunct of Louisburg on Île Royale (Cape Breton) and a refuge for Acadians from the mainland, especially after the treaty of Utrecht, and when Lord Rollo invested it for the British in 1758 it may have held as many as 5.000 settlers, mostly Acadian. Most of these were deported and the island was surveyed and divided into 3 counties. each with a townsite and "royalty." 14 parishes and 67 lots or townships. These nere then awarded, by lot, to upward of 100 applicants for royal favour (Scots predominated) under conditions which should have guaranteed rapid settlement. The grantees (proprietors) did little, however, and by 1800 there were scarcely more settlers than in the 1750s. But the few Highland Scots, American Loyalists and remaining Acadians of the turn of the century were soon joined by thousands of others, dominantly Highlanders and southern Irish and, as the tenant farmers slowly won representative and responsible government (the colony was separated from Nova Scotia in 1769). pressure was increased on the often absentee proprietors to open their lands and the freehold was gradually enlarged. At the time of union with Canada in 1873 only the most recalcitrant of the landlords remained to be bought out.

The little colony joined the new dominion six years late and rather reluctantly; it has been said to have been "bought" into confederation by Canada's assumption of its overwhelming railway debt, promises of better communications across the strait and a large subsidy to take care of the extensive land purchases from the proprietors. Since then it has been ever in the forefront of moves by the smaller provinces to obtain a larger share of federal revenues to help them support schools and other local services at levels nearer those prevailing in central Canada.

Government. — The form of government is that defined by the British North America act (see CANADA: History). The province at first sent 6 members to the Canadian house of commons; it now sends 4 to a house of 262 and 1 of these is occasionally given a cabinet post, usually minor. It has a local assembly of 30 members elected in pairs (a relic of the period of two houses) from 15 constituencies and the government is organized by the majority party in the usual British parliamentary system.

Population.—The population, roughly 30.000 in 1830, reached 80 000 in 1860 and over 110 000 in the 1880s. when immigration had largely ceased and the outflow of population began. The highest census total was 109.078 in 1891; by 1921 it had dropped below 90.000 but rose to 99,285 in 1956 and to 104,629 in 1961. The great tide of emigration affected chiefly descendants of Scots and Irish. A population over half Scots and one-fourth Irish (and about 10% Acadian) in the 1860s had changed to about 30% each of Scots and English (in claimed ultimate origin), about 20% Irish and something under 20% Acadian in the mid-1950s. Other elements in the population are negligible; only a handful of Micmac Indians remain.

The population density is over 47 per square mile but more than one-fourth of the people live in the city (Charlottetown, pop. 18,318 in 1961) and town (Summerside. pop. 8.611 in 1961) and the rural population is much denser west of Charlottetown than in the east. "Farm" population has been declining even more rapidly than "rural" population; it numbered 43,112 in 1956.

Education and Religion. — Public primary school3 provide education to the tenth grade. Four more years of schooling are available at Prince of Wales college in Charlottetown (also the principal teacher-training centre), through the second year of a university course. Full collegiate education is offered by St. Dunstan's Roman Catholic university, also in Charlottetown. Roman Catholics compose the largest single denomination. with about 45% of the population, divided among those of hcadian, Irish and Highland Scots origin. The Protestant majority is made up chiefly of four groups, United Church 26%, Presbyterian 14%, Anglican 6% and Baptist 5%.

Production. — In 1956 about 43% of the population was classed as agricultural and its farms (averaging over 110 ac.) occupied about three-fourths of the surface (much of the rest of which had been farmed in the 19th century). A mixed livestock-and-crop agriculture received most of its revenue from animal products: sales of cattle. swine and dairy products alone yielded half of it. Potatoes (largely seed), which provided about 15% of the total. was the only cash crop of significance. Most farms were self-sufficient to a degree, with 17% of all farm production consumed thereon by farmers. More than 19 out of 20 farms were operator-owned. In 1959 agriculture constituted 36% of the total net value of production.

Fisheries in 1959 yielded about 9% of the total net production. Lobsters. taken in limited seasons, provided two-thirds to three-fourths of that value, cod and related ground fish, herrings. smelts and oysters the rest. Most fishermen and boats were unspecialized. shifting from one fish to another with the season; many of the men were part-time farmers.

The island was the birthplace of silver fox farming, for which it was world famous from 1910 to 1940, but after 1950 foxes all but disappeared and the few fur farms left raised chiefly mink. Forest products, derived from indifferently managed farm ood-lots, played a steady but minor role in the economy.

The net product of manufacturing industries comprised 15% of the total in 1959 but they were chiefly processing industries for agricultural. fishery and forest products; butter and cheese making. meat slaughtering and packing, fish processing and feed milling and mixing predominated. There is an interesting textile industry (bag making for fertilizer and potatoes) and a significant woodworking enterprise although plants are small. The tourist industry. still not strongly developed. offers excellent opportunities if transportation could be improved.

Communications. — The island's railway was begun in 1871 as a narrow-gauge (3 ft. 6 in.) line notable for its curves and grades. The establishment of a car-ferry connection with the mainland (Borden to Cape Tormentine in New Brunswick) during World War I led to a change to standard gauge; by 1960 that service across the strait to and from Charlottetown and Summerside was the chief function it performed. A highway-building program begun in the 1950s greatly increased the mileage of paved roads on the island.

Communication across the strait has been a central problem of island life since the 18th century. Even a supplementary automobile ferry from Wood Islands in the southeast to Caribou (near Pictou) in Nova Scotia has only widened the bottleneck. Good air connections to Summerside and Charlottetown have relieved the situation somewhat.

PRINCES' ISLANDS, a cluster of nine islands in the Sea of Marmora. forming the Adalar district in the *il* of Istanbul, Turkey. They figure in Byzantine history chiefly as places of banishment. A convent in Prinkipo was a place of exile for the empresses Irene, Euphrosyne, Zoe and Anna Dalassena. Antigone was the prison of the patriarch Methodius, and its chapel is said to have been built by the empress Theodora. In Khalki the monastery of the Theotokos (originally of St. John), after 1831 a Greek commercial school, was probably founded by John VI or VII. Area 5.4 sq.mi.; pop. (1960) 19,864.

Palaeologus was rebuilt about 1680, and again in the 18th century by Alexander Ypsilanti, hospodar of Moldavia. Hagia Trias (a school of theology since 1844) was rebuilt by the patriarch Metrophanes. On Prote were the monasteries to which Bardanes (Philippicus), Michael I Rhangabes, Romanus I (Lecapenus) and Romanus IV (Diogenes) were banished.

PRINCETON, a borough of Mercer county. N.J., U.S., the seat of Princeton university (*q.v.*), is located midway between New York city and Philadelphia. Capt. Henry Greenland established a plantation on the site of the present village in 1681 and 15 years later a number of Quaker families settled in the area.

During the colonial period, because of its location. Princeton was the principal luncheon stop for stagecoach passengers traveling between Philadelphia and New York. In the pre-Revolutionary period the College of New Jersey, now Princeton university, became a centre of anti-British feeling; John Witherspoon, its president, Richard Stockton, a resident of the town, and John Hart, from nearby Hopewell, were three of the five New Jersey men to sign the Declaration of Independence. Nassau hall, principal structure of the college, completed in 1756, changed hands three times in the battle of Princeton and it was within its walls that the engagement ended, with Washington's troops defeating the British under Col. Charles Mawhood on Jan. 3, 1777, following the battle of Trenton. The legislature of the state of New Jersey convened in Princeton the following summer and the Continental congress was assembled there from June until Nov. 1783.

Educational institutions in Princeton in addition to the university include the Institute for Advanced Study, established in 1930; Princeton Theological seminary, a Presbyterian seminary established in 1812; Westminster Choir college, a private college established in 1926, and its affiliated Columbus Boychoir school; and several distinguished private schools. The Educational Testing Service, with headquarters there, develops and publishes achievement tests used in schools and colleges throughout the nation. Research laboratories operated by industrial firms and nonprofit organizations have been attracted to Princeton by the presence of the educational facilities.

In addition to a community of scholars who come from many nations, there reside in Princeton business and professional men and women who commute daily to Newark, New York city, Philadelphia and Trenton. Mid-town Palmer square. a business district, is an outstanding example of urban redevelopment emphasizing colonial architecture.

"Morven" in Princeton is the official executive mansion of the governor of New Jersey. The oldest portion was built in 1701 by Richard Stockton, grandfather of the signer of the Declaration of Independence. Walter E. Edge, then governor, purchased it in 1944 and ten years later presented it to the state. The first occupants under its new function, Gov. and Mrs. Robert B. Meyner, moved into it in 1957.

For comparative population figures see table in NEW JERSEY: *Population.* (E. R. D.)

PRINCETON UNIVERSITY, a privately endowed nonsectarian institution of higher learning for men, at Princeton, N.J., until 1896 called officially the College of New Jersey. Its buildings are grouped in the central portion of a campus of about 2.100 ac.. one of the most beautiful in the country. Nassau hall, the oldest and historically the most interesting building on the campus, was at the time of its completion in 1756 the largest academic building in the American colonies. It was designed by Robert Smith, architect of Independence hall in Philadelphia. and named in honour of William of Nassau, William III of England. There in 1783 George Washington received the formal thanks of the U.S. congress for his conduct of the Revolutionary War.

Characteristic of life at Princeton, in addition to the university's rural location and consequently its active outdoor interests, are the residential dormitory system, the system of elective upper-class eating clubs and the form of student self-government illustrated particularly by the honour system, under which undergraduates participate in the administration of university discipline.

In all admissions, regard is given to character, personality and promise as well as to scholarly attainment. Enrollment is limited in both the undergraduate department and the graduate school.

The university offers undergraduate courses in the liberal arts and sciences leading to the degree of bachelor of arts and bachelor of science in engineering. In addition to the arts and sciences, graduate work leading to the master's and doctor's degrees is also ofiered in architecture, engineering and public and international affairs. In 1923, Princeton initiated a "four-course program" for all upper-class candidates for the bachelor of arts degree. Under this program, a student carries on independent study and writing under an assigned supervisor in lieu of a course each term, culminating in the senior year in a major thesis and a comprehensive examination. In 1947, a program requiring the exploration of the major fields of learning by underclassmen was added. Special programs include those in the humanities. American civilization, European civilization. near eastern studies, and public and international affairs.

A feature of instruction is the preceptorial method, introduced in 1905, by which large classes are broken into small groups or informal conferences with preceptors on prescribed reading. Princeton has no professional schools for utilitarian ends, except the school of engineering and possibly the school of architecture, although both of these are strongly humanistic in their curriculums and methods. The school of architecture developed directly out of the department of art and archaeology, and on successful conclusion of the course confers the degree of master of fine arts.

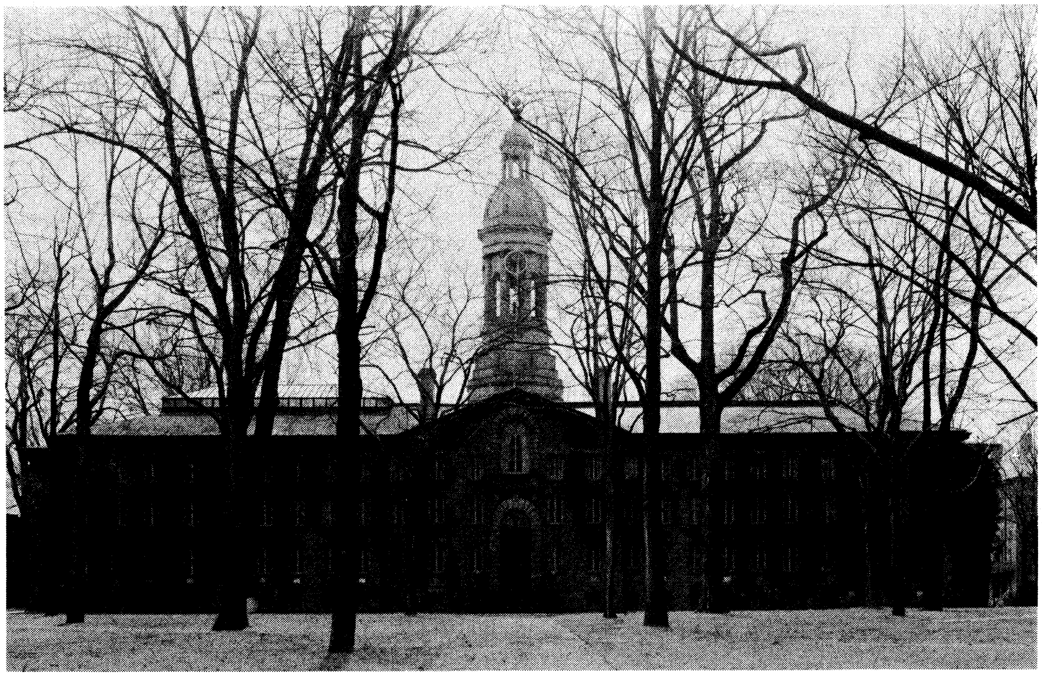
In assuming the university title in 1896, it was definitely concluded that Princeton's future did not lie in developing professional schools but in upholding pure learning and in devoting itself "to the liberal aspects of those studies which underlie and broaden professional and technical education." The university, therefore, became not a congeries of professional schools overshadowing an undergraduate department but a large, homogeneous and well-organized body of undergraduate students, with a small, carefully selected graduate school devoted to the liberal arts and sciences.

History. — The university owes its origin to a movement set on foot by the synod of Philadelphia in 1739 to establish in the middle colonies a college to rank with Harvard and Yale in New England and William and Mary in Virginia. As a result of dissension in the church, no progress was made until 1746, when the plan was again broached by the synod of New York, formed by the secession of the presbytery of New York and the presbytery of New Brunswick, radical (New School) presbyteries of the synod of Philadelphia. Most of the leaders of the presbytery of New Brunswick had been educated at Log college, a school with restricted curriculuin at Seshaminy, Pa., about 20 mi. from Philadelphia, founded in 1726. The opportunity was taken by the synod of New York to found a larger institution of higher learning, broader in scope and training, and to transfer to the new project the Log college interests. On Oct. 22, 1746, John Hamilton, acting governor of New Jersey, granted a charter for erecting a college in New Jersey, which was opened in May 1747, at Elizabeth, S.J. A second charter was granted by Gov. Jonathan Belcher, who on his arrival in the province in 1747 had at once taken the college under his patronage. The college was removed to Newark where the first graduation exercises were held in 1748; but the situation was unsuitable, and in 1752 the trustees voted to remove the college to Princeton. While additional funds were being collected in Great Britain, work was begun in Princeton in 1754 on the first college building, Nassau hall.

John Witherspoon, president during the Revolutionary period, influenced the college strongly by his personality and political prominence, and graduates of his training became leaders in public affairs. The history of the college during the first half of the 19th century was uneventful. Because of its large southern clientele, it suffered in the U.S. Civil War a blow from uhich it recovered only under the energetic administration of Pres. James McCosh (1868–88). The undergraduate enrollment was nearly trebled. gifts amounting to more than $2,000.000 were contributed, only half of which sum was for endowment, 14 new buildings were erected, and important changes were made in the curriculum.

Fellowships were established in 1869, the elective system was introduced in 1870, the John C. Green school of science was erected in 1873, the graduate department was systematized in 1877 and the faculty grew from 17 to 40 and the number of volumes in the library from 25,000 to 65,000.

Under Pres. Francis L. Patton (1888–1902) a school of electrical engineering was established, the honour system was instituted and the plan of electing alumni trustees adopted, 17 buildings were erected, the student body was doubled and the faculty increased to 100. while the endowment reached $2,500,000. In 1902 Woodrow Wilson. of the class of 1879, mas elected president. In his administration the undergraduate curriculum was again revised, the departmental system was organized, and an extensive building



BY COURTESY OF PRINCETON UNIVERSITY

NASSAU HALL. PRINCETON UNIVERSITY. WHEN COMPLETED IN 1756, IT HOUSED THE DORMITORY. REFECTORY, CLASSROOMS AND CHAPEL; IN THE EARLY 19TH CENTURY IT BECAME THE ADMINISTRATIVE BUILDING

program was completed. To obtain the necessary funds, a committee of 50 alumni was formed, later changed into a Graduate council. Through their agency in the eight years of President Wilson's administration the university received more than $4,500,000, the, faculty was greatly strengthened and the library increased to 271,000 volumes. A plan for grouping the university into small self-contained units was prematurely proposed by the president in 1907 and was withdrawn by the trustees. The Princeton plan of a residential building for graduate students was successfully tested on a small scale. and a bequest in 1908, although inadequate for the full project which included professorships and fellowships, gave the plan its first semblance of permanent realization. Additional funds being conditionally offered in 1909, controversy developed as to the site for the building and finally as to the plan itself, the president no longer favouring it. A further bequest of about $2,000,000 for the project brought matters to a head and the president recommended acceptance of the legacy. In Sept. 1910, having received the democratic nomination for governor of New Jersey, he resigned the presidency.

John Grier Hibben. of the class of 1882, professor of philosophy in the university, was the 14th president of Princeton. January 1912 to June 1932. His administration was marked by extended administrative reorganization, by large additions to the endowment and by extensive expansion along material and scholastic lines. Faculty autonomy was made complete: a joint committee of trustees and faculty was organized to consider all matters of educational policy and administration; the faculty was given voice in forming its committees and initiating appointments, promotions and increases of salary; the rights of the individual in cases of dismissal were safeguarded; faculty retiring allowances and insurance were arranged.

In 1913 the erection of the residential graduate college rendered permanent what had been an experimental feature of the Princeton graduate school. The school of architecture was opened in 1920. The school of engineering was reorganized in 1921, and the school of public affairs, designed to give its students a broad background for an understanding of and active participation in local, state, national and international affairs, was founded in 1930. Edward Dickinson Duffield of the class of 1892 and a trustee of the university served as acting president until the election of Harold Willis Dodds, professor of politics, as 15th president in June 1933. The university commemorated the academic year 1946–47 as its bicentennial anniversary and in 1949 established ten bicentennial preceptorships to encourage scholarship and teaching.

In 1951 Princeton established the James Forrestal Research centre in the former plant of the Rockefeller Institute for Medical Research, comprised of 15 buildings and laboratories. The centre was established for the immediate purpose of permitting the university to expand its program of basic research for national defense, and for the long-term purpose of providing additional laboratories and facilities to meet the more exacting requirements of modern scientific and engineering research.

The many research programs are concerned with problems in the fields of aeronautical engineering and jet propulsion, chemical kinetics, catalysis, metallurgy, biochemistry, applied mathematical analysis and applied nuclear sciences.

Buildings include the John C. Green Engineering building (1927), with the engineering laboratory added in 1951; the Palmer Memorial stadium (1914); and the New observatory (1934), with a dome 45 ft. in diameter and a 23-in. telescope. Buildings erected after World War II include the Herbert Lowell Dillon gymnasium (1947); the Harvey S. Firestone Memorial library (1948); the Architectural laboratory and the Class of 1915 Dormitory (1949); Hayes Engineering laboratory (1951); Woodrow Wilson Hall (1952).

In 1953 the university re-emphasized its long interest in the humanities by the establishment of the Council of the Humanities which has the function of assisting members of the faculty and graduate and undergraduate students in interdisciplinary studies in the area. The council provides senior and junior fellowships for such study and supervises several special programs of instruction in which the broad range of the humanities and the social sciences is brought to bear upon programs of fundamental value or upon the civilizations of particular areas of the world.

In 1956, in order to provide more effective channels of communication with industrial corporations, a program of conferences was established to cover general and specialized problems of common interest to industry and the faculty in all areas of the university. The conferences were planned and directed by the various departments and attended by both faculty and interested corporation officers.

On July 1, 1957, on the retirement of President Dodds. Robert Francis Goheen of the department of classics became the 16th president of the university.

Princeton University Press.—Organized as a nonprofit association, closely affiliated with. but legally independent of, the university, the Princeton University press was founded in 1905 and incorporated in 1910. In 1912 it published its first book; approximately 50 new titles are published annually.

The broad aim of the Princeton University press was defined as "the promotion of education and scholarship," and it serves the university by publication and distribution of its research and offers other services to scholars there and elsewhere. (J. D. BN.)

PRINCIPAL AND AGENT refers to the law of agency dealing with salesmen, brokers, managers and other commercial agents having power to make contracts for their employers. This branch of agency came to be treated separately as a result of the great increase in shipping, banking, insurance and other mercantile transactions that occurred during the late 18th and early 19th centuries. See AGENCY.

PRINCIPE ISLAND, a Portuguese island in the Gulf of Guinea, of volcanic origin, 90 mi. N.E. of São Tomé Island with an area of 42 sq.mi. The highest point is Pico-Papagaío, 3,110 ft. above sea level. The island forms, along with São Tomé Island. a Portuguese overseas province.

The population was 4,332 (81 white) in 1950 and 3,108 (56 white) in 1940. The chief settlement is Santo Antonio.

The tsetse fly (which is not found in São Tomé) infested the wooded part of the island, and through it sleeping sickness was spread. Coconuts, coffee and cacao are exported.

PRINGLE, SIR JOHN (1707–1782), British physician, the founder of modern military medicine, was born on April 10. 1707, at Stitchel, Roxburghshire, and educated at St. Andrews. at Edinburgh and at Leiden. He settled in Edinburgh as a physician, but after 1734 also acted as professor of moral philosophy in the university.

In 1742 Pringle became physician to the earl of Stair, then commanding the British army in Flanders, and in 1744 was appointed physician general to the forces in the Low Countries. In 1749, having settled in London, he was made physician in ordinary to the duke of Cumberland, and subsequently received other court appointments as physician, being made a baronet in 1766. In Nov. 1772 he was elected president of the Royal society, but resigned his presidency in 1778. Pringle died on Jan. 18. 1782.

Pringle remedied camp sanitation and the ventilation of hospitals and laid down the principles for preventing dysentery and hospital fever, at the same time showing that the different forms of dysentery were varieties of one disease and that jail fever was the same as hospital fever.

Pringle's chief works are: *Observations on the Nature and Cure of Hospital and Jayl Fevers* (1750); "Experiments on Septic and Antiseptic Substances" in the *Philosophical Transactions* of the Royal society (1750); and especially the *Observations on the Diseases of the Army* (1752). His *Six Discourses* (1783) contains a biography by A. Kippis.

PRINGSHEIM, NATHANAEL (1823–1894), German botanist. who made outstanding contributions to the study of algae, was born in Cpper Silesia on Nov. 30, 1823. He studied at the universities of Breslau, Leipzig and Berlin; graduated in 1818 as doctor of philosophy with a thesis on the form and development of the thickening layers of plant cells; and rapidly became a leader in the great botanical renaissance of the 19th century. His contributions to scientific algology were of striking interest and, together with the French investigators G. Thuret and E. Bornet, he ranks as a founder of the scientific knowledge of the algae. Pringsheim mas among the first to demonstrate the occurrence of a sexual process in this class of plants, and he drew from his observations weighty conclusions as to the nature of sexuality. The conjugation of zoospores, regarded by Pringsheim as the primitive form of sexual reproduction, was a discovery of fundamental importance.

A work (1873) on the course of morphological differentiation in the Sphacelariaceae, a family of marine algae, is of great interest, inasmuch as it treats of evolutionary questions: the author's point of view is that of K. W. von Nägeli rather than that of Darwin. Connected with Pringsheim's algological work was his investigation of the Saprolegniaceae, a family of aquatic algalike fungi. His career as a morphologist reached its peak in 1876 with the publication of a memoir on the alternation of generations in thallophytes and mosses.

From 1874 to the close of his life Pringsheim's activity nas chiefly directed to plant physiology. He founded the *Jahrbuch für wissenschaftliche Botanik* and the German Botanical society. His nork was, for the most part. carried on in his private laboratory in Berlin, he held a teaching post of importance for only four years, 1864–68, when he was professor at Jena. Pringsheim died in Berlin on Oct. 6, 1894.

He wrote memoirs on *Vaucheria* (1855); the Oedogoniaceae (1855–58); the Coleochaeteae (1860); *Hydrodictyon* (1861); and *Pandorina* (1869). His complete norks were published by his children (*Gesammelte Abhandlungen,* 4 vol., 1895–96).

PRINTED CIRCUITS are electrical circuits in which the usual wiring—and. occasionally, resistance elements—are replaced by patterns of conductive material applied on sheets of ceramic, glass. or laminated or solid plastic. The circuit patterns are produced by photographic and mechanical printing procedures much like those used in the graphic arts.

First developed on a large scale after World War II. the techniques for producing printed circuits helped meet the demands of industry for more efficient mass production of electrical equipment. The increasing application of electronic equipment in business and industry during the postwar years created problems of weight, size. reliability and production cost. Most of these problems were solved to a large extent, particularly in the radio and television industries in the United States, by the use of printed circuits.

Of the numerous processes used in the fabrication of printed circuits, the most common were etching, plating, metalizing and printing.

In the photoetching process, a photosensitive film is applied to the copper surface of a copper-clad plastic sheet, and a photographic negative of the circuit pattern is superimposed on the sensitized film. The film is then exposed to ultraviolet light in a manner similar to that used in producing a photographic positive. The exposed film hardens and the unexposed areas dissolve readily in an alcohol solution. The hardened film protects the printed circuit pattern during the subsequent etching process. The exposed copper is dissolved in an acid or ferric chloride etchant bath, leaving the copper circuit pattern.

In stencil etching, a protective film to form the circuit pattern is applied by a printing process such as silk screening, which deposits a film sufficiently thick to protect the copper from the etchant solution. The protective film, an enamel, is dried and the exposed copper is etched as described previously.

In the plating process a plastic laminate is first coated with a material which will conduct electricity. This may be done by forming a ,0001-in. silver coating on the surface of the laminate in much the same way that mirrors are silvered. The silver film is then coated with a plating resist, usually an enamel, by a stenciling process, leaving exposed areas to form the circuit pattern. The plating process is similar to the plating of decorative metals. After a sufficient thickness (0.001 in. to 0.005 in.) of copper is deposited, the plating resist is removed by a solvent. The exposed silver film is removed by acid etching, leaving the much thicker copper plating to form the circuit pattern on the plastic sheet. Another technique, especially for electronic components (switches. commutators and other low-current-carrying parts), is to evaporate metal such as silver directly on an insulating plate through a stencil.

The printing method of producing circuits uses ceramic or glass as a base material in most cases. A silver paste is applied through a silk screen to form the circuit pattern. After the silver paste has dried. the circuit is fired in a furnace at about 750° F., thus bonding the silver pattern to the base. This process also makes it possible to print resistance elements, composed of various forms of carbon. on the circuit pattern.

Printed circuits assumed an important role in industry because they opened the way to mechanized production of electronic equipment. Mechanized production in turn offered the advantages of lower labour costs and better uniformity and quality of product.

Printed circuitry also eliminated one major cause of unreliability in electronic equipment, poorly soldered joints between the electronic component and conductor, by permitting the use of the dip soldering process. In dip soldering, the joints between the electronic component and the conductor are exposed to molten solder and joined in one operation.

Printed circuits were used in practically all types of electronic equipment. including radio and television sets, guided missile controls, electronic computers and industrial control equipment.

PRINTING is the mechanical multiplication of text, pictures or designs by putting ink on paper or some other suitably receptive surface, such as cardboard, cloth, cellophane or metal. Broadly speaking, printing encompasses all production and use of printed matter. This article discusses first the history of printing and then the modern printing processes.

There are three main methods of printing: letterpress (or relief). in which the image is transferred from a printing surface raised slightly above the body of the type or printing plate: intaglio (gravure), from a design engraved below the surface of the printing plate; and offset lithography (planographic printing). from a flat surface. Letterpress, which was used by the first European printers in the 15th century, is still the most common method.

Modern printers use techniques and processes that are continually improved through science and engineering, although the basic machines and methods change slowly. Printers choose the printing process best suited for the work to be done, and frequently they use different methods interchangeably or in combination.

THE HISTORY OF PRINTING

The East. — Printing as western civilization knows it began about the middle of the 15th century in Germany. The Chinese, Japanese and Koreans used printing long before that time, but western printing was invented independently of the oriental art and developed along dissimilar lines. The major reason for the separate development is the difference between Asian and European scripts. Mass production of movable letters for the 15th-century European alphabet of 23 letters was a simple affair; for a language demanding thousands of complicated ideographs, it was impossible.

Chinese printing was until modern times achieved mainly from wood blocks engraved in relief, each with one or more pages of text. printed not under pressure but by rubbing the paper against the inked surface with a dry brush or some other rubbing device. As both sides of the thin, porous Chinese sheet cannot be printed, the traditional Chinese accordion book is folded and stitched at the side so that blanks do not show. The skilled Chinese craftsmen not only could engrave the blocks rapidly and cheaply but also could duplicate with remarkable fidelity the beauty and delicacy of brush calligraphy, esteemed in the orient for aesthetic as well as utilitarian reasons.

How or when printing was first accomplished in China is not known with certainty. It may have derived from engraved seals. used in China from at least the 3rd century B.C. to make impressions in soft clay. The first-known inked impressions on paper date from the 5th century A.D. Similar stamps, used with a red ink made from cinnabar, are still commonly employed in the east for signatures on documents. In the 6th century A.D. large wooden seals were cut and used for printing Taoist charms.

Another hypothesis is that printing developed from the ancient Chinese practice of making inked rubbings or squeezes from stone inscriptions. About A.D. 165 the standard text of the Confucian classics was cut upon stone to ensure permanence and accurate transmission, and soon thereafter the practice of making copies by means of ink rubbings began. The earliest extant rubbing dates from the 7th century. In the east and later in the west the first great patrons of the printer were officials of church and state, who saw in him a useful ally for maintaining canonical purity of Scripture and law. They recognized the value of printing's ability to transmit an almost exact facsimile, so that once an accurate text was established it was possible to minimize the corruption caused by accretion of scribal errors.

The oldest-known true printed piece. dating from A.D. 768–770. comes from Japan, where Buddhist missionaries had introduced printing from China during the previous century. It is a Buddhist charm, printed by order of the empress Shōtoku, from wood blocks or thin cast-metal plates, in an edition of 1,000,000 copies. Numerous examples have survived. The oldest printed book in existence also is of Buddhist origin. It is an edition of the *Diamond Sutra* consisting of six sheets of text and one smaller leaf with a woodcut illustration. printed in A.D. 868. The sole known copy, found in a cave in Turkistan in 1900 and acquired by Sir Aurel Stein in 1907, is now in the British museum. Religious texts, however, did not constitute the whole of eastern printing. Textiles, playing cards and paper money also were printed from blocks. (See also BOOK: The Invention *of Printing.)*

The Chinese attempted to use typography, as distinguished from block printing, despite the difficulties of trying to cast, compose and redistribute the thousands of characters required. The first trials are attributed to one Pi Sheng, who made individual characters of thin. fired earthenware for assembly in an iron form. These proved too fragile to be practical. The Chinese later cast letters in tin and cut them from wood, but none of these methods gained wide popularity. A type foundry was established in Korea late in the 14th century, where numerous fonts of type were cast in bronze. Although the use of metal type spread back to China and Japan from Korea, it superseded the use of the wood block as the principal printing method only in the 20th century.

The West. — Although any attempt to describe the invention and spread of printing in Europe can be based on somewhat firmer premises than the development in the east, there are still many gaps in our knowledge. The year 1440 has traditionally (and arbitrarily) been chosen as the date of the invention, and Johann Gutenberg (*q.v.*) is credited with the feat. However, Gutenberg mas but one of many seeking to speed book production through mechanization; others were carrying out similar experiments in the Netherlands. France, Germany, Italy and elsewhere. Gutenberg was the first to assemble the necessary components of the printing process — type production, ink manufacture, the press, paper supply — into a coherent whole. The 15th century was a propitious time for the work. There existed a great market for books among the students of the rapidly expanding universities and the many literate members of the rising middle class. for reading was no longer a clerical monopoly. There was a well-organized book trade to market the sudden explosion of production. Paper, introduced into Europe through Spain and Sicily in the 11th century, was in abundant supply and no longer suspect as an impermanent material.

As in the far east, block printing was the predecessor of printing from movable type in Europe. By the early 15th century blocks were being used to print textiles. playing cards and religious pictures. Block books, which combined pictures with simple texts and were printed by rubbing from inked blocks, made an appearance in the west soon after the first typographic pieces.

Gutenberg possessed two skills essential for successful volume production of individual movable types: metallurgy and engraving. He was able to develop an alloy of lead, tin and antimony that would cast easily and would be durable. More important, he could engrave single letters on the hardened steel punches used to strike matrices for the casting of type—a technique already in use for the manufacture of coins and medals. Gutenberg's major invention was the mold that could be adjusted to receive matrices of various width (both the letters i and m, for example. had to be accommodated). The other technical problems of printing could be solved by adaptation of existing materials: presses were commonly used to make wine, oil, paper, etc.; the inks used for writing or block printing could be stiffened to the proper consistency for typographic printing. The best of the incunabula (*q.v.;* books printed before A.D. 1501) attained a degree of beauty and technical excellence rarely equaled since.

What little is known about Gutenberg and his invention comes from legal records. Unable to finance his work, he had to borrow from a fellow townsman: Johann Fust (*q.v.*), who became impatient for a return on his investment and in 1455 foreclosed on the inventor. Before then Gutenberg apparently had produced a few small pieces and probably had begun work on the Bible known by his name. Fust employed Peter Schoeffer, later to become his son-in-law, to assist in the new enterprise. Their firm produced many notable books, among them the great Psalter of 1457, the first book to use more than one printed colour and the first to carry a colophon naming its printers and the date and place of publication. The types for these first books copied the hands written at the time; and consequently they contained a great number of ligatures and contractions that were gradually eliminated later as economy demanded simplicity.

Printing spread with extraordinary rapidity. From Mainz it proceeded throughout Germany in the 1460s, chiefly along the Rhine, the principal trade route By 1500 there were presses in more than 60 German towns. The first printers in most European countries were itinerant Germans who had been lured by the promise of patronage or forced to emigrate by the intensity of competition at home. The first Italian press was established at Subiaco, near Rome, in 1464; Basel, Switz., had a press in 1465; Paris and Utrecht, Neth., had printers in 1470, Spain and Hungary in 1473, England in 1476 and Sweden in 1483. All Europe except Russia, which had no press until 1563, had printers during the 15th century. By 1500 more than 1,700 presses in almost 300 towns had produced one or more books. It is estimated that almost 40,000 editions were published during the 15th century, comprising somewhere between 15,000,000 and 20,000,000 volumes. These were mainly liturgical, theological and legal works, but by 1500 many texts of the Greek and Latin classics had appeared, as well as literary works in the various vernaculars. William Caxton (*q.v.*), the first English printer, published almost every important work of literature written in his native language before his death in 1491.

From Germany the centre of the printing industry moved to Italy during the late 15th century, especially to Venice, then at the height of its political and commercial importance. There Nicolas Jenson (*q.v.*), a Frenchman, established his press in 1470 and printed some of the noblest early books. His types included a roman face, based upon Italian book hands, that was widely copied and is still used in modern adaptations. Among modern type designers inspired by it were William Morris and Bruce Rogers. The most influential Venetian printer was the scholar-publisher Aldus Manutius, whose output included the first printed editions of many of the Greek and Latin classics. His three chief roman type faces were cut for him by Francesco Griffo of Bologna, who in 1500 was responsible for the first italic type, based on Italian cursive writing. These types, in small sizes, made possible the most important innovation of Aldus—small books that were the prototype of modern pocket-sized editions. (*See* also MANUTIUS.)

Early in the 16th century Italy lost its printing supremacy to France as a result of political and economic upheaval. Lyons and Paris became the great printing centres. French books had at first a distinctly national character, being printed mostly in *bâtarde* and other French Gothic types and illustrated in local style. Then, like architecture and painting, they began to show a strong italianate influence. A series of elegantly designed and printed volumes produced by Geoffroy Tory (*q.v.*), printer, engraver and philologist, employed various types, decorative initials and architectural borders borrowed from Italian sources. These were highly influential in changing the appearance of French books from the Gothic to the Renaissance style. France's greatest contribution was in type design. Early printers had generally cast their own type, but during the first half of the 16th century type manufacture became an independent trade, highly specialized and centralized in cities with a concentration of printers, notably Paris, Frankfurt and Leipzig. Among the most notable of the early type designers was Claude Garamond (*q.v.*), who established himself in Paris about 1530 and sold his punches and matrices throughout Europe. His roman, italic and Greek types, either in their pure form or as adapted by subsequent cutters, dominated type design until the late 18th century and are highly successful in the modern revivals. Robert Granjon (fl. 1560), who worked primarily in Lyons, was another important type cutter; his work included the earliest *caractères* de *civilité* (a typographic version of the French secretary hand then in use) and flowered ornaments (*fleurons*), which could be combined into innumerable decorative designs.

The wars of religion provided setbacks to the progress of printing in France. Many Huguenot printers emigrated to Switzerland, England and the Low Countries. Censorship and rigid trade regulations impeded French printing until after 1789. The centre of printing activity moved to the Low Countries, especially to Amsterdam and Xntwerp. In Xntwerp the establishment of Christophe Plantin (*q.v.*) became one of the strongest in Europe, with its foundry, bindery and bookshop. The firm remained in the family's possession until 1876, when the city acquired the premises and established the Plantin-Moretus museum. In the museum has been reconstructed a great 16th- and 17th-century printing establishment, with cases of type, punches and matrices, and ancient presses.

The New World.—In the new world printing began in Mexico City in the 1530s. Lima, Peru, had the first press in South America in 1584. In 1638 the first press north of Mexico City was set up at Cambridge, Mass., by Stephen Day (*q.v.*), assisted by his son Matthew. The first two products of this press, which came under the control of Harvard college, were the *Freeman's Oath* and *An Almanac for 1639, Calculated for New England by Mr. William Pierce, Mariner,* of which no copies are known. The *Bay Psalm Book (The Whole Book of Psalms, Faithfully Translated Into English Metre)* of 1640 is the earliest extant colonial book Another interesting volume is the Indian Bible, the first American printing of the Scriptures, translated by the missionary Rev. John Eliot into the Indian language. Samuel Green and Marmaduke Johnson printed it at Cambridge in 1663.

Printing spread with colonization. William Bradford (*q.v.*) started in Philadelphia, Pa., in 1685 and moved to New York in 1693. William Nuthead began printing in Jamestown, Va., in 1682 but was not permitted to continue and moved to Maryland in 1685. Thomas Short, who set up a press at New London in 1709, was the first Connecticut printer, and others established the trade in locations from New Hampshire to South Carolina. Isaiah Thomas, himself a successful printer and the first historian of printing in America, noted that 50 printers were active in the 13 colonies in 1775. The stamp tax on newspapers and advertising was one of the main stimuli for the independence movement in the American English colonies. Printing proved its political power for the second time in the world's history: the book had been the intellectual foundation of the Reformation; the newspaper and the pamphlet prepared America for the War of Independence.

The 18th Century.—The 18th century was the first in which England developed any strong national typographic style and produced any influential innovators. Two are especially noteworthy: William Caslon (*see* CASLON), a gun engraver turned type founder, whose reworkings of Dutch type faces dominated British and American printing for at least a century and still are widely used; and John Baskerville (*q.v.*), a Birmingham writing master, who used a fortune made as a japanner to finance his unprofitable efforts as a printer and publisher. In his first book, the 1757 *Virgil,* Baskerville used wove paper, the first printer to do so. His sharp, thin types, demonstrating his mastery of calligraphy and letter cutting, were a transition to the "modern" types of the early 19th century; and his severe, unornamented pages anticipated the neoclassic style of the 19th century. His most important influence was on the continent, where Giambattista Bodoni (*q.v.*) of Parma and the Didots of Paris (see DIDOT) were admirers of his craftsmanship and his taste

The two most important printing developments of the 18th century, however, were not aesthetic but technical. The first of these was the invention of stereotyping—a method of making duplicate printing plates by casting hot metal in a matrix molded from the original type. William Ged, a Scottish goldsmith, invented a method of stereotyping in 1725; it was not commercially successful, mainly because of opposition from the type founders and compositors. The Didots in France and Lord Stanhope in England improved upon the process, and it gained wide acceptance about 60 years later. The other notable 18th-century invention was lithography, the only major printing method whose development can be fully documented. Aloys Senefelder of Munich discovered and introduced the process during 1796–98. Lithography, which depends upon the immiscibility of grease and water, is the basis of all modern methods of offset or planographic printing. (For a detailed account, *see* LITHOGRAPHY.)

The late 18th century saw the beginning of enormous changes in printing, for during the Indusfrial Revolution printing became one of the first industries to utilize automation. Various technical problems had to be solved and a series of bottlenecks had to be eliminated before the partially mechanized handicraft could be transformed into a high-speed factory operation. The most serious of these was shortage of paper, caused by a scarcity of rags. Various 18th-century scientists, particularly the German J. C. Schaffer, proved that paper could be made from the pulp and fibres of many plants, shrubs and trees. Use of vegetable pulp made practical the development of a machine for making paper in an endless web. The next requirement was a speed-up of the printing process itself, and this was accomplished primarily through modernization of the printing press.

Development of Modern Presses.—The wooden hand press, still essentially the same machine used in the 15th century. was the point of departure in the development of high-speed printing machinery. In this development there were two different avenues of approach.

One group of inventors wanted to maintain the basic design of the hand press but to improve its power and there ith its speed, size and general efficiency. The first steps were to replace wood parts with metal and to design every part on the basis of theoretical mechanics. The first man to do so was Wilhelm Haas (1741–1800) of Basel in 1772. But the local guilds prevented exploitation of this press, and it took a quarter of a century for other inventors to develop workable iron hand presses. Étienne Anisson-Duperon in France, Lord Stanhope in England, George Clymer in America and many others did notable work in this field.

The other approach was to connect the vertical and horizontal motions of the press in such a manner that they would form a complete cycle. The first record of this idea exists in the notebooks of Leonardo da Vinci. More than two hundred years later Friedrich König, a German. independently conceived the idea. He built the first flat-bed cylinder press powered by steam for the *Times* (London). On Nov. 29, 1814, the *Times* proudly announced that the issue in the reader's hand, the first printed on the cylinder press, was the result of "the greatest improvement connected with printing since the discovery of the art itself." The press had inking rollers and its capacity was 1,100 impressions an hour, in contrast to the 300-per-hour capacity of the hand-inked press it replaced. In 1848 Augustus Applegath and Edward Cowper constructed for the *Times* a press capable of 8,000 impressions an hour, which was handfed by men at eight stations on a platform above an upright cylinder of cast iron that carried the type. In 1866 in the Walter press (named for John Walter III, then publisher of the newspaper), the *Times* achieved the prototype of the modern newspaper press—a true rotary press that printed both sides of a continuous web of paper fed from a roll; the rate was 25,000 impressions an hour. In the United States, meanwhile, Richard Hoe (*q.v.*) also developed rotary presses for newspaper work. Most of the changes in press construction since the 1860s have resulted from the demand of periodical publishers for faster, more economical production. (See also PRINTING PRESS.)

Once the press had been mechanized printers faced the problem of the supply of type, type composition and distribution of the individual types after use. Application of a pump to the type mold, which speeded production considerably. was one of a number of advances in hand casting in the early 19th century. Complete mechanization of type founding began with the casting machine of William Church. patented in 1822. which was capable of forming 3.000 sorts (individual pieces of type) per hour.

After the evolution of a number of impractical typesetting machines. the work of many inventors, Ottmar Mergenthaler (*q.v.*) in 1884 patented his Linotype machine, which cast thin slugs of type metal with a printing surface on one edge. Each slug was one line of type, molded from a row of brass matrices assembled by a keyboard operator. After the lines of type were used in printing the metal was melted for re-use. Almost simultaneously (1885) Tolbert Lanston invented the Monotype process. which casts type in individual letters. Both these machines, requiring large numbers of matrices. were made feasible by L. B. Benton's invention of the mechanical punch cutter.

The Linotype, Monotype and other similar composing machines involve the casting of metal type with the printing image in relief. Tremendous growth in the use of lithography, which does not require a raised surface for printing and which is prepared for the press by photographic processes, has intensified in recent years the search for composition methods that avoid the use of metal type. A number of photocornposition machines have been developed to assemble and transfer letters directly onto a sensitized plate from film matrices. (See also TYPESETTING.)

Acceleration of text printing in the 19th century was accompanied by parallel changes in the printing of illustrations as photography was applied to the making of printing plates. J. N. Niepce produced the first photomechanical plate in 1822 when he etched a reproduction of an engraving of Cardinal d'Amboise upon a sensitized metal plate that was subsequently used for printing. Shortly before his death in 1833 Niepce became associated with L M. Daguerre, who subsequently perfected the first practical method of photography. Many experimenters sought to make line engravings on metal by photographic means, and Firmin Gillot succeeded in 1850. William Henry Fox Talbot, the Englishman who in 1839 introduced the calotype, the forerunner of most modern photographic processes, invented photogravure in 1852; Karl Klič (Klietsch) invented rotogravure in 1890. Other important 19th-century inventors include James Clerk Maxwell and Louis Ducos du Hauron, who during the 1860s established the principle of colour separation with filters to pave the way for colour-separation engravings and colour-process printing, and George Meisenbach and Max Levy, who late in the century perfected the halftone screen. which makes possible printed reproductions of paintings and photographs possessing light and shade. (See also GRAVURE; PHOTOENGRAVING; PHOTOGRAPHY.) (J. M. W.)

MODERN PRINTING PROCESSES

In America the word printing (originally restricted to letterpress printing exclusively) is used more and more generically for all kinds of graphic reproduction. Letterpress, before the perfection of photoengraving, was excellently suited for the reproduction of reading matter but much less suited for reproducing pictures and illustrations. Lithography and gravure, on the other hand, were strong in picture printing but weak in reproduction of reading matter. Application of science and photography to all printing techniques wrought a radical change. Letterpress became capable of printing pictures; gravure, lithography and other picture-printing processes were adapted to reproduce typographic copy. The gap between all of them was narrowed, resulting in the concept that "everybody who is concerned with putting ink on paper belongs to the printing industry." This idea found organizational expression in 1945 with the formation of Printing Industry of America (P.I.A.) as the common representative of letterpress, offset, gravure and allied industries.

All printing processes combine four elements: (1) the printing surface or printing-image carrier (*e.g.*, type face, printing plate, gravure cylinder); (2) the press; (3) the ink; and (4) the paper or other printing stock. Each printing process employs its own printing surface, press and ink. The stock, on the other hand, may or may not be specialized.

Letterpress, also called relief printing or typographic printing, is the oldest form of printing and is still the most commonly used. Its range and diversification are vast. It is the only process in which metallic type can be used on the press. It is used in producing books, magazines. newspapers, catalogues, packaging, and commercial printing of all kinds (*e.g.*, letterheads. sales forms, etc.). (For further details see the section Letterpress Printing, below.)

Lithography is also called offset. offset lithography, photolithography, photo-offset and planography. Lithographic plates are in the main made photographically. Metal type cannot be used directly but is used indirectly in the form of a print or procf that is photographed for platemaking; a handwritten manuscript or drawing can be photographed in the same way. In the platemaking process the facsimile reproduction can be made larger or smaller than the original. Lithography is widely used in commercial, book, magazine and newspaper printing. In many instances, such as reprinting a letterpress book job after the type has become worn, it is feasible to convert to offset by photographing proofs from the original type or pages from the first edition. Offset is particularly suitable for making full-colour reproductions of paintings and colour photographs. (*See* also LITHOGRAPHY.)

Gravure is an intaglio printing process in which the printing image consists of small wells in the surface of the printing plate. Ink is carried in the wells, and their depths control the amount of ink transferred to the paper. The process is described by two unfortunately similar words, photogravure and rotogravure. Photogravure includes both sheet-fed gravure printing (used mainly for short-run printing of high-quality work) and rotogravure, the high-speed web-fed process used for big mail-order catalogues. newspaper supplements, packaging materials and other long-run work. As in lithography, text matter is photographed from type proofs or from films prepared in photocomposition machines, and since reading matter as well as illustrations is broken into a screened pattern. fine lines of letters may become weak or ragged. To overcome this condition, a fine screen can be used. (*See* also GRAVURE.)

A fundamentally different kind of printing is silk screen printing (*q.v.*), also called screen printing. The printing-image carrier is a stencil applied tightly against silk or some other fine fabric stretched tautly on a frame. Although the screen process is the youngest of printing methods, it utilizes the oldest principle of graphic reproduction of words and designs. Silk screen printing is the preferred method when a heavy, opaque layer of ink (or paint) is to be applied to a poster, book cover or sheet of glass. Fine detail can be reproduced by photographic methods developed by silk screen printers, and halftones of suitable pictures can be printed as well.

Flexography, originally known as aniline printing, is a form of rotary letterpress printing in which flexible rubber plates and fluid inks are used, mainly to print packaging. The process originated in Germany in the late 19th century, and at first aniline dyes in alcohol were employed instead of ink. After packaging engineers took the process to the United States in the 1920s. thin inks consisting of finely ground pigments in a vehicle of solvent and resin were developed. Extensive use of cellophane as a packing material increased the importance of flexography as a printing method.

Other printing processes include collotype (*q.v.*), also called the photogelatin process, which is a planographic method of printing continuous-tone images without a screen pattern; steel-die engraving, an intaglio process that produces a raised impression on letterheads and calling cards; bank-note printing, another version of intaglio; and xerography, which is fundamentally electrical rather than chemical or mechanical in nature. Through principles of photoconductivity and electrostatics, xerography transfers the printing image (which can be simply a typewritten sheet or a printed proof) to another sheet of paper. Fine powder, used instead of ink, is electrically deposited on the paper and fused into the surface by heat. Related to the processes called printing are the duplicating methods used in offices (see also OFFICE MACHINES AND APPLIANCES).

LETTERPRESS PRINTING

Graphic-arts terminology is neither precise nor fully descriptive. Originally the names of the processes were more or less exact but in the course of history techniques changed and expanded while names remained the same. Letterpress as a term refers to movable types. as does typographic printing. Neither of the two includes or implies the printing of illustrations. Relief printing is a much newer term that overcomes these semantic differences and indicates that only the raised surfaces of the printing-image carrier print. But relief printing as a generic term includes many special fields, such as newspaper printing and flexography. not normally subsumed in current parlance under the term letterpress printing. As used here letterpress printing means the general range of applications, such as commercial. book and magazine printing.

Typesetting.—Letterpress printing is based on type for text and photoengravings for illustrations. Typesetting is done in several ways, Most reading matter for books. newspapers and magazines as well as commercial printing is machine set, either on line-casting machines, like the Linotype and Intertype, which mold each line in one piece, or on the Monotype, which produces lines made up of individual types for each letter, space and punctuation mark. Hand composition, whereby a skilled worker (called compositor) assembles individual foundry types (as many as 60 or 70 for a line of reading matter), has not died out because of the use of mechanical typesetting but the function of the compositor has changed He now devotes himself to setting display type (headlines and artistic arrangements of larger sizes of type) for advertising, title pages and similar typographic art. (Foundry type is type purchased from a type foundry.) The composition of display type was technically advanced by the Ludlow system, which utilizes hand-set matrices in a special composing stick. After assembling and spacing the matrices, the compositor makes a hot-metal casting of the entire line.

Many printers set their own type but others buy type composition from specialized typesetting houses. These typesetters, who are most numerous in large printing and publishing centres, offer printers a broad choice of type faces, or styles. They also set type for advertising agencies and other users of printing who simply want reproduction proofs for offset or gravure printing, or electrotypes or stereotype mats for letterpress work. The type composition specialists do not maintain a pressroom for printing runs but have proof presses to make the desired proofs on glossy paper or cellophane. Some composition companies use photographic composition exclusively. (*See* also TYPESETTING.)

Photoengraving.—Photoengraving converts pictures and artistic decorations into a printable form. The process combines photography, etching and manual engraving in making pictorial relief printing plates known as cuts, blocks or engravings. The illustration to be reproduced is called copy, just as longhand or typewritten reading matter is known as copy for typesetting. Photoengraving copy may be photographs, paintings, wash drawings or other illustrations containing tonal values, which must be reproduced by the halftone process; or it may be pen-and-ink, crayon or pencil-line drawings, a written signature to be reproduced in facsimile or any other similar material that can be rendered in "line cuts" with no tonal values. Such copy is photographed and its image transferred to a metal surface by means of photoprinting. In photographing the image. it can be made either larger or smaller than the original. After the image of the engraver's copy has been photoprinted on the metal surface, the nonprinting areas are removed by etching. This leaves the halftone dots of a tonal picture or the lines of a drawing standing in relief a fraction of an inch above the nonprinting areas.

To obtain tonal values in his reproduction of a photograph or similar copy, the engraver uses a halftone screen when he makes a new negative and prints it on a metal plate. This breaks the image into small dots (65 or more to the lineal inch, or 4.225 or more per square inch) that form the printing surface after etching. The dots vary in size and shape and produce light and dark tones that approximate the highlights and shadows of the original picture when printed. The resolving power of the human eye is not great enough to permit recognition of individual dots of such small size; they blend with the colour of the paper and appear as appropriate tones of the printed colour. The technique of reproducing pictures by this method is known as the halftone process.

In the 1940s a German manufacturer introduced an automatic electronic halftone engraving machine that scans photographs and controls a stylus to cut, rather than etch, the necessary pattern on the printing plate. This machine has been developed to make colour-printing plates from photographic transparencies and other colour copy. (See also PHOTOENGRAVING.)

Duplicate Printing Plates.—Type and relief engravings are used not only directly on the press as printing surfaces but also as originals in the making of duplicate printing-image carriers. Short runs are mostly printed directly, if machine-set type is used, but long runs require duplicate plates. Even for short runs in which some or all of the type is foundry type, duplicate plates are preferred in order to prevent wear of the relatively expensive foundry type, which generally is used only for making electrotypes or reproduction proofs. Rotary printing and other specialized branches of relief printing cannot use type or engravings at all but must have duplicate printing plates.

Duplicate plates (1) preserve photoengravings and foundry type; (2) are suitable for much longer runs than are type and photoengravings; (3) permit combining type and engravings into a single plate that replaces a locked form containing various elements; (4) can be curved for use in rotary printing; (5) make possible the printing of multiples (many units of the same subject) in one press run; and (6) permit simultaneous printing of a subject in several different places, an essential feature for national and international advertising.

The four most important kinds of letterpress duplicate plates are: (1) stereotypes; (2) electrotypes; (3) plastic plates; and (4) rubber plates. Each of these kinds has its own field of application. Stereotypes are most important in newspaper printing, but also are used in bookwork and trade-paper advertising; electrotypes are used for duplicating forms containing fine halftones and for most rotary colour work done on presses other than newspaper presses; plastic plates are used as printing surfaces in bookwork and as intermediaries in machine plates for magazine advertising; rubber plates are used for continuous forms, corrugated containers and flexographic printing.

All letterpress duplicate plates require at least one intermediary step between the original (type or photoengravings, or both) and the final duplicate plate. Both the original and the duplicate are in relief. and it is impossible to make a relief plate from a relief plate without an intaglio intermediary or mold. The intaglio mold is made by pressing some suitable material (either hot or cold) against the original. The duplicate plate formed from the intaglio mold then is a relief plate that is suitable for letterpress printing.

Three qualities are essential in duplicate printing plates: retention of original detail, dimensional stability (or accuracy) and correct printing height. Detail must not be lost during the several steps whereby a duplicate plate is made from an original plate, a requirement particularly important in halftone printing; dimensional exactness is prerequisite for register (the correct position of all printing on the sheet), particularly in colour work; printing height determines fineness of printing quality of all plate areas.

Stereotypes. — Stereotypes for newspaper printing are made routinely in newspaper plants, especially in those using rotary presses where entire pages are cast in stereotypes for mounting on the press. Stereotypes are formed by first making a mechanical imprint of the printing form (type and engravings) in a matrix: or mat, made of a material such as papier-mâché. If many mats are needed, *e.g.*, of a grocery advertisement to be printed in many newspapers on the same day, the original printing form is first converted into an electrotype relief pattern plate that will withstand repeated moldings better than the form itself. The mechanical imprint is thus an intaglio mat, and the final product of stereotyping is obtained by casting hot metal in this mat. Stereotypes are suitable for printing type matter, line cuts, such as cartoons and trade-marks, and coarse halftones.

Assembling the printing form is the first step in matmaking. Thereafter the mat is pressed by one of three methods to produce (1) cold-rolled mats; (2) cold direct-pressure molded mats; or (3) baked direct-pressure molded mats. Cold-rolled mats are made by rolling in a press. The other two kinds are made in a hydraulic press that applies pressure over all the surface of the printing form at the same time. After pressing, the mat is separated from the form, trimmed and made ready for use as the mold for casting hot type metal. Newspaper stereotypes to be used on rotary presses are cast curved; those to be used on flat-bed presses or as part of the printing form for a rotary mat are cast flat. Those for book and publication work usually are used on flat-bed presses and therefore are cast flat. Curved casting is done on equipment that casts, cools, shaves and delivers the completed curved stereotypes ready for the press; equipment is available for performing these functions automatically. Flat casting is much less mechanized. The mat is first backed up (*i.e.*, filled in with pieces of stiff paper) in the nonprinting areas, which would otherwise be flattened by the weight of the metal during casting. Then the mat is baked, or "scorched;" to remove moisture that would turn into steam during casting and could by rapid expansion produce an explosion. After scorching, the mat is placed in a casting box and cast in a vertical position. Stereotypes are either made type high or are shell cast for mounting on a base. They are subjected to various finishing operations and are nickel plated whenever long-wearing qualities are desired.

Electrotypes. — Electrotypes are duplicate printing-image carriers that can combine various kinds of type with photoengravings. They are suitable for long runs: retain the detail contained in the original printing-image carriers with high fidelity, are of excellent dimensional stability, can have premake-ready (adjustment for the proper printing height) incorporated and are well suited for rotary printing. While stereotypes are the press plates used almost exclusively for newspaper printing, electrotypes are the plates used for the rotary letterpress printing of magazines, catalogues and a variety of other products. (See also ELECTROPLATING; ELECTROTYPING.)

Plastic Plates.——Plastic plates are used primarily to print books, multiple forms and newspaper advertisements. Plastic plates can be made either directly from the original printing-image carrier or from an electrotype pattern plate. After the pattern plate is prepared, an intermediary intaglio mold is made with thermosetting material; this mold can be used for making more than one plastic relief plate. If the pattern plate is unnecessary because of the nature of the work, the thermosetting intaglio mold is made directly from the original printing-image carrier. The plastic relief printing plate is then made in the usual manner.

Rubber Plates. — Rubber printing plates offer many advantages. They can print on a wide variety of materials, can be curved and attached to the form cylinder easily and are suitable for long runs. The main use of rubber plates is in flexography; they also are used in letterpress printing; *e.g.*, the printing of forms, envelopes and books. They exhibit good printability except for halftone details.

Rubber plates are made from a thermosetting intaglio intermediary. The original printing-image carrier: which may be type, photoengravings or electrotypes, and the thermosetting molding sheet are preheated and then assembled in a hydraulic press. The pressure does not exceed 400 lb. per square inch for type matter and 1.000 lb, per square inch for photoengravings or electrotypes. The time required for curing the thermosetting mold is approximately 15 minutes; the platen temperature approximates 300° F. After curing, the intaglio intermediary is separated from the relief original and is ready for use in molding the rubber relief plate. Various kinds of synthetic and natural rubber are used for making rubber plates. Molding takes place in a hydraulic press; the pressure does not exceed 1,000 lb. per square inch, the temperature on the platen is 300° F. and the time required is 6 to 12 minutes. After molding, the rubber plate is stripped from the intaglio intermediary and mounted for printing.

Rubber plates can be mounted flat or curved by use of pressure-sensitive adhesives or double-coated adhesive tape. Rubber plates can be mounted directly on the impression cylinder or prepositioned on heavy paper or on a light metal sheet that in turn is mounted on the press cylinder.

Presswork. — During presswork the printing image is transferred to the stock. usually paper. Four elements must be coordinated in this operation: (1) the press (called, except for proof presses, printing machine in Great Britain) ; (2) the printing-image carrier; (3) the ink; and (4) the paper or other printing stock.

Printing presses perform four main functions: (1) they position the unprinted stock (usually paper) for receiving the impression; (2) they ink the printing-image carrier; (3) they make the impression by transferring the ink from the image carrier to the paper; and (4) they remove the printed paper. Four different units that correspond to these four functions can be distinguished on printing presses. They are: (1) the feeding unit; (2) the inking unit; (3) the printing unit; and (4) the delivery unit. In letterpress printing the ink is transferred directly to the paper in all cases but one. This exception is dry offset, in which the printing image is transferred to a rubber blanket and from there to the stock. Dry offset is indirect relief printing; the term dry offset is used to distinguish this process from the usual form of lithographic printing, commonly known as offset. Dry refers to the fact that indirect relief printing dispenses with the dampening necessary in offset lithography.

From the beginning of printing until the first quarter of the 19th century all four main operations — feeding, inking, printing and removing the printed sheet — were done by hand. During the 19th century they were slowly mechanized; modern printing presses perform all four operations automatically. Hand presses have become a rarity and are used only by private presses that print limited editions. (See also PRINTING PRESS.)

All letterpress printing requires many steps. Some of these are executed by the pressman (called the machine minder in Great Britain), some by his assistant and some in the shop's planning department. The first decision is to select the right press for the job at hand. Sometimes the kind of press to be used for a job is self evident. But often detailed analysis and calculation are necessary to determine the right press. The time factor also must be considered; the ideal press may not be available at the proper time and the job may therefore have to be put on another, less appropriate one.

Imposition. — Once the press is selected. the imposition is decided upon. The imposition is the layout for the printed sheet indicating the place of each page on both the front and back of the sheet. (Imposing is the act of executing this plan and must not be confused with making the imposition or deciding on its plan.) There are four styles of imposition, differing mainly in the manner in which the front and back of the sheet are printed. The detail of the job as well as its finishing or binding have a great bearing on selecting the manner of imposition as well as arranging the detail within the selected style.

Preparation for the Press. — Once the imposition is decided. the printing-image carrier is prepared for the press. This operation aims not only at the proper positioning of all printing matter but also at its correct printing qualities, which depend on the correct height of the printing surface. (The standardized height of type is 0.9186 of an inch.) Foundry type, Linotype slugs and Monotypes are all cast type high and therefore merely need leveling. Photoengravings are made of 16-gauge metal, which is the equivalent of 0.065 of an inch. They must be mounted on blocks to become type high and suitable for printing with type matter. Stereotypes are either cast type high or 11 point (0.152 in.); electrotypes are all made 11 point high.

If only duplicate plates are used as printing-image carriers in flat-bed cylinder press printing, the bed of the press is equipped with a metal plate base, often called patent base. The standard height of plate bases is 0.759 in.; when to this is added the height of the electro, 0.152 in., the height becomes 0.911 in., leaving 0.0076 in. for make-ready. Some plate bases are honeycombed, others have a diagonal or rectangular pattern; all come in combination sections. The printing plates are beveled and attached to the base with hooks that grip the edge of the plate and are anchored in the base.

Lockup. — The locking up of forms consisting of type matter and blocked (mounted) photoengravings is done at the stone, as the printer calls the stone- or metal-topped table used for imposing. The many elements of which such a form consists are held in place by a device called the chase. It is a rigid metal frame, reinforced with movable crossbars for large-size flat-bed presses. The printing matter is placed in the chase according to the imposition, an operation called imposing in the printer's language. Empty spaces are filled out with wooden or metal blocks called furniture. Quoins (pronounced "coins"), expandable lockup devices, are used to tighten the form. When the lockup man imposes a form, he is concerned not only with the alignment of its elements but also with its height. All parts of the form are inspected and adjusted, if necessary, so that they are type high. The imposed form is then placed on the bed of the press and made ready for printing.

Make-Ready. — In make-ready the form is further leveled and prepared so that it may yield the best possible print. Three techniques are used: (1) underlaying; (2) interlaying; and (3) overlaying. Underlaying consists in placing paper in various thickness under the printing element; in interlaying paper is placed either between the photoengraving and its mounting or between plate base and stereotypes or electrotypes. In overlaying adjustment is made on the platen or impression cylinder and results in application of the right printing pressure on the various elements of the form: the technique consists in taking an impression and building up the impression cylinder where more pressure is needed by gluing paper of different thicknesses at the corresponding places on the overlay sheet, or by reducing its thickness where the pressure is too heavy. The overlay sheet is covered by the packing and tympan of the impression cylinder. Make-ready, which requires great experience and can be time consuming for big forms, can be reduced by premake-ready operations that help to prepare the form for proper printing before it is put on the press.

On the Press. — Once the press is running, the pressman and sometimes one or two assistants keep constant watch to maintain efficient production and the right quality. They check colour and register often and watch for work-ups or press batters (elements of the form that somehow become loosened). New paper must be put in feeding position and the printed sheets removed. Offsetting (unintentional transfer of wet ink from one sheet of paper to another) is controlled by using drying devices on the press, fast-drying inks or "smut sheets" that are laid between the printed sheets.

PRINTING PRESS, the machine in which type and illustration images are transferred to paper by means of printing ink. Printing presses can be classified into two major groups — flat-bed and rotary — according to whether the form (spelled forme in Great Britain) used for printing has a flat or curved surface. Flat-bed presses can be further subdivided as platen or cylinder according to whether a platen (flat plate) or a cylinder is used for impressing the paper against the printing surface. Presses also can be classified in several other ways; *e.g.,* according to the nature of the printing surface: (1) letterpress, in which the image is printed direct from type or other relief surfaces; (2) planographic (*e.g.,* offset lithography), in which the image is printed from a chemically treated surface; (3) intaglio (*e.g.,* gravure), in which the ink is transferred from wells etched or engraved in the printing surface; and (4) silk screen, in which ink is forced through a silk screen to print an image. Presses also can be described by various other features; *e.g.,* according to whether the paper is fed into them in sheets or as a web from a roll; whether the sheets are fed by hand or by automatic devices; and whether one colour, two colours or more than two colours can be printed. In addition, flat-bed presses often are described by the number of revolutions made by the cylinder for each impression or according to whether the type bed is horizontal or vertical. Presses also are sometimes classified according to the size of the impression area or the number of pages, expressed in various standard sizes, that can be printed in one cycle, impression or cylinder revolution. Modern letterpress and offset machines also are classified as oil ink presses if no drying methods are used to set the ink and as heat-set ink presses if drying means are used. Heat-set presses usually print on both sides of a web of paper; this process is known as perfecting, or backing up. (See also PRINTING; PRINTING TYPE; LITHOGRAPHY; GRAVURE; SILK SCREEN PRINTING.)

Developments Before 1900.—*Early* Hand-Operated Presses.—There is no exact knowledge of the earliest presses although there is no doubt that Johann Gutenberg (c. 1398–*c.* 1468) must have used one. The earliest mention of a printing press is in the evidence given at a lawsuit against Gutenberg in Strasbourg in 1439 by Conrad Sahspach. a wood turner who had constructed a press for one of Gutenberg's partners.

A model for the first printing press was available in the heavy wooden presses used in the paper mills of that time; these presses operated on a principle that can be traced to the Roman wine and olive presses described by Pliny the Elder. They consisted of

FROM "ARCHIV FÜR BUCHGEWERBE," 1909

FIG. 1.— ENGRAVING BY ABRAHAM VON WERDT, 1640–80, SHOWING ANCIENT PRINTING SHOP WITH LIGHTLY CONSTRUCTED WOODEN PRESS

two stout upright pieces of wood joined by two horizontal beams. A screw. working in the upper beam and turned by a long bar, exerted pressure downward upon a wooden plank placed on the paper. Certain modifications had to be made to obtain a quick, precise impression from the type. The pitch of the screw was made steeper than in the paper press so that the necessary rise and fall was gained within the quarter turn obtainable with a fixed bar. The twisting motion of the turning screw was counteracted by suspending the platen (the wooden plank) from a hollow wooden box (the hose) that slid inside closely fitting guides while the screw turned freely within. The upright beams were frequently braced to the ceiling to keep the press steady. To make the type more accessible for inking, it was drawn on rails from under the platen by a windlass. To the back of the "carriage" which bore the type, a frame tightly covered with parchment (and therefore called the tympan) was hinged. This frame bore the paper, which was attached to it by projecting points and by a light folding frame (the frisket).

Most of these features can be seen in the first-known representation of a printing office. a wood engraving of about 1499, and in the many illustrations of presses used as marks by printers during the 16th century. Many of them are very massive, with thick wooden screws. The introduction of a metal screw is credited to Leonhard Danner (d. 1585). a screw maker of Nürnberg; this innovation greatly reduced friction, making the press easier to operate.

In the first of all printers' manuals. *Mechanick* Exercises (1683), Joseph Moxon recommends an improved Dutch press devised by Willem Janszoon Blaeu. Its only improvement appears to have been the substitution of an iron framework for the hose; it may also have been provided with a brass or iron platen, which seems to have been a common feature of presses in Holland, France, Italy and Germany from the end of the 16th century.

Further improvements were attempted during the 18th century. Printers who prided themselves on "fine" printing, such as J. Baskerville, the Didot family and G. Bodoni, took particular care with the construction of their presses.

The radical defects of the wooden hand press were the lack of stability caused by loosening of the joints and the slowness of operation. The output of a hand press, worked by two pressmen, does not appear to have varied greatly and payment was generally calculated on a rate of 250 sheets an hour printed on one side Newspapers might have been printed somewhat faster, but careful work required a much slower rate. The stability of hand presses was improved by the substitution of iron for timber. In 1772. Wilhelm Haas. a typefounder at Basel, completed a press with a framework of cast iron and with an iron platen that covered the whole form at once. Local difficulties prevented its development so that it did not gain the immediate recognition and praise accorded the iron press built to the designs of Charles. 3rd Earl Stanhope (1753–1816), by his engineer, Robert Walker. In this press a system of compound levers added to the power of the screw at the moment of impression.

Shortly after the beginning of the 19th century, many iighter and more powerful iron presses that dispensed with the screw were devised. The Columbian press, invented about 1813 by George Clymer of Philadelphia, used a system of compound levers and became popular in Great Britain, France and Germany. Most other iron hand presses incorporated a kind of knuckle joint. The pioneer among these was the press of John I. Wells of Hartford (Connecticut), patented in 1819, which was superseded by the Washington press of Samuel Rust of New York (1821). In Great Britain, the Albion press, devised about 1822 by R. W. Cope, shared, with Clymer's Columbian, the supreme position among iron hand presses throughout the rest of the 19th century. Its robustness and simplicity gave the iron hand press an almost unlimited working life.

The Cylinder Press and *the* Use of Power.—In 1790 William Nicholson of London patented a printing machine in which the sheet of paper passed between an impression cylinder and a cylindrical printing surface which was inked by a system of rollers. Although this machine was never built because of the difficulty of preparing a cylindrical printing surface, the most important advances of the next century were to be based on it.

The first power-driven printing machine was the work of Friedrich Konig, born at Eisleben in Saxony, who came to England in 1806. Encouraged by some of the London printers, he patented a machine in 1810 that was, in effect, a steam-driven hand press with automatic inking rollers. The first of these machines was built at the expense of Thomas Bensley, for whom it printed sheet H of the *Annual* Register in 1811 at a speed of 800 copies an hour. Konig's subsequent experiments, with an impression cylinder in place of the flat platen, led to an order for two machines from the *Times* (London). These were first used to print the edition of Nov. 29. 1814. which proclaimed itself "the first ne spaper printed by steam." They printed 1,100 sheets an hour on one side; the speed was later raised to 1.800. Konig also built a double cylinder machine that produced 750 sheets an hour printed on both sides. In 1817 he returned to Germany, where he set up his own printing machine works. Important improvements to his machines were made by Augustus Applegath and Edward Cowper, appointed engineers to the *Times* in 1818, who in 1827 supplied new machines capable of 4,000 to 5.000 impressions an hour. Among other early cylinder machines, the one built by David Napier in the early 1820s is notable for the introduction of grippers in the cylinder to hold the sheet of paper.

The mechanical advantage of the cylinder made it possible to print larger sheets. but the weight of the heavy type bed and the necessity for reversing directions as it moved rapidly backward and forward under the roller were severe limits on speed.

A machine following Nicholson's design, but with the type attached to the four sides of a revolving prism! was built by Brian Donkin (patented 1813), and in 1816 Cowper patented a means of forcibly curving stereotype plates, which could then be attached to a cylinder.

The Rotary Press.—The first rotary press employed a number of cylinders that rotated in contact with a central cylindrical printing surface. This obviated the need to move the flat beds of type. The first manufacturer to produce a successful rotary machine was Richard M. Hoe (*q.v.*) of New York, whose "type revolving machine" (patented 1845) was installed by the Philadelphia *Public* Ledger in 1847. The type was locked on a large central cylinder

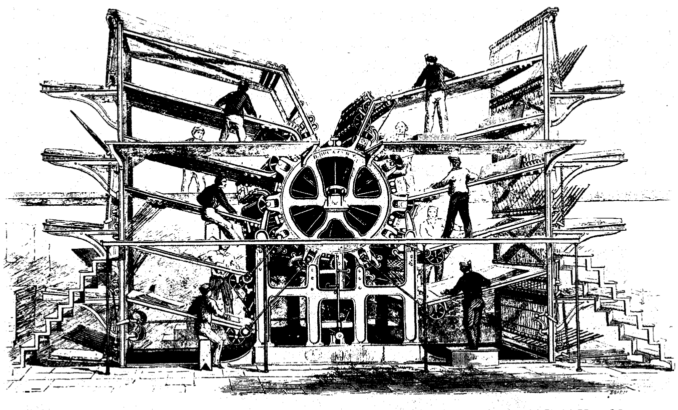

FIG. 2.—TEN-FEEDER "TYPE REVOLVING MACHINE" PATENTED 1845 BY RICHARD M. HOE

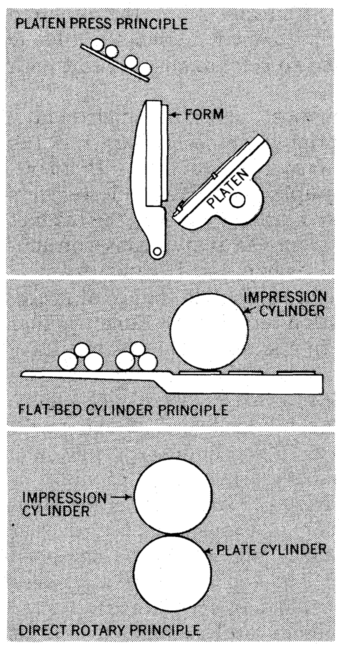
by means of wedge-shaped rules, and four impression cylinders were spaced around it, separated by four inking systems. Each impression cylinder was individually fed, so that the 2,000 revolutions an hour of the central cylinder (whose printing surface was in fact polygonal) produced 8,000 sheets printed on one side. Applegath produced a machine incorporating the same principles for the *Times* (patented 1846, erected 1848), with the difference that the axes of the type cylinder and eight impression cylinders were vertical. The Hoe rotary, with an increased number of impression cylinders, was imported into England to print Lloyd's Weekly Newspaper and in 1858 was adopted for the *Times*.

Two further developments were required before the rotary machine could be used efficiently: a new method of casting stereotype plates, and a mechanical device for feeding the paper. Following Cowper's experiment with forcibly curving stereotype plates, several attempts were made to cast curved plates. The substitution of papier mâché for the earlier clay or plaster mold (a French patent of 1829) enabled Charles Craske to cast curved plates for the New York Herald in 1854, and in 1861 Hoe presses were adapted to take such plates. In the early 1860s paper was still being fed to rotary machines by hand in individual sheets, although papermaking machines had been producing it in continuous webs since the first years of the century. In 1835, Rowland Hill produced an experimental type-revolving machine using a web or reel of paper, but the first application to a large rotary machine was made by William Bullock of Philadelphia. His machine (1865) cut the web automatically before it entered the impression cylinders. The *Times*'s engineers had been working on a rotary web press since 1862 and the result. their Walter press (named for J. Walter, then owner of the *Times*), was put into operation in 1866. When automatic folding devices were added to these rotary machines and a printing cylinder was added for each impression cylinder, the full benefits of the rotary principle were obtained. In the United States, the Hoe firm developed the multiple-unit press for the production of large newspapers.

Book and Job Presses.—The rapid pace of development in printing presses during the 19th century was mainly attributable to the demands of newspaper and periodical publishers, but press manufacturers also produced two important types of book-printing machines. In the stop-cylinder machine, the cylinder rotated in gear with the bed of type on its forward journey and remained stationary on the return of the bed. The best known of these was the Wharfedale, which was the outcome of the experiments of William Dawson and David Payne during the 1850s in the Yorkshire town of Otley. In the two-revolution machine, the cylinder turned continuously, making one complete revolution for each traverse of the bed. The impression was made on the bed's forward traverse and the cylinder was lifted clear for the backward traverse. At the same time the principle of the platen was not wholly abandoned; the Napier double-platen machine of 1830, in which two forms moved alternately beneath a central platen worked by a knuckle joint, was valued for the high quality of its output.

The machine that revolutionized job printing (the printing of small posters and handbills, cards and letterheads) was the treadle platen, produced in Boston (Mass.) by Stephen P. Ruggles in 1851 for printing cards. The vertical bed, holding the type, was hinged to the bottom of the platen, on which the paper was placed. This machine was developed by George Phineas Gordon, who used the same principles and the same source of power (a flywheel driven by a treadle) for his Franklin press of 1858; this press was widely known under the name of the inventor and, from that of its first English manufacturer, as the "Cropper." Gordon introduced more powerful machines, known as art platens, capable of printing wood engravings and halftone blocks. (Js. M.)

20th Century.—The 19th century saw a complete revolution in the mechanical principles of printing; before it was over the foundations of all modern techniques had been firmly established. By contrast, the improvements made in printing in the first six decades of the 20th century, in which so many major advances were made in almost all other branches of technology, were, in the main, relatively insignificant mechanical modifications. In 1900 the standard jobbing letterpress machines were the platen, the stop-cylinder and the two-revolution cylinder press; the rotary principle was employed on a large scale only in the web-fed newspaper field. The rotary offset was already in course of development, and both sheet-fed and web-fed rotary gravure presses were in operation. By 1950 the general situation had altered to the extent that offset lithography had usurped an important part of the letterpress field, but machines were scarcely more advanced technically: letterpress printing was carried out on flat-bed machines very similar to those in operation at the beginning of the century, and, indeed, many presses 50 to 60 years old were still operating and competing successfully with newer machines. Offset lithography presses were substantially identical in design to the first operational models introduced about 1905; and gravure printing had advanced little either in machine construction or in methods for preparing the printing surface. The only major printing process to have developed in the 20th century from the stage of an individual (and very ancient) art to that of a technology was screen printing.



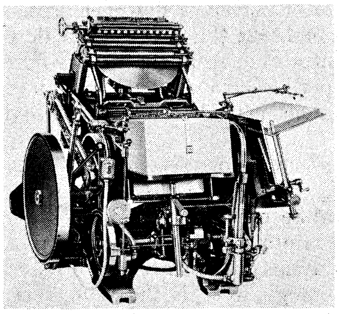
FROM J. S. MERTLE AND G. L. MONSEN, "PHOTOMECHANICS AND PRINTING"

FIG. 3.—PRINCIPAL METHODS OF PRINTING

Flat-bed Letterpress Machines.—In the early 1960s the letterpress machine was still, mechanically, the least refined of all printing presses. The flat-bed principle on which the majority of letterpress machines operates is extremely inefficient since it involves reciprocation, either of the type bed or. in the case of some platen presses, of both platen and bed. The reversal of direction creates two problems, one mechanical and one economic: first, considerable energy of momentum must be absorbed rapidly at the end of each movement without causing excessive vibration or heat; second, because the machine does not print on the return stroke. half of the total running time (on most presses) is unproductive.

In cylinder machines efforts have been directed to designing reciprocation systems in which the stopping and reversing part of the movement is speeded up so that it represents only a fraction of the complete printing cycle; as the form on the bed is not under impression during the return stroke it is possible to introduce special gear segments that take over the drive for this part of the cycle only. A letterpress cylinder machine known as the Printopress and introduced in Ireland in 1960 worked on an entirely different principle, developed from one of the many ideas born but then abandoned during the 19th century. In this press the bed remains stationary while a train of impression cylinders and an inking system moves around it on a planetary track.

Modern platen presses are available in a variety of ranges of size and speed; they are usually especially suited for a particular type of printing job. Most platen presses are used in small print shops for printing letterheads, handbills and similar matter. Their maximum printing areas range from about 7×11 in. to $14\frac{1}{2} \times 22$ in. and their speed ranges from about 2,000 to 5,000 impressions per hour. Most platens are operated by electric motors, are fed sheets automatically and print one colour at a time. Web-fed platens that print up to 6,000 impressions per hour have been developed.



BY COURTESY OF CHANDLER AND PRICE CO.

FIG. 4.— MODERN SHEET-FED AUTOMATIC PLATEN PRESS

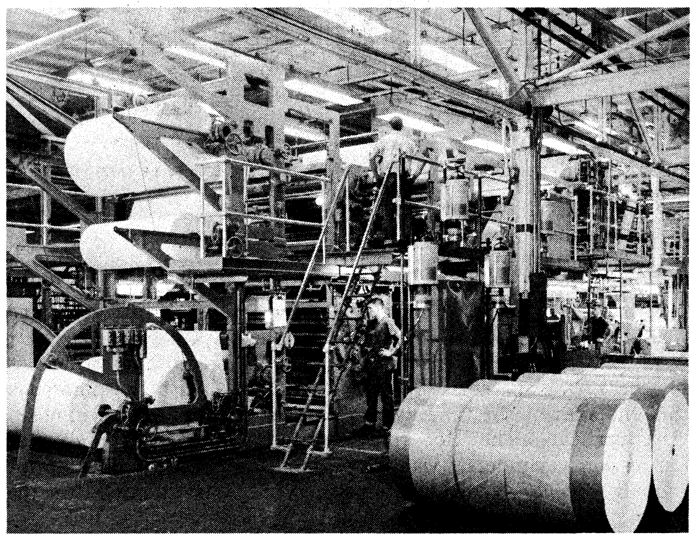
Most modern cylinder presses are designed to print sheets; their printing areas range from about $8\frac{1}{2} \times 11$ in. to $45 \times 68\frac{1}{2}$ in. Hand-fed cylinder presses produce about 2,500 impressions per hour; those with automatic feeding devices can produce up to about 6,500 impressions per hour. Cylinder presses, either sheet- or web-fed, are used to print books, magazines and other matter when good quality of reproduction is desired and when the required quantities call for press runs of up to medium length. These presses are also constructed to print two colours and to print both sides of the sheet.

Offset Lithography. — Possibly the most important single contribution of the 19th century to printing-press technology was the development of offset lithography (see LITHOGRAPHY: History). The great advantage of offset lithography over flat-bed letterpress is the rotary principle. In offset, the printing cylinder (the blanket cylinder carrying the image offset from the plate) runs continuously in one direction while the paper is impressed against it by an impression cylinder. There is no reciprocation, no change of speed, and the fundamental mode of operation remains the same whether the machine is sheet- or web-fed. In addition: offset plates, since they are thin sheets of metal, can be wrapped around the plate cylinder with ease. There is no need to cast or bend thick plates.

Offset presses are built in sizes ranging from that of the smallest platen to that of a medium-size rotary letterpress machine. For web-fed newspaper work, they have a maximum capacity of about 64 standard (or 128 tabloid) pages. These presses are built, as are letterpress rotary units, in four- or eight-page sections that can be arranged to suit the user. Such presses can be equipped for printing two or more colours. The top speed of a modern offset newspaper press is about 30,000 64-page (standard size) copies per hour. Sheet-fed offset presses can be equipped to print up to six colours in one run on one side of the sheet.

Rotary Letterpress. — Many difficulties are involved in printing letterpress by rotary means. The most common example of a rotary letterpress machine is the newspaper press, which has a number of inherent disadvantages: the curved or tubular printing plates, cast in stereo metal, require skill, experience and expensive equipment to produce and may crack under stress; the weight of the heavy plates (which can lead to damaging vibration in the axles of the plate cylinders) and unavoidable inaccuracies in their thickness make it necessary to print on a soft stock and against a soft rubber blanket if high press speeds are to be attained. This means that the quality of printing, particularly that of halftones, is not high.

Many nonmetallic materials have been investigated for molding letterpress plates in an attempt to find a surface combining sharpness with sufficient elasticity to give good halftone reproduction:

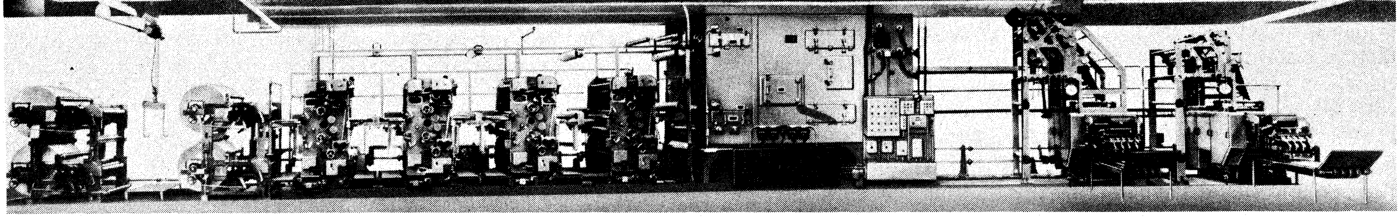


BY COURTESY OF R. R. DONNELLEY AND SONS COMPANY

FIG. 6.— MODERN ROTARY PRESS

these include rubber, Bakelite, polyvinyl chloride (PVC) and nylon. Apart from molding, letterpress relief plates can also be produced by embossing or etching. A small German press, the Printo. intended for use in offices, makes use of the embossing principle. A thin alloy sheet is placed in a standard typewriter, without ribbon, and the matter to be printed is typed onto it, giving a raised reversed image on the underside of the metal. The sheet can then be wrapped around the cylinder of the press and inked as a normal relief letterpress surface.

During the 1950s, following the introduction of new techniques for etching letterpress plates, there was a growing interest in the development of etched plates that could be wrapped around the cylinder of a rotary press and in the modifications necessary for this type of press. Within ten years, more than a dozen different models were in production! covering a wide range of sizes. A press using an etched metal plate differs from one using cast stereos in that the increased accuracy of the plate thickness makes great pressure between the impression cylinder and the plate unnecessary, only a "kiss" impression being required. For this reason modified offset machines were found eminently satisfactory in ex-



BY COURTESY OF THE AMERICAN TYPE FOUNDERS COMPANY, INC.

FIG. 5.—MODERN WEB-FED OFFSET LITHOGRAPHIC PRESS

periments. Modern production models of rotary letterpress machines closely resemble their offset lithography counterparts—indeed, machines adaptable to either process are available. Offset letterpress is also used in a number of applications, mostly of a specialized nature.

Modern sheet-fed rotary letterpress machines are used mainly for producing catalogues, magazines and similar long-run matter. Sheets ranging from about 21 × 15 in. to 52 × 76 in. can be handled, depending on the press. The number of impressions per hour ranges between 3.000 and 6,500. Up to six colours can be printed in one run. For long runs such machines usually can be adapted to print from a roll.

Modern rotary letterpress machines used in newspaper production are fed by web and are made up of basic 4- or 8-page units arranged to suit special needs. The speed of the newspaper press is limited by several factors; *e.g.*, the resistance of the paper web to breaking, the rate at which the paper absorbs ink, and the speed of the mechanisms that collect and fold the printed paper. The units of the press can be arranged in a straight line on one level or can be stacked in several decks. The total capacity of a press varies according to the size of the paper; for example, in the U.S. the capacity of dailies with 10,000 or less circulation averages about 16 pages, those with 10,000 to 50.000 circulation usually have a capacity of between 24 and 48 pages and those with more than 50,000 circulation may be able to print as many as 128 pages in a run. Extra pages can be inserted into an issue by hand or with special folding machines. Web-fed rotary letterpress newspaper machines can print up to about 60,000 copies of 128 standard-size pages per hour; in the interest of reproduction quality and wear and tear on the press, however, newspaper presses usually are operated at about only three-fourths of their rated top speed. Large daily ne spapers may operate as many as ten 128-page press units at one time in order to produce an edition quickly.

Advances in the Printing of Sheets.—Since 1900 the bulk of development in sheet-fed presses, whether printing by letterpress. planographic or intaglio process, has comprised a series of minor mechanical modifications designed to improve the speed of the machines. Stops in sheet-fed presses have been designed that do not cause the sheet to bounce back as it is being fed to the cylinder, and complex mechanical feeders have been devised to work at very high speeds. Swinging grippers take the sheet and accelerate it to the peripheral speed of the cylinder; after the sheet is printed it is taken by other grippers on a continuous chain and delivered printed side up onto a pile; special airblow devices can be employed to slow up the sheet as it is released. To prevent the transfer of wet ink from one printed sheet to the next, a powder or liquid is sprayed on each sheet as it is delivered or the sheet is passed quickly over a small flame to speed drying.

Advances in Web Printing.—In the early 1930s the need for printing mass-circulation magazines at high speed became urgent. To increase the speed of printing on web with the rotary letterpress, methods for drying the printed image to set the ink were introduced. Better plates and paper quickly followed. By 1950 the web-fed rotary letterpress became an immense machine; some models weighed up to 200 tons and produced four- and five-colour folded signatures on smooth, coated paper at the rate of 20,000 per hour. Automatic paper reels also were introduced; these allowed new rolls of paper to be spliced to old ones without slowing the press.

Advances in Rotogravure.—Until the 1950s, rotogravure in the C.S. was used primarily to print newspaper supplements. The quality of this work was generally unsatisfactory because of poor colour register and variations in ink and colour. The introduction of photoelectric means of controlling colour register and of instrumentation for controlling ink density made high-quality rotogravure work possible by the late 1950s. After that time, complex 10- and 12-unit multicolour rotogravure presses with automatic paper reels were used to print magazines and catalogues at speeds up to 25,000 revolutions per hour. (B. I.)

PRINTING TYPE. This article discusses the design and designing of printing type from its earliest times down to the present. Related material will be found in TYPESETTING; TYPOGRAPHY; PRINTING; PRINTING PRESS.

The Beginnings.—The invention in Europe of printing with movable metal types, in the middle of the 15th century, introduced the principle of mechanical mass production to a world in which nearly all man-made objects were made one at a time by hand. The earliest designers of printing types were the goldsmiths and other skilled metal workers whose experience with coinage and medal cutting for replica casting enabled them to attack the far more complex task of carving and filing in steel the sets of male dies called *patrones,* or punches; *i.e.,* model letters to be reproduced in quantity as characters on the faces (flat printing surfaces) of a font of type. The cutting of letters on so minute a scale, with strict consistency in the treatment of straight lines and curves throughout an entire alphabet, demanded a degree of manual skill which seems all the more spectacular in contrast with modern methods of cutting punches pantographically by power-driven tools from large mechanical drawings. But in admiring the virtuosity of the early punch cutters it is too easy to overlook their greater role in history; *i.e.,* that of the first practising industrial designers. What they were making by hand was only a means toward what they were actually designing for batch production, namely the appearance of printed words on paper: specifically the ink prints of type in some particular size and style of a face (design) which would indicate, to a predicted class or group of readers, the general nature and purpose of the book at hand.

FIG. 1.—ALTERATION OF LETTERS IN SAME BODY SIZE BY CHANGING LET- ’’’ WIDTHS ’’’ LENGTHS •’ ’’ CENDERS AND DESCENDERS

The pioneer punch cutter, like any other designer for industry, had to take into account successive mechanical processes which might affect the appearance of the multiple end product. Thus the different letters of the alphabet had not only to be consistent in the treatment of stems, curves and serifs (fig. 2) but also had to appear on the printed page in accurate alignment, a matter which would partly depend upon the successful processing of the brass matrices (female dies) that were to be struck from the punches. The types that were to be cast in molten metal from the matrices would have to fit together snugly into whole word shapes with no distracting gaps between the individual letters. Further allowance had to be made for the effect of the printing: the primitive wooden press would be driving an inked form. or forme, of composed type with heavy pressure into damped sheets of handmade paper and the resulting "squash" of viscous ink would leave the printed images of the characters looking considerably thicker and somewhat less sharp in detail than their steel prototypes. The modern type designer faces similar problems, made more complex by the variety of paper surfaces and reproduction processes in use today.

FIG. 2.—TYPE SAMPLES SHOWING DIFFERENT TREATMENTS OF THICKS. THINS AND SERIFS (TERMINAL STROKES)

Above all, the early punch cutter knew that the printed pages would come as bound books into the hands of readers who were accustomed not simply to deciphering the code symbols of the roman alphabet as such but to distinguishing between different kinds of books at first glance by their conventional styles of lettering. What links the modern type draftsman to the Renaissance punch cutter. and labels them both as type designers, is the need to look ahead through a long chain of production stages toward the ultimate object of all typographic design—the conveyance to the reader of meaningful texts through letter images which that reader will accept as appropriate to that particular kind of printed matter.

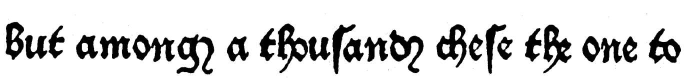
Printing created its own, entirely new kinds of "matter" (notably the periodical), which in turn had to be envisaged by the type designer as functional problems in legibility. From the early 19th century onward, competitive advertising opened up the distinct field of "display" type design ("jobbing") in which the ruling intention is the very opposite of that which disciplines the designer of type for continuous reading. Letters for a handbill may legitimately imitate any fantasy or distortion of sign writing, for the aim is to arrest and focus attention on a few words. The bold type which appears in various modern works of reference (such as dictionaries and timetables) has the similar purpose of attracting the searching eye quickly to the relevant entry by its abnormal thickness. Type for continuous reading has the contrary aim; it must carry the reader forward through line after line by its self-effacing conformity to whatever norm of legibility the reader counts upon for that particular kind of text. Thus the deliberate exploitation of abnormality in type design is a relatively new development and the inventors of eye-catching advertising types, represented by thousands of different designs since the beginning of the 19th century, seem far closer to sign writers than to the metal cutters of the days when books and booklets constituted almost the whole output of the printing press. Even in the earliest years the designers of type were accepting the principle, already fixed by the medieval scribes, that different sorts of book—liturgical, legal, revived-classical, popular-vernacular—should have different styles of letter.

Fortunately for Johann Gutenberg (*q.v.*) and the goldsmith whose services he used while he was at work on his invention, the northern scribes had evolved a formal script for use in short double-column lines, in which high legibility-for-size was gained by the use of a broad stiff pen that gave maximum thickness to the down strokes. To achieve this blackness with least waste of space, curves were condensed by being broken into angles and straight segments. The resulting textura script offered the metal engraver a model peculiarly suited to his file and burin. The readers of a folio bible in double column expected it to be set forth in this strong angular style of letter; hence the 42-line Bible (Mainz, *c.* 1456) gave them no jar of novelty (fig. 3). The round gothic associated with theological and legal texts in Latin, then the international language of the professional literates of Europe, was also relatively easy to reproduce in metal. It too had been evolved

Quod cũ audisset david: descendit in

FIG. 3.—LINE OF TYPE FROM 42-LINE BIBLE, ISSUED AT MAINZ; 1456. ACTUAL SIZE

for use mainly in narrow columns, where the amount of white space between the lines can safely be reduced by shortening the descenders and ascenders and thus increasing the apparent size of the letters. The stubby descenders of the prevailing black letter styles were well adapted to the type cutters' need to strike matrices by hammering the hardened letter punch into a slab of brass. The more informal and free-swinging bastarda style, mainly used for books in the mother tongue, again required little more than simple imitation (fig. 4).



But among a thousand these the one to

FIG. 4.—CAXTON. TYPE NUMBER TWO, FROM DICTES OR SAYENGIS OF PHILOSOPHRES, WESTMINSTER: 1477. ACTUAL SIZE

But as printing spread from Germany to the Italian cities, the pioneer punch cutters faced their first insuperable problem: that of reproducing in separate metal letters, and eventually in type prints, the delicate, open-curved, long-descender style of calligraphy with which the humanist scholars and their scribes were optically distinguishing texts in the Latin of classical antiquity—or their own sedulously "Ciceronian" Latin—from those in the modernized Latin of the schoolmen and lawyers. To the humanists, the "language of divine antiquity" was not only to be studied and imitated, it had even to be equipped with its own style of script in which subtlety and elegance, lightness and amplitude would replace the bold simplicities of the styles which were given the contemptuous sobriquet of "gothic." The script revived by the humanists for this purpose was the minuscule standardized by Alcuin under Charlemagne at the beginning of the 9th century. The type cutters never succeeded in producing a plausible imitation of it in metal; but as crude attempts at copying gave way to deliberate paraphrase in terms of metal casting, what emerged was the first new contribution of type design as a creative art; *i.e.*, the kind of letter which is now called roman, or in French *romain*. Today the word is used broadly for "ordinary print" as distinct from anything exotic or attention-catching. But in Germany, where black letter survived as a language-linked style (Fraktur, Schwabacher), roman still bears its historical name of Antiqua.

Nicolas Jenson, formerly master of the royal mint at Tours,

Quare multarum quoq; gentium pacem diu

lower case and its inscriptional style capitals on the rising tide of humanist scholarship by perfecting a type which became the model for the great French type cutters of the next generation, notably Claude Garamond, and so the direct ancestor of a long line of roman fonts, many of which have been revived for present-day use.

Aldus' roman of 1495 appeared in a literary exercise by Pietro Bembo, the humanist poet, later cardinal, who probably took a personal interest in its typography: successive copies show many variants made while the work was on the press.

Aldus' "pocket editions," dating from 1501, made the first use of the kind of type now known as italic; it originated with him as an imitation of the cursive minuscule in chancery style in which scholars had been swiftly copying out coveted texts. Italic was later equipped with its own sloped-roman capitals and adopted as an auxiliary to roman by being cast in alignment with it.

The subsequent history of roman type design falls into four distinct periods. Through the 16th and 17th centuries its treatment by successive engravers varied only in subtle detail, scarcely perceptible to the layman's reading eye, and its debt to the calligrapher remained evident in the angle of thickening or "stress" of the curves and serifs of the lower case. Type founders began, however, to offer alternative fonts of the same body size: one series (of sizes from small to large) for normal bookwork, with the longer descenders that help to create a channel of white space between the lines, and a larger-looking version with short descenders and condensed curves, suitable for narrow columns such as those of the periodical.

Transition and Revival.—The first effort to rethink and rationalize type design came in 1692–93 when Louis XIV commissioned his academicians to devise, and Philippe Grandjean to produce, a new series of roman and italic for the royal printing office.

e, 25 d'Aouſt, le Gouverneur ſe rendit à l

FIG. 7.—ROMAIN DU ROI, TYPE DESIGNED FOR KING LOUIS XIV BY P. GRANDJEAN. USED IN ROYAL PRINTING OFFICE. PARIS; 1702. ACTUAL SIZE

Type cutting entered its "transitional" phase in which sharp thick-thin contrasts brought a new look to the page. In Paris in the middle of the 18th century the learned printer-type founder P. S. Fournier developed the new style in one direction, with ingenious decorative use of *fleurons*, or border units, cast as type. At the same time John Baskerville in Birmingham, Eng., commissioned a rounder and still more sharply cut roman and italic, one which showed off the elegance of his hot-pressed paper and improved ink. Baskerville's chaste neoclassic style had a profound influence on European type cutters.

The transition was in effect from "this style" to "**this** style," used by G. Bodoni and introduced in France by the Didots shortly before the French Revolution. Here the graver declared its independence from the quill, italic forgot its current script ancestry and the abandonment of the "long s" (ſ) drew the only dividing line in the whole history of roman type that is immediately obvious to the uninstructed reader.

The new short-s style with strong vertical stress and hair-thin horizontals became the prevailing mode for books and periodicals for the first half of the 19th century and the long-s fonts were melted down as antiquities. But just as the humanists had turned from the rigidities of gothic to their "antique" roman, so the Romantic movement in England brought a new appreciation of the "old" (pre-Baskerville) type cut by William Caslon, the first meritorious English punch cutter and letter founder. in 1720. A font preserved by the Caslon type foundry as a museum piece was used as a pastiche type at the Chiswick press from 1840. It found favour among antiquarians and liturgical publishers. In France, the "old" types of the 17th-century Elzevir editions became the inspiration of tentative revivals. The Scottish type foundry of Miller and Richard, sensing a change of taste, brought out in 1860 their historic (to contemporary taste) modification in which for the first time the "old" style reappeared, without its long s, as an alternative to the "modern."

Present Era.—This opened the present era in type design, with the new notion of offering publishers or customers a choice of different styles of roman. At first it meant a costly duplication of the printer's type storage facilities; but the coming of the hot-metal composing machine reduced the problem to that of a simple change from one set of matrices to another. The term modern lost its meaning of "ruling mode of today" and became trade jargon for the sharper-cut style: "old style" and "old face" lost their antiquarian reference and took on a purely morphological meaning.

A present-day printer's type specimen book may offer an even wider variety of "composition faces" (for continuous reading) than is shown below (fig. 8). These examples, all of type faces in commercial use, are selected to indicate the different historical periods from which designs have been revived (with or without intelligent modifications) to meet the modern publisher's need for variety in taste and also for technical and economic reasons. Type (C), for example, is particularly suitable for printing on coated paper, which requires a very light impression; (E) is broad, (D) relatively condensed, and the difference can either save or bulk out 25 pages in a 248-page novel. (M) is effective in the long line of a book, where the space allowed for its deep descenders leaves a useful channel between the lines. but it is inefficient in narrow columns.

From 1885. Linn B. Benton's punch-cutting machine began to replace the hand craftsmen. New faces could thenceforth be drawn to any scale and cut with microscopic accuracy, in any type size from the same master pattern. The invention had little or no direct, immediate effect upon type design, for 19th-century punch cutters were not employed as creative designers; their pride was in their own manual skill, and there the machine surpassed them. The influence of the Benton machine was first shown in the emergence of the family of different versions (bold, condensed, etc.) of the same basic design—variants easily contrived by alterations to 10-in. drawings. Cheltenham, a roman designed by the U.S. architect B. G. Goodhue in 1905, failed as a book face but became the first runaway success in cotnmercial printing as a family of many variant weights and widths. But meanwhile Benton's invention had made possible the composing machine; this major innovation was indirectly responsible for the emergence of a new class of types—the first bridge ever thrown between the quiet

Gill, 1928; (P) Palace Script, copperplate jobbing face; (Q) Egyptian, slab-serif jobbing face world of "book" faces (for continuous reading) and the restless, occasionally raucous and hitherto completely separate world in which the small jobbing printer's compositor had been confecting auction. theatrical and other "bills," trade cards, etc., from an ever-growing range of poster-like or otherwise attention-catching jobbing types.

Those faces, called in French *lettres de fantaisie,* had throughout the 19th century provided a not unprofitable sideline for the type founders. whose main income depended on the book and periodical printers' demand for ordinary text type in the tonnages required for hand composition. Since no one took advertising seriously to begin with. no self-consciousness inhibited the inventiveness of its type designers and their licence to impudence was exploited with honesty and gusto. Delicate pseudocalligraphic script types had appeared for commercial and society printing before the Industrial Revolution, but now "shock" types offered a new field. Capitals without serifs or thick-thin stress (sans-serif) were in use before 1825; fat black "Egyptians" (slab-serif) multiplied. The lithographic lettering artist's free fancies (*e.g.,* on music title pages) prompted the punch cutters to new feats of skill. Much of the most self-conscious avant-garde typography of the 20th century has drawn upon the early Victorian job printer's repertory; the crude sans-serif called "grotesque" ("grot") has been most often resuscitated for modern experimentalist display.

The new composing machines swept away the type founders' main market and left jobbing types as almost their sole remaining stock in trade. American type founders, banding together under the threat of extinction, began to give serious aesthetic attention to advertising faces. Under the new and respectable name of "publicity types." classic faces of the past were revived primarily for use in brochures and displayed press advertising, which the newly arriving advertising agencies were treating with a solemnity unknown to the old handbill printer. Thus book and display faces drew at least within sight of each other. Today, a fine book face is normally cut in sizes up to an inch high, where abnormality of size is alone enough to make it attention-catching; contrariwise, grotesques and sans-serifs have been used in small reading sizes by designers anxious to devise a "contemporary" style—for reasons more sentimental than rational, since no amount of respect for the machine age will reconcile book readers to alphabets which make it hard to distinguish I and l, or a from o.

Sans-serif and other monotone letters have, however, a functional justification in commercial printing, for they can retain their family characteristics through extremes of all-over thickening, condensing, expanding and so on. The sans-serif designed by the English sculptor Eric Gill is a widely used example of the serious treatment of monotone alphabets with care for legibility. Its adoption as a design family for railway printing caused it to proliferate into 25 design variations under the family name of Gill Sans.

The 20th century has seen eclecticism in type choice conquering the earlier' concept of one predominant taste in roman type design succeeding another and rendering it obsolete. In the disciplined book type field, where any queerness or romanticism is fatal, modern designers must compere with the greatest masters of past centuries. Very few new claimants to a place in the book printer's repertory have stood up to that rivalry. In 1932 the *Times* (London) commissioned a roman in the general style that the Dutch letter cutters had evolved for periodical work; *i.e.,* large-appearing, relatively narrow and gaining legibility by the tilted stress of the "old" style. Composing machine manufacturers were permitted to market the face commercially, and its world-wide popularity has made it the nearest approach that an eclectic century has to anything that could be called its own characteristic contribution to history. But modern multiplicity of processes, paper surfaces, different uses for print, to say nothing of the advertiser's constant demand for variety, prevent type design from settling back into the succession of ruling styles and fashions which characterized the centuries in which printing was in effect book printing and used one kind of paper (handmade rag) and one process of multiplication (direct letterpress).

The major languages of scholarship (Greek, Hebrew, Arabic) were exercising European punch cutters from the cradle years of printing. and missionary zeal quickly extended their range. Those nearest to the Latin alphabet, *e.g.,* Russian Cyrillic, have undergone parallel changes in style treatment; Arabic remains purely and stubbornly a calligraphic minuscule. No script among the hundreds which western type founders class as "exotics" has achieved the efficiency and adaptability of the roman font with its different member-alphabets—A, a, *A, a,* A and, where required. "related bold" **A, a.** It will not replace the other great scripts, but as a supranational vehicle of communication it has no rival.

The word "type" is broadly but legitimately used for the printed letters on the page, which are no longer necessarily the prints of metal types; they may be from metal. rubber or plastic plates which, today, need not have been taken from metal printing types; the images may have been photographically composed onto sensitized film. Hence the designers of new faces for filmsetting will still be type designers, subject to the same discipline where continuous reading is concerned and permitted the same licence in the display field, where film offers new possibilities; *e.g.,* novel alphabets can he quickly produced and distorted at will by the camera. Book faces, however, will require extra forethought. The old engravers, who had, of course, to cut a new set of punches for each successive size, subtly altered the proportions and colour value each time for optical consistency. In filmsetting, one set of master letters may have to serve for every size from footnote 6-point upward, and the best designs for filmsetting will be those which best survive arbitrary enlargement and reduction. But film imposes no other mechanical limitation upon the type designer —to his regret. for he would welcome any such technological challenge as stimulating as that which confronted the pioneer punch cutters.

PRIOR, MATTHEW (1664–1721), English poet and diplomatist. was born in Wimborne, Dorset. July 21. 1664, the son of parents of modest station. His humble origin led to occasional difficulties in his diplomatic career, but did not prevent him from moving in distinguished company all his life. He was educated at Westminster school, where he made friends with Charles Montagu, later earl of Halifax. Both went on to Cambridge, and in 1687 collaborated in a piece of mockery directed at Dryden, *The Hind and the Panther Transvers'd to the Story of the Country Mouse and the Town Mouse.* In 1688 Prior's college. St. John's, elected him to a fellowship, which he retained until his death: but he soon entered diplomacy as secretary to the embassy at The Hague. Before long he was given responsible positions, and in 1697 was made secretary to the plenipotentiaries at the peace of Rijswijk. Next year he was transferred to Paris as secretary to the embassy.

He had already written a good deal of verse. both formal and occasional; and throughout his life he maintained his output of what he modestly described as "Public Panegyrics. Amorous Odes. Serious Reflections, and Idle Tales, the Product of his leisure Hours, who had Business enough upon his Hands—and was only a Poet by Accident." His lighter poems were marked by an ease, gaiety and grace unsurpassed in English literature. It is for his mastery in this field that he will always be most admired, although he could at times strike a more sombre note with telling effect. Perhaps his masterpiece is the poem known as "Jinny the Just," which remained in manuscript until the 20th century.

In 1699 he returned from France and sat in parliament in 1701 as member for East Grinstead, being also appointed a commissioner of trade and plantations. Soon after the accession of Queen Anne he transferred his support to the Tory party, and became the trusted confidant of Harley (later earl of Oxford) and St. John (later Viscount Bolingbroke). When the Tories came to power in 1710 his diplomatic talents were again employed. He was concerned in the negotiations which led to the peace of Utrecht; from

1712 until 1714 he resided at Paris as plenipotentiary.

After the death of Queen Anne he was recalled, and shared in the troubles which awaited the leading Tories; but despite rigorous examinations he refused to disclose the secrets of the fallen ministers who were his friends. During two years of mild confinement he wrote *Alma, or the Progress of the Mind,* a discursive and often subtle exercise in Hudibrastic metaphysics. In 1718 he published a stately folio of his collected poems, including *Alma* and his other long poem *Solomon on the Vanity of the World,* a didactic work completed at least a decade earlier. He passed his last years mainly with Lord Oxford, by whose family and household he was greatly beloved. Oxford bought for him a small property in Essex, Down Hall, to which he grew much attached. But his health had never been robust; and he died at Oxford's seat, Wimpole in Cambridgeshire, on Sept. 18, 1721.

As a diplomatist Prior proved himself an excellent negotiator, adroit, resourceful and clear headed. He was gifted with a personal charm and a sweet temper uncommon among the wits of his age. Most contemporary references to him are kindly, and he was fortunate in his friends in every walk of life. He never married, but maintained relations with various women from humbler circles than those in which he habitually moved. Little is known about them; but they included the much-loved Jinny, the subject of his most tender and moving poem.

PRIOR, a title applied generally to certain monastic superiors, but also in the middle ages to other persons in authority. Under the Roman Empire the word *prior* is found signifying "ancestor." In the early middle ages it was commonly applied to secular officials and magistrates, and it remained all through the middle ages as the title of certain officialsin the Italian city states.

In the Rule of St. Benedict and other early rules the titles *praepositus* and *praelatus* (*see* PRELATE) are generally used, but *prior* is also found signifying in a general way the superiors and elders in a monastery; afterwards the title prior (or *claustral* prior) was restricted to the abbot's vicegerent, who was generally charged with the details of the discipline of the monastery. With the foundation of the order of Cluny in the 10th century there appeared the conventual prior, who ruled as head of a monastery. The Regular Canons, and the Carthusians and Dominicans, later gave this title of prior to the heads of their houses

See Sir W. Smith and S Cheetham (eds.), *Dictionary of Christian Antiquities* (1875–80); "Prior" in the *Catholic Encyclopedia.*

PRISAGE AND BUTLERAGE, the names of ancient English customs duties which survived until the beginning of the 19th century. The oldest was a wine duty. Later it became customary to levy upon wool, woolfells and leather. This "customs" duty was known as "prisage." The earliest known prisage was levied in kind; one tun of wine being taken from every cargo of from 10 to 20 tuns, and two tuns from every cargo exceeding 20 tuns; a tun being 252 gal. The king's man took the liberty of sampling all the wine so that the king got his tun or tuns from the best on board. Later. importers were allowed to make a money composition instead of paying in kind. Prisage was payable both by British citizens and aliens.

In the reign of Edward I, by a charter known as *Carta Mercatoria,* aliens were given liberty of trading upon paying "to Us and to our Heirs, by the name of Custom, two shillings (for every hogshead of wine) over and above the antient customs due." This duty was made payable to the king's butler. and was consequently termed "butlerage." Later kings of England granted the produce of the duties of prisage and butlerage to certain of their subjects. In 1785 it was recommended that these duties should be revested in the crown. Thus, the duties of prisage and butlerage in Ireland had been granted to the dukes of Ormond, but parliament purchased those rights for nearly £200,000. In 1809 the duties were abolished by the Custotns Consolidation act of that year.

PRISCIAN (PRISCIANUS CAESARIENSIS) (*fl. c.* A.D. 500), the best-known of all the Latin grammarians, author of the *Institutiones grammaticae* which, together with the work of Aelius Donatus, had a profound influence on the teaching of Latin and indeed of grammar generally in Europe. He was born at Caesarea in Mauretania (the modern Cherchel in Algeria), but taught in &nstantinople. His minor works include *De nomine, pronomine et verbo* ("On Noun, Pronoun and Verb"), an abridgment of part of the *Institutiones guammaticae; Partitiones xii versuum Aeneidos principalium* ("The Parsing of the First 12 Verses of the *Aeneid"),* for the teaching of grammar in schools; a treatise on weights and measures; a treatise on the metres of Terence; *Praeexercitamina,* an adaptation for Latin readers of some Greek rhetorical exercises; a panegyric in verse on the emperor Anastasius I (*see* E. Bahrens, *Poetae Latini minores,* vol. v, 1883); and a verse translation of Dionysius' *Periegesis* (*see* the critical edition by P. van Woenstijne, 1953). Priscian's *Institutiones grammaticae* ("Grammatical Foundations") is a systematic exposition of Latin grammar. Of the 18 books into which it is divided, the first 16 deal mainly with sounds, word-formation and inflexions; the last 2 (which form nearly one-third of the whole work) with syntax. As far as possible Priscian takes the works of Apollonius Dyscolus on Greek grammar as his guide. He draws illustrative citations from many Latin authors and has thus preserved numerous fragments which would otherwise have been lost (for the text of the grammatical works *see* H. Keil, *Grammatici Latini,* vol. ii and iii, 1855–59).

Priscian's work was quoted by Aldhelm in the 7th century and by Bede and Alcuin in the 8th, and was much used by Rabanus Maurus and by Servatus Lupus of Ferrières in the 9th. Subsequently it became the standard work for the teaching of grammar in the medieval schools; and it provided the background for the rise of speculative grammar (the logic of language) in the 13th and 14th centuries. There are about 1,000 manuscripts extant. Of these, the greater part contain only books i–xvi (called *Priscianus major);* a few contain books xvii and xviii *(Priscianus minor)* and some of the minor works; and a few contain all 18 books of the *Institutiones.* Apart from fragments, the oldest manuscripts are of the 9th century. The first printed edition was that of 1470, at Venice.

(R. H. Rs.)

PRISCILLIAN (d. 385), Spanish theologian and the founder of a party which, in spite of severe persecution for heresy, persisted in Spain and in Gaul until after the middle of the sixth century. He was a student of the occult sciences and of philosophy. He was a mystic, and regarded the Christian life as continual intercourse with God. He argued that to make himself a fit "temple of God," a man must, besides holding the Catholic faith and doing works of love, renounce marriage and earthly honour, and practise asceticism. On the question of continence in, if not renunciation of, marriage, he came into conflict with the authorities. Priscillian and his sympathizers, who were organized into bands of *spiritales* and *abstinentes,* like the Cathari of later days, refused the compromise which by this time the Church had established. (*See* MARRIAGE: *Canon Law*) This explains the charge of Manichaeism levelled against Priscillian and to this was added the accusation of magic and licentious orgies. Priscillian's friends included two bishops, Instantius and Salvianus, and Hyginus of Cordova; but, through the exertions of Idacius of Emerita, the leading Priscillianists, who had failed to appear before the synod of Spanish and Aquitanian bishops to which they had been summoned, were excommunicated at Saragossa in October 380.

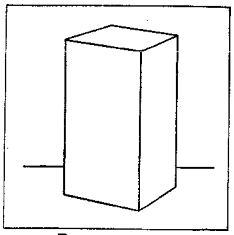
Meanwhile, however, Priscillian was made bishop of Avila, and the orthcdox party appealed to the emperor (Gratian), who issued an edict (afterwards withdrawn) threatening the sectarian leaders with banishment. On the murder of Gratian and accession of Maximus (383) Idacius fled to Treves, and secured the summoning of a synod (384) at Bordeaux, where Instantius was deposed. Priscillian appealed to the emperor, with the unexpected result that with six of his companions he was burned alive at Treves in 385.

The heresy, notwithstanding severe repressive measures, continued to spread in France as well as in Spain. As an openly professed creed it only disappeared after the second synod of Braga in j63.

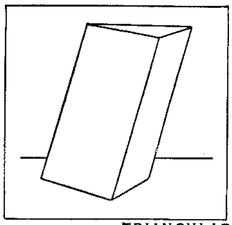
At the Council of Toledo in 400, 15 years after Priscillian's death, when his case was reviewed, the most serious charge that could be brought was the error of language involved in rendering ἀγένητος by *innascibilis.* It was long thought that all the writings of the "heretic" himself had perished, but in 1885 G. Schepss discovered at Würzburg 11 genuine tracts, since published in the Vienna *Corpus.* "They contain nothing that is not orthodox and commonplace, nothing that Jerome might not have written."

See *E. C.* Babut, *Priscillian et le Priscillianisme* (Paris, 1909).

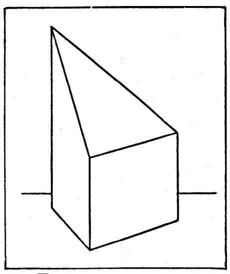
PRISM, in geometry, a polyhedron having two of its faces, known as *bases,* congruent (identical!:; equal) polygons in parallel planes, and the other faces parallelograms equal in number to the sides of the bases. The faces, excluding each base. are called the *lateral faces,* and the intersections of these faces are called the *lateral edges,* being all equal. The perpendicular distance between the planes of the bases is called the *height* or *altitude* of the prism. If the lateral edges are perpendicular to the planes of the bases, the prism is called a *right prism;* if they are oblique to these planes, it is called an *oblique prism.* Prisms are said to be *triangular, quadrangular, pentagonal* and so on according as their bases are triangles, quadrilaterals, pentagons and so on. A prism having parallelograms for its bases is called a *parallelepiped.* If the bases and lateral faces are all rectangles, it is called a *rectangular parallelepiped.* The part of a prism included between the base and a section made by a plane oblique to the base is called a *truncated prism.* A geometric solid which has for its bases two polygons in parallel planes, and for its lateral faces triangles or trapezia (U.S., trapezoids), with one side in one base and the opposite vertex or side in the other base, is called a *prismoid,* a prism being a special case. In optics the word denotes a triangular prism. The volume of a prism of base B and altitude a is aB; of a prismoid with bases B and B', altitude a and area of a mid-cross section M, is $\frac{1}{6}a\,(B+B'+4M)$. *See* CRYSTALLOGRAPHY; LIGHT; REFRACTION; and SOLIDS, GEOMETRIC.



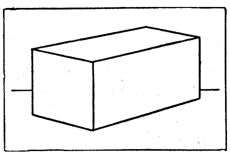
RIGHT PRISM



OBLIQUE TRIANGULAR PRISM



TRUNCATED PRISM



RECTANGULAR PARALLELEPIPED

PRISMOID, a solid bounded by any number of planes, two of which are parallel and contain all the vertices. The two parallel faces are called the *bases.* The volume V of such a solid was found by Thomas Simpson (1710–61) as follows: Let M be a section made by a plane parallel to the bases B and B' and midway between them, and let h be the distance between the bases. Then $V=\frac{1}{6}h(B+B'+4M)$, a formula frequently used in finding volumes and applicable to most of the elementary geometric solids, and in general to any solid bounded by a ruled surface and two parallel planes.

PRISON. In penal systems the function of the prison is threefold: custodial. coercive and corrective. In Roman law the *Digest* of Justinian established the custodial principle with the statement that "a prison is for confinement. not for punishment," and in countries that followed Roman law the principle that imprisonment was not a legal punishment was dominant for 1,000 years. In England also, the high court judges went out to "deliver the gaols"—to clear them, not to fill them. The prisons of the middle ages were therefore concerned only with holding prisoners awaiting trial.

The coercive function was added when, the punishment awarded being a forfeiture of property, the prisoner might be held until the fine or compensation was paid. This function is still active in England, since those committed for nonpayment of fines or debts or for contempt of court may secure release by paying what they owe or purging their contempt.

EUROPE

In England the earliest lawful prison was the common jail. which in legal theory was the king's jail, and in 1403 it was enacted that justices should commit offenders only to the common jails. Mediaeval jails were not specially provided buildings—castle tower, abbey gatehouse or inn cellar might serve. The keeping of jails was farmed out to private persons, whose only responsibility was the'safe-custody of the prisoners, their only interest to make the greatest profit from the fees they were permitted to charge them. To these forcing houses of contagious pestilence and moral corruption every type of prisoner was committed. with no adequate separation by age, character or even sex; and they so continued with little change and less disturbance of general public conscience until the latter part of the 18th century.

Sot less brutal and chaotic than the jails was the penal system they served. By the 16th century the mediaeval system of compensation was giving way to the capital penalty for major offenses, while for minor offenses fines and such punishments as whipping or the pillory were usual. But not all persons found guilty of capital offenses were executed. On the continent there was committal to the mines, galleys and fortifications. In England many escaped under "benefit of clergy" or under crown pardons on condition of agreeing to be "transported beyond the seas" to the American plantations. This practice received statutory sanction in 1679 and was regulated by a statute of 1717. In England the social and economic conditions of the Tudor period led to a poor-relief system enforced through the local justices. Houses of correction were set up for those of the unemployed who required compulsion to work and others who required "to be corrected in their habits by laborious discipline." The first was set up in London in 1553 in the former royal palace of Bridewell, from which they derived the popular name which lingers to this day, and in 1576 justices were required to provide one in every county.

On the continent a similar movement derived from the house of correction known as the Rasp Huis, established in Amsterdam, Neth.. in 1595. The purpose of houses of correction was not that of criminal lam, to cut offenders out of society by banishment or death. but the opposite—to bring them to good citizenship by the discipline of industry. education and religious instruction. Gradually, however, the penal implications predominated; industry as training gave way to hard labour as punishment, and during the 18th century houses of correction became instruments more of penal than of poor law. In England they became assimilated to the jails in all but name, and in 1865 the legal distinction was abolished.

Yet the idea of correction was to have continuing life, in England through the work of John Howard (*q.v.*) and on the continent through the influence of such historic houses of correction as that of Ghent, Belg., or of St. Michael in Rome, It.,—the first penal establishment to be set aside for reclaiming the young.

Beccaria, Howard and Reform.—The publication in 1764 of C. B. Beccaria's (*q.v.*) treatise *On Crimes and Punishments* laid the foundations of criminal science. His basic teaching was that the sole justification of legal punishment was the protection of society by prevention of crime and that the principle of uniform maximum severity, particularly by capital punishment, was not only wrong but ineffective. In England, under his influence, W. Eden, Sir William Blackstone, Sir Samuel Romilly and others fought for reform of the legal system and rationalization of the use of capital punishment; yet by the end of the century capital offenses had increased to more than 200.

Failure to reform the legal system was inevitable so long as there was no effective "secondary punishment," and the use of the prisons of the time to that end was inconceivable either in principle or in practice. Howard not only awakened world conscience to the scandal of the prisons; he showed. too, ho they might become an effective instrument of punishment. His publication in 1j77 of *The State of the Prisons in England and Wales, with Preliminary Observations, and an Account of Some Foreign Prisons* had the same world-wide influence on principles of prison management as had Beccaria's treatise on principles of legal punishment. Prisons, he argued, should be sanitary and secure; the keeper should be the paid servant of the justices who should exercise effective supervision; to break down the physical and moral corruption of the common wards and yards, there should be separate cells for sleeping; and prisoners should have useful work in proper workshops, with regular moral and religious instruction.

Statutes were enacted from 1774 to 1791 giving effect to Howard's views, but enforcement rested with the justices, and only a few progressive magistrates, such as Sir George Paul at Gloucester and Sir T. Beevor at Wymondham, persuaded their counties to build cellular prisons. An account of the work of Beevor was to start in Philadelphia, Pa., that movement for prison reform which later brought back to Europe the ideas for which Howard vainly fought in his own time.

Early 19th Century. — Necessity required many counties to provide larger jails for the growing number of prisoners, and better sanitation against jail fever, but 30 years after Howard's death another group of prison reformers found the prisons much as he had left them. The Society for the Reformation of Prison Discipline, founded in 1816, had as its most prominent members Thomas Foxwell Buxton and Samuel Hoare, leaders of a Quaker group among whom Elizabeth Fry (*q.v.*) was to live in history. Tirelessly and constructively working inside Newgate herself, and forming ladies' committees to do the same elsewhere, she showed that Howard's principles could be practically applied so as to restore criminals as useful members of society. But in parliament interest still centred on the penal system, and her work had no more immediate effect on the general state of prisons than that of Howard.

The question of secondary punishment might have been effectively faced when the loss of the American colonies had temporarily deprived the government of the resource of transportation for those felons whom it did not hang. Alternative arrangements were made in statutes of 1j7j and 1j78 and, though these fell through when in 1787 transportation was resumed. this time to Australia, certain novel provisions had a continuing effect on the 19th-century prison system. The first was the conception of punitive hard labour, defined as "labour of the hardest and most servile kind, in which drudgery is chiefly required. . . . such as treading in a mill or drawing in a capstern. . . . ." The second was to provide that. until they could be transported, convicts might be detained in "hulks" in harbours and river mouths. More important was the decision to build two "penitentiaries," and though nothing was then done. Jeremy Bentham (*q.v.*) here made a notable contribution. Under the influence of Beccaria, he fought for penal and prison reform?laying special emphasis on the provision for prisoners of useful work as against sterile hard labour. In 1794 parliament adopted his novel plan for a penitentiary, which he called a "panopticon." and a site was bought at Millbank, London. But when in 1816 the new building was started on the site, Bentham's plan had been abandoned.

The first effective steps to rationalize the penal system were those taken by Sir Robert Peel (*q.v.*). The capital statutes were reduced and consolidated. benefit of clergy was abolished (1827) and for many felonies which had been clergyable there was prescribed a penalty of up to two years' imprisonment. It was now essential to make the prisons an effective instrument of punishment, and Peel's Gaol act of 1823 was the foundation of the English prison system. The justices were required to organize their prisons on a prescribed plan, with the jailer as their paid servant, to inspect them and to make reports to the home secretary. The graver abuses of the 18th century a-ere swept away and the statute included a code of rules to be followed in every prison. Howard's principles were established; with one exception: the separate cell system was rejected in favour of classification into five groups which were to be associated in productive employment and maintained from the profits.

But the impulse which finally shaped the future of European prisons was to come from another direction. In 1776 the Quakers of Pennsylvania had taken in one stride the steps over which the old world was still to fumble for so long. Murder was made the sole capital offense, and imprisonment the primary legal punishment. The regime of imprisonment which became known as the separate. solitary or Pennsylvania system was based on Howard's cellular system, but went beyond his teaching in requiring the strict separation of the prisoners by day as well as by night. The reformative virtues of this system were held to lie in complete absence of contamination. in religious instruction and silent contemplation. But another school of thought, closer to Bentham and Howard, had greater influence on U.S. development: this required separate cells for sleeping but associated work by day. and in Auburn prison in the state of New York there was enforced, to prevent contamination, a strict rule of silence, from which this system became known as the silent or Auburn system (*see* below). As news of these developments spread in Europe there was a flow of visitors to inspect and report. and there began that battle of the systems of which the echoes have still not died away. But their common factor. the cellular prison: had come to stay. and all over western Europe, in the next 30 years, prisons were built on the new model.

In England this was a period of confusion. Some county jails of Howard's time were cellular; others had been rebuilt after 1823 for the classification plan. Some favoured hard labour and erected treadwheels, some the new silent system. Many were attracted by the profitable aspects of Bentham's useful employment; many more had changed little since Howard first saw them. The government still lacked power to create a coherent system by enforcing its enactments and the next steps were to remedy that constitutional defect and then, following the breakdown of the transportation system, to develop imprisonment as the primary legal punishment.

Central administration was strengthened by the appointment of inspectors of prisons in 183j and of a surveyor general of prisons in 1844; and the home office. after visits by two of the inspectors to the U.S., gave a decided lead in favour of the separate system. Meanwhile public criticism of transportation had come to a head in the report of a parliamentary committee of 1837. and one of the steps taken to reform the system was to institute an initial period of 18 months' separate confinement in a penitentiary for selected convicts believed to be capable of reform. To supplement Millbank, the government in 1842 built a second penitentiary at Pentonville, London, which was also intended as a model to local authorities for the operation of the separate system. Within a few years 54 cellular prisons, with 11,000 cells, were built on the Pentonville plan.

In 1850 home office administration mas further strengthened by the appointment of directors of convict prisons. to take charge of the hulks. Millbank. Pentonville and a prison built in 1839 at Parkhurst, Isle of Wight, for juvenile convicts; the first chairman of the directors was Sir Joshua Jebb. The transportation system was now crumbling under the revelations of its inhumanity and inefficiency: and the refusal of the colonies to accept any more convicts; in 1846 it was suspended and the home office had to develop a system to take its place in the prisons at home. New prisons were required to hold this new population and to replace the hulks: the old "war prison" at Dartmoor. Devonshire, was rebuilt and Portland. Dorset, and other convict prisons followed. The directors based the new system on the differentstages through which a convict passed under the transportation system, and notably on the pioneer work of Alexander Maconochie in the penal settlement of Norfolk Island. where he had sought to recover the self-respect of his convicts through a progressive stage system, based on the earning of marks for good conduct and industry. This system became one of the bases of 19th-century prison treatment; introduced by Jebb into Ireland. it was there further developed under Sir Walter Crofton and, as the "Irish system," much influenced the development of progressive reformatory discipline on the continent and later in the U.S.

To begin with in England there were three stages: (1) 12 months' separate confinement in a penitentiary; (2) associated labour on public works in a convict prison (Portland harbour was largely built by convict labour); (3) ticket of leave to be at large in the colonies. Finally. when it became necessary that the convicts should also be released in England, a new form of sentence called penal servitude was introduced, which in 1857 was legalized for any offense punishable by transportation: the minimum period was three years. Penal servitude. after 1857, was served in three parts: (1) nine months' separate confinement in Pentonville or a local jail; (2) associated labour in a convict prison, divided into three progressive stages carrying increasing privileges to be earned by marks. while marks were also earned to qualify for release before expiration of sentence; (3) after the necessary marks were earned. release on a conditional licence.

Meanwhile, in the local prisons, the classification provisions of 1823 had in 1839 been repealed and permission given for justices to adopt the separate system, to which most informed opinion was now converted; and in 1850 a parliamentary committee had again endorsed the separate system and recommended punitive hard labour rather than useful industry. The battle of the systems was nearing its end.

19th-Century System.— Capital offenses having been reduced in 1861 to treason, murder, piracy and the burning of dockyards, imprisonment was now established in England as the primary legal punishment; in 1863 a committee of the house of lords laid down the principles which were to govern the system for more than 30 years. Meeting under the influence of an increase of serious crime and a reaction against reformative methods, the lords laid down that the object of imprisonment was deterrence by severity of punishment; and the methods should be separate confinement with punitive hard labour—"hard labour. hard fare and a hard bed." They expressed disbelief in the possibility of reform as an aim of imprisonment. Statutory effect was given to these views by the Prison act, 1865, and in 1877 parliament took the final step to ensure that they should be enforced. By the Prison act of that year the ownership and control of all local prisons were transferred to the home secretary and a board of prison commissioners was set up to manage and inspect them. The first chairman of the commissioners was Sir Edmund Du Cane, who had succeeded Jebb, so that all prisons, convict and local. were now under one management.

For 20 years the principles of 1865 were uniformly, efficiently and rigidly applied. Darkness descended on the English prisons. and the "Du Cane regime" became the classic example of a punitive prison system.

But elsewhere were new lights. On the continent the theories of Cesare Lombroso (*q.v.*) stimulated scientific study of criminology, and the formation in 1869 of the Union Internationale de Droit Pénale revived interest in the prevention of crime and the principles and practice of legal punishment. Continental systems were experimenting with variations of the progressive system; but in general the separate system was still rigidly enforced, and in France progress was retarded by the institution of transportation to the penal settlements in Guiana. In the U.S. the first American national prison congress was held at Cincinnati. O.. in 1870, of which the "Declaration of Principles" is a foundation document of modern prison reform. In the same year Enoch C. Wines secured a joint resolution from the U.S. congress creating a special commissioner empowered to invite other nations to an international prison congress in London. This congress of 1873 approved the major principles of Cincinnati: that the moral regeneration of prisoners through hope, not fear, should be the primary aim of imprisonment and that any unnecessary pain or humiliation should be abolished. From this congress followed regular quinquennial congresses in the different capitals and later the International Penal and Penitentiary commission, an intergovernmental organization of official delegates. with a permanent office at Berne. Switz., whose discussions and resolutions have notably promoted knowledge and progress.

Light came again in England when, in 1895, a departmental committee. under the chairmanship of H. J. Gladstone, unsparingly condemned the system of 1865 as being ineffective for the prevention of crime. Prisoners, it was said. had been treated "too much as a hopeless and worthless element of the community . . . Prison discipline and treatment should be designed to maintain, stimulate, or awaken the higher susceptibilities of prisoners . . . and whenever possible to turn them out of prison better men and women than when they came in. . . . Prison treatment should have as its primary and concurrent objects deterrence and reformation." Separate confinement. and hard labour were condemned, and proposals made for the separate treatment of young offenders under 21 and of habitual criminals.

20th-Century System.—*Before* 1914.—By the Prison act, 1898, power was given to the home secretary to provide for detailed regulation of the prison system by statutory rules. and under this more elastic procedure the development of 50 years proceeded without further legislation. Before World War I, however, the most significant changes in English penal practice lay in the steps taken to keep as many people as possible out of prison altogether. The probation system was established by the Probation act. 1907, suitable treatment of young offenders under 17 by the Children act, 1908, and of mental defectives by the Mental Deficiency act, 1913.

The provision in the Criminal Justice act, 1914, requiring justices to allow time for the payment of fines caused a striking fall in the prison population. The Prevention of Crime act, 1908, provided the Borstal system of treating offenders aged 16 to 21 outside the prison system, and the system of preventive detention for the protection of society against the habitual criminal.

The Borstal system was the creation of Sir Evelyn Ruggles-Brise, who succeeded Du Cane in 1895 and served until 1921; it lies outside the prison system. Borstal training is carried out in Borstal institutions: which are wholly educational and reformatory in principle and in method. Borstal had a wide influence throughout Europe and the British commonwealth.

For preventive detention a regime was devised suited to long sentences (five to ten years) which in principle were preventive rather than punitive, the prisoner having already served a sentence of penal servitude for the offense of which he was convicted on the occasion of having been found to be an habitual criminal. This double-track system of punishment together with other procedural disadvantages resulted in very few habitual offenders being sentenced to preventive detention. and was reviewed in 1932 by the departmental committee on persistent offenders, though effect was not given to their recommendations until 1948.

The prison systems of Europe underwent no radical change in the early years of the 20th century. On the continent separate confinement for periods of years was still general. In England there was little change in the convict prisons, but in the local prisons penal hard labour ceased. workshops were built for industrial employment and separate confinement was abolished; in effect, the silent system had returned, the rule of silence being strictly enforced at all times. The progressive stage system was based mainly on additional letters. visits and library books. with increasing gratuities in convict prisons. A classification system was instituted for convicted prisoners: (1) young prisoners, under 21; (2) star class,, for those in prison for the first time and others suitable to associate with them; and (3) ordinary class, for all others. The earning of remission of sentence had by the act of 1898 been extended to persons sentenced to imprisonment, the amount being fixed at one-sixth; for penal servitude it was one-quarter. (During World War II remission for all sentences was increased to one-third.)

At this stage the doctrine that a prison regime must be punitive and humiliating, so as to exercise deterrence through fear both against those subjected to it and against potential offenders in general, was still too deeply ingrained in penal thought and prison tradition for prisons to become an instrument for making better men and women.

Post-World War I.—There was active in Europe a new school of penal thought whose aims were embodied in the phrase "individualization of punishment," in reaction against the mechanical infliction of imprisonment as a standardized punishment irrespective of the condition of the offender. England now moved toward individualization of punishment within the prison and the provision of a regime compatible with the moral and social rehabilitation of the prisoners.

Experience had shown that men and women would be made not better, but worse, by punitive treatment designed to hurt and humiliate them. It was therefore necessary to proceed from the hypotheses that general deterrence lies not in the fear of prison, but in the totality of the operation of the penal system; and that individual deterrence lies in the fact of imprisonment, with the absolute loss of personal liberty and the amenities of normal life, and subjection to labour and disciplinary control. The regime should then be directed primarily to the rehabilitation of every prisoner for whom it might be possible; for others, it should at least seek to avoid such deformative effects as would send them out of prison worse than when they came in, neither willing nor able to take a useful place in society.

The changes which were to follow, at first under the chairmanship of Sir Maurice Lyndham Waller (1922–28), were largely inspired by a remarkable personality, Sir Alexander Paterson, who served as a commissioner of prisons from 1922 to 1947. Deliberately humiliating features of prison life were now removed and the rule of silence disappeared. The system concentrated on training prisoners to take a useful place in society, with an organized system of assistance and aftercare on discharge. Special emphasis was laid on the personal influences of a carefully selected and well-trained staff. and also on those of men and women from the community outside. who were enlisted to provide. as a voluntary social service! both education and entertainment and to pay friendly evening visits to prisoners in their cells. The quality of industrial work was improved. the earning of small sums of money was introduced, and an adult education scheme established. Since this form of training could not be fully carried out in the unsuitable buildings of the 19th-century local prisons. with their mixed populations and diverse functions. special training prisons were set aside for prisoners eligible both by character and length of sentence; and to Wakefield, the first such prison, an open farm camp was attached.

Throughout Europe there was progress in the development of progressive reformatory systems: and many new penal codes were promulgated. The penal farm colony without walls at Witzwil, Switz., had long had a wide influence. and in Sweden, Italy and Greece prison farms were instituted as steps to complete liberty. In these developments the International Penal and Penitentiary commission continued to play a stimulating part, holding congresses in London (192 j), Prague (1930) and Berlin (1935). In 1933 it published standard minimum rules for the treatment of prisoners, which were adopted and recommended by the League of Nations.

Post-World War 11.—Once the initial difficulties of those penal systems directly affected by World War II had been overcome! the first postwar decade proved to be one of remarkable development; by its end, the outlines and direction of a matured zoth-century system were not only visible in practice in the more developed systems. but increasingly accepted in principle throughout the world.

The extent of this progress owed much to sustained international interest and co-operation. The International Penal and Penitentiary commission, resuming its meetings in 1946, undertook a revision of the standard minimum rules of 1933, and its work culminated in the 12th International congress at The Hague. Neth., in 1950. Thereafter its functions were assumed by the Cnited Nations, which through the social defense section of its secretariat, organization of regional groups of experts, holding of seminars in different countries. provision of technical assistance and organization of a world congress at Geneva, Switz., in 19j5, did much to promote and collate knowledge and experience.

Development was based on the acceptance of rehabilitation as the primary purpose of the prison, with individualization of treatment through correct classification based on a thorough study of the character and needs of the individual prisoner. In 1950 the United Nations held in Brussels a seminar to study the scientific examination of offenders on the basis of medical, psychiatric, psychological and social reports. The development of prison staffs into a branch of social service including many specialists—psychiatrists, psychologists, social workers. teachers. trade instructors—was also a subject of international study, emphasis being laid on the need for careful selection and training of all grades on a professional basis.

The open prison system, which had been developed especially in the United States. the United Kingdom and the British commonwealth, and the Scandinavian countries, was recognized as an important contribution to effective rehabilitation.

There was notable extension of the use of psychiatric and psychological science both in diagnostic reports for the courts and for internal use. and in the treatment of abnormal mental states.

Special interest was aroused by the Swedish prison code of 1944 and the English Criminal Justice act of 1948, which gave legislative expression to progressive thought on the treatment of offenders. the former providing particularly for the detention of as many prisoners as possible in open prisons. The Criminal Justice act abolished the outworn forms of sentence to hard labour and penal servitude, leaving the single sentence of imprisonment. New methods of dealing with persistent offenders were enacted: for those still apparently capable of reformation, sentences of two to four years' corrective training might be passed; for others, j to 14 pears' preventive detention in appropriate conditions under special rules. The act also sought to minimize the imprisonment of young persons under 21 years of age and provided additional methods of treatment for them outside the prison system. Similar acts followed in Scotland and Northern Ireland.

During this period there was a marked rise in serious crime in England, leading to a prison population more than double that of pre-World War II years. Serious overcrowding resulted in the local prisons. Nevertheless there were notable developments both in principle and practice. The new systems of treatment for persistent offenders were established. The open prison system was fully developed. Compulsory attendance centres and detention centres were established as alternatives to imprisonment for young offenders. The classification of prisons was pressed further and many new training prisons were opened. Vocational training in skilled trades was extended, leading to the taking of external examinations. A new educational scheme based on professional teachers provided by local education authorities was introduced. Libraries were overhauled and open access to the shelves provided. A central after-care association was established, and the work of local discharged prisoners' aid societies was reviewed. A new building program of seven institutions was started, one being a psychiatric hospital.

Although in some countries there was still adherence to initial periods of solitary confinement, throughout western Europe developments of prison treatment followed similar lines. In France, for example, a national observation centre for diagnosis and classification was established at Fresnes, two prisons were set aside as vocational training centres and central prisons with a progressive system replaced transportation. In Portugal modern prisons were built. notably the youth prison at Leiria, where novel methods of training young prisoners were introduced. There was increased interest in probation, but little positive progress. See also CRIMINOLOGY.

UNITED STATES

In the American colonial period, penological practice fell almost entirely within the first stage of handling convicts, who were punished outside of institutions by means of fines and cruel and brutal corporal punishments. The only exceptions occurred within the Quaker colonies of West Jersey and Pennsylvania, and there only briefly. The Quakers were repelled by the bloody methods of corporal punishment and sought another method of handling convicts, in imprisonment at hard labour in workhouses. The latter were the first true prisons established in human history. West Jersey set up such a system in 1681 and Pennsylvania in 1682. but the British government forced the abandonment of this humanitarian innovation; and in 1718 even the colony of Pennsylvania reverted to the usual practices of corporal punishment.

The second stage of penological practice in the United States: that of providing penal institutions to punish convicts within their walls: gradually emerged between 1776 and 1800. At the close of the American Revolution, the Quakers and other humanitarians, notably Benjamin Rush. quickly restored the Quaker practice of imprisonment. These Philadelphia reformers were also influenced by the recommendations of the great English penologist John Howard and by the cellular jail which had been erected at Wymondham, Eng.. in 1785 as a result of Howard's reform suggestions. Laws were passed by the state of Pennsylvania ordering imprisonment as the normal method of punishing criminals and, immediately after 1790, a small block of cells was erected in the yard of the Walnut Street jail in Philadelphia for the solitary confinement of convicts. This was the first true prison in the United States for confinement of adult felons. It was also the birthplace of the famous Pennsylvania system of prison discipline, which provided the model, with variations, for many prison systems of the world, especially the European, during the 19th century.

Pennsylvania's first state prison, opened at Allegheny near Pittsburgh in 1826, was the first institution to provide for the solitary confinement of all inmates. But the Eastern penitentiary, opened at Cherry Hill in Philadelphia in 1829, became the classic institution in which the Pennsylvania system of solitary confinement was fully developed. From this institution the Pennsylvania system spread over the world and took firm root in Europe during the remainder of the 19th century. Under the Pennsylvania system each convict was locked up by himself in a cell and kept there without any association with other convicts until he died or was released. Hence, the Pennsylvania system was known as the solitary or separate system. Its chief purpose was punishment, but it was hoped that the reflection of the convict upon this punishment for his crimes might lead to his reformation. The Pennsylvania system thus established the second period of penology—the idea and practice of using penal institutions to punish convicts.

The other famous U.S. system of prison discipline and administration was started in Xuburn, N.Y., in 1819, and was a variant of the Pennsylvania system. From 1821 to 1823 the institution was conducted according to the Pennsylvania system of constant solitary confinement. Because of the smallness of the cells ($3\frac{1}{2}$ by 7 by 7 ft.) and the total lack of exercise, many of the confined convicts went insane or died. As a result, the Xuburn authorities introduced in 1825 what became known as the Xuburn system, under which convicts were segregated individually in cells except during the periods of working and eating. They were allowed to leave their cells to work in prison shops and eat in a common dining room. But absolute silence was maintained at all times, and any type of communication between convicts was absolutely forbidden. Hence the Auburn system was known as the silent system.

From about 1825 to 1850 there was a vigorous conflict between the Pennsylvania and Auburn systems. The former was generally adopted by European countries. But, though the Pennsylvania system was experimented with briefly in Maryland. Massachusetts, Maine. New Jersey. Rhode Island and Virginia, the Auburn system had triumphed in every state except Pennsylvania before 1850. Two reasons for its popularity in the United States were that institutions on this plan were more economical to construct and administer, and they were also better adapted to the rising mechanical and shop industry than was the solitary cellular confinement of the Pennsylvania system. Perhaps even more important was the fact that Louis Dwight! secretary of the Prison Discipline Society of Boston. was an almost fanatical partisan of the Auburn system and carried on effective propaganda with state legislatures whenever the construction of a new prison was under consideration.

The third stage of penological theory and practice in the U.S. came into being through the Irish system of prison discipline introduced in the 1850s and 1860s by Sir Walter Crofton and Sir Joshua Jebb. This system aimed primarily to reform convicts rather than to punish them, and determined the duration of imprisonment on the basis of the conduct of the convict while confined. It aroused the interest of leading U.S. penologists such as Enoch C. Wines. Zebulon R. Brockway, Gideon Haynes. Gaylord Hubbell and Franklin B. Sanborn; at the Cincinnati prison congress of 1870 these reformers advocated that it should replace both the Pennsylvania and the Auburn systems. Opposition was so strong, however, that the reformers were able to apply it only to U.S. criminal youth. The result was the creation of the Elmira reformatory system, first set up at Elmira, N.Y., in 1876.

The reformatories usually confined convicted young men between the ages of 16 and 30, often limiting the age group to those between 18 and 2j. The system was based upon the idea of dividing inmates into graded classes, promoting them through these classes because of good conduct, providing adequate vocational education and speedily admitting worthy inmates to release under parole supervision. The reformatories were first to introduce parole into U.S. penological practice on a large scale.

By and large, the reformatory movement proved a disappointment because the high ideals of the reformers of the 1870s were not maintained. Moreover, the reformatory structures! differing little from conventional prisons, were not designed in harmony with the new treatment ideals. Actually, the program failed because it mas never given a fair trial. Most reformatories degenerated into ordinary prisons for young men. In the second quarter of the 20th century, however, there was a revival of interest in the reformatory conceptions and practices. Beginning with the opening of the New Jersey reformatory at Annandale in 1929, reformatories were designed more in harmony with the ideals of the system, and better rehabilitative programs were worked out.

In the interval between 1870 and 1930. the main beneficial influence of the Elmira system was its impact upon the conventional prisons for adult felons. Slowly and gradually, some of the Elinira ideals were introduced in the adult prison system. Among these were the increasing use of parole. speedier release upon the basis of good conduct. better provisions for inmate education and a gradual triumph, in theory at least, of the idea that the purpose of imprisonment should be the reformation rather than the punishment of the inmate. Beginning with the New Jersey prison system in 1918, the rational treatment program, generally known as the principle of classification, was developed. According to this program, the treatment of convicts was adapted not only to the needs of the major classes of convicts but also to those of each individual inmate. The conventional custodial staff was supplemented by a classification clinic or treatment staff, made up of physicians, psychiatrists, psychologists, social workers and sociologists. The "new penology" was exemplified in such state systems as those of New Jersey, Illinois and California and by the federal prison system after 1930 under the direction of Sanford Bates and James V. Bennett. The federal system made the most complete effort to apply the principle of classification in accordance with the types of inmates confined. Hence, the federal institutions became highly diversified. ranging from a supersecurity penitentiary for the more desperate type of criminals at Alcatraz. Calif., to a minimum-security correctional institution at Seagoville, Tex., at which there were no walls and in which the inmates were given relatively complete freedom of movement. An adequate classification clinic or treatment staff was provided for each institution.

Despite the advances represented by the new penology, the more realistic and progressive penologists came to recognize that the dominant ideal of reformation could never be effectively achieved within penal institutions. The public fear of escapes encourages the construction of prisons as a collection of escapeproof steel cages. Moreover, the attention of prison administrators tended to be concentrated primarily upon preventing escapes rather than reforming inmates, and the inmate attitudes produced by all these circumstances created a mental response unfriendly to the efforts of the treatment staff. The best prison community is no more than an extreme totalitarian society, and the most it can produce is a good convict, who is quite different from a good citizen. Penologists came to realize that reform of convicts must be achieved mainly by agencies operating outside prison walls, in the environment to which the convict must ultimately adjust himself if he is to becomea reformed man. The result was at least a preliminary entry into the fourth stage of penological theory and practice—the conviction that reformation of convicts must be attained chiefly outside any penal institution. The same philosophy came to be accepted in the treatment of juvenile delinquents.

Penologists estimate that 15% to 20% of all convicts are nonreformable and must be segregated in maximum-security institutions under humane conditions throughout their natural lives. All others, according to the fourth-stage theory, should be released from institutions as soon as possible and treated in the normal environment of social relationships. This means an ever greater use of probation, conditional release under close supervision, and parole. The penologist who most vigorously recommended transition to this penological practice was Howard B. Gill, who established the progressive Norfolk prison colony in Massachusetts in 1927. The first program designed to make extended application of this practice. at least among criminal youth, was the Youth Correction Authority program drafted by the American Law institute in 1940 under the leadership of John B. Waite. This was based on the principle that expert penologists should decide the treatment of all convicted youth, determining whether they should be treated in institutions or outside under probation, conditional release or parole. California adopted the program in 1941, Minnesota and Wisconsin in 1947, Massachusetts in 1948 and Texas in 1949. The federal government followed suit in 1950 In 1944 California also created an adult correction authority, envisaging application of the same principles to adult felons.

Prison Architecture. — From the time of the building of the Auburn and Sing Sing prisons and the Eastern penitentiary between 1819 and 1829, there was no fundamental change in prison architecture until well after 1900, except for the building of more secure and expensive Auburn-style prisons, with a greater array of forbidding tool-resisting steel cages. The Eastern penitentiary cost about $772,000 to construct. The Attica state prison, opened in New York state about a century later, cost nearly $11,000,000. The Eastern penitentiary was constructed according to the outside-cell layout, with radial wings; a central corridor ran through each wing. and the cells extended from the corridor to the outside wall of the wing. But, since the great majority of prisons built in the United States were erected on the Auburn pattern, it is the latter style of architecture which is chiefly of interest to students of U.S. prisons. The Auburn system discarded the radial wing layout and adopted in its place long rectangular cell houses, usually flanking the entrance to the institution. Within these cell houses, lighted by heavily barred windows in the walls, was the so-called inside-cell block made up of several tiers of heavily barred cells. These cells were located back to back. and were surrounded by a corridor extending all the way around the cell block. Because the cell house completed at Sing Sing prison in 1828 on the Auburn pattern was much larger and more impressive than the Auburn structure, the great majority of prisons erected in the United States after 1830 were based upon this Sing Sing model of long rectangular cell houses enclosing their sombre and ever more escapeproof inside-cell blocks. Hence, the prisons of the United States for more than a century were architecturally gloomy and oppressive and a constant frustration of reform efforts of both the custodial staff and the inmates.

The first revolutionary advance over the Sing Sing pattern of prison architecture came with the opening of the telephone-pole prison at Fresnes, near Paris, in 1898, designed by Francisque Henri Poussin. This split the long cell houses of the Auburn-Sing Sing pattern into two halves by means of a covered central corridor which extended throughout the length of the structure. The resulting external appearance roughly represented the arms on a telephone pole and thus gave rise to the name. This prison was a great improvement over previous structures in that it gave easy and protected access to all sections, reduced the possibility of escape, lessened the distance over which inmates had to move, made their supervision easier and facilitated the proper lighting of cell blocks.

The telephone-pole type of prison was introduced to a limited extent in the state prison at Stillwater, Minn.. in 1914. But the adaptation of the layout to effective prison designing in the United States was mainly the work of Alfred Hopkins, a professional architect who in his mature years gave more and more attention to prison architecture.

Hopkins began his work with a new county prison in Westchester county, N.Y., opened in 1916, but his first complete structures illustrating the telephone-pole layout were the federal penitentiary at Lewishurg, Pa, and the New York state medium-security prison at Wallkill. both opened in 1932 Other architects, notably Robert D. Barnes of the federal bureau of prisons, went further in perfection of the telephone-pole design, as best exemplified by the federal penitentiary at Terre Haute, Ind., and the federal correctional institution at Texarkana, Tex The most notable innovation, however, was the plan drawn for the federal prison to supplant Alcatraz. This provided for elimination of the heavily barred windows of the cell houses and substituted skylighting of the cell blocks.

In the 20th century there was a tendency to diversify prison construction according to the type of inmates confined From 1825, all prisons had been designed more or less exactly alike with the same form of cells for all offenders. Under the leadership of the federal bureau of prisons, institutions were progressively diversified to meet the needs of the very different types of convicts sent to them. In the federal system were the supersecurity penitentiary at Alcatraz, already mentioned, for the most desperate criminals; three maximum-security prisons for serious habitual criminals; two mixed-custody penitentiaries for less serious adult felons; eight medium-security correctional institutions for inmates not requiring excessive precautions for safe-custody; and one minimum-security correctional institution for inmates with good prospects of speedy reform. Housing facilities were also diversified within each institution. For example, in the federal penitentiaries at Lewisburg and Terre Haute, not more than 12% of the inmates were housed in maximum-security inside cells, with the rest detained in outside cells, dormitories and honour rooms This diversified construction enormously reduced building costs and enabled the planners to put more money into various educational and treatment facilities to promote reformation rather than discourage it. There was also a notable tendency to spend less money on expensive walls. The wall of the Attica state prison in New York state, opened in 1931, cost $1,275,000, whereas the federal penitentiary at Terre Haute was built without any wall whatever. A heavy wire fence was found to provide a sufficiently secure enclosure. Finally, later prison planning stressed the desirability of smaller buildings. Enormous prisons like those at Jackson, Mich., and Stateville, Ill., holding up to more than 5,000 inmates, were erected after World War I, but opinion at mid-century would limit prison capacity to not more than 1,200 inmates, approximately the number confined at Lewisburg and Terre Haute.

Prison Labour. — Prison labour has played an important part in US. prison history, because it is intimately tied up with both the prison economy and the health and reformation of inmates. During most of the 19th century labour was carried on under various types of contracting. Contractors usually supplied the raw materials and sold the finished product, paying only for the labour of inmates. The contract stage reached its greatest prosperity in the 1870s and the

1880s, after which it became progressively restricted. During the first third of the 20th century the public-account system dominated most U.S. prison industry. Under this system, the prison authorities manufactured and sold all prison-made products. After the 1920s state-use prison labour laws compelled prisons to manufacture solely for state use but did not make it obligatory for state institutions to buy from prison shops. Laws restricting prison industry did not apply to the federal prisons.

Education.—In a thorough study of prison education, Austin H. MacCormick pointed out that in 1927 not a single prison in the United States had a thoroughly satisfactory program of education. Ten years later there were still 12 prisons without any educational provisions. Probably the best U.S. prison school at mid-century was that of the Rockview penitentiary, near State College, Pa.

PRISONERS OF WAR. The term prisoner of war, often abbreviated as PW or POW, is commonly used to mean any person captured or interned by a belligerent power during war. In the strictest sense it is applied only to members of regularly organized armed forces but by broader definition it has also included guerrillas, civilians who take up arms against an enemy openly, or noncombatants'associated with a military force.

Historical Background. — In the early history of warfare there was no recognition of a status of prisoner of war, for the defeated enemy was usually promptly destroyed on the battlefield. The women, children and elders of the defeated tribe or nation were frequently disposed of in similar fashion, although occasionally they were enslaved by the victor. The captive, whether or not an active belligerent, was completely at the mercy of his captor, and, if the prisoner survived the battlefield, his existence was dependent upon such factors as the availability of food and his usefulness to his captor. Slaughtering of prisoners was sometimes practised to terrify the enemy or to satisfy sadistic impulses of the conqueror. If permitted to live, the prisoner was considered by his captor to be merely a piece of movable property, a chattel. It is difficult to say which was less humane, immediate slaughter on the battlefield or lifetime enslavement.

Even before the dawn of the Christian era, prisoner exchange and ransom had become common, except when the enemies were barbaric tribes or infidels. Differences in war aims often determined the treatment of captives. During religious wars, for example, it was generally considered a virtue to put nonbelievers to death, but in the time of the Roman conquests of Julius Caesar a captive could, under certain circumstances, become a freedman within the Roman empire.

As warfare changed, so did the treatment afforded captives and members of defeated nations or tribes. Enslavement of enemy soldiers declined during the middle ages but ransoming was widely practised and continued even as late as the 17th century in Europe, A notable example was the ransoming of King Richard the Lion Hearted during the crusades. Civilians in the defeated community were only infrequently taken prisoner, for as captives they were sometimes a burden upon the victor. Further, as they were not combatants it was considered neither just nor necessary to take them prisoner. The development of the use of the mercenary soldier also tended to create a slightly more tolerant climate for a prisoner, for the victor in one battle knew that he might be the vanquished in the next.

In the 16th and early 17th centuries some political and legal philosophers expressed their thoughts about the laws of war generally, and, in an incidental fashion, the amelioration of the effects of capture upon war prisoners. The most famous of these; Hugo Grotius, stated in his *De jure belli et pacis* ("Law of War and Peace"; 1625) that victors had the right to enslave their enemies but he advocated exchange and ransom instead. The idea was generally taking hold that in war no destruction of life or property beyond that necessary to decide the conflict was sanctioned. The treaty of Westphalia (1648) which released prisoners without ransom is generally taken as marking the end of the era of widespread enslavement of prisoners of war.

In the 18th century a new attitude of morality in the law of nations! or international law had a profound effect upon the problem of prisoners of war. The French political philosopher Montesquieu in his famous *L'Esprit des Lois* (1748) ("Spirit of the Laws"), wrote that the only right in war that the captor had over a prisoner was to prevent him from doing harm. The captive was no longer to be treated as a piece of property to be disposed of at the whim of the victor but was merely to be removed from the fight. Other writers. such as Jean Jacques Rousseau and Emeric de Vattel expanded on the same theme and developed what might be called the quarantine theory for the disposition of prisoners. From this point on the treatment of prisoners generally improved.

During the American Revolution there was no strict observance of any set of rules for the treatment of POWs. The British sometimes applied the kind of harsh punishment customarily meted out during domestic disturbances. At one stage of the conflict Gen. George Washington warned Gen. Thomas Gage that the colonists would regulate their conduct toward British prisoners "exactly by the rule you shall observe toward those of ours now in your custody." This warning illustrated a basic principle that has influenced prisoner of war practice throughout history. Each belligerent tends to treat the prisoners it holds in the same way, be it good or bad. that its own men are treated by the enemy. Shortly after the end of the Revolution the United States entered into a treaty of friendship with Prussia (1785) wherein for the first time in U.S. history regulations for dealing with prisoners mere systematically set forth. Similar provisions appeared in U.S. agreements with Tripoli in 1805, Great Britain in 1813 and with Mexico in 1848.

By the middle of the 19th century it was clear that a definite body of principles for the treatment of war prisoners was being generally recognized in the civilized world. Most of these principles were summarized in the famous code prepared in 1863 for the U.S. army in the Civil War by Francis Lieber. But observance of the principles in the Civil War and in the Franco-Prussian War left much to be desired, and numerous attempts were made in the latter half of the century to improve the lot of both wounded soldiers and prisoners. whether wounded or not. In 1874 a conference at Brussels, Belg.. prepared a declaration relative to prisoners of war but it was not ratified. In 1899 and again in 1907 international conferences at The Hague. Neth., drew up rules of conduct that gained some recognition in international law. *(See* LAWS OF WAR). But during World War I when POWs were numbered in the millions, there were many charges on both sides that the rules were not being faithfully observed. Soon after the war the nations of the world gathered at Geneva, Switz., to devise the convention of 1929 which was ratified before the outbreak of World War II by France, Germany, Great Britain, the United States and many other nations, but not by Japan or the Soviet Union.

During World War II millions of persons were taken prisoner under widely varying circumstances and experienced treatment that ranged from excellent to barbaric. In the latter category was the notorious Bataan death march of American prisoners taken by the Japanese early in 1942 in the Philippines. As the Japanese code of military conduct did not condone surrender, the number of Japanese taken prisoner by United Nations forces was limited. On the other side of the world, in Europe and north Africa, treatment of prisoners was generally more nearly in accord with the Geneva convention, though there were some shocking instances of mistreatment. The Soviet Union shrouded its actions in mystery, and many difficult problems of exchange and repatriation developed as the war came to a close. In all theatres, efforts were made through the international Red Cross committee to deliver food parcels and medical supplies to prisoners from their families and friends. After the war, international war crimes trials were held in Germany and Japan, based on the concept that acts committed in violation of the fundamental principles of the laws of war were punishable as war crimes.

Geneva Convention of 1949.—Soon after the end of World War II the 1929 Geneva convention was revised and set forth in the Geneva convention of 1949. It continued the concept earlier expressed that prisoners were to be removed from the combat zone and be humanely treated without loss of citizenship or of legal identity. The 1949 convention broadened the term prisoner of war to include not only members of the regular armed forces who have fallen into the power of the enemy but also the militia, the volunteers, the irregulars and members of resistance movements if they form a part of the armed forces, and persons who accompany the armed forces without actually being members, such as war correspondents, civilian supply contractors and members of labour service units. Even civilian inhabitants of a country not occupied by the enemy may become prisoners of war if captured when they spontaneously take up arms to resist invasion at the approach of the enemy, provided that the arms are carried openly and the laws and customs of war are respected by them. The protections given prisoners of war under the Geneva convention remain with them throughout their captivity and cannot be taken from them by the captor or given up by the prisoners themselves.

The 1949 convention specifically charged the capturing nation, or detaining power, with responsibility for treatment given prisoners. Physical mutilation and exposure to medical or scientific experiments were expressly forbidden, and the prisoners were to be protected against acts of violence, intimidation, insults and public curiosity. Reprisals against prisoners were prohibited. A prisoner was required when captured to give only his name, date of birth. service number and rank.

During their internment, which was to be in camps or compounds with other prisoners of their own nationality, language and customs, the prisoners were to be quartered, fed and clothed by the captor nation. They were also to be paid a small amount depending in its size upon their grade. Medical inspections were to be held regularly and the prisoners were to have available to them adequate medical facilities. The prisoners were to be allowed to engage in certain religious. intellectual and physical activities. Enlisted prisoners, but not officers, could be required to work for the detaining power but the work was not to be directly connected with the war and the prisoners were to be paid for the work they performed.

Prisoners were made subject to the laws, regulations and orders of the detaining power. but a distinction was made between offenses which might be punished merely by disciplinary action and those punishable by judicial processes, although those judicial processes might be by a military court. As a general rule, a prisoner was not to be sentenced by military authorities to any penalty not provided for members of the armed forces of the detaining power who had committed the same acts. Collective punishments, torture and cruelty were forbidden and a prisoner might not be punished more than once for the same offense. Only disciplinary punishment. which is relatively mild. was permitted for a prisoner captured after an attempted escape, although the prisoner might be punished more severely if in the course of his escape attempt he committed offenses entailing violence against life or limb, or against public property. or involving theft for self-enrichment. If judicial proceedings were initiated the prisoner was entitled to counsel and was to be allowed to call witnesses and have a qualified interpreter. During the conflict prisoners might be repatriated or delivered to a neutral nation for custody. At the end of hostilities all prisoners were to be released and repatriated without delay, except those held for trial or serving sentences imposed by judicial processes.

The Korean War.—When the Korean war broke out in 1950 neither the United States, the largest contributor of armed forces on the side of the United Nations, nor Communist China and North Korea on the other side, had formally ratified the Geneva convention of 1949, but early in the conflict each side announced its adherence to the principles of the convention. The communists captured about 7,190 Americans in this war while the United Nations forces captured about 120,000 Chinese and North Koreans.

Treatment of prisoners by the communists was frequently barbaric. Movements from the front lines to prison camps turned into death marches for hundreds of POWs. In the prison camps food was meagre, consisting chiefly of rice. Chinese and North Korean spokesmen pointed out that this diet conformed to the Geneva convention in that it was the same as that eaten by the detaining forces, but for U.S. and British troops it amounted virtually to slow starvation, sickness and death. Many United Nations prisoners were subjected to physical abuse, threats and psychological pressures in an effort to extort information of military value or confessions that UN forces had resorted to germ warfare. When obtained, such confessions were widely used for propaganda purposes. The term brain washing was applied to the coercive methods and indoctrination techniques employed by the communists to induce UN captives to change their political outlook and embrace communism.

The truce agreement that ended the Korean war in 1953 included detailed provisions for repatriation of POWs. The prisoners were given an opportunity to choose to return to their homeland, to remain with their captors or to go to some other country. Under supervision of the Neutral Nations Repatriation commission "explanation sessions" were held during which representatives of the prisoner's own nation were permitted to talk with him and possibly persuade him to return home. Over 21,000 communist troops chose not to return home and 21 American soldiers remained with the communists when the final accounting was made. The entire problem of "forced repatriation" was given much attention at the time by international lawyers, and it became apparent that there still existed considerable disagreement as to whether a prisoner was permitted under the Geneva convention of 1949 the right to elect not to return to his homeland.

The Korean war also illuminated another facet of the problem of handling POWs—the effort to make use of prisoner status to further national war aims. In UN prison compounds POWs often rioted and committed acts of violence upon fellow prisoners and upon guards of the UN forces, apparently in an effort to develop propaganda material for use by the communist forces during the long truce negotiations. UN prisoners in communist compounds were subjected to extensive indoctrination programs designed to furnish the communists either with converts or propaganda statements. The prisoner became an important figure in the Korean war, the object of greater attention by the combatants than in either World War I or II. It appeared that a change in the status of the POW might be taking place with the prisoner being considered still a combatant and the prison compounds mere extensions of the fighting areas. If this apparent trend were to continue it would seriously threaten the improved conditions of prisoners afforded by the Geneva conventions.

U.S. POW Code of Conduct.—Upon return of the surviving U.S. prisoners from Korea—about 4,428 men—the U.S. government undertook a formal study of POW problems, appointing a special committee of military and civilian leaders to consider all aspects of the subject. Some of the specific problems considered were the causes of the apparent defections to the enemy by a few U.S. servicemen, the truth about the so-called brain washing, the propriety of punishing returned POWs for collaboration with the enemy under duress. and the existence or creation of a uniform standard of conduct for servicemen in battle and in captivity.

The report of the committee, made public in July 1955, found proper the action of U.S. authorities in bringing some 14 servicemen to trial by courts-martial for their acts of misconduct while in a prison camp. Brain washing was found to have had little lasting effect upon the prisoners in Korea. To guide U.S. servicemen who might be taken prisoner, the committee presented the following code of conduct which the president of the United States directed all servicemen to follow:

I

I am an American fighting man. I serve in the forces which guard my country and our way of life. I am prepared to give my life in their defense.

II

I will never surrender of my own free will. If in command I will never surrender my men while they still have the means to resist.

III

If I am captured I will continue to resist by all means available. I will make every effort to escape and aid others to escape. I will accept neither parole nor special favors from the enemy.

IV

If I become a prisoner of war, I will keep faith with my fellow prisoners. I will give no information or take part in any action which might be harmiul to my comrades. If I am senior, I will take command. If not, I will obey the lawful orders of those appointed over me and will back them up in every way.

V

When questioned, should I become a prisoner of war, I am hound to give only name, rank, service number and date of birth. I will evade answering further questions to the utmost of my ability. I will make no oral or written statements disloyal to my country and its allies or harmful to their cause.

VI

I will never forget that I am an American fighting man, responsible for my actions, and dedicated to the principles which made my country free. I will trust in my God and in the United States of America.

PRISTINA, a town in Serbia, Yugos. Pop. (1961) 40,071. Pristina was the seat of government of Stephen Nemanya, founder of the Serbian empire, and to the west lies the famous Field of Blackbirds where the empire was destroyed by the Turks in 1389.

PRITCHARD, CHARLES (1808–1893), British clergyman and astronomer who was among the first to apply photography to the determination of stellar parallax, was born at Alberbury, Shropshire, on Feb. 29, 1808. He was educated at St. John's college, Cambridge, elected a fellow of his college in 1832, was ordained in 1834 and became a schoolmaster. After his retirement in 1862, he was able to devote himself to his interest in astronomy, and was elected president of the Royal Astronomical society in 1866. In 1870 he was elected Savilian professor of astronomy at Oxford and founded the new university observatory. In 1881 he commenced a systematic study of stellar photometry and measured the relative brightness of 2,784 stars between the north celestial pole and about −10° declination; the results were published in 1885 in his Uranornetria *Nova Oxoniensis,* for which he was awarded, conjointly with E. C. Pickering, the Royal Astronomical society's gold medal (1886). Between 1888 and 1892 he made a systematic measurement of the parallax of second-magnitude stars. Throughout his life, Pritchard regretted being without a pastoral cure. Many of his frequent religious addresses to learned bodies, some of them concerning the harmony between science and Scripture, were published. Pritchard died on May 28. 1893. (O. J. E.)

PRIVAS, town of France, capital of *département* of Ardèche, 95 mi. S.W. of Lyons. Pop. (1954) 4,896.

Privas is first heard of in the 12th century, as a possession of the counts of Valentinois, and later as the seat of a separate barony. As a Protestant stronghold, it suffered during the Wars of Religion. It passed in 1619 to the vicomte de Lestrange, a Roman Catholic noble. A general rising followed, and in 1629 it was besieged and destroyed by Louis XIII, who decreed that it should not be again inhabited; but in 1632 the inhabitants returned.

PRIVATEER, an armed vessel belonging to a private owner, commissioned by a belligerent state to carry on operations of war. The commission is known as letters of marque. Acceptance of such a commission by a British subject is forbidden by the Foreign Enlistment act 1870. Privateers stand in a position between that of a public ship of war and a merchant vessel, and the raising of merchant vessels to the status of warships has given rise to so much difficulty in distinguishing between volunteer warships and privateers that the subject mas made one of those for settlement by the Second Hague conference (1907). By Convention vii a converted merchant ship cannot have the status of a warship unless it is placed under the direct authority, immediate control and responsibility of the power the flag of nhich it flies (art. 1) Conerted merchant ships must bear the external marks which distinguish the warships of their nationality (art. 2). The commander must be in the service of the state and duly commissioned, and his name must figure on the list of the officers of the fighting fleet (art. 3). The crew must be subject to military discipline (art. 4). A converted merchant ship must observe the laws and customs of war (art 5); and such conversion must be announced in the list of warships of the belligerent country. Privateering is now a matter of much less importance as the result of the Declaration of Paris, 1856 (*q.v.*), by which it was abolished.

PRIVET, any shrub of the genus *Ligustrum,* belonging to the olive family (Oleaceae), and containing about 50 species, natives of temperate and tropical regions of the old world; only the common privet (*Ligustrum* vulgare) is a native of Europe and northern Africa. Privets have evergreen or nearly evergreen opposite entire leaves, and dense clusters of small, white, tubular four-parted flowers, followed by small, globular, usually black fruits. The best-known species is the common European privet, which makes good hedges; there are numerous varieties with variegated leaves. The California privet (L. *ovalifolium*), half-evergreen and native to Japan. is the most planted hedge throughout the U.S. and thrives in Great Britain. *L. japonicum,* the wax privet, L. *lucidum* and L. *massalongianum* are fine evergreen species, hardy only in warm regions. Mock privet, *Phillyrea,* a member of the same family, is an ornamental evergreen shrub from the Mediterranean region, hardy only in warm places. (N. TR.)

PRIVILEGE, in law, an immunity or exemption conferred by special grant in derogation of common right. The term is derived from *privilegium,* a law specially passed in favour of or against a particular person. In Roman law the latter sense was the commoner; in modern law the word bears only the former sense. Privilege in English law is either personal or real — that is to say, it is granted to a person, as a peer, or to a place, as a university. The most important instances at present existing in England are the privilege of parliament (*see* PARLIAMENT), which protects certain communications irom being regarded as libellous (*see* LIBEL AND SLANDER), and the privilege of the client by which counsel and solicitor are protected from disclosing, in judicial proceedings, information which has come to them in that relation. This does not extend to clergymen or medical attendants (*see* Observations by Mr. Justice McCardie in *The Times,* July 19, 1927). Privileged copyholders were those held by the custom of the manor and not by the will of the lord. There are certain debts in most countries which are said to be privileged — that is, such debts as must first be deirayed by the executor out of the personal estate of the deceased, in payment, for example, of funeral expenses or servants' wages. There are certain deeds and summonses which are privileged in Scots law, the former because they require less solemnity than ordinary deeds, the latter because the ordinary *induciae* are shortened in their case (*see* Watson, *Law Dictionary, s.v.* "Privilege"). The priority formerly possessed by specialty debts was abolished in 1869. (*See* DEBTOR AND CREDITOR LAW.)

In the United States the term privilege is of considerable political importance. By art. iv, sec. 2 of the constitution, "the citizens of each State shall be entitled to all privileges and immunities of citizens in the several States." By art. xiv, sec. 1 of the amendments to the constitution (enacted July 28, 1868), "no State shall make or enforce any lam which shall abridge the privileges or immunities of citizens of the United States." It will be noticed that the former applies to citizens oi the states, the latter to citizens of the United States. "The intention of this clause (art. iv) was to confer on the citizens of each State, if one may so say, a general citizenship, and to communicate all the privileges and immunities which the citizens of the same State mould have been entitled to under the like circumstances" (Story, *Constitution of the United States,* 1806). The clauses have several times been the subject of judicial decision in the supreme court. With regard to art. iv it was held that a state licence tax discriminating against commodities the production of other states was void as abridging the privileges and immunities of the citizens of such other states (*Ward* v.

State of Maryland, 12 Wallace's Reports, 418). With regard to art. xiv, 1, it was held that its main purpose was to protect from the hostile legislation of the states the privileges and immunities of citizens of the United States, looking more especially to the then recent admission of Negroes to political rights. Accordingly it was held that a grant of exclusive right or privilege of maintaining slaughterhouses for 21 years, imposing at the same time the duty of providing ample conveniences, was not unconstitutional, as it was only a police regulation for the health of the people (*The Slaughter-House Cases,* 16 Wallace, 36). The same has been held of a refusal by a state to grant to a woman a licence to practise law (*Bradwell* v. *The State,* 16 Wallace, 130), of a state law confining the rights of suffrage to males (*Minor* v. *Happersett,* 21 Wallace, 162), and of a state law regulating the sale of intoxicating liquors (*Bartemeyer* v. *Iowa,* 18 Wallace, 129). Suits to redress the deprivations of privilege secured by the constitution of the United States must be brought in a United States court. It is a crime to conspire to prevent the free exercise and enjoyment of any privilege, or to conspire to deprive any person of equal privileges and immunities, or under colour of lam to subject any inhabitant of a state or territory to the deprivation of any privileges or immunities (*Revised Statutes of United States,* sec. 5507, 5510, 5519).

It is sometimes difficult to distinguish between "privileges" and "rights" in the United States, but privileges are more general and the act of suffrage is considered a "privilege" rather than a "right."

PRIVY **COUNCIL,** theoretically the British sovereign's private council, as distinct from the medieval great council, or council of magnates. and from council in parliament, now called parliament. It ceased to be an active body because (1) it lost most of its judicial functions; (2) the sovereign preferred to use informal meetings of ministers in cabinet; and (3) the sovereign ceased to take responsibility for political decisions. Meetings are held from time to time for the taking of formal decisions (*e.g.,* the making of orders in council), but usually only the quorum of three lords of the council are present and there is no discussion.

There is, however, a privy council office, with the lord president of the council as responsible minister. It is concerned with the making of orders in council and with a wide variety of functions deriving mainly from the power of the sovereign in council to issue royal charters, now used chiefly by municipal corporations and by charitable bodies engaged in education, research, the encouragement of literature, science, art, etc. Among the bodies with which it is concerned are the universities, various research councils (*e.g.,* the agricultural research council, the medical research council and the research council of the department of scientific and industrial research) and the bodies concerned with the maintenance of professional standards (*e.g.,* the general medical council). It bears the main responsibility for scientific research through the department of scientific and industrial research. Usually the privy council functions through committees, some standing and some *ad hoc.* The most famous of its committees is, however, statutory, the judicial committee of the privy council, which hears appeals from ecclesiastical courts, prize courts and courts from all colonies and some independent countries of the commonwealth (see PRIVY COUNCIL, JUDICIAL COMMITTEE OF).

History of the Privy Council.—The privy council, like all the British institutions of central government, is descended from the court of the Norman kings. This *curia regis,* composed of the king's tenants in chief, his household officials and anyone else whom the king chose to summon, performed all the functions of central government. According to feudal theory, tenants owed suit to their lord's court; but every great lord had also his household officials to transact his daily business. The *curia regis* expanded or contracted according to the nature of the business under consideration. The ordinary routine would be carried out by the officials, assisted by such barons as happened to be at court; for more important business the king would secure the attendance of a greater number of his tenants in chief; and on really vital matters the household officials would tend to become a numerically insignificant technical element in a large feudal assembly.

As time went by the larger and smaller gatherings came to be distinguished adjectivally; later, these adjectives developed a technical significance, until, although still remaining for a time merely different manifestations of a one and indivisible body, the larger assembly developed into the great council and the parliament. the smaller into the king's council. In early days the presence of many barons at conciliar meetings was the mark of a strong king; later, as the barons came to realize that attendance was not merely a tiresome incident of feudal tenure but a source of political power, that obligation became a privilege. Thus, in the later middle ages there developed a struggle between king and greater barons for the control of the king's council. In the end the barons failed to secure their greater demands—exclusive membership and the control of appointment and dismissal—because, though anxious to control and willing to be appointed, they could never be relied upon for constant attendance. Further, with the passing of the feudal organization of society, baronial counsel ceased to be expert advice on matters of government.

By the time of Henry VII this council had become the instrument of the crown. It was composed of an inner ring of counselors proper, who took an oath and sat at the council board, and of an outer ring of technical experts and dignitaries. Though they might occasionally be called upon for advice, the latter were not members of the board, did not take the conciliar oath, but merely that of their respective offices, and performed the technical and routine work of the central and provincial courts of the council. It was the policy of the Tudors to rule the country paternally by the prerogative exercised through the medium of the council.

This conception of government necessitated precision, subdivision and specialization, and thus the king's council and its functions were divided among the privy council, the courts of Star Chamber, of requests and of high commission (*qq.v.*), and such local offshoots as the courts and councils of the north, and of Wales and the Marches. A distinction between the council with the king and the council at Westminster had appeared from time to time during the middle ages. It now became "sharper and more permanent." The body following the king was commonly known as the council at court, while the other continued to be called the king's council in the Star Chamber. The former body became the privy council.

This conciliar government was admirably suited to a period of transition. But the need of this somewhat arbitrary, if paternal, government had passed with the Tudors. Moreover, this small but all-powerful bureaucracy depended for its efficiency on a resolute and discriminating sovereign, capable of choosing the right men and of superintending their labours. The Stuarts did not possess these qualifications. The house of commons, hitherto accustomed to follow the leadership of privy councilors, had now, with increased experience of partnership in government, developed a mind and policy of its own. Of the judicial aspect of the council's activities the common lawyers were coming to show an even more threatening jealousy, a jealousy justified by the misguided action of the Stuarts in checking the natural evolution of these courts toward independence of executive control and in using them to enforce, not justice, but policy. No wonder, then, that as religious and constitutional controversies developed between crown and parliament the attention of malcontents became focused on conciliar jurisdiction, nor that, when the parliamentary cause at last triumphed in 1641, the whole system of conciliar government was swept away. Only the privy council was spared. It was never legally abolished. It perished in the interregnum (though the name was resuscitated in 1657) and was restored with the return of Charles II in 1660.

Both in the middle ages and for several centuries later contemporary opinion favoured 20 as about the ideal total of conciliar membership. But seldom did practice conform with theory. When the privy council register begins, in 1540, we do, indeed, find 19 members, but by Henry VIII's death there were 29. In Edward VI's reign the record mas 40, in Mary's 44, and, although Elizabeth I reduced the numbers to between 12 and 20, the Stuarts, as usual, were less successful. By 1623 the total had increased to 35, and Charles I's council averaged about the same figure. At the Restoration the problem of numbers became even more acute. Charles II managed to begin with only 28, but the total had reached 47 by 1679. Sir William Temple's abortive attempt at conciliar reform temporarily reduced the figure to 33, but by 1688 it was back again at 48, by 1707 it had reached 60 and, by 1723, 67. In practice, however, Charles II and all later monarchs preferred to have matters of policy discussed privately by their principal advisers in cabinet.

The last serious attempt to restore the privy council to its former influence may be found in the clause of the Act of Settlement (1701), which enacted that, on the Hanoverian accession, "all matters and things relating to the well-governing of the kingdom, which are properly cognizable in the privy council by the laws and customs of this realm, shall be transacted there, and all resolutions taken thereupon shall be signed by such of the privy council as shall advise and consent to the same." But the proposal was by that date impracticable, and the clause was repealed in 1705 before it even came into force. The council board had been not merely short-circuited by the cabinet, it had even lost the power of debating such measures as came before it. In 1711 a debate on the subject in parliament elicited the remark that "the privy counsellors were such as were thought to know everything and knew nothing. Those of the cabinet council thought nobody knew anything but themselves." And the last occasion on which the council asserted its former rights was when, in 1714, as Queen Anne lay dying, certain Whig lords forced their way in at a meeting of the lords of the committee (see CABINET), claimed their right to be present as counselors of the crown, converted the meeting into a session of the privy council and, reinforced by their conciliar colleagues, ushered in the Hanoverian succession. From the accession of George I the privy council may be described as a purely formal body meeting on purely formal occasions to transact purely formal business. By 1960, there were more than 300 "right honourable lords and others of Her Majesty's Most Honourable Privy Council." They were mostly dignitaries who had held, or held, high political, judicial or ecclesiastical office, though the list occasionally included eminent persons in science or letters. Office lasts for the life of the sovereign and six months after, but a new sovereign may renew the appointment. See also references under "Privy Council" in the Index volume.

PRIVY COUNCIL, JUDICIAL COMMITTEE OF.

From the abolition of the Star Chamber in 1641 until 1833, petitions from overseas to the crown, whether by way of appeal or otherwise, came before a general committee of the privy council which gave advice (as does the judicial committee) on what order should be made. In that year, while the approach by way of appeal to the king remained, the procedure was systematized and a judicial tribunal and, later, rules of procedure instituted. Certain matters, such as admiralty, were subsequently transferred to the high court of justice and so, by way of appeal, to the court of appeal and the house of lords.

The Statute of 1833.—This act provided in its first section for a new juridical composition for the council, to be headed by the president for the time being thereof, and the lord high chancellor and other learned dignitaries as there set forth. These, it was enacted, "shall form a committee of his majesty's said privy council and shall be styled the judicial committee of the privy council."

In later years the personnel of the committee was changed and enlarged. It now consists of the lord chancellor, the lord president of the council and the lords of appeal in ordinary, together with certain other members. To them are added such other members of the privy council as shall from time to time hold or have held "high judicial office," that is, membership of the court of appeal and high court or court of session in the United Kingdom, and certain judges of the dominions who are privy councillors.

By the third section of the 1833 act, it was provided: "That all appeals or complaints in the nature of appeals whatever, which, either by virtue of this Act, or of any law, statute, or custom, may be brought before his majesty or his majesty in council from or in respect of the determination, sentence, rule, or order of any court, judge, or judicial officer, and all such appeals as are now pending and unheard, shall from and after the passing of this Act be referred by his majesty to the said judicial committee of his privy council, and that such appeals, causes, and matters shall be heard by the said judicial committee, and a report or recommendation thereon shall be made to his majesty in council for his decision thereon as heretofore, in the same manner and form as has been heretofore the custom with respect to matters referred by his majesty to the whole of his privy council or a committee thereof (the nature of such report or recommendation being always stated in open court)."

Appeals are by petition, and the judgment is in the form of an opinion to the king, humbly advising what judgment should be given. The judicial committee, unlike the house of lords, is not bound by previous decisions, and minority opinions are not publicly expressed.

The Commonwealth.— In 1867 the principal British North America act was passed. By sections 91 and 92 the powers of the Canadian dominion parliament and functions of the provincial legislatures were distinguished. It became evident that the task of defining the respective jurisdictions not only interprovincially but between dominion and province would be a difficult task. The authority of the judicial committee of the privy council so to act was clear from the act of 1833, but the Canadian parliament thought fit to deal further with the matter in the 47th section of their Supreme and Exchequer Courts act (38 Victoria, chap. 11) in the following terms:

"The judgment of the Supreme Court shall in all cases be final and conclusive, and no appeal shall be brought from any judgment or order of the Supreme Court to any court of appeal established by the parliament of Great Britain and Ireland, by which appeal or petitions to her majesty may be ordered to be heard: saving any right which her majesty may be graciously pleased to exercise by virtue of her royal prerogative."

The Statute of Westminster.—Under the powers vested in it, the judicial committee formerly pronounced a series of several judgments on matters of imperial importance, but later, as regards the dominions, this field of judicial activity became very restricted. The effect of the passage of the Statute of Westminster in 1931 was that dominions which had adopted it were in a position to abolish the right of appeal from their courts to the judicial committee. Acting under this power Canada in 1935 abolished appeals to the judicial committee in criminal matters.

The Supreme Court act, 1949, came into force on Dec. 23, 1949. By Section 3 the right of appeal from Canadian courts was abolished, save that appeal was preserved in respect of litigation already in process at the time. By the British North America act, 1949, Newfoundland was incorporated into Canada.

The commonwealth of Australia, a federation of six states, had not yet adopted the Statute of Westminster, but the right of appeal was limited by Australian legislation to provisions specifically reserved in the constitution, and in any case leave of the Australian high court was needed before an appeal to the committee could be brought. This leave was, in practice, rarely given.

In the Union of South Africa, with a unitary and not a federal constitution, the right of appeal, with leave from the supreme court, to the judicial committee was ended in 1950. Previously this right had existed but actually leave to appeal was almost impossible to obtain. Such appeals had never been popular since it was felt that an English court must have an inadequate knowledge of the working of the system of Roman-Dutch law prevailing in the Union.

New Zealand also had not yet adopted the Statute of Westminster, and legal opinion there continued to be strongly opposed to the abolition of the right of appeal to the judicial committee, but in fact very few appeals came to the committee from that country.

The Republic of Ireland, while yet in law a dominion, took advantage of the power to abolish the right of appeal in all cases by the Irish Free State constitution (amendment act, 1943)—a course the validity of which was approved in the case of *Moore* v. *Attorney General for Eire* (1935) A.C. 484. Appeals from Northern Ireland were to the house of lords.

In India, appeals were abolished by the Indian Abolition of Jurisdiction of Privy Council act, 1949. Courts were established in 1726, by charter of George I, in the three settlements of Madras, Bombay and Bengal, and the right of appeal to his majesty in council was given. Subsequent charters constituted supreme courts and these in time were replaced by various high courts created under the charter, Acts 24 and 25 Victoria, chap. 104. These high courts were constituted by letters patent which contained rules providing for appeals to the privy council.

Other high courts were established later, and these were also constituted by letters patent containing similar provisions as to appeals. The Civil Procedure code also gave a right of appeal under prescribed conditions and there followed an order of council of Feb. 9, 1920, which replaced a much earlier one issued under the Judicial Committee Act of 1833. So great, at one time, was the growth of Indian judicial business before the committee, that the latter had to be divided into two sections, one of which was entirely. or almost entirely. occupied with Indian appeals. By sec. 30 of the Judicial Committee Act of 1833, Indian judges were made eligible as members of the committee; in 1928 provision was made for their remuneration.

Indian business was greatly affected by the passing of the Indian Independence act, 1947, which provided for the setting up, as from Aug. 15, 1947, of two separate independent dominions, India (now a republic) and Pakistan. By reason of the Federal Court (Enlargement of Jurisdiction) act, 1949, passed by the legislature of the dominion of India, civil appeals might come to the judicial committee from the federal courts of India, but not from the high courts, while the committee remained the supreme tribunal in criminal cases where broad principles of natural justice were concerned.

Pakistan followed India in terminating the right of appeal.

In the case of the crown colonies and protected and trust territories (not being dominions under the Statute of Westminster, but including the Channel Islands and the Isle of Man) the position remained virtually the same after 1833.

General Opinions.— This procedure has not often been employed in the privy council. By sec. 4 of the act the crown may refer any matter to the judicial committee for hearing or consideration. This enabled the committee to give general opinions otherwise than on immediate facts—a power rarely invoked in British jurisprudence. Such opinions had, however, been given in boundary disputes between Canada and Newfoundland and under the Irish treaty of 1921 and on some other matters.

Ecclesiastical Jurisdiction.— The ecclesiastical jurisdiction of the king in council is derived from the statute 25 Henry VIII, chap. 19, which followed the act of the previous year, 24 Henry VIII, chap. 12, abolishing appeals to Rome. By 25 Henry VIII, chap. 19, an appeal was given from the courts of the archbishop to the king in chancery and it was enacted that upon such appeal:

"A Commission shall be directed under the great seal to such persons as shall be named by the King's Highness his heirs or successors like as in case of appeal from the Admirall Court to hear and definitely determine such appeals and the causes concerning the same."

This commission, known as the High Court of Delegates, was abolished by 2 and 3 William IV, chap. 92; and, by 3 and 4 William IV, chap. 41, ecclesiastical appeals were transferred to the judicial committee. The result was that thereafter appeals irom the two courts of archbishops (*i.e.*, Arches court of Canterbury and provincial court of York) lay to the king in council.

With regard to appeals under the Clergy Discipline act, 1892 (dealing with morals). there was established an alternate right of appeal from the consistory court of bishops either to the court of the archbishop or to the king in council direct. If the appellant elected the former there was no further appeal to the king in council. On the hearing of ecclesiastical appeals under the rules made under the Appellate Jurisdiction act, 1876, five bishops were to be summoned as ecclesiastical accessors, of whom three at least had to be present. Cnder the Endowed Schools act, 36 and 37 Victoria, chap. 87, appeals lay to his majesty in council from schemes prepared by the board of education affecting schools subject to the Endowed Schools act. Under the Union of Benefices measure, 1923, of the national assembly of the Church of England, an appeal lay to the king in council against a scheme of the ecclesiastical commissions uniting two or more benefices.

Practice.— The following is a paraphrase of the privy council rules:

All appeals shall be brought either in pursuance of leave obtained from the court appealed from, or, in the absence of such leave, in pursuance of special leave to appeal granted by his majesty in council upon a petition in that behalf presented by the intending appellant.

A petition ior special leave to appeal shall state succinctly and clearly all such iacts as it may be necessary to state in order to enable the judicial committee to advise his majesty whether such leave ought to be granted. The petition shall deal with the merits of the case only so far as is necessary for the purpose of explaining and supporting the particular grounds upon which special leave to appeal is sought.

Whenever it shall be found that the decision of a matter on appeal is likely to turn exclusively on a question of law, the parties, with the sanction of the registrar of the privy council, may submit such question of law to the judicial committee in the form of a special case, and print such parts only of the record as may be necessary for the discussion oi the same.

The judicial committee may order a full discussion of the whole case, ii they shall so think fit, and, in erder to promote such arrangements and simplification of the matter in dispute, the registrar may call the parties before him, and having heard them, and examined the record, report to the judicial committee as to the nature of the proceedings.

All petitions for orders or directions as to matters of practice or procedure arising after the lodging of the petition of appeal and not involving any change in the parties to an appeal shall be addressed to the judicial committee. All other petitions shall be addressed to his majesty in council, but a petition which is properly addressed to his majesty in council may include, as incidental to the relief thereby sought, a prayer for orders or directions as to matters of practice or procedure.

As soon as the appealhas been admitted, whether by an order of the court appealed from or by an order of his majesty in council granting special leave to appeal, the Appellant shall without delay take all necessary steps to have the record transmitted to the registrar of the privy council, and the registrar shall, with all convenient speed, certify to the registrar of the privy council that the respondent has received notice, or is otherwise aware, of the order oi the court appealed from admitting the appeal, or of the order of his majesty in council giving the appellant special leave to appeal, and has also received notice, or is otherwise aware, of the dispatch of the record to England.

A petition not relating to any appeal of which the record has been registered in the registry of the privy council, and any other petition containing allegations of fact which cannot be verified by reference to the registered record or any certificate or duly authenticated statement of the court appealed irom, shall be supported by affidavit. Where the petitioner prosecutes his petition in person, the said affidavit shall be sworn by the petitioner himself and shall state that, to the best oi the deponent's knowledge, iniormation, and beliei, the allegations contained in the petition are true. Where the petitioner is represented by an agent, the said affidavit shall be sworn by such agent and shall, besides stating that, to the best oi the deponent's knowledge, information and belief, the allegations contained in the petition are true, show how the deponent obtained his instructions and the information enabling him to present the petition.

The registrar of the privy council may reiuse to receive a petition on the grounds that it discloses no reasonable cause of appeal, or is frivolous, or contains scandalous matter, but the petitioner may appeal, by way of motion, from such refusal to the judicial committee.

As soon as an appeal is set down, the appellant shall attend at the registry of the privy council and obtain ten copies of the record and cases to be bound for the use of the judicial committee at the hearing. The copies shall be hound in cloth or in half leather with paper sides, and six leaves of blank paper shall be inserted before the appellant's case. The iront cover shall bear a printed label stating the title and privy council number of the appeal, the contents of the volume, and the names and addresses of the London agents. The several documents, indicated by incuts, shall be arranged in the following order: (1) appellant's case; (2) respondent's case; (3) record (if in more than one part, showing the separate parts by incuts, all parts being paged at the top of the page); (4) supplemental record (if any); and the short title and privy council number of the appeal shall also be shown on the back.

The appellant shall lodge the bound copies not less than four clear days before the commencement of the sittings during which the appeal is to be heard.

The registrar of the privy council names a day on or before which appeals must be set down if they are to be entered in the list of business for the ensuing sittings. All appeals set down on or before the day named must, subject to any directions from the committee or to any agreement between the parties to the contrary, be entered in such list of business and shall, subject to any directions from the committee to the contrary, be heard in the order in which they are set down.

The registrar of the privy council shall, subject to the provisions of rule 42, notify the parties to each appeal by summons, at the earliest possible date, of the day appointed by the judicial committee for the hearing of the appeal, and the parties shall be in readiness to be heard on the day so appointed.

At the hearing of an appeal not more than two counsel may be admitted to be heard on a side.

In admiralty appeals the judicial committee may, if they think fit, require the attendance of two nautical assessors.

Where the judicial committee, after hearing an appeal, decides to reserve its judgment thereon, the registrar of the Privy Council shall in due course notify the parties by summons of the day appointed by the committee for the delivery of the judgment.

Conclusion.—A notable difference between British jurisprudence and the jurisprudence of Rome is that while Rome gave Roman law to its whole empire, the British empire sought to give to its component parts their own particular law. This imposed upon the judicial committee a task of great complexity. Systems of jurisprudence totally different in outward seeming, but respectively in entire accord with the historical and tribal traditions of the various populations and parts of the empire, had to be administered in such a fashion as, compatibly with British notions of natural justice, to accept and respect not only established local traditions, customs and laws but also rules of succession, rights of property and even of religion prevailing in various parts of the commonwealth.

It had been shown that the bonds of empire might be loosened without being broken, and that it was possible for countries within the commonwealth to evolve from a position of subordination to one of equality without thereby endangering the ties mutually binding the member states of the British Commonwealth of Nations. Nevertheless, the years after World War I saw a considerable reduction in the jurisdiction and business of the judicial committee, and in several instances the existence of the right of appeal to the king in council was felt to be incompatible with complete independence. The uniformity of common law principles, applicable in the past to many varying local conditions, may thus be partly lost.

In the case of ecclesiastical appeals, long a matter of religious dissension, the Church of England sought a new canon to establish its own final court of appeal.

PRIVY PURSE is the amount set apart in the civil list (*q.v.*) for the private and personal use of the sovereign in England. During the reign of Queen Victoria it was £60,000 a year, but on the accession of Edward VII the amount was fixed at £110,000 a year, which was the amount paid to the last sovereign (William IV) who had a queen consort. Under Queen Victoria the offices of keeper of the privy purse and private secretary were combined.

These officials, with their subordinates, are of the king's personal staff.

PRIZE, in law, may be defined as the vessels or goods of the enemy or of a neutral, or of a subject of the captor's own state or of a subject of an ally, captured *jure belli* by a belligerent captor on the high seas, or in rivers, ports and harbours and even in some circumstances on land (*see* the *Roumanian*, 1914, I.B. & C.P.C. 75). For England the term "vessels" includes merchantmen, lighters, rafts, tugs, boats and all other naval craft together with their appointments, such as signalling instruments (*see* the *Anickab*, 1919, 3 B. & C.P.C. 611; 1922, A.C. 235). The term "goods" includes "cargoes" which covers "choses in action" (the *Fredrick VIII*, p. 43, 1917); "bonds and securities" (the *Noordam* [No. 2], 1920, A.C. 904); and "moneys" (*Turkish moneys taken at Mudros*, 1916, 2 B. & C.P.C. 336). Not only goods shipped under a bill of lading (*Ten Bales of Silk at Port Said*, 1916, 2 B. & C.P.C. 13) but also goods dispatched by parcel post are carried by the term (*see* the *Tubantia*, 1916, L.R.P.C. 282). The property in prize does not pass to the captor until it has been brought within the jurisdiction and adjudicated upon. But the property in captured warships passes, on capture, to the captor, and they are only brought into the prize court in order that the prize money may be determined.

United States.—The term prize is "used as a technical term to express a legal capture." (*Miller* v. *The Resolution*, 1781, 2 Dallas Reports, 1.) The courts "assume that 'capture' and 'prize' are not convertible terms, and that for the subject of capture to be made prize for the benefit of the captors the taking must meet the conditions imposed by the statutes." (*The Manila Prize Cases*, 1903, 188 U.S. Reports, 254.)

Captures made on inland waters of the United States are not "liable to condemnation as maritime prize." (*The Cotton Plant*, 1870, 10 Wallace Reports, 577.) The act of congress of July 17, 1862, "excludes property on land from the category of prize for the benefit of the captors." (*United States* v. *Alexander*, 1864, 2 Wallace Reports, 404.) The word "ship," however, "embraces her boats, tackle, apparel and appurtenances because part of the ship as a going concern, and, for the same reason, ship or vessel of war includes her armament, search-lights, stores, everything, in short, attached to or on board the ship in aid of her operations." (*The Manila Prize Cases*, 1903, 188 U.S. Reports, 254.) Nonsea-going boats such as barges propelled by sweeps and by poling and boats having no means of propulsion are not regarded as maritime prize. (*Ibid.*) The United States long argued for the exemption from capture of private property at sea, but this doctrine was not accepted by other states or by the courts. The United States abolished prize money by an act of March 3, 1899. (30 U.S. Stat. 1007.)

Other Countries.—The French prize court will not adjudicate on the validity of captures of warships or on captures effected on lakes or other inland waters. Otherwise, prize covers the same property as in England. In Italy prize extends to captures on the high seas and inland waters which include captures in ports, quays, docks and other places in which maritime traffic is carried on. According to the German Prize code, 1909, prize includes enemy and neutral vessels and goods thereon, but not neutral public vessels. Enemy public vessels are confiscatable without other proceedings. German ships and cargoes and German goods on neutral or enemy vessels are excluded. During World War I the German prize courts declared themselves incompetent if the prize was destroyed without being first captured. Thus, claimants were deprived of their legal remedy for the sinking at sight of their vessels, contrary to the accepted customs of war.

PRIZE COURTS AND PRIZE LAW, in naval warfare, are instrumentalities by which the legality of captures of ships and goods at sea and incidental questions are determined. The establishment of such courts is both a right and duty of belligerents. Lord Parker observed that: "but for the existence of Prize Courts no one aggrieved by the acts of a belligerent power in times of war could obtain redress otherwise than through diplomatic channels and at the risk of disturbing international amity. An appropriate remedy is, however, provided by the fact that according to international law, every belligerent power must appoint and submit to the jurisdiction of a Prize Court to which any person aggrieved by its acts has access, and which administers international as opposed to municipal law—a law which is theoretically the same, whether the court which administers it is constituted under the municipal law of the belligerent power or of the sovereign of the person aggrieved, and is equally binding on both parties to the litigation" (*The Zamora*, 1916, 2 *A.C.* 77).

The judgment of a prize court is binding upon the parties to proceedings before it, that is, normally the captor and the individual or corporation, neutral or enemy, that challenges the validity of the capture. It is not necessarily binding. however, on the state whose national is involved, whether or not it is binding being dependent upon the conformity of the judgment with international law. In case of inconsistency the state of the captor becomes responsible to the state of the claimant, individual or corporation. As the U.S. commissioner William Pinkney pointed out before the Anglo-American mixed commission, established pursuant to the Jay treaty of Nov. 19, 1794, to determine the legality of the seizure of the American ship "Betsey" by the British captor:

> A belligerent has this jurisdiction for its own safety—because it is answerable to other nations for the conduct of its captors. It is allowed exclusive cognizance of the capture for the purpose of ascertaining whether it will confirm it and thus complete its own responsibility, or give to the claimant adequate redress against the captor and thus exonerate itself. . . . The judgment of its prize court in the last resort, in general, perfects or destroys that liability. If it grants adequate redress there is nothing to be answerable for, but if instead of doing so it completes the original injury by rendering it irreparable by any ordinary means, the national responsibility is obviously perfect. The injury becomes its own, and the neutral, from being compelled to ask redress against the captor is now authorized to ask it against his nation. . . .

Claims of belligerents against each other arising from capture are usually settled by the peace treaty. Claims of neutrals against belligerents are settled through diplomatic negotiations or, rarely, international arbitral tribunals. At the second Hague peace conference a proposal was adopted to establish an international prize court to settle disputes between neutrals and belligerents (*see* below).

As the objective of war at sea became increasingly the denial to the enemy of all trade, so prize courts and prize law and particularly the latter were gradually adapted to serve this end. Economic warfare became one of the most significant developments in World Wars I and II. This fact was shown in the expanding and eventually all-embracing concepts of contraband and blockade and the increasing severity of measures taken by belligerents, not merely against enemy, but also against neutral vessels, which came to be regarded by prize courts as permissible.

Prize Courts.—Prize courts are municipal (internal) courts and their character and organization are determined by national tradition and law. It is possible to distinguish two categories: judicial and administrative. English and United States prize courts are purely judicial but the prize courts of other nations are either purely administrative or of a mixed character.

In England, jurisdiction in matters of prize was vested from the 14th century by royal proclamations or commissions in the admiral's court along with instance jurisdiction comprising ordinary maritime cases such as collision or salvage. Statutory prize jurisdiction was conferred on the high court of admiralty by the Naval Prize act of 1864 which continued in the second half of the 20th century to be the basic law. It was amended in 1894, 1914, 1918 and 1939. By the High Court of Judicature act of 1891 and the Supreme Court of Judicature (Consolidation) act of 1925 jurisdiction in prize cases was transferred to the high court of justice and exercised by its probate, divorce and admiralty division. The practice continues, though not considered essential since 1864, to issue a royal commission at the beginning of war concerning exercise of jurisdiction in prize cases. Since 1864 appeals have been taken, in prize cases, to the judicial committee of the privy council, whose determinations are final, and in all other cases, to the court of appeal and ultimately the house of lords. The Prize act of 1939 was applicable in the United Kingdom, in the British dominions (but not in Canada and the Union of South Africa), in British protectorates, colonies and territories held under mandate from the League of Nations and in other territories in which the British crown had prize jurisdiction. In these territories prize jurisdiction was conferred upon the appropriate ordinary courts. The act of 1939 applied to ships as well as aircraft.

In the United States, the constitution (art. iii) provides that the jurisdiction of the United States shall extend "to all Cases of admiralty and maritime Jurisdiction." The judicial code (24, par. 3) provides that federal district courts shall have original jurisdiction "of all prizes brought into the United States; and of all proceedings for the condemnation of property taken as prize" (28 U.S.C.A. 41 [3]). Appeals from their decrees lie in prize cases, to the supreme court directly (Judicial Code 238, 28 U.S.C.A. 345). Bounty and prize moneys a-ere abolished by the act of March 3, 1899, which declared that "all provisions of the law authorizing the distribution among captors of the whole or any portion of the proceeds of, or providing for the payment of bounty for the sinking or destruction of vessels of enemy hereafter occurring in war, are hereby repealed" (30 Stat. 1044, sec. 13). In Britain, the Prize act of 1948 abolished prize money. In France, jurisdiction was exercised by an administrative tribunal composed of a member of the council of state *(conseil d'ktat)*, the highest administrative tribunal in France, six members chosen from the *maîtres des requêtes*, and officials of the ministries of foreign affairs and marine. The *conseil d'ktat* itself exercised appellate jurisdiction in prize cases. In Belgium prize courts were of a mixed character being composed partly of judges from the court of appeal of whom two were appointed, and four representatives of the navy and commerce. Appeals lie to the regular court of appeal. During World War II no prize court was established in Belgium. In Italy prize courts were partly judicial and partly administrative in composition; limited appeal was permitted to the court of cassation, the highest judicial authority. In Germany the prize courts of both original and appeals jurisdiction were of mixed character, and Chinese and Japanese prize courts followed the same pattern. No prize court was established in the U.S.S.R. during World War II. The difference in the character of prize courts in various countries does not necessarily mean that these countries do not administer justice, but in the fact that whereas in the United States and England prize jurisdiction is exercised by existing ordinary courts, in other countries it is the business of *ad hoc* tribunals.

Prize Law.—The law applied by prize courts is international law, customary and conventional. In England, the United States and other common-law countries the rule prevails that international law is part of the law of the land: "International law is part of our law, and must be ascertained and administered by the courts of justice of appropriate jurisdiction, as often as questions of right depending upon it are duly presented for their determination. For this purpose, where there is no treaty, and no controlling executive or legislative act or judicial decision, resort must be had to the customs and usages of civilized nations" (Justice Horace Gray, *The Paquete Habana*, 1900, 175 U.S. 677). Lord Parker said: ". . . the law which the Prize Court is to administer is not the national law or, as it sometimes is called, the municipal law, but the law of nations—in other words, international law" (*The Zamora*, 1916, 2 A.C. 77). Similarly Chief Justice John Marshall declared: "The law of nations is the great source from which we derive those rules, respecting belligerent and neutral rights, which are recognized by all civilized and commercial states throughout Europe and America" *(Thirty Hogsheads of Sugar* v. *Boyle*, 1815, 9 Cranch 191).

There is a practice of long standing for belligerents, at the outbreak of war, to enact prize law through statutory legislation dealing with both substantive and procedural rules. Thus England promulgated prize court rules in 1939; France the decrees of Sept. 2, 1939, amplified by numerous instructions; Germany the Prize Court law of Aug. 28, 1939, amended on Dec. 13, 1940; and Canada the Prize act of 1945. In the United States, congress enacted the Prize act of June 24, 1941 (55 Stat. 261), extending prize jurisdiction to aircraft. Such enactments are presumed to be declaratory of international law but they are in any event binding upon the courts. "It cannot, of course, be disputed that a prize court, like any other court, is bound by the legislative enactments of its own sovereign state. . . . But it is none the less true that if the . . . legislature passed an act the provisions of which were inconsistent with the law of nations, the prize court in giving effect to such provisions would no longer be administering international law" (Lord Parker, *The Zamora,* 1916, 2 X.C. 77). The same would be true in the United States as indicated by Justice Gray in the *Paquete Habana* (case 9), and in other countries. The difference between the Anglo-American and continental courts is that the latter do not feel free even to examine the consistency between international and municipal law since they are bound to apply the latter in any event. A difference arises in respect of British orders in council and equivalent decrees in other countries. Such orders in council are not binding upon the courts unless based upon statutes for the king in council cannot change the law administered by the courts in England any more than he can prescribe the law to be administered by prize courts. However, the prize court will apply orders in council when "they amount to a mitigation of the crown rights in favour of the enemy or neutral, as the case may be" (Lord Parker, *The Zamora,* 1916, 2 A.C. 77). Equivalent decrees would be given effect in other countries. No problem arises in connection with conventional law as this is applicable in most countries in accordance with national law. In the evolution of prize law in England and the United States precedents played a decisive role as they did in the formation of common law. Precedents do not have a comparable authority on the continent although a court would not easily depart from or overrule them.

With a view to ensuring greater uniformity in the application of law by prize courts, two methods were tried: on the one hand, the adoption of agreed rules by treaties or conventions and on the other the establishment of an international prize court. The most important among the former are: the declaration of Paris, 1856; some of the Hague conventions of 1899 and 1907 (namely the 6th convention relative to the status of enemy ships at outbreak of war, the 7th relative to the conversion of merchant ships into warships, the 11th relative to certain restrictions on the exercise of the right of capture in maritime war, and the 13th relative to the rights and duties of neutral powers in maritime war); the London declaration of 1909; and the London protocol of 1936 regarding action by submarines against merchant ships. The binding force of the Hague conventions was dubious because it depended to some extent on their having been ratified by all belligerents which was not usually the case. The conventions were, however, applied, in principle, by British prize courts in both World Wars I and II. The London declaration never entered into force but its rules were applied to the extent that they were deemed to be declaratory of customary international law. The London protocol of 1936 was largely disregarded in World War II by the major belligerents. This, at any rate, was the opinion of the Niirnberg International Military tribunal for the trial of major German war criminals:

In view of all the facts proved and in particular of an order of the British admiralty announced on May 8, 1940, according to which all vessels should be sunk at sight in the Skagerrak, and the answers to interrogatories by Adm. Chester W. Nimitz stating that unrestricted submarine warfare was carried on in the Pacific ocean by the United States from the first day that nation entered the war, the sentence on Adm. Karl Donitz is not assessed on the ground of his breaches of the international law of submarine warfare. (Judgment of Oct. 1, 1946. International Military Tribunal, *Trial of the Major War Criminals, Official Documents,* vol. i, p. 313 [1947].)

To ensure greater uniformity in the jurisprudence of prize courts the establishment of an international prize court with jurisdiction on appeals from national prize courts was envisaged at the second Hague conference in 1907. As noted above, judgments of national prize courts, in case of inconsistency with international law, engage the responsibility of the captor states. To provide a judicial method for settling disputes between states in such cases, an international tribunal would be obviously useful. It was also realized that in spite of their professions national prize courts apply international law as interpreted by their governments and they are bound by municipal statutes. However, the Hague convention of 1907 for an international prize court was never ratified.

Task of Prize Courts.—According to the principle "all prizes must be judged," the main question for prize courts is: "prize or no prize." In the past, prize courts, particularly in England and the United States, were also concerned with awarding prize and bounty moneys and allocation of shares between the crown and the admiralty, the so-called droits of the crown and the droits of admiralty. Judgments of prize courts condemning ships or cargoes or both provide a title for the captor which is "good against the world," without prejudice, of course, to the right of the injured state to seek a remedy in accordance with international law. As noted, prize courts were from a functional point of view instruments of economic warfare and continued so to function in World Wars I and II. However. new methods of depriving the enemy of supplies were developed, such as long-distance blockade and various forms of control at the ship's point of departure rather than in the course of its passage on the high seas. In spite of these innovations, which proved very effective, prize courts operated in England, France, Germany and many other countries. However, no prize courts operated in the United States during either World War I or II. In World War I, the president. authorized by the congressional joint resolution of May 12, 1917 (55 Stat. 261), took over about 100 German and Austrian ships lying in United States ports. In the Versailles treaty of June 28, 1919, Germany waived all claims arising from requisitioning, loss or damage of German ships. In World War II, the U.S. congress, proceeding in a similar fashion. enacted the Idle Foreign Vessels act (1941), which applied to all enemy and neutral vessels (55 Stat. 242). Some 80 ships, including the French liner "Normandie" were requisitioned pursuant to this act, which also provided for compensation.

The history of the matter shows that the policy of the United States has tended to avoid resort to capture and prize, and to substitute . . . gentler legal devices such as requisition for use or title upon promise or payment of just compensation. It is a fact that from 1899 to 1945, including six years of the two great wars, no prize ship or cargo was brought into a United States prize court for adjudication. Those who guide our policy . . . have employed other methods of bringing about the end result of getting foreign ships and cargoes into the war service of the United States. Thus our country has maintained its position of endeavoring to lead the world towards a general law or rule of immunity from capture or destruction of peaceful merchantmen and cargoes not contraband. (Arnold W. Knauth, "Prize Law Reconsidered," *Columbia Law Review,* p. 69 [1946].)

On the other hand, the policy against enemy merchant ships and cargoes was expressed in the official United States Navy dispatch of Dec. 7, 1941: "Execute unrestricted air and submarine warfare against Japan." It was estimated that more than 2,000 Japanese merchant ships were sunk, of which more than one half were destroyed by submarines (see SUBMARINE CAMPAIGNS [WORLD WARS I AND II]). Total war by air and on the sea against enemy shipping and stringent controls at the source of neutral shipping, reinforced by a comprehensive concept of contraband and of enemy destination, it was believed, might well reduce the scope and significance of both prize courts and prize law in a subsequent global conflict. In a limited conflict, however, prize courts and prize law continued to render the traditional service as was evidenced by the establishment of a prize court in Egypt in 1948 following the outbreak of hostilities in Palestine. On Sept. 25, 1955, the United States chief of naval operations promulgated the *Law of Naval Warfare* as the officialUnited States navy manual on the subject (NWIPIO-2, reproduced as an appendix in Tucker).

PRIZREN, a town of Sarplaninski, Yugoslavia. Pop. (1953), 22,997, chiefly Albanians, with some Serbs, Greeks and Vlachs.

Prizren is 1,424 ft. above sea level among the Shar Planina mountains. Its chief buildings are the citadel and many mosques. Prizren has sometimes been identified with the ancient *Tharandus* or *Theranda*. In the 12th century it was the residence of the kings of Serbia. The town was taken by the Serbians in 1912, and assigned to them by the treaty of Bucharest (1913). Soon after the outbreak of World War I the government retired there.

PRJEVALSKY (PRZHEVALSKY), **NIKOLAI MIKHAILOVICH** (1839–1888). Russian traveler who by his explorations and route surveys contributed perhaps more than any other of his generation to the unveiling of central Asia, was born near Smolensk on March 31, 1839. He was educated at the Smolensk gymnasium and in 1855 joined an infantry regiment. In 1856 he became an officer and from 1864 to 1866 taught geography in the military school at Warsaw. The next year he was sent to Irkutsk, and in 1870 he set out from Kyakhta, southeast of Lake Baikal. traveled through Urga (Ulan Bator) and crossed the Gobi desert to Kalgan (Chang-chia-k'on), 100 mi. from Peking. Then he visited Mongolia and then returned to Urga. His second journey commenced from Kuldja in 1876 and took him southeastward across the Tien Shan and Taklamakan, for nearly 200 mi. along the foot of the Astin Tagh, and back by the same route. He set out from Zaisan on his third journey in 1879, crossed Dzungaria and continued southward over the Astin Tagh to within 170 mi. of Lhasa. which he was not allowed to visit. He then turned eastward, partly following the line of the upper Huang Ho, and crossed the Gobi to Kyakhta. The fourth journey began at Urga in 1883 and led across the Gobi. south of Koko Nor (Ch'ing Hai) and Tsaydam to the Astin Tagh and Kunlun mountains and then over the Tien Shan to Issyk-Kul. He had intended to lead another expedition. but died at its commencement at Issyk-Kul on Nov. 1, 1888. Prjevalsky made valuable collections of the flora and fauna of the regions he visited and his discoveries include the wild camel and the only known wild horse (*Equus przewalskii*). The accounts of his first two journeys have been translated into English: E. M. Morgan, *Mongolia, the Tangut Country, and the Solitudes of Northern Tibet* (1876), *From Kulja, Across the Tian-Shun to Lop-nor* (1879).

See N. M. Karataev, *Nikolai Mikhailovich Przheval'skii* (1948).
(A. M. F.)

PRO, MIGUEL (MIGUEL AGUSTÍN PRO-JUÁREZ) (1891–1927), Jesuit victim of the religious unrest in Mexico, was born on Jan. 13, 1891, at Concepcibn del Oro, Zacatecas. He had some Indian blood, and his father was a wealthy mining director. He entered the Society of Jesus in 1911; in Oct. 1914 the anticlerical measures under Pres. Venustiana Carranza obliged him. with other students for the Jesuit priesthood, to leave Mexico for California. He continued his studies in Spain, Nicaragua and at Enghien (Belgium), where he was ordained in 1925. He returned to Mexico, now under the religious persecution of Pres. P. Calles. in 1926 and for 15 months carried on his work as a priest among the people of Guadalupe with agents constantly searching for him. Every morning he offered mass secretly in the presence of many faithful. He preached in backyards, garages, factories, strengthening the faith of thousands. refusing no one who came to him for spiritual or material succour and supporting more than 100 poor families on the alms he could beg for them. In Nov. 1927 the police discovered his hiding place; he was falsely accused of complicity in a bomb plot against the life of Pres. Alvaro Obregón and on Kov. 23 was summarily shot. His connection with the international movement of the Jocistes, or Young Christian Workers, formed while he was in Belgium before ordination. helped to spread his fame rapidly.

PROA, swift-sailing craft of Indian ocean pirates. The chief points which characterize these vessels are that while the weather side is rounded the lee side is flat and that there is a small similarly shaped hull swung out from the side of the main hull on poles, which acts as an outrigger. The main hull carries the mast rigging and a triangular sail.

PROBABILISM, in casuistry, is the view that, where one does not know whether an action would be sinful or permissible, one may rely on a probable opinion for its permissibility even though the more probable opinion is for its sinfulness. The word "probable" must here be understood to mean either "provable" (*i.e.,* logically sound). when opinions are said to have "intrinsic probability"; or "approvable" (*i.e.,* sponsored by some recognized authority). when they have "extrinsic probability." Formulated in 1577 by Bartolomé de Medina (c. 1527–80), a Dominican of Salamanca, probabilism was fast developed by the Jesuits. The Jansenists, who maintained that in doubtful cases of conscience one should take the safer view against permissibility (tutiorism, rigorism), attacked the benignity of the Jesuit confessors as leading to laxity of morals (*see* Pascal's *Lettres provinciales*). The excesses of probabilism were condemned by Pope Alexander VII (1666, 1667) and, more forcefully, by Pope Innocent XI (1679). Probabiliorism, which enjoins following the more probable opinion, was predominant in the 18th century before the formulation of equiprobabilism by Alfonso Maria dei Liguori (*q.v.*). *See* also CASUISTRY.

PROBABILITY. Of the precise meaning of probability there are conflicting views among experts (philosophers, mathematicians, statisticians). The reasons for this may be partly grasped from a survey of the various channels through which a scientific concept of probability has emerged.

Commercial insurance against risks was developed in the Italian cities of the early Renaissance. The theoretical foundations of life insurance were laid in the 17th century. John Graunt in 1662 drew attention to the stability of statistical series obtained from registers of deaths. Soon after, the astronomer Edmund Halley (1656–1742) showed how to calculate annuities from mortality tables (*see* ANNUITY).

Another early reason for interest in probability was in connection with the weight of evidence in legal procedure. The theory of judicial evidence occupies a prominent place in probability mathematics up to the mid-19th century. Today the results of earlier research are recognized as false or unsatisfactory.

Mathematical problems relating to games of chance had been considered, though with minor success, by Luca di Paciuolo, Girolamo Cardano (Jerome Cardan), Niccolb Tartaglia and other mathematicians of the Renaissance. The subject was developed into a "geometry of the die" (*aleae geometria*) by Blaise Pascal, Pierre de Fermat and Christiaan Huygens in the 17th century. Fermat treated the problems within a general theory of combinations, to become further developed by the Swiss mathematician Jacques Bernoulli. The latter can be regarded as the founder of probability theory as a branch of mathematics: his posthumously published *Ars conjectandi* (Basle, 1713) can be said to aim at a fusion of the a priori methods of combinatory probability and the a posteriori methods of early statistical theory. The research on probability done by 18th-century mathematicians culminated in the immense work of Pierre Simon de Laplace, the founder of a tradition that dominated the subject throughout the 19th century.

Laplace advocated a strictly deterministic view of the universe: an omniscient intelligence ("Laplace's demon") would be able to predict the course of nature in minutest detail with infallible accuracy. On this view, probability enters into a science of nature only as a theory of errors; *i.e.,* as a systematic study of the deviations from a mean which appear in repeated measurements of a quantity. This study was developed by Laplace, by A. M. Legendre and by K. F. Gauss (the *normal law of error* and the *method of least squares*). The mathematical calculus of probability soon provided tools for handling statistical material in connection with public finance, health administration, the conduct of elections and other social matters beside insurance. The marquis de Condorcet and later the astronomer L. A. J. Quetelet were champions of a social science on a statistico-probabilistic basis.

From the middle of the 19th century, probability gradually gained ground as a part of physical theory. It first appeared in the theory of heat. J. C. Maxwell in 1860 deduced the familiar gas laws from underlying probabilities for the distribution of positions and velocities over the molecules. Ludwig Boltzmann (1877) interpreted the irreversibility of thermal processes as a tendency toward a most probable distribution of the energies of the molecules. The rise of quantum mechanics saw the theory of radiation put on a probability basis by Max Planck (1900). With the further development of quantum physics, probability invaded atomic theory. By the middle of the 20th century the deterministic view of nature was thought in some quarters to be in process of being replaced by a probabilistic view. The concept of probability had become one of the fundamental notions of a modern science and philosophy of nature. This gave a new urgency to the need for clarifying the structure and meaning of the idea.

The Abstract Calculus of Probability. — In the course of the development already outlined, several definitions of probability were suggested. Accordingly, alternative methods were devised for basing the edifice of probability mathematics on those definitions. These alternative calculi take different views of the meaning of their fundamental notion, but they agree, by and large, in having a common logical structure.

These observations offer a starting point for attempts to create an abstract calculus of probability. It abstracts from the various interpreted calculi their common structure, the formal properties of which it studies independently of any definition of probability.

In the abstract calculus developed by the Russian mathematician A. Kolmogorov (1933), probability figures as a function of sets. This theory. which has found much favour among mathematicians, incorporates probability mathematics within the general theory of measurable sets of points.

Abstract calculi of a type that might be called logistic were constructed by J. M. Keynes (1921), Hans Reichenbach (1932), Harold Jeffreys (1939) and other authors. In these systems probability figures as an undefined logical relation betneen propositions or attributes (propositional functions, classes, sets).

Let us introduce, following Keynes, the symbol a/h, which can be read as "the probability of a given h." It is often convenient to speak of a as an "event" and of h as some "conditions" or "evidence." We need not assume that any pair of propositions (or attributes) determines a numerical value of the functor. But if there is a numerical probability, it should satisfy the following four postulates: (1) $a/h \geqq 0$; (2) $h/h=1$; (3) $a/h+$(not -$a)/h=1$, the principal of complementarity; and (4) (a and $b)/h=a/h\times b/(h$ and a), the general multiplication principle. These four postulates suffice, with the aid of a few principles of a subordinate character, for the erection of the whole fabric of probability mathematics.

From the first, second and third postulates it follows that all probability-values are in the interval from 0 to 1 inclusive.

From the third with the aid of the fourth, we can prove the general addition principle: (a or $b)/h=a/h+$ blh $-$ (a and $b)/h$.

If a and b are mutually exclusive alternatives, the probability of their joint occurrence is 0. Thus for exclusive a and b we have the equality: (a or $b)/h=a/h+b/h$. This is called the special addition principle.

If $a/h=a/(h$ and b). we say that a is independent (for probability) of b (in h). The notion of independence is of great importance to the further development of the calculus. It follows from the fourth postulate and the definition of independence that for independent a and b we have the equality: (a and $b)/h=a/h\times b/h$. This is called the special multiplication principle.

The Frequency Theory of Probability. — This is the view that, popularly speaking, the probability of a given h means the relative frequency with which the event a takes place when the conditions h are fulfilled. The probability of a given h, in other words, is the proportion of h's which are a's.

The frequency view of probability has a long history. Aristotle defines "a probability" as being "what men know to happen or not to happen, to be or not to be, for the most part thus and thus." A similar opinion was entertained by writers of the 17th and 18th centuries, who were interested in statistics or in a "theory of evidence."

The history of probability mathematics from Jacques Bernoulli to Laplace and his folloners is allied to a different view of the meaning of probability. The rebirth of the frequency theory followed a criticism of the foundations of the Laplacean calculus, particularly of the use of the so-called principle of indifference for the determination of probability values (see below). The attack was launched by R. Leslie Ellis, J. Stuart Mill and A. A. Cournot in publications of the same year 1843. The frequency conception of probability was first worked out into a mathematical theory by John Venn (1866).

Early proponents of the frequency theory spoke of probability as a relative frequency "in the long run." This loose way of speaking is not very satisfactory. Venn was the first to define an event's probability as the limiting value which its relative frequency approaches as the number of occasions is indefinitely increased. An improved version of this frequency-limit theory was presented by Richard von Mises in 1919; another later well-known adherent of the theory is H. Reichenbach.

Von Mises also thought that a probability cannot be simply (the limiting value of) a relative frequency and added the qualification that the event ought to be irregularly or randomly distributed in the series of occasions, relative to which its probability is measured. This demand of randomness he called the principle of excluded gambling systems.

It is a great merit of Von Mises' to have stressed the importance of the idea of random distribution to a frequency theory of probability. But with this idea he introduced a considerable difficulty into the theory. How is random distribution to be defined? The definition originally proposed by Von Mises has been accused of inconsistency, but it is doubtful whether any of the alternative definitions proposed by other writers (H. Reichenbach, K. Popper, A. Copeland, A. Wald) can be regarded as satisfactory.

The demand of randomness is relevant to the question of the adequacy of the frequency view as a proposed analysis of the meaning of probability. But it is not relevant to the question of the mathematical correctness of the interpretation of abstract probability in terms of frequencies (either in finite or infinite series). It may easily be verified that a frequency definition satisfies the postulates of the abstract calculus.

Even if we disregard difficulties caused by the notion of randomness, many more objections can be raised against the frequency view. Nevertheless, some form of a frequency theory is thought by many writers to offer the best account (at least for a large category of cases) of the relation between abstract probability and empirical reality.

The Range Theory of Probability. — This theory can, in its simplest form, be explained as follows: We analyze h into a number n of alternative conditions. That h is fulfilled means that either h_1 or . . . or h_n is fulfilled. Some of these alternatives, say m, entail the occurrence of a, the remaining ones entail the occurrence of not-a. Using a traditional terminology, we call the first group of alternatives *favourable* to a and the second *unfavourable* to a. The probability of a given h is the ratio $m:n$ of the number of favourable alternatives and the number of all alternatives.

This, if we omit an important qualification to be discussed presently, is substantially the definition of probability that emerged from the mathematical treatment of games of chance and was canonized in the theory of Laplace. We may refer to it as the classical form of the range definition.

It is natural to call the (mutually exclusive) alternatives covered by a proposition (or an attribute) its range. The classical definition given above can be generalized as follows: The probability of a given h is the ratio of the measure of the range of h-and-a and the measure of the range of h alone: $a/h =_{Df} \frac{\text{mr (h and a)}}{mr(h)}$

The notion of a range (in German, Spielraum) was introduced into probability theory by Johannes von Kries (1886). It was used to define probability as a logical relation between propositions by Ludwig Wittgenstein (1922). Substantially the same definition had been given by Bernard Bolzano as early as 1837. A generalized form (answering to the formula given above) of the Bolzano-Wittgenstein definition was suggested by F. Waismann (1929) and was further developed and extensively studied by Rudolf Carnap (1950). The Waismann-Carnap definition is independent of any specific way of measuring the ranges.

The range definition, both in its classical and in its generalized form. satisfies the postulates of absrract probability. The definition, no doubt, is mathematically correct. But does it give an adequate account of the meaning of probability?

The Principle of Indifference. — The main difficultyconfronting a range theory of probability concerns the measurement of the ranges. This difficulty is allied to the question of how to analyze propositions (or attributes) into alternatives. Usually there are several possibilities open for the choice of a measure and the analysis of the data into alternatives.

The classics of probability theory were aware of these difficulties and the first one to discuss the matter fully was Jacques Bernoulli. He stressed that the alternatives into which h (of the probability-functor) is analyzed ought to be equally possible; *i.e.*, "each case ought to have the same facility as any other case of coming about." This condition of equipossibility in the cases was usually added to the classical range definition of probability. The condition, it will be noted. is tantamount to a principle of measuring ranges.

But what does equipossibility mean and on what conditions may we rightly pronounce cases equally possible? In answer to the latter question Jacques Bernoulli laid down a rule which has become knonn under the names of the *principle of insufficient reason*, the *principle of equal distribution of ignorance* or the *principle of indifference* (Keynes). In its classical version this principle states that tao cases are equally possible if no reason is known why the one case rather than the other should come about.

Reliance on a principle of indifference for measuring ranges (probabilities) has a certain *prima jacie* plausibility in games of chance, where there usually is complete agreement among experts as regards the right analysis of the situations into alternatives of equal possibility. In cases which present no obvious analogy to games of chance, reliance on the principle becomes dubious. It was the use of it made by Laplace and his followers, particularly for the notorious doctrine of inverse probability *(see* below and also INDUCTION), that, in the middle of the 19th century. provoked criticism of the foundations of the entire classical fabric of probability theory. Among the earlier critics of the principle of indifference mention should be made of R. Leslie Ellis. G. Boole, C. S. Peirce and J. von Kries.

In modern times J. M. Keynes discussed the principle acutely and in detail. Severely criticizing its unguarded uses. he also attempted to refashion the principle and to make clear its relevance to any philosophy of probability. Warranted use of the principle is tied to the question of symmetry in the unit alternatives under consideration; and the problem of symmetry in its turn is tied to the problem of an ultimate analysis of propositions (attributes) into alternatives. Any judgment of symmetry or ultimacy, as it presupposes that all relevant information about the cases has been taken into account, is, negatively. a judgment of irrelevance or independence for probability among propositions (attributes). Any pronouncement on irrelevance involves, so Keynes thought, an "element of direct judgment or intuition."

The principle of indifference has usually been discussed in connection with the classical range definition, to which ·it was traditionally regarded as a necessary supplementation. It should, however. be observed that the problems connected with this principle recur, *mutatis mutandis*, within any theory which defines probability in terms of the relative magnitudes of ranges.

Is Probability Subjective or Objective? — Bernoulli and Laplace were both of the opinion that anything which happens has a sufficient cause, of which, however, we may be ignorant: man's ignorance, not nature's indeterminateness. is the mainspring of probability. This is why Bernoulli called probability a degree of certainty.

Many authors have spoken of probability as a degree of belief. This has a psychologistic or subjectivist implication which has brought a great deal of confusion into the subject. It carries nith it the suggestion that the principles of probability were mathematical laws concerning psychological facts; viz.. the ways in which people "distribute" their beliefs in conjectured events. It would seem that not even the most advanced attempts to work out a belief theory of probability (F. P. Ramsey, B. De Finetti) have taken this suggestion seriously. Some authors (*e.g.*, Keynes and Jeffreys) avoid psychologism by calling probability, not a degree of belief, but a rational or reasonable degree of belief.

It has been customary to contrast subjectivist or psychologistic views on probability with objectivist conceptions. The terms are unfortunate and obscure the point at issue. The contrast really is between an epistemic view, according to which probability is an attribute (or mode) of our knowledge of things, and an ontological view, according to which probability is an objective feature of the world. The issue between these two views, moreover, is not necessarily tied to the problem of determinism.

The definition of probability as a relative frequency is clearly objectivist. So is also the definition of probability as a relative measure of ranges, provided that the method of measurement does not—like the classical principle of indifference—make reference to a state of knowledge (or ignorance).

We have seen, however, that supporters of the definitions in question have found it necessary, in order to reach an adequate analysis of probability, to add to them ingredients which are not needed from the point of view, of pure mathematical theory. In the case of the frequency vien, this addition was a demand for random distribution of events on a series of occasions. In the case of the range theory, it was a demand for equipossibility in certain unit-alternatives. These additions, with which the notorious difficulties of the two views are intimately connected, easily lend themselves to an epistemic interpretation: of equipossibility in terms of insufficient reasons; and of randomness in terms of ignorance of the manner in which events alternate in a sequence.

Can randomness and equipossibility be satisfactorily accounted for in objectivist terms; *i.e.*, independently of reference to a state of knowledge or ignorance? This can be regarded as the fundamental question in the philosophy of probability. Authors of the classical period openly avowed an epistemic view of probability. Their often uncritical use of the principle of indifference and the dangers of subjectivism to which the epistemic view is exposed provoked a reaction in favour of an ontological conception of probability. By the middle of the 20th century the conflict of views had still not been settled, even provisionally.

Bernoulli's Theorem. — Let us assume that the probability for the occurrence of an event a on a certain occasion of h is not affected by its occurrence or nonoccurrence on previous occasions of h. The occurrences of a, in other words, are independent for probability of one another. And let us assume that this probability is p. A simple use of the special multiplication and addition principles can now be made for calculating the probability that the event a will, on n occasions of h, be realized with a relative frequency in the interval $p \pm \epsilon$. From considerations about this second-order probability we can prove that:

1. The most probable value of the event's relative frequency on n occasions is that value which comes nearest to its probability p.

2. The probability that the event's relative frequency on n occasions will deviate from its probability p by less than a given amount ϵ, however small, approaches 1 as a limit when n is indefinitely increased. Thus, popularly speaking, in the long run the event will almost certainly be realized with a relative frequency corresponding to its probability.

An example will illustrate this asymptotic character of the increasing probability. The probability of head and tail in tossing with a normal coin is $\frac{1}{2}$. The results are independent for probability: no combination of head and tail in previous tosses will influence the probability of getting head or of getting tail in the next toss. A simple calculation shows that the probability of getting 49, 50, or 51 heads in 100 tosses is approximately 0.16; the probability of getting between 490 and 510 heads in 1,000 tosses is 0.47; and the probability of getting between 4,900 and 5,100 heads in 10,000 tosses is 0.95. In other words: in 10,000 tosses it is already almost certain that the proportion of heads will deviate by less than 0.01 from its probability $\frac{1}{2}$.

This remarkable theorem is known as Bernoulli's theorem. It is chronologically the first member of a class of propositions which are called the laws of great numbers. The name was introduced by Siméon Denis Poisson (1837).

Inverse Probability. — In 1763 Thomas Bayes proved that, if m:n is the relative frequency of an event on n independent occasions, then m n is also the most probable value of the event's probability,, provided that any value of this probability is initially (a priori) as probable as any other value. The same theorem was proved independently by Laplace in 1774. Laplace also proved that, on the assumptions mentioned. it will in the long run become almost certain that the probability of the event coincides with its relative frequency.

The Bayes-Laplace theorem is the inversion of Bernoulli's theorem and the cornerstone of the classical doctrine of inverse probability for the estimation of probabilities on the basis of frequencies. The doctrine was developed and put to extensive use by Laplace and his followers. It was thought to be of great relevance to the problem of induction (*q.v.*).

The Achilles' heel of inverse probability is its dependence on initial or a priori probabilities. These were in the classical doctrine often established by deplorably uncritical use of the principle of indifference. The doctrine was challenged in the 19th century, particularly by early proponents of the frequency view. The use of inverse probability is still a matter of debate. Some researchers, among them R. A. Fisher, have altogether rejected it.

Asymptotic **Probabilities** and the Principle of Moral **Certitude.**—It was often thought in the past that, by virtue of Bernoulli's theorem, *events will, in the long run, happen in numbers proportional to the probabilities* (A. De Morgan, 1838). But this is a serious mistake. The theorem only says that it becomes increasingly probable that the frequency coincides with the probability. And this, by itself, does not warrant any conclusion about actual frequencies, not even in the long run.

The error latent in the idea that Bernoulli's theorem provides a bridge from a subjectivist conception of probability as a degree of certainty to an objectivist conception in terms of frequencies was first clearly seen and conclusively criticized by R. Leslie Ellis (1843). There were many relapses into the error afterward, but today the correctness of the criticism is universally admitted.

There is, however, another way of using Bernoulli's theorem and other asymptotic principles of probability (laws of great numbers) as a bridge from (uninterpreted) probabilities to statistical frequencies without committing a logical error. It may be briefly indicated as follows:

Let us assume that, either from observations about frequencies or from considerations about ranges or from some other source, we frame a hypothesis about the probability of a given h. From this hypothesis we calculate that it is "almost" or, as Bernoulli would have said it, "morally" certain (say probable to degree 0.95) that in a series of n trials the relative frequency of the event will deviate from its probability by less than a small iraction (say 0.01). In other words, it is "most unlikely" (morally impossible) that the frequency will fall short of the hypothetical probability by more than this fraction. Now we may adopt a maxim that very improbable events are "practically excluded" or that "moral certainty!' should be treated as equal to full certainty. Consequently, if the event's frequency nevertheless deviates irom the hypothetical value by more than the fraction in question, we say, not that something very improbable has happened, but that our probability hypothesis has to be rejected.

The proposed maxim mas in fact suggested already by Bernoulli. It might be called Bernoulli's principle of moral certitude. Its adoption seems to be in good accord with actual use of probability calculations for scientific and applied purposes. And it partially explains why it is possible, without detriment to the applications of probability, to suspend judgment as regards the meaning of this controversial notion. The calculus is a vehicle which takes us from hypothetical probabilities to predicted irequencies. If the observed frequencies conflict with the principle of moral certitude, the hypotheses are modified or rejected. The boundaries of moral certitude are, of course, elastic; and whether we wish provisionally to fix them at one value rather than at another will depend upon a multitude of circumstances peculiar to each case. Such circumstances are the amount of statistical evidence at hand, the possibilities of repeated trials and the facility with which dependencies between occurrences can be controlled. Among them are also considerations of an ethical nature relating to the gains and losses which we may incur by choosing one probability hypothesis rather than another as a basis of our actions. To analyze and to evaluate these circumstances is a major task of statistical theory.

Has "Probability" One or Many Meanings?— Compare the following uses of probability: (1) "the probability of a normal six-sided'die turning up 'six' is $\frac{1}{6}$"; (2) "the probability that Shakespeare wrote the plays commonly attributed to him is overwhelming"; (3) "Fresnel's experiment increased the probability of the undulatory theory of light." Does "probability" mean the same in all the three statements?

According to Hans Reichenbach, one of the chief proponents of the frequency theory in modern times, there is only one (scientific) meaning of probability. A statement of the second type exemplified above, which concerns the probability of an individual event, is literally meaningless, but may be reinterpreted as a statement about that *which usually is the case under similar circumstances.* Statements of the third type, again, which attribute probability to general propositions (laws of nature, theories, hypotheses) may, according to Keichenhach, be given a frequency interpretation as referring either to a proportion of successiul predictions, or to a proportion of true theories within a class.

A unitary view of probability was also taken by J. M. Keynes, though on quite different grounds. According to Keynes, the difficulties presented by cases such as the second and third types exemplified above mould indicate that probability is a wider notion than the concept which figures in a frequency theory or even in any theory which requires probability to be a measurable quantity. In its wide sense, probability is a (not necessarily measurable) degree of rational beliei (*see* above).

Those who have advocated a dualistic view of probability have usually wished to contrast cases of the third type, or the probability of laws of nature. with other types of probability. Jacob Friedrich Fries (*System der Logik*, 1811; *Versuch einer Kritik der Principien der Wahrscheinlichkeitsrechnung*, 1842) called the probability of laws "philosophical probability" and contrasted it with "mathematical probability." This distinction was adopted by many logicians and philosophers of the 19th century (E. F. Apelt, A. A. Cournot, M. W. Drobisch). Philosophical probability was thought to be nonnumerical in principle. A similar position found favour with many 20th-century authors: B. Russell (1948) contrasts "credibility" and "mathematical probability"; W. Kneale (1949), "acceptability" and "chance"; R. B. Braithwaite (1953), "reasonableness" and "probability."

A dualistic view of a somewhat different nature mas developed by Rudolf Carnap (*Logical Foundations of Probability*). Of the two concepts of probability that he distinguishes, the first (which he also calls "degree of confirmation") is probability in the sense of a range theory; the second is probability in the sense of a frequency theory. Both concepts are mathematical and may be regarded as alternative interpretations of an abstract calculus. Carnap tries to reconcile the rival claims of the two theories by assigning to each concept of probability its proper field of application. In view of the difficulties, however, which both theories encounter as proposed analyses of probability, it cannot he taken for granted that this reconciliation is altogether satisfactory.

Cramér, *Mathematical Methods of Statistics* (London, Princeton, N.J., 1946). (G. H. v. W.)

PROBABILITY AND STATISTICAL THEORY. The theory of probability is that branch of applied mathematics which deals with a priori numerical evaluation of the relative frequencies with which events or combinations of events are predicted to occur under repetition of a set of conditions. Statistical theory deals with the application of probability theory to the collection, analysis and interpretation of numerical observational data.

The branch of applied mathematics which deals with probability and its application to the theory of statistics is called mathematical statistics.

THEORY OF PROBABILITY

The a priori evaluation of relative frequencies is often easy to make. For example: consider an ordinary six-sided die. If, upon preliminary analysis, it appears reasonable to assutne that the die is "true," then an a priori evaluation of the relative frequency with which an ace will turn up when the die is thrown is $\frac{1}{6}$. We predict that if the die is rolled a large number of times, about one-sixth of the trials mill result in an ace; we say that the probability of getting an ace in a single trial is $\frac{1}{6}$. All of these statements about the die are made independently of whether the die is actually thrown. In order to determine whether the statement that the probability of getting an ace with the particular die is $ has validity, a number of experiments would have to be performed, each of which would consist of rolling the die a large number of times and counting the proportions of aces and comparing these proportions with the prediction that "one-sixth of the trials mill result in an ace." This comparison in turn involves probability considerations in order to determine whether the discrepancies between the proportion of aces resulting from the various experiments and the proportion predicted by probability theory are large enough to invalidate the prediction.

Another idea involved is that in the sequence of trials in each experiment the aces and "nonaces" are mixed up in a random fashion in the ratio of about one to five. The notion of randomness is an extremely elusive one to define precisely. The idea of randomness in a finite sequence of events produced in an experiment depends on the consideration of a set consisting of a large number of such sequences and the evaluation of the proportion of the sequences of a given composition (e.g., configuration of aces and nonaces). But even this approach does not completely define the concept of randomness. It is not unreasonable to leave it as an undefined intuitive concept. It turns out that there are "practical" ways of statistically testing the randomness of a sequence, which will be discussed under Statistical Tests, below.

At this juncture we begin to get into statistical theory—the application of probability theory in the interpretation of observational data. It is to be noted, therefore, that the concept of probability involves the notion of the prediction of the proportion of trials in repeated experiments which will have a given property, and also the notion of the randomness with which trials with the given property occur in a sequence of trials. Thus, if we consider two "perfect" dice, we note that there are 36 different ways the two dice can fall, all ways assumed to be "equally likely," and of this number, there is only one way in which the two dice will both turn up aces. The statement would then be made that the probability of getting two aces in a single throw of two dice is $\frac{1}{36}$, which is a prediction that if the two dice are thrown a large number of times, pairs of aces will occur "at random" in the sequence with such frequency that one thirty-sixth of the trials will result in a pair of aces. Similarly, we can evaluate the probability that the total number of dots turning up in a throw of a pair of dice will be four, or the probability that the number of dots will be larger than nine, and so on.

Definition of Probability for Discrete Events.—If an event can occur in exactly one of n different or discrete ways, all "equally likely," in which m have property A, we say that the probability of an A is m/n. The usual notation is to write:

$$Pr(A)=\frac{m}{n}. \tag{1}$$

The term "equally likely" is left as an undefined term, except to remark that if several alternative outcomes of an event are regarded as equally likely, they are given equal weight in evaluating probabilities. To attempt to pursue the term "equally likely" much further will essentially result in tautology, and will lead to confusion in the application of probability theory to statistical theory. It is unnecessary, so far as the theory of probability is concerned, to worry about the statistical meaning of the term "equally likely" as many authors have done. It is an idea involved only in the probability theory and not in its application to a set of observations. Thus, it can be rigorously handled as far as mathematical operations are concerned, even though left as an undefined concept. Various other definitions of probability have been proposed but space does not permit a discussion of them here.

Addition of Probabilities for Events with Mutually Exclusive Properties.—Suppose an event can happen in exactly one of n different ways, all equally likely. Furthermore, suppose that in m' of them the event has property B, and that no event can have property A and also property B. Then the number of ways in which the event will have property A or property B is $m+m'$, and hence the probability of properties A or B occurring is $(m+m')/n$, which is the same as $m/n+m'/n$. But m/n is the probability of property A, and m'/n is the probability of property B. This fact may be summarized as the law of addition of probabilities: *If A and B are mutually exclusive properties which an event can have (i.e., the event cannot have both properties A and B), then the probability of an A or a B is equal to the probability of an A plus the probability of a B.* Stated more briefly: *If A and B are mutually exclusive properties which an event can have, then*

$$Pr(A \text{ or } B)=Pr(A)+Pr(B). \tag{2}$$

More generally: *If A, B, . . . , K are all mutually exclusive properties which an event can have, then*

$$Pr(A \text{ or } B \text{ or } \cdots \text{ or } K)=Pr(A)+Pr(B)+\cdots+Pr(K). \tag{3}$$

As an example of how the law of addition works, consider the probability of getting a total of less than four dots in a throw of two dice. The probability of getting less than four dots is the same as the probability of getting two dots, or three dots. The probability of getting two dots is $\frac{1}{36}$. The probability of getting three dots is $\frac{2}{36}$ (since there are two ways in which three dots can occur). Therefore, since getting two dots and getting three dots are mutually exclusive events, we have, by the law of addition, the probability of getting less than four dots is equal to the probability of getting two dots plus the probability of getting three dots; i.e., $\frac{1}{36}+\frac{2}{36}=\frac{3}{36}$. More briefly:

$$Pr(\text{less than } 4)=Pr(2 \text{ or } 3)=Pr(2)+Pr(3).$$

Conditional Probability.—Suppose an event can result in an A or an $\bar{A}$, and also in a B or a $\bar{B}$. Then the event will always result in one of four mutually exclusive categories characterized as follows: (1) A and B, (2) $\bar{A}$ and B, (3) A and $\bar{B}$, and (4) $\bar{A}$ and $\bar{B}$. If n_{11}, n_{12}, n_{21}, n_{22} are the numbers of ways the event can result in these four categories, respectively, then the situation can be represented by the following table:

	B	$\bar{B}$	
A	n_{11}	n_{12}	$n_{1\cdot}$
$\bar{A}$	n_{21}	n_{22}	$n_{2\cdot}$
	$n_{\cdot 1}$	$n_{\cdot 2}$	n

where $n_{1\cdot}=n_{11}+n_{12}$, the total number of ways A can occur, $n_{\cdot 1}=n_{11}+n_{21}$, the total number of ways B can occur, with similar meanings for $n_{2\cdot}$ and $n_{\cdot 2}$. $n=n_{11}+n_{21}+n_{12}+n_{22}=n_{1\cdot}+n_{2\cdot}$. $n_{\cdot 2}$ is the total number of ways the event can occur.

Now suppose an event (which can actually happen; i.e., $n_{\cdot 1}\neq 0$) is known to have property B. Then the probability that it will also have property A is $n_{11}/n_{\cdot 1}$. But $n_{11}/n_{\cdot 1}=(n_{11}/n)/(n_{\cdot 1}/n)=Pr(A \text{ and } B)/Pr(B)$. We have, therefore, an important law in probability theory known as the *law of conditional probability* which can be stated as follows: *The probability that an event will be an A, given that it is a B, is equal to the probability that it is both an A and a B divided by the probability that it is a B.* This law is usually stated briefly as follows:

$$Pr(A|B)=Pr(A \text{ and } B)/Pr(B). \tag{4}$$

As a simple example, to show how this law operates, suppose we have four kinds of wooden beads all of the same size in the following quantities:

6 beads painted with luminous red paint,
12 beads painted with plain red paint,
10 beads painted with luminous green paint,
14 beads painted with plain green paint.

The situation can be represented in the following table:

	Luminous	Plain	Total
Red			
Green			
Total	16	26	42

Now suppose the 42 beads are put in a bowl and thoroughly mixed. Assume that the colour (red or green) of the beads is exactly the same for luminous as for plain paint, and similarly that the visibility in the dark is exactly the same for red luminous paint as for green luminous paint. A bead is drawn from the bowl in the dark, and observed to be luminous. What is the probability that it is red? The answer is:

$$Pr(\text{red}|\text{luminous})=Pr(\text{red and luminous})/Pr(\text{luminous})$$
$$=\left(\frac{6}{42}\right)\Big/\left(\frac{16}{42}\right)=\frac{3}{8}.$$

If a bead is simply drawn from the bowl the probability of its *being red is* $\frac{18}{42}=\frac{3}{7}$. *If a bead is* drawn *from the bowl in daylight and is* observed *to be red, the probability of its being luminous*= Pr(red *and luminous*): $Pr(\text{red})=\left(\frac{6}{42}\right)/\left(\frac{18}{42}\right)=\frac{1}{3}$.

Multiplication of Probabilities.— It will be seen in the example given above that the probability of getting a red bead knowing that the bead is luminous *is different from the probability of getting a red bead,* when *no use is made of* its *property of being luminous or plain. However, if the ratio of red to green beads with luminous paint mere exactly the same as that for beads with plain paint, no such difference in probabilities mould exist. For example, if the number 14 were replaced by* 20 *in the table we would have such a condition; in this case we would have*

$$Pr(\text{red}\,|\,\textit{luminous})=Pr(\text{red}),$$

or

$$Pr(\text{red } \textit{and luminous})/Pr(\text{luminous})=Pr(\text{red}).$$

This may be rewritten as:

$$Pr(\text{red } \textit{and luminous})=Pr(\text{red})\times Pr(\text{luminous}).$$

Thus, when the ratio of red to green beads is the same for luminous paint as for plain paint (or, what amounts to the same thing, when the ratio of luminous to plain painted beads is the same for red as for green) it follows that if a bead is drawn from the bowl, the probability of its being both red and luminous is equal to the probability of its being red multiplied by the *probability of its being luminous. Under the same conditions it would also follow that:*

$$Pr(\text{red}\,|\,\textit{plain})=Pr(\text{red})\times Pr(\text{plain}),$$

with similar results holding for the values of Pr (green|luminous) and Pr(green| *plain*).

In the more general case it follows that if $n_{11}/n_{12}=n_{21}/n_{22}$ *then* $Pr(A\,|\,B)=Pr(A)$ *and hence formula* (4) *reduces to* $Pr(A)=Pr(A \text{ and } B)/Pr(B)$, which *may be written as:*

$$Pr(A \text{ and } B)=Pr(A)\times Pr(B). \tag{5}$$

If the condition $n_{11}/n_{12}=n_{21}/n_{22}$ *holds, then properties A and* $\bar{A}$ *are said to bc independent of properties B and* $\bar{B}$. *Formula* (5) *is known as the multiplication* law *of probabilities, and it can be stated in words as follows: If A and* $\bar{A}$ *are independent of B and* $\bar{B}$ *then the probability of an event having both properties A and B* is *equal to the product of the Probability of A and the probability of B. Similar results hold, in the case of independence, for* $Pr(A \text{ and } \bar{B})$, $Pr(\bar{A} \text{ and } B)$ *and* $Pr(\bar{A} \text{ and } \bar{B})$.

The notion of independence extends rather readily to the case in which each event may have one of several mutually exclusive properties $A_1, A_2, \ldots, A$, *and also one of several mutually exclusive properties* $B_1, B_2, \ldots, B_q$. *If* n_{11} is *the number of events having both properties* A_1 *and* B_1 *with similar meanings of* n_{12}, $n_{21}, \ldots, n_{pq}$ *then if the numbers* $n_{11}, n_{12}, \ldots, n_{1q}$ *are proportional to* $n_{21}, n_{22}, \ldots, n_{2q}$ *and to* $n_{31}, n_{32}, \ldots, n_{3q}$ *and so on, then* $Pr(A_i \text{ and } B,)=Pr(A_i)\times Pr(B_j)$ *where A, is any given one of the A categories and B, any given one of the B categories.*

As an example, consider a throw *of two dice, A and B. Let* A_1, $A_2, \ldots, A_6$ *denote the faces* 1, 2, . . . , 6 *of die A,* with *similar meanings of* $B_1, B_2, \ldots, B_6$ *for die B. In this example,* $n_{11}=n_{12}=n_{21}=\ldots=n_{66}=1$, *and* we *have independence. The probability of getting a 3 on die A and 4 on die B is*

$$Pr(A_3 \text{ and } B_4)=Pr(A_3)\times Pr(B_4)=\frac{1}{6}\times\frac{1}{6}=\frac{1}{36}.$$

Addition of Probabilities for Events Having Properties Which Are Not Mutually Exclusive.— Under the section Addition of Probabilities for Events with Mutually Exclusive Properties, above, it was shown that if an event can have either property A or property B (not both) then the probability of getting A or B is given by $Pr(A \text{ or } B)=Pr(A)+Pr(B)$ *— the law of addition of probabilities for events with mutually exclusive properties. Now suppose A and B are not mutually exclusive properties, as is the case under Conditional Probability, above. What is the probability of an event yielding property A or property B? Looking at the first table in the above-mentioned section it will be seen that the number of ways in which an event can result in an A or a B is* $n_{11}+n_{12}+n_{21}$, *which may be written as* $(n_{11}+n_{12})+(n_{11}+n_{21})-n_{11}=n_{1\cdot}+n_{\cdot 1}-n_{11}$. *Hence the probability of an A or B is*

$$Pr(A \text{ or } B)=\frac{n_{1\cdot}+n_{\cdot 1}-n_{11}}{n}=\frac{n_{1\cdot}}{n}+\frac{n_{\cdot 1}}{n}-\frac{n_{11}}{n}.$$

But

$$\frac{n_{1\cdot}}{n}=Pr(A),\ \frac{n_{\cdot 1}}{n}=Pr(B), \text{ and } \frac{n_{11}}{n}=Pr(A \text{ and } B).$$

Therefore,

$$Pr(A \text{ or } B)=Pr(A)+Pr(B)-Pr(A \text{ and } B). \tag{6}$$

This is the la of addition of probabilities for events having properties which are not mutually exclusive. Stated in words: If A and B are properties which an event cart have, then the probability of being an A or a B is equal to the probability of being an A plus the probability of being a B minus the probability of being both an A and a B. It will be noted that (6) will hold also when *A and B are mutually exclusive, for in this case,* $Pr(A \text{ and } B)=0$.

In the example of Conditional Probability, the probability of getting either a red bead or a luminous bead is:

$$\begin{aligned}&Pr(\text{red or luminous})\\&=Pr(\text{red})+Pr(\text{luminous})-Pr(\text{red and luminous})\\&=\frac{18}{42}+\frac{16}{42}-\frac{6}{42}=\frac{28}{42}=\frac{2}{3}.\end{aligned}$$

Permutations and Combinations.— The definition of probability expressed in (1) together with the laws expressed in (2), (3), (4), (5) and (6) will *enable one to solve the majority of common probability problems that arise in games of chance and other situations involving a finite number of discrete events. In actually applying these* laws *the main technical problem is that of enumerating the total possible number of events n, and the number of these events m having a given property A. Many of the problems of enumeration reduce to the computation of permutations and combinations.*

Consider the word "and." How many arrangements of two letters can be made from these three letters? The answer is six which are readily seen to be: an, na, ad, da, nd and dn. We *say there are six two-permutations which can be formed from the letters in "and." Or more briefly,* ${}_3P_2=6$. Now, *this number of arrangements can be arrived at more briefly. Consider* two *spaces—to be filled from the letters in "and." The first can be filled by a letter in three ways, and after the choice of a letter has been made for the first place, there are two ways of filling the second place. Therefore, for each of the three* ways *of filling* thr *first place there are two* ways *of filling the second, and hence* the *total number of* ways *of filling both places is* $3\times 2=6$.

To examine a little more complicated case, how *many* three-*permutations are there in the word "problem?"* W*e* would write *down three spaces———. There are seven* ways *of filling the first place, after which there are six* ways *of filling the second, after which there are five* ways *of filling the third. Each choice in the first place can be combined with each choice in the second place, and each pair of these choices can be combined with each choice in the third place. The total number of ways of filling the three places is* $7\times 6\times 5=210$. *That is,* ${}_7P_3=210$.

In general, the number of r-permutations ${}_nP_r$ (*i.e., the number of arrangements of r objects which can be made from n different objects) is given by:*

$${}_nP_r=n(n-1)(n-2)\text{ ------ }(n-r+1)=\frac{n!}{(n-r)!}, \tag{7}$$

where $n!$ (*read n factorial*)$=n(n-1)(n-2)\ldots 2.1$, with *a similar meaning for* $(n-r)!$ *In particular, if* $r=n$, we have ${}_nP_n=n!$

Thus far, we have treated only the case in which all letters are different. Consider what form the formula for ${}_nP_n$ *takes when some of the letters in the original set are repeated. As an example let us take the word "bobbin" and determine how many different six-permutations there are of these three letters. Putting two dashes on the first b and one dash on the second b, it* will *be noted that the six-permutations of the six letters occur in* *sets of six which differ only in the way in which b, b′ and b″ are arranged. For example, one such set of six is boinb′b″, boinb″b, b′oinbb″, b′oinb″b, b″oinbb′, b″oinbb, which is simply the number of ways (i.e., 3!) three objects can be permuted. If the dashes are dropped, these permutations will be indistinguishable. Since there are 6! six-permutations when dashes are retained, and since these occur in sets of six which become identical when the dashes are removed, the number of distinct six-permutations of the letters in "bobbin" is 6!/3!.*

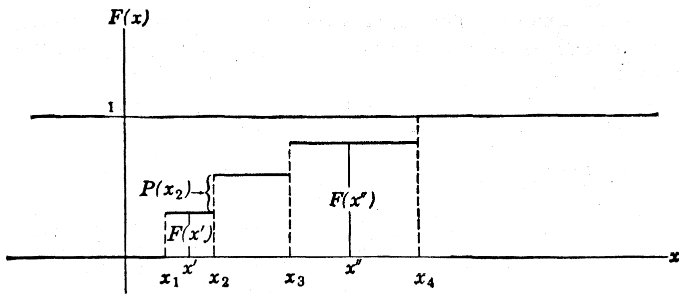

FIG. I.—DISCRETE CUMULATIVE DISTRIBUTION FUNCTION

In general, if a set of n letters (or objects) consists of n_1 letters of one kind, n_2 of a second kind, . . . , n_k of a kth kind, where $n_1+n_2+\ldots+n_k=n$, then the number of distinct n-permutations $_nP(n_1n_2\ldots n_k)$ of these letters is given by

$$_nP(n_1n_2\ldots n_k)=\frac{n!}{n_1!n_2!\ldots n_k!} \qquad (8)$$

It should be noted that if $n_1=n_2=\ldots=n_k=1$, then $_nP(11\ldots 1)={}_nP_n=n!$

For example, the number of distinguishable arrangements of the letters in "banana" is:

$$_6P(321)=\frac{6!}{3!2!1!}=60,$$

since there are three a's, two n's and one b in "banana."

As seen in the foregoing discussion, permutations are defined as arrangements of objects. In many probability problems, the arrangement of the objects is irrelevant, and the important thing is the set of objects. For example, let us return to the word "and" and inquire how many sets or combinations of two letters can be formed from these three letters. The answer is three: an, ad and nd. In considering permutations of two letters the answer is six, because the letters in each of these three sets of two letters can be arranged in two (i.e., 2!) ways. In other words, for each combination of two letters there are two permutations of the two letters. If we denote by $_3C_2$ the number of two-combinations of letters which can be made from the three letters in "and" we have $2\times{}_3C_2={}_3P_2$. In general, the number of different r-combinations $_nC_r$ which can be made from n different letters or objects is given by:

$$_nC_r=\frac{_nP_r}{r!}=\frac{n!}{r!(n-r)!}. \qquad (9)$$

Formulas (7), (8) and (9) can be used for solving many of the probability problems that arise in games of chance and other situations where discrete events are involved. As an example, consider the problem of determining the probability of getting four aces in dealing a hand of 13 cards from an ordinary deck of playing cards. The total number of possible hands of 13 cards out of a deck of 52 cards is $_{52}C_{13}$. The total number of hands each containing four aces is equal to the number of ways of getting 9 nonaces out of 48 nonaces multiplied by the number of ways of getting four aces out of four aces; i.e., $_{48}C_9\times{}_4C_4$. Hence, the probability of getting a hand with four aces is

$$\frac{_{48}C_9\times{}_4C_4}{_{52}C_{13}}=\frac{48!}{9!39!}\div\frac{52!}{13!39!}=\frac{13.12.11.10}{52.51.50.49}=.0028.$$

Treatment of arrangements and combinational problems of a more complex character than can be handled by formulas (7), (8) and (9) will be found, for example, in W. A. Whitworth's Choice and Chance and H. Levy and L. Roth, Elements of Probability.

Random Variables and Distribution **Functions.**—*The Discrete Case.—In dealing with probability problems, it is usually convenient to describe the events under examination by means of values of one or more variables. For example, we can describe the probability theory of a single die by writing down the probability $p(x)$ that x dots will turn up in a throw of the die, which in the case of a true die is given by $p(x)=\frac{1}{6}$, for $x=1, 2, 3, 4, 5, 6$. In other words, the probability is $\frac{1}{6}$ for each value of x. In the case of throwing two dice, the probability $p(x)$ of getting a total of x dots is defined by writing:*

$$p(2)=\frac{1}{36},\ p(3)=\frac{2}{36},\ p(4)=\frac{3}{36},\ \ldots,\ p(12)=\frac{1}{36}.$$

In many cases, one can write down an explicit formula for $p(x)$ in terms of x. For example, the probability of getting x aces in a hand of 13 cards from an ordinary deck is

$$p(x)=\frac{_{48}C_{13-x}\times{}_4C_x}{_{52}C_{13}}$$

which holds for all possible values of x; namely 0, 1, 2, 3, 4. Furthermore, in this example, it can be readily verified that $p(0)+p(1)+p(2)+p(3)+p(4)=1$.

When an event can be described by one of several values of a variable x, say $x_1, x_2, \ldots, x_k$, such that the probability is $p(x_i)$ that x takes on a given value x_i when a trial is made, then we say that x is a random oariable, with discrete probability law (or distribution function) p(x), where $p(x)\geqq 0$. In such a situation we usually abbreviate and say that x is a discrete random variable. The numbers $x_1, x_2, \ldots, x_k$ are sometimes called the event points or sample points of the random variable x. The collection of all of these numbers is called the event space or sample space of x. If rue sum $p(x)$ for all values of i for which $x_i\leqq x'$ and denote this sum by F(x); i.e.,

$$F(x')=\sum_{x\leqq x'}p(x), \qquad (10)$$

then $F(x')$ is the probability that x$x. If x can take on only four values, say x_1, x_2, x_3, x_4 and if $F(x)$ is graphed as a function of x it would look something like the heavy graph in fig. 1. $F(x)$ as defined by (10) is called a discrete cumulative distribution function.

The graph takes a jump at each possible value of x (e.g., x_1, x_2, x_3, x_4 in fig. 1), the jump being equal to the probability that x has that particular value of x. The ordinate F(x) at any particular value of x, say x', is the probability that x will not exceed x' when a trial is made. $F(x)$ remains constant or increases as X takes on increasing values and is such that the value of $F(x)$ ranges from 0 to 1 as x ranges from $-\infty$ to $+\infty$. If we take any two values of x, say x' and x", where $x'<x''$, then it follows, from the law of addition of probabilities, that the probability that $x'<x\leqq x''$ will be given by the difference $F(x'')-F(x')$; more briefly, $Pr(x'<x\leqq x'')=F(x'')-F(x)$. In the case of a die (a "true" die) where x denotes the number of dots, which would appear when the die is thrown, there would be six possible values of X, which are 1, 2, 3, 4, 5, 6, and $F(x)$ would have six jumps, each equal to 1/6, and occurring at each of these values of x. Although the above discussion has been carried out assuming k finite, the same ideas can be extended to the case in which k is infinite. The possible values of x would be $x_1, x_2, x_3, \ldots$ and the probabilities $p(x_1), p(x_2), p(x_3), \ldots$, would form an infinite sequence whose sum would be 1.

The Continuous Case.—Not all events can be described by a discrete random variable x. Some events require a continuum of possible values for description. For example, consider the breaking strength of a piece of a given type of steel wire. If we denote the breaking strength by x, then x may have any value whatever (within certain limits) depending on the fineness of measurement *of the testing machine. If we imagine testing a large number of pieces of such wire, we would get a large number of values of x. If $F_N(x')$ denotes the fraction of these values of x which do not exceed x′, then $F_N(x)$ is the cumulative distribution function of this set of values of x, and for large values of N it would look something like fig. 1, except there would be many more and smaller jumps. If sufficiently small measuring units were available on the testing machine and if a sufficiently large number N of tests*

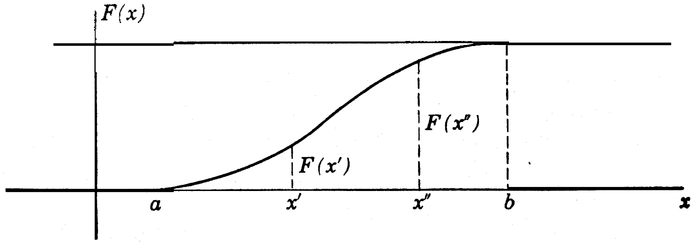

FIG. 2.— CONTINUOUS CUMULATIVE DISTRIBUTION FUNCTION

were made, it is clear that it would be possible to have an $F_N(x)$ which would be as nearly continuous (having no jumps) as we please. A similar situation often arises when a given quantity is measured a large number of times. The measurements will tend to be distributed rather than identical because of errors of measurement. It turns out in many probability problems that one can conveniently associate with the possible events a random variable x which can take on any value in an interval (which may be finite or infinite) and which has a continuous cumulative distribution function $F(x)$. Such random variables are called continuous random variables. In this case the graph of $F(x)$ would look something like that in fig. 2, where $F(a)=0$, $F(b)=1$ and $F(x)$ increases continuously as x increases from a to b, and where a might be $-\infty$ and (or) b might be $+\infty$. If a and b are finite (as shown in fig. 2) it is customary arbitrarily to define $F(x)$ to be 0 for values of x between $-\infty$ and a, and 1 for values of x between b and $+\infty$. For a given value of x, say x′, $F(x')$ is the probability that $x \leqq x'$ in a given trial. The probability that a trial will result in a value of x falling in the interval $(x, x+h)$ is $F(x+h)-F(x)$. Dividing this difference by the length of the interval, h, and taking the limit as $h\to 0$ (assuming it exists) we have the derivative of $F(x)$, with respect to x. Denoting this derivative by $f(x)$, we have:

$$\frac{dF(x)}{dx}=f(x). \tag{11}$$

$f(x)$ is called the probability density function of the continuous random variable x, and since $F(x)$ is constant for values of x outside the interval (a, b), $f(x)=0$ outside of (a,b)—hence, $F(x)$ can be expressed in terms of $f(x)$ by writing

$$F(x')=\int_{-\infty}^{x'} f(x)dx, \tag{12}$$

which is the analogue to (10) for the continuous cumulative distribution function. The interpretation of $F(x')$ in (10) and (12) is exactly the same; namely, the probability that $x\leqq x'$. The interpretations of $p(x)$ and $f(x)$ from which $F(x')$ is obtained in the discrete and continuous cases, respectively, are different. $p(x)$ is probability, but $f(x)$ is probability density and has to be integrated over an interval, however short, before it becomes probability. To get the probability that $x'<x\leqq x''$ in the continuous case we would have, by the law of addition of probabilities:

$$Pr(x'<x\leqq x'')=F(x'')-F(x')$$

$$=\int_{-\infty}^{x''} f(x)dx-\int_{-\mathrm{m}}^{x'} f(x)dx=\int_{x'}^{x''} f(x)dx. \tag{13}$$

The graph of $f(x)$, in general, looks something like the curve in fig. 3. It is called the frequency curve or distribution curve for x. The shaded area in fig. 3 is the graphical representation of the integral

$$\int_{x'}^{x''} f(x)dx;$$

i.e., the probability that $x'<x\leqq x''$. Numerically, the shaded area in fig. 3 is equal to the difference between the two ordinates in x′ and x″ in fig. 2.

Mean Value, Moments, Variance and Other Properties **of Distributions.**—The *mean value* $E(x)$ of a random variable *x is defined as follows for the discrete and continuous cases, respectively,*

$$E(x)=\sum_{i=1}^{k} x_i\, p(x_i)$$

$$E(x)=\int_{-\infty}^{\mathrm{m}} x\, f(x)dx. \tag{14}$$

$E(x)$ is sometimes referred to as the expected value of x, or the mathematical expectation of x. $E(x)$ may be interpreted as the centroid or centre of gravity of the distribution in each case.

Mean value is an extremely important concept in the calculation of expectation of loss or gain, particularly in insurance and gambling. To take a simple example, suppose a person receives $1 for each dot that appears uppermost in the throw of a die. What is his expected winning per throw? To evaluate this, we simply multiply the winning in each possible outcome of the throw of the die, by the probability of that event. This results in

$$1\cdot\tfrac{1}{6}+2\cdot\tfrac{1}{6}+3\cdot\tfrac{1}{6}+4\cdot\tfrac{1}{6}+5\cdot\tfrac{1}{6}+6\cdot\tfrac{1}{6}=\$3.50,$$

which is the expected winning per throw or average winning per throw assuming a perfect die. The fair price to pay for the privilege of playing such a game is $3.50 per throw. A player who would pay more would lose in the long run. More complicated games can be similarly analyzed and fair prices for playing them can be established.

If $u(x)$ is any function of x, the mean value of $u(x)$ is defined in the two cases as follows:

$$E[u(x)]=\sum_{i=1}^{k} u(x_i)\, p(x_i)$$

$$E[u(x)]=\int_{-\infty}^{\infty} u(x)\, f(x)dt. \tag{15}$$

In probability theory it has been found convenient to use what

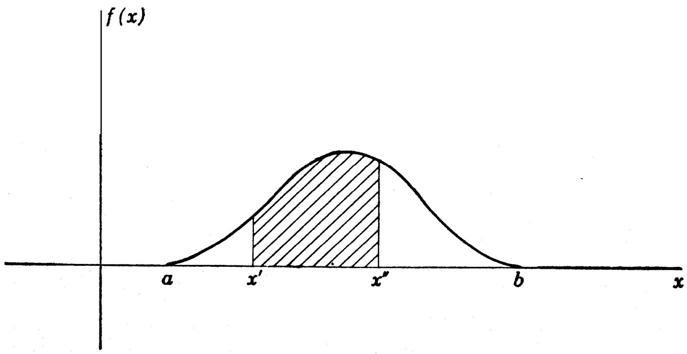

FIG. 3.— FREQUENCY OR DISTRIBUTION CURVE (*see* TEXT FOR FURTHER INFORMATION)

is called the Stieltjes integral, which enables us to write either of the equations in (15) as

$$E[u(x)]=\int_{-\mathrm{m}}^{\infty} u(x)d\,F(x).$$

This integral is simply the sum

$$\sum_{i=1}^{k} u(x_i)p(x_i)$$

in the discrete case and the ordinary integral (Riemann),

$$\int_{-\infty}^{\infty} u(x)f(x)dx,$$

in the continuous case. In particular, expressions (15) define the h*th moment* μ'_h *of* x *if* $u(x)=x^h$.

If we set $u(x)=e^{tx}$, *we have the moment-generating function of* x, *denoted by* $\varphi(t)$; *i.e., using Stieltjes integral notation to cover both the discrete and continuous cases,*

$$\varphi(t)=\int_{-\infty}^{\infty} e^{tx}dF(x). \tag{16}$$

The reason for the term "moment-generating function" is clear when we note that by differentiating (16) h times with respect to t, then setting $t=0$, *we get the hth moment of X.* Briefly:

$$\left[\frac{d^h\varphi(t)}{dt^h}\right]_{t=0}=\left[\int_{-\infty}^{\infty} x^h e^{tx}dF(x)\right]_{t=0}=\int_{-\infty}^{\infty} x^h dF(x)=\mu_h'.$$

The median $\tilde{x}$ *of a random variable x is a value such that*

$$Pr(x<\tilde{x})=Pr(x>\tilde{x}). \tag{17}$$

The mode $\breve{x}$ *of a random variable x, when the mode exists, is that value of x to which corresponds the greatest probability in the discrete case or greatest probability density in the continuous case.*

If $u(x)$ *is made equal to* $[x-E(x)]^2$, *then (15) defines the variance* σ^2 *of x; i.e.,*

$$\sigma^2=E[x-E(x)]^2, \tag{18}$$

which may be written as

$$E(x^2)-[E(x)]^2=\mu'_2-(\mu'_1)^2.$$

The variance σ^2 *is seen to be the mean of the squares of the deviations of x from its mean value. It gives an indication of how much the probability function is spread out along the x axis; the greater the spread, the larger the variance. The quantity* σ, *the square root of the variance, is called the standard deviation of x.*

An important property of any distribution function, discrete or continuous, is expressible in a form known as Tchebycheff's inequality, which states that the probability does not exceed $1/\lambda^2$ *that a random variable x deviates from its mean value by more than* λ *times its standard deviation.* More *briefly:* $Pr(|x-a|>\lambda\sigma)\leqq 1/\lambda^2$.

Some Important Special Distribution Functions.—There are several distribution functions of fundamental importance in the theory of probability and its application to statistics.

The Binomial Distribution.—Suppose that an event or trial can result in either an A or an $\bar{A}$. *Let the probability of A be* p *and that of* $\bar{A}$ *be* q *where* $q=1-p$. Now *if the trial is repeated* n *times, and the trials are independent, we ask, what is the probability that A will occur x times and* $\bar{A}$ $n-x$ *times? Since the trials are independent, the probability of getting x A's and* $n-x$ $\bar{A}$'s *in n trials in a particular order, say* $AA\bar{A}A\bar{A}\bar{A}\ldots A\bar{A}A$ [*x A's and* $(n-x)$ *A's*], *is* $ppqpqq\ldots pqp=p^xq^{n-x}$. *But from (8) it is seen that there are* ${}_nP_{(x,\,n-x)}=\frac{n!}{x!(n-x)!}$ (*also*$={}_nC_x$) *different orders (permutations) in which x A's and* $n-x$ $\bar{A}$'s *can occur. These different sequences of trials are mutually exclusive, and therefore, by the law of addition of probabilities* (3), *the probability of x A's and* $n-x$ B's *is* p^xq^{n-x} *added* $\frac{n!}{x!(n-x)!}$ *times; i.e.,*

$$b(x)=\frac{n!}{x!(n-x)!}p^xq^{n-x}. \tag{19}$$

$b(x)$ *is called the binomial distribution. It will be noted that x is a discrete random variable whose event points are* $0, 1, 2, \ldots, n$. *Furthermore, it should be observed that* $b(x)$ *is the* $(x+1)$th *term of the expansion of the binomial* $(q+p)^n$. *If the terms* $b(x)$ *are summed for all values of x from 0 to n, we get* $(q+p)^n=1$, *since* $q+p=1$.

As a simple application of the binomial law, let us derive the probability that, in tossing two coins five times, both coins will turn up heads three times. The probability of getting two heads in tossing the coins is $\frac{1}{4}$, *and the probability of failing to get two heads is* $\frac{3}{4}$. *Thus, if the act of tossing two coins is performed five times, the probability of getting two heads three times is*

$$\frac{5!}{3!\,2!}\left(\frac{1}{4}\right)^3\left(\frac{3}{4}\right)^2=\frac{45}{512}.$$

The mean and variance of x distributed according to the binomial law can be readily found to be np *and* npq *respectively, by setting up the moment-generating function of x.*

Another useful distribution is the negative binomial distribution

$$\bar{b}(x)=\frac{(x-1)!}{(k-1)!(x-k)!}p^xq^{x-k}, \tag{20}$$

where the event points of x are $k, k+1, \ldots$ *ad infinitum.*

Expression (20) *is simply the probability that x trials mill have to be performed before getting k A's. The mean value of x is* k/p. *The negative binomial distribution arises in such problems as repeated testing of a piece of equipment until a given result occurs as, for example, one failure, or some given number of failures.*

The Poisson Distribution.—Another important discrete distribution function is the Poisson distribution defined by:

$$p(x)=\frac{\mu^x}{x!}e^{-\mu}, \tag{21}$$

where the event points of x are $0, 1, 2, 3, \ldots$ *ad infinitum.*

By putting $pn=\mu$ *in the binomial distribution* (19), *one finds that, when* p *is "small" and* n *"large," the binomial distribution is closely approximated by the Poisson distribution.*

The Poisson distribution law provides a good description of the distribution of events for a fairly wide range *of phenomena. For example, if the number of alpha-rays emitted by radium which strike a given small area (as recorded by a Geiger counter, for example) in a given time, say ten seconds, is called x, and if the values of x for a large number of such time intervals are obtained, the distribution of these values of x will be closely approximated by a Poisson law in which* μ *is set equal to the average number of alpha-rays per time interval. If a* screw *machine is turning out a small percentage* (*e.g.,* 1%) *of defective screws, the numbers of defective screws in boxes of* 100 *will be approximately distributed according to a Poisson law with* $\mu=1$. *The Poisson law also arises in estimating density of bacteria or bacterial colonies in liquids.*

The Normal Distribution.—The most important continuous distribution is the normal or Gaussian law, having probability density function,

$$f(x)=\frac{1}{\sqrt{2\pi}\sigma}e^{-\frac{(x-\mu)^2}{2\sigma^2}}. \tag{22}$$

The mean and variance of x in this distribution are μ *and* σ^2 *respectively.*

The graph of $f(x)$ *is an inverted symmetrical bell-shaped curve, as shown in fig. 4, where* μ *(the mean) is the value of x at the centre of the curve, and* σ *(the standard deviation) is the distance from the centre of the curve out to the inflection point on either side.*

Half the area under the curve lies between the ordinates $\mu\pm.6745\sigma$; *the quantity* $.6745\sigma$ *is called the probable ewor. About* 95% *of the area lies between the ordinates at* $\mu\pm1.9600\sigma$, *and approximately* 99% *of it lies between the ordinates at* $\mu\pm2.57586$.

The cumulative distribution or probability integral of the normalized form of the Gaussian distribution function defined by

$$F(x)=\frac{1}{\sqrt{2\pi}}\int_{-\infty}^{x} e^{-\frac{1}{2}t^2}dt \tag{23}$$

and the farm

$$\Phi(x)=\frac{1}{\sqrt{2\pi}}\int_{0}^{X} e^{-\frac{1}{2}t^2}dt \tag{24}$$

have been tabulated in various books for values of x between -6 and $+6$. The form

$$\psi(x)=\frac{1}{\sqrt{\pi}}\int_0^x e^{-t^2}dt \qquad (25)$$

has also been tabulated and is used extensively by physical scientists, although it is not as convenient as the form (24) for most statistical purposes. Expression (24) is the cumulative form of

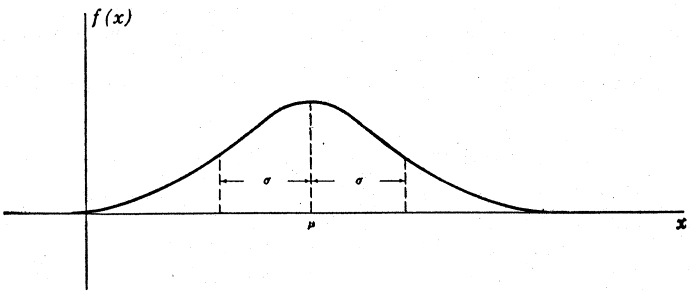

FIG. 4.— NORMAL DISTRIBUTION CURVE SHOWING STANDARD DEVIATION σ FROM THE MEAN μ

the Gaussian lam in which a is taken as the unit of measurement, whereas (25) is the cumulative form when $\sigma\sqrt{2}$ is taken as the unit of measurement.

The normal distribution function arises in many places in probability theory particularly as the limiting distribution function of certain functions of large numbers of independent random variables. One important case occurs in connection with the binomial distribution. It can be shown that the probability

$$Pr\left(\frac{x-np}{\sqrt{npq}}<y\right),$$

where x is distributed according to the binomial distribution (19), has as its limit, as n approaches ∞, the Expression $F(y)$ for any given value of y where $F(y)$ is obtained by replacing x by y in (23). This means that for large values of n, the value of x will be approximately normally distributed with mean np and standard deviation $\sqrt{npq}$, which in turn means that the normal probability tables can be used for approximating the probability that a binomially distributed variable x will lie between any two given values. For example, suppose 400 coins are thoroughly mixed in a sack and are poured out on a table. What is the probability that between 190 and 210 heads will turn up? We have $p=\frac{1}{2}$, $n=400$ and $\frac{x-np}{\sqrt{npq}}$ becomes $\frac{x-200}{10}$. The probability that x lies between 190 and 210 is the same as the probability that $\frac{x-200}{10}$ lies between -1 and $+1$, and this probability is approximately $F(+1)-F(-1)=.6827$, where $F(x)$ is given by (23).

Distribution Functions of Two or More Random Variables.—The Discrete Case.—Thus far we have discussed probability theory in which the significant feature of an event can be characterized by some value of a single random variable. In the extension of probability theory and its application to statistical theory, several random variables are usually required to describe the event under consideration. For example, suppose two dice are thrown, a green one and a red one, and that we wish to keep track of what happens to each die when the pair is thrown. Two random variables are needed, say x and y, where x gives the number of dots appearing on the green die when it is thrown and y the number appearing on the red die. Thus, the event of throwing the two dice can be described by a value of x and one of y. If 2 appears on the green die and 4 appears on the red one, we can briefly state that the values of x and y for this particular event are (2, 4). If the dice are "true," the probability of each of the 36 combinations of x and y: (1, 1), (1, 2), ... , (6, 6), is $\frac{1}{36}$. We can represent the distribution of probabilities in the xy plane by "attaching" a probability of $\frac{1}{36}$ at each of the 36 event points (1, 1), ... , (6, 6). More briefly, we write $p(x, y)=\frac{1}{36}$ for each combination of values of x and y. Now from $p(x, y)$ (that is, the probabilities at these 36 points spread out in the xy plane) we can calculate various other probabilities, such as the probability of getting a total of 4 dots on the two dice [which would be the sum of the probabilities at (1, 3), (2, 2), (3, 1), namely $\frac{3}{36}$], or the probability that neither die turns up more than a 3 [which would be the sum of the probabilities at (1, 1), (1, 2), (1, 3), (2, 1), (2, 2), (3, 2), (3, 1), (3, 2), (3, 3) or $\frac{9}{36}$], etc. In particular, if we add all of the probabilities for which x has a given value, say 2, we get $\frac{1}{36}+\frac{1}{36}+\frac{1}{36}+\frac{1}{36}+\frac{1}{36}+\frac{1}{36}=\frac{1}{6}$, which is the sum of the probabilities at (2, 1), (2, 2), (2, 3), (2, 4), (2, 5), (2, 6). This is the probability that the green die turns up 2 regardless of how the red one turns up. We can abbreviate by saying that

$$\sum_{y=1}^{6} p(2, y)=\tfrac{1}{6}=$$

the probability that $x=2$, regardless of what y is equal to. More generally, we can write

$$p(x')=\sum_{y=1}^{6} p(x', y)=$$

probability that $x=x'$, $p(x)$ (dropping the prime) calculated in this way from $p(x, y)$ is called the marginal distribution of x.

If we have three dice (say a red, a green and a blue one), three random variables x, y and z, each taking on values 1 to 6, would be required to describe completely the results of a throw of the three dice. Two hundred and sixteen combinations of values of x, y and z would, therefore, be required to describe all possible results. These event points (1, 1, 1), . . . , (6, 6, 6) can be visualized as 216 points arranged 6 by 6 by 6 in a cubical lattice in three-dimensional space at each of which the probability to be "attached" is $\frac{1}{216}$. More briefly, $p(x, y, z)=\frac{1}{216}$. From $p(x, y, z)$ one can calculate probabilities of occurrences of all kinds of events in a throw of three dice, such as the probability that the total number of dots is eight, the probability that at least one die turns up a number less than three, and so on. Note that if $p(x, y, z)$ is summed for all values of z from 1 to 6 for any fixed values of x and y, say x' and y', we simply get the probability of getting $x=x'$ and y=y', regardless of what value z may have. More briefly,

$$p(x', y')=\sum_{z=1}^{6} p(x', y', z)$$

is the probability that $x=x'$ and $y=y'$. $p(x, y)$ (dropping the primes) calculated in this way from $p(x, y, z)$, is called the marginal distribution of x and y. If $p(x', y, z)$ is summed with respect to both y and z, we obtain $p(x')$, the probability that $x=x'$, no matter what values y and z may have. $p(x)$ (dropping the prime) determined in this way is called the marginal 'distribution of x.

By further extension one can see how to set up a k-dimensional space for the k discrete random variables required for characterizing a throw of k dice. In general, one can see that if there are k discrete random variables $x_1, x_2, x_3, \ldots, x_k$ characterizing an event such that only certain values of each x can be taken on, then there would be certain event points in the k-dimensional random variable space, among which the probability would be allocated or distributed. We would denote the probability at any point $(x_1', x_2', \ldots, x_k')$ by $p(x_1', x_2', \ldots, x_k')$. Thus, $x_1, x_2, \ldots, x_k$ would be a set of k random variables having a discrete *probability law* or probability *distribution*,

$$p(x_1, x_2, \ldots, x_k). \qquad (26)$$

From $p(x_1, x_2, \ldots, x_k)$ we can find various probabilities concerning the x's by summing $p(x_1, x_2, \ldots, x_k)$ over the appropriate event points in the event space. For example, to find the probability that $x_1+x_2+\ldots+x_k<y$ where y is any given number, we would sum $p(x_1, x_2, \ldots, x_k)$ over all event points whose co-ordinates satisfied the above inequality. By summing $p(x_1, x_2, \ldots, x_k)$ with respect to one of the x's, say x_k, we obtain the marginal distribution of $x_1, x_2, \ldots, x_{k-1}$, which is merely the distribution law for these k−1 variables, ignoring the last one. Mean values and moments are defined for $p(x_1, x_2, \ldots, x_k)$ just as in the case of a probability law of one variable. For example, the mean value of x_1, $E(x_1)$, is defined by multiplying x_1 and $p(x_1, x_2, \ldots, x_k)$ and summing over all event points in the event space. Similarly, the mean value of any function of the x's, say $u(x_1, x_2, \ldots, x_k)$, is defined by multiplying $u(x_1, x_2, \ldots, x_k)$ and $p(x_1, x_2, \ldots, x_k)$ and summing over all event points in the event space. In particular, the mean value of $(x_1-\mu_1)(x_2-\mu_2)$, where $\mu_1=E(x_1)$ and $\mu_2=E(x_2)$, is the covariance between x_1, and x_2. The ratio of the covariance between x_1 and x_2 to the product of the standard deviations of x_1 and x_2 is called the correlation *coefficient* between x_1 and x_2, and is denoted by the ρ_{12}. It can be shown that $-1\leqq\rho_{12}\leqq+1$. The covariance and correlation coefficient can be similarly defined for any other two x's.

Applying the ideas of the section Conditional Probability, above, one can define conditional probability distributions. For example, for k=2, one may write $p(x_2|x_1=x_1')=p(x_1', x_2)/p(x_1')$ which states that the probability law of x_2, given $x_1=x_1'$, is equal to $p(x_1, x_2)$ evaluated for $x_1=x_1'$, divided by the marginal distribution of x_1 evaluated at $x_1=x_1'$.

The Continuous Case.—In case the event which is characterized by $x_1, x_2, \ldots, x_k$ is such that the event points do not form a discrete set, but rather a continuum of values, so that the event points in the k-dimensional space "fill up" a whole region in that space, then we have the case of continuous variables $x_1, x_2, \ldots, x_k$, whose probability law is expressed by a probability density *function* $f(x_1, x_2, \ldots, x_k)$. From this function one can determine various probabilities concerning the x's by integration. For example, the probability that $x_1x_2\ldots x_k<y$, where y is any given number, is obtained by integrating the Probability element,

$$f(x_1, x_2, \ldots, x_k)dx_1dx_2\ldots dx_k, \tag{27}$$

over the k-dimensional space of x's for which the above inequality holds. Similarly, one can find the probability that $x_1+x_2+\ldots+x_k<y$, where y is any given number, or one can find the probability that the largest of the x's in the set $x_1, x_2, \ldots, x_k$ is less than any given value y, and so on. If one integrates (27) with respect to x_k one obtains the marginal probability element of $x_1, x_2, \ldots, x_{k-1}$, which is simply the probability element for the variables $x_1, x_2, \ldots, x_{k-1}$, ignoring x_k. Marginal probability elements for other sets are similarly defined. The mean value of any x, say x_1, is obtained by integrating the product of x_1 and the probability element (27) over the entire space of the x's. More generally, the mean value of any function of the x's, say $u(x_1, x_2, \ldots, x_k)$, is defined as the integral of the product of $u(x_1, x_2, \cdots, x_k)$ and (27) over the space of the x's. The definitions of the covariance and correlation coefficient ρ_{ij} between any two of the x's, say x_i and x_j, are similar to those for the discrete case. The definition of a conditional probability element; *e.g.*, $f(x_2|x_1=x_1')dx_2$, follows at once from the ideas of the section on Conditional Probability together with those expressed in the last paragraph of the Discrete Case.

Some Important Probability Laws of Two or More Variables.—Perhaps the most important application of probability theory of two or more random variables is to statistical theory, to which the remainder of this article will be devoted. However, it is worthwhile to mention two joint or multivariate probability laws which are interesting and important in their own right: the multinomial law and the multivariate normal law.

The *Multinomial* Probability Law.—The multinomial law—a discrete probability law—states that if the probabilities are p_1, $p_2, \ldots, p_k$ that *an* event will result in *the mutually* exclusive *categories* $A_1, A_2, \ldots, A_k$, respectively, then the probability that in n trials x_1 will result in A_1, x_2 in A_2, $\ldots, x_k$ *in* A_k *is*

$$m(x_1, x_2, \cdots, x_k)=\frac{n!}{x_1!x_2!\ldots x_k!}p_1^{x_1}p_2^{x_2}\ldots p_k^{x_k}, \tag{28}$$

where $x_1+x_2+\ldots+x_k=n$ and $p_1+p_2+\ldots+p_k=1$. Since the sum of the x's must be equal to n, (28) is really a probability law of only k−1 random variables. The derivation of this law is similar to the derivation of the binomial law (19), the essential difference being that one deals with permutations of x_1 p_1's, x_2 p_2's, $\ldots, x_k$ p_k's (of which there are

$$\left.\frac{n!}{x_1!x_2!\ldots x_k!}\right)$$

rather than xp's and (n−x) q's. It will be noted that (28) is the general term in the expansion of the multinomial $(p_1+p_2+\ldots+p_k)^n$.

As a simple example of the application of the multinomial law, suppose two coins are tossed 20 times. What is the probability of getting two heads five times, two tails five times and one head and one tail ten times? The event of tossing two coins can result in one of three mutually exclusive events: two heads, two tails, one head and one tail with probabilities $\frac{1}{4}$, $\frac{1}{4}$ and $\frac{1}{2}$ respectively. The required probability is therefore

$$m(5, 5, 10)=\frac{20!}{5!5!10!}(\tfrac{1}{4})^5(\tfrac{1}{4})^5(\tfrac{1}{2})^{10}.$$

The Multivariate *Normal* Probability Law.—The second important probability law in several variables is the multivariate normal probability law of $x_1, x_2, \ldots, x_k$—a continuous probability law. The probability density function of this law is

$$\frac{1}{(2\pi)^{k/2}\sigma_1\sigma_2\ldots\sigma_k\sqrt{\Delta}}e^{-\frac{1}{2}Q_k} \tag{29}$$

where Q_k is a quadratic form in $x_1, x_2, \cdots, x_k$ given by

$$\sum_{j=1}^{k}\sum_{i=1}^{k}(-1)^{i+j}\frac{\Delta_{ij}}{\sigma_i\sigma_j\Delta}(x_i-\mu_i)(x_j-\mu_j)$$

where μ_i and σ_i are the mean and variance of xi, A is the determinant of correlation coefficients ρ_{ij}, (ρ_{ii} being defined as 1) and Δ_{ij} is the determinant obtained by deleting the ith row and jth column in A.

Term (29) is a generalization of the normal or Gaussian law (22) to k random variables. In particular, if $k=2$, we have the bivariate or two-dimensional normal law,

$$f(x_1, x_2)=\frac{1}{2\pi\sigma_1\sigma_2\sqrt{1-\rho_{12}^2}}e^{-\frac{1}{2}Q_2} \tag{30}$$

where

$$Q_2=\frac{1}{1-\rho_{12}^2}\left[\frac{(x_1-\mu_1)^2}{\sigma_1^2}+\frac{(x_2-\mu_2)^2}{\sigma_2^2}-2\rho_{12}\frac{(x_1-\mu_1)(x_2-\mu_2)}{\sigma_1\sigma_2}\right].$$

The probability density represented (30) is greatest at (μ_1, μ_2), since at this point $Q_2=0$. The density diminishes as one moves out in any direction from (μ_1, μ_2) in the x_1x_2 plane in such a way that this density is constant on each of the ellipses in the family $Q_2=c$, where c is any number greater than or equal to zero. If we hold x_1 fixed, say at x_1', and find the mean value of x_2; *i.e.*, evaluate the integral,

$$\int_{-\infty}^{\infty}x_2f(x_1', x_2)dx_2,$$

we obtain

$$\mu_2+\rho_{12}\frac{\sigma_2}{\sigma_1}(x_1'-\mu_1).$$

In other words, the mean value of x_2 for any given value of x_1, say x_1', lies on the straight line in the x_1x_2 plane whose equation is

$$x_2-\mu_2=\rho_{12}\frac{\sigma_2}{\sigma_1}(x_1'-\mu_1), \tag{31}$$

which is called the *regression* line *of* x_2 *on* x_1. It can be shown that the probability density which lies along any line $x_1=x_1'$ is a one dimensional normal probability law of the form (22) with a replaced by

$$\sigma_2\sqrt{1-\rho_{12}^2}$$

and μ replaced by

$$\mu_2+\rho_{12}\frac{\sigma_2}{\sigma_1}(x_1'-\mu_1).$$

Similarly, there is a regression line of x_1 on x_2. The correlation coefficient between x_1 and x_2 is ρ_{12} and measures the degree of statistical relationship that exists between x_1 and x_2. If $\rho_{12}=0$, x_1 and x_2 are statistically independent and the regression lines are perpendicular. If $\rho_{12}=1$ (or -1) the regression lines coincide and have slope

$$\frac{\sigma_1}{\sigma_2}\left(\text{or} -\frac{\sigma_1}{\sigma_2}\right).$$

In each of these extreme cases, x_1 and x_2 are functionally related, and all probability is concentrated along the lines

$$x_1-\mu_1=\pm\frac{\sigma_1}{\sigma_2}(x_2-\mu_2),$$

respectively.

The bivariate law is an extremely useful function in many statistical problems, providing a satisfactory model for describing the joint distribution of two statistically related variables such as range and deflection errors in repeated artillery fire or precision bombing, scores of two examinations taken by a large number of students, two anthropometric measurements on a large number of individuals, etc.

STATISTICAL THEORY

Some of the most important applications of probability theory, particularly of several variables, are in the theory of statistics. In the remainder of this article some of these applications will be discussed.

Sampling Theory. — Sampling From an *Infinite Population.*— Under Distribution *Functions* of Two or More Random Variables, above, we have seen how to set up a probability law for describing the results of throwing two or more dice. It is only a short step from that discussion to see how to set up a probability law for describing the results of making n independent trials where each trial is described by a value of a random variable having, of course, some distribution law. Thus, if x is the random variable having distribution law $dF(x_1)$, [$p(x_1)$ for the discrete case, and $f(x_1)dx_1$ for the continuous case], describing the first trial, x_2 the random variable having distribution law $dF(x_2)$ describing the second trial, and so on, then the probability law for describing the results of n independent trials (as measured by $x_1, x_2, \ldots, x_n$) is the product

$$dF(x_1)dF(x_2)\ldots dF(x_n). \tag{32}$$

In statistical terminology we say that $x_1, x_2, \ldots, x_n$ are the *values of* x *in a sample of* n *items drawn independently from a population having distribution law* dF(x), *where* dF(x) = p(x) *in* the discrete case and dF(x) = f(x)dx in the *continuous case.* Term (32) is called the probability law *of* the entire *sample.* This type of sampling is often called *sampling from an infinite population* (as contrasted with *sampling from a finite population* discussed below); the x's in the sample are independent in the probability sense. We thus have a basis for setting up a mathematical theory of sampling in the case of independent trials. The usual kinds of questions which are considered in sampling theory are these: What is the probability law of the means of the sample $x=(x_1+x_2+\ldots+x_n)/n$? Or the probability law of the sample variance

$$s^2=\sum_{i=1}^{n}(x_i-\bar{x})^2/n-1?$$

Or, the probability law of any other given function of the sample values, say $u=u(x_1, x_2, \ldots, x_n)$? Or the joint probability law of two or more functions $u_1=u_1(x_1, x_2, \ldots, x_n)$, $u_2=u_2(x_1, x_2, \ldots, x_n)$, .. ?

The problem of finding the probability law of any function of the x's in the sample, say $u(x_1, x_2, \ldots, x_n)$, is solved by finding $Pr[u(x_1, x_2, \ldots, x_n)\leqq u']$ the cumulative distribution of $u(x_1, x_2, \ldots$, x,); that is, by integrating (32) (in the Stieltjes sense; *i.e.,* summing in the discrete case and integrating in the continuous case) for all values of the x's for which $u(x_1, x_2, \ldots, x_n)\leqq u'$, where u' is any given number (real). Such an integration will produce a value $G(u')$. Dropping the prime, $G(u)$ is called the *cumulative sampling distribution* of $u(x_1, x_2, \ldots, u_n)$.

To find the joint cumulative sampling distribution $G(u_1, u_2)$ of two sample functions $u_1(x_1, x_2, \ldots, x_n)$ and $u_2(x_1, x_2, \ldots, x_n)$ one integrates (32) over all values of the x's such that both the inequalities $u_1(x_1, x_2, \ldots, x_n)\leqq u_1$ and $u_2(x_1, x_2, \ldots, x_n)\leqq u_2$ hold, where u_1 and u_2 are any two given numbers.

The meaning of $G(u)$ may perhaps be clarified in the following way: Suppose that when a certain trial or experiment is made the outcome is measured by a value of a random variable x, which has a cumulative distribution law $F(x)$. Now if the experiment is performed n times we will get n values of x, say $x_1, x_2, \ldots, x_n$, from which we will calculate the value of $u(x_1, x_2, \ldots$, x,), which might be a mean, sum of squares or any other function of statistical interest. Let this set of n trials be carried out a large number of times. The proportion of times when the computed values of $u(x_1, x_2, \ldots, x_n)$ will be $\leqq u'$ is a number which, under "ideal" conditions is predicted by $G(u')$. For example, if a sample of n items is drawn from a population having the normal distribution (22), then the mean $\bar{x}=(x_1+x_2+\ldots+x_n)/n$ will have as its cumulative probability law; *i.e.,*

$$Pr\left(\frac{1}{n}(x_1+x_2+\ldots+x_n)\leqq u\right),$$

the expression

$$G(u)=\frac{\sqrt{n}}{\sqrt{2\pi}\sigma}\int_{-\infty}^{u}e^{-\frac{n(t-\mu)^2}{2\sigma^2}}dt, \tag{33}$$

from which the probability element of the mean is

$$dG(\bar{x})=\frac{\sqrt{n}}{\sqrt{2\pi}\sigma}e^{-\frac{n(\bar{x}-\mu)^2}{2\sigma^2}}d\bar{x}. \tag{34}$$

This states that if a population has a normal probability law with mean μ and variance σ^2, then the probability law of the mean of n items from this population is normal with mean μ and variance σ^2/n. In general the functional form of $G(u)$ is a simple known function for only a very few specific sample functions $u(x_1, x_2, \ldots, x_n)$ and population cumulative distribution laws $F(x)$. The sampling theory of means, sums of squares and correlation coefficients of x's in samples from normal univariate and multivariate populations was developed thoroughly after 1925 by M. S. Bartlett, R. A. Fisher, H. Hotelling, P. L. Hsu, W. G. Madow, J. Neyman, E. S. Pearson, A. Wald, J. Wishart, S. S. Wilks and others, and published in *Biometrika,* the *Annals of* Mathematical Statistics, the Annals *of* Eugenics, Sankhyii and other journals. Results were also published from time to time dealing with sampling theory for samples from other kinds of populations; *e.g.,* those having binomial, Poisson and multinomial distribution laws. Many technical mathematical devices such as Fourier transforms, n-dimensional Euclidean geometry, combinatorial theory, etc., have been used in solving these sampling problems.

Results for samples from populations having arbitrary distributions are rather meagre. Mean values of means, variances and higher moments in samples from such populations are well known. It might be mentioned that if $x_1, x_2, \ldots$, x, are items in a sample from a population having any given distribution law with mean μ and variance σ^2, then the mean values of the sample mean $\bar{x}$ and sample variance s^2 are μ and σ^2 respectively, where the sample variance is defined as

$$s^2=\frac{1}{n-1}\sum^{n}(x_i-\bar{x})^2.$$

Another general sampling result of importance is the following: *If* $x_1, x_2, \ldots, x_n$ are *items* in a sample from a population whose distribution law has mean μ and variance a², then the limit, as

$n \to \infty$, *of* $\Pr\left(\frac{\sqrt{n}(x-\mu)}{\sigma} < u\right)$ is given *by*

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty}^{u} e^{-\frac{1}{2}t^2} dt.$$

This means that large samples of n items from any population whose distribution law has mean μ and variance u^2 are such that their means are approximately distributed in accordance with a normal distribution law having mean μ and variance σ^2/n. A somewhat more general theorem can be stated, which is known as the central *limit theorem*, but the special case stated above is sufficient to give here, and is very useful in statistical theory.

As a simple application of this theorem suppose a die is thrown 100 times. What can we say about the average number of dots per throw appearing in the n throws; *i.e.*, the total number of dots divided by 100? In this case the population distribution law is $p(x) = 1/6$ for $x = 1, 2, 3, 4, 5, 6$. The mean of this distribution is

$$p = \sum_{x=1}^{6} x p(x) = 3.5,$$

and the variance is

$$\sigma^2 = \sum_{x=1}^{6} (x - 3.5)^2 p(x) = \frac{35}{12}, \text{ from which } \sigma = 1.708.$$

If the total number of dots divided by 100 is denoted by $\bar{x}$, then it follows by our theorem that the cumulative distribution law of

$$\frac{(\bar{x} - 3.5)\sqrt{100}}{1.708}$$

is approximately

$$\frac{1}{\sqrt{2\pi}} \int_{-\infty} e^{-\frac{1}{2}t^2} dt$$

which means that $\bar{x}$ is approximately normally distributed with mean 3.5 and variance $\sigma/\sqrt{100}$; *i.e.*, 0.1708. Referring to the normal distribution in the section *Some Important Special Distribution Functions*, above, it will be seen, for example, that we can state that the probability is approximately 0.95 that $\bar{x}$, the total number of dots in 100 throws divided by 100, will not deviate from 3.5 by more than 1.96(0.1708); *i.e.*, 0.3348.

The Theory of Sampling from Finite Populations.—There is a special class of problems commonly referred to as problems of *sampling from* finite populations in which there is a population with a finite number N of elements or items, each of which is characterized by a value of a variable x, or by values of several variables. It is sufficient here to consider only one variable. Drawing a sample of n elements from such a population corresponds to taking out n of the original N elements. The successive drawings (or trials) of the n elements are not independent and hence the multivariate probability law for the x's in the sample is not given as a product of the form (32). It is more complicated, but essentially consists of considering all possible ways [there are $N(N-1)(N-2)\cdots(N-n+1)$ of them] in which a succession (*i.e.*, permutation) of n items can be drawn from the population of N items and assuming these to be "equally likely" to be drawn; *i.e.*, they are assigned equal probabilities. An alternative approach is to ignore the order in which elements appear and to consider the ${}_NC_n$ possible combinations of n elements which can be formed from the N elements in the population, assigning equal probabilities to all these combinations. In fact this approach can be used when the first one cannot, notably in situations where the n elements are drawn as a set or simultaneously. In either case, each sample consists of a set of n x's, say $x_1, x_2, \ldots, x_n$ from which can be calculated the sample mean, the sample variance or any other function of the x's. The sampling problem in either of these approaches simply amounts to the consideration of how the values of any given function of the sample x's are distributed when calculated for all possible samples of n items from the population of N items. Perhaps the most important results are that the mean and variance of the distribution of sample means for either of the two approaches are μ, and

$$\frac{\sigma^2}{n}\left(\frac{N-n}{N-1}\right),$$

respectively, where μ and u^2 are the mean and variance of x in the population of N elements. Means and variances of the distribution of sample variances, and certain higher sample moments have been worked out.

It can be shown as one would expect, that as N increases indefinitely, the theory of sampling from a finite population reduces to the theory of sampling from an infinite population discussed previously. Although we have considered the sampling theory of single functions of the x's in samples from populations in which each element or trial is characterized by a single random variable x, the whole set of ideas and concepts extend to sampling theory of one or more functions considered jointly, where samples are drawn from multivariate populations.

The theory of sampling from finite populations has been extensively used in *stratified* sampling and acceptance *sampling.* The principal idea involved in stratified sampling is that a population is composed of a number of subpopulations, each having a finite number of elements and having its own distribution. A subsample of a given size is drawn from each subpopulation, depending on certain characteristics of that subpopulation and then the subsamples are combined into a single master sample which is thus a sample of the original over-all population. This type of sampling has been widely applied to the sampling of human populations for social, political and economic purposes. Government surveys, market surveys, etc., are often conducted on samples of households or individuals determined by principles of stratified sampling. The mathematical theory of this type of sampling was worked out by J. Neyman (1934), Hansen and W. A. Hurwitz (1943) and others.

The second important field of application of the theory of sampling from finite populations is that of acceptance sampling of manufactured products. In the simplest application in this field, lots of articles (each article of which is acceptable or not acceptable), varying from several dozen to several thousand or several hundred thousand items, are submitted to an inspector who drams a sample of items, inspects them and on the basis of the results of this inspection decides to accept or reject the lot. Such a sampling plan specifies a number n of items to be drawn from a lot of N articles and an allowable number of defectives c, such that if there are not more than c defective items among the n items of the sample, then the lot is accepted; otherwise it is rejected or subjected to 100% inspection. If the fraction of defectives in the lot is p, then there is a definite probability P that the lot will be accepted on the basis of the sample for the particular sampling plan used. For a given sampling plan, P is a function of p that decreases from 1 to 0, as p increases from 0 to 1, and the curve of P as a function of p is known as the operating characteristic *curve* of the sampling plan. This curve provides both the producer and purchaser information as to what risks each will take in agreeing to use the given sampling plan. For each value of p and a given sampling plan there is an average number, A, of items inspected per lot before a decision is made to accept or reject. A is a function of p and is the *average* inspection number curve. There are many sampling plans which could be devised for deciding whether to accept a lot or not. The type of plan described above is known as single sampling and was originally devised by H. F. Dodge and H. G. Romig (1929). Another type known as *double* sampling, also introduced by Dodge and Romig (1941), provides for the possibility of (1) accepting, (2) rejecting or (3) reserving judgment until a further sample is drawn, in which case either acceptance or rejection of the lot will be decided upon. These ideas were further extended to multiple *sampling* by W. Bartky (1944). Another type of sampling known as sequential sampling, which is essentially a generalization of multiple sampling, was devised by A. Wald (1947) and applied to inspection problems by H. A. Freeman, M. Friedman, F. Mosteller and W. A, Wallis (1948). This plan provides for the possibility of deciding whether to accept, reject or reserve judgment at the end of the drawing of each item or each group of several items. These sampling plans all have operating characteristic curves and average inspection number curves. In general, the sequential methods have been shown to require a smaller amount of inspection, although the usefulness of the various methods of sampling depend to a considerable extent on practical considerations. These sampling methods have been widely used, particularly in connection with the procurement of military matériel.

Importance of Order *Information* in Sampling.—It should be remarked that in the theory of sampling thus far considered we have been concerned with distribution laws of sample means, variances and other functions of sample x's, and not with the distribution law of any quantity which depends on the order in which x's appear as a sample is "drawn." There are many situations in which a sample is drawn one item at a time until there are n items. In such cases a consideration of the ordering of the x's becomes important, to see whether or not the property of "randomness" is being exhibited as the sample is being drawn. W. A. Shewhart (1939) discussed and demonstrated the practical importance of investigating the randomness of sequences which occur in sampling as a source of clues for detecting why an alleged random variable is not behaving like a random variable. He developed criteria for testing randomness of sequences. These criteria proved useful in connection with quality control problems in mass production and industrial research. As a simple example, suppose a sample of seven items is drawn in a sequential manner from a population in which a random variable x has a continuous distribution. Let the order in which the x's are drawn in the sample be $x_1, x_2, \ldots, x_7$, which correspond to seven points in time. One of the x's will be the median; *i.e.*, it will exceed three of the x's in size and will be exceeded by the remaining three. Let $x_1, x_2, \ldots, x_7$ be plotted as ordinates corresponding to $t = 1, 2, \ldots, 7$. We therefore have seven points. Let a horizontal line be drawn through the point whose ordinate represents the median. There will be three points above this horizontal line and three below. If a point lies above the median let this fact be denoted by $+$, and if below by $-$. We would therefore have a sequence of three $+$'s and three $-$'s. For example, the sequence might look like this: $+--++-$. Note that there are two runs of $+$'s, in which therei s a t least one $+$, and two runs of $-$'s, a total of four runs. What is the probability of getting four runs in a "random" ordering? To answer this question, we would consider all possible permutations of the $+$'s and $-$'s, of which there are $6!/(3!)^2 = 20$, and assign equal probabilities to them, and find .out what proportion of possible sequences have four runs. The answer is $\frac{8}{20}$, which is the probability of four runs. One can do this for any possible number of runs from two to six, and hence get a probability law for the total number of runs. In fact, the probabilities of 2, 3, 4, j, 6 runs are $\frac{2}{20}, \frac{4}{20}, \frac{8}{20}, \frac{4}{20}, \frac{2}{20}$, respectively. A small number of runs corresponds to heavy bunching of $+$'s and of $-$'s and hence to a strong indication of nonrandomness as might be caused by some gradual changes being introduced into the x's. The probability law states probabilities for any degree of bunching as measured by total number of runs from two to six under the hypothesis that nothing is causing the sequences to be other than equally likely. If, in a given case, we should get only a small total number of runs, say two, me can claim that something has crept in to cause heavy bunching with a risk of 0.1 of getting two runs if nothing has entered to cause excessive bunching, although we claim that it has.

The probability theory of runs under various conditions was worked out by A. M. Mood (1940), J. Wolfowitz (1945) and others.

It should be pointed out that in statistical practice samples of at least 2j or 30 items are considered in making analyses of runs and trends. The most common graphical method of presenting the sample sequence is the control chart introduced by W. A. Shewhart (1931), in which the sample values are plotted as ordinates in the order in which they are drawn. A horizontal line is drawn through the mean of the ordinates and "control" lines are drawn on each side of this horizontal line and are usually spaced at such a distance that the probability is between .01 and .05 oi a point falling outside the band between the control lines when nothing has entered to upset the randomness of the sequence. This chart is widely used in mass production problems. An exposition of it and its various applications has been given by the American Standards association (1941).

Statistical Tests.—Type-I *and Type-II* Errors *in* a Statistical Test.—In an example at the end of the last section we defined a certain type of run for a sample and described how the distribution law of the total qumber of runs in a sample could be determined. It was pointed out how the total number of runs could be taken as an indication of how thoroughly the $+$'s and $-$'s are mixed or randomized in a sample—the smaller the number of runs the greater the amount of bunching and hence of nonrandomness. In fact, on the basis of the total number of runs, we can make a rule for deciding whether or not to claim that there is significant bunching in a given sample; *i.e.*, more bunching than can be accounted for by the hypothesis of randomness. In fact, suppose we say that there is significant bunching if there are as few as two runs. The probability that we will erroneously claim there is significant bunching, when in fact there is none, is 0.1, which is the probability of as few as two runs under the hypothesis of pure randomness; *i.e.*, that all 20 possible sequences of $+$'s and $-$'s are equally likely. What we have stated above is a simple example of a statistical significance test. or simply a statistical test:

A statistical test is a procedure for testing a given hypothesis about the distribution lam of a population from which a sample is assumed to have been drawn. The hypothesis in its simplest form is whether the cumulative distribution function of the population is some specific function $F_1(x)$ alternative to a specified function $F_0(x)$. It is assumed that the sample comes from one of these populations. To test the hypothesis, a function $u(x_1, x_2, \ldots, x_n)$ of the sample x's isconstructed, and a range R of critical *values* of this function is found so that the probability is a given value 6 (usually .01 or .05) of $u(x_1, x_2, \ldots, x_n)$ lying in R if the population cumulative distribution function is $F_0(x)$, and also such that the probability of $u(x_1, x_2, \ldots, x_n)$ falling in R when the population distribution $F_1(x)$ is made as large as possible—certainly larger than δ. Then the claim can be made that the sample has been drawn from the population having distribution $F_1(x)$ with a risk of probability δ of *making* a type-I error. By a type-I error we mean the error committed by saying that the sample is not from the population having distribution $F_0(x)$, when, in fact, it is. In other words, when the value of $u(x_1, x_2, \ldots, x_n)$ falls in R we run a risk of erroneously claiming the sample not to have come from the population with distribution $F_0(x)$ when it actually does come from such a population. If the value of $u(x_1, x_2, \ldots, x_n)$ does not fall in range R the test calls for the assertion that the sample comes from the population having distribution $F_0(x)$, which is considered as the only alternative to $F_1(x)$ at present. There is a risk of being in error in this assertion, too, because the sample could have come from the population with distribution $F_1(x)$. The probability ϵ of this error is obtained by finding the probability of $u(x_1, x_2, \ldots, x_n)$ not falling in range R, when the sample has actually been drawn from the population having distribution $F_1(x)$. This error is called a *type-II* error. The probability of $u(x_1, x_2, \ldots, x_n)$ falling in R when the sample is from the population having distribution $F_1(x)$ is $1-\epsilon$ and is called the power of *the* test based on $u(x_1, x_2, \ldots, x_n)$. When $u(x_1, x_2, \ldots, x_n)$ falls in R we often say that it is statistically *significant* at the 6 probability level. Usually, $F_1(x)$ is a member of a family of functions $F(x, \theta)$, when θ is a parameter, which would be a specific member of the family, say $F(x, \theta_0)$. In this case the power $1-\epsilon$ for the various alternatives corresponding to all values of θ (except θ_0) would depend on θ and is called the *power* function of the test based on $u(x_1, x_2, \ldots, x_n)$. The essential idea underlying type-I and type-I1 errors was originally introduced by Bell Telephone laboratories' quality control engineers (Dodge and Romig, 1929), who first referred to them in their own applications as producer's risk and consumer's risk, respectively. The producer's risk is the probability that a given lot of products of satisfactory quality offered by a producer will be rejected on basis of the results of an inspected sample from the lot, whereas the consumer's risk is the probability of the consumer's accepting a lot of products of unsatisfactory quality on basis of the results of the inspected sample. J. Neyman and E. S. Pearson (1928) developed the idea which underlies these two risks into the present theory of testing statistical hypotheses described above for a specified sample size. Contributions to this theory and its application to various problems are numerous. Two important examples will be briefly discussed.

A. Wald (1950) further generalized the ideas by developing a theory of statistical decision functions in which decisions regarding a statistical hypothesis may be more numerous than simply acceptance or rejection and where the risks associated with such decisions are measured.

The "Student" Test.—First, consider a sample to have been drawn from some normal population and that we wish to test, on the basis of a sample of n items, whether this population has a given mean μ_0. The criterion for this test is

$$\frac{\sqrt{n}\,(\bar{x}-\mu_0)}{s}=t,$$

say, where s^2 is the sample variance

$$\frac{1}{n-1}\sum_{i=1}^{n}(x_i-\bar{x})^2.$$

The sampling distribution of t when the sample has been drawn from a normal population with mean μ_0 is:

$$dF(t)=\frac{\Gamma\left(\frac{n}{2}\right)}{\Gamma\left(\frac{n-1}{2}\right)\sqrt{\pi(n-1)}}\left(1+\frac{t^2}{n-1}\right)^{-\frac{n}{2}}dt, \qquad (35)$$

where $\Gamma(m)$ is the gamma function which equals $(m-1)!$, if m is a positive integer and provides a good interpolation function for $(m-1)!$ if m is real but not a positive integer. In either case, $\Gamma(m)$ can be expressed as a definite integral. The distribution law expressed by (3j) is known as the "*Student*" (1908) *distribution* law *with* n—I degrees offreedom. The range R of critical values of the function t is taken as the set of values of t outside the interval $(-t_\delta, t_\delta)$ where t_δ is given by the relation

$$\int_{-t_\delta}^{+t_\delta} dF(t)=1-\delta.$$

This means that the probability is $1-\delta$ that the sample will be such that

$$-t_\delta<\frac{\sqrt{n}(\bar{x}-\mu_0)}{s}<+t_\delta, \qquad (36)$$

when the sample is actually from a normal population with mean μ_0. If the sample yields values of $\bar{x}$ and s so that the inequality (36) is not satisfied we reject the hypothesis that the sample is from a normal population with mean μ_0. The risk of rejecting this hypothesis falsely is measured by the fact that the type-I error is δ. Tabulations of values of t_δ have been presented in various statistics books for $\delta = .01$, .05 and other values and for values of n—I from 1 to 30. There are many applications of the Student t test.

The Chi-Squared *Test*.—As a second example, consider an infinite population in which each element belongs to one and only one of the mutually exclusive classes $A_1, A_2, \ldots, A_k$ having probabilities $p_1, p_2, \ldots, p_k$, where

$$\sum_{i=1}^{k} p_i = 1.$$

In a sample of n elements from this population, the probability of getting x_1 A_1's, x_2 A_2's, $\ldots$, x_k A_k's is given by the multinomial law (28). It is important in many statistical problems to test whether the observed frequencies $x_1, x_2, \ldots, x_k$ could have reasonably come from a population in which $p_1, p_2, \ldots, p_k$ have specified values $p'_1, p'_2, \ldots, p'_k$; *i.e.*, whether the x's depart significantly from their expected values $np'_1, np'_2, \ldots, np'_k$ under the hypothesis that the sample came from a population with these specified values of the p's. The criteria for testing this hypothesis which was originally proposed by K. Pearson (1900) is:

$$\chi^2 = \sum^{k} \frac{(x_i - np'_i)^2}{np'_i}, \tag{37}$$

known as the chi-squared test criterion. It will be seen that it satisfies our intuitive requirement that it should somehow measure the discrepancy between each xi and its expected value. The more the x's depart from their mean or expected values, the larger the value of x^2. Thus, the range R of critical values which suggests itself consists of all values of χ^2 greater than a suitable chosen value χ_δ^2. For larger values of n, and assuming that none of the p's are very small, the sampling distribution of χ^2, if the hypothesis is true that the sample came from a population in which the p's have the values specified, is approximately

$$dF(\chi^2) = \frac{\left(\frac{\chi^2}{2}\right)^{\frac{k-3}{2}}}{2\Gamma\left(\frac{k-1}{2}\right)} e^{-\frac{1}{2}\chi^2} d(\chi^2). \tag{38}$$

This is an important sampling distribution, known as the *chi-squared* distribution with k−1 degrees *of* freedom. Values of χ_δ^2 have been tabulated for which

$$\int_{\chi_\delta^2}^{\infty} dF(\chi^2) = \delta$$

has various values from .01 to .99 and for values of k from 2 to 30. There are many statistical functions having sampling distributions which are of the form (38).

As a simple example of the application of the criterion (37), suppose a bridge player has kept a record of the number of aces which he has obtained in each of 500 bridge hands which he has played over a period of time. Suppose that he received no aces in 165 hands, one ace in 210 hands and more than one ace in 125 hands. Is this distribution of aces consistent with the hypothesis of thorough shuffling and fair dealing? Under the hypothesis of thorough shuffling and fair dealing one finds by applying the theory of combinations that the probabilities of no aces, one ace and more than one ace are approximately 0.30, 0.44 and 0.26 respectively. The numbers of hands containing no ace, one ace and no aces in 500 hands are, therefore, 150, 220, 130 respectively. The value of χ^2 computed from (37) is

$$\chi^2 = \frac{(165-150)^2}{150} + \frac{(210-220)^2}{220} + \frac{(125-130)^2}{130} = 2.147.$$

This is not a significantly large value of χ^2. For example, in a large number of sets of 500 bridge hands more than 30% of the sets would yield hands deviating more widely from the expected distribution of aces than in the present case. In order to have significant discrepancies at the 0.05 probability level the observed distribution of aces would have to yield a value of χ^2 equal to about 6 or larger.

The Method of Likelihood Ratios.—In the theory of testing statistical hypotheses, one of the major problems is that of devising a test criterion from the sample. For a wide class of situations which covers many of the practical statistical problems, a procedure is available for constructing the tests, known as the *method of likelihood* ratios. In applying this method we assume that the sample is drawn from a population having a cumulative distribution function of the functional form $F(x, \theta)$, where θ is a parameter. We wish to test the hypothesis that θ has a specified value θ'. The probability law of the x's in a sample of n items is

$$dF(x_1, \theta)\, dF(x_2, \theta) \ldots dF(x_n, \theta). \tag{39}$$

We maximize (39) with respect to θ and denote the maximum of (39) by $P(x_1, x_2, \ldots, x_n, \hat{\theta})$ and then take the ratio

$$\lambda = \frac{P(x_1, x_2, \ldots, x_n, \theta')}{P(x_1, x_2, \ldots, x_n, \hat{\theta})}, \tag{40}$$

where the numerator is obtained by replacing θ by θ' in (39). The ratio λ is known as the likelihood *ratio*, and is a test criterion which has, under certain conditions, optimum properties for large samples. The value of λ varies between 0 to 1, and the critical range R for risk δ of type-I error of values of λ would be those between 0 and λ_δ where λ_δ is chosen so that $Pr(\lambda < \lambda_\delta) = \delta$ when the hypothesis is true that $\theta = \theta'$. The distribution of $-2\log_e\lambda$ in large samples actually drawn from a population having distribution $F(x, \theta')$ is approximately the chi-squared distribution law (38) with one degree of freedom (*i.e.*, when the hypothesis that $\theta = \theta'$ is true). For type-I error of probability δ the critical range R of $-2\log_e\lambda$ are those values greater than χ_δ^2 where $Pr(\chi^2 > \chi_\delta^2) = \delta$, where χ^2 has the distribution law (38) with $k = 1$. This method extends readily to the case of several parameters in which the population cumulative distribution is $F(x, \theta_1, \theta_2, \ldots, \theta_h)$, the hypothesis being that these θ's have specified values $\theta'_1, \theta'_2, \ldots, \theta'_h$.

A. Wald (1941) showed that in large samples the likelihood ratio is the best statistical test that can be devised in a certain reasonable (but technical) sense. The method is applicable to many statistical hypotheses that arise in connection with populations having normal, Poisson, binomial, multinomial and many other types of distribution laws. Wald (1947) also devised a theory of statistical tests based on the likelihood ratio for sequential sampling.

Statistical Estimation.— Under the section Statistical Tests, above, me have discussed the problem of testing whether or not a sample could "reasonably" have arisen from a population with a given distribution or a given type of distribution. More precisely we have discussed the problem of testing the hypothesis that one or more parameters in a population distribution law have certain specified values, regardless of what values certain other parameters in the distribution law may have.

Closely related to this problem is that of estimating, on the basis of a sample, the value of a parameter in a population distribution law. There are two approaches to this problem: point estimatiou and interval estimation.

Point Estimation.—By point estimation in the simplest case, we mean the computation of a function, say $\breve{\theta}$, of a sample of x's drawn from a population having a distribution law involving a parameter θ whose value is unknown, such that in repeated samples $\breve{\theta}$ will "cluster" around θ. Thus, in any given sample the value assigned to θ is $\breve{\theta}$. This value is subject, of course, to an error described, in repeated samples, by the probability law of $\breve{\theta}$. A fundamental problem in point estimation is to devise an *efficient* estimate; *i.e.*, a function so that in repeated samples it will cluster as closely around the true value of θ "as possible." R. A. Fisher (1921) proposed a method by which such a function can be formed which is valid in many of the statistical situations that arise. If $F(x, \theta)$ is the population distribution, in which θ is to be estimated, then, under fairly general conditions, the most efficient point estimate $\hat{\theta}$ of θ for large samples is provided by the value of θ which maximizes the probability (39) at the given sample point $x_1, x_2, \ldots, x_n$—most efficient in the sense that no other function of the sample x's can be devised which has a smaller variance in repeated samples than that of $\hat{\theta}$. The variance of $\hat{\theta}$ is given by $\frac{1}{nV^2}$, where

$$V^2 = \left[E\left(\frac{d\{\log dF(x, \theta)\}}{d\theta}\right)^2\right].$$

As defined in this manner θ is called the *maximum* likelihood estimate of θ. As examples: the sample mean $\bar{x}$ is the maximum likelihood estimate of the mean μ of a normal population having distribution law (22); the sample mean $\bar{x}$ is the maximum likelihood estimate of μ in the Poisson law (21); the maximum likelihood estimate of the probability p of an A in a binomial population is x/n, where x is the number of A's obtained in the sample of n items. The method of maximum likelihood estimation extends to the case in which the population distribution function is characterized by several parameters, say $\theta_1, \theta_2, \ldots, \theta_h$.

Interval Estimation.—By interval estimation we mean the computation of two functions of the x's in a sample say $\underline{\theta}$ and $\bar{\theta}$ such that if the sample is drawn from a population having cumulative distribution law $F(x, \theta)$ then $\underline{\theta}$ and θ will include the unknown value of θ for the population between them with a given probability 1−δ. In practice, 1−δ is usually taken to be a number between 0.90 and 0.99. $\underline{\theta}$ and θ are called *upper* and *lower confidence* limits; the interval $(\underline{\theta}, \bar{\theta})$ is called the confidence interval, 1−δ the *confidence coefficient*. $\underline{\theta}$ and $\bar{\theta}$ are often referred to as $100(1-\delta)\%$ confidence limits. It should be noted that $\underline{\theta}$ and $\bar{\theta}$ are constructed from the x's of the sample and hence are random variables whose values fluctuate from sample to sample. An example of confidence limits can be obtaincd by examining inequality (36). This inequality asserts that if a sample having mean $\bar{x}$ and standard deviation s is drawn from a population having a normal distribution law with mean μ_0, then the probability is 1−δ that the value of $\bar{x}$ and s will be such as to satisfy the inequality (36), which is equivalent to the statement that the probability is 1−δ that the two quantities

$$\bar{x} \pm t_\delta \frac{s}{\sqrt{n}}$$

will include the value of μ_0 between them. These two quantities are confidence limits for μ_0 with confidence coefficient 1−δ. There are usually many ways of constructing $\underline{\theta}$ and $\bar{\theta}$ from a sample but the fundamental problem of interval estimation is to devise $\underline{\theta}$ and $\bar{\theta}$ in such a way that they are as close together as possible in some average sense. Fortunately, there is a method for doing this which is applicable to the case of large samples for a wide class of population distribution laws. The method is based on the fact that in large samples the cumulative distribution function of the quantity

$$\left[\frac{1}{\sqrt{n}V} \cdot \frac{\partial}{\partial\theta} P(x_1, x_2, \ldots, x_n, \theta)\right] = \psi,$$

say (where V is defined in the discussion of maximum likelihood estimation, and $P(x_1, x_2, \ldots, x_n, \theta)$ is the probability given by expression (39)) is approximately given by the cumulative normal distribution $F(\psi)$, where $F(\psi)$ is obtained by replacing x by ψ in (23). To obtain confidence limits for θ for any given confidence coefficient 1−δ one finds x_δ from (23) so that $F(x_\delta) = 1 - \frac{1}{2}\delta$. The probability is approximately 1−δ that in a large sample the value of ψ defined above will be such that $-x_\delta<\psi<x_\delta$. ψ, it will be noted, involves the sample x's and θ, and, when the method is valid, ψ is an increasing or decreasing function of 8. Hence, solving the inequality $-x_\delta<\psi<x_\delta$, one obtains two values of 8, say $\underline{\theta}$ and $\bar{\theta}$, which are the desired confidence limits. For example, if a sample is drawn irom a binomial population in which the probability of getting an A in a single drawing is p, the expression for ψ is $(x-np)/\sqrt{npq}$, which x, n, p and q are defined in (19). To get 95% confidence limits of p, one would solve the following inequalities for p

$$-1.96<(x-np)/\sqrt{npq}<+1.96.$$

The idea embodied in the concept of confidence limits was first pointed out by E. B. Wilson (1927), using the example just given. But the theory of confidence limits was rather fully developed by Neyman (1937). R. A. Fisher (1933) used the term *fiducial* limits instead of confidence limits.

Method of *Moments*.—Another procedure of point estimation extensively used in many statistical problems is the method of moments. In using the method of moments a sample of n x's is available, and it is assumed that the sample is irom a population having a cumulative distribution function of the form, or closely approximated by the iorm, $F(x, \theta_1, \theta_2, \ldots, \theta_h)$, whose functional form is known, but the values of the θ's for the specific problem at hand are unknown. The problem is to estimate the values of the θ's. The principle of estimation by the method of moments provides that the first h moments of the x's in the sample, *i.e.*,

$$\frac{1}{n}\sum_{i=1}^{n} x_i,\ \frac{1}{n}\sum_{i=1}^{n} x_i^2,\ \ldots,\ \frac{1}{n}\sum_{i=1}^{n} x_i^h,$$

be equated, respectively, to the first h moments of x computed from the distribution iunction $F(x, \theta_1, 82, \ldots, \theta_h)$. Since the h moments of this distribution function will be functions of the θ's we have a set oi h equations in h unknowns, $\theta_1, \theta_2, \ldots, \theta_h$ to be solved. The values of the 8's yielded are the point estimates of $\theta_1, \theta_2, \ldots, \theta_h$ by the method of moments. In general, the method of estimation by moments is not as efficient as the method of maximum likelihood. There are cases in which the two methods give identically the same estimates. This is true, for example, in estimating the mean μ and variance σ^2 in the normal distribution (22) iunction on the basis of a sample.

Karl Pearson (1895) gave a general functional form of the distribution function $dF(x, \theta_1, \theta_2, \ldots, \theta_h)$ for the continuous case and for the case h=4, so that the method of moments can be used on the basis of the first four moments. The probability density function is given as the solution of the differential equation

$$\frac{df}{dx}=\frac{(x+\theta_1)f}{\theta_2+\theta_3x+\theta_4x^2},$$

which will involve four unknown parameters. For various combinations of values of the constants $\theta_1, \theta_2, \theta_3, \theta_4$, probability density curves $y=f(x, \theta_1, \theta_2, \theta_3, \theta_4)$ of many different shapes can be obtained which are flexible enough to cover many practical problems.

The Method *of* Least Squares.—Another well-known procedure of point estimation of population parameters is known as the method oi least squares. In this method it is assumed that under "ideal" conditions a variable y can be expressed as some iunction of x, say $g(x, \theta_1, \theta_2, \ldots, \theta_h)$ involving certain parameters $\theta_1, \theta_2, \ldots, \theta_h$. A set of "observational" pairs $(x_1, y_1), (x_2, y_2) \ldots (x_n, y_n)$ are obtained. Often these observational pairs are obtained by picking a value of x, then performing an experiment to get a value of y corresponding to that value of x. Thus by picking $x_1, x_2, \ldots, x_n$ as the values of x, one gets a corresponding set oi values of y; *i.e.*, $y_1, y_2, \ldots, y_n$. The "theoretical" values of the y's corresponding to these values of x are $g(x_1, \theta_1, \theta_2, \ldots, \theta_h)$, $g(x_2, \theta_1, \theta_2, \ldots, \theta_h) \ldots$, $g(x_n, \theta_1, \theta_2, \ldots, \theta_h)$. The least squares estimates of the θ's are defined as the values of the θ's which will minimize the sum of squares

$$S=\sum_{i=1}^{n}[y_i-g(x_i, \theta_1, \theta_2, \ldots, \theta_h)]^2.$$

The idea of least squares can be extended in various directions, and many applications were, for example, treated by W. E. Deming (1943). It turns out that the method of least squares and the method of maximum likelihood yield identically the same result if one assumes that y and $g(x_1, \theta_1, \theta_2, \ldots, \theta_h)$ are such that the "error" $[y-g(x, \theta_1, \theta_2, \ldots, \theta_h)]$ is normally distributed nith mean zero. The distribution function (32) of the entire sample is such that the sum of squares S appears in the exponent, and the problem of maximizing the likelihood (32) with respect to the θ's becomes equivalent to minimizing S.

Tolerance Interval Estimation.—Another important concept in the theory of estimation is *tolerance interval* estimation introduced by W. A. Shewhart. The problem here may be stated as follows Suppose a random variable in a population has a continuous probability law and that the probability element is $f(x)dx$, but where $f(x)$ is unknown. A sample is drawn from the population, and from the sample x's two quantities, say L_1 and L_2, are computed such that we can state that the probability is γ (usually .go to .99), that the proportion of the x's in the population included between L_1 and L_2 is at least p (also usually .90 to .99), no matter what form $f(x)$ may have. More briefly, L_1 and L_2 are such that

$$Pr[\int_{L_1}^{L_2} f(x)dx \geqq \beta]=\gamma,$$

and they are called $100\beta\%$ tolerance limits at tolerance level γ. Order statistics can be used as tolerance limits; *i.e.*, L_1 and L_2 may be taken as the least and greatest x in the sample, respectively, or next to the least and next to the greatest, etc. If the functional form of $f(x)$ is known, other methods of obtaining L_1 and L_2 can be used. For example, if $f(x)$ is known to be normal, $100\beta\%$ tolerance limits of the form

$$\bar{x}\pm t_\beta\sqrt{\frac{n+1}{n}}s,$$

$\bar{x}$ and s^2 being the sample mean and variance, can be used where t_β is such that $Pr(-t_\beta<t<t_\beta)=\beta$, where t is distributed according to the Student law (35).

Design of Experiments.—With the rapid development of statistical theory, an increasing amount of attention is being paid to the original design or setting up oi any type of an experiment or an investigation which depends heavily upon statistical analysis of the results for interpretation. consideration of experimental design led to the development of theory and procedures for determining what combinations of iactors important to the entire experiment should be introduced to simpliiy statistical analysis of the data and its interpretation, and also to determine how many repetitions or replications of the experiment should be performed in order to detect important differences in experimental results attributable to the various factors or combinations of factors. R. A. Fisher was the leading exponent on the importance of carefully designed experiments. Fisher and his school developed experimental designs together mith an appropriate statistical procedure known as the analysis of variance for analyzing the data from such experiments. The principal idea in this work is to arrange the entire experiment in an orderly manner as a set of subexperiments (which may consist of as iew as one trial each), these subexperiments differing from each other by varying one or more iactors, so as to permit the effect of the variation of the factor (or iactors) on the outcome of the experiment to assert itself in case there is such an effect. A statistical test iunction is designed: (1) to detect whether the outcome of the experiment is such that the differences in results irom one subexperiment to another are real, and attributable to the variation of the factors being tested, or whether they are simply chance differences; and (2) to measure such differences ii they are real. Frequently such differences are known to be real in advance and the statistical functions are used to measure the differences.

Experimental Designs by W. G. Cochran and Gertrude M. Cox (1950) should be consulted by the reader interested in details of these developments.

Suppose samples are drawn from each of two populations, and that we can safely assume these two populations to have normal distribution laws with equal variances. The question is this: could the two samples have reasonably come from normal populations with the same mean? If the numbers of items, means and variances oi the two samples are n', n''; x', x''; s'^2, s''^2, respectively, a suitable criterion for making the test is $\sqrt{n}(\bar{x}'-\bar{x}'')/s$ where n$=n'+n''$, and

$$s^2=(n'-1)s''^2+n(n''-2-1)s''^2.$$

Thus, the greater the difference between the sample means in relation to s, the greater the value of the criterion and the more uniavourable it is to the hypothesis of equality of population means. This criterion computed from pairs of samples from normal populations having the same means has a distribution law given by (3j) with $n'+n''-2$ degrees of freedom; *i.e.*, with n−1 replaced by $n'+n''-2$. Therefore, ii the absolute value of the criterion exceeds t_δ, lve say that the samples' means are significantly different at the δ probability level, which means that we can say that the samples are actually irom normal populations mith the same means with a risk of probability δ of making a type-I error. This test is useful in testing whether the effects of two treatments A and B on a given measurable characteristic are significantly different; *e.g.*, whether two rations A and B are different in their effects in increasing the weight of pigs. The experiment might be set up with 30 pigs of a given age to receive ration A and 30 more pigs matched with those in the first group on age and weight to receive ration B. Thus, there are two subexperiments. Aiter a given time interval, say 60 days, each of the 30 pigs in each sample would be weighed, and these t o sets of weights would be the two samples of x's to be used in the criterion.

Note that in using the two-sample criterion described above it has been assumed that the variances oi the populations are equal. Actually, we may wish to test this assumption, assuming only that the two population distributions are normal. A criterion is available for making this test, namely

$$\mathcal{J}=s'^2/s''^2$$

which has the following distribution law when the hypothesis of equal population variances is true:

$$dF(\mathcal{J})=\frac{\Gamma\left(\frac{n'+n''-2}{2}\right)}{\Gamma\left(\frac{n'-1}{2}\right)\Gamma\left(\frac{n''-1}{2}\right)}\left(\frac{n'-1}{n''-1}\right)^{\frac{n'-1}{2}}\mathcal{J}^{\frac{n'-3}{2}} \tag{41}$$

$$\left(1+\frac{n'-1}{n''-1}\mathcal{J}\right)^{-\frac{n'+n''-2}{2}}d\mathcal{J}$$

which is known as Snedecor's $\mathcal{J}$ distribution and defined on the interval $(0, \infty)$. The $\mathcal{J}$ criterion is an intuitively reasonable one since small or large values of it are values unfavourable to the hypothesis of equal population variances. The critical range R of values of $\mathcal{J}$, for a given level of significance δ are found by cutting off the lower tail of the distribution at $1/\mathcal{J}_\delta$ and the upper tail at $\mathcal{J}_\delta$ so that the probability of F falling between $1/\mathcal{J}_\delta$ and $\mathcal{J}_\delta$ is $1-\delta$. The distribution (41) is the basic probability law involved in making statistical tests in the analysis of variance.

Next, let us consider a slightly more elaborate experiment. Suppose it is desired to test whether the quality of screws of a given type as measured by number of defectives per 1,000 varies significantly from machine to machine or from operator to operator. An experiment might be designed along the following lines: consider eight machines and eight operators; let each operator make 1,000 screws on each machine, and let x_{ij} be the number of defectives in the 1,000 screws produced by the ith operator on the jth machine. We assume that x_{ij} is made up of the sum of four parts: m which is the same for all combinations of operators and machines, r_i an "effect" which is due to the ith operator, c_j an "effect" which is due to the jth machine, and a "pure" random error e_i, which is normally and independently distributed for all combinations of i and j with mean zero and variance σ^2. Then $x_{ij}=m+r_i+c_j+e_{ij}$. The r_i and c_j may be thought of as corrections to m, which may be positive or negative; r_i a correction to be made for the ith operator; and c_j a correction for the jth machine. They are such that

$$\sum_{i=1}^{8} r_i=\sum_{j=1}^{8} c_j=0.$$

Now the x_{ij} are sample values and what we wish to do is to set up a criterion for testing whether the operator corrections r_i are all zero (*i.e.*, no average change from operator to operator), and similarly whether the machine corrections c_j are all zero. The likelihood ratio or least squares criterion for testing for no significant variation from operator to operator is

$$7\sum_{i=1}^{8}(\bar{x}_{i\cdot}-\bar{x})^2\Big/\sum_{i,j=1}^{8}(x_{ij}-\bar{x}_{i\cdot}-\bar{x}_{\cdot j}+\bar{x})^2,$$

where $\bar{x}_{i\cdot}$ is the average of $x_{i1}, x_{i2}, \ldots, x_{i8}$, with a similar meaning for $\bar{x}_{j\cdot}$; $\bar{x}$ is the average of all x's. The denominator of this expression is rather insensitive to variations due to operators or machines although the numerator tends to be sensitive to operator variations, and the ratio tends to have large values if there is significant variation from operator to operator. The criterion has as its sampling distribution the $\mathcal{J}$ distribution (41) with $n'-1=7$, and $n''-1=49$ if there is no significant operator to operator variation, which provides a method of obtaining a critical value of the ratio beyond which we would declare that operator variation is significant. A similar analysis would be made for testing significance of machine to machine variation.

PROBATE

PROBATE refers to the formal proof of a will, which in England has to take place at Somerset House, London, or at a district registry. The early jurisdiction of the English ecclesiastical courts over the probate of wills of personalty is discussed under Will. The Court of Probate Act 1857 transferred the jurisdiction both voluntary and contentious of all ecclesiastical, royal peculiar, peculiar and manorial courts to the court of probate thereby constituted, created a judge and registrars of that court, abolished the old exclusive rights in testamentary matters of the advocates of Doctors' Commons, and laid down rules of procedure. Contentious jurisdiction was given to county courts when the personal estate of the deceased was under £200 in value.

The Judicature Act 1873 merged the old court of probate in the probate divorce and admiralty division of the High Court of Justice. Probate may be taken out either in common or *solemn* form. In the former case. which is adopted when there is no dispute as to the validity of the will, the court simply recognizes the will propounded as the last will of the deceased. This formality is necessary to enable the executor to administer the estate of his testator.

Probate in this form is granted simply as a ministerial act if the attestation clause declares that the formalities of the Wills Act have been complied with, or if other evidence to that effect is produced. Such grant is liable to revocation, but it is provided that any person dealing with an executor on the faith of a grant of probate in common form. shall not be prejudiced by its revocation. The executor may within 30 years be called upon to prove in solemn form. A person who doubts the validity of the will propounded may enter a caveat which while in force prevents any probate other than in solemn form. Separate representation may be granted in respect of real estate since the administration of Estates Act 1925, and of a trust estate only, but except or regards trust estates a separate representation may be granted of a known insolvent estate. Under the Law of Property Act, 1925, S. 11, probate and letters of administration convey the legal estate to the personal representative, and this makes the real estate directly available for payment of debt. Probate in solemn form is a judgment of the court in favour of the will propounded, and is only revocable by the discovery of a later will. In order, therefore, to obtain such grant proceedings have to be taken by action, and witnesses produced in support of the will, and the action proceeds in the usual way.

The principal rules now obtaining as to probate are these. Probate, which since the Land Transfer Act 1897 (see New Administration of Estates Act, 192j, ss 79, 80) must be taken out for wills of realty as well as wills of personalty, may be granted either in the principal or in a district registry, and should be obtained within six months after the testator's death. When no executor is named the will is not now invalid, as was once the case, but administration cum testamento annexo is granted. The same course is pursued where the executor renounces or dies intestate before administering the estate of the deceased. After probate, the probate itself (as the official copy of the will is called) becomes evidence, the original will being deposited in the principal registry at Somerset House, London. On grant of probate, estate duty is payable on the gross value of the personal estate and the English real estate (see Estate and Inheritance Taxes). The act of 1881 enables any officer of inland revenue to grant probate where the personal estate does not exceed £300.

In 1867 an act on lines similar to the English act was passed for Ireland and under the Irish Judicature Act of 1877 the then existing court of probate was merged in the High Court of Justice.

In Scots law *Confirmation* includes both the probate and letters of administration of English procedure. It forms the executor's legal title to ingather the estate. Originally confirmation of testaments of movables fell, as in England, under the cognizance of the Church courts. It is now part of the jurisdiction of the sheriff courts and is regulated by statutes, the principal of which are, the Confirmation and Probate Act 1858, the Sheriff Courts Act 1876. and Executors Act 1900. When the will is attested and probation alluding to sects, forms for the execution of deeds, it proves itself, and the onus is on the person challenging it. In other cases the executor may be required to prove the validity of the will in the proceedings for confirmation.

UNITED STATES

Special Courts. — Probate is granted in some States by the ordinary chancery or common law courts, but more frequently by courts of special jurisdiction, such as the prerogative court in New Jersey, the surrogates' court in New York, the orphans' court in Pennsylvania.

"In a great majority of the States the original equitable jurisdiction over administrations is in all ordinary cases — without any special circumstances such as iraud, or without any other equitable feature such as trust — either expressly or practically abrogated. The courts of equity, in the absence of such special circumstances or distinctively equitable features, either do not possess or will not exercise the jurisdiction, but leave the whole matter of administrations to the special probate tribunals" . . . so that "unless the case involves some special feature or exceptional circumstances of themselves warranting the interierence of equity, such as iraud, waste, and the like, or unless it is of such an essential nature that a probate court is incompetent to give adequate relief, or is one of which the probate court having taken cognizance has completely miscarried and failed to do justice by its decree, the courts of equity will refuse to interpose and to exercise whatever dormant powers they may possess, but will leave the subject matter and the parties to the statutory forum which the legislature plainly regarded as sufficient and intended to be practically exclusive" (Rice's ***Probate Law,*** pp. 4 and 5). For the old law on probate, see G. W. Marshall, Ancient Courts of ***Probate* (1895).**

Jurisdiction as to wills and their probate as such is neither included in nor excepted out of the grant of judicial power to the courts of the United States (*i.e.*, the *Federal* as distinguished from the State courts). So far as it is *ex parte* and merely administrative it is not conferred, and it cannot be exercised by them at all until in a case at law or in equity its exercise becomes necessary to settle a controversy by reason of the (diverse) citizenship of the parties. An action to set aside the probate of a will of real estate may be maintained in a Federal court when the parties on one side are citizens of a different State from the parties on the other side *(Ellis* v. *Davis,* 109 US. Reports, 485). Probate in solemn form, *i e.,* after due notice to all parties in interest is the almost universal form in use in the United States. One reason for this no doubt is that all documents affecting title to real estate must be recorded and probate in solemn form concludes all parties to the proceeding and thus tends to establish the title to all real estate passing under the will.

In the United States wills of real property must be separately proven in the proper probate court in each State in which the real property is situated, unless statute dispenses with separate probate (each State being "foreign" to every other for this purpose). Copies of such will and probate should be filed also in the office of the register of deeds of each county in the State in which any real property belonging to the testator is situated.

In the State of *New Jersey* it has been held that an unprobated will is capable of conveying an interest in the property devised, and when a conveyance is made under a power in the will before probate, a subsequent probate validates the conveyance (1906, *Mackey* v. *Mackey,* 63 Atl. Rep. 984).

In Illinois a court of equity has no *inherent* power to entertain a bill to contest a will (1906, *O'Brien* v. *Bonfield,* 220 Ill. Rep. 219).

In *Missouri* a foreign (New York) will of real estate in Missouri, probate of which was duly recorded in Missouri, cannot be *collaterally* attacked, and cannot be set aside by direct proceeding after being filed for record more than five years in Missouri (1907; *Cohen* v. *Herbert,* 104 So. W. Rep. 84)

PROBATION. When a person has been found guilty of an offense, the court may exercise its right to give the offender a chance not to do it again, by putting him or her on probation for a period, in Great Britain, of not less than one, or more than three. years. During this period, a probation officer is authorized to supervise and befriend the offender. Probation officers also act as advisers in matrimonial cases and similar problems involving mediation or advice to the courts.

It appears that the first probation officers were appointed in the United States in about 1878. The principle was recognized in England for first offenders in 1887 when the First Offenders act became law. This was followed by the Probation of Offenders act in 1907 which permitted the use of probation in cases where there were previous convictions if such a course appeared justifiable or desirable. Credit must be given to the London Police Court mission for at once placing its missionaries at the disposal of the court to act as probation officers The mission may thus be regarded as the father of the probation service in England. Through its hostel for students in training for the probation service the mission continues to strive to preserve the vocational approach to the work. Training facilities are provided by the national advisory and training board, appointed by the home secretary. The National Association of Probation Officers exists to improve and strengthen the service as a whole.

Under the act of 1907 the appointment of probation officers was not compulsory and it was in many cases ignored, but this defect was remedied by the Criminal Justice act of 1925 which made obligatory the appointment of a probation committee for every probation area. This area may be either that within the jurisdiction of a single petty sessional court or a combined area including several such courts (approved by the secretary of state).

Probation work among children *(see* also JUVENILE DELINQUENCY*)* differs materially from that among adults and is of even greater importance. It is essential that a child offender should. at first, be under very careful supervision; that his mental, physical and psychological characteristics should receive the closest study; that friendly relations should be established between the parents and the probation officer; that the child should be brought in touch with outside agencies such as boy scouts, clubs, etc.; and that he should feel that in his own officer he has a real friend to whom he can always look for advice, sympathy and help. It will be seen that the essential character of probation is not mere supervision. nor must the popular fallacy be encouraged that probation means that the offender is, in fact. "let off" Not only is the offender expected to report at regular intervals to the probation officer but the officer is in close personal touch with his home and family and is as much concerned with free time activity as with work and home conditions. A U S. writer on juvenile courts has made the point that "Probation is damned if the court, the offender and the public regards it as something amounting to a form of leniency or acquittal." (H. S. Lou. *Juvenile Courts in the United States,* Chapel Hill, 1927). Probation does, in fact, involve considerable discipline and some sacrifice of freedom and spare time.

When the probationer fails for any reason he or she may be brought back to court again and the court may then decide on an alternative punishment of a more serious nature. It is in that sense that probation may be likened to a suspended sentence or judgment which is subject to the behaviour of the person concerned. The probation service depends largely on the sustained and genuine interest of the courts and probation officers, and on their mutual concern in the future of those with whom they deal

By the middle of the 20th century it was possible to judge the probation system on its results. which were generally satisfactory especially with children. Over half the number of children who appeared before juvenile courts were placed on probation and returns from 15 large towns showed that 65% of the children placed on probation did not get into further trouble for at least three years after their probation order was completed. (C. A. JE.)

United States.—As in England, probation grew out of certain practices of the criminal courts under common law, such as the release of offenders on their own recognizance with sureties, or their release on bail. Such procedure involves a conditional suspension of the imposition of sentence, and the abandonment of punitive action if the conditions (primarily good behaviour) are complied with. The origin of probation in the United States took place in Massachusetts during the first half of the 19th century. In Boston in 1841 a cobbler, John Augustus, appeared before the police court and offered to stand bail for a drunkard, and to assist in his rehabilitation. The court permitted him to do so. The experiment was so successful that Augustus then proceeded to stand bail for many more offenders. These were first adult males, charged with drunkenness; but gradually persons committed to him included women and children, and the offenses were not confined to drunkenness. In time the work was extended to the municipal court. Beiore his death in 1859 Augustus had "bailed on probation" nearly 2,000 persons with a large measure of success.

In 1878 Massachusetts passed the first adult probation statute in the United States. This provided for the appointment of a paid probation officer ior the courts of criminal jurisdiction in the city of Boston. The statute directed that those who could be reformed without punishment should be placed on probation. Subsequent laws extended probation throughout the cities and towns of Massachusetts and to all criminal courts. By the turn of the century six other states had given statutory authorization for probation. Great impetus was given to the growth of probation by the juvenile court movement, beginning in Chicago (Cook county) in 1899.

The possibility of probationary treatment is an integral part of juvenile court laws which have been adopted in all states except Maine. That state provides otherwise ior juvenile probation. Statutory provisions ior adult probation exist in all but four states.

Essential to the proper administration of adult probation are the following steps: (1) careiul selection of cases which give promise oi improvement under supervision. Theoretically, this should be made not with exclusive consideration for the degree of gravity of the offense committed, but on the basis of the likelihood of the offender's improvement under probationary treatment. This principle is violated by the laws of those states which deny probation to all those convicted of certain grave crimes; (2) suspension oi sentence for persons selected for probation; (3) supervision of probationers by trained personnel. This means at best the establishment of friendly relations between the probation officer and his client. Probation has been termed "casework in an authoritative setting." Good casework is of the essence of probation. In relatively few areas of the United States is this principle maintained, either because of the lack of trained, efficient probation officers,or because oi case loads so large that individual attention cannot be given; (4) release of the probationer at the end of the period of supervision set by the court, provided that his behaviour has been satisfactory, or revocation of probation and the remanding of the offender to court for sentence on the original charge if he has violated the conditions of his probation either by the commission of a new crime or by iailure to comply with the restrictive rules imposed during the period of supervision.

Careiul studies' of the outcome of probation indicate that approximately 75% of probationers successfully complete their period of probation, that is, without violations of any sort. How large a proportion oi them remain permanently law-abiding in subsequent years is a question concerning which there is little evidence.

It is not too much to say that probation, properly administered. is the most promising innovation in modern penology. It affords a chance for the rehabilitation of offenders apart irom the degrading environment of a prison where it costs ten times as much to keep a man as it would were he on probation. In the United States the National Probation and Parole Association carries on educational work and renders valuable services oi advice to states and communities in relation to their systems of probation. (A. E. WD.)

PROBOSCIDEA, the scientific name of an order of Eutherian mammals represented at the present day by the African and Indian elephants. These animals (see ELEPHANT) differ very widely in their structure from all other living mammals but fossil remains of similar structure have long been known. Only during the 20th century, however, have primitive Proboscidea been discovered capable of comparison with other mammalian forms. The leading characteristics of the living elephants are as follows.

The animal is of large size with pillar-like limbs. The neck is short and the large head is provided with a proboscis, a long flexible muscular organ capable of' being turned freely in all directions, and provided with one or two finger-like processes at its tip which can be used to handle articles as small as a penny. The trunk can also be employed as a prehensile organ by being wrapped as a whole round a large object. It is capable of very considerable accuracy of movement and is used in feeding. The trunk represents the whole anterior part of the face, that is the nose and also the upper lips, the strip of skin along its ventral surface being essentially a part of the palate. The two nostrils lie at the extremity of the trunk and lead into great canals which perforate the whole of that organ opening into olfactory chambers at its base. The mouth is short, placed below the trunk and provided with thick fleshy lower lips meeting anteriorly so as to form a short spout. The eye is small, laterally directed and provided with a pair of eyelids often bearing stiff eyelashes. The pinna of the external ear is large, becoming enormous in certain races of the African elephants. It is usually carried close to the side of the neck but can be erected so as to stand out perhaps a yard from the side of the head. The female bears two teats placed on the pectoral surface just between and behind the forelegs. Most living adult elephants possess very few hairs; there are normally a certain number on the forehead and cheek and always a tuft of long extremely thick hairs at the end of the short tail.

The skeleton of an elephant is as peculiar and characteristic as his external appearance. The skull is very short from back to front, deep, and built up of spongy bone full of air-spaces. Within the great mass of bone there lies a relatively small, though actually large brain cavity, and the olfactory chambers form great perforations which with the naso-pharyngeal ducts penetrate obliquely through the skull uniting only quite posteriorly. The skull of the new-born elephant differs from that of the adult in that whilst the head increases greatly and disproportionately in size, the brain undergoes much less expansion. Thus during the period of growth of the animal the external surface of the skull, by the development of the great air-spaces in its middle layer, becomes more and more widely separated from the layer of hard bone which surrounds the brain. The bony lamellae which separate these air-spaces run radially so as to buttress the external surface. The great size of the adult skull is necessary in order to give adequate areas for the attachment of the immense neck-muscles which support and move the very heavy trunk and tusks, and take the great strains which are produced when these structures are used in digging up and tearing down trees.

The jaw-bones of the elephant and the whole structure of its palate are modified so as to receive and afford adequate support to the tusks and cheek teeth. The bony nostrils lie very high up and are overhung by very small nasal bones to which some of the muscles of the base of the trunk are attached. This attachment is brought as far back as possible in order to increase the range of action of the proboscis.

The dentition of an adult elephant consists of a single pair of exaggerated incisors, the tusks, and either one or two molars on each side of the upper and lower jaws. These molars are built up of a series of plates each composed of a core of dentine surrounded by a layer of enamel; the individual plates, continuous with one another at their base, are held together and supported by an infilling of cement. In the elephant the milk incisors, little teeth about two inches in length, are shed and replaced by the permanent tusks, but the milk molars instead of being pushed out by a permanent pre-molar which develops underneath them, replace one another from behind as follows. The new tooth is developed deep down in the posterior part of the jaw and travels obliquely forwards and towards the mouth, so that more and more of it cuts the gum as the preceding tooth is worn down to its root, until finally the latter is shed and its successor is well in wear. A living elephant in this way works through six teeth in each side of each jaw during its lifetime, wearing down a total thickness of nearly a yard of tooth over an area which increases from about half a square inch to nearly 30 sq. id. on each side of its mouth. This extraordinary dentition is unparalleled, but the process by which it came into existence is fortunately completely known from fossil material.

The elephant's backbone possesses a neck of seven very short vertebrae, the number of dorsals varies from 19 to 21, the anterior having exceedingly long neural spines for the attachment of the nuchal ligament which passes forwards to the back of the skull. There is a short lumbar region of three or four vertebrae and the sacrum is a compact bone built up by the fusion of four vertebrae: there are about 30 caudals. The ribs are of enormous length surrounding the very capacious thorax. The shoulder girdle consists of a very large triangular scapula placed vertically on the side of the thorax. The humerus is longer than the forearm so that the elbow of an elephant lies at a point relatively only a little higher than the wrist of a horse. The radius and ulna are peculiar in that their surfaces of articulation with the carpus are nearly equal, whilst the upper end of the radius is relatively small and lies in front of the ulna, the two bones crossing one another as they are traced downwards. The carpus of an elephant is unusual in that the bones of the two rows of which it is composed do not alternate but are superimposed on one another. In this feature the elephants resemble the Hyraxes. The elephant walks on the extreme tips of his fingers and toes, but the palm of the hand and the sole of the foot are swollen out into great pads of connective tissue which transmit the weight of the animal to the ground directly and so reduce the load carried by the phalanges. The elephant's pelvis is remarkable for its extraordinary width, the ilia being expanded into transversely placed sheets of bone from whose posterior surface muscles pass down to the hind-leg, whilst their margins give attachment to the muscles of the body-wall which support the weight of the viscera within the abdominal cavity. As in the fore-limb the upper segment of the leg is considerably longer than the lower one, and in the tarsus the astragalus is flattened, as a weight carrying adaptation, whilst the calcaneum is produced into a short heel directed backwards and downwards.

The anatomy of the soft parts of the elephant has been repeatedly described but presents few features of special interest except those which result from the modification of the nose and upper lips into the trunk. The animal is peculiar in that there is no pleural cavity. The fact that the testes are abdominal, the uterus bicornuate, and the placenta zonary and deciduate are of importance because similar conditions occur in the Sirenia which may have sprung from an early Proboscidean stock.

The most primitive and earliest known ancestors of the elephant belong to the genus *Moeritherium* and are found in Upper Eocene deposits in the Fayûm of Egypt. *Moeritherium* was an animal resembling in its external appearance and size the living tapir. The eye was placed far forward and the head was low and elongated, probably the end of the snout was slightly flexible and it may have been produced into a short proboscis. The legs were considerably more bent than those of the modern elephants but are still rather incompletely known. *Moeritherium* possesses three upper and two lower incisors of which the second pair are enlarged, those in the upper jaw projecting straight downwards, whilst the lower teeth are directed forwards so that their tips bite against those of the upper incisors. There is a small and very reduced canine tooth; three pre-molars are present in each jaw and there is evidence that each of these vertically replaced a milk predecessor. Three permanent molars occur in both upper and lower jaws, each consisting of two transverse ridges.

The next stage, represented by *Palaeomastodon* from the Lower Oligocene of Egypt, presents a great advance on *Moeritherium.* There are several species of which the largest is not very much smaller than a small elephant, whilst the smallest is little bigger than the largest *Moeritherium.* The back of the skull begins to show the separation of the outer surface from the brain-cavity by air-spaces, which is carried to an extreme in the living elephants. The bony nostril has shifted backwards to a point in the middle of the cheek-teeth, and in front of it the pre-maxillae form an open channel in which lay the base of the trunk. The second incisor is very much enlarged and directed forwards and downwards. The lower jaw is so much longer than the skull that the incisors, which lie horizontally, project forwards several inches in front of the upper jaw, and even extend beyond the tips of the upper incisors. The single "second" lower incisor is enlarged, and with its fellow forms a shovel-shaped termination to the lower jaw. The shape of this tooth is such as to show that its upper surface was worn by contact with some part of the animal and the only explanation of its structure is that the nose, upper lip and palate projected so far forward as to overhang the front of the lower jaw and form there a movable proboscis. The lower incisors are, however, worn all round in a way which suggests that the creature used them for grubbing about in the ground to secure food. There are three upper pre-molars each of which replace a milk tooth, whilst in the lower jaw the three milk molars are replaced only by two pre-molars. Both upper and lower molar teeth' have three transverse ridges, thus differing from those of *Moeritherium.* The body of the animal was much like that of a small elephant but the neck was longer.

In the next stage, which is represented by *Gomphotherium angustidens* from the Miocene and Pliocene of Europe, North America, Africa and Baluchistan, we have an animal somewhat larger than the largest *Palaeomastodon,* with a completely elephant-like body, though with a somewhat longer and more flexible neck. The skull is much more elephant-like than that of *Palaeomastodon* because of the increased bulk of the air-cavities in its bones. It supports a pair of immense incisors, which, unlike the tusks of living elephants, are still down-turned and are provided with a belt of enamel lying on the outer surface of the ivory of which they are composed. The lower jaw is even longer than in *Palaeomastodon,* nearly half its length projecting in front of the bony skull. The lower tusks are directed forwards and bear a wear facet on their upper surfaces made by friction against a pad on the flexible and unsupported anterior part of the face, soon to be, if it had not already become, a true trunk. *Gomphotherium* still possesses milk molars which are replaced vertically by pre-molars, but these latter are comparatively small teeth soon displaced by the cutting of the second and third molars, which push their way forward from the cavity in the hinder part of the jaw in which they are formed. This process is carried so far that the adult has only two molars, the second and third, in position in each jaw. The individual teeth though larger than those of *Palaeomastodon* have still only three ridges, except in the case of the third, which has five. It seems evident that the enormously elongated jaws of *Gomphotherium* developed as an adaptation to allow the animal to reach the ground, when as a whole it was increasing in height while its neck was becoming shorter.

In the next stage represented by such forms as *Gomphotherium longirostris,* the elephants gave up the attempt to reach the ground and came to depend on their trunks both for eating and drinking. As the elongated lower jaw is thus no longer necessary, and must have interfered with the free use of the trunk, its anterior extension becomes very rapidly reduced in size so that it no longer extends in front of the bony upper jaw. In these animals only one milk molar is replaced by a pre-molar and the first two molar teeth have each four or five transverse ridges. The lower tusks are short and rounded whilst the upper tusks become still larger and outwardly directed. In these forms the shortening of the lower jaw allowed the trunk to fall down vertically, as it does in modern elephants and in external appearance they must have been entirely elephantine.

The later mastodons pass gradually into the elephants by a still further reduction of the lower jaw, the lower tusks becoming quite small and eventually disappearing altogether, finally the front of the lower jaw becomes reduced to a very small down-turned spout which is retained in the living elephants. In the later forms the milk teeth are no longer replaced vertically by pre-molars, whilst such teeth when they do occur must have been pushed out almost immediately by the forward movement of the molar teeth. At the beginning of the series, the second molar tooth in either jaw has four or five ridges, separated from one another by deep valleys in which there is no cement. In an intermediate stage, *Stegodon,* the number of ridges varies from 6 to 12 in different forms and the valleys between these ridges become filled up with cement. In the true elephants the ridges are not only more numerous but much higher and the cement forms a plate lying between them Continuation of this process leads to the most highly specialized of all elephants, the mammoth, in which the number of ridges in the second molar may be as high as 16, and the whole tooth was extraordinarily deep.

The history of the evolution of the elephant set forth above is a mere outline. It is really greatly complicated by the existence of a large number of side branches, many of which migrated into North and some even into South America. Of these side branches much the most striking is that represented by *Deinotherium,* an animal with an elephant-like body, apparently with exceptionally long limbs and a trunk. This animal is remarkable because its molar teeth throughout the whole history of the genus have had only two transverse ridges and are very low crowned. The upper tusks are completely absent while the large lower tusks are directed downwards at right angles to the lower jaw. This animal is probably of African origin and is found only in that continent and in Europe and India. See ELEPHANT; MAMMOTH; MASTODON.

(D. M. S. W.; X.)

PROBOSCIS MONKEY, a large, long-tailed, red Bornean species (*Nasalis larvatus*) characterized by the prolongation of the nose of the adult male, which hangs down in front of the upper lip. In the females and young the nose is less developed. This monkey is a leaf eater, nearly allied to the langurs.

See PRIMATES.

PROBUS, MARCUS AURELIUS, Roman emperor A.D. 276–282, was a native of Sirmium, in Pannonia. At an early age he entered the army, where he distinguished himself under the emperors Valerian, Claudius and Aurelian. He was appointed governor of the east by the emperor Tacitus, at whose death he was proclaimed his successor by the soldiers. Florianus, who had claimed to succeed his brother, mas put to death by his own troops, and the senate ratified the choice of the army. The reign of Probus was mainly spent in successful wars, by which he re-established the security of all the frontiers, the most important of these operations being directed to clearing Gaul of the Germans. Probus had also put down three usurpers, Saturninus, Proculus and Bonosus. In time of peace he kept the soldiers at work, which made him unpopular, and while superintending draining operations at his native town he was killed by his own soldiers. Scarcely any emperor has left behind him so good a reputation; his death was mourned alike by senate and people, and even the soldiers repented and raised a monument in his honour.

PROBUS, MARCUS VALERIUS (fl. second half of the 1st century A.D.), Latin grammarian and literary critic, of Berytus (Beirut) in Syria. The title of his lost treatise De *inaequalitate* consuetudinis suggests that he was of the Anomalist school. His critical editions of Plautus, Terence, Lucretius, Horace and Persius and of Vergil's Aeneid are also lost; but there is extant a commentary on Vergil's Eclogues and Georgics under his name. The extant part of De *notis* (probably an excerpt from a larger work), which deals with abbreviations, is printed by H. Keil, Grammatici Latini, vol. iv (1864); but other works ascribed to Probus in that volume are not his.

See J. Steup, *De Probis grammaticis (1871)*; J. Aistermann, *De M. Valerio Probo Berytio* (1910). (R. H. Rs.)

PROCACCINI, a family of Italian painters of the Bolognese school. ERCOLE THE ELDER (1520?–1591?) was born in Bologna but moved to Milan, where he began a school of painting known as the Academy of the Procaccini, in which many fine painters were trained. He himself was a student of Annibale Carracci, a founder of the eclectic school of painting. His best works are in the churches of Bologna.

CAMILLO (1546–1629?), GIULIO CESARE (1548?–1626) and CARLO ANTONIO (1555–1605?), his three sons, studied with their father; Camillo also studied in Rome. The two elder sons painted principally religious subjects in the tradition of Correggio. Camillo was a more successful colourist than his father, and Giulio Cesare followed the style of Correggio most perfectly of the three. Their paintings are found in the churches of Milan, Bologna. Genoa and other Italian cities and hang in the galleries of most European capitals. They died in Milan. The youngest and least talented son painted still life and landscapes.

ERCOLE THE YOUNGER (1596–1676) was born and died in Milan. He studied with his uncle Giulio Cesare and was best known for his still-life pictures. On the death of Giulio Cesare, he became director of the academy.

PROCELLARIIDAE: see SHEARWATER; FULMAR.

PROCESSION, in general, an organized body of people advancing in formal or ceremonial manner. This definition covers a wide variety of such progresses: the medieval pageants, of which the lord mayor's show in London is the most conspicuous survival; the processions connected with court ceremonies; those organized to demonstrate political or other opinions; processions forming part of the ceremonies of public worship. In a narrower sense of "going forth, proceeding," the term is used in the technical language of theology in the phrase "Procession of the Holy Ghost," expressing the relation of the Third Person in the Triune Godhead to the Father and the Son.

Greek and Roman Processions.—Processions are included in the ritual of many religions, and in many countries they accompany such events as weddings and funerals.

Religious and triumphal processions are abundantly illustrated by ancient monuments.

Processions played a prominent part in the great festivals of Greece, where they were always religious in character. The games were either opened or accompanied by more or less elaborate processions and sacrifices, while processions from the earliest times formed part of the worship of the old nature gods and later formed an essential part of the celebration of the great religious festivals and of the mysteries.

Of the Roman processions the most prominent was that of the triumph, which had its origin in the return of the victorious army headed by the general, who proceeded in great pomp from the Campus Martius to the Capitol to offer sacrifice. accompanied by the army, captives, spoils, the magistrate and priests bearing the images of the gods, amidst strewing of flowers, burning of incense and the like. Connected with the triumph was the *pompa circensis,* or solemn procession, which preceded the games in the circus; it first came into use at the ludi *romani,* when the games were preceded by a great procession from the Capitol to the Circus. The praetor or consul who appeared in the *pompa circensis* wore the robes of a triumphant general. Thus, when it became customary for the consul to celebrate games at the opening of the consular year, he came, under the empire, to appear in triumphal robes in the processus *consularis,* or procession of the consul to the Capitol to sacrifice to Jupiter. After the establishment of Christianity, the consular processions in Constantinople retained their religious character, proceeding to Hagia Sophia, where prayers and offerings were made; but in Rome, where Christianity was not so widely spread among the upper classes, the tendency was to convert the procession into a purely civil function. Besides these public processions, there were others connected with the primitive worship of the country people, which remained unchanged, and were later to influence the worship of the Christian Church. Such were those of the Ambarvalia, *Robigalia,* etc., which were essentially rustic festivals, lustrations of the fields, consisting in a procession round the spot to be purified, leading the sacrificial victims with prayers, hymns and ceremonies, in order to protect the young crops from evil influences.

Processions in the Christian Church.—As to the antiquity of processions as part of the ritual of the Christian Church, there is no absolute proof of their existence before the 4th century, but as we know that in the catacombs stations were held at the tombs of the martyrs on the anniversary of their death, for the celebration of the eucharist, it is quite probable that the faithful proceeded to the appointed spot in some kind of procession. There are, indeed. early instances of the use of the word processio by Christian writers, but it does not in any case appear to have the modern meaning "procession." Tertullian (2nd century) uses processio and procedere in the sense of "to go out. appear in public." and, as applied to a church function, processio was first used in the same way as *collecta,* as the equivalent of the Greek *συνάξις, i.e.,* for the assembly of the people in the church.

For the processions that formed part of the ritual of the eucharist. those of the introit, the gospel and the oblation, the earliest records date from the 6th century and even later (see Duchesne, *Origines,* and ed.. pp. 77, 154, 181; 78. 194), but they evidently were established at a much earlier date. As to public processions, these seem to have come into rapid vogue after the recognition of Christianity as the religion of the empire. Those at Jerusalem would seem to have been long established when described by the authoress of the *Peregrinatio Silviae* towards the end of the 4th century (see PALM SUNDAY, for the procession of palms).

Litanies or Rogations. — Very early were the processions accompanied by hymns and prayers, known as litaniae (Gr. λιτανεῖα from λιτή, prayer), rogationes or *supplicationes* (see **LITANY**). It is to such a procession that reference appears to be made in a letter of St. Basil (c. 375), which would thus be the first recorded mention of a public Christian procession. The first mention for the Western Church occurs in St. Ambrose (c. 388, Ep. 40 § 16, Ad Theodos.: "monachos . . . qui . . . psalmos canentes ex consuetudine usuque veteri pergebant ad celebritatem Machabaeorum martyrum"). In both these cases the litanies are stated to have been long in use. There is also mention of a procession accompanied by hymns, organized at Constantinople by St. John Chrysostom (c. 390–400) in opposition to a procession of Arians, in Sozomen, *Hist.* eccl. viii. 8. In times of calamity litanies were held, in which the people walked in robes of penitence, fasting, barefooted, and, in later times, frequently dressed in black (*litaniae nigrae*). The cross was carried at the head of the procession and often the gospel and the relics of the saint were carried. Gregory of Tours gives numerous instances of such litanies in time of calamity; thus he describes (Vita S. Remig. I.) a procession of the clergy and people round the city, in which relics of St. Remigius were carried and litanies chanted in order to avert the plague. So, too, Gregory the Great (*Ep.* xi. 57) writes to the Sicilian bishops to hold processions in order to prevent a threatened invasion of Sicily. A famous instance of these penitential litanies is the *litania septiformis* ordered by Gregory the Great in the year 590, when Rome had been inundated and pestilence had followed. In this litany seven processions, of clergy, laymen, monks, nuns, matrons, the poor and children respectively, started from seven different churches, proceeded to hear mass at Sta. Maria Maggiore (see Greg. of Tours, *Hist.* Fr. x. 1, and Johann. Diac. *Vita* Greg. Magn. i. 42). This litany has often been confused with the *litania* major, introduced at Rome in 598 (vide supra), but is quite distinct from it.

Funeral processions, accompanied with singing and the carrying of lighted tapers, were from very early times customary and in some ways similar to these; also very early, were the processions connected with the translation of the relics of martyrs from their original burying place to the church where they were to be enshrined (see, *e.g.*, St. Ambrose, *Ep.* 29 and St. Augustine, De *civitate* Dei, xxii. 8 and *Conf.* viii. 7, for the finding and translation of the relics of Saints Gervasius and Protasius). From the time of the emperor Constantine I. these processions were of great magnificence.

Origin of Christian Processions. — Some liturgists maintain that the early Church in its processions followed Old Testament precedents, quoting such cases as the procession of the ark round the walls of Jericho (Josh. vi.), the procession of David with the ark (2 Sam. vi.), the processions of thanksgiving on the return from captivity, etc. The liturgy of the early Church as Duchesne shows (*Origines,* ch. i.) was influenced by that of the Jewish synagogue, but the theory that the Church adopted the Old Testament ritual is of quite late growth. What is certain is that certain festivals involving processions were adopted by the Christian Church from the pagan calendar of Rome. Here we need only mention the litaniae majores et minores, which are stated by Usener ("Alte Bittgange," in Zeller, Philosophische Aufsatze, p. 278 seq.) to have been first instituted by Pope Liberius (352–366). It is generally acknowledged that they are the equivalent of the Christian Church of the Roman lustrations of the crops in spring, the *Ambarvalia,* etc. The litania major, or great procession on St. Mark's day (April 25) is shown to coincide both in date and ritual with the Roman *Robigalia,* which took place *a.d. vii.* Kal. *Mai.,* and consisted in a procession leaving Rome by the Flaminian gate, and proceeding by way of the Milvian bridge to a sanctuary at the 5th milestone of the Via Claudia, where the *flamen quirinalis* sacrificed a dog and a sheep to avert blight (robigo) from the crops (*Fasti praenestini,* C.T.L.T., p. 317). The litania major followed the same route as far as the Milvian bridge, when it turned off and returned to St. Peter's, where mass was celebrated. This was already established as an annual festival by 598, as is shown by a document of Gregory the Great (*Regist.* ii.) which inculcates the duty of celebrating *litaniam,* quae major ab omnibus *appellatur.* The *litaniae* minores or rogations, held on the three days preceding Ascension Day, were first introduced into Gaul by Bishop Mamertus of Vienne (c. 470), and made binding for all Gaul by the 1st Council of Orleans (511). The litaniae minores were also adopted for these three days in Rome by Leo III. (c. 800). A description of the institution and character of the Ascensiontide rogations is given by Sidonius Apollinaris (*Ep.* v. 14). "The solemnity of these," he says, "was first established by Mamertus. Hitherto they had been erratic, lukewarm and poorly attended (vague, tepentes, infrequentesque); those which he instituted were characterized by fasting, prayers, psalms and tears." In the Ambrosian rite the rogations take place after Ascensiontide, and in the Spanish on the Thursday to Saturday after Whitsuntide, and in November (Synod of Girona, 517).

Processions in the Modern Roman Catholic **Church.—It** is impossible to describe in detail the vast development of processions during the middle ages. The most important and characteristic of these still have a place in the ritual of the Roman Catholic Church. The rules governing them are laid down in the Rituale *Romanum* (Tit. ix.), and they are classified in the following way:—

(1) Processiones generales, in which the whole body of the clergy takes part. (2) Processiones ordinariae, on yearly festivals, such as the feast of the Purification of the Virgin (Candlemas, *q.v.*), the procession on Palm Sunday (*q.v.*), the *Litaniae* majores and minores, the feast of Corpus Christi (*q.v.*), and on other days, according to the custom of the churches. (3) Processiones *extraordinariae,* or processions ordered on special occasions, *e.g.,* to pray for rain or fine weather, in time of storm, famine, plague, war, or, in quacunque tribulatione, processions of thanksgiving, translation of relics, the dedication of a church or cemetery. There are also processions of honour, for instance to meet a royal personage, or the bishop on his first entry into his diocese (*Pontif.* rom. iii.).

Reformed Churches. — The Reformation abolished in all Protestant countries those processions associated with the doctrine of transubstantiation (Corpus Christi); "the Sacrament of the Lord's Supper," according to the 28th Article of Religion of the Church of England, "was not by Christ's ordinance reserved, carried about, lifted up, or worshipped." It also abolished those associated with the cult of the Blessed Virgin and the saints. The stern simplicity of Calvinism, indeed, would not tolerate religious processions of any kind, and from the "Reformed" Churches they vanished altogether. The more conservative temper of the Anglican and Lutheran communions, however, suffered the retention of such processions as did not conflict with the reformed doctrines, though even in these churches they met with opposition and tended after a while to fall into disuse.

Lutheran Church. — The Lutheran practice has varied at different times and in different countries. Thus, according to the Wiirttemberg *Kirchenordnung* of 1553, a funeral procession was prescribed, the bier being followed by the congregation singing hymns; the Brandenburg Kirchenordnung (1540) directed a cross-bearer to precede the procession and lighted candles to be carried, and this was prescribed also by the Waldeck *Kirchenordnung* of 1556. At present funeral processions survive in general only in the country districts; the processional cross or crucifix is still carried. In some provinces also the Lutheran Church has retained the ancient rogation processions in the week before Whitsuntide and, in some cases, in the month of May or on special occasions (*e.g.,* days of humiliation, *Busstage*), processions about the fields to ask a blessing on the crops. On these occasions the ancient litanies are still used.

Church of England. — In England "the perambulations of the circuits of the parishes . . . used heretofore in the days of rogations" were ordered to be observed by the Injunctions of Queen Elizabeth in 1559; and for these processions certain "psalms, prayers and homilies" were prescribed. The Puritans, who aimed at setting up the Genevan model, objected; and the visitation articles of the bishops in Charles I's time make frequent inquisition into the neglect of the clergy to obey the law in this matter. With the multitude, however, these processions appear to have been very popular. The Commonnealth formally put an end to them, and they only survived in some remote country parishes.

Among the processions that survived the Reformation in the English Church was that of the sovereign and the Knights of the Garter on St. George's day. This was until Charles II's time a regular rogation: the choristers in surplices; the gentlemen of the royal chapel in copes; and the canons and other clergy in copes preceding the knights and singing the litany. In 1661, after the Restoration, "that supplicational procession" was "converted into a hymn of thanksgiving." Akin to this procession also are the others connected with royal functions, which retain many pre-Reformation features.

The only procession formally prescribed in the Book of Common Prayer is that in the order of the burial of the dead. Tapers seem to have been carried in processions, not only at royal funerals, until well into the 18th century. Processions, with the singing of the litany or of hymns, appear also to have been always usual on such occasions as the consecration of churches and churchyards and the solemn reception of a visiting bishop. Examples of processions in use in the English Church are the processional litanies, and the solemn entry and exit of clergy and choir. The use of the processional cross, banners and lights has been largely revived.

PROCESSIONARY CATERPILLAR: *see* ARMY WORM.

PROCÈS-VERBAL, in French law, a detailed authenticated account drawn up by a magistrate, police officer or other person having authority of acts or proceedings done in the exercise of his duty. In a criminal charge, a procès-verbal is a statement of the facts of the case. The term is also applied to the written minutes of a meeting or assembly.

PROCIDA, an island off the coast of Campania, Italy. on the west side of the Gulf of Naples, 12 mi. S.W. of Naples. Pop. (1951) 10,156. It is about 2 mi. in length, and, reckoning in the adjacent island of Vivara, is made up of four extinct craters. It is very fertile. Procida, the only town, lies on the east side; its castle is a prison. It also contains a royal palace.

PROCLAMATION, a historic form of executive action in England and the United States. In England, while the powers of parliament were evolving, the king in council still asserted and exercised a power to legislate, in the 14th century by ordinance and in the 16th and 17th centuries by proclamation. In 1539 the Statute of Proclamations (31 Henry VIII, c. 8) made a general authorization of legislation by proclamation which should "not be prejudicial to any person's inheritance, offices, liberties, goods, chattels or life" and of its enforcement by forfeitures and imprisonment. This statute was repealed, however, in 1547 by 1 Edward VI, c. 12, s. 5. In 1610 the opinion in the *Case of Proclamations* (12 Coke's Reports 74) declared that the king by his proclamation could not create an offense which was not one before; and this became unquestioned after adoption of the English Bill of Rights (1689). Royal proclamations are still employed in the second half of the 20th century, however, to give uide publicity to actions taken by the king in council. such as dissolving one parliament and summoning the next.

In the U.S. proclamations are issued by governors of states and mayors of cities; but of especial importance are those issued by the president, proclamations and executive orders being, aside from messages to congress, the chief kinds of formal presidential action. In U.S. presidential proclamations the body of the proclamation ("Now, therefore, I . . . ,") is preceded by a preamble ("Whereas . . .") and followed by the formula of attestation, the presidential signature. the seal of the U.S. and the countersignature of the secretary of state. The date is stated, by a tradition going back to President Washington, in terms of the independence of the U.S. as well as the Gregorian calendar.

Some proclamations of the president are merely informative or hortatory, while others are exercises of quasi-legislative authority delegated by statute or inferred from powers vested in the president by the constitution. Two of the most famous are Washington's proclamation of neutrality of April 22, 1793, and Pres. Abraham Lincoln's proclamation of emancipation of Jan. 1, 1863. Careful provision is made by law and executive order for the preparation, clearance and numbering of presidential proclamations and for their publication in the Federal Register. Proclamation of treaties is separately handled. (J. HT.)

PROCLUS (PROCULUS) (A.D. 410–485), the most important representative of the later Neoplatonism inaugurated by Iamblichus (*q.v.*), was born at Constantinople of Lycian parents and brought up at Xanthus in Lycia. He studied philosophy under Olympiodorus the elder at Alexandria and then under Plutarch and Syrianus, the Platonic *diadochi* ("successors"), at Athens. He eventually became himself *diadochus* (i e., successor of Plato in the headship of the Platonic Academy at Athens) and held that position until his death in 485. An enthusiastic biography of him by his successor Marinus is preserved.

Proclus is the most notable figure of the Athenian school of Neoplatonism, which was distinguished by its passionate paganism and by its taste for elaborate metaphysical speculation. He was probably not a very original thinker (we have too little detailed information about the works of his predecessors to be quite sure about the extent of his own contribution). But he was a great systematizer. expositor and commentator. The type of Neoplatonism which began with Iamblichus reaches its fullest development in the thought of Proclus, and it is through his works that we know it best. His chief importance in the history of philosophy is as one of the principal sources from which Neoplatonic ideas were diffused through the Byzantine and Islamic worlds and the medieval Latin west. He greatly influenced the Pseudo-Dionysius (Dionysius the Areopagite; *q.v.*), whose influence on the Christian thought of both east and west was immense.

Of the Arabic works nhich transmitted his ideas the most important was the so-called *Liber de causis*, which passed in medieval times as a work of Aristotle. though it is in fact based upon Proclus' *Elements of Theology* (as St. Thomas Aquinas, who knew both works in Latin translations. recognized). The *Liber de causis* and Proclus' own *Elements of Physics* were translated into Latin in the 12th century. Other Latin translations of important works of Proclus, including the *Elements of Theology*, mere made in the next century by William of Moerbeke. the translator of Aristotle and friend of St. Thomas Aquinas. These translations, appearing at a time when very little of Plato and nothing of Plotinus was known in the Latin west, became for the later middle ages the principal source of their knowledge of Platonism.

The philosophical works of Proclus can be classified as follows: (1) his commentaries on Plato, of which those on the *Republic*, on the *Parmenides*, on the *Timaeus* and on *Alcibiades* I are extant nith excerpts from that on the *Cratylus;* (2) his major exegetical work on Plato, the *Platonic Theology;* (3) two systematic manuals, the *Elements of Physics* and the *Elements of Theology*, the former being based on Aristotle's physical works, the latter, which is considerably more important, being a concise exposition of Neoplatonic metaphysics in 211 propositions; and (4) three occasional essays, the *De decem dubitationibus circa providentiam*, the *De providentia et fato* and the *De malorum subsistentia*, which survive only in the Latin translation of William of Moerbeke. Of his nonphilosophical writings there survive some astronomical and mathematical works, including the *Hypotyposis* on astronomical positions and a commentary on the first book of Euclid's *Elements;* some grammatical works (the identity of the author of the *Chrestomathia grammatica* with Proclus the philosopher is disputed); seven hymns and two epigrams, one of which *(Greek Anthology*, vii, 341) is an inscription for the common tomb of himself and his master Syrianus; and some fragments on religious-magical themes. *See* also NEOPLATONISM.

BIBLIOGRAPHY.—The best introduction to the thought of Proclus is to be found in *The Elements of Theology*, ed. with Eng. trans. by E. R. Dodds (1933). For the *Platonic Theology* recourse must still be had to the edition of Aemilius Portus (1618). The Teubner series includes the commentaries on the *Republic*, ed. by G. Kroll, 2 vol (1899–1900), on the *Timaeus*, ed. by E. Diehl, 3 vol. (1903–06), on the *Cratylus*, ed. by G. Pasquali (1908), and on Euclid, ed. by G. Friedlein (1873);

the *Elements of Physics,* ed. with Ger. trans. by A. Ritzenfeld (1912); the *Hypotyposis,* ed. with Ger. trans. by C. Manitius (1909); and the *Hymns,* ed. by A Ludwich with the poems of the empress Eudocia (1897). The part of the commentary on the *Parmenides* that survives in Greek, the commentary on *Alcibiades I* and the three essays *De decem dubitatioizibus, De providentia et fato* and *De malorum subsistentia* are printed in V. Cousin, *Procli opera inedita* (1864); for the important final section of the commentary on the *Parmenides,* extant only in the medieval Latin trans., *see* R. Klibansky and C. Labowsky (eds.), *Plato latinus,* vol. iii (1953). The commentary on the *Parmenides* is also ed. by G. Stallbaum (1840) and that on *Alcibiades* I by L. Westerink (1954).

Thomas Taylor's English translation of the works of Proclus comprises *Philosophical and Mathematical Commentaries of Proclus,* 2 vol. (1788–89; reissue 1792), including the commentary on Euclid and the *Life of Proclus* by Marinus together with the *Elements of Theology; The Six Books of Proclus . . . on the Theology of Pluto,* 2 vol. (1816), with the three philosophical essays; the commentary on the *Timaeus* (1820); *The Fragments* (1825); and a separate edition of the *Two Treatises . . . of the Ten Doubts Concerning Providence and . . . of the Nature of Evil* (1833).

The text of the *Life* by Marinus, ed. by J. Boissonade, is appended to C. G. Cobet's edition of Diogenes Laertius (1850). For a detailed account of Proclus' thought, with a survey of the literature and an English version of Marinus, *see* L. J. Rosán, *The Philosophy of Proclus* (1949). *See* also T. Whittaker, *The Neo-Platonists,* 2nd ed. (1918). (A. H. AG.)

PROCONSUL AFRICANUS. A few fragmentary remains of jams found in Miocene epoch deposits in Kenya in 1931 gave evidence of a new type of fossil ape which was given the generic name *Proconsul.* The British-Kenya expedition of 1947 discovered more remains of this creature. including many jaws and teeth, a few limb bones, and the greater part of a skull—the first example known of a fossil ape's skull of such antiquity. The expedition's collections also showed that east Africa during the Miocene was inhabited by a remarkable variety of anthropoid apes, including three species of *Proconsul* ranging in size from that of a small chimpanzee to a gorilla. A study of the limb bones led to the interesting conclusion that these fossil apes were far more generalized in limb structure and proportions than modern apes. While evidently beginning to assume the arboreal habits of the modern apes, they still possessed features found only in the more primitive monkeys of today. *Proconsul* thus provides concrete evidence of a stage in the evolutionary transition from tailed monkeys to true anthropoid apes—a transition long postulated on the indirect evidence of comparative anatomy. *Proconsul's* nonspecialized morphology provides some reason for supposing that it may have been closely allied with the extinct group from which both man and the modern anthropoid apes were derived.

See W. E. Le Gros Clark and L. S. B. Leakey, *The Miocene Hominoidea of East Africa,* "Fossil Mammals of Africa Series" no. 1 (1951); J. R. Napier and P. R. Davis, *The Fore-limb Skeleton and Associated Remains of Proconsul africanus,* "Fossil Mammals of Africa Series" no. 16, British Museum of Natural History (1959). (W. E. L. G. C.)

PROCOPIUS, Byzantine historian, mas born at Caesarea in Palestine toward the end of the 5th century A.D. He became a lawyer, probably at Constantinople, and was in 527 appointed private secretary to Belisarius, whom he accompanied on his Persian, African and Italian campaigns. After the capture of Ravenna in 540 Procopius seems to have returned to Constantinople, since he minutely describes the great plague of 542 (*op. cit.* ii, 22). It does not appear whether he was with the Roman armies in the later stages of the Gothic War, when Belisarius and afterward Narses foughtagainst Totila in Italy; his narrative of these years is much less full and minute than that of the earlier warfare. Of his subsequent fortunes nothing is known, except that he was living in 559. Whether he was the Procopius who was prefect of Constantinople in 562 (Theophanes, *Chronographia,* 201,202) and was removed from office in the year following cannot be determined, though it is not improbable.

Procopius' writings fall into three divisions: the *Histories* (Persian, Vandal and Gothic wars), in eight books; the treatise on the *Buildings of Justinian (De aedificiis),* in six books; and the *Unpublished Memoirs (Historia arcana),* so called because they were not published during the lifetime of the author.

The *Histories* are called by the author himself the *Books About the Wars.* They consist of: (1) the Persian Wars, in two books, giving a narrative of the long struggle of the emperors Justin and Justinian against the Persian kings Kavadh and Chosroes Anushirvan down to 550; (2) the Vandal War, in two books, describing the conquest of the Vandal kingdom in Africa and the subsequent events there from 532 down to 546 (with a few words on later occurrences); (3) the Gothic War, in three books, narrating the war against the Ostrogoths in Sicily and Italy from 536 till 552. The eighth book contains a further summary of events down to 554. These books contain notices of some of the important domestic events: the Nika insurrection at Constantinople in 532 and the plague in 542. Honever, they tell little about the civil administration of the empire and nothing about legislation.

The *De aedificiis* contains an account of the chief public works executed during the reign of Justinian down to 560 which are of course ascribed to the personal action of the monarch. If not written at the command of Justinian (as some have supposed), it is evidently grounded on official information and is full of gross flattery of the emperor and of the (then deceased) empress. In point of style it is greatly inferior to the *Histories*—florid, pompous and affected. and at the same time tedious. Its chief value lies in the geographical notices which it contains.

The *Anecdota* (date probably 550) purports to be a supplement to the *Histories,* containing explanations and additions which the author could not insert in the latter work for fear of Justinian and Theodora. It is a furious invective against these sovereigns. with attacks on Belisarius and his wife Antonina and on other noted officials. Owing to the ferocity and brutality of the attacks upon Justinian, the authenticity of the *Anecdota* has often been called in question, but the claims of Procopius to the authorship are generally recognized. In point of style, the *Anecdota* is inferior to the *Histories* and has the air of being unfinished or at least unrevised. The history of Philip of Macedon by Theopompus probably furnished the author with a model.

The best complete edition of Procopius is by J. Haury (Teubner Series, 1905–13). There are English translations of the *History of the Wars,* by H. Holcroft (1653), of the *Anecdota* (1674, anonymous), of the *Buildings,* by Aubrey Stewart (Palestine Pilgrims' Text Society, 1888) and by H. B. Dewing (Loeb Classical Library, 1914, etc.).

See as chief authorities: F. Dahn, *Procopius von Cäsarea* (1865); J. Haury, *Procopiana* (1891–93). On the genuineness of the *Anecdota, see* J. B Bury, *A History of the Later Roman Empire* (1889), vol. i and introd. to vol. ii (p. 57) and appendix to vol. iv of his edition of E. Gibbon, *Decline and Fall* (1925).

PROCRUSTES, also called POLYPEMON or DAMASTES, in Greek legend, a robber dwelling in the neighbourhood of Eleusis, who was slain by Theseus (*q.v.*). He had an iron bed (or according to some accounts, two beds) on which he compelled his victims to lie, stretching or cutting off their legs to make them fit the bed's length. The "bed of Procrustes" has become proverbial for inflexibility.

PRQCTER, WILLIAM COOPER (1862–1934), U.S. manufacturer, was born in Glendale, O., Aug. 25, 1862. His grandfather's candle-manufacturing firm had been merged with James Gamble's soapmaking firm to form Procter & Gamble Co.. and after being graduated from Princeton university in 1883 Procter immediately entered the firm. In 1890 he became general manager and in 1907 succeeded his father as president. Procter was active in civic and philanthropic endeavours and entered national politics in 1920 uhen he managed the unsuccessful campaign of Gen. Leonard Wood for the Republican presidential nomination. Procter died on May 2, 1934. (H. J. SG.)

PROCTOR, ALEXANDER PHIMISTER (1862–1950), U.S. sculptor and painter best known for his representations of animals, was born in Ontario, Canada, on Sept. 27, 1862. As a youth he lived at Denver. Colo., spending much of his time in the Rocky mountains; and his familiarity with the ways and habits of wild animals was supplemented later by study in the Jardin des Plantes, Paris. He was a pupil at the National Academy of Design and later in the Art Students' league, in New York and first attracted attention by his statues of wild animals at the Columbian exposition, Chicago. In 1896 he won the Rinehart scholarship, which enabled him to spend five years in Paris, where he studied under Denys Puech and J. A. Injalbert. Among his works of sculpture are: "Quadriga." for the U.S. pavilion, Paris exhibition (1900); the Princeton Tigers, for Princeton university; the equestrian statue of Col. Theodore Roosevelt as rough rider, Portland, Ore.. and groups in the City park, Denver, Colo., and Zoological park, New York city. He died on Sept. 4, 1950. at Palo Alto. Calif.

PROCTOR, a variant of the word procurator, nearly equivalent in meaning to agent; it is now obsolete in English except for certain technical meanings. In law, it was formerly applied to a practitioner in ecclesiastical and admiralty courts, licensed by the archbishop of Canterbury to perform such duties as were performed by solicitors in ordinary courts. With the passing of the Judicature act, 1873, proctor in this sense became obsolete, the term solicitor being extended to include proctors. (See LEGAL PROFESSION: England and Wales.) However, the word is still sometimes used both in Great Britain and in the United States to denote any practitioner in probate and admiralty courts; another trace of it remains in the office of queen's proctor, who represents the crown in British divorce courts and has a duty to expose collusion. In the Church of England a proctor is a representative of the clergy in convocation; at certain universities—notably Oxford and Cambridge—a proctor is an important university official charged primarily with the enforcement of discipline among undergraduates.

PROCUREMENT, MILITARY. This term denotes the acquisition by a military establishment of goods and services, other than military personnel, whether by purchase, rent, lease. manufacture or requisition. It includes determination of requirements, drafting of specifications, selection of sources of supply, determination of contractual terms, expediting, inspection and the payment and audit of accounts.

The importance of military procurement arises from its effects on the nation's economy. Poor procurement practices may promote social tensions and economic instability, and low civilian standards of living. As the art of warfare has become more complicated in the 20th century, procurement has taken on increased importance. In the United States at the peak of World War II, military requirements absorbed about 44% of the gross national product; in Great Britain and Germany about 50%; in Japan 41%. Even in the peacetime years of the late 1950s military requirements absorbed about 12% of the gross national product in the United States and 10% in Britain, and about 15% in the Soviet Union.

Making accurate estimates of requirements in the light of a nation's strategic plans is of major importance to effective procurement. This process involves two steps: (1) determination of the requirements for various end products; (2) the conversion of requirements for end products into requirements for labour, material and productive facilities, and their comparison with available resources in order to determine whether or not strategic plans are feasible. In determining its requirements a country inevitably takes calculated risks and chooses between alternative strategic plans in the light of their costs. Since the impact of procurement on the economy depends upon its timing as well as its magnitude, it is important that requirements be properly phased. Unnecessary strain may be placed on the economy if, for example, contracts for the delivery of ammunition in six months are placed while the weapons that are to use the ammunition will not be ready for two years.

Once the requirements are set up, the objectives of procurement policy are several: (1) fulfillment of requirements in the volume and quantities and at the time and place needed; (2) efficient utilization of resources so that requirements may be fulfilled with minimum impact upon civilian standards of living; (3) budgetary economy; (4) economic stabilization; and (5) sociopolitical objectives, such as elimination of excessive profits, fostering of small business and elimination of discrimination in employment practices.

Most governments have reserved the power to requisition goods and services in times of emergency, but in recent times this power has been used cautiously. Countries vary in the extent to which the government itself undertakes the manufacture of military equipment. In the United States, Great Britain and Germany the military establishments have relied heavily upon purchases from private enterprise.

Two principal purchasing techniques are used in military procurement: the system of public advertising for sealed bids; and the negotiated contract. Under the sealed-bid system the contract is normally awarded, after public opening of the bids, to the lowest responsible bidder who meets the advertised specifications. Consequently, once specifications are determined, the purchase function becomes routine and opportunities for favouritism in selecting suppliers are minimized. Moreover, where there is genuine competition the system protects the financial interest of the government.

Often the sealed-bid system is not a useful device and is replaced by the negotiated contract. Since the procurement officer will frequently negotiate with several sources of supply, negotiation does not preclude competition. Frequently it is desirable to award an unpriced "letter of intent" before specifications can be put in final form and bids sought so that the supplier may have a head start in tooling up, placing orders for materials and recruiting a labour force. In other cases national security makes it inadvisable to publicize specifications. In some industries strategic planning requires the maintenance in readiness of several geographically dispersed sources of supply. Often it is desirable to place contracts in the light of the availability of manpower or other scarce resources rather than on the basis of price alone. In the case of research and development contracts, where confidence in a particular supplier is paramount. selection of a supplier on the basis of a low bid is not practicable. Likewise, where suppliers are few or where costs are uncertain because of rapid change in design or in the rate of output, the sealed-bid system may not be the most efficient way to develop a competitive price. Finally, in situations where military needs can be fulfilled by several products of similar but slightly different specifications, the interest of the government may lie in negotiating on specifications as well as price.

When an economy operates under a general system of price control, the question arises whether such controls should apply to military contracts. In Britain and the United States during World War II, responsibility for the prices of specialized military equipment mas generally placed on the procurement agencies while prices on contracts for standard commercial items were subject to the general controls. This practice facilitates the diversion of economic resources to military needs by leaving the military establishment free to attract suppliers by price incentives and relieves price control authorities from possible charges of interfering with the military program.

The system of negotiation permits the tailoring of contract terms to the circumstances of the particular procurement. There are several basic types of contracts in common use. The type selected in a particular case will depend in part on the relative emphasis on providing incentives to efficient production in contrast to controlling profits. The simplest type of contract is the fixed price contract. It is the easiest to administer and provides the supplier maximum incentives to control costs. The central problem in the use of this type of contract is arriving at a reasonable price; where there is previous experience in producing similar items under similar conditions or where there are alternative suppliers, it may not be difficult. However, in the absence of good cost estimates. unexpectedly large profits may develop, not because of the effectiveness of the supplier in controlling costs but because of ignorance in estimating costs when the contract is negotiated.

Cost plus contracts are nidely used where there are difficulties in estimating costs. Under such contracts the supplier receives a fee for his services as well as reimbursement for his allowable costs. The earlier practice of calculating the fee as a percentage of actual costs left the supplier with a positive incentive to increase his costs. The cost plus-fixed fee contract (CPFF), in which the absolute amount of the fee is predetermined, eliminates the incentives to cost inflation and minimizes the possibilities of excessive profits but provides no financial incentives to cost control. The administrative disadvantages of cost contracts are great, since they require careful audit of the supplier's accounts to verify his costs and frequent inspection of his operations to insure efficient use of resources.

There are many variations of these two basic types of contracts. Incentive features may be added to cost contracts by providing that the fee shall not be fixed but shall depend upon the extent to which the contractor exceeds or falls short of some target cost. Nonprofit organizations often operate under cost contracts without any fee. Fixed price contracts have been modified in many cases to provide for redetermination of price at some time during the life of the contract on the basis of actual cost experience. A fixed price contract may include an escalator clause providing for change in price in the event of some increase in labour or material costs. Such a clause, by relieving the contractor of risks over which he may have no control, makes it possible to eliminate from the contract price an allowance for contingencies.

In the United States, in particular, there has been considerable concern over the tendency to place military contracts with the larger suppliers, popularly known as "big business." This concern arises in part because of the fear that military procurement will accentuate monopolistic tendencies and in part because of the need during periods of mobilization to use all productive facilities. Consequently, various devices have been adopted for encouraging the dispersing of contracts among small businesses.

Control of profits often plays a large part in military procurement policy. Because of difficulties in negotiating close prices on many contracts, profits often turn out to be larger than anticipated. Various noncontractual devices have been tried for recouping excessive profits. Many countries at one time or another have enacted excess profits taxes, which usually take normal peacetime rates of profit as a basis for estimating allowable profits during periods of mobilization. Since 1942 the United States has experimented with a system of contract renegotiation designed to recapture excessive profits at the end of the year after review of the supplier's over-all profit-and-loss position on his government business. In determining whether or not a contractor has excessive profits the renegotiation authorities are required by statute to consider various factors, including the contractor's promptness in delivery; the quality of his product; his risk; and his efficiency. The renegotiation procedure establishes a pattern of allowable profits which serves as a guide to suppliers and procurement officers in their negotiations. It also serves to eliminate excessive profits arising from errors in judgment, deficiencies in contract negotiation or from the efforts of a willful minority to take advantage of the government. While the elimination of excessive profits serves important social purposes, some students believe that the renegotiation process as practised is to some extent in conflict with the objectives of controlling costs and prices. Moderate profits do not insure low prices and low costs.

Another important problem facing procurement officials is the control of prices on subcontracts. This may be achieved in part by direct price controls on many standard items, by renegotiation and by excess profits taxes. Other attempts to control subcontract prices directly have generally met with limited success.

There has been much public discussion in the United States of the relative merits of centralization of the procurement function in a single agency as against decentralization into various divisions of the armed services. During World War II, each of the armed services was responsible for most of its own procurement, and within each of the services procurement was further decentralized to the technical bureaus or services. Although the army, navy and air force have since been absorbed into the department of defense and the formulation of procurement policy and the purchase of some items common to the various services have been centralized, the responsibility for the procurement of most specialized military equipment is still decentralized to the component services.

PROCYON, the brightest star in the constellation Canis Minor (*see* CANIS MAJOR), hence its Bayer equivalent, α Canis Minoris. It and Sirius (*q.v.*) in Canis Major were called the two dog stars, though Dog Star refers to Sirius, which is the brighter of the two. Procyon is a double star consisting of one bright and one very faint component. It is located at a distance of about 11 light-years from the sun and is therefore one of the nearest stars.

PRODICUS OF CEOS (c. 465–after 399 B.C.), Greek sophist, came to Athens from Ceos and became known as a lecturer, writer and teacher. He appears as a character in Plato's *Protagoras*. His *Horae* contained the famous story of the Choice of Hercules summarized in Xenophon, *Memorabilia*, ii, 1, 21 *seq.* He held that the gods were natural objects and forces, together with deified benefactors of mankind. He was also interested in morals and physical science. A lecture or course of lectures *On the Right Use of Words* distinguished between apparent synonyms and influenced Socrates, Plato and others. For fragments and testimonia *see* H. Diels and W. Kranz, *Fragmente der Vorsokratiker*, vol. ii, 7th ed. (1954).

(G. B. KD.)

PRODIGY, an extraordinary, astonishing person, event or deed. The word has been particularly applied to children—*wunderkinder*—who show early signs of genius or exceptional ability along certain lines. Among these are the arithmetical prodigies; the chess prodigies; and the lightning calculators, who have a remarkable memory for figures and vivid visual or auditory imagery, but often do not excel in other ways. Best known are the musical prodigies—Mozart, Schubert and Mendelssohn, all of whom began to compose before the age of 12; Johann Hummel, Chopin and Yehudi Menuhin, who gave public concerts by 11 years of age; and Ruth Slenczynska, who astounded audiences at 6; Brahms, Dvořák and Richard Strauss, whose exceptional musical talents attracted attention from their earliest years.

Far less common is precocious ability in acting, writing, drawing and painting, such as that of the famous 19th century child actor William Betty, popularly known as "the young Roscius"; Minou Drouet, who in 1956 at the age of 8 won fame for poems and letters of doubtful authenticity; and Albrecht Diirer, who painted a self-portrait at 13.

In a somewhat different category are children whose intellectual development has been greatly accelerated, *e.g.*, Pascal who at 11 secretly constructed a geometry of his own; Norbert Wiener and Fred Safier, Jr., who read science and literature at five years and entered college by the age of 12.

How do children become prodigies? They are both born and made—born with retentive memories and a quality of mind that enables them to relate and organize experiences; made in the sense that they receive opportunities and rewards and special practice, instruction or training. The three prodigies last mentioned had radically different home environments. When Pascal was 11, his father deprived him of mathematical books. In marked contrast, Norbert Wiener was subjected to his father's insistent, severe and often painful demands for precise and ready knowledge. Fred Safier's parents, on the other hand, never pushed the boy but encouraged him to cultivate varied interests.

Do prodigies fulfill the promise of youth? Very few of the mental prodigies reported in history have met early expectations. However, musical prodigies seldom fade into oblivion. Original, creative geniuses who achieve the highest eminence could probably have been identified as extraordinary in early childhood.

(RU. S.)

PRODUCTION, CENSUS OF. Strictly speaking, "census of production" should refer to a count of the total production of a country. The term has been used traditionally in certain countries, notably the United Kingdom, to denote periodic censuses of the output and characteristics of industrial establishments. In the United States, the term used is "census of manufactures," indicating that the field concerned is only part of total production, the remainder being mainly covered by the census of agriculture and the census of distribution. Other countries use the term "census of industry" or "industrial production." Such censuses became increasingly important after the middle of the 19th century in connection with the planning and conduct of public and private policies as a consequence of rapid industrialization. The censuses originally had a twofold purpose: to aid the government in its assessment of the internal economy of the country and the formulation and negotiation of commercial treaties with other countries, and to inform the general public of the results of the governments' economic policies. By 1900 only a comparatively few countries had obtained statistics on industrial production, but the number grew rapidly during the early decades of the 20th century. During the first decade after World War II, more than 60 countries conducted censuses which accounted for about 75% of total world industrial production.

Production censuses generally contain detailed statistics on the quantity and value of goods produced. on employment and wages and on the use of materials and power equipment together with statistics on the number of establishments. their location, size and other characteristics. In the earliest censuses, interest tended to centre simply upon the quantity and value of output, but as industrialization increased, more and more countries investigated the structure of industry — the type, size, location, ownership and similar characteristics. All this information is required under modern conditions although the census inquiry itself need not contain all these questions if some of the information is available from other sources such as registers of establishments or social security records.

In addition to the detailed information on products, this census provides aggregates of considerable importance. The total value of industrial production is the aggregate value of all the products produced by industrial establishments. When deductions are made to take account of the materials and products consumed in the process of production, however, one obtains the "net output" of industry. This net output, both for industry as a whole and for individual industries, is an important series as it measures, with certain additions, the contribution of industry to the gross national product.

It is generally the practice that the unit enumerated is the establishment rather than the enterprise, an establishment being defined as an individual plant at a single location as distinguished irom an enterprise which may be composed of more than one plant each of which may manufacture different products. In the case of the establishment, it is possible to associate statistics on the product produced with the geographical location of the plant and with labour and other resources consumed in production. Unless it is a single-establishment enterprise, however, it becomes extremely difficult to associate statistics of plant operations with the financial data which would normally be available only for the enterprise as a whole.

The compilation of value aggregates of total production or of the production of specific subdivisions of industries also presents problems. It is true that most manufacturing plants produce goods for other plants and not for direct consumption. Thus if the gross sales of all plants were aggregated, a misleading total would be reached. It is therefore necessary to deduct the cost of materials and intermediate products used to arrive at "net output" or "value added in manufacture."

A further problem arises from the fact that to obtain true net output the value of capital consumed in the process of production must be deducted. This is done by means of allowances for depreciation and obsolescence. In addition, it is important to distinguish between those activities of the plant which are directed toward producing goods for current consumption and those resulting in the formation of new capital goods.

Production aggregates are indispensable for a correct understanding of modern economy.

It is important to know whether the industrial sector and its innumerable parts are being maintained and extended and in the economically correct proportions.

UNITED STATES

The first census in the United States. that for 1790, covered population only, and not until 1810 was any effort made to secure data on other subjects. Fragmentary data on minerals and manufactures were collected in the censuses of 1810 and 1820, and beginning in 1840 employment and production information for these activities was collected in every decennial census prior to 1949. Questions on agricultural production were included in the 1840 census. and additional inquiries on the acreage and value of farms and related matters were included in 1850. The year 1850 also witnessed the first decennial census of state and local government finances; this census was later placed on an annual basis for the larger governmental units.

During the 19th century the decennial censuses of population and production were conducted by temporary staffs recruited for that purpose. With the creation of a permanent census office in 1902, the quinquennial censuses of electrical industries were added to the program, and the census of manufactures was converted to a five-year basis. The country's need for production information became more generally recognized during World War I; after the war the census of manufactures was made biennial and the census of agriculture quinquennial.

Censuses of construction and distribution were included in the decennial censuses of 1930 and 1940 and a census of service establishments in 1940. Thus at the beginning of World War II the census bureau's program included in one census or another most of the country's economic activity with the major exception of financial institutions: transportation, the professions. domestic service, some business services and the activities of the federal government. While industries such as banking, rail and water transportation and electric and gas utilities are not included in the regular censuses, a large amount of information concerning them is compiled by regulatory agencies.

The biennial census of manufactures was replaced during World War II by an extensive current statistics program. However, the regular census of agriculture was taken in 1945, a census of manufactures in 1947 and a census of business (trade and service) in 1948. At mid-century legislation authorized the bureau to conduct censuses oi manuiactures, minerals and distributive trades and service establishments covering 1953 and every fifth year thereafter. These censuses were actually conducted for 1954.

Census **of** Manufactures. — At its inception in 1810, the census of manufactures covered only a few questions on employees and payrolls, production and selected materials. Beginning in 1849, which may be considered the first scientific survey of manufactures, every subsequent census included questions on the number of production workers and their wages, on total value of products and total cost of materials and the derived figure, value added by manufacture; irom' 1895, information on salaried employees and their earnings was also collected. In other respects there were considerable changes after 1849. The collection of data on capital invested. a feature of every census in the earlier years, was discontinued after 1919; on the other hand, inventory data for the beginning and end of each census year were introduced in 1937, and an inquiry on expenditures for new plant and equipment in 1939. During the earlier years. it was customary to collect information on such costs as rent and taxes, but subsequently the only cost items. other than labour costs: requested were "cost of materials and supplies." "cost of contract work" and "cost of fuels and electric energy." The 1954 census included for the first time an inquiry on the industrial use of water. Data on horsepower of prime movers were collected in all decennial and quinquennial censuses from 1899 and in several of the biennial censuses; this inquiry was not in the 1947 census but was covered in 1954. Data on man-hours of production workers were collected from an expanding list of industries starting in 1933, and since 1947 this information has been obtained regularly from all industries. From 1879, when establishments in a few selected industries were asked to supply data on the quantity and value of individual products made. these data increased steadily with the growing complexity of U.S. industry and the increasing demand on the part of manufacturers and trade associations for this type oi information. In 1954 value data and in most instances quantity data were published for about 7,000 individual manufactured products. For many decades the censuses have also included inquiries on the consumption of the more important types of industrial raw materials and, in some instances, semifinished manufactures. In 1947 and 1954 information was collected on employment in a specified list of metalworking operations.

Table I shows the growth in U.S. industry from 1849 as recorded by the principal census measures of manufacturing activity. So far as possible, the historical data were revised to exclude industries not covered in the later censuses. However, it was not possible to adjust the back figures for three major changes in the scope of the census of manufactures. The decennial censuses through that of 1899 attempted to include all manufactured products, wherever made, whereas after 1904 only factory production was included. Data on hand and neighbourhood industries for 1899 show that this change resulted in the exclusion for that year of about 300,000 establishments employing 600,000 production workers and accounting for about $800,000,000 in value added. The relative, if not the absolute: importance of such activities certainly declined after the turn of the century. In 1919 the minimum size limit for reporting establishments was raised from $500 to $5,000 in terms of value of products. For 1914 approximately 100,000 establishments employing 120,000 production workers and accounting for $150,000,000 of value added reported value of products between these two limits. Many of these smaller establishments mere, however, included in 1919 and subsequent years because of the sharp rise in the price level during World War I. Finally, in 1947, the $5,000 value of products cutoff was abandoned, but establishments with no employees were not covered in that census. This resulted in the addition of some establishments and the exclusion of others, but the effect on employment and value added was only a small fraction of 1%.

The addition of the value of products figures to derive aggregates for groups of industries or for states and other geographic units results in a considerable amount of duplication because of the use of products of some industries as materials by others. With some important exceptions, such as steel, refrigeration and motor-vehicle industries, this duplication is not significant within individual industries. It arises importantly, however, from the addition of industries representing successive stages in the production of a finished manufactured product. Because of the unknown and varying amounts of duplication contained in value of products, and also in cost of materials which is similarly affected, these two figures were not shown in the 1947 census or subsequent annual survey publications for groups of industries or states or local areas, and United States totals are not shown in Table I for any year. Except for 12 of the 453 industries covered in the census, individual industry totals are shown in the census publications both for the United States and for each producing state of significant size for which publication would not disclose the operations of individual companies.

Even where no serious amount of duplication is involved, "value of products" is frequently a very defective measure of the relative economic importance of individual manufacturing industries—principally because of the wide variation in the ratio of materials costs to processing costs. For this reason, the bureau of the census early urged the use of "value added by manufacture" as the most appropriate census measure of .the economic importance of individual manufacturing industries. Value added by manufacture is computed by subtracting from the value of products, the cost of materials and contract work used in making those products.

Value added. does have the advantage that, since it eliminates the type of duplication referred to above, the totals for individual industries may properly be combined to arrive at aggregates for groups of industries and geographic regions.

Value added by manufacture should not be confused with the net contribution of the manufacturing industry to the nation's income, as shown in various national income reports. The principal differences between these concepts are twofold: (1) value added by manufacture does not exclude depreciation, which in many respects should be considered ,as equivalent to a materials cost; and (2) value added also includes taxes (except excise taxes) and other costs such as insurance, rent and advertising which are properly the contribution of nonmanufacturing industries.

Figures for either value added by manufacture or value of products are affected by changes in the price level. In order to measure changes other than those deriving from price influences, indexes of the physical volume of manufacturing production for all manufacturing as well as for individual industries and industry groups have been compiled from census data. For an individual industry, an index of physical production is usually obtained by weighting the changes in the output of individual commodities by their value in a selected "weight period." Indexes for groups of industries and for all manufacturing are ordinarily obtained by weighting the indexes for individual industries by the value added by each industry in the weight period. Indexes of physical production are thus independent of changes in the general price level and so can be compared with physical measures of input such as employment or man-hours worked. The latter figure was collected on a comprehensive basis beginning in the 1947 census but is available in earlier years on a partial basis from the census and other sources. In 1928 the bureau of the census published a monograph of the physical volume of manufacturing output as disclosed by census figures covering the years 1899 to 1923. Since that time improved indexes for census years have been compiled by the National Bureau of Economic Research and by the census bureau in cooperation with the board of governors of the federal reserve system. These indexes are shown for selected years in Table I. Monthly and annual production indexes, of which the most widely used is that of the board of governors of the federal reserve system, are published by various other agencies.

The 1954 census of manufactures covered all establishments primarily engaged in manufacturing as defined in the "Standard Industrial Classification Manual," vol. i, *Manufacturing Industries*, prepared by the bureau of the budget. In accordance with this system of classification, each establishment reporting in the census was classified into one of the more than 450 manufacturing industries, generally on the basis of the principal products made. Individual industries were combined into 20 broad groups of industries, usually known as major industry groups.

Table II shows the distribution of manufacturing activity by major industry group for 1939, 1947 and 1954. Nearly every census had seen marked changes in the definition of a substantial number of individual industries. The 1954 census is unusual in that the classification system is only slightly changed from that of 1947. The major revisions since 1947 were the inclusion of data for establishments engaged in the processing and distribution of fluid milk and logging camps and

Table I.—General Statistics for Manufacturing Industries in the U.S., Selected Years, 1849–1954

Year	Number of establishments (000)	Production workers: Number (average for the year) (000)	Production workers: Wages total (000,000)	Value added by manufacture (000,000)	Index of physical production* (1939=100)
Factories and hand and neighbourhood industries:					
1849	123	957	$ 237	$ 464	†
1859	140	1,311	379	854	†
1869	252	2,054	620	1,395	†
1879	254	2,733	948	1,973	†
1889	354	4,129	1,821	4,102	†
Factories only:					
1899	205	4,502	1,893	4,647	27

TABLE 11.—Selected Statistics for Major Manufacturing Industry Groups, 1939, 1947 and 1954

Major industry group	Number of production workers (average for the year)			Value added by manufacture		
	1939 (000)	1947 (000)	1954 (000)	1939 (000,000)	1947 (000,000)	1954 (000,000)
All industries, total	7,808	11,916	12,373	$24,487	$74,426	$116,913
Food and kindred products	802	1,099	1,138	3,485	9,025	13,400
Tobacco manufactures	87	103	87	350	641	988
Textile-mill products	1,082	1,147	948	1,818	5,341	4,749
Apparel and related products	753	973	1,070	1,386	4,443	5,147
Lumber and wood products	423	596	582	731	2,497	3,188
Furniture and fixtures	189	283	287	418	1,378	1,966
Pulp, paper and products	270	389	436	888	2,875	4,581
Printing and publishing	324	438	500	1,765	4,269	6,265
Chemicals and allied products	276	466	501	1,697	5,365	9,444
Petroleum and coal products	108	170	136		2,015	2,209
Rubber products	121	215	196	406	1,303	1,904
Leather and leather products	327	349	321	583	1,533	1,637
Stone, clap and glass products	267	406	412	856	2,307	3,822
Primary metal industries	672	1,010	966	2,170	5,766	9,717
Fabricated metal products	451	822	821	1,401	4,922	7,596
Machinery (except electrical)	536	1,244	1,171	2,037	7,813	12,339
Electrical machinery	248	639	722	941	3,894	7,403
Transportation equipment	545	987	1,327	1,773	5,869	13,926
Instruments and related products	85	182	196	333	1,080	2,120
Miscellaneous products	242	398	556	630	2,090	4,473

contractors. Census practice is to be retabulated, insofar as possible, the reports submitted in the preceding census in terms of the revised industry classifications! but it was frequently impossible to go further back than one census. Consequently, of the 453 industries tabulated in 1947, comparable data for at least a few census measures were available for 443 industries in 1939, but only 217 could be carried back to 1929, and only 135 back to 1899. Since most of the changes in industry classification! however, occurred within a major industry group, comparable data for 14 of the 20 major groups were available back to 1899. Later changes in the definition of metal products industries affected the industry groups as well as the individual industries with the result that for four of these major groups census data could not be carried further back than 1937. Historical data for industries and industry groups were published in vol. ii, *Statistics by Industry,* of the census of manufactures. This volume also contains detailed statistics on employment, payrolls, value of shipments, cost of materials, inventories and capital expenditures for each industry as well as the quantity or value of the principal products of the industry and, in some cases, the quantity and value of the principal materials consumed.

In addition to industry data for the United States as a whole, the census of manufactures also provides information for states and local areas. In vol. iii, *Statisfics by States,* employment and payroll. value added by manufacture and capital expenditures data were shown for all counties and for all urban places having a population of more than 10,000 in the latest census of population. Industry data were shown for states and selected metropolitan areas and industrial counties. In vol. i, *General Summary,* the more significant information presented in vol. ii and iii was arranged by subject matter and both industry and state comparisons were presented. (M. R. C.)

Mineral **Industries.**—The censuses of 1810 and 1820 included only fragmentary data on the mineral industries and some discussion of their potential development. The law providing for the 1840 census made the first specific provision for a census of mining. Subsequent minerals censuses were conducted at approximately 10-year intervals, with the exception of a 1 j-year interval between the 1939 and 1954 censuses. Legislation provided for a minerals census every five years thereafter.

Prior to 1880, the same form was used for collecting data on manufactures, agriculture and mining, somewhat limiting the adequacy of the data collected for the mineral industries. Beginning in 1880 experts on mining were used to design special forms and to present appropriately the results of the minerals census. The basic types of information obtained, however! were always closely similar to those of the manufactures census described above. In addition special statistics were provided on mining, such as information permitting the classification of establishments by method of mining—open-pit, underground, etc.—and data on number of days and number of shifts worked.

For 1939 and 1954 statistics were developed on man-hours by department for all mineral industries, on loading equipment by type and kind of fuel, on drilling costs in oil and gas fields, on capital expenditures for development of mineral properties, and reports were obtained for contract services performed for mineral establishments. Figures on the value of inventories were generally excluded from the minerals census, although some quantity inventory figures have been obtained.

Computations of value added in mining were not published prior to 1954. The value of shipments figures for individual mineral industries or for all mining combined contain relatively little duplication, and the contribution of other industries to mining is less than such contribution for manufacturing industries. However. a concept of value added in mining was developed for the 1954 census which includes, besides the usual measure of value added in production during the year, a measure of value added in development of mining properties. Value added, thus computed, ranges for industry totals from 20% to 40% below value of shipments. This special concept for value added in mining mas needed because of the importance of development activities which may be carried on for several years without any resultant production, whereas during a period of peak demand, production may be obtained with relative ease by concentrating activities on developed ore bodies and postponing further development.

The 1954 census of mineral industries covered establishments primarily engaged in mining as defined in the "Standard Industrial Classification Manual," vol ii, *Nonmanufacturing Industries.* Mining operations were classified in five major groups representing metal mining; anthracite mining; bituminous coal and lignite mining; crude petroleum and natural gas extraction; and nonmetallic minerals, except fuels. These five major groups were subdivided into 72 industries. Special statistics are shown in the minerals census for each of these industries. wherever such publication would not approximately disclose the operations of individual companies. Statistics are also shown for certain subindustries, such as special figures for geophysical exploration contract services and for producers of glass sand and producers of asbestos.

The minerals census also includes tabulations, where possible, of the industry statistics by state. The minerals census does not include mining activities which are conducted as part of manufacturing establishments, such as stone quarrying at cement plants and clay mining at brick plants. However, data on such activities are collected in the manufactures census and statistics based on them are reproduced in the minerals census publications.

The minerals census for 1954 included about 36,000 establishments, corresponding to about 19,000 mines and about 500,000 producing oil and gas wells. Table III shows the number of employees, and value of shipments, for each of the five major industry groups for census years 1880–1954. This table also includes index of production figures, constructed by the bureau of the census, for the same industry groups and years, except that data for 1952 (the latest figures available for this index), rather than 1954, are shown.

The census of mineral industries final results are published in two volumes: vol. i, *General Summary and Industry Statistics,* and vol. ii, *Area Statistics.* The general summary includes, in addition to a chapter showing summary statistics, chapters on size of establishment; employment and related statistics; company characteristics; power equipment; energy, water, and selected supplies; and type of operation. Volume i includes summary statistics chapters for the four major mining areas: metal mining, coal mining, crude petroleum and natural gas extraction and nonmetallic minerals

Table 111.—Selected Statistics for Mineral Industries, by Industry Group, Selected Years: 1880–1954

Item and year	All mineral industries	Metal mining	Anthracite mining	Bituminous coal and lignite mining	Crude petroleum and natural gas extraction	Nonmetallic minerals (except fuels) mining
Number of employees (000):

1952	525	223	70	219	3,863	949

*Not available. †Excludes sand and gravel operations The number of employees of such operations in 1929 was 22,000 and the value of shipments was $112,000,000 ‡Based on Bureau of the Census *Working* Paper S o. *1*.

(except fuels) mining. as well as separate chapters for individual industries or groups of industries. Volume ii includes separate chapters for individual states, which contain industry statistics for establishments within the state and also county statistics.

(V. E. S.)

Methods of Collection. — The agricultural censuses have been conducted by means of a field canvass. The report forms are delivered to the farm operator and collected by personal visit from enumerators charged with a complete canvass of all farms in preassigned districts. In the 1939 census of manufactures, the forms were similarly handled by field enumerators who were responsible for the collection and distribution of report forms for the census of business and for most firms in the manufactures census. The minerals census of 1939 was conducted largely by means of a mail canvass; however, in certain industries, where the establishments were typically small and widely scattered, a field canvass was used.

Unless the census of manufactures is taken in conjunction with that for business or population. the field canvass is inordinately expensive and has some technical limitations for the complex manufactures questionnaires. Consequently, in 1947, as in the earlier biennial censuses, the manufactures canvass was conducted largely by mail. Report forms were mailed to firms known or believed to be engaged in manufacturing activity and field enumeration was resorted to only in those instances in which satisfactory reports could not be obtained by mail or by telephone calls from the nearest district office of the bureau. The names and addresses of manufacturing establishments were derived from lists maintained at the bureau or made available by other government agencies or private organizations. In 1947 an important new source of manufacturers' names became available — the files of the bureau of old-age and survivors insurance of the Federal Security agency, to which all employers in manufacturing, as in most other industries, were required to report. In 1954 these records, together with the corresponding names and addresses from the internal revenue service, were used as the primary universe to be covered, not only by the census of manufactures, but for the larger trade. service and mining establishments as well. **All** of these censuses mere conducted by mail in 1954.

Despite the most careful handling of report forms, no census is ever 100% complete. In order to test the coverage of the 1947 census of manufactures, there was undertaken late in 1948 an intensive field canvass of selected areas throughout the country. Preliminary results of this coverage check showed that more than 98% of all employees properly classified as engaged in manufacturing activities were covered in that census. The bulk of the establishments not included in the census were small and engaged in marginal manufacturing activities closely related to construction. distribution or other nonmanufacturing activities. For this reason, these establishments either did not appear on the lists used or were classified as nonmanufacturing when their report forms were reviewed.

Tabulation. — When the returns are received in the Washington. D.C., office of the bureau, they are carefully edited to identify omissions and discrepancies. When such errors are significant, correspondence is undertaken with the manufacturer. In the 1947 census nearly half of all reporting firms were asked to complete or clarify their returns. In 1954 electronic computers were used to do much of the work of inspecting returns that had previously been done by clerks or technicians. Internal relationships for each report were tested on the basis of industry, size and regional standards. Failures in larger cases were "rejected" for correspondence. In the case of very small establishments, missing data and evident discrepancies mere corrected by reference to fairly stable relationships between the figures reported on various sections of the form.

Publication. — When a significant part of the tabulations are completed for a particular county (agriculture and business) or industry (manufactures and mineral industries). a preliminary statement, often restricted to the more significant types of information, is issued. Later, one or more printed bulletins containing final detailed figures for each state or industry are published. Finally, these separate pamphlets are collected into bound volumes which constitute the official report on the census. These are, however, frequently supplemented by a general report presenting the more significant data for each state and industry. The final census volumes are generally published two to three years after the close of the census year, though much of the information will have been in print for some time. For example. in the census of manufactures, preliminary industry releases usually begin to appear about a year after the close of the census year. In both the 1947 and 1954 censuses. the first industry report in manufacturing was released in December of the following year.

Current Production Statistics. — Much of the information collected in the production censuses was published in the 1950s on a monthly, quarterly or annual basis in part by the bureau of the census and in part by other government agencies and private organizations. In the agricultural and mineral fields current data were provided by the department of agriculture and the bureau of mines, respectively. In the manufactures field, employment and payroll data were published on a current basis by the bureau of labour statistics of the department of labour, and information on production of individual commodities from a wide variety of sources, principally the regulatory agencies of the federal government and a large number of trade associations.

Formerly, it was only in respect to commodity production information that the bureau of the census attempted to keep any of its census of manufactures on a current basis. The bureau's program was designed to cover the more important types of products not covered by other organizations. Among the products included were: wheat flour, confectionery, shoes, textiles, selected items of apparel, lumber, paper and pulp, household furniture. the major inorganic chemicals, fats and oils, ferrous and nonferrous castings, containers, heating and cooking apparatus, plumbing fixtures, tractors. machine tools and agricultural machinery. Current data on the quantity and value of the output of these and other manufactured products were published in the bureau's "Facts for Industry" series. After the inauguration of the annual survey of manufactures in 1949, annual figures were published on the value of shipments of classes of products for approximately 600 classes accounting for almost 90% of shipments by manufacturing establishments. These class of products data, together with individual product statistics excerpted from the "Facts for Industry" series, are shown in the publication *Annual Survey of Manufactures,* which also presents annual estimates of employment, payrolls, man-hours, value added by manufacture, inventories, expenditures and similar statistics by industry and by state. Many of these series are also incorporated in the monthly *Survey of Current Business* prepared by the office of business economics, a convenient source of production data also for other manufactured commodities as well as for general information on factory employment, payrolls, shipments. inventories and expenditures for new plant and equipment. On an annual basis, the more important production statistics are conveniently summarized in the *Statistical Abstract of the United States,* a publication of the bureau of the census. Selected production series are carried back as far as available in a companion publication, *Historical Statistics of the United States, 1789–1945.*

The statistical data published before mid-20th century on a current basis a-ere deficient on three important counts. First, much of the general information collected between censuses by agencies other than the bureau of the census was on a company rather than on an establishment basis. Consequently, it was difficult to carry forward data on an industry basis and, in particular, impossible to relate employment with the volume of production associated with it. Second, information on cost of materials was not collected and value added by manufacture could not, therefore, be derived from any of these sources. Finally, there were important gaps in the current coverage of manufactured commodities. To remedy these inadequacies, a survey of manufactures was taken in 1949, and similar surveys were conducted for each subsequent intercensal year through 1953. After the 1954 census, the annual series was resumed again, beginning with 1955. These surveys were to canvass all large establishments in each industry but in general only a sample of the smaller establishments. The tabulation plan is similar to but in considerably less detail than that followed in the census. Data are presented for over 300 of the country's industries, accounting for over 90% of total employment and value added, all major industry groups and all states. Data are also shown for the more important major industry groups within each state. (M. R. C.)

Census of Agriculture. — A nation-wide census collection of the vast store of essential facts about agricultural production was started in 1840. This first farm census provided data on the output of the principal crops and for the numbers of livestock and poultry on farms. The agricultural census of 1850 extended the coverage of farm census information to include the acreage of farmlands, value of farms and farm machinery and the value of animals slaughtered. By 1860 the number of inquiries in the farm census had grown to 48 and by 1870, to 52. The coverage of the censuses of 1880 and 1890 greatly exceeded that of prior censuses, and more than roo separate detailed inquiries were made for a large number of agricultural products such as cereals, fruits, tobacco, hogs and other livestock. During the 20th century, the questionnaire for the census of agriculture continued to expand, as the complexity of agriculture increased, until it contained, by 1950, more than zoo separate inquiries.

For more than a century, the periodic censuses of agriculture have furnished, decennially from 1840 to 1920 and quinquennially since 1920, the only available detailed data on agricultural production in each county and state. During recent decades the farm censuses provided detailed data on the output of each agricultural crop, and of major livestock products, the slaughter of livestock on farms, the use of farm products on farms together with detailed figures on agricultural resources, such as farmlands classified by use, principal power machines, livestock classified by age and sex, farm facilities, etc. The farm census statistics have furnished the bench marks for a large number of seasonal and annual state and national estimates of agricultural production made by the United States department of agriculture.

Recent censuses of agriculture supply detailed data indicating the kind of farm specialization in agricultural production, measures of scale of farm operation and indexes of the unfolding development in the power mechanization of agriculture during the last half century. The classification of farms by type, together with related data on resources. source of sales, production, etc., give data on the increasing high degree of specialization in agricultural production. The scale of operation for the central core of 3,000,000 competing independent commercial farms is indicated by the classification of farms by the total value of farm products sold. The 20th-century revolution in agriculture, resulting from the substitution of mobile tractor power for horses and mules, is indicated by the classification of farms by type of power.

Roughly half of all the money spent for all goods and services by consumers in the United States goes for food, clothing and other products of farm origin. However, farm products undergo many changes between the farm and consumer — they are transported, processed and incorporated with other products of nonfarm origin, etc. Large quantities of products of farm origin are processed in nonfarm factories and returned to the farm as food, clothing and other articles required by farmers and their families. During the 20th century, many activities once conducted on farms were transferred to the nonfarm sphere because they could be performed more efficiently there. Forces of modern agricultural technological changes — mechanical, chemical, genetic and social — have sprung from many nonfarm sources. Fertilizers, tractors, new farm machines, pesticides, etc., are some of the nonfarm products used by farmers in their factories to produce food and fibre for the rapidly growing nonfarm population.

Statistics from the census of agriculture on agricultural production and its organization are of interest and useful to those selling food, clothing, machinery, chemical and other products to farmers. Statistics on farm value, farms classified by type, farms classified by gross value of farm products sold, the production of several hundred agricultural products, the inventory of power equipment on farms, etc., not only indicate the potential farm market in each county and state, but also enable manufacturers and dealers to direct their sales efforts into counties or areas where the market possibilities are the greatest. Census figures show the location of areas of agricultural production, together with measures of output, and thus assist manufacturers and others to locate manufacturing plants — canneries, butter factories, fertilizer plants, etc., in the most advantageous location.

(See also AGRICULTURE.) (R. H.)

UNITED KINGDOM

Legislative Authority **and** Scope. — Censuses of production in Great Britain are taken in accordance with the provisions of the Statistics of Trade act, 1947, which lays down that the board of trade shall, for purposes of providing general surveys of the state of trade and business, take a census of production in respect of the year 1948 and of every subsequent year. The first census was taken in the United Kingdom in respect of 1907 under the provisions of the Census of Production act, 1906.

The necessity of annual censuses was recommended by the White Paper on employment policy (Cmd. 6527) presented to parliament by the coalition government in May 1944, and the 1947 act gave statutory effect to the recommendations of the *Report of the Census of Production Commzttee* (Cmd. 6687, 1945). This act gave compulsory powers to the government to ask questions on a wide range of subjects, among them the nature of the undertaking, including its association with other undertakings; the persons employed, the nature of their employment, their remuneration and the hours worked; the output, sales, deliveries and services provided; stocks and work in progress; the outgoings and costs and capital expenditure; the power used or generated; the fixed capital assets; the plant and the premises occupied. The scope of these questions is sufficient to permit an effective analysis of most of the important aspects of production. In 1954 the advisory committee on the censuses of production and distribution reported on the operation of censuses carried out under the 1947 act, and made representations for future policy.

The original 1906 act limited the scope of the census broadly to a summary of employment and output. It permitted questions to be asked mainly about the value for any product, together with the aggregate estimated value of materials used, the amount paid for work given out and such related data as employment, number of days worked and power used and generated. The quantitative data that could be asked for about output was limited, and none could be obtained compulsorily about materials, but power used covered coal and coke. Just as the original Census act arose out of the tariff reform controversy at the beginning of the century, an extension of compulsory powers to collect more information was given by the Import Duties act, 1932, in respect of the production of goods covered by the new tariff. This act enabled detailed information to be obtained about both output and materials. These powers were extended by the Finance act, 1933, to goods covered by the silk and McKenna duties and to all products by the Census of Production act, 1939. No census was taken. however, under this latter act (repealed in 1947) because of the outbreak of World War II. Wages were specifically excluded as a subject of inquiry by the original Census act. Voluntary sample inquiries by the ministry of labour, conducted at about the time of each census, made possible, however, an estimate of the wages bill in the various industries. By all these means, even the pre-World War II census reports became a rich source of data on British industry, covering a wide range of subjects in a systematic and consistent manner.

Details of Individual Censuses.—Before World War II censuses were taken in respect of the years 1907, 1912 (incomplete), 1924, 1930 and 1935. Inquiries undertaken in connection with the Import Duties act, covering a selection of industries protected by the tariff, were held for 1933, 1934, 1935 and 1937. The first postwar census taken was for 1946, but this covered selected industries only. After 1948 annual censuses were held but these varied considerably in coverage. The 1948 census covered nearly the whole range of questions permitted by the 1947 act. In addition to detailed information on sales? materials used and employment, such as had been obtained in earlier censuses, for the first time questions were asked regarding investment expenditures and payments for services and miscellaneous items. In 1949 and 1950 skeleton censuses were taken; a considerable volume of information was collected concerning the total receipts, payments. investment expenditures, etc., of the establishments, but no questions were asked about quantities and values of individual products and materials. The censuses in respect of 1951 and 1954 were more comprehensive, and included most of the items covered in 1948. In addition the census for 1951 included questions on the new topic of shift working, and data on power equipment available were collected for the first time since 1930.

For 1954 information on pension schemes was included. For 1952 and 1953, sample inquiries were made covering the same type of information as that collected for 1949 and 1950. It was intended that full inquiries should in future be held every three (or possibly five) years, with sample inquiries in the intervening years. (See the Report of *the Committee* on the Censuses of Production and Distribution, Cmd. 9276, H.M.S.O., London, 1954.)

The final reports of each census give comprehensive definitions as well as the full results. In addition a summary volume was published for the 1948, 1949 and 1950 censuses which also included information for 1935 reclassified on the same basis as the later inquiries. The results of the 1912 census, insofar as available, were published together with the results of the 1924 census and the final results of the 1937 inquiry with those of the 1948 census.

Industries and Area Covered.—The postwar censuses, like earlier ones, generally covered undertakings in manufacturing, mines and quarries, building and contracting, public utilities and a few distributive and service trades, accounting together for about half of the total labour force in civil employment. For other branches of the national economy no similar comprehensive range of information is available but for the distribution and service industries, the first census of distribution, taken in respect of 1950, provides much of this information. As a result a number of trades which overlap with the distribution and service industries were excluded from the 1950 census of production.

The postwar censuses covered productive operations carried out in Great Britain, but in all years except 1948 censuses in Northern Ireland were conducted at the same time and the results incorporated in the reports, which thus cover the whole of the United Kingdom. The censuses for 1907 and 1912 covered the whole of Ireland. No Northern Ireland census of production was taken for 1948, however, and the figures for that year relate to Great Britain only. Reports for later years again covered the whole of the United Kingdom.

Collection of Information. — Information for purposes of the censuses is collected on the basis of questionnaires sent out to each individual firm in the industries covered. For the purposes of the 1930 and all later censuses, however, firms employing ten or fewer persons were (with some exceptions) only required to furnish information about the number of persons employed and the nature of their business. The 1907 and 1924 censuses included production of all establishments irrespective of size. The final report of the 1951 census was based on data supplied by nearly 77,000 establishments with more than ten workers; in addition, simplified returns were made by 108,000 small firms with ten or fewer workers. The data relating to the firms and their plants are classified by industries according to the nature of their major products, as far as possible in conformity with the standard industrial classification. The 1951 census distinguished 157 individual industries such as cotton spinning and doubling, etc. These industries were grouped into the 14 manufacturing orders and j relevant nonmanufacturing orders of the standard industrial classification for purposes of the summary reports.

Main Census Results. — Table IV gives certain aggregate results for the United Kingdom in 1951, with comparative .figures for gross output, net output and employment in 1907 and 1935. Data on wages and salaries, stocks and investment were not collected in the earlier inquiries. The gross output of a trade is the total vaiue of goods made and other work done during the year. The net output of a trade represents the value added to materials by the process of production and constitutes the fund from which wages, salaries, rents, rates and taxes, advertising and other selling expenses and similar charges have to be met, and from which depreciation and profits are provided. It indicates broadly the contribution of industry to the total national output, whereas the aggregate of gross output includes duplication: as the end product of one industry — for example, steel — is the material used by another industry—*e.g.,* engineering.

TABLE IV.—*Summary Results of Census of Production in the United Kingdom*

Item	1907*	1935*	1951†	
			All industries	Of which manufacturing
Production (£000,000):				
1. Value of gross output (selling value of goods made and value of work done)	1,765	3,543	18,032	15,428
2. Cost of materials and fuel used anh amount paid for work given out	1,053	1,817	10,850	9,725
3. Value of net output (excess of (1) over (2) after deducting excise taxes)	.697	1,640	6,692	5,045
4. Wages and salaries			3,764	2,737
5. Stocks of materials and fuel, finished products and work in progress (at beginning of year)	...	...	...	2,502‡
6. Investment in new plant, machinery, vehicles and buildings	...	...	...	492
Employment (000):				
7. Operatives	6,493	6,462	8,426	6,188
8. Administrative, technical and clerical staff	492	835	1,593	1,305
9. Total	6,985	7,297	9,974	7,453
10. Total employment (including that in small firms)	...	8,130	10,669	7,827

*All firms. †Establishments employing more than ten persons. ‡Excludes stocks in three trades accounting for 3.8% of net output. §Including working proprietors.

Note: Results for the three years are not strictly romparahlr; 1907 is not comparable with 1935 because of (1) inclusion of firms in the territory which is now the republic of Ireland; (2) inclusion of small firms; (3) inclusion of trades subsequently omitted; (4) deficiency of returns. The over-all effectof (1–4) is that output has to be reduced by nearly 6% to make it comparable with 1935; 1951 includes some trades (accounting for about 2% of net output in that year) which were omitted in 1935.

Production and Productivity. — Changes in the value of output between the various censuses are the result of changes both in prices and in quantity. A measure of the quantitative changes can be arrived at by eliminating the effect of price changes and thus estimating changes in the volume of production. The estimates given in Table V were prepared on the basis of data contained in

TABLE V.—*Productivity in Manufacturing in the United Kingdom*

Year	Volume of production	Output per operative	Output per man-hour
1907	100	100	100
1924	133	121	142
1930	142	128	...
1935	177	152	171
1948	246	170	203

Source: A. Maddison, "Output, Employment and Productivity in British Manufacturing Industry in the Last Half Century," Bull. *Oxf. Univ. Inst. Statist.*

the censuses and of data on hours worked. They relate to the manufacturing industries only and are thus not comparable with the data in Table IV, which include also mining, building and public utilities. Between 1907 and 1948 the volume of production increased at the annual compound rate of 2.2%, output per operative increased by 1.3% and output per man-hour increased at the compound annual rate of 1.7%.

Mechanical Power.—One factor in the increase in output per worker shown in Table V is clearly the striking increase in mechanical power available to industry. Information on this subject is included in the censuses for some years. The estimated horsepower of prime movers and of electric motors in manufacturing driven by purchased electricity increased from about 1.5 h.p. per worker in 1907 to 2.0 in 1924, 2.4 in 1930 and 3.1 in 1951.

These figures exclude equipment returned as "idle or in reserve," except in 1907.

Employment.— Between 1907 and 1924 the number of persons employed by all firms; including small firms, covered by the two inquiries increased in Great Britain by about 14%. Later figures available for the whole United Kingdom indicated an increase of 2% between 1924 and 1935, both years of only moderately good employment. Between 1935 and 1954 employment in trades covered by the censuses of both years increased by about 34%. Over the whole period, therefore. employment in the census industries expanded by about 56%, but this figure is approximate only, as various small changes in coverage have not been allowed for.

The census results indicate that the number of administrative, technical and clerical staff expanded throughout the period. The total of the controlling and clerical staff amounted in 1907 to 7% of the total employed, in 1926 to 8.7%, in 1935 to 11.4% and in 1951 to 15.4%. One reason for this increase is the change in industrial structure. Industries growing in proportionate importance, *e.g.,* metals, employ more administrative and clerical staff than those which are diminishing in importance, *e.g.,* textiles.

TABLE VI.—*Industrial Distribution of Persons Employed in the United Kingdom in All Firms (Per Cent)*

Trade group*	1907†	1924	1935	1948‡	1954§
Iron and steel	8.6	7.8	8.3	10.0	9.2
Engineering, shipbuilding and vehicles	14.3	16.6	18.8	27.3	29.0
Nonferrous metals	1.9	1.9	2.0	2.5	2.1
Textiles	21.3	18.4	15.5	10.4	10.7
Leather	0.9	0.8	0.8	0.7	0.6
Clothing	10.6	9.0	9.3	6.7	6.5
Food, drink and tobacco	7.7	7.8	9.2	8.5	8.9
Chemicals	2.4	2.7	3.6	4.1	4.3
Paper and printing	5.5	5.4	6.4	5.3	5.6
Timber	3.1	2.7	3.8	3.2	2.9
Clay and building materials	3.5	3.1	3.9	3.5	3.4
Miscellaneous	1.6	2.6	2.9	3.6	3.6
Total manufacturing	81.4	78.8	83.9	85.8	86.8
Mining	16.4	18.5	12.4	10.2	9.1
Gas, water and electricity	2.2	2.7	3.7	4.0	4.1
Total, all above trades	100	100	100	100	100
(000)	5,888	6,950	6,899	8,158	9,118

*The classification is that used for pre-1939 censuses, but employment in government departments has been distributed among the other industries according to products, and only part of the utilities group is included. Trades covered only in some years are omitted throughout. Reclassification of data for 1948 and 1954 is approximate only. †Includes the republic of Ireland. ‡Excludes Northern Ireland. §Preliminary.

Some of the other reasons for increase are the greater attention given to production planning, designing, research, cost accounting and other similar work, and an extension of the preparation for sale and of the control of sales, carried out by the manufacturers' staffs.

Industrial Change.— Subsequent censuses reveal a considerable change in the distribution of productive energies and output among the different industries. The change in the distribution of employment among the manufacturing industries, mining and public utilities is shown in Table VI. Generally speaking, output per worker has increased faster in the expanding industries than in those which are stationary or contracting, so that the distribution of real output would show even greater changes.

Over the period of nearly 50 years covered by the census reports the share of total employment engaged in engineering, shipbuilding and vehicles more than doubled, and by 1956 this group accounted for nearly 30% of the total. A similar expansion occurred in the gas, water and electricity group, due primarily to the large expansion of electricity production; in chemicals; and in the miscellaneous industries, which include scientific instruments, rubber and plastic materials. This expansion was offset by a sharp decrease in textiles, whose share was halved; in mining, particularly coal mining; and in clothing and leather.

The position of the remaining groups, which include basic metals, building materials, timber and gaper, changed little and they accounted for about one-third of total employment both in 1907 and in 1954.

Concentration of Production.—The census throws light on the relative importance of different-sized firms operating in British

TABLE VII.—*Relative Importance of Different-Sized Manufacturing Firms in the United Kingdom in 1949*

Size of firms (average no. employed)	No. of firms	No. of firms (per cent)	Net output (per cent)	No. of persons employed (per cent)
11–99	43,514	75.68	21.49	22.49
100–499	11,673	20.30	34.15	34.29
500–999	1,418	2.47	13.93	13.76
1,000–7,499	860	1.50	25.92	24.65
7,500 and over	31	0.05	4.51	4.81
Total*	57,496	100.00	100.00	100.00

*Omits 598 unclassified firms.

industry. In 1949 there were in the census manufacturing industries 79,138 small firms employing not more than 10 persons which together employed about 368,000 persons or just over 5% of the total. Another 58,094 establishments with more than 10 employees employed 6,721,500 persons or 95% of the total. As the small firms are to a large extent engaged in such activities as repair work, it is more relevant to consider the degree of concentration among firms with more than 10 employees. In 1949, 76% of these establishments had fewer than 100 employees and they accounted together for 21% of the value of net output and 22% of the employment; 22% of the firms employing between 100 and 999 accounted for 48% of the net output and of employment; there mere 891 big firms with 1,000 employees or more accounting for 1.6% of all firms but producing 30% of the net output and employing 29% of all employees. (*See* Table VII.) Several firms may be owned or controlled by a single company, and on a company classification the degree of concentration would therefore be even greater. This is illustrated by a study by H. Leak and A. Maizels of concentration in the three largest companies in various industries in 1935, the latest year for which data are available. At that date the three largest companies in the chemical and allied trades accounted for 48% of all employment, in the miscellaneous industries for 47%, in engineering and vehicles for 43%, in iron and steel for 39% and in food, drink and tobacco for 32%. In textiles, paper, printing and building materials the proportion was about 22%–23%, and in clothing, wood products and leather only 10%–15%.

The average for all manufacturing industries was 29%, or 26% if mining, building and public utilities are added.

Regional Distribution of Industry.— Table VIII indicates the relative importance of the various regions of the United Kingdom in 1949.

A comparison with earlier censuses indicates the geographic shifts in working population. The principal changes in the years before 1949 were the increase in the importance of greater London and of the south of England in general, and also of the midland area, at the expense of the north of England, Wales and Scotland. These changes were not due to a movement of industry to the south but rather to contraction or expansion of industries concentrated in particular regions, notably the decline in the cotton industry in Lancashire.

Table VIII.—*Regional Distribution of Manufacturing Industry, United Kingdom, 1949*

Area	Establish-ments	Employment (000)	Net output (£000,000)	Wages and salaries (£000,000)
Northern	2,169	358	194	117
East and West Ridings of Yorkshire	6,618	745	423	232
N. midland	4,558	538	303	169
Eastern	2,450	301	178	100
London and southeastern	13,469	1,294	799	458

Scotland	5,472	675	347	204
N. Ireland	1,209	167	67	39
United Kingdom*	58,094	7,063	3,968	2,288

*Includes 459 unclassified establishments not included in any region.

OTHER COUNTRIES

In addition to the United States and the United Kingdom a small but increasing number of countries make a practice of carrying out surveys yielding data relating to production and not merely to products. Details of these are given in a United Nations report on industrial censuses published in 1953, which also gives full information on the methods and requirements of production censuses. Canada early adopted the practice of the U.S. It passed from a decennial to a quinquennial inquiry after 1900, and the system of annual censuses of manufactures was established from 1917. Similar annual inquiries have been carried out in the other countries of the Commonwealth of Nations: in Australia from 1903; in New Zealand from 1918–19, following quinquennial inquiries extending back to 1867; and in the Union of South Africa from 1915–16. There were two previous inquiries in South Africa in 1904 and 1911 and none in either 1930–31 or 1931–32. Southern Rhodesia has taken a voluntary annual census of industrial production since 1938, and Northern Rhodesia since 1947. India took a detailed census for 29 industries in 1946. This was the first of an annual series whose coverage was extended in 1947 and 1950. The first census in Ceylon was carried out in 1951. The republic of Ireland made the first of such inquiries in 1926, then in 1929, 1931 and thereafter annually. These inquiries are very detailed in respect of subjects covered, comparable to the U.K. and U.S. inquiries; all of them give regional details.

All four Scandinavian countries conduct annual censuses of production, but the range of subjects covered is smaller than that of the British and U.S. censuses; additional information is available, however, from their censuses of establishments, held at less frequent intervals.

Several of the eastern European countries, among them Poland, Czechoslovakia, Hungary and Rumania. had taken annual censuses of manufactures of a limited scope before World War II, usually (except for Poland) not including data on the quantity of output. Of other major European countries Germany and Italy had very complete censuses of production relating to the years 1936 and 1937–39 respectively. A more restricted inquiry was also made by the German Federal Republic in 1950. In the Netherlands a Census of production was found necessary in connection with wartime organization in World War I and in 1918 an inquiry was made relating to 1916 and 1913. Later annual inquiries covered a small number of industries only, and referred to the bigger firms only. In Belgium the first of an annual series of censuses was taken for 1946. In France an attempt was made in 1931.

A number of the South American countries have taken censuses of production at infrequent intervals. The most recent censuses were taken in Brazil, Mexico and Guatemala for 1950; in Uruguay for 1948; in Argentina for 1946; in Colombia for 1944–45; and in Venezuela for 1936.

PRODUCTION MANAGEMENT is the process by which the physical output of a business organization is planned and the operations employed to produce the output are directed, coordinated and controlled. As production management has mainly to do with how, when and where products are to be made it is more important in manufacturing firms than in any other business organization. The techniques and methods of production management however are both widely applied. The problem of scheduling machine operations for preparation of customers' statements by a public utility, for example, may be analogous to the problem of scheduling machines for production of an item in a machine shop. The factors considered in an analysis of materials handling are basically similar, whether the site is a shop, a warehouse or an industrial plant. Likewise, choices among alternative sets of equipment for a nonmanufacturing function may be made in much the same way as they would be in the case of production equipment. While the term "production management" may be construed to take in more than "manufacturing management" and cover less than "industrial management," seldom is any clear distinction made among these labels. The following will make evident the objectives and approaches of the branch of management discussed. No particular purpose is served by insisting on one special title and rigid definition. It is convenient to refer to the management principles and practices described in the setting of the manufacturing firm and production-centred activities as production management.

Organizational Arrangements. — Production management is no more confined to a particular organizational segment within a firm than it is restricted to a particular type of firm. Eecause manufacturing firms frequently have production divisions and because heads of production activities frequently are given the title of production manager, there is a tendency to identify production management either as the management of a production division or as the work done by a production manager. In reality however it is unusual to find the whole of production management being accomplished by a single department; almost invariably persons other than production managers perform functions or make decisions that fall within the scope of production management.

Some management activities involved in planning what to produce and nhat methods of production to use are "staff" activities conducted in staff departments that are not under the administrative control of the production division. The "line" production organization is primarily concerned aith performance and has the responsibility of producing output of acceptable quality, in proper quantity, at the right times and at reasonable levels of cost. Since good organizational practice dictates that authority be commensurate with responsibility, the production organization usually has the final word about the execution of plans. Where production responsibility overlaps another kind of responsibility however an independent organizational unit may be created to handle the problems of coordination and planning that arise; or management may decree that certain decisions affecting production be made outside the division. In many firms, production-planning groups—staff agencies outside the manufacturing division—are expected to reconcile conflicting marketing and production goals such as sales division pressure for small-lot, specially designed items for favoured customers opposed by manufacturing division preference for long runs of standard products. Other specialized organizational subdivisions are frequently found in establishments where the scale and complexity of operations are such that some technical issues can best be handled by experts concentrating their efforts in a narrow field. Organizational arrangements and terminology vary, but separate departments or units may be set up for the performance of any of the following functions: product research, development and design; process development and design; specification and procurement of materials and supplies; standardization; inspection. testing and quality control; cost analysis and control; and study and preparation of work standards and methods. Usually some staff positions are created within the manufacturing division to deal with matters closely connected with its operations; other functional specialties are assigned outside the division.

To secure the advantages derivable from specialization and division of labour, the "line" portion of a manufacturing division is usually divided into departments in a way that reflects the physical organization of production. In small companies having only one plant, the functional form of organization predominates: production processes or manufacturing functions are represented individually by departments or closely related functions are grouped together to compose departments. For example, the line subdivisions in a functionally organized manufacturing division of a metal-working concern might be: (1) shipping. receiving and warehousing; (2) casting and forging; (3) machining; (4) plating and polishing; and (5) assembling and testing.

Although the functional type of organization is also found in large companies, either as the basic organizational form or within plants, some other variant is likely. For multiplant companies, individual plants may be designated as the primary organizational units of the manufacturing division; or, if several production facilities are located together, the geographical area may be made the administrative unit. Large companies with diversified product lines in some instances establish product divisions under which all operations and facilities required for production of a single product type or class of products are grouped. Product line organization is sometimes extended to the company as a whole, with a separate production department (and other line and staff departments as well) in each product division. Some manufacturing firms organize production operations according to the markets for which outputs are destined; *e.g.,* industrial machinery, industrial materials and components, consumer products and military products. Integrated producers who perform all or several of the manufacturing processes entailed in the transformation of raw materials to finished products may organize by production stages. as extraction, transportation, refining and separating, product treatment and packaging.

The representative production organization. then, tends to be built around a line and staff structure containing components to do the staff work of advising, coordinating, controlling and providing services to line executives and departments, in addition to line subdivisions to which responsibility for the conduct of operations is delegated. In small firms, the structure is generally simple and all internal staff services may be provided by one or a few departments; in large firms, intricate administrative structures with numerous levels and a number of superimposed organizational forms can be found. Engineering functions such as product and process design. plant engineering and industrial engineering may be centralized or split among divisions; research may be divorced wholly or in part from production; purchasing and inventory control may be combined or separated, handled as part of production or not. Which production staff services are provided within a manufacturing division and which provided outside it depends on the particular company situation and history.

Functions and Problems. — The management of production may be treated in terms of: (1) the functions normally performed; (2) the problems that must be solved or decisions that must be made; or (3) both the problems encountered and the functions performed in planning. directing and controlling operations. In this discussion. emphasis will be placed on decision making because though essentially the same problems have to be solved in every manufacturing enterprise, there are many ways in which tasks can be combined in jobs, jobs grouped by functions and functions distributed to organizational units.

In the ultimate analysis, production management consists of making choices about the use of money, men, materials and time in production; *i.e.,* production problems are simultaneously human, technological and economic. While one aspect may be dominant in a particular instance. a production decision generally involves selection from the available alternatives of an economical and technologically feasible solution conforming to enterprise objectives and subject to constraints imposed by human factors. Seldom can decisions about production be based on examination of a single factor. What is technically best can be disproportionately expensive. Capabilities of man-machine combinations and not just machines or human skills alone determine performance.

In order to reduce a review of production management problems to reasonable dimensions, some classification is necessary. At the first level a small number of general problems may be distinguished. each of which is resolvable into a series of specific subproblems at the second level of classification. It is helpful to think of production as a system whose over-all function is transformation of sets of inputs into sets of outputs. Two kinds of processes go on in the system: the physical processes of handling and working materials for conversion of material inputs to product outputs; and the decision-making processes that govern operations. When production is viewed in this way, the general problems of production management are discerned as deciding, on the one hand, what the system shall be—what physical equipment shall be employed, what methods of operation shall be followed, what form of organization and channels of communication shall exist and what rules shall be applied for making routine decisions—and deciding. on the other hand, how the system as a nhole shall function at any point in time—what the quantity and assortment of output shall be, which production facilities shall be utilized and at what rates and what the composition of inputs shall be. As the solution to each of these general problems is a composite of sub-problem solutions and the functions of production management are just the things that are done to arrive at decisions and put them into effect, this discussion may move immediately to specific problems.

Forecasting. — Predictions of what products can be sold and in what quantities they can be marketed usually originate outside the manufacturing organization. Forecasting is nonetheless an important part of the production management process since production programs are shaped by expected general economic conditions, the outlook for the industry and the results of specific product market studies. While accuracy in forecasting is most vital when new products are being introduced, and especially when their introduction accompanies the launching of a new business, it is always a prime determinant of the effectiveness of production planning.

Consideration of production factors begins once existence of demand for a product is demonstrated. After the general prospects for new products are determined and before much time, effort and money are spent in developing detailed sales forecasts and plans based on them, preliminary estimates of production capability should be made: this requires answers to a number of questions. What will production costs be? Are the existing or proposed production facilities suitable for the volume and quality of output involved? What particular production problems will be met; for example, are materials available in dependable supply, are there processing hazards to be guarded against, will the work force have to be expanded or given special training and will the production pattern fit with that of other products? When dealing with established products in going concerns, answers to such questions are more easily available, but the same kinds of factors must be reviewed each time production plans are formulated for an extended period. If it appears that production can be accommodated to fit general product and volume objectives, more refined sales forecasts and plans for financing, staffing, purchasing and marketing can be attacked.

When a sales forecast in its final form is delivered to production executives, its requirements — expressed as product quantities and delivery dates — must be translated into a production program. In firms that manufacture exclusively to customers' orders, forecasts may possess little detail beyond estimates of total volume and general nature of work to be expected for stages following the immediate sales period in which orders in hand are covered. Where manufacturing is performed in anticipation of sales, product characteristics are predetermined and stocks of goods are carried in inventory; sales forecasts and production will usually be in considerable detail. Preparation of the master schedule for production — which takes into account lags between production stages, inventory status in the several product lines, changing sales patterns and availability of various production facilities — by production executives and their staffs is the central planning activity in production management and the point at which the diverse elements in production are finally coordinated.

Production Planning and Control. — The importance and complexity of the task of anticipating and planning for production requirements accounts for the existence of departments of production planning and control as separate entities in manufacturing organizations. These staff groups may be assigned additional functions but their main focus almost invariably is on problems of routing, scheduling, control and dispatching.

Routing. — The routing problem is one of determining for each product to be made the sequence of operations to be performed. Each part must be routed through processes, machines to perform each operation must be chosen and the instructions to operatives of what should be done and how to do it must be written up. In plants of the type called "job-shop" where the production layout groups equipment in departments on the basis of similarity of functions and each product lot may follow a path through the layout that differs from what precedes and follows, rather complete instructions (job orders) relating to tooling, machine operation, product specifications and the like must accompany each individual job released to work. The routing sheet is the form on which most of this information is collected. In plants of the line production type where the production layout has equipment and work centres placed physically in the sequence that successive operations occur on a representative product unit and each product run follows substantially the same path, the routing has been built into the plant arrangement. While doing the original routing and layout design is a complicated job, determination and communication of the order of operations is routine thereafter.

Scheduling. — Scheduling consists of setting the times at which operations will be accomplished. When numerous orders or runs with complex routings requiring many transfers of materials during production are to be in process simultaneously, the task of arranging over-all schedules for products, operating schedules for departments and machines and schedules for supply of materials and parts is formidable. With fluctuating demands for products, it takes considerable skill and intimate knowledge of production to arrive at schedules that are both feasible and economical in view of requirements for overtime work, inventory levels, stable employment and balanced utilization of equipment.

Control. — The problem of control consists of seeing that things get done when and as planned. Quantity, quality, timing and cost are the principal controllable variables dealt with; the control process consists of comparing current progress to planned performance and initiating corrective action as deviations appear. The aspect of control which production planning and control groups are most directly concerned with is control of output through the preparation and enforcement of schedules. However, since it is often convenient to collect data on several dimensions of performance simultaneously, the report forms and procedures handled by the production control staff are likely to be multipurpose, and the staff itself acts in a coordinating role.

Dispatching. — Dispatching, the function of issuing orders and instructions to the workplace and securing data on performance for transmission to management, is important enough to warrant identification as a separate activity in production planning and control. When only general routings and schedules are set up and some freedom is left dispatchers regarding order of work and assignment to machines and operatives, it is essential that they exercise good judgment, make fast decisions and deal with supervisors and workmen skillfully if the system is to operate satisfactorily.

Inventory Decisions. — Inventory problems are closely connected with operations planning and scheduling and, in consequence, inventory planning and control functions are usually combined with production-planning functions in organizations. Inventories in production are either planned to function as buffers between processing stages to allow their independent operation or appear as unavoidable concomitants of operations.

Inventories of raw materials are maintained to facilitate an even flow to processes as protection against interruptions of supply or because quantity purchases offer economies. The size of work-in-process inventories depends on how production is organized, the size of lots transferred between operations and the way in which schedules are constructed. Finished goods inventories are maintained so that production can be stabilized by building up inventory during slack seasons which is depleted during rush periods and so that various assortments of ordered items can be shipped without delay.

The general inventory problem consists of deciding at what points in the production system stocks shall be held and what their form and size shall be. As some unit costs increase with inventory size — storage, obsolescence. deterioration, insurance, investment, etc.—and other unit costs decrease with inventory size — setup or preparation, shortage, etc.—inventory management in part consists of determining optimal purchase or production lot sizes and base stock levels that balance opposing cost influences. Another part of the general inventory problem is deciding the levels (reorder points) at which orders for replenishment of inventories are to be initiated.

In addition to analytical problems, inventory presents problems of system design. Inventoried items must be identified, coded and catalogued so that they can be located readily when needed. Stock additions and withdrawals must be recorded so that inventory status is readily ascertainable and cost figures are kept current. Provision must be made for physical custody of inventories, storage space arrangements planned and procedures for delivering parts and supplies from stock points to work centres devised.

Facilities Problems. — Attention has thus far been centred mainly on problems of planning operations in a production system, the presence of the physical components of the system being assumed. The capacity and operating characteristics of the system, of course, are set by instrumental decisions on plant and equipment; moreover, such decisions are long-run in nature and normally result in large expenditures. they are crucial for the success of the enterprise. Initial decisions about physical facilities for production, honever, are continually modified in the majority of concerns as they grow, as the pattern of output is adapted to altered marketing conditions and as need for replacement of equipment becomes apparent.

In large manufacturing concerns, decisions about the size and location of plants must be made. It is necessary to choose how manufacturing functions will be distributed among decentralized operating units and where plants will be placed in relation to markets and material sources in view of costs of transportation, plant construction and operation and factors such as climate. community attitudes availability of utilities and presence or absence of competitive or complementary industries. The location of a factory within a selected general area and its siting so as to capture advantages of accessibility, ease of expansion and low construction cost are also significant decisions for the single-unit manufacturing firm as well as the multiplant firm.

Design of the internal arrangement of the plant and choice of the type of construction are further facilities problems to be solved. Analysis of production requirements imposed by the attributes of the products to be manufactured usually precedes selection of a general layout as it indicates what production processes and equipment units must be provided. Limitations on space and physical arrangement are posed by the size and shape of proposed production and materials — handling equipment. the need for access to work and storage spaces and building requirements. Working within these limitations, the planners endeavour to develop a scheme of layout minimizing product flow distances in a logical, orderly, easily maintained and safe arrangement.

Process design and equipment selection normally proceed parallel with layout: the problems are simultaneously technical and economic The technical problem is determining how desired product attributes can be created in manufacturing processes and nhat equipment can serve; the economic problem is deciding among process and equipment alternatives on the bdsis of over-all cost. The same general factors operate both in the case of original equipment selection and replacement of equipment which becomes inefficient or technically obsolete uhether production, material handling or other equipment is under examination High original costs may be justified by correspondingly high durability. increasing quality of output, ease of operation or other operating advantages. Optimal equipage must be determined in light of unit capacity, rate of operation, expected life, maintenance requirements, direct cost of operation, adaptability and versatility and any relevant special considerations.

Other Problems. — The résumé of production management problems given here can only be indicative not exhaustive the list is virtually endless. Some mention, however, should be made of the other parts of production management. No production system is complete unless means for quality control have been built into it. Production management is responsible for clear specification of product and process standards complemented by procedures for inspecting. testing and evaluating conformance to quality objectives. Simplification of nork methods by application of motion- and time-study techniques is yet another powerful tool, as is its extension to development of time standards and incentive systems. All the personnel problems of selecting. placing, rating and compensating production employees come within the scope of production management. Finally, the total job of production management is rounded out with responsibilities for plant and equipment maintenance, material handling, traffic management, provision of plant services. and analysis and disposition of a multitude of other physical problems of production.

Analytical Developments. — Because much of production management consists of contending with physical processes and variables with reasonably predictable behaviours, it always has tended to rely heavily on quantitative analysis. Viewed one way, production management is simply an arrangement for solving the classic econoniic problem of allocating scarce resources to relatively unlimited ends. The conceptual apparatus of economic analysis, as for example its marginal cost-marginal revenue approach, is immediately usable for production decision purposes. Cost minimization models for determining optimum inventory levels and making choices among production methods and equipment alternatives have long been used as a matter of course. Applications of probability theory in sampling inspection and process control are commonplace *(see* PROBABILITY; PROBABILITY AND STATISTICAL THEORY) Empirical and computational approaches to scheduling, designing and operating production processes, setting work standards and laying out workplaces are part of the intellectual equipment of every competent production manager.

Developments in the field of operations research or, more broadly. in the management sciences make it possible to push the quantitative emphasis in production management even further. Mathematical programming techniques are applicable to a variety of production allocation and scheduling problems. Queuing theory is being utilized in analysis of production lines and maintenance problems. System simulation, made feasible by stored program electronic computers, is being used to study the characteristics of complex production systems with the aim of improving system designs and decision rules. As automation of production and automatic control technology continue to advance, more reliance on mathematical research can be expected. Substantial contributions to the solution of production problems are still to come from game theory *(see* GAMES, THEORY OF), organization theory and information theory.

Despite the possibility that production management and other specialized managerial functions may eventually disappear and be replaced by a "universal" management science, no immediate and discontinuous change looms. Analytical methods shown to be helpful in making production decisions will be drawn from varied sources and used; but production management mill not soon become a mere package of techniques or management by formula. Production decisions are made by people in human organizations existing in a dynamic environment in which only the fact of change is constant. The ratio of science to art in production management may increase steadily, but it increases slowly. *See* also MANAGEMENT SCIENCES. (J. D. Rs)

PRODUCTIVITY, ECONOMIC: *see* ECONOMIC PRODUCTIVITY.

PROFESSOR, a term now confined to a teacher of a special grade at a university or college (Lat *profiteri*, "declare publicly." "profess"). The educational use is found in post-Augustan Latin. In the universities of the middle ages the conferring of a degree in any faculty or branch of learning meant the right or qualification to teach in that faculty, whence the terms *magister*, "master." and *doctor* for those on whom the degree had been granted. To these names must be added that of "professor." The "three titles of Master, Doctor, Professor, were in the middle ages absolutely synonymous" (H. Rashdall, *The Universities of Europe in the Middle Ages,* i. 21. 1895).

The first endowed professorship at Oxford was that of divinity, founded by the mother of Henry VII in 1502 and named after her the Lady Margaret professorship. The foundation of the Regius professorship by Henry VIII in 1546 tended to the general modern use of the word In England subordinate public teachers in faculties, or in subjects to which a professorial "chair" is attached. are known as readers or lecturers. In colleges and universities of the C.S professor indicates a teacher of the highest rank.

PROFIT, a term used by businessmen to describe the result of their operations when that result is favourable. When the result is unfavourable the term loss is commonly used. Strictly speaking, the word profit means "result," whether favourable or unfavourable; but it is obviously more convenient to speak of an unfavourable result as a loss than as a minus profit. As used by businessmen, the word profit must not be confounded with profits assessable to income tax or supertax. The rules for determining the liability of individuals or companies to these imposts are determined by statute. and are extremely artificial; similarly, profits in the business sense must not be confused with the economist's idea of profit.

If it were practicable for the businessman to wait until his business was discontinued and wound up before attempting to arrive at any idea of what his profits were, it would be possible for him to accept the economic definition of profits as "the surplus remaining over from the employment of capital after defraying all the necessary expenses and outlay incurred in its employment, and after the capital has been replaced or provision made for its replacement." But the businessman has to determine his profits as he goes along (1) because in no other way can he determine the most advantageous way in which to carry on his business; (2) because, in general, it would be impossible to obtain capital for business purposes, save upon the terms of distributing profits not less frequently than once a year, so that those contributing capital to enterprise may receive in return income by way of dividends. Hence the necessity of determining divisible profits from year to year.

It is absolutely impossible to determine the profits of a going concern from year to year with precision, because nothing more reliable than estimates can then be formed of the value of its outstanding obligations and unrealized possessions. But it would be unwise to distribute the whole of the profits year by year even if they were ascertainable, as mere this to be done there would be no margin left to cover contingencies, and experience shows that unexpected losses are bound to occur from time to time. The problem that besets the businessman year by year is not therefore how to ascertain the precise annual profits, but how to determine a figure of profit which can be divided without unduly jeopardizing the future prospects of the undertaking.

Further, because distributions out of profits are made regularly at definite intervals and are treated by those who receive them as income, it is important that no kind of gain should be treated as divisible profits which by its very nature cannot be expected to recur.

Capital Profits and Revenue Profits.—The businessman accordingly distinguishes between capital profits and revenue (recurring) profits. and pays dividends only out of the latter. Capital profits are increases of wealth arising from causes not directly connected with the carrying on of the business of the undertaking; *e.g.*, increases in the value of its fixed assets (*i.e.*, those assets held permanently as part of its equipment), a rise in the market value of which adds nothing to the fund out of which alone dividends can be paid.

Indeed, a permanent rise in the value of fixed assets is a source of embarrassment rather than of congratulation, in that it increases the ultimate cost of replacements as and when such assets are worn out, and thus then at least tends to deplete the fund available for the payment of dividends. Conversely, capital losses arising from a fall in the value of fixed assets do not affect divisible profits so long as these assets continue to be equally effective as profit-earning equipment, while a fall in the cost of renewals is advantageous from a revenue point of view.

Of course, if and when a business is discontinued and wound up, capital losses and profits will materialize. If on balance there have been profits on capital, the fixed assets will realize more than they otherwise mould have realized, and a correspondingly larger sum will be available out of which to make a return of capital or, rather, there will be a balance of capital profits to divide after capital itself has been returned in full.

Conversely, if on balance there have been capital losses, the fixed assets will not realize a sum sufficient to enable the whole of the capital to be returned, and there will therefore be a realized loss on liquidation. Where the business is owned by a limited company, this means that the shareholders (or the holders of some class or classes of shares) will not receive the whole of their capital back; but if the business be owned by a concern not subject to limited liability. *e.g.*, a partnership, the members will have to contribute among them the ascertained loss pro rata, according to the shares in nhich they were entitled to participate in profits, and there will then be a sufficient fund to enable the whole of the capital to be returned to those who provided it.

In the case of a partnership, it is usual to divide the nhole of the profits as shown by the annual accounts; but in the case of a company, it is not usual to pay away as dividends the whole of the profits shown by the annual accounts. A part of these profits is normally held back as a reserve against unforeseen contingencies, and another part is normally "carried forward," partly with a view to equalizing dividends in good and bad years, partly to avoid the inconvenience of paying away profits which have perhaps not entirely been received in cash.

PROFITEERING, a term that came into use during World War I. It is generally applied when an individual or firm makes unreasonably large profits during a public emergency which adversely affects the fortunes of others; it usually connotes that the recipient of these profits has acted improperly in obtaining them. Although the term has been used most frequently in connection with wartime situations, it is applied during other types of emergencies as well; *e.g.*, excessive inflation. While the word itself is comparatively new. it describes an old phenomenon. During every war, some individuals and firms have made inordinate profits, particularly those producing and selling munitions.

Numerous situations make profiteering possible. For example, an embargo may shut off the supply of certain articles; the government may suddenly and substantially increase its purchases of scarce materials; individuals with higher incomes as a result of wartime employment may buy more goods and services; and with all this, the state may fail to effectively regulate prices and profits. The history of profiteering and its sequel, antiprofiteering legislation, discloses continuous public concern with the problem and greater refinements in the devices employed to eliminate it.

United States.—During the Revolutionary War the Continental Congress recommended to state legislatures that they regulate the prices of commodities and services in view of the "spirit of sharping and extortion . . . being confined within no bounds." Most of the state legislatures responded with laws that regulated the price of practically every commodity as well as labour wages. One of these laws was directed against the "wicked arts of speculators, forestallers, and engrossers, who infest every corner of the country."

During the Civil War. government suppliers often received higher than market prices for their goods. One supplier might have been preferred over another because he had hired an influential representative to deal with the government. An attempt to prevent such conduct was made by changing the procedures for awarding and checking on contracts. Contracting officials were required to advertise all contracts they proposed to award, where this was practicable, and new criminal statutes to eliminate bribes of public officials were enacted. In addition, a special commission was established to review certain contracts in connection with the awarding of which improper dealing was suspected. This commission had no power to require adjustment of contracts but the publicity given to these transactions persuaded some contract holders to agree voluntarily to accept lower prices than those for which they had originally bargained. No attempt was made during the Civil War however to eliminate profiteering which took place outside the area of government contracts or to control prices and the profits received under government contracts.

Before the Spanish-American War, congress for the first time sought to limit the profits of defense suppliers directly when it imposed a maximum price at which armour plate might be purchased by the navy department.

The outbreak of World War I increased the demand for United States goods. When the U.S. entered the war in April 1917, prices had risen 70%; there was also a sharp increase in corporate profits. Before the U.S. entered the war, congress made no serious effort to limit profits, confining itself in this regard to a special tax of

$12\frac{1}{2}\%$ on profits from the production of munitions and an 8% over-all excess-profits tax. After the U S. entered the war several devices were employed in an attempt to eliminate what was now called profiteering.

First, a new kind of contractual arrangement was evolved The profits of defense suppliers could not be controlled merely by requiring competitive bidding because as prices of raw material and labour began to rise rapidly contractors refused to take fixed-price contracts. In an effort to protect suppliers against the risks of unanticipated costs and the government against excessive prices, the government began to negotiate contracts under which the supplier was paid his actual costs plus a fixed percentage which represented his assured profit. It became apparent however that this type of arrangement stimulated the supplier to increase rather than decrease his costs of performance and was potentially more costly to the government

Second, congress and a variety of administrative agencies established maximum prices for certain commodities: basic raw materials and fuels, munitions of war and general consumption necessities. In general. profits were not considered to be sufficiently regulated by this method and a third device, the excess-profits tax, was ultimately relied upon as the principal method of eliminating excessive profits during World War I. The first such tax was imposed in 1916. The rate of tax upon excess profits was increased in subsequent years until it reached 80% in 1918. Although over-all profits of corporations declined in 1918, individual companies, especially those engaged in supplying the government directly, nere able to make what were regarded to be abnormal profits despite the measures just described.

While profiteering was doubtless curtailed by the more aggressive controls of World War I, it was by no means entirely eliminated. During the period between World Wars I and II there was a continual outcry against the war profiteering that had taken place. It was even contended that by their desire for profits, munitions makers had helped bring about the war. The American Legion backed various bills to limit mar profits and in 1924 the platforms of both the Democratic and Republican parties contained planks for the control of profits realized from war production.

The first positive action in this area was taken by congress in 1930 when it eitablished a commission to investigate methods of equalizing the burdens of war and determine how war profits could be eliminated: this commission recommended a wartime excess-profits tax of 95%. In 1934 the Nye committee of the senate began hearings to investigate the munitions industry. The committee recommended such measures as the nationalization of the peacetime munitions industry and the imposition of a wartime tax of 99% on personal incomes over $20,000 as well as an excess-profits tax on corporations. Although congress proceeded more moderately. it did take a step in the direction of eliminating large profits from defense contracts when it enacted the Vinson-Trammell act in 1934. This law, as amended and supplemented in the following years, limited the maximum allowable profits of airplane and vessel builders and certain of their suppliers to a percentage of the contract price: the allowed profit was 10% and 12% depending on the type of article involved. This limitation mas suspended in 1940 in favor of an excess-profits tax of 90% on all corporations, whether or not they were government suppliers. While this bill was designed primarily to raise revenue, it sought to achieve this by distributing the burden of national defense in a manner calculated to prevent profiteering.

With the entrance of the U.S. into the war in 1941 and the attendant expansion in munitions production, the concern over profiteering mounted. Congress initially used an approach similar to that employed in the suspended Vinson-Trammell act. It considered limiting the profit-cost ratio of munitions makers to 6%. While such an approach doubtless would restrict profits, it discouraged rather than encouraged reduction of costs and production of the most effective munitions in the most economical manner.

In 1942 a new and more flexible device for profit control called renegotiation was introduced; thereafter it played an important role in attempts to control profiteering. Renegotiation involved an annual review by the government of a supplier's profit after the performance of his contracts and the refund by him of portions of his profit that the government regarded as excessive under all the circumstances. The advantage of this procedure was that it provided a spur to efficiency since. in theory, the efficient producer might retain more of his profits than the inefficient producer.

Two other devices were employed to eliminate profiteering during the war: one was the excess-profits tax, already discussed; the other was price control. The Office of Price Administration was established in 1941, "to prevent spiraling, rising costs of living, profiteering, and inflation resulting from market conditions." The OPA imposed maximum prices on most commodities and services other than those sold to the military departments.

The activities of the renegotiation and excess-profit authorities suggest in some measure the extent of profiteering that occurred during the war. From defense expenditures of over $190,000,000,000 that mere subject to profit control, renegotiation led to the direct recovery by the government of over $10,000,000,000. Additional amounts estimated at about $4,500,000,000 were refunded through voluntary adjustment of contracts by firms subject to renegotiation. The government also recovered from the defense and nondefense sectors of the economy about $16,000,000,000 in excess-profits taxes.

In 1948. when the nation embarked on unprecedented peacetime expenditures for defense, profit controls in the form of renegotiation were reinstated, principally upon aircraft manufacturers and some of their suppliers. In 1950, after the beginning of the Korean war, profiteering again became a matter of major concern and a series of laws was passed by congress. The Defense Production act of 1950 conferred authority upon the president "to prevent profiteering." A new excess-profits tax law was enacted whose main purpose was the raising of revenue by assessing those "corporations whose profits are higher than they probably would have been in the absence of hostilities and a large military budget." Finally, in March 1951, a new renegotiation act was enacted which applied to most defense contractors and suppliers.

The first two laws ceased to be effective in 1953; as early as 1952 congress directed that price regulations be suspended immediately in cases where no inflationary pressures existed. The excess-profits tax lasted only a short time after the end of hostilities in Korea. Only the Renegotiation act of 1951 which applied solely to profits from defense contracts was continued although its scope was gradually whittled down so that its main impact was on the aircraft and space industries.

Great Britain and Etarope.—As in the United States, profiteering in England and on the continent is an old phenomenon; the legislation enacted to combat it is perhaps the best evidence that profiteering existed. Price control laws are found as early as the 4th century in the Roman empire. In 1793. while France was being blockaded by the British fleet, the French government passed the "Law of the Maximum," nhich fixed prices for grain and other commodities with reference to 1790 prices and set wages at a level of 50% above those of 1790. In England prices and wages were regulated from time to time from the 14th century.

Beginning in the mid-19th century, army purchasing procedures in England were centralized and tightened in an effort to eliminate profiteering; however. these procedures had to be loosened at the beginning of World War I when it became necessary to purchase uncommonly large amounts of supplies within a short time. Among other things, competitive bidding for contracts had to be abandoned.

As soon as purchasing controls were relaxed. much criticism developed concerning speculation and profiteering in mar contracts. As a result, the government took over production of many munitions; it also adopted new contracting procedures in connection with the defense production performed by the civilian sector.

Among these was the use of the target cost contract: this prescribed in advance a target cost of production and provided that if the costs actually incurred by the contractor were below this figure, then a share of these savings was to be paid to the contractor along with his actual costs and the profit previously agreed upon. The virtue of this type of contract as compared to the traditional fixed price was that it prevented a defense supplier from profiteering and at the same time gave him an incentive to produce as efficiently as he could.

The British government also began in 1915 to tax excess profits being generated from the war. This form of profit control spread rapidly to other parts of the British empire and all of Europe. In addition to these relatively new devices to combat profiteering the British government employed the old device of price fixing; by 1916 the maximum price of several commodities was being prescribed by the government.

The excess-profits tax was continued in England for a short time after the war; price fixing was not only continued but reinforced by the Profiteering act of 1919. Under this law, which was the first to include the term "profiteering" in its title, the Board of Trade investigated the prices of many commodities and the profits derived from dealing in them: it then issued reports reflecting the results of its investigations. The act lapsed in 1921 before it accomplished a great deal; the problem of profiteering to which it had been addressed ceased to exist as soon as unfavourable economic conditions began to push the price level downward.

The inflation which raged in Germany in 1923 resulted in the establishment of a cartel court which had the responsibility of bringing about reductions in and preventing increases in prices when profiteering seemed to be taking place. During most of the interwar period in Europe profiteering was not a matter of great concern; rather, during the great depression there was the apprehension that profits and prices were not adequate for the proper functioning of the economic system.

As soon as World War II began there was again a preoccupation with ptofiteering. Germany began the war with a thoroughgoing system of price control which at first sought to hold prices and wages at 1936 levels and which required justification for any price increases or for the maintenance of prices that appeared to be yielding excessive profits.

Bitter memories of World War I and its aftermath reinforced the resolution of the government in Great Britain as well to prevent windfall gains from arising as the result of the war. In 1939 the Price of Goods act was enacted to fix prices at levels designed to freeze sellers' incomes at prewar levels. This act and the Goods and Services act passed in 1941 prevented undue price rises at the retail level but was largely ineffectual at the manufacturer's level. The difficulty was that it was necessary to leave prices high enough to provide an incentive for the production required for the prosecution of the war. This meant that the low-cost producers frequently earned high profits; accordingly, the attack upon profiteering in this area had to be made from another direction.

In general an attempt was made to set firm prices on contracts; however, in order to minimize profiteering the government in many cases postponed the establishment of a firm price until production was well advanced and cost experience had been gained. The objection to this was that. to the extent that the price finally was based upon realized costs, the contractor had no incentive to keep down his costs. An attempt was then made to use target cost contracts as in World War I in order to restore this incentive, but it was usually as difficult to negotiate a realistic target cost in advance as it was to negotiate a fixed price. Ultimately, a choice had to be made in connection with each purchase between the fixed-price contract with its inherent risk that excessive profits would be realized by some contractors and various types of contracts under which the supplier's compensation was determined primarily with reference to actual costs incurred by him.

In general there was no attempt to recapture excessive profits from prime contracts after they were realized, as renegotiation did in the United States; however, an informal procedure resembling renegotiation was instituted with respect mainly to subcontractors. They were required to submit periodic over-all trading reports which disclosed the profits they had made from defense contracts; they were required to refund that portion of their profits considered by the contracting agency to be unreasonable. By 1948 some £57,000,000 had been recovered in this manner from several thousand contractors.

Beyond all this, an excess-profits tax was imposed which, after May 1940, was at the rate of 100% and which was computed with reference to profits earned from 1935–37. Parliamentary concern with the question was so great that the adoption of this extreme remedy against war profiteering did not result in the discontinuance of the other efforts to prevent excess profits.

After the end of World War II, most of the wartime controls over prices and production were maintained because of shortages. Food rationing did not entirely cease until the summer of 1954 and some price controls lasted even longer. Other measures directed against profiteering however lapsed at the end of the war.

PROFIT SHARING is a system by which an employer pays to his employees a share of the profits of the undertaking in which they are engaged in accordance with a scheme defined in advance. The way in which profits will be divided between the shareholders and the employees is therefore known beforehand, and the amounts distributed vary from year to year according to the profits actually earned.

EUROPE

As far back as 1889 an International Congress on Profit Sharing held in Paris defined profit sharing along these lines as payments made in accordance with a freely agreed scheme, of a share, determined in advance and not variable year by year at the discretion of the employer. of the profits of an undertaking to a substantial proportion of its ordinary employees. These payments are distinct from and additional to wages. which are generally paid by the undertaking at rates current in the industry and locality. By the requirement that schemes must be "defined in advance," profit sharing proper excludes gifts, gratuities or other payments made by an employer to his employees out of profits at his discretion without being bound by a scheme. An employer is usually free to terminate a profit-sharing scheme at any time, but until he does so he has bound himself to observe its provisions. The Paris definition excludes schemes in which a share in profits is paid only to a small number of administrative and technical staff and not to manual workers.

As the payments must be related directly to profits, any systems of production bonus, individual or group piece rates, or other methods of payment based on output are not profit sharing. Similarly, systems by which the total production or gross proceeds of an undertaking are divided in predetermined proportions—for example, by share fishermen, and in some forms of land tenure (*e.g.*, metayage)—must be excluded, as something other thin profits is being shared.

On the other hand, copartnership (*see* below) is a form of profit sharing if employees are given shares in the capital of the undertaking in which they work or if such shares can be acquired by them on specially favourable terms.

Early Examples.—France can claim to have been the pioneer in profit sharing, several schemes having been started before the middle of the 19th century. The earliest known example was that introduced by the French National Fire Insurance company in 1820, and in 1842 the Paris firm of E. J. Leclaire, house painters and decorators, started a scheme which attracted wide attention in France and abroad. During the next few decades other French firms started schemes, some of which were highly successful; for example, those introduced by Godin of Guise and by the Bon Marché store.

Development in Great Britain.—The French schemes attracted considerable attention in England about the middle of the 19th century, and their principles were advocated particularly by the Christian Socialists, who influenced co-operative societies to apply them to their employees. Later the co-operative movement developed along somewhat different lines, and most of the consumers' co-operative societies and the co-operative wholesale societies ceased to practise profit sharing, though the system was retained by some co-operative production societies especially in the boot and shoe industry and in clothing. printing and building.

Outside the co-operative movement the first important scheme was that of Henry Briggs, Ltd , a firm of Uorkshire colliery owners, which introduced profit sharing in 1865. At first the scheme was very successful, but the directors ended it because their employees took part in a strike for higher wages. During the period 1880 to 1910 about 240 schemes are known to have been started, at a rate of about 80 each decade, most of them being straight profit-sharing schemes, but some of them took the copartnership form by which employees aere given opportunities to share in profits by the acquisition of shares on specially favourable terms. The rate of growth was much greater during the years from 1910 to 1920 when prices were rising rapidly and big wartime and early postwar profits were being earned. More than 200 schemes were started in this decade. After the onset of depression in 1921 fewer schemes were started. but the number was still around 140 in the ten years to 1930. During the depression years of the 1930s still fewer schemes were started. However, during these interwar years more schemes were soundly based, as there was better knowledge of what was involved than when the earlier schemes were started. Some of the earlier schemes nere based on wrong motives and unsound methods, and about 85% of those started before 1900 had been discontinued by 1930, many of them having a life of only 10–20 years. A few, however, continued successfully for more than 50 years and were still in operation in the mid-20th century. Also many of the discontinued schemes could claim success during two or three decades. As would be expected more schemes are started in years of prosperity than during periods of depression, and the discontinuance of schemes is greatest in depression years.

Among firms with long-established and highly successful schemes mention may be made of Clarke, Nicholls and Coombs. Ltd.. J. T. and J. Taylor, Ltd., Reckitt and Colman, Ltd., Rowntree and Co. Ltd.. E. S. and A. Robinson, Ltd., Bryant and May, Ltd., and the Bradford Dyers' Association, Ltd.

An average of not much more than one-half of the employees participate, some being excluded because they have not worked uith the company for a specified minimum period or because in some schemes only adults are entitled to benefit. At the beginning of 1954, in approximately 350 profit-sharing companies in Great Britain, the number of participating employees mas fewer than 300,000, or less than 2% of the total number of persons in employment throughout British industry (excluding those in the nationalized industries, professions and central and local government services in which profit sharing could not be applied).

The industry in which profit sharing is most widely applied is the chemical industry. In most other industries there are some profit-sharing companies, though they form only a small minority in any industry. Until after World War II the biggest development was by the gas companies, especially in the London area. This began in 1889 when the South Metropolitan Gas company introduced a scheme by which employees were paid a cash bonus varying with the profits of the company. After revision the scheme took the form of copartnership, half the bonus due to the employees being used to buy for them ordinary shares of the company, and the other half being left with the company to accumulate with interest but with the right of withdrawal by the workers in special circumstances.

Finally, in 1920, the scheme was made statutory by legislation which provided that surplus profits, after payment of prescribed basic rates of dividend on capital, were to be divided in the proportion of three-quarters for the benefit of consumers by reducing the price of gas, and the remaining quarter in equal parts to the ordinary stockholders by increasing their dividends and to the employee copartners as a percentage bonus on their salaries and wages. 4s before, half the bonus was capitalized and the other half invested subject to the right of withdrawal in special circumstances. Nearly all the leading gas companies and many of the smaller ones introduced similar schemes, which proved highly successful and resulted in large amounts of the capital of the companies being owned by the workers. They were, however. terminated by legislation passed in 1948 to nationalize the gas industry; compensation was arranged to cover loss of the remuneration which the employees had received as copartners.

In the years of prosperity immediately after the middle of the 20th century, increased interest in profit sharing and copartnership was shown by certain leading firms, and both the Conservative and Liberal parties in Great Britain favoured the adoption of schemes as a means of promoting better relations between management and employees. The biggest company to propose a scheme was Imperial Chemical Industries, Ltd.. which announced in May 1954 a plan of the directors to introduce profit sharing which would initially cover about 75,000 of its total of 107,000 workers in Britain.

The scheme provided for payment each year to adult employees with $2\frac{1}{2}$ years' service or more of an amount equal to 1% of the employees' annual remuneration for each 1% by which the dividend to ordinary shareholders exceeded 5%. These amounts would be invested in the ordinary stock of the company at the current market price and would be held by trustees until an employee had a minimum of £25 of stock to his credit,, when it would be turned over to him without any restriction. The directors retained power to amend or terminate the scheme. They regarded it as a further step in their progressive personnel policy, and as a means of developing a better understanding among their employees of the economic problems of the company and of the country.

Types of Scheme. — Most schemes of profit sharing and copartnership have been devised on the initiative of individual firms, and in consequence schemes vary widely to suit the conditions of each company and the purposes and attitudes of the employers who introduced them. Some undertakings are in process of growth while others have reached stability, some are in industries which experience wide fluctuations in prosperity and need to set aside bigger reserves in good times to meet periods of depression than are required by undertakings in industries which enjoy steadier demand, and some undertakings have much higher labour costs in relation to total cost than others. In some companies, equity capital forms only a small proportion of total capital, whereas in others it is a high proportion or even the whole of the capital.

Profit *Sharing*.—Schemes are of three main categories, namely profit sharing alone, profit sharing combined with some kind of copartnership through ownership by employees of shares in the company, and shareholding without copartnership. Schemes of profit sharing usually provide first for payment of all working expenses, amounts necessary to cover depreciation and reserves, interest on debenture stock and preference shares and a specified percentage, often 5% or 6%, as dividend to ordinary shareholders. Then employees entitled to participate receive a defined share of any surplus profit. This surplus may be divided equally between employees and shareholders, or shared in some other proportion. An alternative is to distribute to employees an amount not exceeding a specified sum, say £50,000, the remainder of the surplus being paid in additional dividends to the ordinary shareholders. One variation is for one-half of surplus profits to go to the employees, one-tenth to the management and two-fifths to holders of ordinary share capital.

Where capital costs are high, less than one-half of surplus profits may be distributed to the employees, the proportion being sometimes only 10% of the surplus.

In order that an employee may be entitled to share in surplus profits, a qualifying period of employment in the firm is required by most schemes, the period often being a year, but in some schemes it is several years and in others only three months. Some schemes provide for bigger shares according to length of service, one scheme, for example, providing that an employee with ten years' service shall receive five times the share of an employee with one year's service; usually, however, when length of service is taken into consideration the increase is much less. Lateness is penalized in some schemes.

Some schemes restrict participation to adults in manual and similar grades; in others juvenile workers receive lower rates of payment than adults. Some schemes pay higher rates to managerial and other salaried staff than to manual workers, this method being based on the belief that salaried staff have a bigger influence than manual workers on 'the amount of profit. For this reason some schemes provide for payment of a higher rate to foremen than to manual workers.

Surplus profits are usually divided among the participants on the basis of each employee's wage or salary. This ensures that persons will share in profits roughly according to their value to the firm, the skilled workers receiving more than the unskilled. The amount which a worker receives varies considerably from industry to industry, from company to company and from year to year. A frequent rate, however, has been about 6% of earnings or an addition equal to about the amount a worker would earn in three weeks.

In more than one-half of all British schemes of profit sharing and share ownership the share of profits is paid in cash or is credited in a savings account. Nearly one-fifth of all schemes consist of the issue to employees of shares in the company on specially favourable terms or provide for the payment of dividends varying with profits on deposits made by employees. In a few schemes the amounts due to the workers are paid into a provident or superannuation fund.

Share *Ownership.*—Employees of a company, like any other persons, can buy its shares on the stock exchange, but some firms have made available special shares which can be obtained only by their employees. There is great variety in these schemes. but each is a method of saving and is intended, like profit sharing, to give employees a better understanding of the economic and financial problems of the firm for which they work and to increase their interest in its success. Some schemes combine profit sharing with share ownership by providing that the whole or part of the amount due to an employee may or shall be invested in the firm's shares. Thus, such investment may be voluntary or compulsory. Alternatively, shares in some schemes may be bought by installments paid out of personal savings, often by deductions authorized by the worker from his wages. The shares may be sold to employees at par, at market price or under market price.

These schemes, which enable employees to accumulate substantial amounts in shares over a period of years, have a greater "expectation of life" than profit sharing in which only cash bonuses are paid. As these amounts are savings which employees can ill afford to lose, many companies provide safeguards to maintain the value of the special shares issued to them. Dividends on employees' shares are usually at the same rates as on ordinary shares, but some companies issue special preference shares, with a specified rate of interest (*e.g.,* 6%), and these shares may or may not receive additional interest if dividends beyond a given rate are paid to ordinary shareholders.

Where a company has profit sharing and share ownership, participating employees receive their share in the profits and also interest or dividends on the shares they hold.

Most schemes impose restrictions on the holding of special shares, often providing that the shares must be returned to the company on the death of the employee or on his leaving the company's service. Many companies pay the par value when such shares are returned. but some pay the market value. Payment of par value protects these savings of employees against loss but reduces the value of the scheme as an education in the risk run by investors. The employee holders have a stake in the business by receiving dividends which vary with changes in the firm's prosperity, but their capital is safeguarded against the effects of such changes. Ordinary shareholders are free to sell their shares whenever they wish and can exercise their judgment when to sell so as to make a profit or avoid loss, but employees holding special shares are not able to do so, and this is one reason why they are often given the safeguard of a guaranteed value.

Copartnership.—Copartnership between employers and employees implies some participation by the employees in the management of the business. This may range from consultation in works councils or joint production committees to attending and voting at annual and other general meetings of shareholders and electing employee representatives to the board of directors. An increasing number of companies regularly give to their employees information about the economic and financial position of the business, its problems, policy and prospects. The managing director may make statements on these matters, and arrange for summaries to be published in the works magazine. In many firms. representatives of the employees take part in the management of welfare and social activities. These methods result in greater influence by employees on the business in which they work, and their status is raised.

Often the extent of copartnership with employees may be slight and nebulous. In copartnership in its more developed form, the holders of employee shares have the same rights as other shareholders to attend and vote at general meetings, and they also cooperate with management by some method of joint consultation. Only a few schemes provide for employee shareholders to be represented on the board of directors, and even then their representatives are in a minority and their influence is often small, as they lack adequate experience of the economic, financial and technical problems of the business. In these schemes, only those employees who have had considerable service with the firm (for example, ten years) and who hold a specified minimum number of shares can be nominated for election as directors.

Attitudes of Employers. — The fact that, after a century during the larger part of which there has been active propaganda in favour of profit sharing, not more than about 900 companies have adopted schemes, and that nearly one-half of this small minority of companies discontinued their schemes within two or three decades, is a clear indication that the great majority of employers have not been attracted by profit sharing.

Most employers consider that in the same way as they pay market prices for their raw materials, they should pay to their employees current rates of wages, and they point out that in periods of prosperity employees gain higher wages and thus share in prosperity. Profits should, in their opinion, accrue to those who undertake the financial risks of the business. Some argue that if employees share directly in profits they should similarly carry directly a part of the burden in years when losses are incurred. Many do not regard profit sharing as an appreciable incentive to more sustained effort, especially as those employees who work harder receive only the same share as those who make no greater effort. They claim that there is no satisfactory way of measuring what increase in output results from profit sharing. Against this, however, several hundred employers whose schemes have worked successfully, while not claiming that they can measure results in terms of increased output, are satisfied that profit sharing leads to better industrial relations. as the employees feel that the company is giving them a fair deal and that there is social justice in employees' participating directly in profits toward which they have contributed by their labours.

Attitude of Trade Unions. — Trade unions have been generally hostile to profit sharing and copartnership, partly because, in the early days, some employers used them as a weapon against the unions. The workers were told that they would gain more from these schemes than from action by trade unions to raise wages. Also workers in some firms were warned that the profit-sharing schemes would be terminated if they went on strike for higher wages and other trade-union demands. Trade unions fear that profit sharing will strengthen the loyalty of workers to their firm and weaken their interest in the trade-union movement. The policy of trade unions is to gain the best possible general level of wages and working conditions for their members. and in Great Britain the unions have worked to secure standard rates of wages throughout an occupation or industry. With profit sharing the workers' incomes would vary from firm to firm according to the profits of each, but British unions are not concerned with special differential advantages for employees who are fortunate enough to be employed by firms here and there which are exceptionally prosperous. Also. as profit-sharing schemes are usually introduced on the initiative of employers, the workers receive benefits which the unions have not won for them. The unions have found no method of regulating profit-sharing schemes by collective bargaining agreements.

The former hostility of trade unions changed somewhat in the interwar years and after World War II, and the attitude became one of indifference or mild acquiescence. This was largely because employers ceased to use profit sharing as a weapon against the trade unions but tended instead to discuss schemes mith their employees and often with trade-union representatives before introducing them. The greater strength of the unions would enable them to oppose successfully the misuse of profit sharing by employers. Workers in firms with profit-sharing schemes welcome the additional remuneration they receive.

Value and Limitations. — Reasons have been given why many employers have not introduced schemes and why many schemes have been discontinued after a few years. Those employers who have introduced schemes because they believed their workers would be stimulated to greater effort and that output would rise appreciably have been disappointed. This has been largely because profits depend upon many factors in addition to the efforts of the workers; for example, the efficiency of management and market demand for the products of the undertaking. As an inducement to greater production by the workers, the relationship between effort and reward is not close enough. Profit sharing is much less effective as an incentive than systems of payment by results where remuneration is directly related to the efforts of a worker, and where he receives his reward with little delay, whereas his share in profits is remote. having to wait until after the annual general meeting of the company. During periods of depression when profits have been small or nonexistent, schemes have foundered because they ceased to interest either employers or employees. A scheme may be sponsored by an employer who has faith in profit sharing and operates it successfully, but the firm may later come under new management unfavourable to profit sharing and the scheme is terminated. Even the success of some schemes has resulted in their being discontinued; for example, companies with stable profits have frequently distributed amounts which varied so little from year to year that the share in profits has finally been used to increase rates of wages and sharing of profits has been abandoned.

Profit sharing or copartnership provide only one among many ways of promoting good relations in industry. The most successful schemes have been those in companies where profit sharing or copartnership have formed part of a comprehensive program for promoting good will. Applied in this way, profit sharing and copartnership can strengthen the mutual interest which capital, management and labour have in the efficient running of the undertaking, ensure a better understanding by the employees of the. economic problems of business enterprise, broaden the basis of capital ownership and raise the status of employees.

Other Countries. — Detailed information is given in a separate section on the United States where profit sharing has had proportionately less application than in Great Britain, and where the rate of termination of schemes has been somewhat greater. In most of the countries of western Europe, including France. Germany, Belgium, the Netherlands. Switzerland and Italy, profit sharing has been adopted by a small number of firms but the numbers of firms and of participating employees have been relatively fewer than in Great Britain. Among these countries the greatest development is in France, where the biggest application is by insurance companies, some of which have had schemes in operation successfully for half a century. Among the few schemes in Germany which have had a long life, the best known is that of the Zeiss firm of optical glassmakers. In European countries copartnership is rare, most of the schemes providing that the share of profits due to employees shall be paid to them in cash or as credit in a savings fund. There are a few profit-sharing schemes in Australia, and also in New Zealand where an Employee Partnership institute has undertaken propaganda for copartnership.

Profit sharing is compulsory in Venezuela, this being required by the Labour law, and substantial amounts are paid annually to employees by the larger firms, including the oil companies. The law provides that specified proportions of profits shall be shared nith employees up to a maximum equal to two months' wages in large firms and one month's wages in small firms; the proportion ranges from 2.05% of profits in small firms to 12.45% in large firms. In Chile a law was passed in 1950 making it compulsory for firms to pay a share of profits to their white-collar employees. In France laws have been enacted to make profit sharing compulsory for workers' productive co-operative societies, but these societies, which are usually small, differ from the usual kind of business. In several countries, *e.g.*, France. New Zealand and New South Wales, permissive legislation has been passed to enable compliance with the Companies acts to be effected by undertakings wishing voluntarily to introduce profit-sharing schemes.

UNITED STATES

The term profit sharing is recognized in the United States to include varied types of plans and concepts. The old idea that a genuine profit-sharing plan had to provide that an employer would pay to his employees, over and above their regular wages, a share of the company's profits in accordance with a predetermined formula was modified in America by actual developments. Important companies which do not have a "predetermined formula" have shared profits with their employees over many years. A U.S. senate committee included under the term any plan which provided extra income from the employer, over and above regular wages, under a systematic plan. This was a broader concept than that generally accepted.

However, neither the National Industrial Conference board (NICB), which issued five reports on profit sharing (1920 to 1948), nor the Profit Sharing Research foundation (PSRF) reports considered profit sharing to be so inclusive. The latter. in its 1954 report, *Profit Sharing Patterns,* said: "Profit sharing is any procedure under which an employer pays employees, in addition to regular pay, special current or deferred sums based on the prosperity of the business as a whole." This concept was substantially the same as that of the National Industrial Conference board.

Some companies have "limited" profit-sharing plans which cover only officers and "principal employees"—those persons who know that their own efficiency directly affects profits. Such plans are primarily incentives to executive personnel and must be distinguished from "true" profit sharing, which shares a part of the profits mith rank and file employees. The remainder of this article discusses only "true" profit sharing.

Unions and Profit Sharing. — After 1940 profit-sharing plans were established in many U.S. companies whose labour relations were subject to union-management collective bargaining. This was a distinct departure from the situation which existed before 1940, when profit sharing and collective bargaining were seldom found in the same companies. Unions were suspicious of the bookkeeping procedures used in figuring profits; they looked upon profit sharing as a clever device to attach employees to their employers and weaken the appeal of unions; they thought that it would lead to "the speedup" and that it was incompatible with collective bargaining.

In 1954, 258,530 of 600,830 employees working for 300 companies with profit-sharing schemes were in unionized plants and 47,270 more in partly unionized plants. The reason for this change is clear. In 1942 new federal tax rulings enabled employees to get, in lieu of wage increases denied them during the war, profit-sharing benefits under plans conforming to certain government specifications. Naturally, unions were alert to this opportunity.

By the early 1950s some unions had changed their attitude sufficiently so that they wanted to include profit sharing in the list of matters dealt with in collective bargaining. For instance, in 1951 both General Electric company and the Westinghouse company received union requests that union-management committees be set up to explore the possibilities of profit sharing and that the report of such committees be considered during contract negotiations. Neither company agreed. but profit sharing may become a subject of collective bargaining at least in some industries.

History. — Previous to 1942 profit sharing never attained considerable proportions in the U.S. Though experiments with it began as early as 1867, only 50 plans were known to exist in 1896 and only 12 of them remained in operation until 1916. C. C. Balderston's study published in 1937 found only 67 plans in active operation at that time. But in 1942, sec. 165 of the Internal Revenue code. subsection (h), provided that employers' contributions to profit-sharing funds. collected and disbursed as specified by the code, should be deductible expenses for purposes of taxation and there was an immediate upsurge in profit sharing. With wage and salary rates practically frozen during the war many employers saw in tax-deductible contributions to profit-sharing funds a means of supplementing employees' wages and decreasing labour discontent. For concerns in excess-profit brackets only about 15% of each dollar set aside for profit sharing came out of the company and the other 85% out of money which would otherwise have been paid as taxes.

In addition to the value of the contributions and the investment earnings of the reserve fund to their credit, employees stood to gain from the fact that when they received the annuities to be paid to them after they retired, they would pay taxes only on the reduced income they would then be receiving. In other words, they would be in a lower income bracket than they were during the years when the fund was being accumulated.

An employer was not permitted by the federal tax code to deposit to the credit of an employee in any year a sum greater than 15% of the employee's wages or salary during that year. Moreover, the employers' contributions had to go into trust funds for deferred benefits. They could not be paid to employees as current cash income. The plan had to be for the exclusive benefit of employees and their beneficiaries, had to be put into written form and its provisions made known to the employees and, specifically, could not be a device to increase dividends of stockholders or to distribute more of the profits to officers of the company and supervisory employees.

Prevalence of Profit Sharing. — A substantial growth in profit sharing occurred from 1942 to 1954. In *Profit Sharzng Patterns* the opinion is expressed that the number of plans by the latter date ran into four figures. In the National Industrial Conference board survey in 1946, however, plans were reported by 401 companies out of 3.498 questioned. This was an increase from only 158 out of 2,700 companies studied in the 1939 survey. There was, 1942–54, a trend toward greater use of profit sharing, but such plans were still confined to a small minority of employers.

The bureau of internal revenue reported that up to Aug. 31,1946, it had processed 2,508 profit-sharing trust plans for establishments employing 1,312,226 people (cf. NICB report no. 97, p. 5). How many of these were actually put into effect and how many were actual profit-sharing plans is not clear.

Between 1947 and 1951 about 350 concerns joined the Council of Profit Sharing Industries. This organization's objective was to promote sound, well conceived profit-sharing plans.

The most complete studies published during the period 1948–54 covered only a few hundred plans. *Profit Sharing Patterns* was a study of 300 companies with 736,000 employees (1954), or 1.5% of the 48,948,000 nonagricultural wage earners in the U.S. Of these 300 companies, 7j employed 654,600 of the employees covered by the study. Though the report made clear it nas but a partial enumeration of the plans in existence, it undoubtedly constituted the most complete description published up to the mid-1950s of the kharacteristics of United States profit sharing during that period.

The 300 plans analyzed were in 31 states — 44% of them in New York. Illinois and Ohio. The largest concentrations were within 300 mi. of New York city, Cleveland and Chicago. Los Xngeles, Calif. was the only important concentration area on the Pacific coast. The plans were in a wide variety of industries: 223 plans, covering 397,900 employees in manufacturing industries; 38, covering 265,970 employees in wholesale and retail trade; 24, with 68,500 employees in finance and insurance; 14, with 3,590 employees in professional and service organizations.

Cash and Deferred Payment Plans. — Profit sharing may take the form of periodic (usually annual) payments in cash or deferred payments, usually retirement annuities, out of a trust fund accumulated over many years through employer contributions credited to each employee and invested for his benefit by the trust fund. The PSRF report stated that among the 300 companies studied intensively, cash plans predominated among small companies, deferred plans among large, and plans which combined cash and deferred methods characterized middle-sized companies.

Two factors account for the favour of the deferred plans among large companies. They became more interested, and so did unions, in providing wage earners with great lifetime economic security. And they wished to take advantage of the 1942 tax provisions. To do so their profit contributions had to be paid into a trust fund from which their employees would draw annuities in later years.

The smaller companies liked plans under which they could pay employees their shares of profits annually in cash or company stock because it is simpler, and perhaps safer, for them to pay off their obligations annually rather than to handle the complexities of long lived trust fund retirement plans.

Sears, Roebuck company. through a deferred payment plan started in 1916, built up a trust fund valued at about $350,000,000. The company contributed 45%; the employees 15%; and interest, dividends and appreciation in the value of Sears, Roebuck stock contributed the other $118,000,000 to the fund.

While the government restrictions were largely removed after the end of the mar, interest in such deferred payment plans continued at a high level.

Mortality of Profit-Sharing Plans. — The death rate of profit-sharing plans was high during most of the period after their introduction in the United States. There were many reasons. Employers who hoped that profit sharing would prevent unions in their plants or cause employees to be more "loyal" to their employer, that it would make employees work harder, prevent employees from going on strike, or even reduce labour turnover, were often disappointed in their expectations.

Industrial depressions also wrecked many plans. When employees fail to receive benefits to which they have become accustomed, it is hard to convince them that it is because the employer cannot make the payments. Employees' good will, co-operation or loyalty are not bought by a profit-sharing plan. Experience seems to indicate that where employers have discussed fully and continuingly with their employees the essentials of profitable business operations and have based their profit-sharing plans upon mutually shared understandings and objectives, the plans have been more likely to succeed.

The National Industrial Conference board revealed that of 202 companies which had profit-sharing plans in 1937, 35 or 17.3% had discontinued them by 1947. "The ratio of discontinuance is ten times as great among the current distribution plans as among the deferred plans." Nearly two-thirds of the plans discontinued had been operating for more than five years.

Characteristics of Profit Sharing in the 1950s. — Leaders in the profit-sharing movement by the 1950s had become aware that the successful management of profit sharing requires as careful attention to principles and techniques as other aspects of business management.

Such matters are vital as: (1) the skill with which an employer establishes good understanding of the plan among his employees; (2) the amounts and types of employer contributions; (3) the rules governing employee eligibility; (4) whether employees must or may contribute to a deferred plan fund; (5) the method of allocating benefits to employees; (6) whether employees shall have a vested right to the amount of the fund credited to them personally; (7) whether employees shall have a right to withdraw their shares if they take employment with another company; (8) frequency of payment under cash plans; (9) what per cent of the company's net profits shall be set aside for stockholders before any of the profits shall be available for profit sharing; (10) how and by whom the plan shall be administered; and (11) how employees' shares shall be computed.

(D. D. L.)

PRO FORMA INVOICE. When a consignment of goods is made for sale on commission, or when goods are forwarded on approval, it is usual to invoice them in a form identical with that of an ordinary invoice but bearing the endorsement "Pro forma." The consignee is thus fully advised of the contents, descriptions, qualities and prices of the goods consigned.

PROGNATHISM, the term applied with its opposite *Orthognathism,* to describe the degree of projection of the upper jaw.

PROGNOSIS, a term used in modern medicine, as it was in Greek, for an opinion, forecast or decision as to the probable course, duration and termination of disease. It is to be distinguished from "diagnosis," the determination or identification of a disease in a particular case from an investigation of its history, symptoms and findings.

PROGRAMME MUSIC, a nickname which is the only current term for instrumental music without words but descriptive of non-musical ideas. Musical sounds lend themselves to descriptive purposes with fatal ease. A chromatic scale may suggest the whistling of the wind or the serenades of cats. Reiterated staccato notes may suggest raindrops or the cackling of hens. Again, music is powerfully suggestive of emotion; and the emotions it calls up may fit some particular story, or may resemble those inspired by a sunset or a storm. But chromatic scales, reiterated notes, emotional contrasts and climaxes, are also normal musical resources; and nothing infuriates a musician more than the non-musical explanation of such things where the composer's aim was purely musical. Sound as it occurs in nature is too inorganic to form the raw material for art, and so there is no natural tendency in music to include, as a "subject," any item not inherent in the art-form. Explicit programme music has thus never been a thing of cardinal importance, though it has often been prominent and always popular. But the conditions of artistic creation are not to be confounded with any correct theory of art. The doctrine of art for art's sake is correct: but it concerns results, not processes; and many of the purest works of art have been produced for ulterior purposes.

Until recent times no composer has written for the voice without words; for speech is a privilege which the human voice will not willingly renounce. No doctrine of absolute music will prevent a good composer from shaping his vocal music to the words which he sets. Good literature will inspire him to explore and express its inner meaning. Bad literature may suggest to him the truths it misrepresents; and the great composers are quicker to seize the truth than to criticize its verbal presentation or to suspect insincerity. The earliest mature musical art was, then, inevitably descriptive, since it was vocal. While programme music derives many of its characteristics from ancient times, it cannot properly be said to have existed until the rise of modern instrumental music, based upon external ideas and independent of the use of words.

A complete code of musical symbolism came to maturity in the 16th century. Part of it was profoundly true and characteristic of moods; part was harmlessly mechanical; and a few details were manifestly false, as when "atra nox" is represented by a curiously jaunty rhythm because that rhythm is indicated by black notes. When symbolism, true or false, has thus arisen in vocal music it may be expected to retain its intention in music without words. But we must not expect too much descriptive power in early instrumental music; and when a scholar tells us that a funeral piece for organ by Froberger depicts in its final rising melisma the ascent of the soul to heaven, he unwittingly accuses Froberger of sinister intentions in a precisely similar funeral piece which ends with a descent to the lowest bass.

The resources of the modern orchestra can attain a realism which at first seems less ridiculous than that of earlier descriptive music. But the expensive realism of the dozen muted brass instruments that in Strauss's *Don Quixote* accomplish in ten rehearsals what a flock of sheep achieve extempore, is not less, but more childish than the thunderstorm in the Fitzwillian Virginal Book.

Beethoven's Theory of Expression.—On the other hand when superior persons object to the childishness of the birds and the thunderstorm in Beethoven's *Pastoral Symphony* it is they who are childish in supposing that realism is in question at all. The real cuckoo, nightingale and quail happen to be musical birds whose themes are exactly what Beethoven wants for a break in the rhythm at a point of *repose* in the coda of his slow movement. Similar final digressions can be seen in slow movements with no programme at all, *e.g.,* in the violin sonata of 24, the pianoforte sonata in D minor (op. 31 No. 2), and the string-quintet in C major, op. 29. Not a bar of the *Pastoral Symphony* would be otherwise if its "programme" had never been thought of. The "merry meeting of country folk" is a subject that lends itself admirably to Beethoven's form of *scherzo* (*q.v.*); and the thunderstorm, which interrupts the last repetition of this scherzo and forms a tremendous introduction to the peaceful finale, is as musical as other unique features in Beethoven's pure art-forms.

Beethoven is recorded to have said that he always composed according to a "picture" he had in his mind; and he sometimes gave his friends an explanation, jocular or evasive, of some particular composition. But the word *Bild* is much more indefinite than "picture"; and Beethoven's dull Boswell, Schindler, often exasperated him into defending himself by saying the first nonsense that would serve to stop foolish questions. Composers who have much to express cannot spare time for translating it into other terms than those of their own art. The *Eroica Symphony,* though inspired by Beethoven's short-lived belief in Napoleon as the liberator of mankind, is not programme music at all. The funeral march represents heroic death and a mourning world, but not the obsequies of a biographical subject; and when critics tell us that the finale is "an inappropriate concession to sonata form" they merely show themselves unmusical without thereby becoming literary. The profound and subtle sonata *Les Adieux, l'Absence et le Retour* is true programme music. It represents Beethoven's feelings on parting from the Archduke Rudolph when the royal family left Vienna shortly before its bombardment. It deals only with the parting, the absence and rejoining of the two men. Nothing is heard of war, and the sentiment is as deep as it is manly. Beethoven's private sketch-books record that the work is "written from the heart": no courtly formula, even if this was shown to the Archduke. Ingenuity is misplaced in tracing external details. (The end of the first movement of *Les Adieux* has been compared to the departure of a coach.) The real emotional basis is universal and musical.

Beethoven summed up the whole theory of great programme music in his note to the Pastoral Symphony; "rather the expression of feelings than sound-painting." Overtures to plays or operas cannot so easily dispense with story-telling; but Beethoven refuses to be drawn into a chronological series of illustrations. His overtures to *Coriolan*, *Egmont* and *Leonora* deal with salient emotions roused by their subjects. Wagner was able to place the substance of the *Coriolan* overture in Shakespeare's scene between Coriolanus and his mother and wife before the gates of Rome; but Thayer found that the forgotten poet Collin's play, which was Beethoven's subject, sheds far more light on the music. The music, however, once it took shape, could do without Collin or Shakespeare. The *Leonora* overture was at first (in the form known as No. 2) a huge prelude to the opera, with a gigantic exposition and development, and the shortest wind-up compatible with adequacy, after the trumpet-call behind the scene has relieved the tension. In the later version *(Leonora No. 3.)* Beethoven ruthlessly compresses the exposition until the trumpet-call becomes the middle point of the design, which afterwards expands in a further development, full recapitulation and a climax which makes this overture the first and greatest of all "symphonic poems" (*q.v.*). Critics who cavil at the trumpet-call as a weakness from the point of view of absolute music only show that they cannot tell absolute music from absolute nonsense. Distance is surely too elementary a phase of sound to be excluded from absolute music, nor can the fanfares of a trumpet be separated either from the instrument or from its associations. As a piece of absolute music *Leonora No. 3.* is a huge movement in sonata form rising steadily to a point at which the tension is relieved by the new incident of a distant trumpet-call, after which the music expands from sheer joy. Beethoven's maxim *mehr Ausdruck der Empfindung als Malerei* therefore holds here, and bridges the gulf between absolute and illustrative music.

Portrayal of Characters and Moods.—This is equally true with archaic and modern programme music; it is always characters and moods that are successfully portrayed, while chronology is useless and the illustration of incidents is apt to be ridiculous unless it contrives to be witty. Thus, the *Bible Sonatas* of J. Kuhnau (published in 1700) and their clever imitation in Bach's early *Capriccio on the Departure of a Beloved Brother* rely mainly on moods, and are successful with incidents only when these would be accompanied by music in real life or drama. If Kuhnau's music were half as vivid or inventive as his prose introductions it would be immortal. But much may be learnt from noting how his unconsciously humorous prose describes other things than the music attempts to portray and omits the very things in which the music is at its best. While Kuhnau strains himself, like a bad nurse telling bogey-stories, in his prefatory description of the size and appearance of Goliath, in the music it is the boasts *(le bravate)* of Goliath that are portrayed. The best movement in the Goliath sonata is a figured chorale *(Aus tiefer Noth schrei' ich zu Dir)* representing the terror and prayers of the Israelites. On the other hand the cast of David's sling, with the fall of Goliath, is not nearly so sublime as the fall of a tea-tray. Kuhnau's other subjects *(Saul cured by David's music; The Marriage of Jacob; The Healing of Hezekiah; Gideon,* and *The Funeral of Jacob)* are all thoroughly musical; more so than he succeeds in making them. Bach's *Capriccio* describes the anxiety and sorrow of the friends of the departing brother; and his utmost realism takes the form of a lively fugue on the themes of the postilion's coachhorn and cracking whip. Buxtehud illustrated the "nature and characters of the planets." This is an astrological, not an astronomical subject: the planets signify temperaments and their motions are the music of the spheres. No wonder, then, that this musical subject has been adopted in one of the outstanding masterpieces of modern orchestral music, *The Planets,* by Holst.

Adaptability of Lyrical Music.—Instrumental music on the lyric scale lends itself to illustrative purposes more readily than larger forms. Nearly all the harpsichord pieces of Couperin have fantastic titles, and a few of them are descriptive music. His greater contemporary and survivor, Rameau, wrote important operas and much extremely graphic harpsichord music. La *Poule*, with its theme inscribed "co-co-co-co-co-co-cocodai," is an excellent movement in spacious form, and is also one of the most minutely realistic compositions ever written. French composers have always contributed *con amore* to music that takes advantage of external stimulus; and already in 1801 descriptive music was considered so specially French that Haydn apologized for his imitation of frogs in *The Seasons,* saying that this "franzosische Quark" (rubbish), had been forced on him by a friend. But throughout the growth of the sonata style, not excepting Haydn's own early work, the tendency towards gratuitously descriptive music often appears; partly because there was no definite distinction between early symphonic music and overtures or incidental music to plays (*e.g.,* Haydn's *Il Distratto*). Dittersdorf's symphonies on the metamorphoses of Ovid are excellent music in which the descriptive elements do not disturb the symphonic form until the metamorphosis which is then illustrated in almost Wagnerian breadth. For instance, the first three movements of the *Change of the Lycian peasants into Frogs* show the rusticity of the peasants, the gracefulness of the goddess, and the rudeness of the peasants to the goddess; and then the finale indicates an altercation ended, after a pause, in a low mysterious quivering sound as of frogs in a marsh.

Dittersdorf is not a great composer; but many more learned and resourceful artists have shown less than his common-sense in distributing the descriptive and the formal elements of their music. It seems incredible that any composer could be so foolish as to commit himself to describing a chronological sequence in a sonata-form which compels him to go through a full restatement of events which only happened once; yet many composers refused to abandon either the sonata form or the chronological sequence. Lyric forms presented no such difficulties.

Schumann and **Spohr.**—Schumann sometimes invented his titles after his pianoforte lyrics were finished, and sometimes wrote on the inspiration of literature. In either case, as with Beethoven, the music throws far more light on the programme than the programme throws on the music. Musical people may profitably study E. T. A. Hoffman and Jean Paul Richter in the light of Schumann's *Novelletten* and *Kreisleriana;* but if they do not already understand Schumann's music, Jean Paul and Hoffman will help them only to talk about it. In revising his early works Schumann sometimes made them more musical and sometimes destroyed grotesque touches that are musically as well as psychologically true. For instance, in the *Davidsbündler-tanze* (op. 6.) the hot-headed Florestan, having finished an impassioned tirade, feels that he has been making a fool of himself. His last note pauses unharmonized and he sits down awkwardly. In a later edition, with unnecessary scruple Schumann suppressed this detail together with the prose titles and signatures. The fashion of fantastic titles affected even the most formal composers during the romantic period.

No one wrote more programme music than Spohr; and, while Spohr's programme constantly conflicted with the externals of his form and ruined the latter part of his symphony *Die Weihe der Tone,* it did not broaden his style. Mendelssohn's Scotch and Italian symphonies, and his Hebrides overture, are cases of generalized local colour. His Reformation symphony, which he himself regarded as a failure, and which was not published until after his death, is a descriptive work less attractive but more coherent than Spohr's *Weihe der Ton.* The overture to the *Midsummer Night's Dream* is a marvellous musical epitome of Shakespeare's play; and the comparative slightness and conventionality of its second theme closely correspond with Shakespeare's two pairs of lovers, though it does not illustrate their quarrels under the fairy spells.

Influence of **Berlioz.**—Berlioz made programme-music a vital issue in the 19th century. With an inextinguishable gift for voluminous composition he is utterly incapable of focussing his attention on either his music or his programme. The most trivial external detail may distract him at the height of his rhetoric. The moonshine and sentiment of the *Scène d'amour,* in his *Romeo and Juliet* symphony is charming; and the agitated sighing episodes which interrupt its flow, can be understood in the light of

Shakespeare's balcony scene, if not by their musical sense. But when Berlioz thinks of the nurse knocking or calling at the door, he makes a realistic noise without either musical or dramatic purpose. It does not interrupt the duet, nor increase the emotional tension, nor illustrate Juliet's artifices for gaining time, nor her agitation at the interruptions of the nurse. Perhaps this was the passage on which a lady once congratulated Berlioz for his vivid representation of *Romeo arrivant dans son cabriolet.* This piece of purely orchestral music has an introduction in which real voices are heard from convivial persons returning home from the ball. Berlioz complains that the public has no imagination and that therefore certain sections which presuppose an intimate knowledge of Shakespeare's play *avec le dénouement de Garrick* should be omitted. But what the public lacks for these sections is neither imagination nor familiarity with Garrick-Shakespeare, but a capacity to take the butterfly vagaries of Berlioz's mind as their basis of reference.

With all his absurdities, Berlioz's genius for composition carried him further towards a new music than Liszt was able to advance in his symphonic poems. These, as has been said in other articles (*see* MUSIC, sections 8–10, and SYMPHONIC POEM) are the beginnings of an instrumental music that achieves the same continuity as Wagner achieved in music-drama. But Liszt hardly even began to achieve the right sort of movement; and his conscientious plan of deriving the whole piece from transformations of a single figure was quite irrelevant even when it was effective. As a musical illustrator he is clever; but he ties himself down to chronological sequence, which, though it does not conflict with his forms, is always open to Weingartner's objection that it cannot control the pace of the listener's thoughts. The composer's first view-halloo may make one listener fancy himself in at the death of the Blatant Beast, while the mind of another will plod to the end, to learn that that event never takes place.

Strauss.—The symphonic poems of Strauss are invulnerable by this objection, even though it is often true of their details. Most listeners will probably identify Don Quixote's tilting at windmills with the passage in which Strauss uses a stage windmachine; but this represents a later adventure in which Don Quixote and Sancho are seated blindfold on wooden horses and are persuaded that they are flying on winged steeds through the air. Strauss's music, however, does not really depend on this sort of thing at all. His earliest symphonic poems are masterpieces of new form and movement: *Don Quixote* is sectional only because its subject lends itself to an episodic treatment which Strauss has as much right as Humpty Dumpty to call variations, and in it, no less than in *Also sprach Zarathustra, Ein Heldenleben,* the *Sinfonia Domestica* and their aftermath the *Alpensinfonie,* single designs are triumphantly accomplished in music of Wagnerian continuity. It is not necessary that the designs should be perfect. Uncles and aunts may interrupt it to say that the baby is the image of its dada or mamma; and the wickedness of critics may devastate pages of the music of the hero who gave them their opportunity when he paused on a dominant chord to look round for applause; but local defects do not annihilate fundamental qualities.

Caricature.—One thread remains to be gathered into this account. Caricature is a rare and dangerous element in music, but it is as old as Orlando di Lasso. Mozart, besides the subtleties of *Cosi fan tutte* and the comic parts of *Die Zauberflöte,* produced in his *Musikalischer Spass,* a burlesque of village players and bad composers. On paper the work is a delicious study in the psychology of "howlers," and in its finale Mozart idealises all the nightmare stagnation of the composer whose *tempo* gets faster and faster while his phrasing gets slower and slower. In performance the effect is even more surprising than analysis would lead the reader to expect. But the Leipzig editors of the parts have crowned Mozart's farce by correcting the mistakes!

Caricature enters prominently into Strauss's *Till Eulenspiegel, Don Quixote* and *Ein Heldenleben;* and also into many passages in Mahler's symphonies. Its danger is that it often opens these composers to suspicion when they intend to be touchingly simple.

But nothing is more vexatious than the laying down of *a priori* limits to what is legitimate for artists. If sermons in the mind of the painter help him to paint, and pictures in the mind of the composer help him to compose, by all means let them get on with the work. (D. F. T.)

PROGRESSIVE EDUCATION. Although the sources of progressive education go back to far before the 1850s, the movement sprang into prominence in both the United States and Europe simultaneously but independently at the end of the 19th century. This article traces its origins and European development and then describes its considerable effect on U.S. education and its decline as a separate educational movement.

Origins and European Development. — Modern progressive education has its ancestry in a complex of ideas and practices which, from the 16th century onward, have been concerned with a reconsideration of the nature of individual man, of the societies in which he lives and of the relationship between them. At different times the emphasis has fallen upon one side of the relationship or upon the other; now on the need to free the individual from social pressures which limit his development, now on the need to provide the kind of social environment which will foster this development. Jean Jacques Rousseau's *Émile* and *Du Contrat social* (1762) are source books for students of progressive education. The roots of the movement, as has been pointed out by W. H. G. Armytage, can be traced back to the utopian tradition which derived from Thomas More and Francis Bacon in the 16th century and embodied the notion that man can, as it were, make a fresh start, *i.e.,* redeem the loss of the fall, by founding a new society or by restructuring an existing one. The implications of this for education are seen in the work of Samuel Hartlib, John Dury and J. A. Comenius; in the communitarian approach of the Quakers to both religion and education; in the work of Robert Owen and in the practical application of Rousseau's ideas by J. B. Basedow, J. H. Pestalozzi, Philipp Emanuel von Fellenberg and Friedrich Froebel.

The link between social reform and education is implicit in the movement which led to the founding of Abbotsholme school for boys, Derbyshire, by Cecil Reddie in 1889. Reddie was a member of the Fellowship of the New Life, founded in 1882. The fellowship promoted the founding of experimental schools, and the utopian tradition is clear in their assertion: "All schools ought to be communities, miniature commonwealths or states, as they were in the Middle Ages."

A secession from Abbotsholme led to the foundation of Bedales at Petersfield, Hampshire (1893); this later became the first coeducational boarding school. Later progressive schools in England were St. Christopher, Letchworth, Hertfordshire, originally intended as one branch of a many-sided community life; Frensham Heights, Farnham, Surrey; King Alfred's, Hampstead; Malting House school, Cambridge; Beacon Hill near Harting, Sussex (founded in 1927 by Bertrand and Dora Russell); Summerhill, in Suffolk, founded by A. S. Neill; and Dartington Hall, Totnes, Devon. Most of these schools are coeducational and stress with varying emphases the freeing of the child from adult pressures and the provision of a rich and varied community life.

Abbotsholme inspired the founding in Germany of the Deutsche Landserziehungsheime (1898) by Hermann Lietz and in France that of L'École des Roches by Edmond Demolins in 1899. In Italy, in 1894, the sisters Agazzi opened a home for preschool children which stressed training in sense perception and play activities in rural surroundings, and this later became the model for preschool education in Italy. In 1907 Maria Montessori began her Children's Houses in Rome, and devised the "didactic apparatus" to enable children to develop their capacities by self-education (*see* MONTESSORI SYSTEM).

Other pioneers of new methods in education were Ovide Decroly in Belgium, Adolphe Ferribre in Geneva, and Elizabeth Rotten in Germany. In 1921 about 150 pioneers from countries throughout Europe met at an international conference in Calais. France, organized by Mrs. Beatrice Ensor who, in 1920, had initiated the *New Era,* a magazine for the exchange of ideas and experience concerning the new education. At this conference the New Education fellowship was formed to link pioneers in different parts of the world. After 1921 the fellowship organized many international conferences; national sections promoted its interests in 11 European countries as well as in Australia, India, Egypt, Pakistan, New Zealand, South Africa and South America. Until 1955 it was linked with the Progressive Education association of the U.S. (called, from 1945 until its end in 1957, the American Education fellowship).

After 1900, the progressive ideas and practices developed in the United States, especially those of John Dewey, flowed back to join with the European progressive tradition. The effect of this was to strengthen the emphasis on social education and the relating of the individual's needs to the needs of a rapidly changing society.

The influence on schools within state systems of education was seen in the development of "activity" and "centre of interest" methods in the education of young children, in the use of "projects" and "assignments" with older children, and in general in the greater emphasis on social and emotional education and the modification of the formal and the academic in both content and methods. After 1946 there was a sharpening of the criticism of progressive ideas and methods, with restatements of the traditional aims, and this in turn challenged the progressive movement to redefine its assumptions and objectives.

United States.—In the United States progressive education began during the latter decades of the 19th century as one aspect of that larger program of social reform known as the progressive movement. It was essentially a pluralistic phenomenon, comprehending a remarkable diversity of pedagogical protest and innovation. In the universities it emerged as part of a spirited revolt against formalism in philosophy, psychology and the social sciences. In the cities it was but one facet of a wider program of municipal clean-up and reform. Among farmers it became the crux of a moderate, liberal alternative to radical agrarianism. It was at the same time the "social education" demanded by urban settlement workers, the "schooling for country life" demanded by rural publicists, the vocational training demanded by businessmen's associations and labour unions alike, and the new techniques of instruction demanded by avant-garde pedagogues. It enlisted to its cause parents and teachers, starry-eyed crusaders and hard-headed politicians. And in less than two generations it transformed the character of the U.S. school.

The sources of progressive education lie in part in the stream of pedagogical reform in Europe from the 17th through the 19th century cited above. They lie also in the revolution wrought before the Civil War by Horace Mann and his confreres in convincing Americans of the necessity of universal education in a free society. The very success of this revolution, in bringing into primary and secondary schools a greater diversity of children than ever before, inevitably exerted a transforming influence on the character of the schools themselves. Finally, the sources of progressive education lie in the transformation of society itself under the pervasive influence of industrialism. The advancement of technical and productive processes and the growing complexity of urban life—compounded in the United States by large percentages of non-English-speaking immigrants—led to pressures for the schools to assume educational responsibilities formerly borne by family, shop and neighbourhood.

The first evidence of progressivism in U.S. education appeared as early as the 1870s. Francis W. Parker, later referred to by John Dewey as the father of progressive education, undertook to reform the Quincy, Mass., schools beginning in 1875. He vigorously attacked rote learning and introduced new pedagogical techniques designed to make school subjects more meaningful to children. His reforms attracted national—indeed world-wide—attention as "the Quincy system"

Following upon the revelations of the Russian system of technical instruction at the Philadelphia centennial 'exhibition of 1876, Pres. John D. Runkle of the Massachusetts Institute of Technology, Calvin Woodward of Washington university, and Col. R. T. Auchmuty, a New York businessman, sharply criticized the narrow intellectual emphases in the secondary school program, demanding a central place for industrial training and vocational education. Throughout the 1870s conventions of the National Grange and other farmer organizations passed resolutions deploring the lack of practical agricultural training in schools and colleges.

Protests like these multiplied during the following decade, and by the 1890s they had assumed all the earmarks of a full-fledged social movement. The themes of this movement were many and various, but they were one in their attack on the narrowness and formalism of traditional education. Businessmen's organizations, and later labour unions as well, contended that under the modern factory system apprenticeship had deteriorated into an exploitive rather than an educative relationship and that because of this, schools would have to assume the classical functions of apprenticeship. Settlement workers, sensitive to the pedagogical vacuums created by broken homes and working parents, and compellingly aware of the education of the streets, vigorously urged instruction in hygiene, domestic science, manual arts and child care. Likewise, rural educators, deploring the flight from farm to city, argued for a new kind of rural school which would orient young people to the joys and possibilities of country life and equip them technically to realize these possibilities. Finally, university professors and educationists, basing their proposals on the new sciences of psychology, sociology and pedagogy, pressed for revamped school programs which would afford greater importance to scientific studies, tie learning more closely to doing, and educate "whole children"—that is. pay attention to physical and emotional growth as well as to intellectual development.

Outstanding Americans from many walks of life espoused ideas such as these during the quarter-century before World War I, among them Theodore Roosevelt, Jane Addams, Jacob Riis, William James, Charles W. Eliot, Henry Wallace, Walter Hines Page, and James Earl Russell. No one saw the movement whole, though, quite as well as John Dewey. for 50 years the commanding figure among theorists of progressive education. In a series of books, pamphlets and essays, beginning with *The School and Society* (1899) and culminating with *Democracy and Education* (1916), Dewey illuminated the close relationship between progressive education and the larger social transformation being wrought by science, democracy and industrialism. The curse of traditional education, Dewey argued, had been its aristocratic character and its isolation from life. The crux of progressive education was its universality and its closeness to life. Dewey urged that schools be made into "embryonic social communities," active with the occupations and permeated with the values of the surrounding society. "When the school introduces and trains each child of society into membership within such a little community," he wrote, "saturating him with the spirit of service, and providing him with the instruments of effective self-direction, we shall have the deepest and best guarantee of a larger society which is worthy, lovely, and harmonious." (John Dewey, *The School and Society,* p. 44, The University of Chicago Press, 1900.) (*See* also DEWEY, JOHN.)

Progressive education made considerable headway on an experimental basis after 1890. Joseph Mayer Rice found in an 1892 survey that the school systems of Indianapolis and La Porte, Ind., and of Minneapolis and St. Paul, Minn., having freed themselves from undesirable political control, had begun to put teaching on a "scientific basis," to "develop the child in all his faculties instead of simply crowding his mind with facts," to introduce new work in manual and creative arts, and to seek desirable correlation among the several subjects of study. In 1896 Dr. and Mrs. Dewey founded a Laboratory school in Chicago specifically to test the validity of his pedagogical theories. In 1904 Junius L. Meriam established an experimental school at the University of Missouri, Columbia. and in 1907 Marietta Johnson opened her School of Organic Education at Fairhope, Ala. The following year, William Wirt, school superintendent of the newly created steel town of Gary, Ind., began the sweeping educational innovations which came to be called the "Work-Study-Play" plan. Widely publicized by the progressive press after 1914, the Gary plan represented the best-known effort to apply Dewey's precepts to the public schools of a burgeoning industrial community. Finally, vocational education of every sort advanced rapidly after 1900, and in 1917 congress passed the Smith-Hughes act providing federal aid for trade. agricultural, home economics and distributive instruction in public secondary schools.

The founding of the Progressive Education association in 1919 marks a significant divide in the history of the progressive education movement. since what had forinerly been a loosely defined revolt against pedagogical formalism now gained a vigorous organizational voice. Under the initial leadership of Stanwood Cobb and Eugene Randolph Smith, the association quickly gained a notable place in U.S. education. Its membership climbed steadily, passing 5,000 in 1927 and reaching a peak of 10.500 in 1938. Its quarterly. *Progressive Education*, launched in 1924, quickly became a clearinghouse for educational experiments of every conceivable kind. During the 1930s. aided by well over $1.000.000 in foundation money, the association sponsored a number of widely publicized experiments, among them an eight-year study involving 30 secondary schools and over 200 colleges and designed to test the effects of introducing greater flexibility into high school curricula. The results, published in 1942, were taken as decisively in favour of the experimental programs.

Spurred on by the efforts and propaganda of the association, progressive education won ever greater acceptance in school systems across the nation. Success, though, brought ideological schism in its wake; and the quarter-century after 1919 was marked by sharpening conflict over just what progressive education was, and what it meant. One group of educators, epitomized by Marietta Johnson, combined the doctrines of liberty and self-expression into a highly individualistic pedagogy which held that schools in which children are encouraged freely to develop their uniquely creative potentialities are the best guarantee of a larger society devoted to human worth and excellence.

A second group, following the leadership of George S. Counts during the 1930s, sought to tie progressive education much more closely to specific programs of political reconstruction, contending that educators could lead in the building of a new social order. A third group, typified by Elsie Ripley Clapp, saw the crux of progressive education in school activities directed to the social and economic regeneration of local communities. A fourth group, exemplified by Eugene Randolph Smith, concentrated on reorganizing and enlivening the traditional school studies. And finally, there were those like William Heard Kilpatrick, Boyd H. Bode and Den ey himself who continued to regard progressive education as the pedagogical expression of the larger philosophy of experimentalism, with its emphasis on naturalism, scientific method and democratic social planning. Given this conflict over goals, the movement during the later 1930s was increasingly paralyzed by a factionalism which weakened not only its forward thrust but its resistance to outside criticisms as well.

From its earliest days progressive education had elicited sharp and sustained opposition from a variety of sources. Humanists and idealists had vigorously criticized its naturalistic orientation, its Rousseauan emphasis on freedom and interest, and its cavalier treatment of the classics and foreign languages. During the 1930s a group calling themselves the Essentialists had taken progressives sharply to task for failing to pay sufficient attention to the need for disciplined study of systematic knowledge. A number of Christian educators, Roman Catholic and Protestant as well, had accused progressives of materialism and a general denial of supernatural spiritual values; while elements of the patriotic press had been unremitting in their charges of radicalism and "un-Americanism." Criticisms such as these became more insistent after World War II, when progressive doctrines in general seemed eclipsed by a revival of conservatism in U S. politics and social thought. Unable to meet the challenge, the Progressive Education association disbanded in 1955; and the journal *Progressive Education* ceased publication two years later. For all practical purposes, the movement died in 1957, but not without leaving an indelible impress on the thought, character and spirit of U S. education.

PROGRESSIVE PARTY, U.S. Three so-called Progressive parties have in the U.S. represented third-party movements in the presidential campaigns of 1912. 1924 and 1948.

The Progressive party movement of 1912 began as an insurgent outbreak among Republican members of congress in 1910 against the speaker of the house of representatives. Joseph G. Cannon. Opposition to the administration of Pres. William Howard Taft crystallized in 1911 when the National Progressive Republican league was organized by Sen. Robert M. La Follette of Wisconsin. Theodore Roosevelt soon placed himself at the head of that Progressive movement. Alleging unfair tactics on the part of the "Old Guard," his followers left the Republican national convention in Chicago, Ill. (June 1912), and Roosevelt was nominated for the presidency by a Progressive national convention, also held in Chicago. early in August. As a result the Republican party was hopelessly split, Roosevelt receiving a popular vote exceeding that of Taft by more than 600,000. Woodrow Wilson, the Democratic candidate, carried all but eight states. The electoral vote was 435 for Wilson. 88 for Roosevelt, 8 for Taft. The popular tally was 6,286,000; 4,126,000 and 3,484,000 for Wilson, Roosevelt and Taft respectively.

In 1916 harmony was restored in the Republican party. Roosevelt declined a second Progressive nomination and supported the Republican ticket. During World War I partisanship was in abeyance, but upon its termination the old rift soon reappeared. The administration of Harding encountered dissatisfaction among farmers. as did the Coolidge administration.

In 1924 Wisconsin and other farm states, after sitting in the Republican convention at Cleveland, O., held a conference for progressive political action. Senator La Follette was nominated for president and Sen. Burton K. Wheeler of Montana, a Democrat. for vice-president. The platform promised a "house cleaning" of executive departments, public control of national resources, public ownership of railnays, tariff and tax reduction. Republican strategy in 1924 consisted largely in denouncing the alleged radicalism of the La Follette platform, while ignoring Democratic attacks. Coolidge won easily, and La Follette carried only Wisconsin.

Unlike its predecessors the Progressive party founded by Henry A Wallace in 1947–48 stressed foreign issues in its platform—principally abandonment of the Marshall plan and the Truman doctrine (*qq.v.*). This party was formally organized in Philadelphia, Pa., July 22–25, 1948, naming Wallace as its candidate for president and Sen. Glen H. Taylor of Idaho for vice-president. On Aug. 6, the national convention of the Communist Party of the U.S announced its support of the Wallace-Taylor ticket. In the presidential election of 1948, the party polled only 1,157,172 popular votes and no electoral votes.

(R. C. B.; R. Tu; X.)

PROHIBITION is a method for the legal regulation of the manufacture, sale and transportation of alcoholic beverages. It has such extensive and varied applications as to make its other uses in legal terminology of minor importance. National prohibition was adopted in the U.S.A. by the ratification of the 18th amendment to the constitution, Jan. 16, 1919, effective one year thereafter, and repealed by the ratification of the 21st amendment, Dec. 5, 1933. Both amendments were adopted by large majorities only after full and free discussion, with determined and well-directed opposition, and neither can truthfully be said to have been "put over" by a fanatical minority or selfish economic interest.

National prohibition was the logical result of nearly 100 years' experience with state and local prohibition. It was not adopted without due appreciation of the difficulties it would encounter, nor until other expedients were tried to avoid the necessity of this experiment. Some of these expedients and the legislative background of national prohibition and its repeal are more fully discussed in the article Liquor Laws and Liquor Control (*q.v.*). Well-considered public opinion, pro and con, with respect to prohibition, cut deeper across the lines of political parties, rural and urban life, churches and families than any other question of the generation in which the 14 years 1920–33 fell. Its application on a national scale over an area so large as the U.S.A., and to a population living under such diverse racial and climatic conditions, made it by common consent the greatest social experiment of modern times.

Local Option and State **Prohibition.**—Local option started in Maine (P.A. 1829, c. 133), Indiana (L. 1832, c. 170) and Georgia (A. 1833, 125) in the first third of the 19th century, and state prohibition in Maine in 1851. Most local option statutes permitted the electorate in local political units, usually counties, but sometimes cities, villages, towns and even districts of a city, to vote "yes" or "no" on licences to sell "on" or "off" the premises for a limited period, usually one or two years. Some statutes embodied the local option principle by requiring a licence applicant to get the approval of a majority or two-thirds of the voters in the area to which the licence applies; or providing that no licence be issued, if a majority petitioned for its refusal. Other variations of local option were tried. Thus Arkansas (Digest Stat., 1884, par. 4515) had prohibition with a "licence" local option, and Iowa bad prohibition for a time with selling permitted under the mulct law, Code (1897) par. 2448. (Cf. Clark Byse, "Alcoholic Beverage Control Before Repeal" [in "Alcoholic Beverage Control" (1940)], *Law and Contemporary Problems*, vol. vii, No. 4, Duke University Law School.)

Licensing systems date back to colonial times. Combined with local option they furnish for the U.S.A., in the light of its experience with both state and national prohibition, the best hope for the possible effective application of the principle of prohibition. A properly drafted high licence statute with local option for prohibition in well-defined areas, or a prohibition statute with local option for licence in carefully planned areas, would go far to remove the majority of the social evils of the liquor traffic without resort to absolute prohibition. State licence systems in the absence of similar legislation by congress have been upheld by the U.S. supreme court as a constitutional exercise of the state police power. (*Cf. The License Cases*, 46 *U.S.*, 5 How., 504, 1847).

State prohibition stems from the development of the temperance movement of the second quarter of the 19th century. In the first quarter that movement was primarily individualistic. The thousands of temperance societies in the northern states, most of them in New England, resulted from a great religious revival and their efforts centred in personal regeneration and what the individual could do for himself. Its progress though encouraging was too slow to stem the rising tide of liquor consumption and its disastrous social consequences. The next logical step was to federate the temperance societies in strong state and national associations and exert political power to regulate or prohibit the production and sale of intoxicating beverages. The greater and more influential national organizations like the Woman's Christian Temperance Union (W.C.T.U.), the National Temperance society, the Total Abstinence brotherhood (T.A.B.), the National Prohibition party and others took up the cudgels after the Civil War; and the Anti-Saloon league with its powerful state and national organization, in the closing years of the century.

The continuous agitation of the temperance societies resulted in "limited" state-wide prohibition by an Indiana statute (1816) making sale of liquor on Sunday illegal, and the "15 gallon" law in Massachusetts (L. 1838 c. 157) prohibiting sale of "less than 15 gallons of spiritous liquor or mixed liquor part of which is spiritous (except for medicinal and mechanical uses) to be delivered and carried away at one time." This apparently accomplished little and was repealed in 1840. The first absolute state prohibition law, due to Neal Dow, organizer of the Maine Temperance Union, was an act "to restrict the sale of intoxicating drinks," approved Aug. 7, 1846. It was too weak in many of its provisions to be effective but was strengthened by the act "for the suppression of drinking houses and tippling shops" approved June 2, 1851. This act repealed all but 13 sections, those containing certain enforcement provisions, of the 1846 statute. The Maine law of 1851 remained substantially unchanged for 70 years and became the model in the next decade for no less than 13 state-wide prohibition laws. But by 1863 in all but five of these states the statutes were repealed or invalidated by state supreme court decisions.

(*Cf.* Ernest A. Grant, "The Liquor Traffic before the Eighteenth Amendment." in *Annals*, vol. 163, Sept. 1932.)

The second stage of organized effort for state prohibition was an outgrowth of reconstruction following the Civil War. It began with the organization of the National Prohibition party in 1869 at Chicago, and the Woman's Christian Temperance Union (1874); marked the return of some states that had tried prohibition in the first period and had given it up; and reached its zenith in the decade 1880–90. Eight states enlisted but only three remained by 1904.

The third and last stage of state prohibition before national prohibition was tried covers the first two decades of the 20th century, was largely due to southern and western rather than New England forces, and was led by the Anti-Saloon League of America (1895) and the state anti-saloon leagues. Thus when national prohibition went into effect (Jan. 1920) state-wide prohibition under state laws was already in effect in 33 states (more than two-thirds of all the states), and in 18 of them by constitutional amendment adopted or ratified by referendum election. In addition Alaska, Puerto Rico, the District of Columbia and Hawaii were included in 1917–19 in the prohibition area. Ninety per cent of the townships and rural precincts, 85% of the counties and more than 75% of the villages of the United States were under prohibition by state legislation. Two-thirds of the members of the senate and house of representatives came from states or districts having state prohibition which together with local option had put 63.3% of the population and 95.4% of the land area under prohibition. These statistics and similar ones for local option alone may be misleading unless cautiously interpreted as to their real significance, as later experience with national prohibition amply demonstrated. They are not an exact measure of the dryness of a community because often they do not mean a desire to be rid of liquor altogether but only the ugly aspects of the saloon and the liquor traffic in a residential neighbourhood so long as ample supplies may be had from near-by wet areas. Many communities find the ubiquitous bootlegger the lesser evil, and "near-by" has been greatly extended by improved transportation facilities, roads and automobiles. (Cf. *The Local Option Fallacy,* Distilled Spirits Inst., Washington, D.C., rev. ed., Oct. 1942, p. 32; Raymond B. Fosdick and Scott, *Toward Liquor Control,* pp. 22–27.)

Federal **Aid** to State and Local Prohibition. — It has been said that "liquor consumption did not decrease during the period when the state-wide prohibition movement was strongest" (C. Byse, *op. cit.,* p. 561). The statistical support for such a statement is far from conclusive. Such evidence as does exist, like that regarding local option and state prohibition, must be examined with caution, and deductions and implications made with reserve. If per capita consumption of spirits, wine and beer be combined and some allowance be made for mounting illegal consumption in the years when state prohibition was strongest, possibly a fairly tenable case can be made for the assertion just quoted, but the implied charge that this is the measure of the so-called breakdown of state prohibition is far from true. The cost and difficulties of enforcement, and the protection of dry areas from the inroads alike of the liquor traffic and bootleggers from bases in near-by wet areas were objects of greater concern to the supporters of prohibition.

The states first sought in various ways to protect their dry areas by their own powers. For example, Texas in 1910 made the sale of liquors in no-licence territory a felony. All tried to check the flow of liquor having the constitutional protection of interstate commerce over which the federal government had exclusive jurisdiction. For 43 years the U.S. supreme court followed the rule laid down in the celebrated License Cases (46 U.S., 5 How., 504, 590, 1847) that state legislation could prohibit the sale of liquor without a licence even if imported in the original barrel brought in by interstate commerce. This reversed a ruling in 1827 that held a state law unconstitutional which imposed a licence tax on an importer of liquor. But the still more celebrated Original Package case in 1890 practically reversed the 1847 rule by holding that a state could not prohibit a liquor dealer from importing liquor in interstate commerce for resale in original packages (135 U.S. 100, *Leisy* v. *Hardin*). This nullified state prohibition and congress at once sought by the Wilson act (26 Stat. 313, 1890) "to divest intoxicating liquors of their interstate character" by providing that "liquors transported into a state . . . shall . . . upon arrival in such state . . . be subject to the operation and effect of the laws of such state enacted in the exercise of its police powers, to the same extent . . . as though such . . . liquors had been produced in such state." While this act presented grave constitutional difficulties, the supreme court upheld it in *In re Raher* in 1891 (140 U.S. 545), but in a later case (*Rhodes* v. *Iowa,* 170 U.S. 412, 1898) the court construed the word "arrival" to mean delivery to the consignee and not merely arrival in the state. So the mail-order business, skillful advertising and traveling salesmen still made the evasion of prohibition easy. The U.S. supreme court did try to help the states to find their own remedy, by upholding (1) a Missouri statute which imposed an inspection fee on all liquors shipped from other states into Missouri and offered for sale (190 U.S. 17, 1905), and (2) a South Dakota statute putting an annual licence charge on the business of soliciting orders to be filled from liquors at the time outside the state (*Delameter* v. *South Dakota,* 205 U.S. 93, 1907). In some other cases, however, the Wilson act was further emasculated, by refusing the state the right to prohibit C.O.D. shipments of liquor (*Adams Express Co.* v. *Kentucky,* 206 U.S. 129, 1907), and by not permitting a state to compel a resident-consignee to certify to a state official the quantity and kind of liquor to be imported, or a nonresident-consignor to attach a certificate to the package (*Vance* v. *Vandercock,* 170 U.S. 438, 1898).

The Webb-Kenyon Act.—Passed March 1913, over President William Howard Taft's veto, "An Act divesting intoxicating liquors of their interstate character in certain cases" (37 Stat. 699) was the most aggressive step that congress and the federal government had taken to aid state prohibition. Broader than the Wilson act which merely sought to remove the bar of the original package decision, it was intended to remove the federal protection which liquor enjoyed as an article of interstate commerce. It forbade the transportation of intoxicating liquors into a state by any persons interested therein "to be received, possessed, sold or in any manner used either in the original package or otherwise, in violation of any law of such state." Notwithstanding President Taft's own opinion, and that of his attorney-general, and able lawyers in the senate who advised him, to the effect that the act was unconstitutional, the supreme court sustained it in the Clark Distilling Co. cases, decided Jan. 8, 1917 (242 U.S. 311). This was further strengthened by the adoption of the Reed "bone-dry" amendment to the P.O. Appropriation act of March 3, 1917 (39 Stat. 1069, c. 162) which sought to eliminate completely the illegal mail-order liquor traffic.

The Webb-Kenyon law at first stimulated state prohibition. In 1914 state constitutional amendments were adopted by popular vote and substantial majorities in Arizona, Colorado and Oregon, but rejected by substantial majorities in California and Ohio. Statutory prohibition was adopted in Washington on an initiative measure by 18,632 majority, and in Virginia by a majority of 30,365 in 150,000 votes cast. Congress for the first time adopted in this year a resolution in one house by a majority vote (193–189), but it did not obtain the requisite two-thirds required for the submission of a prohibition amendment to the federal constitution. Considerable extension of dry territory under local option votes was secured in many other states. In 1915 Alabama re-enacted a prohibition law adopted in 1907 but repealed in 1911; and Idaho, Iowa, Arkansas and South Carolina adopted state prohibition statutes. Idaho also submitted to the people a constitutional amendment to the state constitution which was adopted the following year. The year 1916 also recorded the adoption of constitutional state prohibition in Michigan, Montana, Nebraska and South Dakota.

In 1917 the resolution for the submission of the prohibition amendment to the federal constitution received the necessary two-thirds vote in congress which also enacted prohibition for the District of Columbia and the territory of Alaska. A referendum on prohibition was voted on in Puerto Rico in July and adopted by 99,774 votes for prohibition to 61,295 against. Indiana, New Hampshire and Utah adopted state-wide prohibition statutes, and New Mexico, a state constitutional amendment. Minnesota voted also for a constitutional amendment by a majority of 15,932 of all the votes cast, but this was 756 short of the majority the state constitution required for its adoption. Missouri and California defeated constitutional amendments by substantial majorities. By the end of this year before the federal amendment was submitted for ratification, statutory or constitutional prohibition was the law in 25 of the 48 states, and in the District of Columbia. Alaska and Puerto Rico. In nearly every state in one way or another dry territory had been greatly extended.

In 1918, while ratification was proceeding, Florida, Nevada. Ohio, Texas and Wyoming adopted state-wide prohibition statutes, and Utah a prohibition amendment to its state constitution. Congress enacted a prohibition statute for Hawaii, and passed the War Prohibition act as an amendment to the agricultural appropriation bill. Several states adopted constitutional prohibition amendments in 1919.

The 18th Amendment. — The text of the amendment ratified Jan. 16, 1919, by the 36th state making the necessary three-fourths of all the states required for its adoption is as follows:

"Section 1. After one year from the ratification of this article the manufacture, sale, or transportation of intoxicating liquors within, the importation thereof into, or the exportation thereof from the United States and all territory subject to the jurisdiction thereof for beverage purposes is hereby prohibited.

"Section 2. The Congress and the several States shall have concurrent power to enforce this article by appropriate legislation.

"Section 3. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by the Legislatures of the several States, as provided in the Constitution, within seven years from the date of the submission hereof to the States by the Congress."

The amendment as ratified and proclaimed in effect on Jan. 16, 1920, was subsequently ratified by ten additional states, and in six of these (South Dakota, Idaho, Washington, Kansas, Utah and Wyoming) by unanimous vote in both houses of the legislature. Only two states (Connecticut and Rhode Island) did not ratify it. Dr. Ernest H. Cherrington in an article entitled "World Wide Progress Toward Prohibition Legislation" (*Annals*, vol. 109, p. 223, Sept. 1923) says: "No amendment to the Federal Constitution ever received as strong official sanction by the States as the 18th amendment. The original Constitution was adopted in the thirteen original States by a majority of about two to one. The aggregate vote in the State senates and State houses of representatives for the ratification of the 18th amendment shows a majority of more than four to one."

Forty-seven states enacted laws to help carry into effect the provisions of the 18th amendment, though one such law in Nevada was held unconstitutional because of a defect in title. New York, Montana and Wisconsin repealed their enforcement statutes by the end of 1929, but until then the great mass of state legislation tended to strengthen state efforts to enforce prohibition. In the next five years, however, by the end of 1934, all but nine states had voted to repeal their statutory or constitutional prohibition measures, or both, or they had enacted liquor control of the state monopoly or licence type, sometimes with local option for limited prohibition. After the repeal of the 18th amendment by the ratification of the 21st amendment, effective as of Dec. 5, 1933, and the repeal of the prohibition provisions of the Volstead act in Aug. 1935, there were only three states left (Kansas, Mississippi and Oklahoma) in 1942 with state-wide statutory prohibition.

THE ERA OF NATIONAL PROHIBITION

These 14 Years.—From Jan. 16, 1920, to Dec. 5, 1933, is 14 years lacking a few weeks, a short period in the life of a nation, but a momentous one in the social history of the American people. Not since the slavery issue of the middle years of the 19th century has any question been so widely debated, so bitterly contested or pursued with so much determination and idealism as national prohibition by the people of the United States. It came with surprising suddenness, yet the way had been prepared for over 100 years. The new techniques and devices of a greater variety of governmental agencies employed today in the work of liquor control, rather than prohibition, and a new reliance on scientific research for guidance on the complex problems of alcohol, as exemplified by the Research Council on Problems of Alcohol, of the American Association for the Advancement of Science, and as now carried on by temperance and educational organizations everywhere, and even by agencies of the liquor traffic itself, such as Distilled Spirits Institute, Inc.—these and other similar forces give some assurance that the "experiment noble in motive" of national prohibition may not have been in vain.

The Background Influences.—A sufficient indication of the long-time trends in prohibition legislation in state and nation has already been given to account in part for the tidal wave of demand for action on a national scale. Social and economic factors played perhaps as great if not a more important role than the more noticeable moral, religious and political influences organized with increasing effectiveness. New scientific knowledge in the early years of the 20th century caused a mounting public interest in health and efficiency, and the new industrial economics of expanding large-scale production brought increasing support, both moral and financial, to every effort to curb the liquor traffic and reduce the ravages of alcohol. New educational forces at work viewed with growing disfavour the saloon as the so-called poor man's club, and finally there was manifest everywhere increasing irritation with the saloon as a political menace.

World War I was not the cause of the demand for national prohibition though it probably did accelerate it. The absent soldier vote if cast at the time would not have made any substantial change in the decisions reached at the polls. As soon as the United States entered the war, two economic factors—the fear of the loss of manpower on account of intemperance, and the loss of food used in the manufacture of alcohol but needed to supply the army of the United States and that of its allies—served to crystallize an overwhelming sentiment in favour of permanent constitutional prohibition as well as war prohibition. The War Prohibition act of Nov. 1918, an amendment to the Agricultural Appropriation bill, enacted ten days after the Armistice was signed, did not go into effect until June 30, 1919, six months after the ratification of the 18th amendment, but it set a standard until the end of demobilization. It forbade the use of grain, cereals, fruit or other food products in the manufacture or production of beer, wine or other intoxicating malt or vinous liquor for beverage purposes, and made it unlawful to sell for any beverage purposes any such product or any distilled spirits from bond except for export. Such acts, together with earlier congressional enactments such as the Food Control act of Aug. 1917 and the act restricting or prohibiting the sale of liquor at military stations or to members of the military forces in uniform, or in or near military camps, all had a marked effect in support of national prohibition.

The Volstead Act.—The National Prohibition act (41 Stat. 305), popularly known as the Volstead act, and sometimes referred to as the Prohibition Enforcement law, passed the house of representatives, July 22, 1919, by a vote of 287 to 100, three members voting "present." It passed the senate with slight amendments and without a roll call on Sept. 4, 1919. The conference report was adopted in the senate, Oct. 8, without roll call or record vote, and in the house by a vote of 321 to 70 on Oct. 10. It then went to President Woodrow Wilson who vetoed it, and returned it Oct. 27. The house on the same day, by a vote of 176 to 55, passed it over the president's veto, and the senate did likewise the next day by a vote of 65 to 20. Therefore on Oct. 28, 1919, this measure became law applicable by its terms immediately for the enforcement of the War Prohibition act, and "when the 18th amendment to the Constitution goes into effect," intended to carry out the purposes of that amendment. The act is notable for its definitions, including the fixing of ½ of 1% of alcohol by volume as the test of intoxicating liquor, and the delegation of power to the commissioner of internal revenue to make regulations, with the approval of the secretary of the treasury, having the force of law, for carrying out the provisions of the act. The ½ of 1% definition was not new. It was in use in many state prohibition laws and had been the standard since 1902 for internal revenue taxation.

The constitutional validity of the adoption of the 18th amendment, and the constitutionality of the Volstead act with its definition of intoxicating liquor were tested in the U.S. supreme court and promptly sustained in the leading cases of *Hawke* v. *Smith*, decided June 1, 1920 (253 U.S. 221), and *Rhode Island* v. *Palmer*, decided June 7, 1920 (253 U.S. 350), in which the court disposed of several cases pending. Prohibition as embodied in the 18th amendment was held within the amending power, a part of the constitution, and "must be respected and given effect the same as other provisions of that instrument," and was "operative throughout the entire territorial limits of the United States . . . [and] of its own force invalidates every legislative act, whether by Congress, by a state legislature, or by a territorial assembly, which authorizes or sanctions what the [first] section forbids." The court had previously sustained the War Prohibition act and the ½ of 1% limit which it specified. The liquor interests hoped for greater latitude by construction of the first section of the 18th amendment which did not specify the content or define intoxicating liquor. The court, how-ever, without stating or discussing this contention, cited the war prohibition cases in support of the conclusion that while "recognizing that there are limits beyond which Congress cannot go in treating beverages as within its power of enforcement, we think those limits are not transcended by the provisions of the Volstead Act."

THE WORKING OF THE NATIONAL PROHIBITION ACTS

Enforcement.—The Volstead act provided for drastic enforcement, and was intended to give the government ample powers, through the commissioner of internal revenue of the treasury department, to detect and suppress all manner of violations. Congress was at liberty to amend these administrative features and set up any agency of enforcement it chose. It did in fact put the prohibition unit of the treasury under a new assistant secretary, and by the act of March 3, 1927, created a bureau of prohibition in the treasury department with a commissioner of prohibition responsible directly to the secretary of the treasury.

The Supplemental Prohibition Enforcement act of Nov. 23, 1921, (42 Stat. 222) made the already drastic regulations for physicians' prescriptions, and for sacramental wine, more so. It provided that only spirituous or vinous liquor, the latter containing not more than 24% of alcohol by volume, could be prescribed, and that not more than ¼ gal. of vinous liquor nor any quantity of liquor containing more than ½ pt. of alcohol could be prescribed for the use of any one person within 10 days, and that no physician might have more than 100 permits within 90 days unless to meet emergency needs, to be demonstrated to the satisfaction of the commissioner who issues such permits. These restrictions on physicians' prescriptions were upheld as constitutional by the supreme court in *Lambert* v. *Yellowley* (272 U.S. 581). Other provisions of the Supplemental act gave the enforcing authorities control over importations for non-beverage purposes; provided that both the Supplemental and the National Prohibition acts applied not only to the United States but to all territory subject to its jurisdiction; that liquor laws in force when the National Prohibition act was adopted, and not in conflict therewith, should continue in force; and also made it unlawful for any U.S. officer to search any private dwelling without a search warrant. The court, however, in 1925 in *Carroll* v. *U.S.* (267 U.S. 132) upheld the search of an automobile or vehicle of transportation without a warrant where the search was not malicious or without probable cause. A Georgia statute which prohibited the possession of liquor which had been legally acquired before national prohibition went into effect was upheld as within the police power of the state, in another supreme court decision, *Samuels* v. *McCurdy* (69 L. ed. 371). The department of justice approved the wider use of the padlock and abatement of nuisance provisions of sec. 22 and other sections of the National Prohibition act. The methods employed in the enforcement of prohibition, as in the case of tariff and revenue laws generally, and in other laws where there is a strong motive to defeat their purpose, raise many nice questions of constitutional guarantees of liberty and the protection of innocent persons, but the supreme court decisions throughout the prohibition era went far to sustain the government and congress in the exercise of the fullest constitutional powers to enforce prohibition.

The Concurrent Power. — The second section of the 18th amendment clearly indicates by the grant of concurrent power "to congress and the several states" the joint duty and responsibility of the national and state governments to enforce prohibition through co-operation and each government performing that part of the task for which it mas peculiarly fitted. In ***Rhode Island*** v. *Palmer* (253 U.S. 350) the court defined and interpreted "concurrent power" as the power to enforce prohibition by appropriate legislation, but not to enable congress or the several states to defeat or thwart it; that it is not joint power requiring that the legislation thereunder by congress to be effective should be approved or sanctioned by the several states or any of them; neither does it mean that the power to enforce is divided between congress and the several states along the lines which separate or distinguish foreign and interstate commerce from intrastate affairs. The court also added that concurrent power, "while not exclusive, is territorially co-extensive with the prohibition of the first section of the amendment, embraces manufacture and other intrastate transactions as well as importation, exportation and interstate traffic, and is in no wise dependent on or affected by action or inaction on the part of the several states or any of them."

As thus construed the concurrent power section of the amendment reserved to the states their police power over intoxicating liquors, with the single limitation that they could not exercise it to permit what the amendment prohibits. The former policy of strengthening the police power of the state by removing constitutional barriers was now changed to one of co-operation in which the states and the federal government had equal responsibility and power. It was not a grant of any new police power to the states, but an enlargement of the police power they possessed, by extending concurrent power to interstate commerce and to importation and exportation of intoxicating liquors. Neither did concurrent power impose any new obligation on the states, but merely emphasized an old one, as Governor Alfred E. Smith noted as follows: "After repeal there will still rest upon the peace officers of this State the sacred responsibility of sustaining the Volstead Act with as much force and as much vigor as they would enforce any State law or local ordinance" (memo accompanying his approval in 1923 of the repeal of the N.Y. Prohibition law).

If the plain intent and ideal of sec. 2, as interpreted by the U.S. supreme court, had been realized more fully, enforcement would not have broken down so soon nor would hare come the demand for repeal with overwhelming force in 1935. The states, however, with few exceptions, refused to co-operate whole-heartedly; and partly on account of old conflicts under the federal-state system, but chiefly because of practical politics and partisan advantage, by so doing sealed the doom of the 18th amendment.

Administrative Difficulties. — The chief obstacles to efficient enforcement did not come from the courts, but rather from administrative difficulties arising from untrained and incompetent personnel, and the lack of enforcement machinery, or its location in several departments of the government. The failure at the outset to put all enforcement officers under civil service caused increasing trouble. Some conflict and overlapping in the efforts of the treasury and the department of justice led the judicial conference of the senior circuit judges, with the concurrence of Chief Justice William Howard Taft, to recommend in Nov. 1924 that the prohibition unit of the treasury be transferred bodily to the department of justice, and that all appropriations for enforcement be expended under the attorney-general. It was thought that a closer co-ordination of the experience and technique of the treasury department with prosecutions by the department of justice would avoid the prosecution of trivial, futile and unimportant cases which crowded the dockets, and would enable district attorneys better to prepare those cases which would really deter the principal offenders. Partly because of the nature of the proceedings in federal courts requiring jury trial, and partly due to the absence of federal police courts to dispose of petty cases, "the resources of the federal government in administration and judicial machinery were sufficient to cope successfully only with what might be called the 'wholesale' aspects of the enforcement problem — smuggling, including report of arrests, seizures, etc., made by federal prohibition officers, the withdrawals of bonded liquors, the diversion and conversion of industrial alcohol to beverage uses, interstate transportation of liquors and the major conspiracies to violate the law, some of which are of giant proportions" (*see* BOOTLEGGING AND SMUGGLING). For the rest, state and local machinery would have to be relied upon to enforce the law.

In response to these and many other suggestions, and to bring the problems of prohibition enforcement more directly under the eye of the secretary of the treasury and the president, congress reorganized the prohibition unit, and created by act of March 3, 1927, a bureau of customs and a bureau of prohibition in the department of the treasury. This was recommended by the secretary of the treasury and centralized responsibility for enforcement of prohibition in a commissioner directly responsible to the secretary of the treasury. It provided for the appointment of a staff under the commissioner, subject to the provisions of the civil service law. In the opinion of the commissioner the civil service requirement did bring about a marked improvement in personnel, and enabled the new bureau to continue more effectively the policy previously followed, namely, decentralization of the prohibition service, and concentration upon the things that federal enforcement could do best, whether the state and local authorities did their part or not.

Treaties to check liquor smuggling were negotiated with Great Britain in Jan. 1924 (ratified and proclaimed, May 22, 1924) and the principal countries of Europe, and Canada, Cuba, Panama and Mexico. These treaties embodied the so-called 12-mile limit, or one-hour run, for boarding and examination of private vessels under foreign flags. They were liberally construed by the U.S. supreme court. (*See* SMUGGLING.)

The major effort in the reorganization of prohibition enforcement was the Prohibition Reorganization act of May 27, 1930 (Pub. No. 273, 71st Cong.). This act, effective from July 1, 1930, established the bureau of prohibition in the department of justice, and the bureau of industrial alcohol in the treasury department. They were previously a single bureau in the treasury department. It was a functional change which greatly accelerated improved enforcement of the prohibition laws, but it came too late to repair the public's shattered confidence in the enforcement agencies, either federal, state or local. Albert E. Sawyer, technical expert of the National Commission on Law Observance and Enforcement, thought that there were losses as well as gains in the reorganization, and that "the undeniable improvement in the effectiveness of prohibition work since the transfer may be the direct result of the aggressiveness which has characterized the attorney-general and his assistants." (For chart and excellent discussion, *see* "The Enforcement of National Prohibition," *Annals*, vol. 163, Sept. 1932, pp. 10–29.)

National Commission on Law Observance and Enforcement. — President Herbert Hoover appointed May 20, 1929, a commission of 11 eminent citizens including one woman, the president of Radcliffe college, to make "a thorough inquiry into the problem of the enforcement of prohibition under the provisions of the 18th amendment of the constitution and laws enacted in pursuance thereof, together with the enforcement of other laws." Eight days later the commission with George W. Wickersham as chairman met at the White House and President Hoover emphasized that he wanted a broad inquiry dealing not only with one law or the laws of the federal and state governments separately, but with the enforcement of, obedience to, and attitude toward all law.

The commission performed its task ably, thoroughly and with commendable speed. Through public hearings in various parts of the country, by special studies of experts engaged by the commission, it assembled from both official and unofficial sources much valuable data not previously available in consolidated form. A preliminary report was submitted in Nov. 1929, and a supplementary report in Jan. 1930. Both dealt chiefly with legal and constitutional questions of procedure in law enforcement. The president sent both reports to congress on Jan. 13, 1930, with a message, accompanied by memoranda from the attorney-general and the secretary of the treasury, endorsing recommendations for more centralization of administrative responsibility for enforcement, more courts and better judicial and prosecuting procedure (H.R.Doc. No. 252, 71st Cong., 2nd Sess.). Congress and the public alike, however, awaited the appearance of the major report on the larger issues involved. This appeared a year later with the title: "A Report on the Enforcement of the Prohibition Laws of the United States," and was sent to congress with a message from the president on Jan. 7, 1931 (H.R.Doc. No. 722, 71st Cong., 3rd Sess.). After a time several volumes of documents and evidence followed.

Thus the commission under pressure for too great speed in making a full report had not quite achieved the larger purposes for which it was organized. It was courageous in its exposé of the wealiness of the first seven years of what it called "imperfect enforcement," and sparing in its praise of the improvement of the three years of reorganization. The lack of a master plan, of skilful leadership, of proper co-operation and a united front between such important key agencies as the customs, coast guard, and prohibition bureau, and even the activities of the pressure groups and political forces, pro and con enforcement, are dealt with frankly and fearlessly, and if the report could have been issued five years earlier might have built up normal support of public opinion for normal observance of the prohibition laws. But in 1930 it was too late to expect that, and the commission seemed to think that some modification of the prohibition policy was necessary to restore public confidence in the enforcement agencies of government, either federal, state or local. Yet five of the nine major recommendations and conclusions of the report were squarely opposed to repeal of the 18th amendment; the restoration in any manner of the legalized saloon; the modification of the N.P. act to permit light wines and beers; authorizing federal or state governments to go into the liquor business; inadequate co-operation of the states. Condensed and authoritative statements and interpretation of the commission's report by its chairman, and chief technician, mill be found: (1) *Amer. Bar Ass'n Jour.*, vol. 16. Oct. 1930, pp. 654, 660–61 (Wickersham, "Program of the Commission on Law Observance and Enforcement"); (2) two articles by A. E. Sawyer, *Michigan Law Review*, vol. XXX, Nov. 1931, and *Annals*, American Academy of Political and Social Science, vol. 163, pp. 10–29, Sept. 1932.

The Economic and Social Results of Prohibition. — Here is the nub of the controversy that raged so violently in the decade preceding repeal of the 18th amendment. That much more heat than light emanated from the millions of spoken and written words on this theme was to be expected. Scientific standards of measurement and scientific data on which to base sound judgment were, for the most part, lacking, even for such items as uniform records of arrests for drunkenness, of law violations, prosecutions, sentences, alcoholic morbidity and mortality, etc., on which the government should have been able to disseminate accurate information. Looking back it is clear that the prohibition "authority" of the federal government, wherever located, did a poor educational job, because in the last analysis it was the social and economic aspects of national prohibition, rather than the moral or legal, that decided the fate of the 18th amendment. In every state of the union there was a middle-of-the-road contingent, which cast perhaps 75% of the vote. It could have been lined up for or against national prohibition on clear-cut statements of fact concerning social and economic consequences of one policy or another.

The report of the Federal Council of Churches (Research Bulletin No. 5, p. 83, 1925) is one of the best of the unofficial inquiries and furnishes some significant conclusions based on good scientific handling and sampling of questionnaire testimony of social workers. This shows a preponderant opinion at that time that prohibition had helped secure better furnished homes for working people; better mental health of the home as shown by better family co-operation, respect of children for parents, and of parents for children, and by better educational ideals; also larger proportion of the hsuband's income going to wife and family, and improved marital relations. Favourable community effects were recorded in this special poll: less children's delinquency; less malnutrition; liquor for minors less accessible. But in contrast the inquiry also showed more drinking by young people, and a worse attitude toward law enforcement and respect for laws in general. The Federal Council report, however, does not support the theory that prohibition had caused a moral breakdown among young people. The report's most conclusive finding is that social legislation is no substitute for social education, and that "the illicit liquor traffic will be finally overcome only when and where education in temperate living strongly reinforces the arm of the law."

Similar reports, not all of them so well documented, appeared from many social agencies, business men's organizations, and civic groups, and some dealt more definitely with the wage-earner's stake in prohibition. Still other reports emanated from organizations and groups opposing prohibition: the Association Against the Prohibition Amendment, Repeal Associates, Women's Organization for National Prohibition Reform, the Moderation League, the Crusaders, etc., presented studies of the new evils, and their social and economic consequences, attendant on the failure to enforce, or as some contended, the unenforceability of national prohibition. Matters emphasized in these reports are: the speakeasy as a substitute for the saloon; the public disregard for all laws; public corruption for protection of illegal traffic; the effect on the administration of justice of overflowing prisons and courts cluttered with prohibition cases; the threat, to social and economic security, of huge revenues from the illegal liquor traffic in the hands of well-organized criminals.

Among the many individual studies of the social and economic consequences of prohibition, typical and well-balanced, are: (1) Prof. Irving Fisher's Prohibition at Its Worst (1926) and Prohibition Still at Its Worst (1928), and his report to the American Economic Association (1927, A. E. Review, xvii, No. 1, suppl. March) which claimed that the country was at least $6,000,000,000 better off as a result of prohibition. (2) Prof. Herman Feldman's Prohibition: Its Industrial and Economic Aspects (1927) based on a nine months' personal study of industrial plants, documentary material, and questionnaires sent to 1,200 concerns with over 1,250,000 employees. Feldman finds that "the economic benefits of legal prohibition are based upon substantial prohibition in fact; on the actual abolition of the saloons, or their reduction to a negligible quantity, not on the mere change in name; on a greatly lessened consumption of alcoholic beverages; on a general influence in promoting temperance and discouraging over-indulgence." (3) Dr. Clark Warburton's Economic Results of Prohibition (1932), and in briefer form, *Prohibition* and *Economic* Welfare (Annals, American Academy of Political and Social Science, vol. 163, pp. 89–97, Sept. 1932). This is an able study, but largely negative in its conclusions and results because of the lack of positive statistical evidence and unwillingness to weigh or consider any other kind of evidence. In general, Dr. Warburton concludes that "prohibition had little to do with the prosperity of the Nation from 1923 to 1929 and the increased purchases during those years of many types of luxury and semi-luxury goods."

To this brief statement of very general conclusions from many sources, and in rather sharp contrast to that of Dr. Warburton, just cited, should be added the statement of Secretary of Commerce Herbert Hoover in an address before the U.S. chamber of commerce, as quoted in the Christian Science Monitor, March 11, 1925, as follows:

"There can be no doubt of the economic benefits of prohibition. Viewing the temperance question only from this angle, prohibition has proved its case. I think increased temperance over the land is responsible for a good share of the enormously increased efficiency in production, which statistics gathered by the Department of Commerce show to have followed the passage of the dry law. Exhaustive study from many angles of production . . . indicates that while our productivity should have increased about 15% due to increase in population, the actual increase has been from 25% to 30%, indicating an increase of efficiency of somewhere from 10% to 15%. . . . There is no question in my opinion that prohibition is making America more productive."

REPEAL OF THE 18TH AMENDMENT AND THE POST-REPEAL ERA

The revolt against the 18th amendment, and the agitation for its repeal, did not assume serious proportions until the presidential campaign of 1932 when it became a national issue. Conscientious objectors, like Dr. Nicholas Murray Butler, had voiced their protest even before the amendment was ratified. In the Borah-Butler debate in Boston, April 8, 1927, Dr. Butler said:

"The 18th amendment must come out of the Constitution because it does not belong there. It affronts and disfigures it. It contradicts every principle upon which the Constitution rests, and the difficulties, the embarrassments, the shocking scenes reported daily from every part of the land are the natural and necessary result of the inner contradiction that has been set up between the Constitution as it was and the 18th amendment added to it in 1919. . . .

"We talk of law enforcement. You cannot enforce conflicting laws—something must give way; and, when it is the 18th amendment and the legislation based upon it on the one hand and the whole body of the Constitution, the Bill of Rights, the whole of political English and American History on the other, which do you suppose will have to give way? It must be this new and invading element in our public law."

Such was the moral objection which was intelligently and forcibly presented by a sincere small minority. It might have won more sustainers if it had shown greater recognition of the economic facts that underlie public morals, and of the effectiveness of the constitution and the government it set up, to deal with the social problems of modern democracy.

The Modificationists.—They were a second and more numerous group of less conscientious objectors. They wanted more alcohol, "light wines and beer" (or by any other name the people might prefer), than the 18th amendment allowed under the implementing Volstead act, or than the supreme court would sanction if that act were amended to increase the ½ of 1% standard of intoxicating liquor. Hence they advocated repeal of the Volstead act, leaving to the states the enactment of such prohibitory laws as their citizens might desire the implement the 18th amendment within their boundaries and provide varying degrees of dryness or wetness to suit local tastes. Prof. Howard Lee McBain (Prohibition: Legal and Illegal [1928]) considered this suggestion and others like it to circumvent the 18th amendment, but his conclusions gave scant encouragement to those who did not want to conform to the dictates and spirit of national prohibition while the 18th amendment remained a part of the constitution.

The political demand for repeal lagged behind the changes taking place in public opinion. In 1928 the national party platforms of both major parties pledged vigorous (Republican) and honest (Democratic) enforcement, but by 1930 the state party platforms in 21 states (14 Democratic and 7 Republican) demanded repeal of the 18th amendment, and in 1932, both national party platforms favoured repeal with safeguards to protect state prohibition territory, or the submission of a proposal to revise in a way to furnish such safeguards.

Supporters of the Experiment.—Opposed to repeal or modification were two groups: (1) the extreme and uncompromising upholders of constitutional prohibition as the only practical method of dealing with the organized liquor traffic and bringing it under social control. In the main the officials of the Anti-Saloon leagues and most of the temperance societies, and such political leaders as Senator Morris Sheppard and Congressman Volstead were spokesmen for this group; (2) a large group of no less sincere but more moderate prohibitionists who were more keenly alive to the economic foundations and implications of national prohibition. This included such national leaders as Senator William E. Borah, Herbert Hoover and many captains of industry, like Henry Ford, Thomas A. Edison and others. This group favoured a longer trial and a greater effort to secure co-operation of both state and national governments, and enlist the active support of the great mass of law-abiding citizens, before saying that the 18th amendment and its supporting legislation could not be enforced. Many excellent suggestions offered in the W. C. Durant prize contest, Aug. 27–Nov. 30, 1928, "for the best and most practical plan to make the 18th amendment effective," showed conclusively that it was not lack of brains or technical skill on the part of the leaders who would and could have enforced the 18th amendment if they had had the strong support of a favourable public opinion such as caused its adoption. Countersuggestions showing the trend towards and the character of the demand for repeal, will be found in the W. R. Hearst temperance prize contest, Jan.–Apr. 1929, "for the best plan to repeal the 18th amendment and substitute in place of prohibition a more liberal and more American measure," later changed to "the best plan to achieve temperance." For a full account of these contests and the winning plans see W. C. Durant, ed., Laze, Observance, p. 573 (1929); and Francis J. Tietsort, ed., Temperance or Prohibition, p. 397 (1929).

The presidential campaign of 1932 settled the issue overwhelmingly for repeal. The plank in the Democratic platform was unequivocally for repeal, and the Republican plank, as recommended by the majority of the resolutions committee, apparently favoured the submission of a proposal to revise the 18th amendment with some safeguards attached. Dr. Butler, Senator Borah and other leaders claimed, however, that the minority recommendation of the resolutions committee favouring outright repeal more nearly represented the majority sentiment of the convention, but had been defeated by controlled votes. The *N.Y. Times* of June 7 and 9, before the Republican convention had acted, quoted two of the most influential supporters of the 18th amendment, John D. Rockefeller, Jr., and John R. Mott, as respectively in favour of repeal and resubmission.

Submission and Ratification of the 21st Amendment, Repealing the 18th.—The second session of the 72nd congress meeting within a month of the November elections lost no time in preparing a joint resolution which was adopted by two-thirds majority in both houses; in the senate, where the joint resolution originated, by a vote of 63 for, to 23 against, on Feb. 16, 1933, and in the house on Feb. 20 by a vote of 289 for, to 121 against. It was deposited in the department of state, Feb. 20, and the following day was sent by the secretary of state to the respective governors of the 48 states.

The proposed amendment, as subsequently ratified, becoming the 21st amendment to the constitution, reads as follows:

"Section 1. The eighteenth article of amendment to the Constitution of the United States is hereby repealed.

"Section 2. The transportation or importation into any State, Territory, or possession of the United States for delivery or use therein of intoxicating liquors, in violation of the laws thereof, is hereby prohibited.

"Section 3. This article shall be inoperative unless it shall have been ratified as an amendment to the Constitution by conventions in the several States, as provided in the Constitution, within seven years from the date of the submission hereof to the States by the Congress."

This was the first use to be made of the method of ratification by conventions instead of by legislatures, but in less than 10 months conventions did meet in 36 states which ratified and two (North Carolina and South Carolina) which rejected the amendment. On Dec. 5, 1933, the secretary of state certified the ratification. The president followed this certification on the same day with a proclamation, pursuant to sec. 217a of the National Industrial Recovery act, in which he declared the 18th amendment repealed. While the president did call on all citizens to co-operate with the government in getting rid of the illicit liquor traffic, and to note the new prohibition against wet states invading the territory of those who wished to remain dry, not even the president seemed to realize the full significance of the second section of the 21st amendment.. That was left for Justice Louis D. Brandeis and the supreme court to reveal in two little-noticed but remarkable decisions: (1) *State Board of Equalization of California* v. *Young's Market Co., et al.* (299 U.S. 59) decided in 1936; and (2) *Finch & Co.* v. *McKittrick* (305 U.S. 395) decided Jan. 3, 1939. The gist of these two decisions of Justice Brandeis may be seen in two sentences. One taken from the first, speaking of the 21st amendment, says that the words of the amendment "are apt to confer upon the States the power to forbid all importations which do not comply with the conditions which it prescribes"; and the other, from the second decision, to the effect that: "Since that amendment (the 21st), the right of a State to prohibit or regulate the importation of intoxicating liquor is not limited by the commerce clause." Prof. Noel T. Dowling of the Columbia university law school noted within a month after the first decision was handed down, its revolutionary character in constitutional law and history. He raises the question whether it was the intent of the 21st amendment to go so far, and whether the court would go the whole way to permit the states to put themselves in a position oi economic isolationism with respect to intoxicating liquors. The second decision gives an affirmative answer to both questions. (*See* Noel T. Dowling, "Liquor and the Constitution," *Independent Journal,* Dec. 18, 1936, Col. Univ.) The second section of the 21st amendment not only put the Webb-Kenyon law substantially in the constitution, and thereby placed it beyond the power of congress to change, but by the interpretation given to it in the Brandeis decisions "the states," as Prof. Dowling says, "seem to have been lifted to a new, surprising, extraordinary position of power in the American federal system."

After Repeal.—At the end of nearly a decade after repeal (1943) it was still impossible to predict how far the states would succeed with the new powers in doing what they failed to do before national prohibition, and what the federal government without their full co-operation failed to do during the era of national prohibition. The president's proclamation of repeal also promised federal aid, and among other things said: "The objective we seek through a national policy is the education of every citizen toward a greater temperance throughout the Nation."

Steady progress toward legal tax control was made by the Federal Alcohol administration and in the individual states through the licensing and monopoly control in all except those areas which, by local option, have prohibition. (*See* LIQUOR LAWS AND LIQUOR CONTROL.) During 1942, local option elections in nearly 1,500 geographical areas showed more pronounced dry gains than in any one of the previous nine years, all of which showed some dry gain. It was reported that in that period in over 12,000 local option elections the drys won nearly two-thirds of them. Both the liquor interests and the temperance forces were suspicious of each other fearing that advantage would be taken of the war situation to renew old controversies. Polls indicated a rising tide of dry sentiment even to a reported 36% in one poll favourable to national prohibition. Although there was something in the pattern of World War II events to suggest the antecedents of prohibition in the years 1917–19, the background of legislative demands and action was radically different. The temperate statement of the executive committee of the Federal Council of Churches on Nov. 27, 1942 (*Information Service,* Dec. 5, 1942), presented positive measures to control and reduce the evil effects of beverage alcohol, with particular reference to the wartime situation. These probably fairly represented the attitude of the Protestant Churches, and indicated the trend of thought in most of the temperance societies, Protestant and Catholic.

Too great or sole reliance on legal compulsion defeated national prohibition. The better course that combines education and restraint, both legal and voluntary, in the suppression of the evils of the liquor traffic, was well illustrated in a broadcast of Prime Minister Mackenzie King of Canada, on Dec. 16, 1942, from Ottawa, on "Temperance and a Total War Effort." He asked the provinces to further restrict the hours of sale to eight per day; he lamented the increased consumption of alcoholic beverages as unseemly in wartime when so many are sacrificing so much; and he announced the decision of his government under its war powers to prohibit after Feb. 1, 1943, all liquor advertisements throughout Canada for the duration.

Whatever may be said of prohibition, law, enforcement or repeal, these facts remain: During the prohibition era, a vast, illicit and vicious business of bootlegging was active. It could not have existed without enormous purchases, *in toto,* of bootleg stuff by otherwise reputable citizens who not only resisted the law but defied it and disobeyed it, thus lowering the standards of civic honour.

When repeal came in, it proved to be no immediate remedy for the appalling disintegration of social, intellectual and moral ideals, caused in large part by the illegal practices connected with bootleg liquor. In 1942, war brought additional questionings and difficulties. Many were inclined to believe that certain strict governmental protective and prohibitory measures might still be necessary for social welfare, but that the real progressive solution of the liquor problem might lie in the acceptance of individual responsibility; in voluntary commitment to the temperance cause; in scientific study; in home training and parental example; in the teaching and nurture of the church; and in better social customs.

In a word, the solution might lie more in the educational and spiritual realm, than in the legislative and political.

A new pragmatic emphasis on social and economic results and less controversy about ideologies may characterize the post-repeal era.

PROHIBITION IN LAW, a term meaning the action of forbidding or preventing by an order, a decree, etc. As defined by Blackstone, prohibition is "a writ directed to the judge and parties of a suit in any inferior court, commanding them to cease from the prosecution thereof, upon a surmise either that the cause originally or some collateral matter arising therein does not belong to that jurisdiction, but to the cognizance of some other court." A writ of prohibition is a prerogative writ—that is to say, it does not issue as of course, but is granted only on proper grounds being shown. Before the Judicature acts prohibition was granted by one of the superior courts at Westminster; it also issued in certain cases from the court of chancery. It is now granted by the high court of justice. By the Judicature act, 1873, s. 24, it is provided that no proceeding in the high court of justice or the court of appeal is to be restrained by prohibition, a stay of proceedings taking its place where necessary. In the case of courts of quarter sessions, the same result is generally obtained by certiorari (see WRIT).

In Scots law prohibition is not used in the English sense. The same result is obtained by suspension or reduction. In the United States the supreme court has power to issue a prohibition to the district courts when proceeding as courts of admiralty and maritime jurisdiction.

Most of the states have also their own law upon the subject, generally giving power to the supreme judicial authority in the state to prohibit courts of inferior jurisdiction. (*See* LIQUOR LAWS AND LIQUOR CONTROL; TEMPERANCE.)

Prohibition is a writ which lies to restrain the unlawful exercise of judicial functions on the part of a lower court, issuing from a court of higher jurisdiction. Again, it may be used to restrain an official from doing an administrative, ministerial or legislative act not falling within his province.

PROHIBITION PARTY, THE NATIONAL, a minor political party of the United States which set as its primary objective the legislative prohibition of the manufacture and sale of intoxicating liquors. From time to time it also proclaimed its interest in other reforms. The party was organized in 1869 and in 1872 placed its first candidate for president in the field. It offered candidates for president and vice-president in every succeeding presidential election. Though one of the most persistent of the third parties, it polled fewer votes in most elections than some others of more radical character. Its highest figure, 271,058 votes out of a total of 12,043,603 cast, was in 1892. In 1948 it polled only 103,216 out of 48,833,680 cast. While the 18th amendment was in effect, the party agitated for its enforcement, but growing hostility to prohibition and the amendment's final repeal in 1933 forced the party to resume the political struggle within individual states.

PROJECTION, IN MATHEMATICS. Let A, B, C, D, etc., represent points of a straight line 1 and A', B′, C′, D′, etc., points of another straight line l′ in the same plane with 1. If the straight lines, AA', BB', CC', DD', etc., are all perpendicular to the line l′, the set of points A', B', C, D', etc., is said to be an orthogonal projection of the set, A, B, C, D, etc., (fig. 1). The correspondence between the two sets of points, by which A corresponds to A', B to B', etc., is called an orthogonal projection. In case the straight lines AA', BB', etc., are all parallel, without being necessarily perpendicular to l′, we use the term parallel projection instead of orthogonal projection (fig. 2). In case the lines AA', BB', CC', etc., all meet in a point O we speak similarly of central projection. In all three cases we say that the two sets of points A, B, C, D, etc., and A', B', C, D', etc., are in perspective and that the points of one set are projected into the points of the other set. The point O is called the centre of perspectivity or the centre of projection of the two sets of points as indicated in the accompanying diagram (fig. 3).

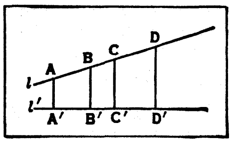

FIG. 1

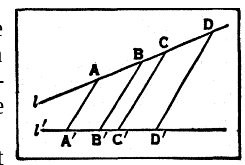

FIG. 2

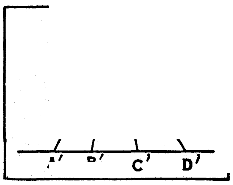

FIG. 3

These conceptions have been generalized in various ways. For example, let A, B, C, D, etc., be the points of any figure F in space and A', B', C', D', etc., be corresponding points of a figure in a plane π. If the straight lines AA', BB', CC', etc., are all parallel or all meet in a point O the figure in the plane π is called a projection of the other figure. If the lines AA', BB', etc., are all perpendicular to the plane π, the figure in π is called an orthogonal projection of the other figure. (*See* also DESCRIPTIVE GEOMETRY; PERSPECTIVE; PROJECTIVE GEOMETRY.) (O. V.)

PROJECTIVE GEOMETRY. Projective geometry is a branch of mathematics which originated in the study of projections as applied to problems of perspective in the drawing of pictures and in optical instruments. These practical applications are now studied under the captions of descriptive geometry (see DESCRIPTIVE GEOMETRY) and geometrical optics (*q.v.*), while projective geometry itself is cultivated for its intrinsic interest. It is a well co-ordinated and symmetrical theory of considerable aesthetic merit, which on the one hand enables us to view elementary geometry as a completed whole, and on the other hand serves as the starting point of the higher algebraic geometry. For a more detailed study the reader is referred to one or more of the text books listed at the end of this article. The article itself attempts merely to state some of the general ideas, definitions and theorems in an introductory way and without proof.

One-dimensional **Projectivities.**—The notion of projection is defined in the article on that subject (see PROJECTION, IN MATHEMATICS). Suppose that the points of a line a are projected into the points of a line b, and the points of b into the points of a line c, the points of c into the points of a line d, and so on, ending up with the points of the line k. Every point A of the line a then corresponds to a definite point K of the line k. This correspondence is called a *projective* transformation or projectivity, and is sometimes indicated symbolically by

$$. \; . \barwedge \{K\}$$

The set of all points of a line l is called a range (or a pencil or row) of points, so that in the books on projective geometry there is often talk of projective ranges. In case we wish to discuss the correspondence, not of all the points of a, but only of certain ones, say A_1, A_2, A_3, A_4, we may write

$$A_1A_2A_3A_4 \barwedge K_1K_2K_3K_4.$$

The first theorem about projectivities is that any three points of a straight line can be projected into any three points of a straight line. In other words the statement

$$A_1A_2A_3 \barwedge K_1K_2K_3,$$

is true whenever it is true, (1) that A_1,A_2,A_3 are distinct and collinear, and (2) that K_1,K_2,K_3 are distinct and collinear. It is also true that if the points A_1,A_2,A_3 and K_1,K_2,K_3 are on different lines the projectivity can be brought about by the intervention of not more than two intermediate projections. That is, if the points A_1,A_2,A_3 and K_1,K_2,K_3 are given on different lines it is possible to find a line b such that A_1,A_2,A_3 can be projected respectively into the points B_1,B_2,B_3 of b, and these points into K_1,K_2,K_3, respectively. If A_1,A_2,A_3 and K_1,K_2,K_3 are on the same line, three intermediate projections may be needed.

A second theorem is that any projective transformation of a line is fully determined by the fate of three of the points of the line. In other words, if it is specified that A_1 goes to K_1, A_2 to K_2, A_3 to K_3, then for any point A_4 of the line A_1A_2 there is a uniquely determined point K_4 of the line K_1K_2 to which A_4 goes. This theorem is often referred to as the *fundamental* theorem of projective geometry.

Points at Infinity.—From the point of view of elementary geometry, there are certain exceptions to these theorems, due to the existence of parallel lines. For example in fig. 1, the point A_0 is not projected into any point of the line b because the line from

A_0 to the centre of projection is parallel to b. This circumstance complicates the statement of the theorems about projections if we adhere to the point of view of elementary geometry. In projective geometry it is avoided by introducing the conception of points at infinity, or ideal points. To every straight line a there is attributed one point at infinity and every line parallel to a is said to meet a in the point at infinity of a. In fig. 1 the point A_0 is therefore said to be projected into the point at infinity of the line b. The points at infinity of the straight lines of a plane are said to constitute a straight line, the line at *infinity* of this plane. All the points at infinity of a three-dimensional space are said to constitute a plane which is called the plane at infinity.

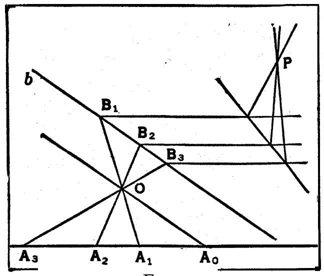

FIG. 1

We shall not attempt here to justify the conception of points at infinity. The question is discussed at length in the books on projective geometry. It may be remarked however that the ordinary points are just as much idealized as are the points at infinity. No one has ever seen an actual point or realized it by an experiment of any sort. Like the point at infinity it is an ideal creation which is useful for some of the purposes of science. With the aid of these conceptions we obtain great simplicity and symmetry in the statements of geometry. For example we have: (a)' any two points have one and only one straight line in common; (b) any two straight lines in a plane have one and only one point in common; (c) any two planes have one and only one line in common; (d) a straight line and a plane have one and only one point in common, unless the line lies in the plane; (e) a straight line and a point are on one and only one plane, unless the point is on the line. Each of these statements would have to be split up into at least two propositions in order to state its full content in the language of elementary geometry; and each of the propositions would be more complicated to state than the more general projective proposition in which it is contained.

Principle of Duality.—If we restrict attention to the points and lines of a single plane there is a duality between the two propositions (a) and (b) in the list above. They can be written:

(a) Two points are on one and only one line.

(b) Two lines are on one and only one point.

Either proposition remains true if the words point and line are interchanged. The same thing is true of every theorem of the projective geometry of the plane. If it is properly formulated it remains valid when the words point and line are interchanged. This statement is called the principle of duality in the plane. *(See* **DUALITY.**) Its exact meaning depends, of course, on what we mean by a theorem of projective geometry. This is explained below with the aid of the notion of the projective group.

After the principle of duality in the plane has been comprehended it is necessary only to state one of each pair of dual theorems. The other one goes without saying. Indeed, after we have arrived at a number of propositions from which we are going to deduce all the rest by logical processes without appeal to other knowledge, and after we have verified the duals of these fundamental propositions, we know in advance that the principle of duality will hold for all the theorems which we are going to derive. This way of dealing with the principle of duality requires that the material of projective geometry shall be organized as a distinct body of knowledge (see the remarks on axioms, etc., below).

The principle can also be established by showing the existence of "duality transformations" which carry every plane figure into a dual figure in which the points and lines of the first are replaced by the lines and points of the second.

There is also a principle of duality in space, according to which the propositions of three-dimensional projective geometry when properly stated remain valid when the words point and plane are interchanged. In the list above, the propositions (a) and (c) are dual, (d) and (e) are dual, and (b) is dual to the proposition that any two straight lines with a point in common are in a common plane. In like manner there are principles of duality in spaces of any number of dimensions.

Pencils of Lines.—We must now understand that the statements which we have made about one-dimensional projectivities hold without exception, and therefore include all the special cases which arise when one or more of the points in question is a point at infinity. Glancing again at fig. 1, it is evident that there is a one-to-one correspondence between the points of the line a and the lines through the point O which are in the same plane with a, namely, each point corresponds to the line joining it to O. Such a system of lines is called a pencil of lines and the point O in which all lines of the pencil meet is called the centre of the pencil.

The notions of projectivity and perspectivity are now extended so as to apply to pencils of lines as follows: The correspondence between a range of points and a pencil of lines in which each point lies on its corresponding line is called a *perspectivity;* and any correspondence between two pencils of lines, or between a pencil of lines and a range of points, or between two ranges of points which is the resultant of any number of perspectivities is called a *projectivity.* This definition includes the definition previously given of a projectivity between two ranges of points as a special case. Under this definition, in fig. 1, the range of points on *a* is projective with the pencils of lines at O and P as well as with the pencil of parallel lines; and each of these pencils of lines is projective with the others; each of the projectivities being a one-to-one correspondence determined by the figure. Just as in the analogous case of ranges of points, if a_1,a_2,a_3 are lines of one pencil and b_1,b_2,b_3 are lines of another pencil, there is one and only one projectivity in which a_1,a_2,a_3 correspond to b_1,b_2,b_3 respectively.

Conic Sections.—The corresponding lines of two distinct projective pencils of lines in the same plane intersect in the points of a conic section (*q.v.*), provided the line joining the centres of the two pencils does not correspond to itself. For example, in fig. 2, the two pencils of lines at A and B are projective in such a way that corresponding lines are perpendicular, and they intersect in points of a circle. If the corresponding lines had not been perpendicular the corresponding lines would have intersected in an ellipse, or in a parabola, or in a hyperbola.

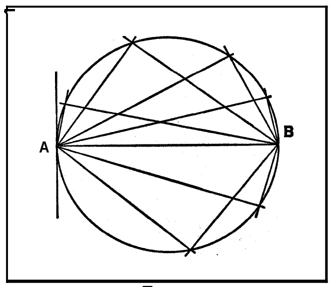

FIG. 2

This theorem of the generation of a conic by means of projective pencils makes it possible to deduce all the properties of conic sections from the theory of one-dimensional projectivities. For example, the fact that there is one and only one conic through five coplanar points, no three of which are collinear, is an immediate consequence of the fact that a projectivity between two pencils of lines is fully determined by the correspondence of three lines of the one pencil with three lines of the other. The theorem is a good example of the unifying power of projective geometry, for it includes as special cases a host of theorems about the construction of conic sections when the given five points are in special position from the point of view of elementary geometry. An equal number of additional theorems is obtained by applying the principle of duality in the plane; and a corresponding group of theorems about cones is obtained by space duality.

The Ruled Quadric.—Let A_1,A_2,A_3,A_4 be four points of a line a and B_1,B_2,B_3,B_4 four points of a line b which is not in the same plane with a. In case

$$A_1A_2A_3A_4 \;\overline{\wedge}\; B_1B_2B_3B_4,$$

then any straight line c which meets the three lines A_1B_1, A_2B_2, A_3B_3, will also meet A_4B_4. Hence there is a whole family of straight lines which meet the lines A_1B_1, A_2B_2, A_3B_3, A_4B_4. The lines of this family fill up a surface which is called a quadric surface because its equation is of the second degree. It is called a *ruled quadric* because of the straight lines which lie upon it. Indeed, the surface may be described as follows: let *a, b* and *c* be the three lines already described under these names. There is a family of lines each of which meets a, *b* and *c* and there is just one line of this family through each point of *a, b* or *c*. This family may be called the *first ruling* or *regulus* of the quadric. Any line which meets three lines of the first ruling meets all lines of this ruling, and the family of all such lines is a regulus just like the first ruling. The quadric consists of the points on the t o rulings. There is one line of each ruling through each point of the quadric, and the plane containing these two lines is tangent to the quadric. But for further discussion of this question the reader must be referred to the article on surfaces *(see* SURFACE) and to the appropriate chapters in books on projective and analytic geometry. The ruled quadric from the point of view of Euclid is either a hyperbolic paraboloid or a hyperboloid of one sheet, according as the plane at infinity is or is not tangent to it.

One-dimensional Forms.—This by no means exhausts the list of seemingly complicated geometric figures whose theory can be deduced from the simple propositions about one-dimensional projectivities. The essential element in any such deduction is to find a family of geometric figures which are in such a correspondence with the points of a line that the theory of projectivities can be applied. Any such family of geometric figures is called a *one-dimensional form*. Examples are: a range of points, a pencil of lines, the set of all planes having a line in common, the points of a conic section, the lines of a regulus, the generating lines of a cone, the points of a rational cubic curve in space, the tangents to a conic section, the set of all conic sections having four points in common, and so on. When the general ideas about projectivities of one-dimensional forms are combined with simple theorems about the particular figures to which they are being applied, they often give us flashes of insight into unexpected branches of mathematics, such as, for example, quaternions (*q.v.*) and biquaternions.

Cross Ratio.—If two points, A,B, go by projection to two points, A',B', there is no general relation between the distance AB and the distance $A'B'$. The same remains true of the ratios

$$\frac{AB}{AC} \text{ and } \frac{A'B'}{A'C'}$$

of two sets of collinear points A,B,C, and A',B',C'. But it is not true of the ratio of two ratios

$$\frac{AC}{AD} \div \frac{BC}{BD}$$

(each ratio computed with proper regard to algebraic sign). The fact is that

$$ABCD \barwedge A'B'C'D'$$

if and only if

$$\frac{AC}{AD} \div \frac{BC}{BD} = \frac{A'C'}{A'D'} \div \frac{B'C'}{B'D'}$$

provided the points in each set of four are collinear. Such a ratio of two ratios is called a *cross ratio* or a *double ratio* or an *anharmonic ratio.*

A cross ratio of four collinear points is the same as the corresponding cross ratio of any four points into which they are projected. This fact enables us to define the cross ratio of any four elements of any one-dimensional form, and in each case the cross ratio has a significant geometrical meaning. For example, we can define the cross ratio of four points of a conic as that of any four points of a straight line which are projective with the given four points of the conic. It then can be proved very simply that whenever the cross ratio $ABCD$ is -1 the tangents to the conic at A and B intersect on the line CD; and conversely, if the tangents at A and B intersect on the line CD then the cross ratio $ABCD$ is -1. Whenever the cross ratio $ABCD$ of any four elements of a one-dimensional form is -1 we say that the four elements form a *harmonic set* and that the elements *AC harmonically separate* the elements BD.

Co-ordinates in One-dimensional Forms.—If A,B,D are three elements of a one-dimensional form (*e.g.*, three points of a line) any fourth element C is uniquely determined by its cross ratio $ABCD$. That is, if C is given, the cross ratio is a unique number x, and if a number x is given, there is one and only one element C such that x is the cross ratio $ABCD$ (if $C=A$, $x=0$; if $C=B$, $x=\infty$; if $C=D, x=1$). The number x is what we call the *co-ordinate* of the element C of the one-dimensional form. A co-ordinate is a number which serves as a name for the element; and these names have been assigned in such a way that any two distinct elements have distinct names. It can be proved that any projectivity by which each element of a one-dimensional form corresponds to an element of the same form, can be represented by an equation

$$\bar{x} = \frac{ax+b}{cx+d}, \quad ad-bc \neq 0.$$

That is to say, for any projectivity of a one-dimensional form, there are four numbers a,b,c,d such that every element x is carried by the projectivity to that element whose name $\bar{x}$ is related to x by the equation written above.

Invariants of Binary Forms.—This theorem opens the way for a study of projective geometry by means of algebra. In practice it is found advantageous to use homogeneous co-ordinates. An element whose non-homogeneous co-ordinate is x is represented by any pair of numbers x_1,x_2 such that

$$\frac{x_1}{x_2} = x.$$

In case $x_2=0$, the pair of numbers $(x_1,0)$ represents the element ∞ (represented by B in the discussion above). Homogeneous co-ordinates give a multiplicity of names for the same element, for whenever

$$\frac{x_1}{x_2} = \frac{y_1}{y_2}$$

(x_1,x_2) and (y_1,y_2) represent the same element. Any homogeneous algebraic equation represents a finite number of elements. For example

$$px_1^3+qx_1^2x_2+rx_1x_2^2+sx_2^3=0$$

represents three elements, because there are three values of the ratio x_1/x_2 which satisfy this equation. The left-hand member of a homogeneous equation of this sort, of any degree, is called a *binary form* (binary because there are two variables).

A projective transformation is represented in homogeneous co-ordinates by linear homogeneous equations of transformation

$$\begin{aligned}\bar{x}_1 &= ax_1+bx_2 \\ \bar{x}_2 &= cx_1+dx_2\end{aligned} \qquad ad-bc\neq 0$$

and the projective geometry of one-dimensional forms reduces, algebraically, to the study of the effect of transformations of this sort upon binary forms. This study centres about the theory of *invariants (see* ALGEBRAIC GEOMETRY; TENSOR ALGEBRA) of binary forms, an invariant being a function which is unaltered except for a factor by the transformations. In geometric applications it is found, in general, that the vanishing of an invariant represents a geometric property which is unaltered by projectivities.

Two-dimensional Projective Geometry.—It is natural to call such collections of elements as the set of all points in a plane, or the set of all lines in a plane, or the set of all planes through a point, etc., *two-dimensional forms.* The concept of a projective transformation can be extended to two dimensions without difficulty. It turns out that any projective transformation of a two-dimensional form is fully determined by the fate of any four elements no three of which are in the same one-dimensional form.

Non-homogeneous co-ordinates are introduced in such a way that an element is named by an ordered pair of numbers (x,y, the first and second names of the element). If the elements are points, then these co-ordinates are ordinary cartesian co-ordinates *(see* ANALYTIC GEOMETRY). Homogeneous co-ordinates are sets of three numbers (x_1,x_2,x_3) such that

$$x = \frac{x_1}{x_3}, \qquad y = \frac{x_2}{x_3},$$

and projective transformations of the points of a plane into points of the same plane are given by equations of transformation of the type,

$$\bar{x}_1 = a_1^1x_1 + a_1^2x_2 + a_1^3x_3$$
$$\bar{x}_2 = a_2^1x_1 + a_2^2x_2 + a_2^3x_3$$
$$\bar{x}_3 = a_3^1x_1 + a_3^2x_2 + a_3^3x_3,$$

in which the determinant of the coefficients is not zero. These transformations are also called *collineations* because they transform collinear points into collinear points.

Geometry of the Complex Domain. — Since it is possible to perform all the operations of algebra with complex numbers (see COMPLEX NUMBERS)--that is to say with the numbers of the form $u+v\sqrt{-1}$ where u and v are real—it is possible to work out the algebraic theory of projective transformations on the assumption that the co-ordinates, x_1,x_2,x_3, and the coefficients of the equations of transformations, are complex numbers. The objects which are transformed are sets of triads of numbers (x_1,x_2,x_3) where a given set contains all triads $(\rho x_1,\rho x_2,\rho x_3)$ obtained by letting ρ be any real or complex number except zero. We call these objects complex *points*. The collection of complex points which satisfy a homogeneous first degree equation

$$ax_1+bx_2+cx_3=0$$

is called a complex line, and the collection of complex points which satisfy a homogeneous second degree equation a complex *conic,* and so on The totality of complex points is called a complex *projective* plane Thus there is built up, by simple algebraic processes, a complex *projective* geometry.

The propositions of this geometry are, to a large extent, the same as those of the projective geometry of reals. Two points determine one and only one line; two lines meet in a point; five points, no three collinear, determine a conic; and so on. But a great many propositions assume a simpler and more symmetric form than they do in the real geometry. For example, in the real geometry a line which is not tangent to a conic may meet it either in two points or not at all; in the complex geometry a line which is not tangent always meets the conic in two points. This is because the problem of finding the points of intersection of a straight line and a conic reduces to the solution of a quadratic equation. In general any geometric problem depending on the solution of an algebraic equation of higher than the first degree will assume a simpler form in the complex than in the real domain.

Among the complex points there is a sub-class consisting of those for which the ratios x_1/x_3 and x_2/x_3 (or x_1/x_2, if $x_3=0$) are real. The co-ordinates of these points can always be taken to be real, so that these points can be identified with the ordinary real points. Hence the real projective plane is habitually thought of by mathematicians as immersed in a complex projective plane. Every real straight line or real conic is thought of as containing not only all its real points but also a collection of complex points. Moreover, free use is made of imaginary straight lines, conics, and so on. For example, if we were to limit attention to real figures we should have to say that from certain points of the plane it is impossible to draw lines tangent to a given conic. From the point of view of complex geometry we say that there are two tangents through any point not on the conic; if the point is exterior to the conic the two tangents are real lines, but if the point is interior they are conjugate imaginary lines. No attempt is made to visualize the "imaginary" complex elements We simply make such inferences about them as follow by the rules of logic from the definitions adopted. The results so obtained are bound to be as self-consistent as any theorems about numbers.

Geometry of *N* Dimensions. — Three-dimensional projective geometry can be approached from the point of view of elementary geometry much as we have approached one and two-dimensional projective geometry in the discussion above, or it may be derived by a purely logical process on the basis of its own axioms; or it may be taken up analytically in the manner explained above for the two-dimensional complex geometry. Points are then defined in terms of sets of homogeneous co-ordinates (x_1,x_2,x_3,x_4). If these co-ordinates are restricted to real numbers we obtain the real projective geometry of three dimensions. If they are allowed to be any complex numbers we obtain the complex projective geometry of three dimensions.

From the algebraic point of view, there is no reason why the number of homogeneous co-ordinates should be restricted to four, and no such restriction is made by mathematicians. A point in a projective space of n dimensions is defined by $n+1$ homogeneous co-ordinates $(x_1,x_2, \ldots, x_{n+1})$ and projective transformations are defined by equations of the form

$$\begin{aligned}
\bar{x}_1 &= a_1^1x_1 + a_1^2x_2 + \cdots + a_1^{n+1}x_{n+1} \\
\bar{x}_2 &= a_2^1x_1 + a_2^2x_2 + \cdots + a_2^{n+1}x_{n+1} \\
&\;\;\vdots \\
\bar{x}_{n+1} &= a^1_{n+1}x_1 + a^2_{n+1}x_2 + \cdots + a_{n+1}^{n+1}x_{n+1}.
\end{aligned}$$

If the co-ordinates and coefficients are real we arrive at the real projective geometry of n dimensions, if complex, at the complex projective geometry of n dimensions

As the number n increases the geometry becomes more complicated because the number of primary figures to consider becomes greater, but it does not become more difficult in principle. It is no longer possible to visualize our results as we do in the one-, two- and three-dimensional cases, but the logical processes by which they are proved remain the same. In order to explain the situation rapidly we have based the conception of an n-dimensional space on the notion of co-ordinates, but this is not necessary. It can also be developed without the use of co-ordinates from a purely descriptive set of axioms.

Projective, Affine and Metric Geometry. — The set of all projective collineations of a plane form a group (see the article GROUP). The properties of any figure which remain unaltered when this figure undergoes the transformations of this group are called projective properties For example, the property of a curve of having a second degree equation, *i.e.,* of being a conic section, is unaltered. Likewise the property of a point, line and conic section, that the point is the pole of the line with regard to the conic, is a projective property. The theory of all projective properties of plane figures is the subject matter of the projective geometry of the plane,

The set of all projective collineations of a plane which leave a particular straight line invariant is a group which Is called an *affine* group, and the theory of those properties of plane figures which are unaltered when the figures undergo the transformations of this group is called affine geometry (see AFFINE GEOMETRY). The invariant line is called the line at infinity of the affine geometry. An affine group has several subgroups, the most interesting being the ones determined by requiring that two points of the line at infinity shall be invariant. If the two points are real, the subgroup is one studied in the special theory of relativity (*q.v.*) and includes the Lorentz transformations. If they are conjugate imaginaries, the group is the group of similarity transformatiocs of Euclidean geometry.

The Euclidean geometry can be characterized as the group of theorems which state those properties of figures which are left unaltered by the group of similarity transformations. Thus it makes no essential distinction between a large triangle and a small one which is similar to it, though it does deal with the ratio of the two triangles But the latter is an attribute of the figure composed of the pair of triangles, not of either triangle separately. The theorems of affine and projective geomerry are all included in Euclidean geometry, because any property which is left invariant by the projective group is of course left invariant by all its subgroups. Thus affine geometry is a subclass of very general theorems of Euclidean geometry which it seems desirable to isolate from the rest and study together. Projective geometry is a still smaller class of still more general theorems We seem by leaving out some of the details which distract our attention in the more elementary way of looking at geometry to get a deeper insight and a better grasp of the subject as a whole. Afterwards we are able to return to these details and grasp them rapidly by studying the particular subgroup which determines the Euclidean metric. A study of the latter group with special reference to the two invariant points gives a rapid and comprehensive survey of Euclidean geometry. For example. the circles are the conic sections which pass through these two points, and the points are therefore called the circular points at infinity. Perpendicular lines are pairs of lines which meet the line at infinity in pairs of points which harmonically separate the circular points. The four tangents to a real conic from the circular points meet, in general, in four other points. Two of these are real and are the foci of the conic, and so on.

Non-Euclidean Geometry. — Another subgroup of the projective group which is of great interest is the group leaving a conic invariant. In the real geometry there are two cases to consider according as the conic is real or is composed entirely of imaginary points. The theorems stating properties invariant under the first group constitute what is called the hyperbolic non-Euclidean geometry *(see* GEOMETRY: *Non-Euclidean Geontetry),* those stating properties invariant under the second group constitute what is called the elliptic non-Euclidean geometry. The metric geometry or system of measurement of geometric figures which is developed in these geometries is quite different from, though analogous to, the system followed by Euclid. Historically they were developed in antithesis to the Euclidean system, but they have the same projective geometry.

Axioms. — Since projective geometry is a collection of general and significant propositions from which it is possible to specialize in a variety of directions, it is an attractive idea to make projective geometry the starting point of the logical formulation of geometry as a whole and arrive at the various more special branches by a process of specialization. The still more general branches will of course continue to be reached by the process of generalization. The problem of stating the axioms in purely projective terms and deriving the theorems from this foundation by purely logical processes engaged the attention of several mathematicians.

History. — The conception of points at infinity goes back to G. Desargues *(1593–1662; q.v.),* and many of the individual conceptions of projective geometry can be traced back to remote antiquity; but it may be said to appear first as a definite branch of science in *1822* in the work of J. V. Poncelet *(q.v.).* The development of the science was participated in by nearly all the geometers of the 19th century, notably by L. N. M. Carnot, C. J. Brianchon, J. D. Gergonne. M. Chasles, A. F. Möbius, G. hlonge, J. Steiner, J. Pliicker. W. K. Clifford! L. Cremona, H. J. S. Smith and H. Wiener. The clear separation of projective from metric properties dates from the publication of the *Geometrie der Lage* of K. G. Ch. von Staudt (Nuremberg, *1847)* and his *Beiträge zur Geometrie der Lage* (Nuremberg, 1857). The formulation of the group-theoretic classification of geometries is due to F. Klein. The axioms and the logical organization of the science as a separate entity were studied by many mathematicians, notably M. Pieri.

PROKOFIEV, SERGEI (1891–1953), Russian composer, was born at Ekaterinoslav, south Russia, April 23, *1891.* In 1910 the Rubinstein prize was awarded him for his first piano concerto. From the first his compositions attracted attention by their originality and audacity. In writing for the stage he chose subjects which had elements of grotesqueness or harsh satire, such as *Chout (The Buffoon)* (1921), and *The Love for Three Oranges (1921).* His *Scythian Suite* for orchestra had also an obvious program. Other orchestral works include the *Symphonie Classique,* a *Sinfonietta,* the *Overture on Yiddish Themes* and *Peter and the Wolf (1936).* He died near Moscow on March 4, 1953.

PROKOP, the name of two prominent Hussite generals.

1. PROKOP, surnamed Veliky ("the Great") or Holy ("the Bald"). was a married utraquist priest who belonged to an eminent family of Prague. Though a priest. he became the most prominent leader of the advanced Hussite or Taborite forces during the latter part of the Hussite wars, comman'ding them at their victories at Usti nad Labem (Aussig) in *1426* and Domazlice (Tauss) in 1431, during their frequent incursions into Hungary and Germany, particularly the Bohemian invasion of Saxony in 1429, after which Prokop concluded the treaty of Kulmbach (Feb. *6,* 1430) with Frederick of Brandenburg, burgrave at Nuremberg. He was the most prominent member of the Bohemian embassy to the council of Basel (1433). Following this fruitless journey, when renewed fighting broke out, he besieged the Romans at Plzen but was forced by indiscipline in his own camp to raise the siege and return to Prague. The Bohemian nobility, both Romanist and utraquist, having leagued itself against the Taborites, a struggle began at Prague. Aided by the nobles, the citizens of the old town took the more democratic new town, which Prokop unsuccessfully attempted to defend. He now called to his aid Prokop the Lesser. *(See* below.) They jointly retreated eastward from Prague; but their forces, known as the army of the towns, were defeated by the nobles at Lipan, between Kourim and Kolin, Prokop the Great perishing in this battle (May *30,* 1434).

2. PROKOP the Lesser, or PROKUPEK (the Bohemian diminutive of Prokop), was one of the greatest Hussite generals. Little is known of his early life. He took part in all the later campaigns of Prokop the Great in Germany and succeeded him as commander of the Taborite army besieging Plzen. After the formation of the confederacy of the nobles he was recalled by Prokop the Great, with whom he shared the command of the army of the towns at the battle of Lipan, in which he also perished.

PROKOPOVICH, THEOFAN (1681–1736), Russian archbishop and statesman, one of the ablest coadjutors of Peter the Great, was educated at the Orthodox academy of Kiev in Poland and at Rome in the College of the Propaganda. On his return to Russia he became professor, and subsequently rector, of the academy of Kiev. He reformed the teaching, substituting the historical method of the German theologians for the antiquated orthodox scholastic system. In 1709 Peter the Great, while passing through Kiev, was struck by the eloquence of Prokopovich in a sermon on "the most glorious victory" *(i.e.,* Poltava) and in *1716* summoned him to St. Petersburg. Theofan was rapidly promoted, becoming in 1718 bishop of Pskov and finally; in 1724, archbishop of Novgorod. As the author of "the spiritual regulation" for the reform of the Russian church, Theofan must: indeed, be regarded as the creator of "the spiritual department" superseding the patriarchate and better known by its later name of the Holy synod, of which he was made the vice-president.

PROLETARIAT. In ancient Rome the proletariat *(proletarius)* constituted the body of poor, landless freemen. It included artisans and small tradesmen who were gradually impoverished by the extension of slavery. The proletariat was the lowest rank among Roman citizens, literally "producers of offspring" *(proles)*; the first recognition of its status was traditionally ascribed to Servius Tullius. Its power resided exclusively in the rights its members enjoyed as Roman citizens. In some periods of Roman history it played an important role, not as an independent force but as a mass following, in the political struggles between the Roman patricians and the wealthy plebeians. Since it had little opportunity for productive work, which was performed in the main by slaves, its existence was largely parasitic on the Roman economy. On occasions it was quieted by doles of bread from the state and diverted by spectacles.

Marxian Socialist Theory. — The proletariat, in the restricted usage adopted by Karl Marx *(q.v.),* designates the class of wage workers engaged in industrial production whose chief source of income is derived from the sale of their labour power. As an economic category it is distinguished in' Marxian literature from the poor, the working classes and the *Lumpenproletariat.* Because of its subordinate position in a capitalist society and the effects of periodic depressions on wages and employment, the proletariat is described by Marxians as usually living in poverty. But it is not therefore identified with the poor, for some members of the proletariat, the highly skilled or labour aristocracy, are recognized as not poor, and some members of the entrepreneurial class as not wealthy. Despite synonymous use in agitational literature. the term proletariat is distinguished from the working class as a generic term. The former refers to those engaged in industrial production, the latter to all who must work for their living and receive wages or salary, including agricultural labourers, white-collar workers and hired help occupied in the distribution services. The *Lumpenproletariat* consists of marginal and unemployable workers of debased or irregular habits and also includes paupers, beggars and criminals.

The proletariat in this sense appeared comparatively late on the historical scene. Its existence is essentially bound up. according to Marxian analysis, with the development of modern capitalism. Many causes have been assigned for the emergence of the proletariat, the chief of which is the expropriation of the peasants from their individual holdings by the statutory enclosure of commons land, forced sales and bankruptcies, thus compelling them to drift to the cities where they could find a market for their power to work. The proletariat was therefore considered as an urban phenomenon whose size was vastly extended by the Industrial Revolution. Among the contributory factors of the process of proletarianization have been cited the breakup of the medieval guilds, the dispersion of the monasteries, the liberation of the serfs and large increases in the population relative to the possibilities of employment in traditional vocations. The incidence of these factors on the rise of the proletariat varied from country to country.

Capitalist Class as Creator and Enemy of Proletariat.— According to the Marxian analysis, the existence of the proletariat as a definite class presupposes the existence of the capitalist class. Where the capitalist class disappears or becomes subordinate in the control of production to other social groups that abrogate the free market, there is no longer a proletariat. This conclusion, together with the prediction that in the course of its evolution capitalist society necessarily becomes polarized into two classes. was questioned in the light of 20th-century developments in Germany, the U.S.S.R. and the United States. The assumption that in time the proletariat would constitute the overwhelming majority of the population was also challenged on the ground that increasing mechanization and rationalization of production led to a relative decline in the number of unskilled, manual workers and an increase in the numbers of those engaged in managerial functions and distribution services.

More significant in Marxian theory than its meaning as a strictly economic category is the social-psychological conception of the proletariat. Slowly educated by their hardships and their struggles for better conditions and wages, the workers are believed to become conscious of the objective antagonisms that divide them as a class from their employers. The first stage in their awareness is usually marked by the organization of trade unions within the existing framework of society. The second is their acceptance of doctrines which teach either that they cannot permanently improve their human existence in a commodity-producing society because unemployment, crisis and war are endemic to its operation, or that a more just and efficient organization of social relations is possible which would increase their material welfare and remove invidious social distinctions. The third stage is reached in the development of political parties which take on the designation of labour or socialist parties whose ultimate program is directed not to the improvement of the individual lot of the worker or to facilitating social mobility from class to class, but to the reconstruction of the whole society which, in abolishing all traditional economic classes, would abolish the proletariat as a class.

Further, by setting up a common faith and objects of ideal allegiance, Marxians seek to unify the diverse ethnic, religious and national differences among the proletariat and to reinforce the sense of solidarity which is presumably born out of consciousness of common material interests. In respect to this function of proletarian ideology, it should be observed that it enjoyed some limited success in overriding ethnic and religious differences among the members of the proletariat, but failed almost completely in transcending consciousness of national differences. In times of national conflict, the proletariat behaved no differently from the *bourgeoisie* of their respective countries.

Marxians seek organizational support for their ideology primarily, but not exclusively, among industrial workers for two reasons. The first is the assumption that whereas the economic grievances of all other working groups, such as the farmers, intellectuals and lower middle classes, can be removed without fundamental social change, the position of the industrial worker is so tied up with the exigencies of capitalist production that he cannot be liberated except by transformation of capitalism itself. The second is the expectation that, in the event of a struggle for power, the industrial workers will be most strategically situated in determining the issue—an expectation also called in question by the development of modern industrial and military technology.

Communist Party the Self-Designated "Vanguard of the Proletarian."—The appeals of proletarian ideologies nevertheless have been addressed to the community at large, to all men of "insight" and "good will," couched in moral terms which try to invoke the ideals of justice, humanity and human freedom Many elements in the population are won to adherence to proletarian causes whose social antecedents are by no means proletarian. It has been widely observed that many outstanding political leaders of working-class parties in all countries have been drawn from other classes. And since most inspirers of proletarian ideologies have rarely been members of the working class, it has been inferred that the working class, left to itself, is not likely to develop beyond the level of trade unionism The universalism implicit in the premises of proletarian ideologies led their carriers to proclaim that they represented the best understood interests not only of one class in the community, but of the masses of people. In this way the voice of moral prophecy acts to give force and persuasive effect to the analysis of historical destiny. The result, sometimes concealed, sometimes acknowledged, is a broadening of the meaning of proletariat from a term designating a narrow economic class to a term that loosely encompasses all who support the ideology of the class, and ultimately to the masses who are presumed to enjoy its future benefits.

The various ambiguities in the meaning of the term proletariat come to a head in the phrase "the dictatorship of the proletariat." As Marx used it, it denotes the political rule of the proletariat, through representative organs, during a transitional period from capitalism to socialism. It is a dictatorship in that political power is used to abolish the social relations of production which create profit and rent. Since Marx assumed that the proletariat would constitute the overwhelming majority of the population as the polar class to the *bourgeoisie,* the dictatorship of the proletariat was conceived as a form of workers' democracy. It was not conceived as a dictatorship of the minority or of a political party, but of a social class, and emphatically not the dictatorship of a political party over the proletariat. This is evidenced not only by the language of the *Communist Manifesto,* but also by F. Engels' public reference to the Paris Commune as an illustration of a proletarian dictatorship.

After the Russian October Revolution of 1917 the meaning of "the dictatorship of the proletariat" changed. Lenin, Trotsky and Stalin declared that it represented substantially the dictatorship of a minority political party. This party consists of the self-denominated vanguard of the proletariat, although its members need not be proletarian in origin. It speaks and acts for the whole of the proletariat and ultimately for the whole working class. The latter, however, cannot freely accept or reject its leadership since no rights of opposition to the ruling party are recognized. To add to this shift in meaning, it should be observed that although the U S.S.R. was officially proclaimed to be a socialist society without any classes, it continued to be characterized as a dictatorship of the proletariat. Under such circumstances the term proletariat is emptied of differentiating content and functions more as a sloganizing device than as a precise designation of a social or economic group. Because of these ambiguities, the term must always be interpreted in relation to the specific historical situation and the concrete social context in which it is employed. *See* BOLSHEVIKS; COMMUNISM; COMMUNIST PARTY; MARXISM; SOCIALISM.

PROLOGUE, a prefatory piece of writing, usually composed to introduce a drama. The Greek *prologos* included the modern meaning, but was of wider significance, embracing any kind of preface. In Greek drama, a character, often a deity, stood forward or appeared from a machine before the action of the play began, and made from the empty stage such statements as it was necessary that the audience should hear. It was the custom to explain everything that had led up to the play, the latter being itself, as a rule, merely the catastrophe following on the facts related in the prologue. The importance, therefore, of the prologue in Greek drama was very great. With Euripides, as has been said. it takes the place of "an explanatory first act." On the Latin stage the prologue was often more elaborately written than in Athens, and in the careful composition of the poems which Plautus prefixes to his plays we see what importance he gave to it; sometimes, as in the preface to the *Rudens,* Plautus rises to the height of his genius. Molière revived the Plautine prologue in the introduction to his Amphitryon; Racine introduced Piety as the speaker of a prologue to Esther. The tradition of the ancients vividly affected the early English dramatists. Not only were the mystery plays and miracles of the middle ages begun by a homily, but when the modern drama was inaugurated the prologue came with it, directly adapted from the ancient practice. Thomas Sackville prepared a sort of prologue in dumb show for his Gorboduc of 1562; and he also wrote a famous Induction (practically a prologue) to a miscellany of short romantic epics by diverse hands. In the Elizabethan drama the prologue was very far from being universally employed. In the plays of Shakespeare it is rare. After the Restoration, prologues became obligatory. They were always written in rhymed verse, and were generally spoken by a principal actor or actress. See also EPILOGUE.

(E. G.; E. E. K.; G.W.A.)

PROME, a district in the Pegu division of lower Burma, with an area of 2,938 sq.mi. and a pop. (1941) of 436,714. It occupies the valley of the Irrawaddy, between Thayetmyo district on the north and Henzada and Tharrawaddy districts on the south. There are two mountain ranges. The Arakan Yoma extends along the western side. The portion of the district on the right bank of the Irrawaddy is broken up by thickly wooded spurs running southeastward. Cultivation is confined to the parts adjacent to the river. On the eastern side lies the Pegu Yoma, and north and northeast of the district its forest-covered spurs form numerous valleys and ravines, the torrents from which unite in one large stream, the Na-win. The staple crop is rice, but cotton and tobacco are grown, while the custard apples are famous. The forests yield teak and cutch.

The early history of Prome is veiled in obscurity. After the conquest of Pegu in 1758 by Alompra, the founder of the last dynasty of Ava kings, Prome remained a portion of the Burman kingdom till the close of the second Burmese war in 1853, when the province of Pegu was annexed to British territory. Prome, the chief town, is on the Irrawaddy, 161 mi. N. of Rangoon, pop. (1953) 36,997.

PROMETHEUS, in Greek mythology son of the Titan Iapetus by the sea nymph Clymene or by Themis (occasionally other parents are named). He was the friend and benefactor of mankind. He defended men against Zeus, who, according to a widely diffused mythical theory, desired either to destroy the human race and supplant it by a new and better species, or to avenge himself because men had got the better of him. The pedigree and early exploits of Prometheus are given by Hesiod.

At a meeting of gods and men at Mecone, it was the business of the assembly to decide what portions of slain animals the gods should receive in sacrifice. On one side Prometheus arranged the best parts of the ox covered with offal, on the other the bones covered with fat, as the meat was covered in Homeric sacrifices. Zeus, invited to make his choice, chose the fat and found only bones beneath. A similar fable of an original choice, in which the chooser is beguiled by appearance, recurs in Africa and North America. Zeus, enraged at this trick, according to Hesiod, or, according to other versions, desirous of exterminating the few people who had escaped the deluge of Deucalion, either never bestowed the gift of fire or later withdrew it. Prometheus stole fire, concealed in a hollow fennel stalk (Hesiod, Works *and Days)*; and a fennel stalk is still used in the Greek islands as a means of carrying a light (*cf.* Pliny, *Nat. Hist.*, xiii, 126). According to some legends, he gained the fire by holding a rod close to the sun. Probably the hollow fennel stalk in which fire was carried got its place in myth from the fact of its common use. Prometheus is thus found in the position of the fire bringer, or fire stealer, and so connected with a wide cycle of similar mythical benefactors, divine, human or bestial, among various peoples.

In considering the whole question of fire mythology, one must beware of the hasty analogical method of reasoning t~~ common among mythologists. For example, when a bird is spoken of as the fire bringer, we need not necessarily conclude that, in each case, the bird means lightning. Again, because a hero is said to have stolen or brought fire, we need not regard that hero as the personification of fire nor explain all his myth as a fire myth. The legend of Prometheus has too often been treated in this fashion, though he is really a culture hero, of whose exploits, such as making men of clay, fire stealing is no more than a single example. Prometheus and Hephaestus (*q.v.*) are frequently brought into contact, generally as opponents; in some forms of the legend, Prometheus steals fire from Hephaestus' workshop, not from heaven. It is quite possible that Prometheus was an old and genuinely Greek deity, whose province included fire and its earlier industrial applications, but that he was later superseded by the popular oriental deity. If such were the case, it must have been very early, before either Homer or Hesiod wrote, probably not long after the first coming of the Achaeans to Greece. (A. L.; H. J. R.)

PROMETHIUM (symbol Pm, atomic number 61), is often referred to as the missing member of the rare earth series. Considerations, based on the Mosley diagrams and modern theories of atomic structure, indicate that an element should exist with this atomic number, having the properties of the trivalent rare earths. Numerous claims have been made concerning its existence based on new lines observed in the arc spectra of rare earth concentrates or on X-ray lines observed in connection with these concentrates. In 1926 B. S. Hopkins. J. A. Harris and L. F. Yntema were the first definitely to claim the discovery and concentration of this element and offered considerable evidence in support of their claims, based on the arc spectra, the absorption spectra in solution and the X-ray emission spectra. They named the element illinium after the University of Illinois where the work was performed. In the same year J. M. Cork, C. James and H. C. Fogg claimed its independent discovery and measured its X-ray spectra. L. Rolla and L. Fernandez claimed priority in this discovery and named the element florentium. This element is definitely known to occur among the fission products of plutonium, thorium and uranium and considerable quantities (grams) are known to exist in the residues from the atomic chain reacting piles built during World War II. In 1947 J. A. Marinsky, L. E. Glendenin and C. E. Coryell first isolated element 61 from atomic reactor residues. Later it was claimed that the absorption spectra and arc spectra of element 61 isolated from the uranium chain reactions are different from the spectra of that element as claimed by Hopkins. As a result of these claims, the International Union of Chemistry accepted the name promethium for this element, as suggested by Glendenin and Marinsky, instead of illinium as suggested by Hopkins. Controversy continued as to whether nonradioactive element 61 existed. Evidence indicated that if it did exist naturally it must be present in nature in very minute quantities. (See RARE EARTHS.) (F. H. SP.)

PROMISSORY NOTE: see BILL OF EXCHANGE.

PRONGHORN or PRONGBUCK, the sole existing representative of a family (Antilocapridae), intermediate between deer and cattle; the forked horns resemble those of the latter group, but are annually shed and renewed. Standing about 3 ft. high at the shoulder, the male pronghorn has the black horns rising vertically above the eyes. The colour is bright sandy fawn, with much white on the face, three white bars on the throat and white under parts and buttocks. The long white hair on the buttocks can be erected and expanded into bunches, these being guides to the herd when in flight. The tail is short. Female pronghorns produce one or two young at a birth, and are either hornless or furnished with more or less rudimentary horns. Pronghorns (*Antilocapra americana*) are among the swiftest running mammals. They inhabit the open plains of the temperate districts of western North America, where they were formerly abundant.

PRONUNCIATION. By means of his organs of speech man has at his disposal, for the purpose of speech, certain devices. He can make a great variety of sounds and, subject to the limitations imposed by the physical structure of his speech apparatus, he is able to modify these sounds in certain ways: (1) he can modify the length of time during which a sound persists; (2) he can modify the degree of physical energy devoted to the production of a sound; (3) he can, in the case of sounds that involve a periodic vibration of the vocal cords, regulate the periodicity of this vibration so as to produce varieties of pitch. These modifications of length, stress and pitch may serve different purposes, or may be used in various combinations.

Nature.—The spoken variety of a language consists of a certain number of sounds, influenced by the three modifications outlined above. These features, in the case of any given spoken language, constitute what may be termed the acoustic matter of the language, and the reproduction of these acoustic features by a speaker is what is known as a pronunciation of the language. The term "pronunciation" is used to denote the general acoustic features of a language; thus we speak of English pronunciation, or the pronunciation of Marathi. It is also used to denote the particular variety of acoustic phenomena used by an individual speaker, or by a particular section of a community; thus we may speak of disliking a man's pronunciation, or of liking the pronunciation of a certain district or social class.

Analysis of Pronunciation. — Detailed analysis of the pronunciation of individual speakers is the foundation of knowledge of the pronunciation of languages and dialects, and those whose business it is to carry out such analysis should so train themselves that they can give reliable and accurate information upon all the aspects outlined above. Sounds must be described in detail, and the modifications, their function and distribution must be noted. Such detailed description of pronunciation is necessary for:

(1) The study and teaching of the mother tongue, and of foreign languages.

(2) The devising of scientific systems of orthography for hitherto unrecorded languages.

(3) Comparative philological work.

(4) Pronouncing dictionaries.

Pronunciation and Language. — A spoken language persists as a language so long, and only so long, as those who speak it pronounce it in such a way as to be readily intelligible among themselves throughout the area in which the language is spoken. Local variants, or fashions of pronouncing, arise in proportion to the extent of the territory over which the language is spread, but so long as those who use these local variants are conscious that they are in the main using the same language, and provided that they continue to use the written language common to the rest of their compatriots, their speech will be regarded as a variant, a dialect, of the main language.

If, for political or other reasons, any one group of dialect speakers desires a linguistic tradition of its own, and proposes to make a new written form of its pronunciation, embodying a new and local vocabulary, then the seed of a new language is sown. In the past, whenever a language has, through the political expansion of a nation, spread over an area larger than that which gave it birth, disintegration has set in, beginning with divergence of pronunciation, ending with the establishment of new languages. Thus Sanskrit has given birth to the Aryan languages of India—Hindi, Bengali, Marathi, Gujarati, etc.; Latin has given us Italian, Spanish, French, Portuguese and Rumanian.

Pronunciation and Nationality. — Speech habits, among which must be included habits of pronunciation, differ from language to language. There is, however, a certain measure of similarity between the pronunciation of the various languages of a language family; and the language families of the world differ among themselves as considerably in the matter of pronunciation as in any other respect. The clicks of the Hottentot Bushman languages are found only in certain of the Bantu languages. The cerebral consonants of the Aryan and Dravidian languages of India are seldom found in other language families. When a language takes over words from another language and embodies what are called foreign words, the pronunciation of such words will be made to fit in with the general scheme of pronunciation of the borrowing language. French words taken into English will receive English sounds, English rhythm, English stress and English intonation. The very considerable Arabic element in Persian is pronounced in the Persian way, for the pronunciation system of Persian has nothing in common with that of Arabic. So European words are squeezed into Japanese moulds.

It very seldom happens that a language will adopt exotic sounds, or embody in its system sounds other than those which are its linguistic heritage. Instances of this, however, do happen. The cerebral consonants of the Indo-Aryan languages, which are uncommon in the rest of the world, are presumed to have been taken over from the Dravidians. The Arabic 4 is preserved in educated Urdu, but in southern Urdu colloquial is replaced by χ (the sound of "ch" in "loch"), and in Persian, except in the case of speakers who are influenced by a knowledge of Arabic, it is generally replaced by ǥ (the sound of Arabic غ).

Representation of Pronunciation. — Among a civilized community, language consists of two forms—a series of sounds, and a series of visual symbols, or letters, representing sounds. This method of making a visual language is known as a phonetic method of writing, and the system of symbols used is known as an alphabet.

On the other hand the visual language may be made without any apparent reference to the pronunciation of the oral language. Such a system is known as an ideographic system.

Most of the languages of the world have a phonetic visual form, the important exception being Chinese. The most widely used alphabets are the Roman, the Arabic and the Indian, each with certain additions and modifications. The Arabic alphabet, for instance, is made to represent such widely diverse phonetic systems as those of Arabic, Malay, Hausa, Persian, Urdu and, until recently, Turkish.

So it has come about that alphabets, designed to represent the pronunciation of specific languages spoken many centuries ago, have spread over the modern world and are used to express the pronunciation of many languages that have nothing in common with the pronunciation systems for which they were designed.

Since, as has been said, sight and sound are irreconcilable, it follows that any attempt to represent by means of visual symbols things that have no visual existence will be at best but partially successful, and will rest upon a variety of conventions. Each symbol will originally do duty for one "sound"; various devices may be employed to indicate the relative length of sounds, if it is felt desirable to denote this feature of the pronunciation; the position of what is known as the stress or accent may, or may not, be marked; it may be evident from other data. The intonation is not as a rule indicated, but there are certain devices, such as punctuation marks, interrogation and exclamation marks, and the use of a form of type differing from the rest, which are conventionally associated with certain features of the intonation.

The phonetic medium, although evidently the most expedient, is a clumsy one for the general purpose of representing language, but it is the only one for representing pronunciation. The world's great alphabets are, as is seen, in reality obsolete, because each was designed to represent the pronunciation of one language many centuries ago. When extended to other languages they have proved either inadequate or redundant. The Roman alphabet, suitable for a language such as Latin with its simple system of five vowel sounds, is completely inadequate for English with its twelve vowel sounds. The Arabic alphabet, designed for the peculiar word formation of Arabic, with its scanty vowels and abundant consonants, is inadequate for the Persian vowel system, and redundant for the Persian consonant system. Similarly the Devanagari alphabet proves inadequate to represent the pronunciation of the modern Indian vernaculars.

When, for various reasons, the visual language is a poor representation of the existing state of the pronunciation of a language, the language is commonly said to be unphonetic. This means that there is an absence of regularity in the conventional relationship between sound and symbol, which may be due to the unsuitability of the alphabet, or to the fact that the visual language, having become established in popular use at some distant period, has refused to register the phonetic changes that have taken place since. Attempts to readjust the relationship between spelling and pronunciation are usually vigorously resisted in all languages, there being a universal desire, apparently, to see in the historical form of the visual language something either sacred, as in the case of Arabic, or etymologically valuable, as in the case of English. In some parts of the English-speaking world tentative attempts at this readjustment, which is known as spelling reform, are being made.

Where, as in the case of many African languages, no traditional visual languages exist, systems of writing, usually with the Roman alphabet, less frequently with the Arabic alphabet, have been designed; but there again the inadequacy of the alphabets has proved a serious obstacle. The sound systems of the great African language families have nothing in common with the sound systems of Europe, and little in common with one another. It is interesting to note that there a special alphabet has been designed, based largely on the Roman, suitable for the representation of the pronunciation of the principal African languages.

To remedy the deficiency of traditional alphabets, many more detailed and adequate visual systems have been designed for the representation of pronunciation. These are of four classes:

(1) Based on no existing visual forms; *e.g.,* the Bell-Sweet system.
(2) Based on a code; *e.g.,* Jespersen's Analphabetic system.
(3) Based on existing Roman letters with abundant diacritical marks; *e.g.,* the Lepsius alphabet.
(4) Based on existing Roman signs, but using new letters instead of diacritical marks; *e.g.,* the International Phonetic Association alphabet.

One or other of these systems must be used when it is desired to describe a pronunciation in detail, as in pronouncing dictionaries, descriptions of languages, and in comparative philological works.

Phonetically there is little to choose between these systems, but recent investigation into their comparative merits would appear, upon psychological, pedagogical and typographical evidence, to favour alphabets of the fourth class.

Influence of Spelling upon Pronunciation. — There is observed, in the case of highly civilized and educated communities, where the majority of the speakers are familiar with the visual language, a very marked influence exerted by the visual language upon the pronunciation. The visual language, which was originally designed to represent the pronunciation and to be subservient to it, tends to become the criterion of accuracy and to dominate the pronunciation.

As familiarity with the visual language increases, so a new standard of accuracy in pronunciation arises, namely, the printed word. This is very evident from a consideration of the pronunciation of English place names. Historical pronunciations are being abandoned in favour of pronunciations more in keeping with the visual forms which became familiar only with the advent of postal and railway communication. Daventry is now pronounced as written, though a local pronunciation, Daintry, existed for centuries. It is interesting to record these old pronunciations, but it is doubtful whether they can now be restored to general use. If Daintry is to be admitted at the expense of Daventry, then "ain't" must be given preference to "haven't," for the principle that governs the disappearance of the medial "v" is the same in both cases. The influence of the visual upon the spoken language is likely to be a prominent feature in determining the future pronunciation of language.

Standards of Pronunciation. — The impression that one form of pronunciation is better than all others appears to be common in the languages of most civilized communities; it is found even in the case of those African languages that have never been written. The prestige of this form of pronunciation varies from language to language, and the degree of adverse criticism levelled at those who do not use it varies from country to country. It is by no means certain that there is now, or that there has ever been at any time in any language, with the possible exception of classical Arabic, what is popularly called a standard pronunciation; but it is quite evident that the desire for such a criterion is widespread.

The greater the territorial extent of the nation, the greater will be the number of metropolitan centres; the more organized and complex the social life, the greater will be the number of social classes, each with its own conventions of pronunciation. Where, as in the case of English, separate nationalities, at different ends of the earth, speak the same language, there will tend to grow up in each centre of national life a different ideal as to what is considered the most desirable pronunciation. There is no more evident manifestation of national entity than a national language, and a new national language will begin when any one of the national groups of the English-speaking world desires to establish a national standard of pronunciation at variance with that in vogue in the geographical area where the language was born. History tends to teach that disintegration was inevitable in the conditions that prevailed in the past; it may be checked by increased oral communication, increased intermingling of population, but most of all by the definite teaching throughout the area of one form of pronunciation. This teaching has preserved the entity of classical Arabic; it has not prevented the disintegration of the Arabic into the various colloquial pronunciations that prevail in the different parts of the Arabic-speaking world.

In England there are local variants and class variants of pronunciation. The higher we ascend the social scale in all districts, the greater the uniformity in the pronunciation. The uniformity of the educational system — public school and university — of certain social classes leads to a uniformity in the pronunciation of those classes. This type, provided it is free from pedantry and affectation, is generally regarded as the nearest approach to a standard pronunciation of southern English. It is the style of pronunciation heard most often in public speech, in parliament, in the church, in the law courts, in the universities and the public schools, and in such of the state schools as recruit their teaching staff from the ranks of those who use this style of pronunciation. In detail it may differ slightly from county to county, from school to school, from speaker to speaker, but in the main it is recognizable as one pronunciation. Those who use it have approximately the same vowels; its rhythm is the same wherever it is heard; its intonation follows the same general principle; it uses the same means to achieve the effects of emphasis; and it is characterized, among other things, by a peculiar treatment of the "r" sound. In most of these respects southern pronunciation differs from what is known as northern pronunciation, and in all of them it differs from U.S. and Canadian pronunciations which have their own vowels, their own rhythm, their own intonations, their own distinctive treatment of the "r" sound, which reacts in no uncertain manner upon their vowel systems. The U.S. and Canada have their own pronunciation problems, for their enormous geographical extent is giving rise to local varieties and localized standards. There is no standard pronunciation of English in these countries, any more than there is in Great Britain. The increased use of intercontinental oral communication by means of telephone and wireless broadcasting, the interchange of teachers and actors, and the use of the speaking film, may tend toward a certain degree of uniformity in the pronunciation of the English-speaking world, but these must be supported by definite action on the part of those responsible in all countries for the teaching of the mother tongue. It is agreed that a uniform pronunciation of English is desirable, but it is by no means certain how it is to be brought about.

In 1926 the British Broadcasting corporation set up an advisory committee to deal with doubtful questions of English pronunciation, and to settle, in the case of (1) unfamiliar words, (2) words having alternative pronunciation of equal currency and authority, (3) foreign words, upon one pronunciation to be used by the official speakers of the corporation. The first list of this committee's recommendations was published in 1928.

Change of Pronunciation. — The study of language reveals an inability, on the part of pronunciation, to persist unchanged in any given place or community over a long period of time. The universal law is change; during their lifetime languages change slowly, imperceptibly, but nevertheless surely. It is not possible to assign any adequate reason for this universal and eternal change. It is possible that the change has its origin in man's physical and mental limitations. The link that holds the speech of one generation to that of the next is but a feeble one; speech persists as a series of recollected auditory images, associated with certain kinesthetic movements, which are however of secondary importance as far as the speaker is concerned. He is more concerned with the expression of his thought than with the physical adjustments by means of which his thought receives audible expression. This combined mental and physical process appears to produce upon the mind of the listener impressions of a fugitive character, which are less durable than the impressions created by the combined visual and physical processes involved in the visual language. Speech, as such, perishes instantaneously, having no permanent existence, being handed on by oral tradition, and suffering during the centuries like all else that lives only by word of mouth. So pronunciation changes from age to age. partly because it hangs on so fragile a thread as man's aural memory, and partly because the unconscious physical processes that give rise to the sounds in themselves suffer modification owing to the lack of consciousness with which they are controlled.

"Pottage" and "porridge" are now different words. They are in reality but two pronunciations of the same word, and the curious story of their separate existence can still be learned by listening to the bus conductor who announces Swiss Cottage as Swiss "Corridge" It is probable that wider study will tend to establish the fact that a given speech sound, under given conditions, will always change in a certain way. But it must not be forgotten that it has hitherto proved impossible to define what is meant by the term "speech sound," and it should be remembered that the governing conditions are likely to prove more complicated than they appear upon examination of cases that have happened in the past. The principles governing the change in vowel sounds, the formation of which involves no tactile sensation in the mouth, appear to have nothing'in common with the principles governing the change of consonant sounds. in the formation of which there is definite contact between two parts of the mouth, or enough constriction to give an impression of contact.

Teaching of Pronunciation. — The study of the mother tongue, and of foreign languages, if it is to be sound. must rest upon a knowledge of pronunciation, which lies at the root of things so widely apart as sentence structure, syntax, rhythm and systems of versification.

The teaching of pronunciation requires, on the part of the teacher, training of a highly specialized order. and it should not be considered that a teacher is competent to teach the pronunciation of a language merely because that language happens to be his mother tongue. We are all, without special training, unaware of the various features that constitute the pronunciation of our language; we become conscious that there is a highly complicated system underlying our pronunciation only when we hear the system disturbed by foreigners who speak our language badly; *i.e.,* with the pronunciation system of their own.

The pronunciation of most European languages has been studied on modern phonetic lines, and there is an abundance of reliable literature on the subject. Research into the phonetic structure of American, Asiatic and African languages is proceeding, and reference libraries of gramophone records of languages and dialects are being established in many universities.

Pronunciation of the mother tongue is taught in the principal centres of education in the countries of Europe and America. It has already been stated that the traditional pronunciation of Arabic, reputed to have been that used by Mohammed, is still regularly taught throughout the Mohammedan world.

In Europe there is, in the case of French, a traditional stage pronunciation taught at the Conservatoire in Paris, and used in the state theatres and opera house. In Germany an attempt has been made to standardize a form of German pronunciation suitable for the theatre throughout German-speaking countries.

No such attempt at standardization has been made in England or America. As far as England is concerned, the pronunciation current upon the stage is that used by the educated people in the southeastern part of the country.

This pronunciation, with, however, a certain degree of latitude, is taught in England for use on the stage, in public speaking, and in singing. In the universities and public schools of England the pronunciation is left to look after itself, but there is a strong tradition as to what is and what is not permissible.

In the state schools there appears to be an awakening to the importance of equipping children with a form of pronunciation that will not prove a handicap in social life; and endeavours are being made to provide instruction.

Conclusion. — It is difficult to forecast the future, for we are faced with a new set of conditions. Increased speed of transport has made the world smaller; the complication of modern life leads to an international vocabulary; increased travel and increased oral communication familiarize us with hitherto unfamiliar pronunciations; the increase of education familiarizes millions with visual language, while wireless broadcasting tends to make the inhabitants of a widely spread linguistic area acquainted with a selected form of pronubciation. It is possible that these combined forces may tend to prevent linguistic disintegration of the principal languages of the modern world. (A LL.-J.)

PROOFREADING, the process of correcting for the press printed proofs of articles, books or other matter before publication. That the proofreader's profession goes back to the early days of printing is proved by reference to a corrector of the press in a book printed by R. Pynson in 1530 (the word proofreader seems originally U S.). A Pynson contract of 1499 also held the author finally responsible for correction of proofs In modern practice proofs are made first in galley (usually three or four pages unbroken on a long sheet). the first rough proof usually being corrected by the printer before being sent to the publisher and ultimately to the author. Page proofs and galley proofs frequently bear queries that show the proofreader's skill involves not only seeing that there is an exact correspondence between the copy given to the printer and its printed form, but also the catching of errors of fact. Lawsuits between printers and authors, and lists of errata. author's apologies and complaints at not seeing proof in printed books were common through the 15th. 16th, 17th and 18th centuries and are not unknown in modern publication.

Marks commonly used in proofreading follow:

	Delete	em |	Em dash
	Delete and close up	en |	En dash
	Reverse	; |	Insert semicolon
	Close up		Insert colon and en quad
#	Insert space		Insert period and en quad
¶	Paragraph	? |	Insert interrogation point
	Indent one em		Query to author
	Move to left		Use ligature
	Move to right		Spell out
	Lower	tr	Transpose
	Elevate	wf	Wrong font
	Insert marginal addition	bf	Set in **boldface** type
	Even space	rom	Set in roman type
	Broken letter	ital	Set in *italic* type
	Push down space	caps	Set in CAPITALS
	Straighten line	sc	Set in SMALL CAPITALS
	Align type	lc	Set in lower case
	Insert comma		Lower-case letter
	Insert apostrophe	stet	Let it stand
	Insert quotes	no ¶	Run in same paragraph
= |	Hyphen	ld	Insert lead between lines

PROOF SPIRIT. The term is applied to standard mixtures of ethyl alcohol and water which form the basis of customs and excise duties in Britain, U.S. and elsewhere. A distilled liquor was originally defined as proof spirit if, when poured over gunpowder and lighted, it would burn and finally ignite the .powder. If the alcohol content is less than 49.3% by weight, the water left after the burning of the alcohol is sufficient to prevent ignition of the powder.

In the United States proof spirit is held to be that alcoholic liquor which contains one half its volume of alcohol of a specific gravity of 0.7939 at 60° F., referred to water at 60° F. as unity (*Gauging Manual*, U.S. treasury department). Proof spirit has, at 60° F., a specific gravity of 0.93426 *(in vacuo)* 100 parts by volume of the same consisting of 50 parts of absolute alcohol and 53.73 parts of water. The difference of the sum of the parts of alcohol and water and the resulting 100 parts of proof spirit is caused by the contraction which takes place when alcohol and water are mixed. The specially designed hydrometers used in determining the alcoholic strength of aqueous solutions are so graduated as to indicate the number of parts by volume of proof spirit equivalent to 100 parts of liquor at the standard temperature of 60° F.; and they read 0 for water, 100 for proof spirit and 200 for absolute alcohol.

In Great Britain the Spirits act of 1816, legalizing Sikes' hydrometer for revenue purposes. gave for the first time a legal definition of proof spirit as follows: "that which at the temperature of 51° F. weighs exactly ++ of an equal measure of distilled water." Unfortunately, the act did not specify the water temperature thereby giving rise to considerable controversy. Subsequently, documentary evidence was produced which established that the temperature of the water was intended to be 51° F. Later investigation established the fact that at 60° F. proof spirit has a specific gravity of 0.91976, compared with water at the same temperature. and that it contains 49.28% by weight or 57.10% by volume of ethyl alcohol.

Spirits at strengths other than proof may be described as containing a percentage of proof spirit or as being overproof or underproof. The percentage of proof spirit is that number of volumes of proof spirit which can be obtained from 100 volumes of the mixture. Thus at 50° F., 100 volumes of absolute alcohol if diluted with water to proof strength give 175.35 volumes. It is therefore said to contain 175.35% proof spirit or to have a strength of 75.35% overproof.

In the Dutch system, proof spirit contains 50% of anhydrous alcohol at 15° C. (59° F.). (D. G. Z.)

PROPAGANDA is the making of deliberately one-sided statements to a mass audience. It is an act of advocacy in mass communication. Although the fact of propaganda is old, the term is comparatively modern. Usage was affected when the organization set up in 1622 by the Roman Catholic Church to carry on foreign missionary propaganda was called the College for the Propagation of the Faith.

In order to reach the mass audience, propagandists rely upon every medium of communication—oral, printed, pictorial, plastic, musical or dramatic. Every new channel is promptly laid hold of When the art of printing from movable type appeared in Europe, the printed word began at once to overtake oral media as the preferred means of persuasion. In the 20th century the motion picture, radio and television helped restore the spoken word to its former eminent position.

Communication effects are sometimes obtained with the aid of physical devices which are not usually employed for the purpose. The act of killing is no ordinary method of communication, yet killing is spoken of as "propaganda of the deed" when political assassinations are carried out as a means of affecting attitudes. Since any act of policy may influence mass opinion regardless of the means employed, an important part of total policy is the calculating and managing of psychological impacts. The most comprehensive term is "propaganda" or "communication" policy. When directed against an enemy in wartime, this is "psychological" or "propaganda" warfare.

Propaganda as an act of advocacy is distinguished from such closely allied uses of communication as instruction. information and inquiry. It is advocacy to editorialize or to select the content of channels of communication for the purpose of influencing attitudes on controversial issues. When the government distributes a pamphlet on the care and feeding of babies, the act is informative and instructive, not propagandistic, unless there is doubt about the authenticity of what is said. or the desirability of babies is in debate It is inquiry, not propaganda, to analyze controversial doctrines for the sake of sharing enlightenment. Private arguments among intimates are not spoken of as propaganda unless they are part of a campaign to spread controversial viewpoints, which indeed they often are. The mass audience with which the propagandist is ultimately concerned is not only characterized by size, but by the relative impersonality and shallowness of the tie that exists between the communicator and his audience.

Determiners **of** Propaganda.—The study, as well as the practice, of propaganda has a long history. The use of mass means of communication for military purposes was advised in *The* Book of *War* in the 5th century B.C. Sun-tzu wrote that "In night fighting beacons and drums are largely used; in day fighting, a great number of banners and flags, and the enemy's eyes and ears are confounded." In the East Indian classic of statecraft, Kautilya's *Arthaśāstra,* it is noted that "Astrologers and other followers of the king should infuse spirit into the army by pointing out the impregnable nature of the array of his army." Secret agents should circulate among the enemy, spreading rumours of their certain defeat.

From Graeco-Roman times are inherited manuals on how to win an argument and even how to win an election. The literature of propaganda has manuals on converting the heathen, indoctrinating the young, instigating subversion, preventing subversion, obtaining gifts and making sales. Indeed, there are few purposes for which there is no book of know-how.

Despite these practical guidebooks, it was only in comparatively modern times that scholars and scientists began to assess the place of mass persuasion in the social process. Many incentives for propaganda activity are known. Leaders of political and social revolutions often see that they can save soldiers and money by using symbols to induce obedience to a new regime. The foundation was laid for large and enduring empires when conquerors learned to convert rather than exterminate the conquered. The fifth-column technique of penetrating a state with political propaganda was probably the result of observing the successful missionary operations of the great proselyting religions of Buddhism, Zoroastrianism, Christianity and Mohammedanism.

Propaganda is a favoured instrument in the hands of political oppositionists, since it is both elusive and cheap. The unification of Germany, Italy, and of every modern state was preceded and accompanied by the fervent promotion of national sentiment, often by persecuted minorities. The propagandas of social revolution developed modern methods of persuasion to the highest pitch, working especially through party and auxiliary organizations.

Nonpolitical movements depend upon propaganda to induce hostile authorities to refrain from interfering with them. A movement is nonpolitical when it disclaims any intention of changing the institutions of power and favours rendering unto Caesar that which is Caesar's. All movements have consequences, however, which in some degree affect the internal and external balance of power, regardless of conscious purpose. The holders of power, sensing the degree to which all social processes are linked together, often persecute minority movements or try to manipulate them for political ends. Nevertheless, propaganda has sometimes been effective in staving off political intervention, especially when the propaganda appeal is made in the name of natural or divine law.

It is no surprise to discover that incentives to engage in propaganda decline when hopes are frustrated. Labour movements have gone through periods of revulsion against "mere talk" in favour of "strictly economic" methods or even terror.

Perhaps the greatest incentives for propaganda in the 20th century have been economic and connected with the growth of industrialism. Advertising fanned the spirit of speculation which fed the reservoirs of capital upon which the expansion of commerce and industry depended. Since the advantages of large-scale production could be realized by the successful stimulation of consumer demand, advertising trained hundreds of millions of buyers to change their tastes in clothes, interior decoration, personal adornment, cooking and amusement.

The use of mass persuasion was furthered by the spread of literacy and of education generally, and by the enormous growth of mass media. In free countries the media generate special interests of their own in propaganda, since controversy makes circulation and circulation boosts revenue from advertising.

The volume of propaganda is affected by whatever discredits the old or reduces the difficulty of acting in new ways. In the United States arose a "culture pattern of novelty," with great zest for the new gadgets turned off the assembly lines of industry. In order to reduce the difficulties connected with acquiring something new, simplified designs appear continually on the market. Consumer credit, liberal allowances on trade-ins and related practices are examples of ways invented to ease the path of the purchaser.

Of significance to propaganda is the sheer size and heterogeneity of a population. Even in totalitarian states a vast labour of internal persuasion is essential to overcome the bonds of attachment to the old. or the sentiments of fear, hatred and confusion at the prospect of a new way of life. In soviet Russia (after 1921) the full orchestra of poster, broadcast and lecture was mobilized in a series of gigantic campaigns on behalf of literacy. proper care of tractors and elementary habits of personal hygiene. Glacierlike resistance was thawed by the blowtorch of symbols supported by every other influence.

The most general conclusion about propaganda is that it increases whenever the equilibrium of society is threatened or upset, and decreases with the restoration of the imperilled equilibrium or with the emergence of a new level of adjustment. This hypothesis needs to be more specific in order to account for the use of propaganda, rather than coercion, when social equilibrium is endangered. In addition, the likelihood of propaganda is increased whenever there are traditional institutions of freedom, whether free government, free market, free education or free religious proselyting.

Summing up in another way, it can be said that during any given period the volume of propaganda activity depends upon such factors as: the intensity of the determination on the part of propagandists to introduce or to discourage new acts; the availability of mass media and the prevailing level of literacy and general education; the degree of discontent with the old and the difficulty of the new; the number of persons asked to perform or to refrain from performing a new act; and the depth of devotion to persuasion in place of coercion. Whatever arouses controversy is likely to foster propaganda until the incentives which sustain the use of mass persuasion are reduced and rival methods of social action are tried; or discontent is dissipated without result (that is, catharsis occurs); or a new positive adjustment is made in prevailing social practice.

Strategy. — The proper strategy of propaganda depends upon the over-all frame of policy and the circumstances which favour or stand in the way of success. The overriding aims of policy range from the comprehensive reconstruction of society to local and immediate matters, and from complete reliance upon persuasion to the ultimate elimination of propaganda.

When a comprehensive plan of social change is pursued by peaceful means, a major problem of strategic planning is whether to expedite success by making concessions of detail. At one time in China the Jesuits dressed like native scholars as a means of modifying the strangeness of the Christian mode of living. The pope decided to forego immediate advantages and put a stop to these practices. In the absence of unified command. Marxian Socialists split into many branches over the nature and timing of revisions. Leading revisionists softened or abandoned the doctrine of violent class struggle and entered electoral or cabinet coalitions.

A related question of strategy is how far to concentrate upon the teaching and preaching of doctrine. and hon far to go in using auxiliary appeals. Lenin insisted upon the necessity of propaganda, which he defined as indoctrination, and also of agitation, which meant the exploitation of concrete grievances. In foreign missionary work, auxiliary activities became standard means of providing an indirect approach to prospective converts. Buddhist missions always encourage charity, but it is reported that in China the translation of the Buddhist canon played a more important part than good works, since the translation aroused the curiosity of the scholar class. On a humbler level. it is known that it has long been established commercial practice to supplement the verbal appeal of advertising nith "giveaways" and prizes.

Sometimes the task of propaganda is to prepare the way for activities which, if fully disclosed in advance, mould unquestionably fail. Before the seizure of power in Germany, the National Socialist strategy was to prevent a combination of Socialists. Communists and conservatives which would have stalled their advance. Once the National Socialists were in power, the problem was transferred to the arena of world politics and became that of forestalling joint action by west and east while the country rearmed, occupied the Rhineland. absorbed Austria, partitioned Czechoslovakia and began war against Poland. After the break with Russia, the major strategic aim mas to pry apart east and west in order to escape from two-front war. Historians of the American propaganda of secession and independence from Britain, such as Evarts Greene, commented upon the skill of the leadership in carrying along many moderate persons who, though not desiring independence, had co-operated with the radicals to such an extent that they could not effectively withdraw.

The correlation of propaganda inside the frame of totalitarian policy involves many fundamental and, at first sight, paradoxical problems. One long-run objective of totalitarian policy is the substitution of ritual and ceremony for discussion and persuasion, hence of propaganda. A totalitarian state is a command state that swallows the whole society. The task of managing the media of communication under such conditions is to foster a world of fantasy wherein the hero at the top of the pyramid is the champion of all against the encircling forces of evil which, though powerful, cannot ultimately prevail. The propagandist does not use current happenings for news and comment, but for sermons and fables adorning the dogma is infallibly interpreted by the ruling machine. Since commands from above allow no answering criticism from beneath. healthy self-assertion is repressed or turned against the lower strata or the outside world. In such a garrison-police state leaders live in perpetual anxiety of losing control and require the reassuring balm of ritual adulation. All this is in vivid contrast to the operation of a free society which revels in the clash of news and views.

Tactics. — The tactical problems of the propagandist are to adapt the situation to the limits imposed by strategy. This implies that some policies, persons, groups and institutions must be presented in a favourable light, while others are put at a disadvantage. Appropriate audiences and channels must be chosen to obtain the desired effects. An organization capable of the degree of devotion and expertness called for by the objectives sought must be assembled. The choices open to the tactician are ultimately to disseminate. to withhold or to modify a statement; to use, omit or block a channel; to select or reject a person.

In deciding what to disseminate, the perspectives of the audience must be given careful consideration. These perspectives consist in conceptions of the self and in cherished demands and expectations. Perspectives can be conveniently classified according to culture, class, crisis and personality. Assume that the tactical problem is to induce as many surrenders as possible from among enemy soldiers and officers. The propagandist will take note if enemy culture has long inculcated the ideal of military honour. He will try to discover whether there are circumstances in which the enemy admits that it is honourable to give up. Let us suppose that the answer is "yes. nhen no military purpose can be served by resistance." and "when an authoritative procedure is laid down" for members of the armed forces. The propagandist therefore circulates statements to the effect that further resistance has no military sense. He will also provide an authoritative-appearing directive to be obeyed. For use among the Germans in World War II. a "safe conduct" pass was developed which was a surrender leaflet printed in an official shade of green ink, with parallel translations in three languages and signed by the supreme commander. The propaganda tactician took class differences into account by working out special ways of addressing officers and men on programs. It was also recognized that the youth of Germany had grown up in a crisis period in which their values and loyalties had been given special shape. Appeals were therefore aimed at different age levels in the German army. Personality differences were considered on the theory that the older army leaders were less ruthless types than the fanatical youth.

In deciding what to withhold, the perspectives of the audience continue to be crucially important to the tactician. In World War II it was generally understood that German audiences were wary of being "deceived once more" by Allied statesmen, and that they were on guard against propaganda. British and U.S. propagandists decided to take the long road of winning confidence through accurate reporting. The plan was to win the "battle of credibility" by adhering to the truth, especially by playing up statements which the audience could directly verify. As a result of studying what the audience of a totalitarian country could believe, true statements were often toned down, not to deceive, but to sound plausible. Military successes, weapon production, food supplies and quantities of equipment were sometimes understated in order to carry conviction.

In deciding whether to remain silent or to reply in response to an accusation, it is essential to bear in mind that the pattern of conduct deemed appropriate for an honourable man differs widely. In some upper class circles only statements by a class equal are taken with enough seriousness to warrant reply. Sometimes the honourable man is expected to display the utmost indignation in denying accusations. Elsewhere the badge of innocence is calmness. In many cases it is difficult to judge how much influence an adverse whispering campaign can have. When Pres. Woodrow Wilson mas the target of a campaign against his character, he declined to take any notice of it on the'ground that it was false and that all who knew him understood it was false. He thought that he would give more currency and dignity to the "smear" by replying in public than by keeping silent.

So far as facts are concerned, it is generally agreed that some facts cannot be successfully concealed from an audience. Hence it does less damage to release bad news promptly than to appear both unreliable and inefficient. Railroads learned to release news of accidents and air lines followed suit. Often there are facts which are extremely disagreeable to both sides if disclosed. In bitter controversies it is customary for propagandists to obtain from intelligence services material which can be used privately to intimidate an adversary from spreading material that stigmatizes one's own candidate or cause.

Innumerable devices are at the command of the working propagandist for nullifying statements. Thus a Russian spokesman remarked that the nazis had created a new category of war casualty, the "slightly killed." Wit, humour, calmness, the casting of doubt upon sources, the combining of favourable and unfavourable news, and the playing down of unfavourable statements are standard ways of modifying adverse references. Also there are ample means of inflating favourable statements by emphasis and elaboration.

A continuing tactical problem is how much to praise the self and to condemn rivals or enemies. Commercial competitors for the same large market usually refrain from attacking one another on the theory that doubt is cast upon the type as well as the brand of product. Unlike business propaganda, it is characteristic of political propaganda to present politics as a drama in which the forces of good and evil stand opposed to one another. Revolutionary or urgent reform movements commonly try to induce a sense of guilt among opponents and self-righteousness among adherents. This tactic may succeed in provoking conflicts of conscience, since agreed value standards are applied to the disadvantage of the old and the advantage of the new.

In selecting media the propagandist keeps in mind considerations similar to those which apply to the choice of statements. If the problem is to nin the support of the rich, powerful and wellborn, favourable mention in organs which they look down upon is no asset. If the aim is to win confidence among the masses, the task is to enlist the leaders and media which they trust.

In the choice of media time considerations are important, since if aims can be accomplished over long periods the more permanent media, such as scholarly books, magazines and schools, have a significant role. If the goals are short run, the tactician must adapt to the existing network and employ fast rather than slow media.

The audience of a going channel has selected itself on the basis of predispositions which cannot be disregarded. During World War II. U.S. broadcasters to Germany quickly learned that crisis audiences differ from other kinds. Clandestine listeners who had risked their lives to hear news and comment from the outside world were furious when they tuned in on entertainment.

In the choice of personnel for propaganda work, one question is when is it a good thing to be emotionally involved. The history of propagandas of religion and revolution make it clear that dangerous propagandas need to be in devoted hands. Where less sacrificial considerations are at stake professional talent can be employed in the same way that a lawyer takes over the claims of a client, not because the claim is right but because the client has a right to be heard.

The 20th century has been notable for the rapid application of the social and psychological sciences to the problems of propaganda technique. It is standard operating procedure to pretest posters, labels, slogans and other details before they are brought to the notice of the eventual audience. A pretest uses a small group which is representative of the large audience which it is planned ultimately to reach. Posttests are utilized in the hope of evaluating the effectiveness of propaganda messages or channels. These tests are of the utmost diversity. They may be based on brief or prolonged interviews, upon the participant observation of behaviour, upon the analysis of a wide range of responses such as voting, giving, buying. selling, depositing, hoarding, investing, quarrelling, fighting, joining. seceding, boycotting, striking or attending. Methods have been devised to describe in quantitative terms the contents of the media of communication. Research is also done upon the control pattern that prevails in different countries, such as the degree of government monopoly or regulation, of private monopoly or competition.

Control. — It is impossible to scan the long history of attempts to control propaganda without being impressed by the power that men attribute to words. The fear of propaganda is fed by apprehension of the magical potency of language for the infliction of harm. These primitive attitudes continue to be an undercurrent in civilizations where the dominant attitude about language is detached and managerial. The only control problems that disturb a modern totalitarian regime are questions of expediency in the realm of power. In nations nhere the dignity of man is upheld, the issues are more complex, since the institutions appropriate to a free society include freedom of information, propaganda and political decision. Freedom is part of the respect due to the individual and is a condition of enlightenment and democracy.

But freedom of utterance is nowhere without qualification. No free society fails to use community coercion against some forms of speech on the ground that the results endanger important values without corresponding gain. Some gestures are condemned as obscene because we believe that youth will be corrupted if they are exposed to or use such gestures. Some communications are called fraudulent, libelous or slanderous. and left outside the protection of the community. In controlling propaganda the aim is to safeguard news and comment without permitting incitement, which is an act of coercion.

A consensus arose about the more extreme situations in which words become part of a coercive act. It is incitement when uniformed, armed and trained formations organize and act. Such activities signify that society is dissolving and can be restored only by bringing coercion back into the hands of organized government.

There is less agreement about what to do about statements provocative enough to arouse the anger of members of an audience whose religious, ethnic or political sentiments are affronted. One view is that restrictions must be imposed when there is "clear and present danger" to public order. A more daring conception is that it is the purpose of a free society to maintain a kind of public order where coercive acts are not permitted in response to words, however offensive.

In time of war, popular governments are compelled to recognize that statements circulated by an enemy are part of the enemy's coercive activities. But what of statements uttered by members of the commonwealth who have no connection with a foreign power? Some defenders of freedom assert that enough protection is given to the body politic if repressive measures against domestic propaganda are kept at a minimum and reliance is put upon the positive advocacy of the majority viewpoint, coupled with the disclosure of parallels, intended or unintended, between domestic propaganda and the line taken by the enemy. It is conceded that without remarkably successful civic training in self-restraint, the police and the courts, to say nothing of the ordinary citizen. may be unable to tolerate dissent in the midst of crisis.

One of the greatest dangers arising from the prevalence of propaganda in a free society is that the vigorous prosecution of special interests prevents the formation of a genuine public will. In times of general crisis this may put democratic countries at a disadvantage when, on the assumption that the globe is in a chronic state of civil war, the ruling groups of totalitarian countries institute and maintain strict censorship and propaganda. The purpose on the one hand is to insulate the home audience from outside influences, and on the other to obtain maximum access to nontotalitarian audiences.

The very presence of propaganda raises searching problems for the friend of freedom. Does the calculated manipulation of attitudes imply a denial of respect for freedom of opinion? This is true if the forum of communication is not equally accessible to all and if educational opportunities are open only to the privileged. Hence. in countries that aspire toward freedom, stress is laid upon measures designed to achieve genuine equality., The legislative and judicial institutions of society proceed by the use of discussion in order to subject rival propaganda claims to a common discipline of balanced presentation and of critical evaluation of evidence. Whatever solutions of the control of communication are achieved, it is evident that the degree of protection received by unpopular opinion and propaganda will continue to be one of the chief working tests of freedom.

PROPANE, a colourless, gaseous compound of carbon and hydrogen, the third member of the paraffin series following methane and ethane. The formula for propane is C_3H_8. It is separated in large quantities from natural gas. light crude oil and oil refinery gases and is commercially available as liquified propane or as a major constituent of liquified petroleum gas (LPG).

As with ethane (*q.v.*) and other paraffin hydrocarbons. propane is an important raw material for the ethylene petrochemical industry. The decomposition of propane in hot tubes to form ethylene also yields another important product, propylene. From propylene organic chemicals like acetone, propylene glycol and many others are derived. The oxidation of propane to such compounds of carbon, hydrogen and oxygen as acetaldehyde is also of commercial interest.

Although a gas at ordinary atmospheric pressure, propane is readily liquified under elevated pressures. It is therefore transported and handled as a liquid in cylinders or tanks. In this form, alone or mixed with liquid butane, it has great importance as a fuel for domestic and industrial uses and for internal-combustion engines.

In the mid-20th century, world reserves were estimated at about 10,000,000,000 tons. The annual production was about 0.2% of this figure. Consumption was about equally distributed among chemical uses, LPG and as an unseparated constituent in natural gas used as fuel. (F. B. B.)

PROPELLANTS, chemical compounds or mixtures of compounds used to: (1) propel rockets or missiles or (2) to propel projectiles through the tubes of guns, howitzers, mortars or other firearms. Their propelling force results from rapid burning and evolvement of hot gases that exert a sustained forward force or pressure on the missile or projectile. One important feature of a propellant is that it supplies its own oxygen, whereas fuels such as coal and gasoline must obtain oxygen from the air. This feature is essential for missiles to continue accelerating as they reach outer space.

SOLID PROPELLANTS

History.—Gunpowder, or black powder, was the original propellant that used controlled explosive forces. This material may have been known much earlier than the 14th century and may have been used in various rockets and other mysterious fire-producing devices, but the evidence is not donclusive. For more than 550 years. uith some variation in composition and physical form. gunpowder adequately served man in the full range of firearms, both military and sporting. (*See* GUNPOWDER.)

But gunpowder had recognized deficiencies. Because it was a mechanical mixture of carbon, sulfur and potassium nitrate or sodium nitrate. its composition and properties were bound to vary. Gunpowder was also far from clean burning, it left troublesome residues in guns and produced large clouds of smoke and usually bright muzzle flashes. Other problems were caused by the tendency of some of the ingredients, notably the nitrate, to absorb moisture; there were also serious hazards in the manufacture of gunpowder.

The successor to gunpowder as a propellant was a substance called smokeless pomder. the term smokeless reflecting the cleaner burning of the nitrocellulose propellant as compared with gunpowder Nitrocellulose. originally termed guncotton. was invented accidentally in 1845 when Christian F. Schonbein (1799–1868), a German chemist, is said to have spilled some nitric acid on his wife's cotton apron. In modern terminology, guncotton means nitrocellulose with a nitrogen content of 13% or more. The term more common than guncotton is high-grade nitrocellulose.

The first attempts to utilize nitrocellulose as a propellant were unsuccessful, some actually disastrous, for two main reasons: (1) the material was chemically unstable, because of the reactions of the residual acid in the fibres, and (2) the raw fibrous nitrocellulose presented an excessive burning area to the flame front. Later the stability problem was solved by a more complete removal of the residual acid from the nitrocellulose fibres and by an addition of chemical stabilizers such as diphenylamine.

Schonbein is also credited with being the first to treat nitrocellulose with alcohol and ether to form collodion (*q.v.*). However, it remained for Paul Vieille (1854–1934), a French physicist and chemist, to utilize this colloiding action of solvents in molding the now homogeneous mass into shapes of controlled dimensions and surface areas. This was an extremely important discovery because it laid the groundwork for successful development of colloidal nitrocellulose propellants with improved and controllable ballistic characteristics. The French army adopted the new and more powerful propellant about 1885 as poudre B.

The next step in propellant development occurred in 1888 when Alfred B. Nobel (*q.v*), a Swedish chemist and engineer, discovered the solvent and colloiding actions of nitroglycerin on nitrocellulose and combined them into a more powerful propellant termed ballistite. As it contained both nitroglycerin and nitrocellulose, it was described as a double-base propellant.

In 1890 Sir Frederick A. Abel a British chemist. invented cordite, another double-base propellant consisting of 65% nitrocellulose, 30% nitroglycerin and 5% mineral jelly. Cordite was made by extruding the colloid into long cords, whereas both Vieille and Nobel had rolled the colloid into sheets and then cut the sheets into flakes of various sizes. Before the end of the 19th century, the U.S. navy adopted smokeless powder, favouring the single-base type of Vieille and using nitrocellulose of approximately 12.6% nitrogen — it was often called pyrocellulose or simply pyro.

Early 20th Century. — These two general types, single-base and double-base, served almost exclusively as standard propellants for military and civilian use during the early 20th century. Even when the rocket or jet-propelled type of weapon came into military use, the double-base propellant, still termed ballistite, found extensive application.

After World War I, important refinements were made in U.S. army single-base propellants. For example, the ingredients dinitrotoluene and dibutylphthalate were added to the nitrocellulose, effectively moisture-proofing the propellant grains. Ingredients in this improved propellant were also proportioned to eliminate muzzle flash when fired from the French 75 mm. gun which was extensively used by the Allied armies. The new propellant was known as flashless-nonhygroscopic (FNH) or more officially as duPont FNH-M1 in recognition of the co-operative developmental efforts of E. I. duPont de Nemours and company. Later it mas designated as propellant M1, and a slight variation for the larger guns as propellant M6. Table I shows the nominal formulas and two calculated properties of these important U.S. propellants.

TABLE *I.—Data on M1 and M6 Propellants*

Ingredients	M1	h16
Nitrocellulose (13.157,) N	85	87
Dinitrotoluene	10	10
Dibutylphthalate	5	3
Diphenylamine*	1	1
Isochoric flame temperatures (°K)	2417	2570
Ballistic force (ft.lb./lb.$\times 10^{-3}$)	305	317

*Diphenylamine is added and serves as a chemical stabilizer for the nitrocellulose.

World War II Era.—During World War II a number of important developments affected the military propellant field. A more nearly flashless gun propellant (cordite N) was introduced in England. Rockets and jet-propelled missiles gained in importance of the first magnitude. Large rockets. in turn, brought into prominence another type of solid propellant, termed composite, as well as liquid propellants.

Cordite N was a triple-base type that contained a third explosive compound, nitroguanidine, in an amount of approximately 55%. This compound was also used by Germany and perhaps other countries, but usually with somewhat smaller percentages of nitroguanidine. The high nitrogen content (55%) in nitroguanidine imparts a special cool-burning property to the propellant, thus aiding in flash control and reducing erosion rates. Addition of salts such as potassium sulfate (K_2SO_4) in small percentages (cordite N/P) further increased the flashless properties of this type of propellant, though even 1% of K_2SO_4 greatly multiplied the amount of smoke produced.

Cordite N propellant was adopted in the early 1940s for many guns in the United Kingdom services and in Canada, and by the U.S. navy even for its largest guns. The U.S. army adopted a slight modification of cordite N as the M15, carefully designed for optimum flashless-smokeless performance where this double feature had special importance, as in tank guns. The U S. army also adopted a further modification as the M17, designed especially to impart maximum muzzle energy to solid armour-piercing types of projectiles. Typical nominal formulas and important characteristics of these three triple-base propellants are shown in Table II.

These values of flame temperature and force represent about the normal range for military gun propellants. Double-base types for mortars, rockets and recoilless rifles have considerably higher flame temperatures.

Small Arms.—The earliest small arms propellant was gunpowder and many a vivid picture comes to mind of the western U.S. pioneer tamping the powder charge and the bullet into his muzzle-loader. The earliest colloidal propellant was probably made in the form of flakes but later more progressive burning, and therefore greater efficiency, was secured by using an extruded grain with a single perforation and by applying a deterrent coating to the outside of the grains. This design was standard for almost all types of military rifles and culminated in the development of the well-known IMR (Improved Military Rifle) propellant by the duPont company. The IMR propellants and most other small-arms propellants were of the single-base type, although some double-base types were used in pistols and shotguns.

TABLE *11.—Approximate Formulas and Calculated Properties for Cordite N, M15 and M17*

Ingredients	N	M15	M17
Nitrocellulose	19.0	20.0	22.0
Nitroglycerin	18.7	19.0	21.5
Ethyl centralite*	7.3	6.0	1.5
Nitroguanidine	54.7	54.7	54.7
Crvolite	0.3	0.3	0.3
Isochoric flame temperature (°K)			
Ballistic force (ft.lb./lb.$\times 10^{-3}$)	2450 320	2	3364

*Diethyl diphenyl urea.

In the United States the non-military use of small-arms propellants has always been considerable; this was especially true during the early periods when game was plentiful and was a significant item of food. More recently the small arms ammunition market has been expanding in the area of sporting contests and target practice.

An important propellant development was made by the Western Cartridge company (later a division of the Olin-Mathieson Chemical corporation) in the 1930s. The propellant was called Western ball powder. The production technique was to dissolve or disperse the nitrocellulose and other ingredients in a solvent such as ethyl acetate. Upon agitation and the addition of a protective colloid, the lacquer was broken up into small spherical globules. The process provided an effective means of purifying the nitrocellulose and also lent itself well to making either single-base or double-base propellants. The particular design submitted for military use in small-arms weapons showed a significant improvement in the form of longer barrel life for the weapons. The novel spherical form and design of the propellant grain may have contributed to this fortunate result. However, the relatively low flame temperature of the particular composition in use in those specific tests appears to have been the most significant factor. See also SMALL ARMS, MILITARY.

Rockets and Missiles.—As noted earlier, the double-base ballistite type was the popular solid propellant used in rockets of small and some medium sizes—notably the bazooka (*q.v.*). As made by the extrusion process, ballistite had definite limitations as to diameter of strand. Therefore, as missile sizes increased, various casting and pressing processes had to be devised to fabricate larger sizes of propellant grains required by the motors. Various complex shapes of grain were also needed to produce the desired burning characteristics. (The word grain is still used to designate discrete particles regardless of size.)

The casting and other methods of fabrication opened the way for the composite type of propellant for missiles and JATOs (jet-assisted take-off devices) with an almost unlimited range of sizes and capabilities. In these heterogeneous mixtures of chemical compounds there may be fuels, either organic or metallic; oxidizers (nitrates. perchlorates, etc.); binders and other special-purpose ingredients such as burning-rate controllers or accelerating additives.

The composite type of propellant provides for considerable flexibility in design and in the variety of fabrication methods. Solid-propellant grains may be cast with liquid nitroesters or other compounds filling the voids, thus providing the typical heterogeneous mass with evenly distributed components. The casting or pressing may be done in a special mold or an inert plastic container which later acts as an inhibitor and thus restricts burning to the end of the composite mass. Or the entire charge may be cast or pressed into the missile motor itself, the walls of which automatically provide an inhibiting action.

To develop a solid propellant for a given purpose, skillful design and careful manufacturing control are essential for each specific application because of the many severe performance requirements and limitations placed upon modern propellants. In addition, most propellants, especially in military use, must be stable chemically and ballistically for safe storage over long periods of time. The chemical compounds must include only such ingredients as are compatible or nonreactive until actual functioning is desired.

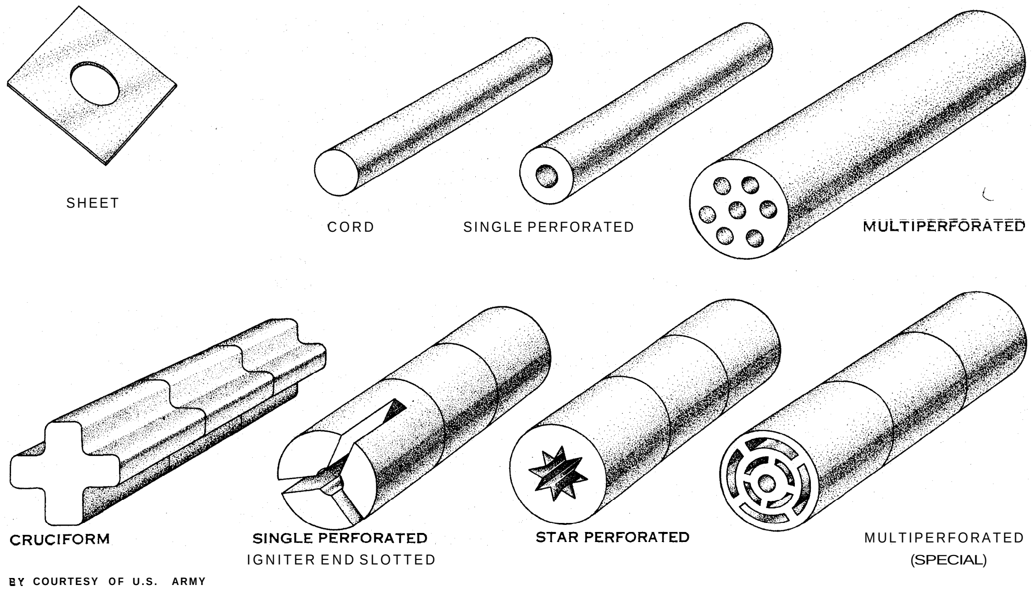

FIG. 1.— SOLID-PROPELLANT GRAIN CONFIGURATIONS

Certain stabilizing compounds such as diphenylamine may be needed to neutralize the effects of the possible slow hydrolysis of nitrocellulose or other nitrates.

LIQUID PROPELLANTS

Although solid propellants have been the work horses for many centuries, liquids have gained distinctive roles in modern missile technology. The experiments of Robert H. Goddard (*q.v.*) in the 1920s charted the course; he visualized a system using liquid hydrogen and liquid oxygen as being capable of energizing even an interplanetary rocket. The German V-2 missile of World War II was a milestone in actual application of two liquids, alcohol and liquid oxygen (LOX).

Liquid systems are of two types: monopropellants and bipropellants. A monopropellant may be a single compound such as ethyl nitrate, or it may be a compatible mixture such as hydrazine, hydrazine nitrate and water. Bipropellants consist of two liquids. one an oxidizer and the other a fuel; they are kept separate until they reach the combustion chamber. Most bipropellants ignite spontaneously on contact and are therefore said to be hypergolic. Typical oxidizers are liquid oxygen, fuming nitric acid and hydrogen peroxide; fuels include aniline, hydrazine and alcohol. Monopropellants are usually chosen for the few gun applications of liquids; most liquid-missile systems use bipropellants because of their greater energy capabilities.

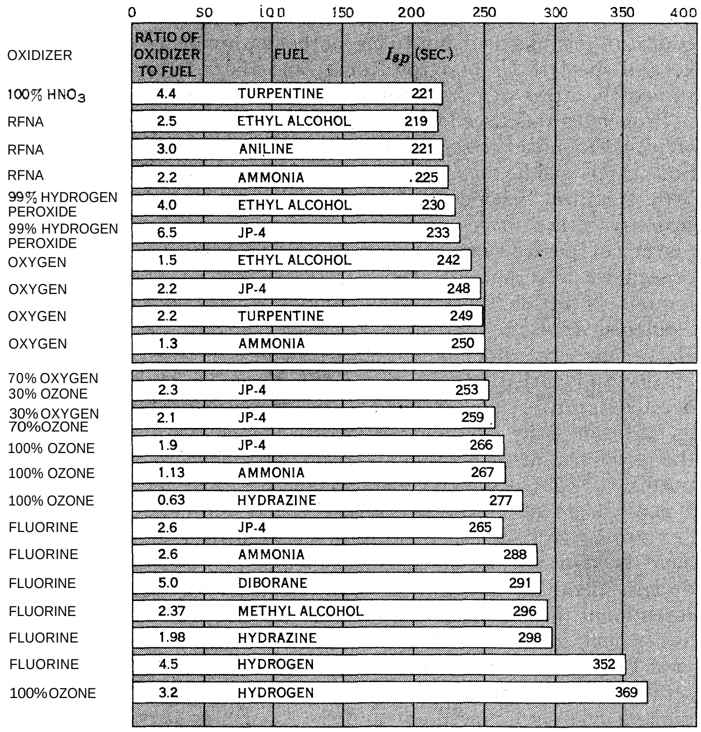
The choice between liquid propellants and solid propellants for a given missile often depends upon the nature and severity of the launching and flight requirements and on the limitations of the missile system itself. In practice the larger missiles may utilize two or more stages, with liquid and solid propellants in different stages of the same missile. Each stage consists of a separate motor that may be discarded after propellant burnout is complete.

Another important factor is the time period required for operational stability. Many solid propellants remain essentially unchanged for years, whereas the high energy of liquid oxygen is available for a very short time unless elaborate refrigeration is provided. Practical considerations include tactical convenience and safety in supply, transportation, handling and storage. Solid propellants are easy to handle and may be kept for long periods in a ready-to-fire status; liquid propellants offer higher specific impulse but at the cost of many tactical problems.

Perhaps the two most fundamental properties of many propellants, at least solids, are that their functioning is essentially a surface-burning phenomenon and that the burning rate at any instant depends upon the pressure existing in the surrounding gaseous medium. Thus, Vieille in 1888 showed that the burning rate r is proportional to the pressure P: $r = c\ P^n$, where c is a constant characteristic of the chemical composition and n is essentially constant, usually in the range 0.8 to 1.0. Surface burning (rather than detonation of the mass, as in explosives like TNT) is utilized to guide the reaction toward maximum efficiency. Thus the pressure may be sustained by designing the solid-propellant grain so that the area exposed to the flame front remains constant, or may even increase, as burning proceeds. This is done by varying the geometry of the grain (see fig. 1) or by using inert deterrent materials on grain surfaces. The value of c in Vieille's lam may be altered materially in modern practice by incorporating selected high-energy fuels (as magnesium or aluminum), by rate control strands, by using additives with a high-burning rate and by incorporating special ingredients that broaden the pressure-time curve and thus increase the total-thrust energy imparted to the missile.

For long-range missiles the urgent demand is for the maximum possible power or sustained thrust. The fundamental measure for power of a given propellant is specific impulse (abbreviated I_{sp}). In the simplest form $I_{sp} = F/W$ sec., where W is the average rate of propellant consumption in pounds per second. to produce the average total thrust F in pounds. This relationship shows the value of high-energy compounds, capable of producing high values of F; and of chemicals with low molecular weight, thus lowering the value of W. In these relationships liquid compounds show great potential gains over solids, because of the variety of fuels containing hydrogen and of such high-energy oxidizers as liquid oxygen, fluorine and ozone.

Fig. 2 indicates the broad possibilities for specific impulse, but



FROM "CHEMICAL AND ENGINEERING NEWS," VOL. 35, NO. 21, P. 20 (1957)

FIG. 2.— THEORETICAL SPECIFIC IMPULSE (I_{sp}) FOR LIQUID-PROPELLANT COMBINATIONS

of course the practicability of using these high-energy combinations depends upon many other factors. By way of comparison, double-base solid propellants develop a specific impulse of about 230 sec., composites do somewhat better, in the order of 250 to 290 sec. These values for **I„** should be contrasted with the fig. 2 levels of up to 369 for high-energy liquid systems. Such values of **I„** may well be approaching the upper limit attainable by combinations of conventional chemical compounds. Further increases into ultraenergy regions may depend upon success in harnessing free radicals and atomic energy sources.

PROPERTIUS, SEXTUS (c. 50–*c.* 15 B.c.). the greatest of the elegiac poets of Rome, was born of a well-to-do Umbrian family at or near Asisium (Assisi). Ovid says that Propertius was his senior, but also his friend and companion; and that he was third in the sequence of elegiac poets, following Cornelius Gallus, who was born c. 70 B.c.. and Tibullus, and immediately preceding Ovid himself, who was born in 43 B.C. It may be supposed then that he was born c. 50 B.C.

His early life was full of misfortune. He lost his father prematurely; and after the battle of Philippi and the return of Octavian to Rome, Propertius, like Virgil and Horace, was deprived of his estate to provide land for the veterans, but, unlike them. had no patrons at court and was reduced from opulence to comparative indigence. When the widespread expropriations had provoked an insurrection, Propertius lost another of his relatives, who was killed by brigands while making his escape from Perusia (Perugia), the centre of the revolt. The loss of his patrimony, however, did not prevent Propertius from receiving a superior education, thanks no doubt to his mother's providence. Eventually he and she left Umbria for Rome; and there, c. 34 B.C., he assumed the dress of adult manhood.

Propertius was urged to take up a pleader's profession; but, like Ovid, he found in letters and gallantry a more congenial pursuit. Soon afterward he made the acquaintance of Lycinna (about whom little is known beyond the fact that she subsequently excited the jealousy of her successor, Cynthia) and was subjected to all her powers of persecution (*vexandi*). This passing fancy was succeeded by a serious, attachment! the object of which was the famous "Cynthia." Her real name was Hostia (according to Apuleius, Apologia, 10); and she was a courtesan of the superior class, somewhat older than Propertius and, it seems. of singular beauty and varied accomplishments. Her own predilections led her to literature; and in her society Propertius found the intellectual sympathy and encouragement which were essential for the development of his talent. Her character, as depicted in the poems, is not an attractive one; but she seems to have entertained a genuine affection for her lover. Their intimacy lasted from c. 29 to 24 B.C. These years must not. however. be supposed to have been a period of unbroken felicity. Apart from minor disagreements an infidelity on Propertius's part excited the deepest resentment in Cynthia; and at some time he was banished from her society for a year. When he had known Cynthia for about a year Propertius published his first book of poems, which was inscribed with her name. Its publication placed him in the first rank of contemporary poets and procured him admission to the literary circle of Maecenas. The subsequent relationship between the poet and his mistress, honever, was one of growing disenchantment; neither was faithful to the other; the mutual ardour gradually cooled; motives of prudence and decorum urged the discontinuance of the connection; and disillusion changed insensibly to disgust.

Although their parting might have been expected to be final, it is not certain that it was so. Though Cynthia, whose health appears to ,have been weak, does not seem to have survived the separation long, the poem (iv, 7) in which Propertius describes a dream of her that he had after her death suggests that they were once more reconciled and that in her last illness Cynthia left to him the duty of carrying out her wishes with regard to the disposal of her effects and her funeral. Almost nothing is known of the subsequent life of the poet. He was alive in 16 B.c.. as some allusions in his last book show. Moreover, two passages in the letters of the younger Pliny mention a descendant of the poet, one Passennus Paulus; and this had given rise to the suggestion that Propertius may have married in order to comply promptly aith the *leges Juliae* of 18 B.C. (which offered inducements to marriage and imposed disabilities upon the celibate) and had at least one child.

Propertius had a large number of friends and acquaintances, chiefly literary men belonging to the circle of Maecenas. Among them may be mentioned Virgil, an epic poet called Ponticus, a certain Bassus (probably the iambic poet) and at a later period Ovid He says nothing of Tibullus or of Horace, who also never mentions Propertius. This reciprocal silence may be significant.

In person Propertius was pale and thin, as was to be expected in one of a delicate and even sickly constitution. He was very careful about his personal appearance and paid an almost foppish attention to dress and gait. He was of a somewhat voluptuous and self-indulgent temperament. which shrank from danger and active exertion. He was anxiously sensitive about the opinion of others. eager for their sympathy and regard and. in general, easily influenced by them. His over-emotional nature passed rapidly from one phase of feeling to another; but the more melancholy moods predominated. A vein of sadness runs through his poems, sometimes breaking out into querulous exclamation, but more frequently expressed in gloomy reflections and prognostications. He had fits of superstition, which in healthier moments he despised.

The Poems.—The poems of Propertius, as they have been preserved. consist of four books containing just more than 4.000 lines of elegiac verse. Book i. the *Cynthia* or *Monobiblos*, was published probably in 29 or 28 B.C As its title indicates, it is concerned almost exclusively with the poet's passion for Cynthia. The arrangement of the poems is. in the Alexandrian manner, one of artful disorder: the phases of the liaison and of Propertius's feelings are described in a series of brilliant isolated impressions, in nhich a strict chronology is carefully avoided (compare Ovid's *Amores*). This is not the only reason why it is unsafe to draw inferences about Propertius's actual life and loves from his poetry. Throughout, but particularly in the first book, reality and convention, experience and literary artifice, love and learning, are too intimately blended for the reader to be sure of disentangling them. It is important to remember the poet's essentially urban character and the relatively small and highly sophisticated circle of redders to whom his poetry was intended to appeal. for them his mythological allusions, uhich are frigid and indeed barely intelligible to the modern reader, mould be immediately moving and evocative. Books ii and iii, which were published probably c. 25 and *c.* 22 B.C. respectively, are of somewhat more varied composition than book i. The poet's love for Cynthia still dominates them. but his tone is more declamatory and less personal, and other themes are heard.

Book iv (c. 16 B.C.) offers a remarkable contrast. Propertius had indeed already announced, at the beginning of book iii. that he aspired to follow in the footsteps of Callimachus and Philetas, but there he had been referring only to formal and stylistic obligations, not to subject matter; whereas now (iv. 1, 61–70) he proposed, as the Roman Callimachus. to deal with the history and antiquities of Rome in the manner of the Aetia. In fact such themes. which were taken up later by Ovid in the *Fasti,* only occupy five of the poems in the book The rest, a varied collection, include the poem (3) which seems to have given Ovid the idea for his *Heroides;* a delightfully humorous description of Cynthia's surprising Propertius in the act of being unfaithful to her (8); and the eulogy of the dead Cornelia, which some have thought to be his finest work (11).

The writings of Propertius are noted for their difficulty and their disorder. The workmanship is unequal, curtness alternating with redundancy, and carelessness with elaboration. A desultory sequence of ideas, an excessive vagueness and indirectness of expression, a peculiar and abnormal latinity. a constant tendency to exaggeration and an immoderate indulgence in learned and literary allusions — all these are obstacles lying in the way of a study of Propertius. But those who surmount them will find their trouble well repaid. For power and range of imagination, for freshness and vividness of conception, for truth and originality of presentation, few Roman poets can compare with him when he is at his best; that is, when he is carried out of himself. when the discordant qualities of his genius are, so to say, fused together by the spark of immediate inspiration. His vanity and egotism are redeemed by his fancy and his humour.

Two of the lasting merits of Propertius seem to have impressed the ancients themselves. The first they called *blanditia,* a vague but expressive word by which they meant softness of outline, warmth of colouring, a fine and almost voluptuous feeling for beauty of every kind and a pleading and melancholy tenderness; this is most obvious in his descriptive passages and in his portrayal of emotion. His second and even more remarkable quality is poetic facundia, or command of striking and appropriate language. Not only is his vocabulary extensive but his employment of it is extraordinarily bold and unconventional: poetic and colloquial latinity alternate abruptly, and in his quest for the striking expression he frequently seems to strain the language to breaking point.

Propertius's handling of the elegiac couplet, and particularly of its second line. deserves especial recognition. It is vigorous, varied and even picturesque. In the matter of the rhythms, caesuras and elisions which it allows, the metrical treatment is much more severe than that of Catullus, but noticeably freer than that of Ovid, to whose stricter usage, however, Propertius increasingly tended (particularly in his preference for a disyllabic word at the end of the pentameter). An elaborate symmetry is observable in the construction of many of his elegies, and this has tempted critics to divide a number of them into strophes.

Influence. — As Propertius had borrowed from his predecessors, so his successors. Ovid above all, borrowed from him; and *graffiti* on the walls of Pompeii attest his popularity in the 1st century A.D. In the middle ages he was virtually forgotten; and since the Renaissance he has been studied by professional scholars more than he has been enjoyed by the general public. To the modern reader, acquainted with the psychological discoveries of the 20th century. the self-revelations of his passionate, fitful, brooding spirit are of peculiar interest.

PROPHET (προφήτης), a Greek word used in the Greek Old Testament to translate the Hebrew *Nābī* נביא and consequently adopted into other European languages. In classical Greek it denoted one who, uttering or interpreting an oracle, was believed to speak not his own thoughts but a revelation "from without"; *cf.* the description of Cassandra (Agant.) and the Prophet of Apollo (Eztmen.), by Aeschylus; of the blind seer, Teiresias, by Sophocles (Oed. Tyr.), and by Euripides (Bacchae); of the Cumaean Sibyl, by Virgil (Aen vi.); and note Plato, *Timaeus* 71 b., where be argues that persons who seek to give rational meaning to oracles "are not to be called prophets at all," but only those who speak in ecstasy. At the Delphic Oracle, however, not the frantic priestess, the Pythia, was designated "prophet," but the Guardians of the Shrine who ostensibly shaped her frenzied ejaculations into comprehensible replies. Etymologically προφήτης denoted "forth-telling," not "fore-telling"; but since προ could mean "before" in time, and since prophecies constantly dealt with future events and foreknowledge is not deemed to occur in conditions of normal consciousness, the notion that prediction and ecstasy are the essential elements in prophecy was an easy growth. Thus in the Hellenic period Philo of Alexandria looked on divination and oracular interpretation as imposture, but had high regard for the ecstatic who "speaks nothing of his own." Προφήτης was the best word available in Greek, for rendering the Hebrew *Nābī* (it was preferable to μάντις), but the Hellenistic view of prophecy as ecstatic prediction obscured for centuries the wealth of religious interest in the Hebrew prophets. Why προφήτης was used to translate *hm-ntr,* the title of certain Egyptian priests, is unascertained.

HEBREW PROPHECY

The Hebrew noun *Nābī* ("Prophet," *pl. Nebi'im)* is obscure in origin. Derivations implying intense excitement (נבע "to bubble up"; נבע Assyr., "to fall in transports") are etymologically improbable. The verbal form (an intensive) used in Hebrew often denotes frenzy or even lunacy, but this may reflect merely one aspect of prophetic development, and the fact that it is an intensive stem may imply simply that it is a loan-word in Hebrew. Conceivably it is not Semitic at all — there are Hittite possibilities. The likeliest Semitic connections are Arab. naba'a "to announce" (conjug. ii.); Bab.-Assyr. *nabû* "to name" (cf. the god, Nebo, Is. 1 1) *Nābī,* like προφήτης, may thus in origin be a colourless term: "One who utters a god-given message."

The Fanatical Prophets. — From a trustworthy narrative in I Sam. x. we learn that bands of prophets (*Nebī'īm*), devotees of the national deity, Jehovah (Yahweh), existed c. 1000 B.C. at Hebrew localities (Gibeah, Ramah). Stimulated by rhythmic music, dancing and chanting, they wrought themselves into ecstasies when their frenzied behaviour and abnormal physical power exercised hypnotic effect over onlookers (I. Sam. x. 5–13), and, as it seemed to testify the might of the god whose spirit possessed them, encouraged popular trust in Jehovah and resistance to the Philistines. Since there is no earlier reference to collective prophesying in Hebrew history (Nu. xi. 25 sqq. cannot be regarded as of the Mosaic age), probably it was a feature of Palestinian-Syrian religion, first evoked in Israel in Samuel's time. There is no direct evidence for Wellhausen's assertion that "among the Canaanites such Nebi'im had long been familiar" but the indirect evidence is impressive. An Egyptian record (c. 1100 B.C.) relates how an envoy, Wenamon, secured a hearing when a youth in attendance on a Phoenician prince prophesied ecstatically in Wenamon's favour. Very instructive is the famous passage in I. Kings xviii. 19 sqq. concerning the 850 prophets of the (Phoenician?) Baal and of the Asherah, maintained by Queen Jezebel. At a much later period the orgiastic rites celebrated by devotees in honour of certain ostensibly Greek deities (Apollo, Dionysos) prove to have connections with the Baal worship of Syria and Phoenicia (so T. H. Robinson). When parallel phenomena are still exhibited by the dervish fraternities in Islam, it seems probable that this form of religious excitement was peculiarly congenial to the peoples of Western Asia Minor, and may well have been of immemorial antiquity in Palestine.

Certain it is that fanatical prophets became a feature of Israelitish society. They are mentioned in connection with many towns of special sanctity and importance, *e.g.,* Bethel, Jericho, Samaria. Possibly they had some organization (the phrase "schools of the prophets" has no warrant), and were supported by popular piety or by kings anxious to obtain inspired counsel in perilous moments. Along with the priests and the wise men, they were esteemed one of the three indispensable sources for the guidance of the State (Jer. xviii. 18). Even in the post-exilic period they lingered on, distinctive by their rough mantle and leathern girdle, mouthing out oracles for the superstitious (cf. the χρησμολόγος in Aristophanes, Birds, 959 *sqq.*)—so great a public nuisance that father and mother are exhorted to slay the son turned "prophet" (Zech. xiii. 3). The causes of degeneracy can be discerned. Thanks to Eastern respect for the psychologically abnormal, the calling afforded a livelihood and might attract impostors, for it was easy to share in, or simulate, ecstasy, and declare "Thus saith Jehovah." The violent emotions were dangerous to the moral stability of even the honest Nᵉbi'im, and if simpler means of inducing ecstasy failed, the temptation to use noxious drugs was great.

The fanatical prophets, it may be concluded, manifested a real patriotism that helped to establish the State during the Philistine and the Syrian conflicts, but contributed nothing to the discernment of those dynamic religious beliefs which, as the power of Assyria and Babylon rose and engulfed .the petty monarchies of Israel and Judah, alone made possible the astounding survival of the Jewish nation.

The Seer.—But the word *Nābî* acquired a wider connotation. Later than the age of Samuel it came to be applied to persons who in earlier times would have been called Seers (*Rō'eh*, "Visionary"; or *Hōzeh*, "Gazer": I Sam. ix. 9). The Seer, ubiquitous in antiquity and ranging in dignity from the itinerant soothsayer to the guardian of some famous sanctuary, was credited with power, through interpretation of omens or (more impressively) through trance-visions, to gain knowledge from a spiritual being inaccessible to ordinary men: he was, as others were not, a "man of God." Balaam (Nu. xxii.–xxiv.) is typical: "essentially an Arab *Kāhin* or seer of that early type which combined the priest's offices of ritual and sacrifice, the diviner's reliance on omens and lots, and the prophet's experience of ecstasy and dreams" (G. A. Smith). The possibilities in the calling for good and evil are obvious. Affinities with the baser forms of divination—wizardry, necromancy, etc.—were close, and degenerate seers became only too numerous in Israel (Is. ii. 6, Mic. iii. 7), notwithstanding a strong tradition that such arts were peculiarly abhorrent to the God of Israel (I Sam. xxviii. 3, sqq. Ex. xxii. 18, Is. viii. 19). But the famous seers created the expectation of individuals in mysterious contact with God, "standing in his counsel," "knowing his secret," whose words should therefore have absolute authority in hours of crisis. Much more than the Nᵉbi'im with their collective "inspiration," the seer is of the lineage of the great prophets. Yet a distinction may be drawn. The ordinary seer made his powers his profession and livelihood (Am. vii. 12), and his functioning was habitually passive: he waited to be consulted. The great prophets were men of diverse callings, driven by an irresistible constraint actively to declare to Israel the word of its God. Thus to his contemporaries Samuel was not one of the Nᵉbi'im but the Priest-Seer of Ramah, whom a Saul could consult about strayed animals. Later generations rightly accounted him a prophet of the great type because of his initiative in rousing the people against the Philistines, in creating a monarchy, and later in rejecting Saul for David.

The Higher Prophecy.—But all the seers and prophets of antiquity would have but infinitesimal interest, were it not for the appearance in Israel of certain individuals of amazing spiritual insight, whom we, like their contemporaries, for lack of a better word must call "prophets." Their work and words endow Prophecy with almost inexhaustible importance for religion and for social organization. The diversity of the occupations and circles to which these higher prophets belonged is significant. A few, especially in the earlier period, pertained to the professional prophetic class: Samuel was a famous seer, Gad and Nathan official prophets of David's court, Micaiah one of the recognized Nᵉbi'im (I Kings xxii.—a passage which should be studied). But Elisha was a prosperous farmer: Amos a shepherd of Judaea, Isaiah a citizen of Jerusalem. Micah a Judaean villager. Jeremiah a youth of ancient priestly family. Ezekiel a priest of the Temple. The unifying characteristic is that to each came an overmastering conviction that, temporarily or permanently, he must forsake his way of life and declare what God would say to His people. Their prophesying was the constraint of a vocation, not the pursuit of a profession. When their teaching is coordinated certain principles they held in common can be analysed (*see* articles on the several prophetical Books; BIBLE: Old *Testament*, etc.) with results sufficiently impressive. But such surveys are meagre and mechanical: what counts is the stress of circumstance from which the great ideas were won, and the heroic application of beliefs to events. Knowledge of Hebrew prophecy is knowledge of the lives of glorious personalities; only when name after name of the prophets calls up the memory of lonely insight into truth, of unbreakable loyalty to duty, maintained through scorn and hatred and despite despair, can its splendour be realized.

Historical Development.—Complex as are the Pentateuchal narratives concerning Moses, it seems certain that an influential section of the mixed population under the Hebrew monarchies held a tradition that a great leader of prophetic character (yet not an ordinary seer, Nu. xii. 6–8; but such as Samuel had been, a man whom a Hosea or Jeremiah could call a Prophet, Ho. xii. 13, Jer. xv. 1) had led their ancestors out of Egypt to the independence of the desert, and had fired them with such confidence in the God Jehovah as had given them the unity necessary for a successful assault on Canaan. However dimly recalled, and by however few, the tradition of Moses, it may be held, preserved potent ideas: that Jehovah required a standard of morality that differentiated Him from other gods, and that in Moses himself—remembered as a life of splendid patience and mercy, of unswerving integrity and awe-inspiring intimacy with the invisible God—there had been seen a true servant of Jehovah. Subsequently in Canaan the leadership of Samuel not only established the national existence, but created in the popular consciousness the sense that their kingdom was truly, and not nominally, a theocracy, where kings must heed the word spoken by God's prophets to an extent startling in the ancient East (I. Kings xxi. 7). The vigilance of prophetic censorship over the dynasty was notably displayed against David (by Gad and Nathan), against Solomon (by Ahijah), against Rehoboam (by Shemaiah); and momentously in Elijah's adamantine opposition to Ahab and Jezebel, whereby the alliance with Phoenicia was broken and Israel Left to face unsupported the impending attack by Damascus.

The deep motives in the higher prophecy now became apparent. Not by political wisdom was Elijah actuated, but solely by an imperious religious instinct which swept aside all other considerations in the assertion that Jehovah demands an absolutely exclusive worship, and that He champions the rights of the humblest against even the king. This principle holds good throughout. Attempts (cf. Winckler) to explain the actions and attitude (*e.g.*) of Isaiah or Jeremiah primarily by political foresight or predilections can be shown in detail to be misconceived. Prophecy had created the nation, and wished to sustain it; not, however, in the interests of the nation, but in the interests of its God. The important account of Elijah's flight to Horeb, I. Kings xix. (taken in conjunction with the sequel: Elijah's sense of a commission to anoint Jehu king over Israel, and Hazael over Syria, followed by the achievement of those ends by Elisha, his disciple, and by high-minded prophets) shows that the parable read by Elijah in the quiet of the enduring mountain, following the storm, was not that the ways of God are gentleness alone, but on the contrary that the prophet's resolve to overthrow the house of Ahab must be pursued to its bitter end through revolution in Israel and war with Syria. The nation must pass through the tumult: thereafter the unalterable good purpose of its God would be apparent. In face of the grim realities of evil true religion must send first not peace but a sword.

The Golden Age.—*A* century later (*c*. 7jo B.C.) the Golden Age of Hebrew prophecy, wherein the universal aspects of religious truth were perceived as the real significance of Israel's national faith in Jehovah, began with the oracles of Amos and Hosea in Northern Israel, to be continued in Judah, especially by Isaiah, Micah and Jeremiah. For Amos there is but one God of the whole earth, controller of other nations as well as Israel, whose favour everywhere is determined solely by such concern for moral conduct that not even the wrongs of a slave go unheeded by Him. Amos is styled the "Prophet of the Justice of God," but the phrase is wholly inadequate. Positive goodness, forbearance, mercy, kindness are the inexorable divine demand. Between Jehovah and Israel a special relation exists; but the implication is not (as the people imagine) favouritism, but responsibility: "to whom much is given, of them shall much be required" (Am. iii. 2). Faced by the iniquities of their times, earlier prophets had assailed the dynasty at whatever risk to the national fortunes; but Amos, appalled by corruptions that rotted society from top to bottom, uttered logically a judgment almost incomprehensible to the ancient mind—God will bring overwhelming ruin upon the nation itself (Am. vi.–ix. passim). Lastly, Amos marks a new era for religion by his special declaration that the immemorial forms of worship—sacrifices, fasts and feasts—are sheer futility: God is to be sought not through material offerings, but spiritually in upright and generous conduct (Am. v. 5, 14, 21–24). Here is the enunciation practically, if not also theoretically, of ethical monotheism. The profundity of these beliefs, which thenceforth became the gospel of the higher prophets, needs no emphasising. Not unjustly Amos has been called the forerunner of Kant.

To Hosea love seemed fundamental in the attitude of God to Israel. Deeper than the necessity for moral retribution lay the divine love. It has been observed that Amos and Hosea significantly complement one another; they "form a pair—law and love" (S. A. Cook).

Taught, it would seem, by some poignant personal experience, Hosea agonized with the dilemma: God must shatter the sinful nation, yet to do so would seem to end his gracious purpose in defeat (Ho. xi. 8, 9). What if the disaster, which is sure, be after all a means to an end—πάθει μάθος? Out of the ashes of Retribution, Hope must rise (Ho. ii. 15). Far more deeply than Amos, Hosea probed the problem of sin. The cultus was not merely futile; it was a prime source of iniquity, and must be abolished. He pities the masses; they sin indeed, but it is for lack of knowledge (Ho. ii, 8). Thus was prophecy released from pessimism. However near and overwhelming the "day of the Lord" in judgment, the prophet must exhort men to penitence and belief in an ultimate divine salvation.

The view (Gressmann. H. Gunkel) that Amos and his successors inherited a cut-and-dry eschatological expectation of woe followed by bliss—whether derived from native Israelite sources (Sellin) or influenced by Egyptian (Ed. Meyer) or Babylonian literature—rests on inadequate or misinterpreted evidence. The message of doom announced by Amos was startling to his hearers, and it would seem that the higher prophets' anticipation of some impending judgment catastrophic yet congruous with an undefeated divine purpose was radically the unaided product of their own reflection on the righteousness, power and goodness of God. In Hosea and Isaiah the element of hope beyond catastrophe is prominent. Whether it was conceived vaguely. or more definitely (Messianic) depends on the dubious authenticity of certain passages (see REVELATION. BOOK OF: MESSIAH).

For the achievement of an order of perfect righteousness apocalyptic cataclysm is, in reality, irrelevant; since love cannot be compelled. In their passionate pleading for reform the prophets mere feeling their way to a deeper comprehension, which at last was attained when Jeremiah based his hope of a divine consummation simply on faith in God's effecting the moral regeneration of the human heart (Jer. xxxi, 31–34).

Isaiah and Jeremiah.—The task which lay before the great prophets of Judah (c. 740–586 B.C.)—who, in contrast to the facile optimism of the ordinary prophets "healing lightly the hurt of the daughter of Zion," continued convinced that the ruin of the state was at hand—was to discover how faith in Jehovah could survive the political destruction. In effecting this infinitely difficult task it was their sublime achievement "to liberate the eternal truths of religion from their temporary national embodiment. and disclose their true foundation in the immutable character of God and the essential nature of Man" (Skinner).

To Isaiah is due the conception of an Israel within Israel, a believing nucleus; a "Church of God." Convinced that he knew the mind and power of the living God ("Mine eyes have seen the King, the Lord of Hosts," Is. vi, 5), he reasserted on a higher level the earlier prophetic claim to control the national policy. Thorough social reform must accompany quiet trust in God, and in Him alone, for the fate of the nation (*cf.* Is. xxx, 15). Assyria is resistless, not in virtue of its vaunted might but because it is the weapon in Yahweh's hand against his sinful people (Is. x.). Whatever sufferings it inflicts in invading Judah will be the discipline of divine wisdom, and will leave behind a purified remnant of the faithful in Zion, through whom God's purpose shall be fulfilled (*cf.* Is. x, 20–23, xxviii, 16). Rejected by king and people, apparently he gave substance to his hopes by seeking disciples who accepted his principles (Is. viii, 16). At the crisis of the Assyrian invasion (701 B.C.?), he foretold the inviolability of Zion and this momentary form of his teaching was preserved in popular memory superstitiously apart from its spirit and the moral conditions on which his doctrine of Faith (Trust) rested (*cf.* Jer. vii, 1–15).

"Prophecy had already taught its truths, its last effort was to reveal itself in a life"—the life of Jeremiah. Living through the dreadful years mhich saw the two successful sieges of Jerusalem by the Babylonian armies, ending in the destruction of the city and temple and the deportation of its chief inhabitants, Jeremiah found himself forced either to utter unrelieved predictions of ruin to a people distracted alternately with panic and delusive relief, or, being silent, to deny the conviction of inspired knowledge that burned like a fire in his bones. The task entailed for him desperate loneliness, hatred and persecution—sufficient torment to a man of shrinking and sensitive temperament. But further he was tortured at times by doubt of his inspiration. Was he but self-deceived or even deceived of God? Were the confident prophets of peace right? And if the nation perished, how could the worship of Jehovah survive? "Hitherto there had been nations with their religions, but there never had been in the world a religion without a nation to act as its embodiment" (A. C. Welch). Out of the agony of his perplexity, preserved in some infinitely moving passages (Jer. xv, 10–18, xviii, 9, 10, 14–18, xx. 7–18) came the solution: recognition of how wonderful mas the fact of the relation between his conscious self and the Divine Being he longed to serve. In his ultimate peace in God and victory over "fears without and fightings within," me mark the beginning of the modern view of religious faith. Whatever the function of the nations in God's sight, no conception of a moral God is credible unless the unit of divine interest be the human personality.

"Jeremiah had discovered that, wheresoever men live, they may find God, if in humility they do justice and love mercy. So he wrote (xxix, 4–14) to the exiles in Babylonia to live there that life of goodness which the prophets had seen to be the worship God desires: a momentous letter, for in the acceptance of his belief lay the continuance of the Jewish race, and the future of religion "The spirit of Jeremiah, mhich breathed out on his people after his death, bore fruit in an experience of fellowship with God which satisfied the deepest aspirations of the human soul" (Skinner).

It was now conceivable that religion might survive the state. The last act of the higher prophecy was to give effect to the possibility. Through the constructive idealism of Ezekiel, and the magnificent, monotheistic, oracles preserved in Is. xl–lv, and no less through the courage and insight of Haggai and Zechariah, whose exhortations effected the rebuilding of the temple in Jerusalem (520 B.C.) and thus set religion in the iorefront of the renascent community's life. the Jews—sole link between the ancient Semitic empires and the new era of Persian and Greek domination—began both to preserve their identity in exilic settlements, and in Palestine to revive as a people increasingly conscious that it existed through, and for, its distinctive faith.

The Achievement of Prophecy.—Tine prophets were thus the saviours of their people. But their achievement should be realized in a wider setting. In their declaration of monotheistic belief and social idealism the world received an interpretation of human life applicable to every people and every age.

Ethical Monotheism.—For intelligent men they shattered for ever the mental and moral dangers of polydaemonism and polytheism, proclaiming instead the reality of one only God, to be conceived as the infinitude of moral perfection. If modern terminology is permissible, they held both the transcendence and the immanence of God, and whatever the philosophical obscurities, this doctrine of God, as not less than "personal" in His relation to us, has been the succour of the human spirit, and the source of high and generous virtue for western civilization. The precise stage at which monolatry (God as the only Being his people must worship, but one among other gods) rose into the pure monotheism patent in II Isaiah—whether it goes back to Amos, to Elijah, to Moses—cannot be determined; for who shall measure genius? Perhaps the question is wrongly put. In antiquity no one ceased to believe in the existence of many spiritual beings (*cf.* Eph, vi, 12), and practical monotheism was achieved whenever it was felt that there is but one creative Spirit, alone meriting worship, other "gods" being wrong conceptions of God as He truly is, or lesser Spirits who beguile men's worship, and their images assuredly "non-entities," the works of men's hands.

The *Worth* of the Individual.—The prophets discovered the immeasureable worth of human personality. It may be that not until Jeremiah did the significance of the individual's aspiration towards God become vividly apparent; but his experience was creative. and thereafter, aided by Ezekiel's teaching concerning individual responsibility, the instincts of personal piety were liberated to reach out, even through the problem of death, into deeper confidence in Man's worth to God. But this religion of the individual, the product of Prophecy's fundamental thinking and genius for ultimate values, was in no wise individualistic. The heart of prophetic doctrine had been insistence that the mill of God is to create a world-order of perfect justice, and that, so long as the moral obligations of each and all go unhonoured, and the lowliest is denied mercy and kindness, there shall be no peace ior Man. To the prophets thereiore we owe that inestimable incentive ior good, the idea of the "Kingdom oi God" as the goal of social order.

Worship.—"In primitive life," wrote Robertson Smith, "all spiritual and ethical ideas are still wrapped in the husk of a material embodiment. To free the spiritual truth from the husk was the great task that lay before the-ancient religions . . . but none of the ritual systems of antiquity mas able by natural development to shake itself free from the congenital defect inherent in every attempt to embody spiritual truth in material forms. A ritual system must always remain materialistic, even if its materialism is disguised under the cloak of mysticism." (Religion *of* the Semites, ed. by S. A. Cook, mhose note, p. 676, should be studied.) The prophets' criticism of worship was revolutionary, but fundamental and constructive, because they saw with absolute lucidity that true worship is a relation of personality, thereiore spiritually, and not materially, determined. The human spirit can so use, or regard, material objects that (with vigilance) they may be symbolically or aesthetically helpful to the communion of God and man; but the material must never under any circumstances be treated as in itseli an indispensable aid, or barrier, to the reception of divine influence by man. To suppose so is fatally to misapprehend the essential nature of a personal relationship. The prophets were clear: "God's iavour is to br iound by man's becoming, like Himself, just and merciful . . . Not gifts hut fellowship, and the way to fellowship lay not through the sacrificial system re-interpreted, but through conduct: not giits but justice, not sacrifice but mercy" (G. Buchanan Gray, Sacrifice, p. 44).

Privilege—The prophets did not abandon the old idea of Israel as a nation privileged of God; but they transfigured it by the contention that privilege is responsibility, election a call to service. And prophecy itseli culminated in the vocation of Jeremiah to a life of sorrow and suffering, heroically accepted ior a nation that hated him; and secondly, in the Servant-Songs of II Isaiah (see ISAIAH) where the iunction of Israel is conceived as a selj-sacrificial consecration, through unparalleled trials, for the redemption of mankind.

Knowledge of God.—There were many prophets in Israel. How came it that the few advanced toward a rational faith, and the many—equally convinced that their "Word" was from the Lord—failed? To whom, and why, is revelation given? Here again Jeremiah is illuminating. No outward criteria, he felt, avail to discern the true from the ialse prophets. Ultimately he saw that they mere not sensitive, as he was, to the moral obliquity around them, or alive to the evil in their own heart; and he rested at last on the iaith that if he surrendered himself absolutely to God's service, accepting whatever loneliness, pains or even death it might entail, God would speak truly through him (Jer. xv. 19). But this attitude had been the basic fact regarding all the great prophets; diverse in many ways, they were men of absolute sincerity and self-surrender. The example of their character is the last and greatest gift of the prophets to mankind, ior it is the clue to sound religious experience everywhere: "the pure in heart shall see God."

The Prophetic Consciousness.—Until as late as the 17th century A.D., interest in the prophetic writings mas almost exclusively concentrated on the predictive element.

As to this aspect, it should be noted that there are indeed instances oi fulfilled presentiments (*e.g.*, Ez. xxsiii, 21, 22), and close correspondences of events with prophetic anticipations: but the prophets are wronged when, as is still sometimes maintained, the validity of their inspiration is ielt to depend crucially on fulfilment of predictions, instead of broadly on the rightness of their interpretation oi Life as ethical duty, dependent on the reality of the living God. The Suffering Servant anticipates Jesus Christ because the prophet was inspired by the vision of a life of absolute self-sacrifice, and Jesus accepted the conditions of that life and endured its issues. After the Reformation recognition of the poetical form oi the prophetic literature led to the necessary analysis of the Books bearing the prophets' names. Criticism in the 19th century was marked by enthusiasm for the prophets as preachers of social righteousness; hut present research, psychological and historical, reveals them primarily as men of religious genius, who must be studied in intimate connection with their eastern environment. In modern times it is urged (especially G. Holscher) that the inner experiences, and outward behaviour. of the great prophets were closely akin to the ecstasies of the early Nᵉbi'im. Certainly the subconscious is a highly important consideration in studying Hebrew prophecy, but the theory has been pushed to extremes and is sometimes maintained by grotesque forcing of the evidence. There ought to be more careful discrimination of terms. and "ecstasy" reserved for conditions in which the subject has lost ali control oi mind and body. Stress, inducing at times trance, with audition and vision, is exemplified in the great prophets (especially the "Call" experiences, *cf.* Is. vi); but to argue that these men virtually never ielt conviction break on them at any less intense level of the infinite gradations of emotion, never saw an illuminating parable in nature, never employed a symbolic action, unless in a state of uncontrolled ecstasy, is to go too far. There are indications that they distrusted increasingly the iervours oi their opponents (so A. B. Davidson). Whatever resemblances they had to the ordinary prophets, it is the profound differences that will repay study. The extreme forms of the theory are ruled out by the grand consistency of the great prophets: the coherence of their teaching is the supreme psychological fact; and either the oracles me possess are the record of passionate but conscious reflection, or in these men conditions existed which caused the subconscious to produce the rational and the relevant to an unparalleled extent. In any event, an Amos or an Isaiah is infinitely better understood by the analogy of Paul, with his vision on the Damascus road and his enthusiastic yet controlled temperament, than of the ecstatic seer or frenzied Nᵉbi'im. It is true that the Hebrew prophet says, never "I saw," "I know," but "The Lord shewed me," "Thus saith Jehovah." Explanation is found in the psychological ideas which he shared with his contemporaries. H. Wheeler Robinson rightly emphasizes that Man was regarded as intimately dependent on God in his psychical as well as his physical properties; his "breath-soul" open to the invasion of spirits divine and demonic. Hence not only in the trance-experience, but under any intense emotional stress the Hebrew felt that he had "become another man." the "spirit of the Lord had laid hold upon him"; so that it is easy to realize sympathetically why the prophet mas convinced that he spake never of himself hut as "the messenger of Him that sent me."

The Prophetic Succession.—Hebrew prophecy possesses the unity of a single movement, having origin, development and climax. It ended not in exhaustion, but in the liberation of energy, manifested in personal piety, in efforts to systematize the great ideas (Judaism), and in inextinguishable Hope of a divine purpose in the world (Apocalypse). Hebrew Prophecy recurs not, but "true" prophets—called by many names. Saint. Preacher, Reicrmer, Scholar—have not ceased to be; ior it was part of the work of prophecy to reveal that "all the Lord's people should be prophets." and that the prophet is he for whom God is the living God. Whenever discernment of truth in new aspects is Imperative, the interpreting prophetic personality is prominent, and is ever the vitalizing element in religion. Amidst the turmoil at the close of the last century B.C. and the first A.D., it is easy to see why individuals appeared who were manifestly prophetic in type—John the Baptist, Jesus Christ (though the term be inadequate for Him), Paul. Johanan ben Zakkai.

PROPHETS IN THE CHRISTIAN CHURCH

In the nascent organization of the Christian communities (Acts xi, 27, Eph. iv, 11, 1 Cor. xii, 28) prophets are mentioned, ranking next to the Apostles. Sometimes itinerant. sometimes settled in one locality. they were the evangelists of the early Church, credited with a direct spiritual inspiration (χάρισμα) for enlightenment and edification. Men can be appointed to an office; they cannot be appointed to prophecy. The conviction that in Christ all things were made new evoked minds sensitive to spiritual issues.

Therein the Christian prophets were in the true succession; but in all else how different irom the lonely Hebrew seers. The Christian prophets were expected to provide intelligible utterances (I Cor. xiv, 32), and were thus differentiated from the ecstatic "speaker in tongues," while they were also distinct from the permanent local officials—catechists, deacons, presbyters, bishops. From the valuable information in the *Didache* it appears that the high regard felt for them lasted fully a century; yet their position was always precarious. Sane enthusiasm might lapse into futile ecstasy (I Cor. xiv, 29–33). Hypocrites might simulate the gift—the *Didache* insists that the prophet is worthy of maintenance and respect only if his piety is indubitable and his conduct "worthy of the Lord." The prestige of the permanent officials increased in comparison with the occasional prophet, whose sole virtue seemed to be his edifying speech. But that gift might also be found among the regular ministers: and if so, how preierable! Lastly the zeal of the prophets might claim an authority over or make ascetic demands on the church which roused antagonism. At the end of the 2nd century the wild prophesying in the Montanist party (significantly oi Phrygian origin) hastened the end. Armed with the now-accepted Canon of Holy Scripture ("the law and the prophets until John"), the authorities ruled that "Ecstasy was of the devil not of God" and that "Prophets must not accept giits," and ere long they ceased as a distinctive class in the church's organization.

BIBLIOGRAPHY.—The literature on this subject is so extensive that only a selection of important, or recent, works can here he cited. PROPIOLIC ACID forms colourless crystals melting at 18° C. to a liquid that boils at 144° C. It is soluble in water and has an odour like that of acetic acid. It has the constitution of acetylenemonocarboxylic acid, $HC\vdots C.CO_2H$, and is of interest as being the simplest acetylenic acid. It is obtained by the following reactions: succinic acid is brominated, and dibromosuccinic acid by the action of alcoholic potassium hydroxide yields acetylenedicarboxylic acid, $CO_2H.C\vdots C.CO_2H$. This acid or its monopotassium salt on boiling with water loses carbon dioxide, and propiolic acid is produced. Furthermore, carbon dioxide reacts with monosodium acetylide, C_2HNa, under pressure to give the sodium salt of propiolic acid. On exposure to light, propiolic acid polymerizes into trimesic acid (benzene-1:3:5-tricarboxylic acid). (G. W. Wd.)

PROPORTIONAL REPRESENTATION, an electoral arrangement designed to secure that the representative assembly shall be an exact reflection, a "snapshot," of the voting strength of parties among the electorate. To its proponents the case for proportional representation (P.R.) is fundamentally the case for representative government; every trace of opinion, be it ever so small, ought to be represented in the legislature as near as possible to its proportional mathematical claim.

Opponents of P.R. consider the system logical only if parliament is conceived, in the words of Edmund Burke, as "a Congress of ambassadors from different and hostile interests." If, on the other hand, parliament is "a deliberative assembly of one nation with one interest, that of the whole," the majority system is required. The latter introduces a process of integration, making it necessary for all parties to appeal to a cross section of the various groups of which a country consists. Thus, a common denominator is found for all of them.

P.R. owes its intellectual standing in continental Europe and Latin America mainly to Victor Considérant, and in the Anglo-Saxon countries to John Stuart Mill. Mill emphasized the need for adequate representation of minorities; Considérant felt that while final parliamentary decision required the rule of the majority, the earlier stage of parliamentary deliberation was well compatible with the introduction into a parliamentary body of a variety of groups by P.R. The appeal of these arguments has been widespread. The end of World War I left, among the countries generally accepted as democratic, only the Anglo-Saxon countries and France with the majority system.

In the case of both the majority system and of P.R. there are a number of variations. In Great Britain, the members of the commonwealth and the United States, the plurality system dominates; in a single-member district the candidate with the highest vote is declared elected even if he has secured less than 50% of the total. Imperial Germany used the system of runoff elections; if no candidate had an over-all majority in the first ballot, a second ballot decided between the two strongest competitors. In the France of the third republic a more liberal form of the second ballot was used, in which all candidates, even those who had not participated in the first ballot, could compete. The candidate with a plurality of the votes won, although coalitions between the rightist and leftist parties usually cut down the number of candidates and made attainment of an absolute majority likely. These coalitions were often connected with unsavoury intrigues. To obviate these difficulties, Australia adopted, for its house of commons, the alternative vote, which requires an absolute majority and where there is only one ballot, in which the voter instead of marking his choice with an "X," marks the candidates in the order of his preference (whence "preferential vote" system), 1, 2, 3, etc.; and then the returning officer eliminates the bottom candidates in turn, distributing among the top candidates the preferences marked on the eliminated ballots.

All varieties of majority voting deviating from the plurality system increase the chances of minor parties and have proved incompatible with a two-party system. P.R. attempts to do more than assure an absolute majority for the victorious candidate. It begins by creating large constituencies with a number of seats. In the English Proportional Representation society's suggested program, called the "single transferable vote," a constituency of at least 300,000 inhabitants was suggested and at least five seats. In the German system prevailing between 1919 and 1933, the constituencies averaged nearly 1,000,000 electors, and 15 or 16 representatives. The severalty of representatives made it possible for any well-knit minority with a quota of votes (*i.e.,* the lowest number required, in the circumstances) to get representation. Votes cast for a member were not to be lost to the party if he personally should fail, for they were transferred or accredited to other members of the party who held them to make up the quota. This can be done in a number of ways. The system advocated in England is that the voter shall be free to indicate his preference by numbers against the long list of candidates, the returning officer then distributing the surplus preferences of successful candidates and those with no chance among those who are designated by the preferences, until all the seats are filled by those with quotas. This system leaves the voter free of party dictation.

Other list systems permit the voter to mark a preference for one or several candidates; in some cases, such preferences may even be given to candidates of more than one party. The parties get the mathematical share of the seats to which their aggregate vote entitles them. In Germany each party got one representative for each 60,000 votes it secured, while fractions of 60,000 were added together for each party (within certain limits), and again for each such 60,000 the party was permitted to nominate an extra member.

The French system of P.R., adopted in 1945, was based on party lists, in the framework of the *département.* It was feared that this election law, which, because of the D'Hondt system, favoured large parties, would, if applied in the elections of 1951, have given the Gaullists and Communists a majority of the seats even with somewhat less than a majority of the votes. Therefore, it was provided that wherever a party or a coalition of parties secured the absolute majority of the votes in a constituency, it obtained all the seats, although for Paris and its suburbs, where the extremists were strong, a form of P.R. more favourable to the centrist parties than the D'Hondt system was used.

Germany used for the bundestag elections of 1949, as well as for a number of elections within the various Länder, a system which combined single-member constituencies with P.R. In each of the constituencies the candidate with a plurality of the votes was elected. Over-all proportionality between the votes cast for a party and the seats attributed to it was attained by distributing additional seats, usually 40% of the total, on a so-called "reserve list," to the parties which had obtained fewer seats than corresponded to their share of the votes.

The merits of P.R. lie, according to its supporters, in its equity. The demerits of the system as they operate in Europe are these: (1) The personal contact between member and constituency is reduced; in its place the party machine rules by deciding the order of candidates on the list and by requiring teamwork among candidates which results in the "star" man helping the mediocrities. (2) A premium is placed upon the use of mechanical devices to make electors go to the poll—this is a direct result of a large constituency. (3) Small parties are kept in existence, or encouraged to organize themselves, which seriously disturbs the process of parliamentary government where a compact and single-party majority in office faced by an opposition similarly constituted is essential to stability, vigour and responsibility of executive. Opponents of the system hold that in a number of countries, including Italy and Germany, the various factors making for the weakness of democracy would not have sufficed to make possible the victory of dictatorship had it not been for the dispersal and the demoralization of the prodemocratic forces by P.R.

P.R. has, in the form of the single transferable vote, also been used for a number of U.S. cities, most of which, however, later abandoned it. Adopted to facilitate the victory of reform groups over political machines, it was held to have led to the frustration of the voter who could not cope with its complexities, to the intensification of racial and alphabetical voting and (in particular in New York city) to the election of extremists. By 1952, only nine municipalities retained it, six of them in Massachusetts. The leading P.R. city is Cincinnati, O.

France took a step away from P.R. in the election law of 1951 and Italy in the election law for municipalities adopted during the same year; in 1952 the Greek government endorsed the majority system after the U.S. ambassador had, with the approval of the U.S. state department, expressed the view that P.R. led to a degree of instability which jeopardized the success of U.S. aid. The proponents of P.R. scored a success, however, when in 1950 the single transferable vote, also used in Ireland, was adopted for the Australian senate.

PROPOSITION. In scholastic and traditional logic, a proposition was understood as an expression in words having the meaning of an assertion. An example is Petrus Hispanus, *c.* 1245, "Propositio est oratio verum vel falsum significans indicando." Thus a proposition is not simply a declarative sentence, in the grammatical sense, but is such a sentence taken together with its meaning. Consequently propositions may be different though the sentences are the same (*e.g., I am hungry,* uttered by two different persons). And also, although this consequence is less emphasized by traditional writers, propositions are different when the sentences are different and even if the meaning is the same (*e.g.*, *Tempus fugit* and *Time flies*).

The usual scholastic term was the Latin *propositio*—first found in this meaning in the writings of Lucius Apuleius, *c.* 150, and Manlius Severinus Boethius. *c.* 500. However, *enuntiatio* (enunciation)—a term taken from Cicero—was also employed, and some of the scholastics used this as the general term, reserving *propositio* for some more special meaning.

This scholastic-traditional notion of a proposition is inconvenient or unsatisfactory in many contexts because of its dependence on the particular form of expression in words, or on a particular language. Hence the different notion of a mental proposition (*propositio mentalis*) came to be introduced, and also, chiefly later, that of a judgment (*iudicium*).

According to William of Ockham, and later scholastics who followed him, the mental proposition must be formed internally before a corresponding proposition in words is put forward. It is not of any language. Its parts are mental terms or concepts, which are analogous to the spoken or written terms and share with them all properties essential to the meaning. but not such purely grammatical properties as having a particular (grammatical) gender or belonging to a particular declension or conjugation.

The notion of a judgment. as the mental act of assent or dissent, has some mention in the writings of various scholastics. and was made an explicit part of the treatment of logic by Petrus Ramus and later by such logicians as Isaac Watts (*1725*) and Christian Wolff (*1728*). It was still later that the definition of a proposition as a "judgment expressed in words" became a commonplace.

Immanuel Kant. and many traditional logicians who have followed him, replace the consideration of propositions almost entirely by that of judgments. Thus Kant speaks usually, though not always. of an analytic or synthetic judgment (German, *Urtheil*) rather than proposition (German, *Satz*), of a categorical judgment, etc.

However, the mental proposition and the judgment have a psychological reference which may often be as unsatisfactory as the dependence on a particular language which is involved in the traditional notion of a proposition. For some purposes at least there is needed a more abstract notion. independent alike of any particular expression in words and of any particular psychological act of judgment or conception—not the particular declarative sentrnce, but the content of meaning which is common to the sentence and its translation into another language—not the particular judgment, but the objective content of the judgment, nhich is capable of being the common property of many. Such an abstract notion may be seen in the Stoic *Lekta* (*see* LOGIC, HISTORY OF) and the *complexe significabilia* of some 14th and 15th century scholastics, but these ideas fell into oblivion and were reintroduced in different terminology in modern times. By modern logicians the word "proposition" has come to be used for the abstract notion, and we shall therefore here distinguish between *proposition in the traditional sense* and *proposition in the abstract sense.*

Bernard Bolzano attributes the use of *propositio* for proposition in the abstract sense to G. W. von Leibniz in *Dialogus de Connexione inter Res et Verba*. This may be a misunderstanding. But this dialogue does set forth clearly one important ground of the need ior the abstract notion. An explicit distinction between the sentence and the proposition (in the abstract sense) which the sentence expresses is made by Bolzano in his *Wissenschaftslehre* of *1837*, where *Satz an sich* is used for the latter. Gottlob Frege in *1892* uses *Gedanke* for the sense of a declarative sentence, giving to this German word (as he explains) an objective, rather than its more natural subjective, meaning. *Proposition* is used in the abstract sense by Bertrand Russell in *The Principles of Mathematics* (1903), where Russell recognizes that Frege's *Gedanke* is approximately "what I have called an unasserted proposition," and in *Principia Mathematica* A. N. Whitehead and Russell speak of "what we call a 'proposition' (in the sense in which this is distinguished from the phrase expressing it)." Russell also uses *proposition* in the traditional sense; *e.g.* in *Introduction to Mathematical Philosophy* defining a proposition as "a form of words which expresses what is either true or false"; but more recent writers have generally followed him in the abstract usage.

See R. M. Eaton, *General Logic*, i, 3–5 (New York, 1931); Xlonzo Church, *Introduction to Mathematical Logic*, sec. 04 (Princeton, 1955). (Ao. C.)

PROPYLAEA, the name given to porches or gatehouses at the entrance of sacred or other enclosures in Greece; propylaea usually consisted, at their simplest, of a porch supported by columns both without and within the actual gate. The name is especially given to the great entrance hall of the Acropolis at Athens, which was begun in 437 B.C. by Pericles. Probably because of political difficulties and the outbreak of the Peloponnesian War, the building was never completed according to plan, but the portion that was built was among the chief glories of Athens and afforded a model to many subsequent imitators. The architect was Mnesicles; the material Pentelic marble, with Eleusinian blackstone for dados and other details.

The plan of the Propylaea consists of a large square hall, from which five steps lead up to a wall pierced by five gateways of graduated sizes, the central one giving passage to a road suitable for beasts or vehicles. On the inner side. facing the Acropolis, this mall is faced with a portico of six Doric columns. At the other end of the great hall is a similar portico facing outward; and between this and the doors the hall is divided into three aisles by ro s of Ionic columns. The western or outer front is flanked on each side by a projecting wing. with a row of three smaller Doric columns between antae at right angles to the main portico. The north wing is completed by a square chamber which served as a picture gallery, but the south wing contains no corresponding chamber, and its plan has evidently been curtailed; its front projected beyond its covered area, and it is finished in what mas evidently a provisional way on the side of the bastion before the little temple of Athena Nike.

From this and other indications W. Dorpfeld inferred that the original plan of Mnesicles was to complete the south wing on a plan symmetrical with that of the north wing, but opening by a portico on to the bastion to the west; and to add on the inner side of the Propylaea two great halls, faced by porticoes almost in a line with the main portico. but with smaller columns. This would have interfered with sacred objects such as the precinct of Artemis Brauronia and the altar of Nike. and the architect was probably forced to modify his plan even before work on the building stopped. The Propylaea were approached in Greek times by a zigzag path, terraced along the rock; this was superseded in Roman times by a broad flight of steps. In medieval times the Propylaea served as the palace of the dukes of Athens; they were much damaged by the explosion of a powder magazine in *1645*. The tower of Frankish or Turkish date that stood on the south wing was pulled down in *1874*.

The term is also applied to various monumental gateways of modern times, especially in Germany. Examples are: the propylaea at Munich (1862) and the Brandenburger Tor in Berlin (*1784*). *See* GREEK ARCHITECTURE.

See W. J. Anderson and R. P. Spiers, *The Architecture of Ancient Greece*, rev. by W. B. Dinsmoor, new ed. (1950); D. S. Robertson, *A Handbook of Greek and Roman Architecture*, 2nd ed., corrected (1943). (E. GR.; C. M. RN.)

PROPYL ALCOHOLS, two compounds of this name, with the same formula C_3H_7OH exist, and both come into prominence in connection with modern developments of industrial organic chemistry.

Normal propyl alcohol, $CH_3.CH_2.CH_2.OH$, is obtainable as a by-product in the synthesis of methyl alcohol (*q.v.*) by condensing carbon monoxide and hydrogen in presence of a zinc-chromite or zinc-cobalt-chromite catalyst at 400° C. under zoo atm. pressure. (*See* PRESSURE CHEMISTRY.) It is a colourless fragrant liquid boiling at 97.4° C. and miscible with water in all proportions. It cannot be separated from water by distillation since the two compounds form an azeotropic mixture. (*See* DISTILLATION.) n-Propyl alcohol occurs in fusel oil and may be prepared by any of the synthetic methods applicable to primary alcohols. (*See* ALCOHOL.)

Isopropyl alcohol, $(CH_3)_2CH.OH$, is manufactured on an extensive scale from propylene, $CH_3:CH:CH_2$, obtained by the cracking of petroleum. *(See* OLEFIN.) This olefin is absorbed in sulfuric acid. the liquid diluted with water and distilled. when isopropyl alcohol is obtained. It is a colourless. fragrant liquid boiling at 82.7° C. It is used as a solvent and as a reagent in organic chemical synthesis.

PROPYLON, in architecture, a monumental entrance gate; in Egypt two great piers with a flat lintel set before the front pylon of a temple In Greece a columned porch on both sides of a wall of doors gives entrance to a sanctuary or agora.

PROSCENIUM, originally, in the Greek theatre, the colonnade supporting a platform in front of the scene building (*σκηνή*, Latin *scena*). Scenery was set between the columns. In the modern theatre the word proscenium is used particularly in connection with the arch (proscenium arch) framing the stage.

PROSE, the plain speech of mankind, when written or composed without reference to the rules of verse. It has been usual to distinguish prose very definitely from poetry (*q.v.*). Pierre de Ronsard said that to him prose and poetry were "mortal enemies." But "poetry" is a more or less metaphysical term. which cannot be used without danger. For instance. an ill-inspired work in rhyme cannot be said to be poetry, and yet most certainly is not prose. On the other hand, a work of highly wrought nonmetrical writing is often called a prose-poem. This shows that the antithesis between prose and poetry is not complete. Prose, therefore, is best defined as comprising all forms of careful literary expression which are not metrically versified. and hence the definition from *prorsus* (direct or straight), the notion being that it is straight and plain, and is used for stating that which is true in reason or fact

Prose, however, is not everything that is loosely said. True, it is the result of conversation, but that conversation is not necessarily, nor often, prose. Prose is not the negation of all laws of speech; it rejects merely those which depend upon metre. What its laws are is not easy to say. But this is plain; as prose depends on the linking of successive sentences, the first requirement is that these sentences should be lucidly arranged. In prose, that the meaning should be given is the primal necessity. But as it is found that a dull, clumsy, monotonous arrangement of sentences is fatal to the attention of the listener or reader, it is needful that to plainness should be added various attractions and ornaments. The sentences must be built up in a manner which displays variety and flexibility. There should be a harmony, and even a rhythm, in the progress of style, care being taken that this rhythm and this harmony are not recognizably metrical. Again, the colour and form of adjectives, and their sufficient yet not excessive recurrence, is an important factor in the construction of prose. The omission of certain faults, too, is essential. In every language grammatical correctness is obligatory. Here we see a distinction between mere conversation, which is loose, fragmentary and often even ungrammatical; and prose, which is bound to weed away whatever is slovenly, and to watch closely lest merely colloquial expressions should slip in. What is required is a moderate and reasonable elevation without bombast or bathos. Not everything that is loosely said is prose, and the celebrated phrase of M. Jourdain is not exactly true, for all the loose phrases which M. Jourdain had used in his life, though they were certainly not verse, were not prose either. We must be content to say that prose is literary expression not subjected to any species of metrical law.

Greek. — The beginnings of Greek prose are very obscure. It is probable that they took the form of inscriptions, and gradually developed into historical and topographical records. We come down to something definite when we reach Hecataeus and Herodorus; and, although their writings have disappeared, we know enough to see that by the jth century B.C. the use of prose in its modern sense had been established. We even know the character of the style of Hecataeus, and we hear of its clearness, its grammatical purity, its individuality — qualities which have been valued ever since. These writers were succeeded by Hellanicus, who wrote many historical books now lost, and by Herodotus, whose noble storehouse of chronicle and legend is our earliest monument of European prose. When once non-metrical language could be used as by Herodotus, it was plain that all departments of human knowledge were open to it. But it is in Ionia and the Asiatic islands that we find it cultivated by philosophers and critics. The earliest of these masters of prose survive only in much later records of their opinions; in philosophy the actual writings of Thales, Anaximander, Pythagoras and Empedocles are lost, and it is likely that their cosmological rhapsodies were at least partly metrical. We come into clearer air when we cross to Attica: Thucydides' priceless work has most fortunately come down to us; and Xenophon continued it in the spirit of Thucydides, and carried Greek prose to a great height of easy distinction. But it is in philosophy that prose in Greece gains flexibility and variety, proving itself an unsurpassed vehicle for the finest human thought. The philosopher Plato is the greatest prose writer of Greece, and, in the view of many well qualified to judge, of the world. In his dialogues we see what splendour, what elasticity, what exactitude, this means of expression had in so short a time developed; how little there was for later prose-writers to add. The rhetoricians were even more highly admired by antiquity than the philosophers, and ancient, unlike modern, opinion would perhaps have set Demosthenes higher than Plato. In Aristotle we see the conscious art of prose-writing subordinated to the preservation and explanation of facts, and after Aristotle's day there is little to record in a hasty outline.

Latin. — The Romans obeyed the universal law by cultivating verse long before they essayed the writing of prose. The earliest historians of whom we have definite knowledge, Fabius Pictor and Cincius Alimentus, wrote in Greek. The earliest annalist who wrote in Latin was Hemina; the works of all these historians are lost. A great deal of primitive Roman prose was occupied with jurisprudence and political oratory. By universal consent the first master of Latin prose was Cato, the loss of whose chief works is to be deplored; we possess from his pen only a treatise on agriculture. In the next generation we are told that oratory was carried to the highest point by Marcus Xntonius and Licinius Crassus — "by a happy chance their styles were exactly complementary to one another." Unfortunately none but inconsiderable fragments survive to display their qualities. Happily, however, those qualities were combined in a man of genius, whose writings have come down to us; this is Cicero, whose prose exhibits the Latin language to no less advantage than Plato s does the Greek. From 70 to 60 B.C. Cicero's literary work lay mainly in the field of rhetoric; after his exile he was chiefly occupied with theoretical treatises. The beautiful essays of his old age comprise two little masterpieces, *De amicitia* and *De senectute* (45 B.C.). It is to the collection of the private letters of Cicero, published after his death by Atticus and Tiro, that we owe our intimate knowledge of the age in which he lived, and these have ever since been held models of epistolary prose. Of Cicero's greatest contemporary, Julius Caesar, much less has been preserved, and this is unfortunate because Roman critical opinion placed him among the very chief of prose-writers; but we retain his *Commentaries*. The prose of Sallust, who followed Caesar, is hard, brief and sententious. The writers who succeeded him neglected these qualities, and Latin prose became more diffuse and rhetorical. But it was wielded by one writer of the highest genius, Titus Livius, who enriched the tissue of Latin prose with ornament which hitherto had been confined to poetry; this enables him "to advance without flagging through the long and intricate narrative where a simpler diction must necessarily have grown monotonous" (Mackail). The periodic structure of Latin prose, which had been developed by Cicero, was carried even further by Livy. The style of Pollio, who wrote a *History of the Civil Laws*, was much admired, and the loss of this work must be deplored. A different species of prose, the *plebeius sermo*, or colloquial speech of 'the poor, is partly preserved in the fragments of a Neronian writer, Petronius Arbiter. Of the Latin prose-writers of the silver age, Seneca, Quintilian and Tacitus, nothing need here be said.

English. — The independence of English prose is a fact which rests on a firm basis. "The Code of Laws of King Ine" dates from the 8th century, and there are various other legal documents which may be hardly literature in themselves, but which are worded in a way that seems to denote the existence of a literary tradition. After the Danish invasion, Latin almost ceased to be known, and translations began to be required. In 887, Alfred wrote in English, with the help of scholars, his *Hand-Book;* this, probably the earliest specimen of finished English prose, is unhappily lost. His English version of the *Cura pastoralis* was probably completed in 890. Later still Alfred produced translations from Bede. Orosius, Boethius and other Latin authors, and, in 900, closing a translation from St. Augustine, we read "Here end the sayings of King Alfred." The prose of Alfred is simple and clear without pretension. After him the first name of eminence which we encounter is that of Aelfric, who, about 997, began to translate, or rather to paraphrase. certain portions of the Bible into a very finished English. A little later vigorous prose was put forth by Wulfstan, archbishop of Pork (d. 1023). At the Conquest, the progress of English prose was violently checked, and, as has been said, it "was just kept alive, but only like a man in catalepsy." The *Annals* of Winchester, Worcester and Peterborough were carried on in English until 1154. Except in a few remote monasteries, English ceased to be used, even for religious purposes, and the literature became exclusively Latin or French. We may perhaps say that modern English prose begins with the *Testament of Love* of Thomas Usk (*c.* 1388). To the same period belong *The Tale of Melibee* and *The Parson's Sermon* by Chaucer; the treatises of John of Trevisa, whose style in the *Polychronicon* has a good deal of vjgour; and the three versions of the *Travels* of Jean à Barbe, formerly attributed to "Sir John Mandeville." The composite text of these last-mentioned versions really forms the earliest specimen of purely secular prose which can be said to possess genuine literary value, but again the fact which has been ascertained that "Sir John Mandeville" was not an original English writer robs it of much of its interest

The anonymous compiler-translator can no longer be styled "the father of English prose." That name appears to belong to John Wyclif, who. in the course of his career as a controversialist, more and more completely abandoned Latin for English. The translation of the English Bible was begun by Nicholas Hereford. The completion of this work is usually attributed, but on insufficient grounds, to Wyclif himself A new version was almost immediately started by John Purvey, another Wyclifite, who completed it in 1388. We are still among translators, but towards the middle of the 15th century Englishmen began, somewhat timidly, to write original prose. Capgrave, an Augustinian friar, wrote a chronicle of English history down to 1417; Sir John Fortescue produced about 1475 a book on ***The Governance of England;*** and Reginald Pecock attacked the Lollards in his *Repressor of Over Much Blaming of the Clergy* (*c.* 1450). The prose of Pecock is sometimes strangely modern, and to know the ordinary English prose of the 1jth century it is more useful to turn to *The Paston Letters.* The introduction of printing into England is coeval with a sudden development of English prose, a marvellous example of which is to be seen in Caxton's edition of Malory's *Morte d'Arthur,* in which the capacities of the English language for melody and sweetness were for the first time displayed. Caxton himself, Lord Berners and Lord Rivers, added an element of literary merit to their useful translations.

With the Renaissance, *Richard* **Ill.,** whether by Sir Thomas More or by Cardinal Morton, was a work of considerable importance; *Utopia* (1516) was unfortunately composed in Latin, which still held its own as a dangerous rival to the vernacular. In his *Governour* (1531) Sir Thomas Elyot added moral philosophy to the range of subjects thought proper for English prose In the same year Tyndale began his version of the Bible, the story of which forms one of the most romantic episodes in the chronicles of literature; at Tyndale's death in 1536 the work was taken up by Coverdale. The *Sermons* of Latimer (1549) introduced new elements of humour and vigour. The earliest true biography was the *Life* of *Cardinal Wolsey,* by George Cavendish, written about 1557, but not printed until 1631. In the closing scenes of this memorable book, which describe what Cavendish had personally experienced, the perfection of easy English style is reached for the first time. The prose of the middle of the 16th century—as exemplified in Sir Thomas Wilson, Roger Ascham, and Sir John Cheke—is clear, unadorned and firm, these Englishmen holding themselves bound to resist the influences coming to them from Italy and Spain. Equal simplicity marked such writers as Foxe, Stow and Holinshed, who desired a straightforward prose in which to present their information. But Hoby and North introduced not a few exotic graces, and prepared the way for the innovations of Lyly in *Euphues* (1579). The extravagances of Lyly outdid those of his continental prototypes, and euphuism became a disturbing influence which, it may be, English prose has not, even yet, entirely thrown off. In spite of its popularity, it was opposed in its own day, not merely by the stately sobriety of Hooker, but by the sweetness of Sir Philip Sidney. Raleigh wrote an English prose perhaps more majestic than any which preceded it, but he revelled in length of sentence and ponderosity of phrase, so that the prestige of *The History of the World* on the whole delayed the emancipation of English prose. The direct influence of euphuism was seen for some time in the work of poets like Lodge and Greene, and divines like Andrewes; its indirect influence in the floweriness and violence of most prose down to the Restoration.

Donne had a sonorous majesty of style; and Burton could use English with humour and vivacity when he gave himself the chance In spite of the skill with which, during the civil wars and the Commonwealth, authors like Jeremy Taylor, Fuller and Milton manipulated prose, and in spite of the magnificence of Sir Thomas Browne, it was not until shortly before the Revolution that English prose reached its perfection. According to Dr. Johnson, Sir William Temple (1628–99) was the first writer who gave cadence to English prose. The new tendency was all in favour of brevity and crispness of shorter sentences and easier constructions. Not a little of the majesty of the earlier age was lost; but for practical purposes prose became a far more businesslike implement than it had hitherto been. The treatises of Halifax, or the sermons of South, mark the change. The power of English speech was first comprehended perhaps by Dryden, who combined dignity and even pomp of movement with an ease and laxity on occasion which gave variety to prose, and approximated it to ordinary speech. This then may be called the foundation of modern English prose, which has extended into no departments not recognized, at least in essence, by Bunyan, Dryden and Temple. The ensuing varieties have been mainly matters of style. In the 18th century, for instance, there was a constant alternation between a quiet, rather cold elegance and precision, which was called the Addisonian manner, and a swelling, latinized style, of which Johnson is the most famous exemplar. But as far as arrangement and syntax are concerned, it cannot be said that English prose has altered essentially since about 1680. It is, however, to be noted that in the course of the 19th century attempts were made to restore the beauty and variety of early 17th-century diction.

Icelandic.—The independent invention of prose by the Icelanders is one of the most singular phenomena in history. It resulted from the fact that story-telling was a recognized form of amusement in the isolated life of an Icelandic household. Something of the same kind had existed in Norway before the exodus, but it was in Iceland that it was reduced to an art. It is remarkable how suddenly the saga, as a composition, became a finished work. The deliberate composition of sagas began about the year 1030, and it is recorded that Ari Fródi (1067–1148) was the first man in Iceland who wrote down stories. Many of Ari's books are lost, but enough survive to show what Icelandic prose was in his hands, and the impress of his rich and simple style is felt in all the succeeding masterpieces. Snorri, and the anonymous authors of *Njala*, *Laxdaela,* and the rest, exhibit simple prose style at its highest. The great historian. Sturla (1214–84), is the latest of these classic writers of Iceland, and after his death there was a rapid decline. The splendid prose of these two centuries stands unrelated, an unparalleled portent in European literature.

Spanish.—In Castilian, as elsewhere, verse is far advanced before we meet with any distinct traces of prose A religious treatise is attributed to a monk of Navarre, writing in the 13th century. Between 1220 and 1250 a chronicle of Toledo was indited. But the earliest prose-writer of whom Spain can really boast is King Alphonso the Learned (1226–84), in whose encyclopaedic treatises "Castilian makes its first great stride in the direction of exactitude and clearness" (Fitzmaurice-Kelly). Almost all the creditable prose of the end of the 13th century is attributed to Alphonso, who was helped by a sort of committee of authors. The king's nephew, Juan Manuel (1282–1347), author of *Conde Lucanor,* carried prose to a further point in delicacy and precision. The poet Ayala (1332–1407) was another gifted artificer of Spanish prose, which suffered a setback in the hands of his successors, Santillana and Mena. It rose once more in *The Sen* of *Histories* of Pérez de Guzmán (1378–1460), in whom the lucid purity of Castilian prose is for the first time seen. In the 1 jth century the shapeless novel of chivalry was predominant, while in the age of Ferdinand prose decayed. The next great writer whom we meet with is Guevara (d. 1545), whose *Dial of Princes* exercised an influence which even extended to English prose (in North's well-known version). The historians of this period were of less value. The earliest picaroon novel, *Lazarillo de Tormes* (1554), introduced a new form and exhibited Castilian prose style in a much lighter aspect. Still greater elegance is met with in the writings of Juan de Valdés and of Luis de León. Of the latter Fitzmaurice-Kelly says that "his concise eloquence and his classical purity of expression rank him among the best masters." The instrument, accordingly, was ready to the hand of the supreme magician Cervantes, whose *Don Quixote* was begun a few years (about 1591) after *Los Nombres de Cristo* of Luis de León. The prose of Lope de Vega is stately and clear: but admittedly has little importance in comparison with his verse. Quevedo's style had the faults of antithesis and obscure ingenuity; but his *Visions* (162;) are of course famous. The latest struggles of a decadent critical conscience, battling against affectation, are seen in Graciin (1601–58) and Molinos (*c.* 1640–97). When Spanish prose revived in the 19th century, in the person of Larra (1809–37), the influence of French models was found to have deprived it of distinctly national character: while giving it a fresh fluidity and grace.

French. — There had long been a flourishing versified iiterature in the vernacular of France, before anyone thought of writing French prose. It was the desire to he exact in giving information which led to a partial divergence from metre. The translator of the *Chronicle of Turpin* mentions that he writes in prose "because rhyme entails the addition of words not in the Latin." Thus about 1200 verse began to be abandoned by chroniclers who had some definite statements to impart. They ceased to sing; they wrote as those around them spoke. The earliest French prose was translated from the Latin, but Baldwin VI. (d. 1205) is said to have commissioned several scribes to compile in the vulgar tongue a history of the world. If this was ever written it is lost, but we possess a *Book of Stories* written about 1225 by a clerk at Lille, which may fairly be said to be the beginning of French prose history. When once, however, a taste for prose was admitted, the superiority of that medium over verse as material for exact history could not but be perceived. The earliest French prose-writer of genius was Villehardouin, who put down memoirs of his life between 1198 and 1207; he left his hook, *The Conquest* of *Constantinople*, incomplete. In the history of prose, Villehardouin takes an eminent place. In his style are seen many of the most precious elements of French prose, its lucidity, its force, its sobriety and its charm. He had been trained as an orator, and was content to write as he had learned to speak. He was followed by other admirable writers of memoirs, Robert of Clari, Henri of Valenciennes, the anonymous chronicler of Béthune, to whom we owe the famous description of Bouvines, and the Minstrel of Reims. The last-named finished his *Récits* in 1260. These works in the new easy manner of writing were found to be as elegant and as vivacious as any in verse. They led the way directly to the earliest historian of modern Europe, Joinville, who finished his *Histoire de St. Louis* in 1309. A century later Froissart left his famous *Chroniques* unfinished in 1404, and again 100 years passed before Philippe de Commines dropped the thread of his *Mémoires* in 1 j11. These three are simply the most eminent figures in a great cloud of prose-writers, who helped to facilitate the use of the national language. In the 15th century, moreover, Antoine de la Salle deserves mention as practically the earliest of French novelists. But with the Renaissance came the infusion into France of the spirit of antiquity, and in Rabelais there was revealed an author of the very highest genius. The year 1532, in which the first brief sketch of *Gargantua* appeared, was critical in French literature. In 1549 appeared the *Défense et illustration de la langue française* of Joachim du Bellay, in which the foundations of French literary criticism were firmly laid. The liberation of the language proceeded simultaneously in all directions. In 1 j39 it was officially decreed that all judicial acts were thenceforward to be written "en langage maternal français." Calvin led the theologians, and his precise and transparent prose gave the model to a long line of sober rhetoricians. It is in Calvin that we meet for the first time with a simple French prose style, which is easily intelligible to-day. There is some pedantry in St. François de Sales, some return to the spirit of mediaeval French in Montaigne; so that the prose of these great writers seems to us more antiquated than that of Calvin. Yet the *Institution* belongs at latest to 1560, and the immortal *Essais* at earliest to 1580. We are approaching the moment when there should be nothing left for French prose to learn. But we pause at Brantôme, in whom the broad practice of French as Froissart and the mediaeval chroniclers had used it was combined with the modern passion for minute and picturesque detail With the beginning of the 17th century there sprang up almost an infatuation for making prose uniformly dignified, for avoiding all turns of speech which could remind the reader of the "barbarous" origins of the language; the earliest examples of this subjection of eloquence to purely aristocratic forms have been traced back to the *Servitude volontaire* of La Boétie (1530–63). In the pursuit of this dignity the prose writers of the 16th century ventured to borrow not words merely but peculiarities of syntax from Greece and Rome. The necessity of remaining intelligible, however, checked excess, and after a few wild experiments the general result was discovered to be the widening of the capacities of the language. In the 17th century a great stimulus was given to easy prose by the writers of romances, led by d'Urfé, and by the writers of letters, led by Balzac, with whom French prose lost its heaviness and its solemnity; it became an instrument fit to record the sentiments of social life; here was discovered what Voltaire calls the *nombre et harmonie de la prose.* French style became capable of still more when it was used by Descartes and by Pascal to interpret their majestic thoughts. At this moment, in 1637, the French Academy was founded, for the distinct purpose of purifying and enlarging the French language; and in time, out of the midst of the academy, arose the important *Remarques* (1647) of Vaugelas, a work of grave authority, which was the earliest elaborate treatise on the science of prose in any language. Antiquated as Vaugelas now seems, and little regarded by modern writers his work is still the basis of authority on the subject. In common with his colleagues he laid down laws by which harmony of structure, a graceful sobriety and exactitude of expression, could be secured to every practised French writer. He was not accepted as infallible, even in his own age; he was immediately exposed to the criticism of La Mothe le Vayer, who, however, was radically at one with him regarding the basis of his definition. The great demerit of the early academicians was that they knew little about mediaeval French. They thrust everything aside which they regarded as barbarous, and the work of the 19th century was to recover from a past behind Rabelais elements of great value which the 17th had arbitrarily rejected. In the succeeding centuries there has been a vast extension of the practice of French prose, but in spite of all neologisms, and of the waves of preciosity which have periodically swept over the French language, the treatise of Vaugelas remains the final code in which the laws that govern French prose are preserved.

Italian. — The case of prose in Italian has this unique feature that, instead of gathering form obscurely and slowly, it came into sudden existence at the will of one of the greatest of writers. Latin had almost universally been used in Italy until the close of the 13th century, when Dante created a vernacular prose in the non-metrical part of his *Vita Nuova* (c. 1293). For a long time the prose of Dante stood practically alone, and Petrarch affected to despise the works which his great predecessor had written in the vulgar tongue. But about 1348 Boccaccio started his *Decameron,* which gave classic form to the prose romance of Italy. It should have been greatly to the advantage of Italy that in the hands of Dante and Boccaccio prose was born full-grown, and had not to pass through the periods of uncertain development which awaited it elsewhere. After this brilliant beginning, however, there was a decline, the writers of the next age lacking the courage to be independent of antiquity. There was a return to Latin phraseology which made many works almost macaronic in character; the famous Hypnerotomachia of Colonna is an instance. Something of the purity of Boccaccio was recovered by Sannazaro in his *Arcadia* (1489); even Sannazaro, however, did not see how needful it was to cast off Latin constructions. At length Machiavelli and Guicciardini succeeded in releasing prose from the yoke of Rome, and in writing undiluted Tuscan. In the 16th century the prose writers of Italy became extremely prolific, with Pietro Bembo at their head. The novelists were now prominent, but, although they take a foremost place in the history of Italian literature, there was little art in their employment of language. Many of them were born out of Tuscany, and, like Bandello, never learned the rules of pure Italian prose. Since the 16th century Italian would seem to have undergone no radical changes, and its prose has been stationary in form At the close of the 19th century a new school of writers, with Gabriele d'Annunzio at its head, created a demand for a new prose, but the remedy suggested by these innovators was neither more nor less than a return to Boccaccio and Machiavelli.

German. — The earliest attempts in German prose belong to the age of Charlemagne, and the first example usually quoted is the Strassburger *Eidschwüre* of 842. For all literary purposes, however, metrical language was used exclusively during the *mittelhochdeutsch* period, which lasted until the end of the 13th century. What little prose there was, was limited to jurisprudence and theology. David of Augsburg (d. 1272) is named as the earliest vernacular preacher, but only one of his sermons has reached us. More important was Berthold "the Sweet" (1220–72), whose sermons were published in 1824. Historical prose began with the Saxon Chronicle of 1248. There was little to record in the next two centuries, until prose was revived by Geiler von Kaisersburg (1445–1510) in his sermons. About the same time translations were made of the Decameron and other Italian novelle. The development of prose in Germany is. however, negligible until we reach Luther's Bible (N.T.. 1522), on which all classic German prose is based. Johann Fischart composed important secular books in the vernacular, in particular the Bienenkorb (1579) and an imitation of *Gargantua* (1575), the earliest German novel. Nearly a century passes before we reach the curious picaresque romance of *Simplicissimus* (1669) of Grimmelshausen. But the neglect of prose by the German nation was still general. Even men of the stamp of Leibnitz wrote in Latin or French. What Luther had done was, however, completed and confirmed in the middle of the 18th century by Lessing, the creator of modern German prose. The critical period in this revival was 1764 to 1768, which saw the production of Laocoon and the *Hamburgische Dramaturgie.* We pass presently to Jean Paul Richter, and so to Goethe, in nhose hands German prose became the organ of thought and eloquence which it has been ever since.

PROSECUTION, the procedure by which the law is put in motion to bring to trial a person accused of crime (see CRIMINAL LAW; INDICTMENT). In theory in Great Britain the king is in all criminal offenses the prosecutor, because such offenses are said to be against his peace, his crown and dignity, but in practice such prosecutions are ordinarily undertaken by the individuals who have suffered from the crime. This is a different procedure from that prevailing in Scotland and European continental countries, nhere a public department or officer prosecutes offenses.

In the Cnited States, crimes against the federal government are prosecuted by the different United States attorneys under the general supervision of the United States attorney general. In the states, prosecution is by district, state's or county attorneys, somewhat under the supervision of the state attorney general. Sometimes a special prosecutor is named.

PROSERPINE, generally accounted the Latin form (*Proserpina*) of Persephone. See PERSEPHONE.

PROSODY, CLASSICAL. Ancient Greek metre differs fundamentally from modern English metre in that it is based not on stress but on quantity. Greek verses are composed of comparatively complicated and rigid patterns of long and short syllables. Most Latin verse too is composed on a quantitative system in imitation of Greek.

Greek. — The length of a syllable is determined by the length of the vowel sound contained in it: w, η and diphthongs are long by nature; a, ι, υ may be long by nature (*e.g.*, χωρᾱ, λῡω, ῑμεροs). Vowels with ι subscript or a circumflex accent are long.

A vowel may become long by position when followed bv two or more consonants, or by the letters ζ, ξ, ψ; *e.g.*, ἐλπιζον κεαρ. But certain combinations of consonants, known as "mute and liquid," do not invariably lengthen the preceding vowel. Such combinations are: πλ. φλ, κλ, χλ, τλ, 0X, κμ, τμ, θμ, πν, φν, KV, χν, θν, τν, πρ, φρ, κρ, τρ, Op. The letters β, y, δ lengthen the preceding vowel always when followed by μ or ν, usually when followed by λ, but not when followed by p. In Sappho and Alcaeus combinations of mute and liquid almost always lengthen the preceding vowel; in Homer, Pindar and Bacchylides more often than not; in Attic drama usually not.

Elision.—When a word ending with a short vowel is followed by a word beginning with a vowel. the final vowel of the first word is usually omitted, *e.g.*, τωνδ' ἀπαλλαγην.

Epic *Correption.*—In Homer a final long vowel or diphthong may be shortened when the following word begins with a vowel; *e.g.*, ἐγω̆ οὐ.

Crasis.—Certain short words ending in a vowel may fuse with the initial vowel of the following word; *e.g.*, και ἐμε becomes κἀμε.

Synezesis.—Certain pairs or groups of vowels other than diphthongs may sometimes be scanned as one syllable; *e.g.*, εω, μη οὐ.

Hiatus.—Where a final vowel is follo ed by an initial vowel without either vowel being in any way affected, there is said to be "hiatus." In many apparent hiatuses in Homer the consonant "digamma" (ϝ) was originally present, although not written in the manuscripts. The digamma is sometimes present in Pindar.

Greek verse is of two main types: spoken, or "stichic," and sung, or lyric.

Greek Lyric Verse.—Some lyric verse is composed in set stanzas, notably the sapphic and alcaic (*q.v.*), but most in "strophae" (see STROPHE), stanzas, often long and complicated, composed according to the poet's fancy. These stanzas may be analyzed into verses. The Greek verse is roughly equivalent to the line in English poetry, although one verse is often printed as more than one line in Greek texts. The end of a verse always coincides with the end of a word. When a verse ends with a vowel and the following verse begins with a vowel there is hiatus. The last syllable of a verse is always, in principle, long. If a short syllable occurs at the end of a verse, it is counted as long and called *brevis* in longo.

Each verse consists of one or more "cola" (κῶλον ["limb"]). Some cola are analyzable into "metra" (μέτρον ["measure"]). The elements used in the composition of both metra and cola are. long (–). short (⏑), anceps (⏓, meaning that the position may be occupied by either a long or a short syllable), biceps (⏖ the position may be occupied by either one long syllable or two short ones). Thus ⏓–⏑– is described verbally as "anceps, long, short, long," and –⏖ as "long, biceps."

Metra.—Iamb (⏓–⏑–), trochee (–⏑–⏓), dactyl (–⏖), anapaest (basically ⏑⏑–⏑⏑–, but all four elements are bicipitia), ionic (⏑⏑––), cretic (–⏑–), choriamb (–⏑⏑–). Cola are usually formed of two or more metra of the same type and are named according to the number of metra they contain; *e.g.*, ionic dimeter ⏑⏑––|⏑⏑––. (See IAMBIC; TROCHEE; DACTYL; ANAPAEST; CHORIAMBIC VERSE.)

Catalexis.—Many types of colon may be varied by the omission *of one quantity at or near the end. Thus,* ⏓ – ⏑ – | ⏑ – – *is a catalectic iambic dimeter;* ⏑⏑ – – | ⏑⏑ – *is a catalectic ionic dimeter.*

In the following types the cola are not analyzable into metra.

Aeolo-Choriambic.—Basic *constituents: anceps, choriamb,* – ⏑⏑ – ⏑ –. Two ancipitia *commencing the colon form the* "aeolic *base." A common aeolo-choriambic colon. the "glyconic" (q.v.), consists of base and* – ⏑⏑ – ⏑ –. *Longer cola, the so-called "asclepiads." are formed by the addition of one or two choriambs between base and* – ⏑⏑ – ⏑ – *(see* Choriambic Verse).

Prosodiac-Enoplia.—Cola *of this type combine single-short and double-short rhythm They cannot be analyzed and are perhaps best regarded as prolongations of* – ⏑⏑ – ⏑ –. *Examples are:*

– ⏑⏑ – ⏑ ⏑ – ⏑ – –
καρδιοδηκτον ἐμοι κρατυνεις
⏑⏑ – ⏑ ⏑ – ⏑ –
βιον ᾧ τε δοκει ψεγω.

Dochmiacs.—The *dochmiac may be regarded as an unusually long and variable metron. It consists of anceps,* two *bicipitia, anceps. biceps. The most common forms are:* ⏑⏑⏑ – ⏑ –, ⏑ – – ⏑ –, – ⏑⏑ – ⏑ –. *Dochmiacs are confined to Attic drama.*

Dactylo-Epitrites.—These *occur in Attic drama, and about half the extant poems of Pindar are composed in this metre. Its most common constituents are* – ⏑⏑ – ⏑⏑ – *(hemiepes),* – ⏑ – *(cretic) and* – ⏑⏑ – *(choriamb). which are linked together by ancipitia, usually long, to form compounds like*

– – ⏑ ⏑ – ⏑ ⏑ – – – ⏑ –
κλειναν Ἀκραγαντα γεραιρων εὔχομαι.

The link anceps may sometimes be omitted, and verses may begin with acephalous (headless) elements, e.g.:

⏑ ⏑ – – ⏑ ⏑ – ⏑ ⏑ – – – ⏑ –
Ἀσιας εὐροχορου τριπολιν ναυον πελας.

Several types of metre may be combined in the same stanza. Iambs are found combined with most types of metre. Aeolo-*choriambs and prosodiac-enoplia often occur together. Dochmiacs sometimes receive an admixture of iambic. Dactylo-epitrites are rarely mixed with other metres.*

Greek Stichic Verse.—This *is composed in lines* (στίχοι) *of the same length and type: dactylic hexameters in Homer. etc.. iambic trimeters and trochaic tetrameters in the spoken portions of* drama. Stichic *lines are always divided by word-end at or near the middle. If this division falls within a metron it is called "caesura" (marked thus: ||), if at the end of a metron "diaeresis." (For the rules governing caesurae and other features of stichic composition see* *Hexameter*; *Iambic*; *Trochee*; Anapaest; *Elegy.)*

Latin.— The Saturnian (q.v.) is the only indigenous Latin verse. Other metres are borrowings and adaptations from Greek.

The length of syllables is determined as follows: *Diphthongs are long. A single* vowel followed *by a single consonant may be long or short by nature; e.g., mălus "bad," but mālus "mast." A vowel followed by* two *consonants is long by position. The vowel is not* always *lengthened if the second of the two consonants is l* or *r; e.g., volŭcri* or *volūcri. If, however, the first consonant and the following l or r belong to different* words, *the preceding vowel is always lengthened; e.g., arcebāt longe.* Vowels *are always lengthened before ll and rr.*

Elision occurs when a word *ending with a* vowel *or a* vowel *and m is followed by a word commencing with a vowel; e.g., conticuer(e) omnes, quamqu(am) animus. The* vowel *i must be distinguished from consonantal i, printed in older texts as j; e g, vitis Iaccho, Coeumqu(e) Iapetum, but auxiliūm iubeat, irē* iubes. *Initial h does not count as a consonant; i.e., it does* not *lengthen or prevent elision (e.g., omnīs humo, monstr(um) horrendum). In Latin texts elided syllables are printed, not replaced, as in Greek, by apostrophe.*

The principal types of Greek metre used in Latin are dactylic hexameters and elegiacs. Horace uses various lyric metres. notably sapphics and alcaics (q.v.), asclepiads, glyconics, etc. (see Choriambic Verse *and* Glyconic). *Catullus and* Martial *use the "choliamb" (see* Iambic) *and the "phalaecian" or* "hendecasyl*lable," an aeolo-choriambic colon composed of base,* – ⏑⏑ – ⏑ –, *bacchiac* (⏑ – –):

– – – ⏑ ⏑ – ⏑ – ⏑ – –
Cui dono lepidum novum libellum
– ⏑ – ⏑ ⏑ – ⏑ – ⏑ –
arzda modo pumic(e) expolitum.

Iambic trimeters of Greek type are found in Catullus, Horace and Seneca (see Iambic).

The verse of republican comedy differs fundamentally from the metres enumerated above. The lines are analyzable into feet, not metra. *The equivalent of the iambic trimeter, the "iambic senarius." consists of six* feet, *the last of which must be an iamb* (⏑ –). *In the other feet a spondee* (– –), *a tribrach* (⏑⏑⏑), *a dactyl* (– ⏑⏑), *an anapaest* (⏑⏑ –) *and even (especially in the first foot) a proceleusmatic* (⏑⏑⏑⏑) *may be substituted. There is usually caesura in the third foot, sometimes in the fourth:*

⏑ ⏑ ⏑ ⏑| – ⏑ ⏑|– || –|⏑ –| – –|⏑ –
ego quia non rediit filius quae cogito.

The iambic octonarius (eight feet) and septenarius (seven and a half feet) also occur in comedy.

The "trochaic septenarius" (equivalent of Greek trochaic tetrameter catalectic) is the commonest verse in comedy after the iambic senarius. The seventh foot must be a trochee (– ⏑). Spondees, dactyls, anapaests and tribrachs may be substituted in the first six feet. There is usually diaeresis after the fourth foot:

⏑ ⏑ –| – ⏑|– ⏑ ⏑| – –| – ⏑⏑⏑|–⏑|– |
ubi me dixero dare tanti testis faciet ilico.

In comedy the rules governing the length of syllables differ in some respects from those for other types of classical Latin verse. Syllables which would elsewhere *be long must in comedy sometimes be scanned as short. Pronouns especially are often shortened; e.g., ĭlle, ĭste. Adjacent vowels are often contracted into one syllable by synezesis, as fuisse, seorsum:*

– –| ⏑ –| ⏑ –|⏑ || ⏑ ⏑| – –| ⏑ –
non fuit necess(e) habere; sed id quod lex iubet.

The reasons for these particularities are much disputed. Some metricians attribute them to the presence of stress; others deny that stress had any influence on Latin versification.

Study **of** Classical *Metre.— The most important ancient work on metre* which *has survived is an abridgment of the treatise of Hephacstion (q.v.). This work,* however, *records theories formulated when the principles of classical metre were no longer well understood. His chief mistake* was *to attempt to analyze all types of Greek metre into short "feet" (e.g., iamb* ⏑ –, *as in Latin comedy, instead of* ⏓ – ⏑ –). *This system is still found in out-of-date metrical works. His terminology (e.g., names of feet) has been adopted even in English metrical theory, to* which *it is* ill-*suited. Since about* 1800 *classical metricians have discarded much of Hephaestion's theory and terminology, but misleading terminology is still in use. and there are few reliable modern works.*

PROSPER OF AQUITAINE *or Prosper Tiro (c.* 390–*c.* 465), *Christian writer and disciple of St. Augustine, was a native of Aquitaine. In* 431 *he appeared in Rome to interview Pope* Celestine *regarding the teachings of St. Augustine and then all traces are lost until* 440. *the first year of the pontificate of Leo I, who had been in Gaul and probably had met Prosper. Prosper* was *soon in Rome, attached to the pope in some secretarial or notarial capacity. Gennadius (De script. eccl. 83) mentions a* rumour *that Prosper dictated the iamous letters of Leo I against Eutyches. The date of his death is not known, but his chronicle goes as far as 455, and the fact that* Ammianus *Marcellinus mentions him* under the year 463 seems to indicate that his death was shortly after that date Prosper attacked the Pelagians in a polemical poem of about 1,000 lines, *Adversus ingratos*, written about 430. After Augustine's death he wrote three series of Augustinian defenses. especially against Vincent of Lerins *(Pro Augustino responsiones)*. His chief work was against Cassian's *Collatio*, his *De gratia dei ut libero arbitrio* (432). He also induced Pope Celestine to publish an *Epistola ad episcopos Gallorum* against Cassian He corresponded with Augustine and made an abridgment of his commentary on the Psalms, a collection of sentences from his works. He also put into elegiac metre, in 106 epigrams, some of Augustine's theological dicta

Prosper's *Epitoma chronicon* is a careless compilation from St. Jerome in the earlier part, and from other writers in the later, but the lack of other sources makes it very valuable for the period from 42j to 455 of which he had personal knowledge. There were five different editions, the last of them dating from 455, after the death of Valentinian. For a long time the *Chronicon imperiale* was also attributed to Prosper Tiro, but without the slightest justification.

PROSTEJOV or PROSSNITZ, an old town in Olomouc, Czech., lies in the fertile valley of the Hanna, a tributary of the Morava. Pop. (1950) 33,183. Germany occupied the town in March 1939, at the time of Czechoslovakia's dismemberment.

PROSTHODONTICS is the branch of dentistry that deals with the artificial replacement of natural teeth and associated tissues for the restoration or maintenance of function, appearance, comfort and health of the patient. This type of dentistry is divided as follows: (1) fixed partial denture prosthesis; (2) removable partial denture prosthesis; (3) complete denture prosthesis; and (4) maxillofacial prosthesis.

History. — The earliest dental prostheses known are banded bridges made by the Etruscans and wired restorations constructed by the Phoenicians. In early history human teeth, animal teeth or teeth carved from wood or ivory were substituted for natural teeth, and complete dentures for either the upper or the lower jaw were sometimes carved from one solid piece of wood or ivory. Early prosthetic appliances were crude, awkward and almost useless in mastication; they mere unhygienic and unsightly.

Porcelain teeth were introduced during the latter part of the 18th century, and in the 20th plastic teeth came into use. Continued research with both these materials has produced lifelike imitations of teeth to match the large number of variations found in the colours and forms of natural teeth. Gold alloys and chrome alloys possessing the correct amount of rigidity, yet with sufficient flexibility to be suitable for clasps, bars, bases and attachments, have been highly developed. Methods and techniques of manipulating the various materials, and specialized instruments and equipment used in the construction of prosthetic restorations. have kept pace Crowns. bridges and partial or complete dentures (*see* below), as well as the several maxillofaciai replacements, can be made so realistic in appearance and so functional that they almost defy detection.

Fixed Partial Denture Prosthesis. — This includes the design, construction and maintenance of dental restorations such as crowns and bridges that cannot be readily removed from the mouth by the patient or dentist. These types of restorations are rigidly fixed to the natural teeth. which furnish support to them, and may be made of porcelain, plastic or metal. A crown is a replacement used to restore the natural form of an impaired tooth that cannot be preserved by an inlay or other type of restoration. A bridge, as the name implies, consists of a span of one or more artificial teeth, with abutment attachments that are cemented to the adjacent natural teeth in the mouth.

Removable Partial Denture Prosthesis. — This includes the construction and maintenance of dental restorations so designed that they can be removed at will by the wearer or dentist. A removable partial denture consists of a base, constructed of plastic material or metal, or a combination of the two, which accurately fits the mouth ridges and tissues and supports the artificial replacement teeth in proper alignment. It is held in position in the mouth by flexible metal bands or clasps encircling adjacent natural teeth, or by other means of attachment to the teeth.

Complete Denture Prosthesis. — This involves the artificial replacement of all the natural teeth and associated tissues in either the upper or the lower jaw or in both. In this type of prosthodontics, restoration of the functions of mastication, speech and appearance is of the greatest importance. Establishing and maintaining these functions by means of artificial dentures is accomplished by attaching porcelain or plastic teeth to bases (plastic material. metal or a combination of the two) that have been accurately adapted to the soft tissues of the mouth.

Maxillofacial Prosthesis.—This deals with the artificial replacement of tissues in cleft palates and other oral abnormalities. Cleft palates are abnormal openings of varied size and form in the palate of the mouth, usually of congenital origin. Mastication, swallowing and speech are seriously impaired by this type of abnormality. Closure of the opening by inserting a removable prosthesis can greatly improve these functions. Maxillofacial prosthesis has also come to include artificial restorations of some extraoral conditions of the face and head, resulting from accident or disease, or congenital.

Prosthodontics as a **Specialty.**—Accident, extensive disease or congenital abnormality may present conditions that make artificial replacement very difficult and require specialized skills, ideas and ability. In the United States, dentists with the necessary training and experience to deal with all types of dental prostheses, after examination by the American Board of Prosthodontics (authorized in 1948 by the American Dental association). are granted certification by that board, designating them as specialists in the field of prosthodontics. In the United States and also in Great Britain special training in prosthodontics, additional to that taught at the undergraduate level, can be obtained in many dental schools. *See* also DENTISTRY; TEETH, ARTIFICIAL. (B. L. H.)

PROSTITUTION is defined in the *Shorter Oxford English Dictionary,* in relation to women, as "the offering of the body to indiscriminate lewdness for hire." A prostitute is defined as "a woman who is devoted or (usually) offers her body to indiscriminate sexual intercourse, especially for hire." Both definitions are confined to women, but male prostitution is a universal problem, though not so commonly encountered: the dictionary definition could equally well extend to males as well as females. In general parlance, prostitution has acquired a wide meaning implying some form of debasement or degradation not necessarily physical. The legal attitude is more restricted and varies in different countries. In British common law the term common prostitute "is not limited so as to mean anyone who permits acts of lewdness with all and sundry or with such as hire her when such acts are in the nature of ordinary sexual connection. We are of the opinion that prostitution is proved if it be shown that a woman offers her body commonly for lewdness for payment in return" (lewdness in this definition was given a very wide meaning and was not confined to full intercourse). The payment of money is by no means a necessary ingredient of the legal offense: for example, in the United States under some statutes a woman prostitute is defined as a woman who submits herself to indiscriminate sexual intercourse with or without hire. In this article the words "prostitute" and "prostitution" will be used to denote promiscuity in return for money or its equivalent without any specific attachment to the particular partner. unless the context implies some other meaning.

The phenomenon of prostitution is universal, and in every civilized country legal measures, varying in severity, are taken to keep it more or less under control While the law takes cognizance of overt manifestations, which are for the most part connected with economic factors and with prostitution as a trade. the sociologist, the psychiatrist and the psychoanalyst have to consider the more profound emotional problems where the money-earning factor is not necessarily emphasized.

HISTORY

Primitive Peoples and the Ancient World. — Studies in social anthropology do not concern themselves very much with prostitution Among primitive people the existence of polygamy and the early age of marriage conceal or even obviate promiscuity for hire. If promiscuity were alone the test then the practice of the utmost sexual freedom would be within the definition. From studies of existing primitive communities it would appear that sexual freedom and strict observation of the matrimonial norm vary considerably. Margaret Mead in her book *Male and Female*

(New York, 1949; London, 1950) does indeed refer to the prostitution of slaves captured in war by the Manus tribe in Melanesia: this is done in order to make money by a tribe described as "efficient puritans" among whom there is a general devaluation of sex.

In rather more advanced communities, the prostitution of unmarried girls seems to have been a common practice and the reasons for it are various: namely, as a puberty ceremony (that is, a sacrifice of virginity) ; as a puberty rite to earn a dowry: and as religious prostitution in the service of a goddess. Generally, however, the system of female kinship. where descent was traced through the mother and not through the father. would seem to have gone hand in hand with a greater laxity in morals than is observed by Christendom, where marriage is accepted as "the voluntary union for life of one man and one woman to the exclusion of all others."

In Babylon, in Cyprus, among the Phoenicians and in many parts of western Asia it is recorded that women prostituted themselves as a religious duty at the sanctuary of a goddess. whose name varied with the locality. Sir James Frazer in The Golden *Bough* observes that, despite the change of name, her type remained constant, namely, the great Mother Goddess of western Asia (see GREAT MOTHER OF THE GODS; APHRODITE; also ASTARTE). The Babylonian custom, as recorded by Herodotus, required every woman, rich or poor, to sit in the temple of Ishtar and have intercourse with a stranger: who signified his choice by throwing a silver coin of no matter how small value into her lap. The woman had then to accept the coin and have intercourse with the stranger. Ill-favoured women under this system might wait a long time, even years. before they had performed their service. Once the rite had been observed the woman was absolved from her obligations to the goddess; and then, according to Herodotus, money would in no case purchase her. The customs in Cyprus and elsewhere seem to have followed a similar course. In some cases, and perhaps generally, the man had to be a stranger.

Whatever the motive for these customs. whether as a sacrifice of virginity, to earn a dowry or as a religious service, the practice was a solemn religious duty. It is a widespread belief that a woman never forgets the first man with whom she has had intercourse. On this hypothesis. the practice of submitting to a stranger in the service of a goddess may have been an emotional safeguard, attaching the woman primarily to the deity rather than to an individual. Frazer suggests that these religious duties were closely knit with the reproductive energies of nature as a whole. Their observation reflects an earlier period of sexual communism where marriage was unknown or barely tolerated as an immoral infringement of these old communal rights.

Attempts have been made to trace the origin of religious prostitution to the purely secular and precautionary practice of destroying the bride's virginity before her marriage. There is no doubt that, in some communities, there is a fear that a man will be endangered by some peril attaching to virginity. It is certain that defloration of virgins has played and still does play an important role; but its significance is far from clear. This custom is thought ultimately to have developed into the *jus primae noctis* (*q.v.*) vested in the local lord or priest. The rites accompanying the sacrifice of virginity in a woman are paralleled perhaps by the puberty rites observed in primitive communities in relation to youths as recorded, for example, by Theodor Reik in *Probleme* der *Religionspsychologie* (Leipzig and Vienna, 1919).

Among the Jews, who stood apart from the surrounding peoples, the object of the Mosaic law was clearly to preserve the purity of the race and the religion. Prostitution in itself was not forbidden, but it was to be confined to foreign women. Jewish fathers were forbidden to turn their daughters into prostitutes (Lev. xix, 29). and the daughters of Israel were forbidden to become prostitutes (Deut. xxiii. 17), but no penalty was attached to disobedience, except in the case of a priest's daughter, who was to be burned (Lev. xxi, 9). There is abundant evidence in the Old Testament that prostitution prevailed extensively in Palestine, even in the earlier and more puritan days. The women were forbidden Jerusalem and places of worship; they infested the waysides, and there is some evidence of a distinctive dress or bearing, which was a marked feature of the trade among the Greeks and Romans. The remarkable series of ordinances laid down by Moses in the interest of public health contains unmistakable recognition of venereal disease and its contagious character (Lev. xv).

The earning of a dowry is also shown by ancient customs to have been a motive for prostitution. The girls of Lydia regularly prostituted themselves to earn a dowry, and the Palau (Pelew) Islanders systematically prostituted their daughters for hire and derived an income therefrom, perhaps with the intention likewise of providing them with a dowry. A similar custom was prevailing as late as the early years of the 20th century among the Ouled Naïl of Algeria: the girls of this tribe would go to the larger towns (*e.g.*, Biskra) as dancing girls and earn money by prostitution; then they would return home and marry; and the more money they had acquired. the more desirable they were considered as wives. While it may be that this motive of earning a dowry had itself originally some religious rather than economic purpose, it is clear that in later times the economic aspect featured much more largely. In communities of varying states of advancement the practice certainly grew up for the bride to be bought by the prospective husband; but in the course of time the custom of transferring property in return for a bride was superseded by that of the parents' presenting a dowry to the daughter. This change occurred perhaps with the gradual introduction of monogamy, when the supply of women outstripped the demand. with the result that no longer did the future husband pay for the lady; instead, the father endowed her as a method of encouraging the prospective bridegroom.

Superficially at least, then, prostitution was in many countries once connected with religious worship. The priests in early times seem to have often been the state's financial experts; and it cannot be doubted that the money paid to the women in the temples came in the course of time to find its way into the priests' coffers. An example is provided by the huge temple of Aphrodite in Corinth. where there was a large staff of prostitutes in attendance to accommodate sailors frequenting the port. It may therefore be suggested that the advent of the secular brothel did not take place until the system that regulated prostitution in accordance with religious rites had broken down, while the demand for tht prostitute's services continued.

The regulations of Solon in Athens were designed to preserve public order and decency. He established houses of prostitution (dicteria), which were a state monopoly and confined to certain quarters. The *dicteriades* were forbidden the superior parts of the' town and were placed under various disabilities: they were compelled to wear a distinctive dress and. far from being connected with religion, were not allowed to take part in religious services. These laws do not seem to have been carried out at all effectually and were presently relaxed; but it is clear that, as time went on. the Athenian authorities experienced the difficulties encountered by modern administrations in carrying out state regulation. On the other hand the hefaerae, independent courtesans of the most expensive class. had an enviable place in Greek society, where their intellectual as well as their physical attainments were widely respected (see ASPASIA; PHRYNE; LAIS).

In ancient Rome the moral tone seems to have been of a very different stamp: the Romans combined a pride of race like that of the Jews with a regard for public decency like that of the Athenians and had also a standard of austerity all their own. In early times female virtue was highly honoured and strenuously preserved by the Romans (*e.g.*, in their institution of the Vestal virgins): to frequent the company of prostitutes was accordingly considered disgraceful—though we may cite the opinion, attributed by Horace (Satires, i, 2) to the conservative Cato, that it was right (*aequum*) for young men driven by lust to go to brothels rather than molest other men's wives. The Roman system of regulation was especially severe: prostitutes were placed under stringent control (their registration by the police foreshadom-s modern European practice), had to wear distinctive dress and to dye their hair or wear yellow wigs and were subject to various civil disabilities. The state's taxation of prostitutes, which had been transmitted from the Roman republican to the imperial period and had been further regulated by Caligula. was however partly renounced in the Christian 4th century by Theodosius (on the representations of Florentius, a wealthy patrician, who offered to make good the loss of revenue out of his own pocket) and was finally abolished in the jth by Xnastasius I, and the old registers were destroyed. Then some of the civil disabilities of prostitutes were removed by Justinian in the 6th century. Edward Gibbon attributes Justinian's action to his desire to marry Theodora, whose life had been notorious; but though no doubt she influenced him in the matter. Gibbon admits her virtue after marriage and gives her credit for "the most benevolent institution" of Justinian's reign, the rescue home for fallen women in Constantinople. This though it did not succeed, marks a turning point in the treatment of a class which had never met with public sympathy before.

The Middle Ages.—In the middle ages prostitution was tolerated, the caprice of the passions being recognized as a necessary evil. Nevertheless, efforts were made to check it, or at least to keep it nithin reasonable bounds. Christianity put an increasing emphasis on chastity and on the sanctity of the marriage vows, though the observation of the monogamous status of marriage was accepted only gradually. Saint Augustine of Hippo took the view that a plurality of wives. as distinct from a plurality of husbands, is not contrary to the nature of marriage. "*plures enim feminae* ab *uno viro fetari possunt, una* vero a *pluribus* non *potest*" ("for more women than one can be made pregnant by one man, whereas one woman cannot [at the same time] be made so by more men than one": De *Bono Conjugali*). He and others following him regarded this natural law as modified at a later date by the institution of monogamy as a discipline imposed by the divine authority on Christians. In furtherance of the more humane Christian doctrines, attempts were made to better the lot of prostitutes and to induce them to reform. The church indeed became exceedingly active in prevention and rescue work and was assisted by a devout and zealous laity: rescue missions were organized, convents were founded everywhere for the reception of penitents. and dowries were subscribed to procure them husbands. . Fulk of Neuilly was a conspicuous figure in this work, holding missions, preaching and collecting large sums for marriage dowries. Pope Innocent III pronounced it a praiseworthy act to marry a prostitute; and Gregory IX wrote to Germany that brothel-keepers were not to prevent prostitutes from attending missions and that clergy and laity who drew profit from prostitution were banned. "Urge bachelors," he wrote, "to marry repentant girls, or induce the latter to enter the cloister."

Meanwhile, apart from the church's doctrine, the feudal order of society had its own influence on the mediaeval attitude toward relations between the sexes. In feudal times, when the possession of land was the criterion of wealth and status: marriage among the greater landowners, though subject to the laws of the church, was most often primarily a political matter, to be arranged by open bargaining between overlord and overlord or between the heads of the two families concerned; love, then, did not enter into the question (indeed it would appear that love, as understood in the 20th century, is a comparatively recent development in human life). Women of the highest rank in feudal society were thus treated to a large extent as salable chattels; and their status cannot have been without its reflection in the contemporary attitude toward women in general. On the other hand! the feudal service due from a vassal to his lord provided the model for the lover's service to his lady according to the code of chivalrous or courtly love which the troubadours conceived and formulated in the 11th, 12th and 13th centuries. This new idealization of love was clearly hard to reconcile with indiscriminate recourse to prostitutes; but insofar as courtly love was regarded as existing not between husband and wife but extramaritally (a "court of love" is said in fact to have pronounced love between husband and wife to be impossible), it must have contributed to the divergence from Christian standards that made prostitution acceptable to those at least who were not chivalrously in love.

In an era when almost the whole population came to be divided into guilds, prostitutes would appear to have iormed a regular guild of their own; at the very least, they seem to have had a recognized function in social life. A general distinction, however, can be made between the resident prostitutes. who lived in "bordells," and the itinerant ones, who were either vagrant or else informally attached as camp followers, to the temporal or spiritual armies that snept to and fro across Europe, now waging wars, now fulfilling vows. Prostitution indeed was not merely tolerated but protected, licensed and regulated by law and constituted in many places a source of public revenue.

In France prostitutes were distinguished by a badge and forbidden to wear jewels and fine stuffs and to frequent certain parts of the towns. Public brothels on a large scale mere established at Toulouse, Xvignon and Montpellier: at Toulouse the profits were shared between the city and the university; at Montpellier and Xvignon the trade was a municipal monopoly and farmed out to individuals; at Avignon. where the establishment was kept up during the whole period of the popes' residence, the inmates were subjected to a meekly examination. In some parts of France prostitutes paid a tax to the seigneur. In Germany, according to Fiducin, the public protection of Lustdzrnen was a regular thing in all the large tonns during the middle ages. Frauenhauser, similar to the French brothels, existed in many places. In Italy and also in Spain the system appears to have been very much the same: in Bologna prostitutes had to wear a distinctive dress, in Venice they were forbidden to frequent the wineshop, and in Ravenna they were compelled to leave a neighbourhood on the complaint of other residents. In Naples. moreover, a court of prostitutes was established, having jurisdiction over everything connected with prostitution. It led to great abuses and was reformed in 1589 and abolished about a century later.

In England the most notorious "bordells" or "stews" were those which occupied a row of buildings in the Borough (Southwark) near London bridge, originally licensed by the bishops of Winchester (according to John Noorthouck) and subsequently sanctioned by parliament; John Stow quotes the regulations enacted in the year 1161, during the reign of Henry II. These bordells were closed in 1506 but reopened until 1546, when they were abolished by Henry VIII. In London also we get an early regulation directed against the spread of venereal disease: the act of 1161 forbade the bordell-keepers to have women suffering from the "perilous infirmity of burning"; and by an order of 1430 they were forbidden to admit men suffering from an *infirmitas* nefanda. As in other countries. regulations respecting the dress of prostitutes were made in England: by a royal proclamation of Edward I, the wearing of miniver or sendal (a kind of thin silk) on hoods and dresses was forbidden to prostitutes.

The Reformation and Its Aftermath.— The spread of humanist ideas since the mediaeval beginnings of the Renaissance was bound to raise the status of women; and the rise of monarchical absolutism in the 16th century meant the end of the old feudal order, which, as we have seen, tended to keep them in subjection. The Reformation brought a radical change in sexual morality: not only was the former insistence on celibacy, which had deprived the many thousands of clerks of any licit outlet for incontinence, abandoned in many countries, but also, to balance this liberalization of marriage, the Christian condemnation of extramarital licence was emphasized. The Reformers' stricter attitude to unchastity was moreover echoed by the Catholics of the Counter Reformation, conscious as they were of the harm that had been done to the church by its toleration of more licentious conduct. In this climate of opinion the many statutes enacted throughout Europe to control the prostitutes were apparently enforced to some effect: for example, in Strasbourg, where the cathedral seems formerly to have been a common place of resort for soliciting and the open activity of the numerous prostitutes a scandal, there were by 1536 only two brothels, and four years later public prostitution seems to have been effectually suppressed. In England under the Commonwealth, fornication was made a felony upon a second conviction, punishable by death, without benefit of clergy (1650); but this statute was repealed at the Restoration.

From the legal point of view in England, meanwhile, the type of offense with which prostitutes might ordinarily be charged began to pass, after 1640, from the jurisdiction of the ecclesiastical courts to that of the common law. Public nuisance then became the basis of prosecution, a development of this being the misdemeanour which is committed by anyone who does any grossly indecent act in any open or public place in the presence of more than one person. The liberty of the subject was jealously guarded, and intervention was not permitted except in the case of a disturbance such as would have necessitated action even in the most respectable mansion in the land. Brothels, however, were included among the establishments against which the Disorderly Houses act of 1751 was aimed.

The Industrial Revolution.— After the creation of the police force in the 19th century. the control of prostitution and its offshoots took on a more ordered appearance (see below). Almost concurrently. however. the question of prostitution began to assume a problematic form as the industrial revolution set its mark upon the world: mass movements took place away from the country into the towns, where people were crowded together under wretched housing conditions, their leisure occupations restricted and their everyday work monotonous and emotionally unsatisfying. The modern problem of prostitution is essentially an urban one, its character largely depends on the size and locality of the town.

Henry Mayhew, in an appendix to his London Labour and the London Poor (London. 1861), divided prostitutes into three classes: first, those women who were kept by men of independent means; second, those women who lived in apartments and maintained themselves by their trade; and third, those who dwelt in brothels. There were in addition the amateurs who took money but only practised prostitution as a sideline to their daily occupation (this latter group included servant girls and nursery maids). The squalor of the slums combined with addiction to drink induced a terrible apathy and recklessness in these women. The open running of night houses, where the men and women could meet as though on a more reputable social occasion, was another aspect of the trade. Yet even under these conditions the spread of enlightenment and education in the shape of an energetic police force and better parochial management was making itself felt.

The religious revivalist movements. such as the Evangelical movement and the Salvation Army, during the latter half of the 19th century, do not, from all accounts, seem to have had a very profound effect on the poorer classes as a whole. The general report seems to have indicated indifference to religion. This is brought out in relation to London by Charles Booth in Life and Labour of the People in London (London. new ed., 1902–03). Though this author deals with the years 1890 to 1900, he quotes ministers of religion who had been in their respective parishes for 30 years or more. On the other hand, the rescue work undertaken by the various missions established in poverty-stricken areas was remarkable. The success achieved was mostly confined to the women who had recently joined the ranks of the prostitutes; many of these were promptly picked out and in some way rehabilitated. The workers effected this change through their personal influence, though they themselves were inspired by deep religious feeling. According to the reports. they found that the favourable time for persuading a prostitute to change her way of life was immediately after the birth of the first child; with this we may compare the experience of later social investigators in the U S.S.R., who found that one of the most significant times for reclamation was during the treatment for venereal disease.

Legislation and Police Procedure, 19th–20th Centuries.— The law and morals are not of course coterminous, and in all countries the administrative problem of enforcing legislation so closely related to variable moral codes of behaviour is fraught with difficulties: as soon as the law enters the sphere of morals, both its interpretation and its execution may be called in question as unjust or indeed immoral, at least by some members of the community, so that it loses all its certainty and the reverence that rightly belongs to it. In Great Britain. for example, the Contagious Diseases Prevention acts of 1864, 1866 and 1869, which introduced a measure of state regulation and inspection of prostitutes, had to be suspended in 1883 and repealed in 1886 as a result of the campaign initiated against them in 1869 by Josephine Elizabeth Butler (*q.v.*), the founder of the International Abolitionist federation; thenceforward there was little that the law could do in relation to the prostitutes themselves except to see that the police maintained a certain standard of order, which had. of necessity, to be regulated by local conditions and by the reaction of the public at any given moment (see below). In some countries, on the other hand, special "morals police" were instituted, with more power than the English "vice squad" and with the function, among others, of observing the inscribed women and watching the uninscribed; but the arbitrary power that these "morals police" could exercise caused considerable misgiving. Yet again, some countries, for instance Belgium, favoured the employment of women police to deal specifically with prostitutes. It may be stated, however, that the laws controlling prostitution and kindred offenses in the different countries of the world are very similar once the fundamental distinction has been made between those of countries in which houses of prostitution have been abolished by law and those of countries which permit brothels and require prostitutes to be inscribed (of course, some countries cannot be classified in this way).

In Great Britain, legislation. apart from laws dealing with soliciting and offenses against decency in public places, is directed not at the prostitute or her client but against those third parties—brothel-keepers, procurers. pimps—who find her commerce so easy to exploit. For these purposes a brothel has been defined, in reference to a statute of 1885, as premises used by at least two women for the purposes of prostitution. The Criminal Law Amendment act of 1885 (in this connection see STEAD, WILLIAM THOMAS), as amended, and the Vagrancy act of 1898, as amended, legislate against the keeping of brothels, against procuration (including procuring for the purpose of gross indecency between males) and against a man's living on a prostitute's immoral earnings. Offenses between males are further dealt with by the Offences against the Person act of 1861. The punishment for a person found guilty under these statutes is a sentence of imprisonment of varying length. The Children and Young Persons act of 1933 affords protection to children and young persons. The laws relating to soliciting in England are for the most part contained in the Vagrancy act of 1824, the Metropolitan Police act of 1839, the Town Police Clauses act of 1847 and the Criminal Law Amendment act of 1951; in addition, there are local bylaws. The punishment for soliciting is usually a fine but can, in certain cases, be a short term of imprisonment. The practical outcome of the law on soliciting, as interpreted by the courts, is reflected in the regulations promulgated for the guidance of constables by the commissioners of police (see for example the Report of the Street Offences Committee, *1928,* [Cmd. 3231], p. 24, which quotes with approval the orders laid down for Edinburgh).

The difficulties that attend the abolition of houses of prostitution in a country where they have been long established are illustrated by the course of events in France. In 1946, state registration was ended and the maisons de *tolérance* were closed; then a subsequent law. in the same year. established a *fichier* sanitaire for all prostitutes and regulated their inscription for purposes of hygiene (*i.e.,* for contact-tracing and the treatment of venereal disease); and a further enactment (1948) seemed to make prostitutes subject to examination even before their occupation mas proved, the effect being practically a return to the regime of state registration.

The law of 1946 had indeed resulted in the closing of the brothels in France, but little was done for the rehabilitation of their inmates, and it soon appeared that the latter were pursuing their old trade under worse conditions than before. Marthe Richard, a national heroine of World Wars I and II, who had been among the first to urge the closing of brothels in Paris and indeed was held to be primarily responsible for the enactment of the law, showed that she had changed her mind about the rightness of the measure (see her book, *L'Appel* des sexes, Paris. 1951). To make a compromise between the abolitionists and those who wanted to repeal the law of 1946 it was proposed that brothels should be allowed in the neighbourhood of army camps at least.

In the United States, brothels or houses of prostitution are illegal in most states. as also is procuring; and the majority of the states penalize soliciting and living on the earnings of prostitution. A detailed analysis of the laws controlling prostitution and kindred offenses in the various states is contained in the *Digest of Laws and Regulations Relating to the Prevention and Control of Syphilis and Gonorrhea* (American Social Hygiene Association, Inc.. New York, 1940, with supplements). It may here be remarked that the attempt to "clean up" Chicago in 1929 provided a notable demonstration of the danger of driving prostitution underground, where it can become more vicious and disruptive to society than when it is allowed to exist, to some extent, openly (*see* Walter C. Reckless, *Vice in Chicago,* Chicago, Cambridge, 1933). Such a development is to be expected on the closing of brothels when at the same time no fundamental alteration of the social pattern is effected: the removal of the controls exercised by the brothel system clears the way for a "vice racket" in which both prostitute and client are exploited by third parties. In the United States strictly business organizations largely took control of prostitution, managing it on a national or regional basis; this, however, was generally true also, though in a lesser degree, of many other abolitionist countries.

By the second half of the 20th century, then, legislators might be confronted with the dilemma of choosing between an abolitionist policy, active support for which was forthcoming from many quarters both religious and secular, and a policy of regulation, arguments for which could be drawn from sad experience. There was thus little cause for surprise whichever policy was adopted: in Dec. 1954, for instance, the Argentine government, despite the contemporary world's general tendency toward abolitionism and in the face of the particular abolitionism of the Catholic Church: authorized the re-opening of brothels. on the ground that their suppression in 1937 had led to an increase of venereal disease, sexual perversion and crime; and less than a month later, in Jan. 1955, a majority in the Italian senate, disregarding the cautionary spectacle that France had just provided. approved Lina Merlin's bill for abolition. which, it was estimated, would involve the closing of more than 700 licensed houses and the planning of "reeducation" for some 4.000 women.

In the U.S.S.R., the bold claim was made that no prostitution exists (*see* H. E. Sigerist and J. Older, *Medicine and Health in the Soviet Union,* New York, Toronto, 1947; E. H. Culver, "An Experiment in Social Hygiene," *British Medical Journal,* London, 1937). No doubt the claim asserted that no brothels or trafficking in the streets existed any longer. While it is difficult to know to what extent the emotional problem had been affected, the legislation and administrative orders promulgated indicated that the problem had been treated very seriously. Before the Revolution, prostitution existed on a very large scale in Russia. The desire of the revolutionaries to abolish it would seem perhaps to emanate from the urge toward female emancipation and equality of the sexes. With regard to prostitution, the Soviet authorities repeatedly emphasized that the war against it should on no account degenerate into a war against prostitutes. It was maintained that the disappearance of prostitution in the U.S.S.R. was due in effect to the changing of the cultural patterns in Russian and Soviet society. The exact meaning of this asseveration is difficult to assess: the U.S.S.R. is a very large country comprising a number of republics, each with its separate codes of law and in a varying stage of development; and in some of these republics tribal customs, in particular those connected with child marriage and with the bride price. would seem to have survived for a long time.

For a detailed account of international activity for the suppression of the traffic in women and children, culminating in the assumption by the United Nations of the "functions and powers of the League of Nations" in this respect, *see* WHITE-SLAVE TRAFFIC.

PSYCHOLOGICAL ASPECTS

The psychiatrists and the psychoanalysts see prostitution as a much wider problem than the lawyers do: they trace its roots to emotional factors. perhaps via economic ones. The theory of instincts in classical psychology differentiates between two groups of instincts: those of self-preservation and those for the propagation of the species. One group represents the interests of the individual. the will to live; the other, the interests of the race, that is, the instinct of reproduction. Prostitution utilizes the latter to satisfy the former. Arthur Schopenhauer, one of the precursors of this school of thought. was of the opinion that in true sexual passion the advantage of the individual is subordinated to the needs of the race. (*Die Welt als Wille und Vorstellung,* 2nd ed., Leipzig, 1844). In the light of this classical theory, Tibor Agoston ("Some Psychological Aspects of Prostitution: the Pseudopersonality," *International Journal of Psychoanalysis,* London, 1945) points out that prostitution would be a deflection of the race-preservation instinct from its original aim, insomuch as sexual intercourse, which theoretically serves the preservation of the species, is carried out for the purpose of earning a living. The psychoanalytic observations respecting prostitution and the prostitute take into consideration factors relating to the instincts which have been classified and described. Edward Glover (*Psychopathology of Prostitution,* Institute for the Study and Treatment of Delinquency, London, 1945) suggests that prostitution is connected with the lack of or deficiency in a love-object: "Promiscuity serves to deny that there was a one and only parental object of infantile love." Agoston also believes that psychiatric experience shows that promiscuousness in prostitution implies an intentional, defiant indifference in the selection of partners: anyone at all will do; the relationship is usually marked by brevity; the partners are contemptuous of each other and remain incognito; and the incognito is fortified by fictitious tales about themselves and their families. It may follow from this "façade" theory that in fact the parties to prostitution act out a phantasy in a manner satisfactory to themselves: unable to face the reality of married life with its everyday pleasures and compromises, satisfaction is found in an imaginary relationship, which either replaces or supplements ordinary conjugal relations. The content of these phantasies may be infinitely varied, from dreams of grandeur to pleasure in degradation.

It is impossible to consider remedies or causes in relation to prostitution till more is known of the emotional problems involved or, indeed, till it is quite clear what type of person is in question. "It is absurd." says Edward Glover, "to talk at large of remedies for prostitution without establishing a reasonably exact classification of prostitutes. For that part, we ought also to have an accurate survey of allied groups. including, for example, the enthusiastic amateur, the gold-digger, the type of individual who marries for money. But if we go so far we might well consider the significance of the dowry and the marriage settlement." There are already many different classifications of the prostitutes who come before the courts in different countries; but further light can be shed on the subject by taking into consideration women who are blatantly promiscuous but should not strictly be called prostitutes as they do not ply their trade openly or for direct reward: the wealthy nymphomaniac, for example. or even any women of substance who refuse to confine themselves to one man. The police do not usually concern themselves with women of this latter type, and indeed it would be difficult to show that money or its equivalent passed to them, even though there would certainly be an element of barter in the sense of gifts or pleasures. That money is a precipitating factor in many cases of true prostitution is undoubted; but the deeper problem of why the particular trade of prostitute is chosen and why many in dire poverty do not take the same course is left unanswered.

The age of prostitutes is worth considering in this connection. The average age of prostitutes is found to lie generally around 27 years of age or perhaps a little younger (*see* Tage Kemp, *Prostitution,* London, New York, 1936; the League of Nations report, *Prostitutes: Their Early Lives,* 1938; L. F. Freed, *The Problem of European Prostitution in Johannesburg* (Cape Town and Johannesburg, 1949). What becomes of the one-time prostitute is a matter that has never been investigated in any detail; but it is generally agreed that the majority of prostitutes do disappear. There is evidence to show that some marry and settle down to a conventional married life; others retire as respectable spinsters. It would be reasonable to conclude that with maturation a greater emotional stability is achieved; on the other hand, the increase in years would result in a loss of attractive power.

No approach can be made to the subject of the prostitution of women unless the counterpart, the men who constitute the demand, is considered. On the whole it is fair to say that one does not cause the other: the inclination must first be present in either party. To speak broadly, there are at least five chief types of men who frequent prostitutes, namely: young men and students in the experimental stage of development; men sexually isolated. whether for a short or for a long time, such as soldiers and commercial travelers; vicious or sexually perverted men; married men with frigid or invalid wives; and the men who have defective love-objects. such as the pimp and the gigolo.

The gigolo is generally of good education. well-dressed and pleasing to women. He attaches himself to older women of wealth, who provide for him, and at the same time carries on relations with others. The pimp, less-educated counterpart of the gigolo, lives on a prostitute's earnings, arranges her work and treats her, generally, with brutality.

It is sometimes said that female homosexuality is linked with prostitution as a cause or precipitating factor. It is difficult to say how much reliance can be placed upon this asseveration. Research workers have records of prostitutes with strong and acknowledged homosexual inclinations; and the opinion that this inclination is developed in a marked degree during terms of imprisonment or confinement in reformatories is notably supported by information gathered from prostitutes in Denmark.

Exclusively male prostitution, that is, the prostitution of males to males, though it clearly falls within the definition of prostitution, is invariably treated as a distinct phenomenon, being altogether inseparable from the general problem of homosexuality.

In conclusion it should be mentioned that Cesare Lombroso and Guglielmo Ferrero were of the opinion that the natural form of regression in women was prostitution, not crime. This point of view might at first seem to be at variance with the main arguments set forth in this article. It does however accord with the hypothesis that in many women sexual activity is a substitute for antisocial behavior—a view supported to some extent by criminal statistics and by many persons who have been associated with female criminals.

PROTACTINIUM, a chemical element, has the symbol Pa, atomic number 91 and chemical atomic weight 231.05. It is the second member of the rare-earthlike transition series, the actinide series, which includes the elements of atomic numbers 89 to 103 inclusive, and in which an inner electronic shell (the 5f shell) is being filled, but it also resembles tantalum in its chemical properties.

The first isotope (mass number 234) was discovered in 1913 by K. Fajans and O. H. Goring, who named it "UX_2" or "brevium." The long-lived isotope. Pa^{231}, was discovered by O. Hahn and L. Meitner in 1917, and independently by F. Soddy and J. A. Cranston at about the same time. The name for this isotope, protactinium (progenitor of Ac^{227}), has now been generally adopted for element 91. Over a dozen radioactive isotopes, natural and artificial, are known, of which Pa^{233} is of especial interest as the progenitor of fissionable U^{233} produced by the absorption of neutrons in thorium.

The isotope Pa^{231} (half life 34,300 years) is a member of the natural. $4n+3$, radioactive family and exists in uranium ores to the extent of 0.34 parts per 1,000,000 parts of uranium. Using this source the first pure protactinium was isolated by A. V. Grosse and others in 1934. Protactinium can also be synthesized in quantity by irradiation of ionium (Th^{230}) with neutrons from nuclear reactors.

Metallic protactinium is quite electropositive. The element displays the tetrapositive and pentapositive oxidation states with an estimated potential of $+0.1$ volts for the $Pa(IV) \rightarrow Pa(V)$ couple. The former state behaves like the other tetrapositive actinide elements in aqueous solution and in the solid compounds. The pentapositive state undergoes hydrolysis so readily that it is extremely difficult to keep in acidic solution. and complexing agents such as fluoride ion are often used for this purpose. Included among the identified solid compounds are Pa_2O_5, PaO_2 (and intermediate oxides), PaH_3, PaF_4, $PaCl_4$, PaOS, and probably $PaBr_4$, PaI_4, PaN_2, PaF_5, $PaCl_5$, $PaBr_5$ and PaI_5. (G. T. SG.)

PROTAGORAS (*c.* 490–after 421 B.C.), of Xbdera in Thrace, was the first and the most famous of the Greek sophists. He is a principal character in Plato's Protagoras. His work entitled Truth began with the statement "Man is the measure of all things," which was probably intended to express the relativity to the individual of all perceptions and, as some hold, of all judgments as well. In *Concerning the Gods* he professed agnosticism as to whether the gods exist or not. Several other writings of his are listed, and he was perhaps the first to study grammar systematically. He professed to teach the art of politics and, as a friend of Pericles, had considerable success in Athens, exercising a great influence over contemporary thought on moral and political questions.

For iragments and testimonia *see* H. Diels and W. Kranz, *Fragmente der Vorsokratiker,* vol. ii, 7th ed. (Berlin, 1954). *See* also M. Untersteiner, *The Sophists,* Eng. trans. (Oxford, 1954). (G. B. KD.)

PROTEACEAE, a family of dicotyledonous plants comprising about 50 genera and some 960 species. of which about 600 are Australian. including the silky oak (*Grevillea robusta*) introduced into Ceylon for shade and timber, the Queensland nut (*Macadamia ternifolia*), cultivated in Hawaii, California and Florida, and the Australian honeysuckles (*Banksia*); there are about 260 species in southwestern Cape of Good Hope, including the silver tree (Leucadendron argenteum); the remaining species have a wide but irregular distribution in Asia, Africa, America and Australasia. Most of the species are trees or shrubs, and the majority are xerophytic (*i.e.,* inhabit arid country).

PROTECTION. By protection in the restricted sense is meant the use by the government of special forms of regulation or restraint, particularly import duties and analogous fiscal expedients, in order to encourage or to maintain essential industries which are endangered by foreign competition. The free-trade theory assumed that every man knew his own interest better than anyone else did; that everyone would follow his own interest rather than the interest of anybody else; and that the interest of the individual coincided with the interest of the community. On these assumptions rested the whole doctrine of *laissez faire* (*q.v.*). Society was an aggregate of individuals assumed to be equal to one another in the competitive struggle. Protection, on the other hand, involved a different conception. There was the interest of the individual. the interest of trade and the interest of the commonwealth. The last was the most important. On the free-trade theory the government should not interfere by tariff or other regulations in order to foster trades which did not make their own way in the competitive struggle, or to direct existing trades into channels in which they did not flow under purely individualist conditions. Insofar as such attempts were successful they involved loss to the whole body.

The country practising free trade was realizing "natural" conditions; tariffs or other regulations which interfered with such conditions were artificial, imposing obstacles in the way of the free movement associated with the "natural" state. Protection was therefore prejudicial to the realization of the greatest prosperity. A reversion to protection as a policy involves not merely the sporadic use of tariffs in order to safeguard particular industries, but a conception of the state. To the free trader wealth is the end in view; to the protectionist wealth is the means. The real end governing the policy of protection may not be economic at all in the narrow sense. but may be national or imperial solidarity and power. though undoubtedly a protectionist holds that while the free-trade policy may lead to the greater wealth of individuals, the protectionist policy. properly administered, will bring about a balance of economic activities, involving a higher maximum of efficiency to the community as a whole and a more equitable distribution between the economic groups.

If agricultural enterprise under free competition and free trade could not be made to pay, the free trader would abandon it and concentrate on those industrial activities that under such conditions are more profitable. The protectionist on the other hand would argue that this is a shortsighted view. In the first place agriculture is necessary to the state for its security. the maintenance of a healthy population and many other purposes not directly and immediately economic. But more than that, the protectionist would say that it is absurd from the economic point of view for a country to sacrifice its agriculture. for agriculture is the guarantee of a large home market for the country's manufactures, and the large and expanding home market is the best security for the successful exportation of manufactures. Given the home market, continuous running of the manufactories, and the proportionate reduction of the burden of standing charges, cheapens cost of production and makes possible easier entry into markets abroad and a higher remuneration for the workers at home. The free trader would say that if an industry does not pay its way under a policy of free importation, it is better that the capital employed in that industry should be invested in some other branch of economic activity which is remunerative; that the artificial maintenance of such an industry by the imposition of protective tariffs is an economic loss to the community. The protectionist would point out that the capital of such a depressed industry cannot be transferred to another industry, that capital is in the concrete form of factories and workshops and machines and many other forms which cannot be realized if the industry has fallen. It may indeed be desirable in certain circumstances to abandon it, but such a question cannot be decided without weighing carefully the number of persons employed, the possibility of their finding employment in other industries, the place of the industry in the national life, its relation to other industries in the scale of production. the possibility of obtaining its products in a suitable manner from other sources, its bearing on national security, and many other considerations of the highest importance. The free trader would not use tariffs or other artificial means for establishing in a country a new industry not hitherto practised. If such an industry were not likely to develop as the result of the unaided efforts of individuals, the free trader would not use government aid to promote it. The protectionist would consider the resources available in the form of raw materials, the possibility of acquiring the necessary skilled labour, the available organizing ability, the demand for the products of such an industry at home and the accessibility of markets, and if the prospects were favourable would not hesitate to impose a definitely protective tariff with the intention of encouraging the industry in view, even though for a few years it might involve higher prices to consumers at home, and he would do that all the more readily if there was plenty of capital for investment in the country for which he was responsible.

The Fall of the Old Policy.—In the middle ages the source of England's wealth was the exportation of raw materials, with which it purchased the manufactures and the luxuries of other countries. In those ages many of the regulations adopted were not. as they have been regarded by free-trade writers, restraints upon liberty, but the conditions of its exercise. Freedom is only possible where there is security. Before the close of the middle ages manufactures were greatly extended as a result of encouragement, by the native aptitude of the people and by the immigration of skilled artisans. Movements analogous to those of modern times took place on a small scale, and there were signs of a growing nationalism long before the close of the middle ages. Action taken by the trading companies, especially the great Merchant Adventurers company, encouraged foreign trade, and we can trace in numerous statutes the foundations of what was subsequently called the mercantilist system. Then took place a development not dissimilar to that in continental countries in modern times. Internal barriers were removed. England and Scotland were united. Great Britain and Ireland became one economic area. By that time the United Kingdom, under the policy which was so widely condemned later on by economists, achieved economic supremacy. With apparently illimitable supplies of coal and other requisites of production. Britain's industries growing by leaps and bounds from the use of new inventions, the whole organization and structure of great industries rapidly changing, the old laws and methods of regulation became obsolete, and the tariffs worked out to suit the more primitive stages of industrial development were simply embarrassing or irrelevant in the new conditions. Attempts to adapt them failed and the old duties were swept away. It might have been more statesmanlike and prudent to keep at least the framework of the old system, but with wealth as the supreme end in life and with the opportunities which the new industrialism gave. this was the accepted course of contemporary statesmen. By 1860 free importation mas the established policy of the country and the methods by which English statesmen had built up the economic power of the country were remembered simply as the economic fallacies of a former generation.

The Mercantile System in England.—The older policy was not protection in the narrow sense in which the word has been used in modern controversy. The idea of building up a great industrial commercial state by that policy ran through most of the economic measures which were adopted, affecting agriculture. trade and commerce. commercial treaties, finance, labour legislation. the poor lams and colonial policy for several generations. and discriminating duties were imposed not from logical necessity or through loyalty to some theoretical system, but as practical expedients like any other form of regulation to deal nith problems as they were at the time understood. Whole trades and branches of trades were left free. The mercantilism of England was always different in important respects from the Colbertism of France (see COLBERT, JEAN BAPTISTE) and the tariff systems, generally, of continental states. Adam Smith comments on the "liberality" of English policy as contrasted with that of other states. It was a "free-trade" system in (1) its extension of the powers of the central government over the trade and industry of the country at the expense of local and sectional bodies. close corporations. etc.; (2) the consequent equalizing of opportunities and development of free enterprise; (3) the "nationalizing" of great trades such as the East India trade. the trade of the Levant, etc.; (4) the removal of internal restrictions, such as those on the corn trade; (5) the introduction of free trade first between England and Scotland and then between Great Britain and Ireland.

The term "free trade" was used in many different senses in contemporary literature and practice, but scarcely at all in its modern sense. It was applied to the freedom of intercourse between states as secured by treaty, to privileges granted to alien traders by which they were put on equal terms with the denizens of the country. It sometimes suggested illegality, piracy and unfair avoidance of established regulations; it mas applied to the "interlopers" who carried on free trade with no regard to the regulations of the chartered companies. and to the smugglers who escaped the payment of duties levied by the state. In modern times free trade does not necessarily involve the meaning applied to it in England. but the policy of free exchange and the levelling of conditions by means of a tariff or other regulations to secure equality of competition between the countries concerned. Free importation in the modern English sense is peculiar to England, just as in England the term protection has come to be restricted in its application to the imposition of duties. It is also to be noted that the role played by the colonies under the mercantile system was roughly that which Richard Cobden (q v.) and his followers expected both colonies and foreign countries to play when the United Kingdom adopted free importation, and if the mercantilists sometimes imposed special regulations to direct colonial trade into channels considered favourable for the development of the mother country, the adherents of the Manchester school not infrequently used the power and influence of England to keep the economic activities of neutral and eastern countries in a stage considered favourable to the interests of British industry and to prevent the due expansion of those countries on lines more in accordance with the wishes of their people and the national resources.

There is a further distinction between the older system and Cobdenism. Both were forms of national as distinct from imperial policy, but under the former'the colonies had a great part to play. They were in a position in relation to the United Kingdom entirely different from that of foreign countries, and the system of preferences which then existed would have lent itself to the building up of the empire. Under the Cobdenite system the colonies had no part to play at all different from that of foreign countries, and the "interests of the consumer" took the place of the "interests of the commonwealth" as the basis of public policy. The older system looked forward, as it were, to the establishment of a great empire. Cobdenism was not really internationalism viewed from the point of view of British policy, but nationalism in a narrow. insular sense and the policy of England under its influence was based upon the economic monopoly secured by the rapid progress of invention. The influence of the new industrialism broke the cautious continuity of British policy. Sir Robert Walpole and William Pitt revised the fiscal system by removing duties on raw material and reducing other duties with the view to increasing revenue. William Huskisson revised the fiscal system in much the same spirit. The measures throughout this period were more in accordance with the cautious and statesmanlike line of Adam Smith's *Wealth of Nations* rather than with the later economists. If this movement had not been interrupted England would probably have retained the means of conducting international negotiations for consolidating the empire and providing a mide basis for revenue without any violent changes. but under later influences the policy of free importation was carried to extremes. People pursued the logical consequences of free trade rather than the practical interests of the country. The free traders on the one hand and the protectionists on the other were in violent and direct opposition on grounds of abstract theory rather than practical policy. But there is no important economist of the free-trade school uho does not admit important exceptions to the doctrine of free importation. The idea that all economists of that school were Cobdenites is without foundation. Reference has been made above to Adam Smith and his cautious attitude, but the great classical economists fairly generally admitted cases in which duties on imported manufactures might be desirable. Allowing therefore for the very different philosophical conceptions which were the basis of economics at that time and the very different economic conditions which prevailed, there is not so much to distinguish the attitude of the writers of the early part of the 19th century from those of the early 20th century in regard to practical policy as may be thought from manifestations of feeling during the fiscal controversy. The views of economists must be distinguished from the use made of them by political and social controversialists. The Ricardian theory of rent (*see* RICARDO, DAVID). the high prices and the practical difficulties of the times gave such people magnificent opportunity for working up a crusade against landlords, and the free-trade movement, which at first had been a most reasonable and proper effort to get rid of tiresome obsolete restrictions, became in the hands of extremists an instrument of social and political revolution. It is in England especially that the free-trade movement was directed mainly against the landlord class and later on the capitalists, and it has grown by natural stages into the socialistic movement of modern times, while protectionism in all its branches has been more identified with methods of creating an industrial and commercial state of the modern type

The qualifications of the free-trade doctrine admitted by John Stuart Mill went far to undermine the whole basis of the doctrine. His famous admission in regard to infant industries of a new country could be made to cover a very large proportion of the protectionist expedients adopted in later times. The economic conditions and the rapid growth of the United States in the 19th century naturally made an immense impression. It was necessary to work out an explanation for such progress under an economic policy so different from that of England. But historically speaking, analogies to the development of the United States policy could be found the uorld over. The word "new" in regard to industry cannot be confined in its application to the historic position of a country or an industry. It must apply to the stage of organization of particular industries and if it is once admitted that a high tariff is justified from that point of view. the tariff policy of Europe during the 19th century finds much justification from the writings of the economists. But the admission could easily be extended to cover many other important steps of policy. The case may be taken of the country whose industries have been actually devastated by war or destroyed in the sense that the existing organization for production has broken up, markets lost by the diversion of great works into activities for which they were not built and where vast works of reconstruction are required to bring them back to the peace efficiency which they once had. On Mills' admission it is difficult to deny the claim for protection while reorganization is being carried out. The question becomes a matter of practical expediency. Obviously the policy to be pursued cannot be decided on purely abstract grounds.

The German Zollverein. — The most remarkable instance in modern times of the constructive use of a protective tariff in the building up of a great empire is to be found in the history of Germany. At the beginning of the 19th century Germany consisted of a number of small states each enjoying fiscal autonomy, separated from one another by customs frontiers, and. after the Napoleonic wars, German statesmen and economists saw that if national industries were to be established on a modern scale, these numerous areas would have to be unified. Standing alone and more or less isolated economically from their neighbours. they could not get the full advantages they could obtain in production by the development of their materials from their numerous population and from their mutual commercial relations. Germany had to choose between a large-state and a small-state policy, and Prussia began the work of organization by the adoption of the tariff of 1818. Internal tariffs in the provinces of Prussia were swept away. Prussia as a whole was given protection against all external competitors, and other German states were invited to enter into union with it. The result of this movement was the formation of the Prusso-Hessian *Zollverezn.* This was followed by the *Zollverezn* between Württemberg and Bavaria and other combinations These combinations were then brought into union and the first treaty of the *Zollverezn* was adopted in 1834. The larger part of Germany thus became more or less a homogeneous economic area, except for a survival of a number of internal duties which it took many years to get rid of. The treaties mere in the first instance for 12 years. By the end of the first period other states had acceded and so the process went on until the German *Zollverezn* was completed. The *Zollverein* was not corerminous with the German empire, but it was the condition and the means by which the German empire mas created.

This movement was not understood in England, mhcre it was regarded as protectionist in the narrow sense in which the word was used in English controversy. There were gloomy prophecies as to uhat would happen to Germany and what would happen to the trade of England with Germany. In fact the German movement was not dissimilar from that extending over a long period during which the economic union of England, Scotland and Ireland was effected, and many internal barriers were swept away. The formation of the *Zollverein* brought about freedom of trade over a vast area, and its trade was protected against foreign competition by a carefully devised tariff around its external frontier. It is obvious that the Internal union could not have been secured without the external protection. The German tariff and the internal organization were necessary parts of the same movement, and the tariff organization was supplemented by great schemes of reconstruction affecting every aspect of German life. The progress which followed the movement is without parallel, and the German empire became the most powerful competitor in the world with other countries. This feat of statesmanship was all the more remarkable as it was carried out in the teeth of British competition. When Great Britain entered upon an era of rapid commercial progress. it was first in the field with the inventions which revolutionized industrial processes and had the manufacturing monopoly of the world. Germany at the beginning was technically behind Great Eritain. but there was one great help to its progress. Just when Germany was applying on a vast scale the principles of policy which had made Great Britain mistress of the world, that country turned its back on its own traditions and made a free present of its market to any country which could exploit it. The rapid industrial progress of Germany was undoubtedly partly due to the fact that German exporters had free entry into the English market for their goods. Eefore World War I, it was quite common for great German factories to be planned, erected and organized on the basis that they could always dispose of their surplus production in the English markets to an advantage at any price they could fetch.

This illustration from Germany is given in order to show how misleading was and is the practice of abstract English free traders of grouping the commercial policies of the world under two categories. free trade and protection. Nor is it enough to say that the actual policies are a combination of both theories. The actual policies of countries are the expression of the living activities of great societies as they have been determined by their long history and the powers and functions which they have developed, and they never follow the lines of an abstract theory divorced from the facts of that development. Moreover, the development of large-scale production at this period tended to alter the structure of economic activity so as to remove all trace of those free and perfectly competitive conditions without which such theories cannot become a reality. Many German students for years before World War I studied very carefully the course of events in England in order to avoid the mistakes that were being made there.

The growth of the *Zollverein* brings into clear relief the mutual relations of the measures adopted in carrying out a great policy of economic nationalism, and the conditions under which such a policy can be achieved. Internal fiscal differences have to be swept away as far as possible. and that required the provision of some alternative means for furnishing the revenue which in the first instance has to be sacrificed. So a tariff against external countries is organized and the development of means of direct taxation developed. The process further involved a policy for application to the means of communication, especially the railway system and transport by sea. In all these processes there was necessary some political reorganization. The small states had to sacrifice their autonomous fiscal powers when they entered into the new union. The *Zollverein* on the German model could not be achieved without such sacrifice, a condition which could not have been realized in the British empire where the dominions would certainly not have given up their fiscal autonomy.

The German measures could not be carried through without social reorganization and mainly under the influence of the German Zentrum party and their arrangement with Bismarck a whole code of new social laws was evolved. To enlarge still further the economic borders and to bring fresh markets on the continent within their ambit, the German treaty system was developed. Later on in order to meet the economic pressure which followed from their rapid development, Germany pushed into a colonial policy; and the exigencies of diplomacy, quite apart from the necessities of defense, forced Germany into a naval policy, and the German navy was established. Thus the German empire was gradually forced to adopt in a modern form all the leading characteristics of the old English national system, and the instrument by which these changes were brought about was the German tariff. This immense constructive movement, the greatest example we have of modern economic nationalism, obviously cannot be described as simple protection. It was a great scheme of organization in which for one purpose or another the German tariff had to be used as an instrument. (W. A. S. H.)

The Modern **Attitude** Toward **Protection.**—After World War I, the trend toward protection mas pronounced all over the world. This arose not primarily from the conscious adoption of any theory of economics, but as a by-product of the rising tide of nationalism especially in evidence in the small states created as a result of the dissolution of the Austro-Hungarian empire and the defeat of Russia. Free trade seemed now to belong to a dim past, to the age when passports were unnecessary to travel and the passage of ideas across national frontiers was unimpeded by propaganda ministries.

In the 1920s new factors came into play that had the effect of changing beyond recognition the terms in which the old controversies over international trading policies had been conducted. Competitive capitalism had developed to a point at which regular alternation between world booms and world slumps began to be regarded as a feature of its normal functioning. and at which the attainment of some degree of security against these fluctuations began to be a principle preoccupation of every government in the world. The demand for economic planning became strident everywhere, and. because of the strength of nationalism, it was inevitable that the unit of planning should be the national state. It became a general practice to seek to protect domestic industries by imposing high tariffs against the dumping of cheap goods from abroad. The result was a steady and general progress toward autarchy or national economic isolation. Freedom from the contaminating influence of foreign finance, and the patriotic duty of buying in one's own country, were essential themes in all the great revolutionary and counter-revolutionary movements of the time.

At the same time, however, the ancient free-trade doctrines retained a considerable measure of prestige, beginning to emerge in a somewhat new form: although it was no longer possible to preach the virtues of absolute freedom of trade, it was still possible to condemn the practice of trade discrimination, and this condemnation was heard with particular force from the United States which, itself protected by high tariff walls, was preoccupied with the problem of getting foreign outlets for its surplus production and accordingly anxious to prevent the exclusion of its goods from any part of the world as a result of the emergence of regional economic groups based on mutual trading preferences. Controversy now raged not over the relative merits of protection and free trade but over those of discriminatory and nondiscriminatory trade. In 1932, the famous Ottawa agreements introduced a measure of reciprocal preferential trading between the member states of the British Commonwealth, aimed at protecting them from some of the worst hazards of world competition. These measures aroused bitter criticism from the advocates of nondiscriminatory trading, and attempts to emulate them elsewhere were frustrated. The choice which the exclusion of reciprocal preferences left seemed to be between high national tariff applying indifferently to all the foreign producers of the commodity taxed, and low national tariffs opening the domestic market to the full rigours of foreign competition. Since total economic isolation was not a practicable course of policy for anyone, the tendency was for states anxious to achieve economic security to pursue that end by political conquest aimed at creating economic empires large enough to be viable on a basis of isolation. Such, for example, was in part at least the explanation of Japan's aggressions in the 1930s, and later of Italy's and Germany's. Hard-pressed states also tried to bypass the tariff question altogether by instituting a direct governmental control of foreign trade. By means of official bulk purchasing and the strict control of foreign exchange operations (practices associated with the name of Hjalmar Schacht. the economic magician of Nazi Germany), it was possible for a nation to govern the direction of its foreign trade without recourse to the use of tariffs.

World War II again changed the problem fundamentally. In the first years of peace, the persistence of direct economic controls in most of the belligerent countries made tariffs largely irrelevant, because without recourse to them governments had the power to limit and direct foreign trade. At the same time, European dependence on the U.S. inclined Europe toward the acceptance of U.S. views on international trade. The U.S. (see below) continued to work for the reduction of tariffs everywhere, but it now sought to encourage planned international economic co-operation through the careful planning of production and finance. Large free-trade areas in which stability would be maintained by making finance available to counter slumps and by encouraging the planning of production under the auspices of supranational authorities but without necessarily taking ownership out of private hands was the current recipe of liberal capitalism. The extent of international. economic interdependence made the case for high protective duties increasingly difficult to sustain. The emphasis was switched from the negative idea of protecting markets against foreign competition to the positive idea of maintaining a high and stable volume of international trade. Critics of this liberal capitalist recipe demanded international planning on a basis of direct governmental control, on a basis, in short, of socialism. There remained some advocates of the preferential tariff as a means of combining stability with flexibility, but, like the classical advocates of free trade, they apparently belonged to an almost extinct tradition.

UNITED STATES

As the American economy developed from a colonial economy to the world's most powerful industrial machine, the factors influencing tariff policy changed substantially in importance. Revenue considerations lost much of their force as the share of customs in the general revenue of the federal government fell from about 90% as late as the 1850's to 7% by mid-20th century. The development particularly of the federal reserve system in 1913 eliminated mcnetarp and cyclical aspects of tariff policy which at times had conflicted with the protectionist aims of tariff advocates: before the creation of an efficient central banking system, the possible deflationary pressure of a budget surplus could be eliminated only by a reduction of the most important tax. the tariff. Even the protective alms proper have changed from the days when the tariff was intended to speed the development of the young economy to the protection of minor individual producer groups. Finally, as purely econoinic considerations declined, political factors increased in importance. Particularly after the end of World War II, the needs of foreign policy and of strengthening the countries of the free world through closer economic ties with each other and with the United States increasingly became paramount considerations.

Until 1816 revenue considerations dominated tariff-making. The period 1816–32 saw vigorous protection for rising young manufactures, followed by declining protective duties until 1860. From the Civil War to 1934, the United States followed a consistent protectionist policy, interrupted only by the relatively moderate Wilson and Underwood tariffs of 1894 and 1913. With the Trade Agreements act of 1934, a new period of trade liberalization started which was somewhat modified after 1948.

Before the U.S. constitution was adopted customs were a prerogative of the states. When congress met under the constitution, the first bill introduced in the house of representatives was a measure to provide revenue by means of a customs tariff. Though there clearly was also a nillingness to use the tariff to encourage domestic industries, the rates enacted were low (in general only 5%) with specific duties on certain articles selected for special encouragement. During the 20 years following. the European wars created a great foreign market for American raw products, and made shipbuilding and shipping highly profitable, particularly in New England; thus there was little growth in U.S. manufactures and no appreciable increase of protectionist sentiment, despite the strong argument for protection put forth in Alexander Hamilton's *Report on Manufactures* (1792). As more revenue was needed, tariff rates were raised, but with no special attention to their protective aspects, and down to 1816 customs duties were only remotely protective.

The Embargo and Non-Intercourse acts of 1807 and 1809, however. and the War of 1812 with England cut off a large part of exports and imports. Small manufactures sprang up to meet pressing needs. Financially weak and often ill-equipped, they were in no position to meet the competition of the more-advanced British manufactures on the return of peace. The tariff legislation of 1816 was designed to raise revenues as well as to aid manufacturers. Nevertheless, this measure embodied only moderate duties, running as high as 25% on textiles. for three years only with a provision for minimum valuation. Though bad crops in Europe kept farm prices high for a time, the farmers too found themselves in difficulties after the crisis of 1818–19, and their thoughts turned toward the possibility of a home as opposed to a foreign market. These conditions led after 1819 to an agitation for internal improvements and a vigorous protective movement which aimed to insure national self-sufficiency by encouraging young manufactures and affording the farmer a home market. This so-called "American system," popularly identified with the name of Henry Clay, its foremost spokesman, had its early strength in the middle and western states. New England at first holding aloof because of its predominant shipping and commercial interests. As industrialization proceeded. however, New England swung over, and from the latter part of the 1820s that section became a foremost advocate of the protective system, which Pennsylvania had favoured from the first.

In response to the demand for protection, congress passed the Tariff act of 1824, raising the duties on textiles, and also on iron, wool, hemp and other articles of particular interest to the middle and western states and to the farmers. Agitation was renewed after the crisis of 1825–26, culminating in the celebrated Harrisburg convention of 1827. In the following year, as a result of extraordinary political manoeuvres, the so-called "tariff of abominations" was enacted which sharply increased rates, particularly on wool, and on other goods whose protection was especially distasteful to New England. Four years later a new act put the tariff into a form satisfactory to its friends. Goods not produced domestically paid low rates while textiles, iron and other articles which it was desired to protect paid high ones. Thus woollens were taxed 50%, while the specific duty on rolled bar iron at 1832 prices was equal to 95%.

The southern states, being without manufactures, were interested chiefly in cotton exports. Realizing that protection worked to their disadvantage, they had from the beginning sharply opposed it. The opposition became so fierce that South Carolina undertook to nullify the act of 1832. The firmness of Pres. Andrew Jackson maintained the federal authority. Southern opposition, however, led to the compromise tariff of 1833, providing for a reduction of duties over a period of 10 years, until in 1842 no rate should exceed 20%. Manufactures were in fact well established by 1832 and interest in the tariff waned, while other questions, such as internal improvements and slavery, came to occupy public attention. The final low rates of the act of 1833, it so happened, were in effect only two months, since the Whig party in 1842, for political rather than economic reasons, but in part also to raise more revenue, passed a new high-tariff measure. However, with improved business conditions, revenue increased and in 1846 the moderate Walker tariff was passed which reduced rates substantially. In 1857 a redundancy of revenue led to further reductions from 30% to 20% for the most important articles. The act of 1857 marked the lowest level of protective rates since the beginning of active protection. Under the circumstances then existing, the reduction of duties commanded general approval even among the manufacturers. Farmers and manufacturers alike turned to means other than tariffs to insure their prosperity and no real or supposed national interest was successfully invoked to stay the growing movement toward freer international trade. A revenue shortage following the crisis of 1857 occasioned the enactment of the Morrill tariff of 1861, framed to attract protectionist votes to the Republican party in the campaign of 1860. Undertaking only to restore the rates of 1846, its authors yet thought to give added protection to Pennsylvania and the western states by changing ad valorem to higher specific duties and by raising rates on iron and wool. Even so, the measure belongs essentially to the period of tariff liberalization beginning in 1833.

Civil War.—The Civil War brought profound industrial changes and gave a new direction to tariff policy. Hitherto customs duties had been virtually the sole source of government revenue. The needs of war finance required an elaborate fiscal system of which the imposts on liquor and tobacco remained as a permanent and highly important part, thus affording legislators somewhat more leeway to deal with customs duties without primarily budgetary considerations. The heavy taxes imposed on many commodities by the internal revenue acts of 1862 and 1864 were naturally accompanied by corresponding increases of import duties. Since those who framed the laws were protectionists, almost any duty asked for was granted. The tariff structure, "in many ways crude and ill-considered," establishing "protective duties more extreme than had been ventured on in any previous tariff act," to quote a leading authority, was originally designed to meet the war emergency. At the end of the war, however, the structure, instead of being rebuilt, was preserved practically intact, and with relatively minor modifications continued to serve as one of the two pillars of federal finance down to 1913.

Post-Civil War Period.—After the war, the internal revenue taxes, except those on liquor and tobacco, were promptly swept away, but the protected interests successfully resisted the reduction of tariffs. The demand for tax reduction and tariff reform was met in 1870 by lowering the rates on pure revenue articles like tea and coffee, while actually raising certain protective duties, including those on steel rails and nickel. Two years later it became necessary to reduce revenue. Fearing worse things, the protectionists consented to a horizontal 10% reduction of all duties, on condition of the entire repeal of the nonprotective duties on tea and coffee. When more revenue was needed in 1875, the 10% was easily and quietly restored. The high mar rates on wool and woollens had been raised yet higher as early as 1867 at the instance of certain woollen manufacturers and sheep breeders represented in the Syracuse convention; and the elaborate scheme of classified duties on wool, together with compound specific and ad valorem compensating and protective duties on woollens introduced in the Morrill act, had been further developed. Similarly, the Lake Superior copper producers succeeded in 1869 in getting congress to raise the duties on copper ore and ingots. In 1870 the 45% duty on steel rails was changed to a slightly higher specific duty of $28 a ton. Rail costs fell rapidly, and by 1877 this amounted to almost 100%. The small number of American companies owning the Bessemer patent made enormous profits and expanded their business rapidly.

In 1883 a redundant revenue compelled a reconsideration of the entire situation. A tariff commission made up of protectionists on the whole recommended reductions, but little attention was paid to it. The protectionist forces in control of congress managed to get rates raised on goods which continued to be imported despite the existing protective duties—such as fine woollen cloths and dress goods, cotton hosiery, laces and embroideries, iron ore and various special manufactures of steel—while duties were lowered chiefly in cases in which the new rates were as prohibitory as the old, such as cheap cottons, steel rails and copper. The act made no fundamental change in the protective system. Tariff discussion continued, and Pres. S. Grover Cleveland's annual message to congress in Dec. 1887, urging general tariff reduction, particularly on raw materials, made protection the outstanding issue of the campaign of 1888. The Republicans won and proceeded accordingly to make the tariff more highly protective. The McKinley act (1890) raised the duties on wool and woollens, as well as on such cottons as continued to be imported. Linens went up sharply. and velvets and plushes of all sorts were charged high rates in an effort to establish a new industry. With the same purpose, tin plate, which had been entirely imported, was charged 2.2 cents a pound. It was, however, to be admitted duty-free after 1897 if the tariff failed to provide substantial domestic production. The duty of two cents a pound on sugar was repealed and domestic producers, who supplied only a tenth of consumption, were given a two-cent bounty instead, the two measures together taking something like $60,000,000 a year out of the treasury. The whole act was a distinct extension of the protective system.

Tariff Changes Under Democratic **Administrations.**—In the two succeeding political campaigns the Democrats, returned to power, pledged to reduce tariffs. Party quarrels over the silver question, however, together with the narrowness of the party majority in the senate and the determination of certain Democratic senators to maintain protection for particular interests, resulted in the emasculation of the tariff measure passed by the house, and the Wilson act of 1894 was allowed to become law without the president's signature. Even so, it constituted a break in the series of increasingly protective measures enacted since the Civil War. First, and most important, wool was made free, and the complicated duties on woollens were replaced by simple ad valorem duties, which, however, afforded the manufacturers as much protection as they had enjoyed under the McKinley act. Rates on the finer cottons and on iron and steel were lowered somewhat, and the rate on tin plate was cut in two. Coal and iron ore, as raw materials, were made free by the house, but the senate restored both to the dutiable list, though at reduced rates. The great battle was waged over sugar; the outcome was a duty of 40% ad valorem on raw sugar, and of 40% plus one-eighth of a cent a pound, plus an extra tenth of a cent a pound on sugar coming from any country that gave an export bounty on refined sugar. This result was commonly regarded as a victory for the "sugar trust" and a violation of party pledges. The measure as a whole was a great disappointment to the tariff reformers.

Dingley (1897) and Payne-Aldrich **(1909)** Acts.—The money question carried the Republicans back into power in 1897, but political conditions made monetary legislation impossible, and Pres. William McKinley called congress in extra session for the sole purpose of tariff revision. The Dingley act was passed without delay, restoring essentially the system of 1890. The wool and woollens duties of that year were re-established, with some changes, mostly upward. Specific duties, even higher than the previous high ad valorem ones, were laid on silks and linens. The farmer got a duty on flax, and the ranchman, for the first time in 25 years, a tax on hides. As the iron and steel industry was largely beyond reach of foreign competition, rates were left in good part where they had been put in 1894, but certain imported specialties, such as razors and cutlery, were raised by changes in classification, while tin plate was given rates little in advance of those of 1894. Rates on raw sugar were pushed above those of the Wilson act, thus at once increasing revenue and giving added protection to the beet-growing industry, and the refiners kept the one-eighth of a cent differential of 1894. The Dingley act thus gave up no part of the protective structure of 1890, and at a number of points extended it beyond its previous limits.

The rapid growth after 1898 of industrial combinations, popularly supposed to be special beneficiaries of the tariff, the rise in the cost of living, along with the restiveness of the middle-nest farmers and the growth of manufactured exports combined in putting the protectionists on the defensive. The Republican party, accordingly, in the campaign of 1908 enunciated the "true principle" of protection, that duties should equal the difference between cost of production at home and abroad. The Payne-Aldrich act of 1909, however, was written along the same lines as its predecessors, without regard to the "true principle." The house committee proposed to admit coal, lumber, iron ore and hides free. Hides were freed in fact, the other materials merely paid reduced rates. Important upward changes were made in the textile schedules, as in the rates on mercerized cotton, cheap hosiery and silks. The iron and steel duties, most of which had long since become ineffective, were generally reduced; but razors, pliers, cheap cotton gloves, asbestos fabrics and other particular articles whose claims were effectively presented by their producers to the legislators mere given added protection. Figs, prunes and lemons were protected. The act brought no substantial modification of the protective system, but the whole tone of its supporters indicated inability or unwillingness to push much further the aggressive protectionist policy of the 1890s.

The backhanded reciprocity provisions of the acts of 1890 and 1897, authorizing the president to retaliate against countries discriminating against the United States. were omitted from the act of 1909. Instead, the rates of 1909 were declared the minimum tariff and those rates plus 25% (of the value of the goods) the maximum. After March 31, 1910, the maximum rates were to go into effect automatically, except in the case of those countries where the president had satisfied himself that "no undue discrimination" was exercised against the United States. The administration managed to avoid the imposition of the maximum rates, though tariff wars with France, Germany and especially Canada were narrowly averted. The president also construed a provision of the maximum and minimum clause as authorizing him to appoint a tariff board, which proceeded to make studies on the basis of the "true principle," the moderate protectionists believing that its findings might serve as a second line of defense against the reduction of genuinely protective duties. The same moderate group, under the leadership of Pres. William Howard Taft, was eager to do something for the export manufacturers, whose interest in foreign markets had been recognized in the act of 1909 only in the ill-judged maximum and minimum provisions. A measure was accordingly driven through congress, against the bitter opposition of the extreme protectionists. approving a treaty for a moderate measure of reciprocity with Canada, and freeing wood-pulp irrespective of Canadian action. To the disappointment of the moderates, Canada rejected the treaty.

Woodrow Wilson's Administration.— The year 1913 found the Democrats in control of the presidency and of both branches of congress. Pres. Woodrow Wilson promptly called congress in special session, and a new tariff measure was enacted which was widely hailed as marking the beginning of a new era in U.S. tariff policy. Announcing the principle of a "competitive tariff," and declaring their intention to injure no "legitimate industry," the party in power yet proceeded to a downward revision looking to definitely moderate protection. Wool was admitted free; and woollens after Jan. 1, 1914, were to pay a straight ad valorem rate of 35%. Sugar, the duty on which; with the growth of the beet industry, had become a protective one, was to be free after May 1, 1916, by which time the newly enacted income tax was expected to yield income effectively. Cottons were sharply reduced; though most of the reductions were nominal the new rates meant the probability of increased imports of the finer goods. Silks were cut somewhat, though the general rate was still 45%. Coal and lumber were freed, and leather and boots and shoes followed hides to the free list. Iron ore and crude iron and steel products likewise were made free, and rates were cut to a maximum of 20% on the advanced products. To meet the farmers' wishes, agricultural implements, by a harmless gesture, were carried to the free list; but at the same time wheat, flour. cattle and meats were freed in response to the demand for a lowered cost of living, thus introducing the possibility of a less restricted border trade. The "jokers," special rates imposed at the behest of particular favoured producers, which had become so conspicuous and unpleasant a feature of protective acts, for the greater part disappeared. The act repealed the maximum and minimum provisions of 1909, and in 1916 a tariff commission mas established. While many of the reductions of the Underwood act were politically rather than economically important, it represented a genuine though cautious attempt at a wider freedom of trade.

During World War I, U.S. industries, despite reduced duties, had no European competition whatever. Various of the so-called "war babies.!' notably the chemical industry, grew enormously to meet immediate needs. With the return of peace, some of them faced sharp foreign competition. The spectacular fall of prices in 1920 plunged agriculture into distress, and the farmers turned to protection as a supposed remedy.

Fordney-McCumber (1922) and Smoot-Hawley **(1930)** Tariffs.--When the Republicans returned to power in 1921, they promptly laid high duties (quite incapable of raising prices under the circumstances) on various farm products that had been freed in 1913, notably wheat, corn and meat, as also wool and sugar. This "emergency" measure was followed by the Fordney-McCumber tariff of 1922, follou-ing the lines of the act of 1909, but surpassing it in the application of protection. Agricultural rates were higher than in 1909. Generally without economic significance, they did in fact mean the probability of higher prices for such products as California fruits, wheat on occasion, and notably sugar. Wool was given increased protection, and the elaborate system of compensating and protective duties on noollen manufacture was restored. Textiles generally fared about as in 1897 and 1909. Iron alloys and specialties subject to foreign competition, like cutlery and firearms, were raised above the rates of 1909, as were china ware jewellery, toys and laces, the last-named paying 90% ad valorem. Coal-tar products, dyestuffs and chemicals, which had sought absolute prohibition, were granted extremely high rates.

The act authorized the president, after investigation by the tariff commission, to raise or lower rates (within the limit of 50% of the prescribed duties) as might be necessary to equalize costs in the principal competing country. Under this provision the president raised rates in a number of cases, but lowered them in no important instance.

The farmers failed to share the prosperity of the 1920s, and early in his administration Pres. Herbert Hoover called congress in extraordinary session to revise the tariff for their benefit. Congressional action promptly took the form of a general upward revision of duties, giving rise to a fierce legislative struggle. Export manufacturers urged moderation, financial experts pointed out the necessity of increasing imports in view of the creditor position of the United States, protests against threatened injuries came from 40 foreign countries. and more than 1,000 economists signed a memorial advocating the defeat or veto of the measure. Nevertheless it was enacted in 1930, after a notorious process of logrolling. The act raised the average rates in every schedule, the increase being greatest on agricultural products. Sugar, cattle, dairy products, grains, lemons and other California products, wool, woollen and silk goods. manganese and tungsten bearing ores, and pig iron all went up. Lumber. brick, cement, hides, sole leather and boots and shoes, all of which had been free, were subjected to duties.

There were increases on many small manufactured products, like watch and clock movements, cheap toys and matches, unimportant to the United States, but highly important to certain foreign exporting countries.

The flexible tariff provision was retained. The raising of U.S. duties at a time when international trade was already declining caused sharp resentment abroad, and was promptly followed by higher tariffs in many countries. From 1929 to 1933 the foreign trade of the world. according to League of Nations figures, fell by 25% in quantity and 65% in value.

Reciprocal Trade Agreements Acts and **G.A.T.T.**—The failure of the Smoot-Hawley tariff of 1930 to prevent the depression of the 1930s, as well as foreign retaliation against U.S. exports, led to the realization that trade was a two-way street. With the Democrats once more returned to power, the Reciprocal Trade Agreements act of 1934, based on the earlier flexible tariff provisions, was passed, osrensibly as a measure to increase exports by bilaterally reducing tariffs. The failure of earlier reciprocity measures induced congress to delegate to the executive the power to negotiate tariff concessions bilaterally which were then to be extended to other countries with whom the United States had commercial treaties through the unconditional most-favoured-nation clause. The law. passed for three years, permitted the president to reduce tariffs up to 50%, but prohibited changes in the free list. The act was reneued in virtually unchanged form in 1937, 1940 and 1943.

In 1945 two major changes were made. In the 29 trade agreements negotiated between 1934 and 1945, the president had almost exhausted the tariff cuts permitted to him. The act of 1945 allowed him to cut rates another 50% from the level then prevailing. At the same time the administration inserted an escape clause into every trade agreement, though the law did not require this until 1948. With its renewal in 1948 by a Republican-dominated congress, the act became once more somewhat more protectionist. The escape clause, used for the first time in the Mexican trade agreement of 1942, permitted the president to withdraw unilaterally a concession made if serious injury was threatened to a domestic industry as the result of the concession. A "peril-point" amendment authorized the tariff commission to investigate how far tariffs might safely be reduced on individual commodities, though their recommendations were not binding on the president.

In 1949 the Democrats succeeded in temporarily restoring the original, less-protectionist form of the act, but from 1951 the escape- and peril-point clauses were reinserted.

Because the method of negotiating bilaterally with one country at a time has limitations in that each country is fearful of weakening its bargaining position vis-a-vis third countries as concessions are generalized through the most-favoured nation clause. simultaneous negotiations by the U.S. with 22 countries were held in 1947 in Geneva, Switz., which led to the establishment of the General Agreement on Tariffs and Trade (G.X.T.T.), which. after further negotiations at Annecy, Fr., and Torquay, Eng., in 1949 and 1950–51, 33 countries had joined by 1953. G.A.T.T. negotiated tariff concessions on about 45,000 items, making up about two-thirds of world trade.

G.A.T.T. embodied the principles of U.S. trade policy with qualifications, some of which were entered by the United States itself. The most important one was that although the United States was in principle against all quantitative restrictions as discriminatory and inconsistent with a free market economy, it would agree to them, as far as other countries were concerned, in the event of balance of payments difficulties; and the United States itself imposed quotas on agricultural imports when they conflicted with domestic agricultural programs which were frequently inconsistent with the avowed principles of foreign trade policy.

By the 1950s the escape clause had been sparingly used, the withdrawal in 1954 of lower rates originally negotiated in 1936 on Swiss watches and movements being the most important case. Undoubtedly tariffs were substantially reduced under the Trade Agreements program and G.A.T.T. An investigation by the tariff commission put the tariff level on dutiable imports in 19j3 at about 12% ad valorem, about half the level of 1934. Yet much of this reduction was also attributable to the general rise in prices which reduces the impact of specific duties, in addition to the reduction of rates. And even in 1954 there were still a substantial number of rates of 50% or more. Furthermore, other methods of protection. such as quotas, special legislation relating to sugar and wool, complicated customs procedures, arbitrary valuations, overly specialized customs classifications and other weapons in the arsenal of administrative protectionism became rapidly more important as restrictions on imports than mere tariffs. *(See* FREE TRADE; TARIFFS.)

PROTECTIVE COLORATION: *see* ANIMAL COLORATION; MIMICRY.

PROTECTORATE, a term used in international law to describe the relationship between two states, one of which exercises control over the other. The use of the term to designate such a relationship is comparatively modern; it is significant that the word does not occur in Sir George Cornewall Lewis's *Essay on the Government of Dependencies* (1841). Nevertheless the relationship is an ancient one. There have always been states which dominated their neighbours. but which did not think it politic to annex them. Edouard Engelhardt and other writers on the subject have collected a large number of instances in antiquity in which a true protectorate existed, even though such terminology was not used. Thus the hegemony of Athens. as it existed about 467 B.C., was a form of protectorate; although the subject states were called allies., they were, in all important legal matters, obliged to resort to Athens.

In dealing with dependent nations Rome used terms which veiled subjection. Thus the relationship of subject or dependent cities to the dominant power was described as that of *clientes* to *patronus.* Such cities might also be described as *civitates foederatae* (allied communities) or *civitates liberae* (free communities). Another expression of the same fact was that certain communities had come under the power (*in deditionem*) or under the trust (*in fidem*) of the Roman people. The kingdoms of Numidia. Macedonia. Syria and Pergamum were examples of protected states, their rulers being termed *inservientes* (subjects). The Romans drew a distinction between *foedera aequa* and *iniqua* (equal and unequal treaties). The latter created a form of protectorate. the protected state remaining free,

In medieval times this relation existed, and the term protection was in use, but the relationship of subordination of one state to another was invariably expressed in terms of feudal law. One state was deemed the vassal of another. and the ruler of one did homage to the other. In his work *De la République* (1576) Jean Bodin treats of "those who are under protection" or as the Latin text has it, *de patrocinio et clientela.* In Bodin's view such states retain their sovereignty (i, c, 8). Discussing the question, whether a prince who becomes a *cliens* of another loses his *majestas,* he concludes that, unlike the true vassal, the *cliens* is not deprived of sovereignty. Elsewhere he remarks. "the word protection is special and implies no subjection on the part of the party under protection." He distinguishes the relation of *seigneur* and *vassal* from that of *protecteur* and *adherent.* At times letters of protection were granted by a prince to a weak state, as, for example, by Louis XIII in 1641 to the prince of Monaco.

Reverting to the distinction in Roman law, Hugo Grotius and Samuel von Pufendorf. with many others, treat protection as an instance of unequal treaties; that is, "where either the promises are unequal, or when either of the parties is obliged to harder conditions."

In the 16th century, the rise of European national states led to increasing use of the system of protectorates as a prelude to annexation. particularly by France. This use was also developed during the 19th century as a means of colonial expansion. After the Napoleonic wars, however, establishment of protectorates by the great powers became a means of maintaining the balance of power. Thus. by the treaty of Paris (1815) the Ionian Islands became a protectorate of Great Britain in order to prevent Austria from gaining complete control of the Adriatic. The gradual elimination of the smaller European states by the unification of Italy and Germany, and the strengthening and neutralization of those that remained (*e.g.,* Switzerland and Belgium), brought to an end this development in the use of the protectorate. A curious situation arose. however, with the disintegration of the Ottoman empire. Provinces which owed allegiance to Turkey began to revolt against Turkish rule and, as a stage in their struggle for independence. were sometimes placed under the protection of a foreign power. Thus. Moldavia and Walachia, which became protectorates of Russia in 1829, were placed under international protection in 1856 and in 1878 united to form the independent state of Rumania (*q.v.*).

Definitions.— "The one common element in protectorates is the prohibition of all foreign relations except those permitted by the protecting state. What the idea of protectorate excludes, and the ideas of annexation. on the other hand, would include, is that absolute ownership which was signified by the word *dominium* in Roman law, and which, though not quite satisfactorily, is sometimes described as territorial sovereignty. The protected country remains. in regard to the protecting state, a foreign country; and this being so, the inhabitants of the protectorate. whether native-born or immigrant settlers, do not by virtue of the relationship between the protecting and the protected state become subjects of the protecting state." (Sir William Rann Kennedy, *Rex* v. *Crewe,* 1910, 2 K.B., 576.)

The term protectorate is used loosely to designate a variety of degrees of control of one state by another. from that situation in which it means no more than that the protecting state guarantees and protects the safety of the other. to a situation which is a masked form of annexation. in the manner of the German protectorates established in Czechoslovakia in March 1939. Strictly, it is distinguished from suzerainty (*q.v.*), but nevertheless both relationships display the same characteristics of the observance of such ancient forms and traditions in the protected state as are consistent nith necessary change, and the reservation of nominal freedom while securing real power to the protecting state. Protectorate is probably best regarded as a form of international guardianship and the modern emphasis is upon the responsibility and duty of the protecting state to the international community as well as to the protected state.

There are tno principal classes of protectorates, those exercised over more highly civilized countries having a stable form of government and a historical tradition of their own. and those exercised over underdeveloped peoples, the latter being sometimes called colonial or pseudo-protectorates and being especially common in Africa. Examples of the former exist in Europe in Andorra and San Marino. Strictly, there can be no protectorate over a domain nhich is uninhabited or ruled by no organized state, but the distinction has not alnays been maintained.

In its narrowest and strict meaning, the relationship established in a protectorate must be distinguished from the relationship existing between the United States and the states of Central and South America (*see* PAN-AMERICAN CONFERENCES and MONROE DOCTRINE, THE), from the former relationship between Great Britain and the Indian states (*see* INDIA) and from so-called spheres of influence (*q.v.*).

Protectorates and International Law.—"The extent of the powers of a protecting state in the territory of a protected state depend. first upon the treaties between the protecting state and the protected state establishing the protectorate, and secondly upon the conditions under which the protectorate has been recognized by third powers as against whom there is an intention to rely on the provisions of these treaties. In spite of common features possessed by protectorates under international law, they have unlimited legal characteristics resulting from the special conditions under which they were created, and the stage of their development." (*Advisory Opinion, The Nationality Decrees in Tunis and Morocco,* "Series B," no. 4, p. 21, 1923.)

The majority of protectorates have been established by treaty by the terms of which the weaker state surrenders the management of all its more important international relations, although some have been imposed by force. *e.g.,* the unilateral declaration by Great Britain concerning Egypt in 1914 (*see* EGYPT). The treaty defines the position of the protected state in the international community: with special reference to its treaty-making powers and its right to diplomatic and consular representation.

There is a conflict of opinion whether or not the protected state loses its sovereignty. Many writers have supported the view that there is no such loss, and have gone so far as to state that the arrangement is *res inter alios acto* ("a thing done between others") and concerns only the parties to it. This is not the modern view, however, and it is now generally accepted that the relationship of protectorate must be recognized by third powers. The right of the protecting state to interfere in all matters of external affairs constitutes a definite loss of sovereignty, and since in orthodox theory sovereignty is one and indivisible. such a situation must imply a loss of sovereignty on the part of the weaker state. Neither position is without its anomalies; for example, it is clear that the sovereign of the neaker state yet has jurisdictional immunity in at least the territory of the protecting state (see *Duff Development Co.* v. *Kelantan [Government] and A. G.,* 1924 A.C. 797).

On the other hand, it was equally clear that on the assumption of the status of protectorate, the weaker state ceased to qualify for membership in the United Nations.

The relationship does not affect the nationality of the members of the weaker state, although there are frequently facilities for the peoples of the protectorate to become nationals of the protector, and they one a certain ill-defined allegiance to the protecting state. Thus the British Nationality act, 1948. made provision for the naturalization of British protected persons, the requirements to be fulfilled being less onerous than those imposed upon aliens. Nor, generally speaking, does the territory of the protectorate become part of that of the protecting state. although the applicability of legislation of the dominant state can only be judged from the construction of its terms.

The older view of the position of a protectorate according to international law is contained in the decision of Stephen Lushington in "The Case of The Ionian Ships" (2 Spink 212. 164 E.R. 394 [1855]).

The Ionian Islands were at that time subject to the protectorate created by the treaty of Paris. 1815, and it was held that notwithstanding the declaration of war by Great Britain against Russia. the Ionian Islands remained neutral. It was not disputed that as the head of the protecting state the British sovereign had the right to declare war or make peace on behalf of the islands. "Such a right is inseparable from protection." But the intention to involve the protected state in the wars of the protecting power must be clearly expressed, and the state of mar does not arise *ex necessitate* on the protecting power's going to war, for there may very well be advantages to one or other of the parties to the protectorate if the protected state is not so involved. It is said that the protected state is only implicated in the wars to which the protecting state is a party where the latter has acquired a right of military occupation of the territory of the former.

(E. H. LD.)

PROTEINS are highly complex substances that are universally present in living organisms. They are of great nutritional importance, have numerous industrial uses and are directly involved in the chemical processes necessary for the maintenance of life. Compounds with properties identical to those of the naturally occurring proteins had not been made in the laboratory by the second half of the 20th century. All of the proteins known and in use have therefore been synthesized by living cells. After water has been removed from the soft tissue of an animal. whether it be the human body or a one-celled animal, the major portion of the solid residue is found to be a mixture of proteins.

Proteins make up about 80% of the dry weight of muscle, 70% of the dry weight of skin and 90% of the dry weight of blood. The interior substance of plant cells is also composed largely of proteins.

Biological Function.—Some proteins, such as those of hair, wool. silk and bone. serve an obvious structural function for the organism that has made them. Other proteins, such as those of milk, eggs and seeds. are accumulated as storage depots of food for the young, growing organism. The proteins in the above two categories are extracellular. Another group of proteins present nithin the living cells participates very directly in the chemical processes essential for the existence of the cell. These proteins serve as specific catalysts, or enzymes (*q v*), bringing about and directing the chemical processes of metabolism. It is impossible to describe life processes at a molecular level without taking into consideration the functional role of the enzymes. There appears to be at least one kind of enzyme for each type of chemical reaction that occurs in a cell. Since there are a large number of such reactions, it follows that there are a large number of different enzymes.

The central role of proteins in biochemical processes was recognized by chemists in the early 19th century when they coined the name for these substances from the Greek word, *proteios,* meaning "holding first place."

Proteins in Nutrition.—Green plants and many microorganisms do not require protein food. For man and all animals, however, protein is an essential constituent of the diet. Without it, death is inevitable. Strictly speaking, it is not protein itself that is required, but the building blocks of protein, the amino acids (*see* below). A protein molecule is very large compared to molecules of sugar or salt, and consists of a large number of amino acids joined together to form long chains, much as beads are arranged on a string. In the digestive tract of the animal, enzymes act to degrade the protein of the food by breaking these long chains into shorter chains and free amino acids. The amino acids are absorbed across the walls of the intestinal tract and transported by

The Naturally Occurring Amino Acids

Name	Formula	Minimum daily nutritional requirement for average man
Glycine	$\mathrm{H\overset{H}{C}(NH_2)-COOH}$	None
Alanine	$\mathrm{CH_3\overset{H}{C}(NH_2)-COOH}$	None
Valine	$\mathrm{(CH_3)_2CH-\overset{H}{C}(NH_2)-COOH}$	0.8 g.
Leucine	$\mathrm{(CH_3)_2CH-CH_2-\overset{H}{C}(NH_2)-COOH}$	1.1 g.
Isoleucine	$\mathrm{(C_2H_5)(CH_3)CH-\overset{H}{C}(NH_2)-COOH}$	0.7 g.
Serine	$\mathrm{H\overset{H}{C}(OH)-\overset{H}{C}(NH_2)-COOH}$	None
Threonine	$\mathrm{CH_3-\overset{H}{C}(OH)-\overset{H}{C}(NH_2)-COOH}$	0.5 g.
Cysteine	$\mathrm{H\overset{H}{C}(SH)-\overset{H}{C}(NH_2)-COOH}$	None
Methionine	$\mathrm{H\overset{H}{C}(SCH_3)-CH_2-\overset{H}{C}(NH_2)-COOH}$	1.1 g.
Aspartic acid	$\mathrm{COOH-CH_2-\overset{H}{C}(NH_2)-COOH}$	None
Glutamic acid	$\mathrm{COOH-CH_2-CH_2-\overset{H}{C}(NH_2)-COOH}$	None
Lysine	$\mathrm{H\overset{H}{C}(NH_2)-CH_2-CH_2-CH_2-\overset{H}{C}(NH_2)-COOH}$	0.8 g.
Arginine	$\mathrm{NH_2-C(=NH)-N(H)-CH_2-CH_2-CH_2-\overset{H}{C}(NH_2)-COOH}$	None
Phenylalanine		1.1 g.
Tyrosine		None
Histidine	$\mathrm{HC{=}C-CH_2-\overset{H}{C}(NH_2)-COOH}$ (ring: N, NH, CH)	None
Tryptophan		0.25 g.
Proline	$\mathrm{CH_2-CH_2-CH_2-NH-CH-COOH}$ (ring)	None

the blood to the tissues. The cells then assemble their own proteins from these amino acid building blocks. Each species of animal or plant has a unique set of proteins different from those of other species. This difference is the reason that an animal cannot make direct use of the protein of a plant or of another species of animal, without first breaking that protein down to amino acids.

There are about 20 different amino acids that occur naturally in proteins (*see* Table). About half of these can be synthesized from other materials in the cells of the animal body. Eight of these amino acids cannot be synthesized by the human body, however. and must therefore be furnished in the diet (*see* Table). Normally, these essential amino acids are furnished in the form of protein food. The nutritional requirements of an animal for protein can actually be satisfied by feeding a mixture of essential amino acids. but since adequate amounts of such a mixture would be very expensive and not very palatable, there is little likelihood that man will substitute amino acids for good protein food such as meat, milk and eggs. It is striking that the proteins produced in nature for the nourishment of the young (for example, the milk proteins of mammals, the egg proteins of birds and the proteins laid down in seeds by plants) all provide adequate amounts of the essential amino acids. A diet that includes an inadequate supply of one or two essential amino acids, but is otherwise adequate, can be improved by adding the particular amino acids that are in short supply. It is also possible to feed an individual, who may for some reason be unable to ingest food. by intravenous injection of amino acids. The intact protein of ordinary foods cannot be used in this way.

Growth experiments have shown that all of the essential amino acids must be ingested simultaneously if they are to be utilized effectively. If the essential amino acids in the protein of the diet are balanced, then the minimum requirement of a man of average size is about 44 g of protein a day In 1943 the United Nations Conference on Food and Agriculture adopted certain dietary allowances that were regarded as the deiirable goal for all peoples of the world. These recommendations included the following average values for protein in grams per day: man, 70; woman. 60; woman in the latter half of pregnancy. 8;; woman in lactation, 100; girls 16 to 20 years, 75; and boys 16 to 20 years, 100. These goals are based on the assumption that an adequate number of calories and an adequate supply of vitamins are included in the diet. Authorities differ on these values. some setting the requirements appreciably higher.

Metabolism of Protein. — At first thought there may seem to be no reason why an adult should require protein in the diet, since an increase in the mass of body proteins occurs only during growth. Protein is continuously lost from the body, however. The proteins of dying cells, denatured protein and degradation products are broken down into amino acids by enzymes of the tissues. Some of these amino acids find their way back into new proteins. The remainder are degraded further, along with the amino acids that have been taken in the food and which are left over from protein synthesis. All of the amino acids contain nitrogen in the form of an amino group. This nitrogen is converted into urea by the liver, and the urea is excreted as a waste product in the urine. The normal adult excretes between 7 and 1j g. of nitrogen per day. The carbon compounds that remain after the removal of nitrogen are oxidized by the tissues into carbon dioxide and water. In this process the proteins may supply energy to the body. Normally, less than 20% of the energy requirements are supplied by the burning of protein. In the latter stages of starvation, however, large amounts of the tissue proteins are burned away.

The continuous breakdown and synthesis of new protein results in the renewal of all of the proteins in the body. Some tissue proteins are more susceptible to change than others. For example! the proteins of the liver. the blood plasma (but not the, red cells) and the lining of the intestine are broken down very rapidly, whereas the proteins of muscle, skin, brain and skeleton are broken down slowly. The average life of the hemoglobin in the red cells is about 120 days. but the serum albumin of the blood is renewed in a few neeks.

Proteins and **Immunity.**—When a protein of a different species is injected into the blood stream of man or an animal, an immunity to that protein may develop. Antibodies to the foreign protein appear in the blood stream. The antibody is itself a protein that has the ability to combine with the foreign protein eliciting its formation. If the foreign protein has toxic properties, these are thereby neutralized. By this mechanism the animal protects its body from invasion by bacteria. The bacterial proteins induce antibody formation that renders the bacteria harmless and incapable of invading the animal.

Industrial Use of Proteins.—Since animal tissues contain a much higher proportion of protein than plant tissues, most of the proteins of industrial importance are obtained from animal sources. Apart from the food proteins, the proteins which are utilized in the largest quantity are keratin found in wool and fibroin in silk of the textile industry (see WOOL; SILK AND SERICULTURE: *Physical* and *Chemical* Properties of **Silk;** SILK MANUFACTURE). and collagen in the processed hides of the leather industry (see LEATHER). Glues and sizes are prepared from the casein (*q.v.*) of milk. from the proteins of blood and from the crude gelatin of boiled bones (see GLUE). Bone protein, called ossein, is similar to collagen. The gelatin (*q.v.*) used in the food industry is obtained from scraps of hide, connective tissue and tendons. Waste proteins, including blood, horn, hooves, bones, etc., are used for plant fertilizer as a source of organic nitrogen.

The plant protein, zein, is a by-product of the starch industry. After starch has been extracted from corn (maize), the protein is separated from the residues by extraction with isopropyl alcohol, in which it is soluble. Zein has industrial uses similar to those of casein. Both proteins have been used to a limited extent in the manufacture of yarns. Seed proteins, such as those from the soya bean and the peanut have been converted into plastics. Wheat yields a protein, gluten, which is rich in glutamic acid and serves as a source for the condiment. monosodium glutamate. Another protein used in cookery is papain from the papaya plant. an enzyme which is applied to meat before cooking in order to make it more tender.

Properties of Proteins.—Proteins vary greatly in their properties. Some, such as the bright red hemoglobin of blood, contain pigments built into the molecule. Other proteins are colourless. Some proteins, such as hair, wool and silk, form long thin fibres completely insoluble in ordinary solvents. Others, for example the albumin of egg white. are very soluble in water but solidify on heating. Muscle cells contain fibres of protein that have the property of contracting and relaxing when the cell is stimulated. All proteins have the common property of being built from the same subunits, the amino acids, according to the same general plan. The amino acids are joined together by primary bonds, called peptide bonds, to form long chains. About 20 different kinds of amino acids are present in one protein molecule, but there may be a hundred or more amino acid subunits in the molecule. some of the amino acids recurring many times along the length of the chain. The sequence of amino acids along the chain is characteristic for each protein. It is clear that the number of possible arrangements of amino acids in the chain is very large, thus explaining why there are such an enormous number of different kinds of proteins.

Proteins, as they are found in nature, are characterized not only by the sequence of amino acids in their chains but also by the three-dimensional configuration of the chains themselves. Certain atomic groupings along the chains are able to form bonds with one another and to stick together. As a result, the chains are held in definite coiled or folded configurations. The properties and biological function of each protein depend upon the maintenance of a specific configuration. Larger aggregates are also formed. composed of several. or even a very large number, of molecules. held together more or less firmly. Since the structure of the native protein molecule is organized in a specific way. it follows from the geometry of these molecules that the structure of the aggregate is also organized into a pattern. Thus the structure of proteins is organized at three levels: (1) the sequence of the amino acids in the chains; (2) the folding of the chains into functional units; and (3) the combination of these units into larger patterns. It is this ability to form organized structures of great complexity and variety, inherent in the chemical nature of proteins, that is the basis for their function in living matter.

Differences in solubility are sometimes used for classifying proteins but as more is learned, this basis of classification loses its usefulness. Frequently the more soluble fraction of a mixture of proteins is called the albumin fraction, and the less soluble fraction is called the globulin fraction. Albumins are soluble in pure water, whereas true globulins are insoluble in water but are soluble in dilute salt solutions. Proteins insoluble in water or in salt solutions may dissolve in dilute acid or dilute alkali. High concentrations of a salt such as ammonium sulfate uill precipitate both albumins and globulins. The chemist makes use of these differences in solubility for the isolation and purification of individual proteins.

Molecular Size.—Many of the properties of proteins result from their large molecular size. They are very large compared with a molecule of water. which has a molecular weight of 18 times the neight of a hydrogen atom, or compared with a molecule of cane sugar, which has a molecular weight of 342. Though some proteins may have a molecular weight as small as 6,000. others have molecular weights greater than 100.000. Some aggregates of protein molecules, uniform in size and composition, are known to have particle weights greater than 1,000,000; *e.g.*, the virus proteins. Since protein molecules are very heavy, they can be caused to fall out of solution in a large centrifugal field. High speed centrifuges (ultracentrifuges) are used to determine the molecular weight of proteins by measuring how fast they will move to the bottom of a rotating vessel.

Compared with smaller molecules, proteins in solution diffuse very slowly from one place to another in the liquid. Those proteins with the shape of long, thin rods give viscous solutions. The large size of proteins prevents them from diffusing through natural membranes such as the walls of the blood vessels or through synthetic membranes such as cellophane. nhereas molecules as small as sugar diffuse freely. As a consequence, proteins are able to produce a permanent osmotic pressure across a membrane. That is, pressure is required to prevent water placed on one side of the membrane from penetrating into the protein solution placed on the other side of the membrane.

Denaturation.—Unlike most simple organic molecules, the physical and chemical properties of a protein are markedly altered when the substance is boiled in water. Similar changes are produced by the following reagents: dilute acid, dilute alkali, alcohol, detergents or concentrated solutions of urea The process by which these reagents alter the protein is called denaturation In general. denaturation results in lowered solubility of the protein in neutral solution. In some cases, a gel or coagulum is formed, as when egg white is heated. More significantly, denaturation usually results in the loss of the biological function of the protein. For example, enzymes lose their catalytic powers and hemoglobin loses its capacity to carry oxygen. The changes that accompany denaturation have been shonn to result from the destruction of the specific pattern in which the amino acid chains are folded in the native protein. All of the agents able to cause denaturation are able to break the secondary bonds that hold the chains in place. Once these neak bonds are broken. the molecule falls into a disorganized tangle. devoid of biological function

Conjugated Proteins.—Some proteins contain other chemical groups in addition to amino acids. Such proteins are called conjugated proteins If the nonprotein portion of the molecule is known to have a biological function. it is referred to as the prosthetic group. A large number of enzymes have prosthetic groups that participate in the catalytic activity. Some of these prosthetic groups are derived from vitamins (see VITAMINS; ENZYMES). If the prosthetic group is coloured, the conjugated protein which contains it will also be coloured. For example. hemoglobin, the main constituent of the red cells of blood, consists of the protein globin and a coloured substance called heme Four heme molecules, each of nhich contains one iron atom, are firmly attached to each globin molecule. In the lungs, an oxygen molecule is bound to each iron atom and is carried by the blood stream to the outlying tissues. Other proteins are known that contain metal atoms bound to the protein structure. The cerulo-plasmin of blood is a bright blue protein containing copper.

Proteins and Heredity.—The most important conjugated proteins are the nucleoproteins, which consist of proteins combined with nucleic acids (*q.v.*). Nucleoproteins are found not only in the nuclei of cells, but also in extranuclear particles. Chromosomes, viruses and the heads of sperm cells all consist largely of nucleoproteins. These substances serve the mechanism by which hereditary characteristics are transmitted from cell to cell, and are intimately involved in the processes of self-duplication which are basic to life.

Amino Acids.—Proteins may be broken down into their constituent amino acids by prolonged heating with acid, by heating with alkali, or by treatment with certain enzymes which cause a breaking of the bonds between the amino acids. Molecules of the natural amino acids have the common structure shown in the formula:

$$\mathrm{R-\overset{H}{\underset{NH_2}{C}}-COOH}$$

As indicated by the structure, the four covalent bonds of the *a*-carbon atom are linked to an amino group ($-NH_2$), a carboxylic acid group ($-COOH$), a hydrogen atom ($-H$), and a fourth atomic grouping which is called the side chain ($-R$). As with all organic compounds in which a carbon atom is linked to four different groups, there are two different ways in which the groups may be arranged around the central carbon atom. Only one of these arrangements is found in the amino acids isolated from proteins, and this arrangement is designated by the symbol L. Thus the subunits of proteins are described as L-α-amino acids. The amino acids obtained from proteins are distinguished by their different side chains. The table gives the names of the most important naturally occurring amino acids and their structural formulas, and indicates the importance in nutrition of each substance.

A few additional amino acids occur in proteins only rarely, and so are not listed in the table. An example is thyroxine, an iodine-containing amino acid occurring in the protein of the thyroid gland. One of the compounds listed in the table, proline, is strictly speaking an imino, rather than an amino acid. Aspartic and glutamic acids are frequently classified as acidic amino acids; histidine, lysine and arginine are classified as basic amino acids, and the remaining amino acids are described as neutral. In actual fact. since the carboxyl group is acidic, and the amino group is basic, all amino acids are both acids and bases, but the acidic and basic groups neutraiize each other, to give a molecule with the dipole structure shown:

$$\mathrm{R-\overset{H}{\underset{NH_3^+}{C}}-COO^-}$$

The **Peptide** Bond.—Two amino acids may be joined by condensation between the carboxylic acid group of one molecule and the amino group of the other molecule, with the splitting out of a molecule of water:

$$\underset{\text{alanine}}{\mathrm{H_2N.CH(CH_3).COOH}} + \underset{\text{serine}}{\mathrm{H_2N.CH(CH_2OH).COOH}} \xrightarrow[\text{yields}]{} \underset{\text{alanyl-serine}}{\mathrm{H_2N.CH(CH_3).CO.NH.CH(CH_2OH).COOH}} + \underset{\text{water}}{\mathrm{H_2O}}$$

The bond formed between the carbonyl group ($-CO-$) and the imino group ($-NH-$) is called a peptide bond. A dipeptide is a compound formed by the union of two amino acids through one peptide bond, such as aianyl-serine shown above. A tripeptide is formed from three amino acids joined by two peptide bonds. while a tetrapeptide is formed from four amino acids, etc. When many amino acids are linked into a chain by peptide bonds. the structure is called a polypeptide. Thus proteins may be described as molecules that are composed of polypeptide chains.

When a polypeptide chain is split into the component amino acids by the action of acid, or alkali, or certain enzymes (peptidases), the condensation reaction is reversed. A molecule of water is added to each peptide bond by a process called hydrolysis, and one carboxyi group and one amino group are reformed. If hydrolysis is not complete, the products may consist of di-, tri-, and higher peptides, besides free amino acids. The fact that proteins can be hydrolyzed to amino acids and peptides by the action of certain enzymes which are known to attack the peptide bonds of synthetic peptides provides convincing proof that the peptide bond is the principal means by which amino acids are linked in proteins. A number of simple peptides are found in nature. Among them are the pituitary hormone, oxytocin. and the tripeptide glutathione (*q.v.*). These peptides, and many others resembling them, have been synthesized in the chemical laboratory.

Structure of Protein.—If the structure of a protein is to be completely determined, one of the problems that must be solved is the sequence of the amino acids in the peptide chain. Methods whereby sequence can be determined are known, but the techniques are difficult and laborious. An event that marked a milestone in the advance of knowledge of proteins was the determination by Frederick Sanger (*q.v.*) in the early 1950s of the sequence of amino acids in the polypeptide chains of insulin. This

ATOMIC MODELS OF POLYPEPTIDE CHAIN (a-HELIX): (LEFT) THE CORE: (RIGHT) CORE WITH VARIOUS SIDE CHAINS ATTACHED

hormone. which counteracts diabetes, is composed of two different polypeptide chains, one 30 amino acids long and the other 21 amino acids long. Subsequent work by others resulted in the determination by the 1960s of the complete amino acid sequences of the enzyme ribonuclease and the protein subunit of the tobacco mosaic virus.

The polypeptide chains of native proteins are not free to take random configurations. They are fixed by cross-linkages between points on the same chain and between points on different chains. One type of cross-linkage is formed between the sulfur atoms of two molecules of the amino acid cysteine, giving a disulfide ($-S-S-$)bond. Another type of cross-linkage may be formed by phosphorus in the form of phosphoric acid, which may serve to link pairs of side chains.

Another type of bond prevalent in proteins is the so-called hydrogen bond formed between oxygen and nitrogen atoms. A hydrogen atom is found between the two atoms that form such a bond; *e.g.*, O—H---O and N—H---O. Although hydrogen bonds are weak compared with primary bonds, the presence of a large number of hydrogen bonds in proteins results in an accumulative effect that contributes significantly to the stability of particular structures. Investigations of proteins by means of X-rays have indicated that hydrogen bonds hold portions of the polypeptide chain in a helical (spiral) configuration. A model of the helical structure of a polypeptide chain is shown in the accompanying photograph. On the left, the side chains have been removed to show the hydrogen bonds between the carbonyl groups and the imino groups of the peptide linkages. On the right, the side chains are in place. The model demonstrates how the side chains of the different amino acids project out from a roughly cylindrical core within which the hydrogen bonds are buried. Many properties of proteins can be explained by this model.

Electrical Charge. — Although the amino acids have a dipole structure, the peptide bond is relatively uncharged. However, a protein generally contains amino acids with acidic side chains and also amino acids with basic side chains. These groups may carry electrical charges. In acidic solutions most proteins carry a positive electrical charge, while in alkaline solutions they carry a negative charge. An electrical process, called electrophoresis, is used by the chemist to analyze and separate mixtures of proteins according to the electrical charges of the molecules.

Synthesis **of Proteins.**—Polypeptide chains have been synthesized that are several hundred amino acids in length and that contain several different kinds of amino acids. Though the properties of these substances resemble the properties of proteins to a limited extent, they cannot be said to be protein in nature since the sequence of amino acids and the configuration of the chains are undetermined and random. The problem of how the living cell synthesizes protein had not been completely elucidated but by the early 1960s several laboratories had clearly achieved net synthesis of specific proteins in cell-free extracts containing enzymes, nucleic acids and subcellular particles. These events were expected to open the way for detailed analysis of this interesting and important process.

PROTESILAUS. In Greek legend, Protesilaus was the commander of a Greek contingent from Thessaly who was the first to spring ashore on Trojan soil, although, according to the Latin author Gaius Iulius Hyginus, he knew it meant instant death. Catullus attributed Protesilaus' fate to his previous failure to make a sacrifice to the gods before building a house.

Protesilaus' wife Laodamia besought the gods below that he might be permitted to return to earth for the period of three hours. Her prayer was granted and on the expiration of the time allotted she returned with him to the nether world.

According to Hyginus, however, she made a waxen image of her husband, and a slave, having detected her in the act of embracing it and supposing it to be a lover, informed her father. He ordered her to burn the image, whereupon she threw herself with it into the flames. In another account by the Roman mythographer Conon, Protesilaus survived the fall of Troy and carried off Aethilla, the sister of Priam. During a halt on the peninsula of Pallene, Aethilla and other captive women set fire to the ships. Protesilaus, unable to continue his voyage, remained and built the city of Scione. His tomb and temple were near Eleus in the Thracian Chersonese.

Nymphs were said to have planted elm trees facing toward Troy, which withered away as soon as they had grown high enough to see the captured city.

Protesilaus was the subject of a tragedy by Euripides, of which some fragments remain, and William Wordsworth wrote a poem entitled *Laodamia*.

PROTESTANT, the generic name for an adherent of those churches which base their teaching on the principles of the Reformation.

The name is derived from the formal *Protestatio* handed in by the evangelical states of the empire, including some of the more important princes and imperial cities, against the *recess* of the diet of Spires (1529), which decreed that the religious *status quo* was to be preserved, that no innovations were to be introduced in those states which had not hitherto made them, and that the mass was everywhere to be tolerated.

The name Protestant seems to have been applied first to the protesting princes by their opponents, and it soon came to be used indiscriminately of all the adherents of the reformed religion. Its use appears to have spread more rapidly outside Germany than within Germany itself, one cause of its popularity being that it was negative and colourless, and could thus be applied by adherents of the "old religion" to those of the "new religion," without giving offense, on occasions when it was expedient to avoid abusive language.

As the designation of a church, "Protestant" was unknown during the Reformation period and for a long while after. In Germany the Reformers called themselves usually *evangelici,* and avoided special designations for their communities, which they conceived only as part of the true Catholic Church.

It was not until the period of the Thirty Years' War that the two main schools of the reformed or evangelical churches marked their definitive separation: the Calvinists describing themselves as the "Reformed Church," the Lutherans as the "Lutheran Church." In France, in England, in Holland the evangelicals continued to describe their churches as *ecclesiae reformatae,* without the *arrière pensée* which in Germany had confined the designation "Reformed" to the followers of a particular church order and doctrine.

As to the word "Protestant," it was never applied to the Church of England or to any other, save unofficially and in the wide sense above indicated, until the style "Protestant Episcopal Church" was assumed by the Anglican communion in the United States.

PROTESTANTENVEREIN is the name of a society in Germany the general object of which was to promote the union (*Verein*) and progress of the various established Protestant churches of the country in harmony with the advance of culture and on the basis of Christianity. It was founded at Frankfurt-on-the-Main in 1863 by a number of distinguished clergymen and laymen of liberal tendencies, representing the freer parties of the Lutheran and Reformed Churches of the various German states.

PROTESTANT EPISCOPAL CHURCH, THE, in the United States is spiritually the direct descendant of the Church of England, and is a part of the Anglican Communion. From the Church of England the Protestant Episcopal Church inherits its faith, its liturgy and its spiritual traditions, though it is entirely independent in its own life and government. The preface of the American Prayer Book, officially set forth in 1789, affirms the substantial identity and continuity of the two churches in the following words "This Church is far from intending to depart from the Church of England in any essential point of doctrine, discipline or worship; or further than local circumstances require." The Protestant Episcopal Church is therefore in full fellowship with the Anglican Communion, while at the same time it is wholly free and Independent in the ordering of its life and the fulfilment of its mission in the United States.

Although services were held in various parts of the country by the clergy who, as chaplains, accompanied groups engaged in exploration, the first permanent settlement of the church was at Jamestown, Va., in 1607. The church was legally established in Virginia from the start, and became established in Maryland after the Revolution of 1689. At the beginning of the American Revolution, it was established in all of the southern Colonies, and in five counties in New York. Trinity church, New York, was chartered by the crown in 1697. The Church of England obtained a foothold in Massachusetts in 1686, in Pennsylvania in 1695 and in Connecticut in 1706. By the end of the colonial period, it was represented in all of the Colonies, though its members were a small minority in some of them. Its growth during this period was fostered by the Society for the Propagation of the Gospel in Foreign Parts. Founded in 1701, through the efforts of the Rev. Thomas Bray, a missionary in Maryland, this body helped to support ministers and schoolmasters in communities where the local maintenance was inadequate. Through all this period, however, the church had no bishop in the American colonies. It was under the jurisdiction of the bishop of London, who naturally could do little for this far distant field. Without bishops, the Episcopal Church was in an anomalous position. Those desiring to be ordained to the ministry were compelled to make the long and perilous voyage to England. The people could not be brought to confirmation. Efforts to secure the consecration of bishops by the mother church in England were strongly opposed by the Nonconformist churches in the colonies, especially in New England.

Revolutionary Period.—The Revolution was a time of severe trial for the Church of England in the colonies. Many of the clergy felt called upon to give up their parishes and return to England, though others, especially in the south, remained at their posts and gave their support to the American cause. Of the laity a large majority was on the side of the Revolution, and many of them were among its most active leaders. Two-thirds of those whose names are signed to the Declaration of Independence were members of the Episcopal Church. William White, afterward the first bishop of Pennsylvania, was chaplain of the Continental congress. George Washington, himself a member of the church, went, accompanied by both houses of congress, to St. Paul's chapel. still standing on Broadway and Vesey street, New Tork city, for the religious service which completed the ceremonies of his inauguration as first president of the United States, and this service was conducted by Samuel Provoost, the first bishop of New York and rector of Trinity church.

At the close of the war, the church was left without bishops or a central organization. The first bishop was Samuel Seabury, elected by the clergy of Connecticut, who, impatient of delays in England, secured consecration from the nonjuring bishops of Scotland on Nov. 14, 1784. The development of a central organization resulted from a movement which centred in the middle states, under the leadership of the Rev. William White, rector of Christ church, Philadelphia, Pa. Stare conventions, including the clergy and representatives of the laity, were first formed, and these were united in a general convention which drew up a constitution, began a revision of the Prayer Book and secured the consecration of two bishops in England. William White of Pennsylvania and Samuel Provoost of New York. on Feb. 4, 1787.

The whole church was united in the General convention of 1789, when Bishop Seabury and delegates from New England joined the representatives from other states. This meeting revised the constitution to provide for a separate house of bishops in General convention, and completed the revision of the Prayer Book along more conservative lines than those originally proposed. Another bishop, James Madison of Virginia, was consecrated in England on Sept. 19, 1790. All four bishops united in the first consecration on American soil, that of Thomas John Claggett as bishop of Maryland in 1792.
